FEATURES
- 32 dBm P_{SAT} with 22% PAE
- P_{1dB} P_{OUT}: 31.5 dBm
- High OIP3: 39.5 dBm
- High gain: 24.5 dB
- 50 Ω matched input/output

APPLICATIONS
- Point to point radios
- Point to multipoint Radio
- VSAT and SATCOM

GENERAL DESCRIPTION
The HMC7229 is a four-stage, gallium arsenide (GaAs), pseudomorphic high electron mobility transfer (pHEMT), monolithic microwave integrated circuit (MMIC), 1 W power amplifier with an integrated temperature compensated on-chip power detector, operating between 33 GHz and 40 GHz. The HMC7229 provides a typical range of 23 dB to 24.5 dB of gain and a range of 30 dBm to 32 dBm of saturated output power (P_{sat}) with 12% to 22% (typical) power added efficiency (PAE) range across a band of 33 GHz to 40 GHz from a 6 V supply. With an excellent OIP3 with a range of 37 dBm to 39.5 dBm across a band of 33 GHz to 40 GHz, the HMC7229 is ideal for linear applications such as high capacity point to point or point to multipoint radios or very small aperture terminal (VSAT)/satellite communications (SATCOM) applications demanding 32 dBm of efficient saturated output power. The radio frequency (RF) input/output ports are internally matched and dc blocked for easy integration into higher level assemblies.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

**ESD CAUTION**

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

THEORY OF OPERATION

The HMC7229 is a GaAs, pHEMT, MMIC, 1 W power amplifier consisting of four gain stages in series. Figure 34 shows a simplified functional block diagram of the HMC7229.

The input signal of the HMC7229 is evenly divided into two paths and each path is amplified through the four independent gain stages. The amplified signals are then combined at the RF output. A portion of the RF output signal is directionally coupled to a diode for detection of the RF output power. When the diode is dc biased, it rectifies the RF power and makes it available for measurement as a dc voltage at V_{DET}. To allow for temperature compensation of V_{DET}, a symmetrically located and identical detector circuit, minus the coupled RF power, is available via V_{REF}. As shown in Figure 32, taking the difference of V_{REF} – V_{DET} provides a temperature compensated signal that is proportional to the RF output power.

The HMC7229 has single-ended input and output ports with impedances nominally matched to 50 Ω internally over the frequency range from 33 GHz to 40 GHz. Consequently, the HMC7229 can be directly inserted into a 50 Ω system with no impedance matching circuitry required.

Impedances nominally matched to a 50 Ω system also means that multiple HMC7229 amplifiers can be cascaded back to back without external matching circuitry.

Similarly, multiple HMC7229 can be used with power dividers at the RF input and power combiners at the RF output to obtain higher output power levels.

The input and output impedances are sufficiently stable compared to the variations in temperature and supply voltage that no impedance matching compensation is required.

It is critical to supply very low inductance ground connections to the backside of the HMC7229, ensuring stable operation. Guidance on mounting the HMC7229 is given in the Mounting and Bonding Techniques for Millimeter Wave GaAs MMICs section.

To achieve the best performance from the HMC7229 and not to damage the device, do not exceed the absolute maximum ratings.
APPLICATIONS INFORMATION
MOUNTING AND BONDING TECHNIQUES FOR MILLIMETER WAVE GaAs MMICs

Attach the HMC7229 directly to the ground plane eutectically or with a conductive epoxy. To route the RF signal to and from the HMC7229, use a 50 Ω microstrip transmission line on 0.127 mm (0.005 inches) thick alumina, thin film substrates (see Figure 35).

To minimize the bond wire length, place microstrip substrates as close to the HMC7229 as possible. Typical chip to substrate spacing is 0.076 mm to 0.152 mm (0.003 inches and 0.006 inches).

HANDLING PRECAUTIONS
To avoid permanent damage to the device, adhere to the following precautions:

- All bare HMC7229 ship in either waffle or gel-based ESD protective containers, sealed in an ESD protective bag. After opening the sealed ESD protective bag, store all chips in a dry nitrogen environment.
- Handle the HMC7229 in a clean environment. Never use liquid cleaning systems to clean the chip.
- Follow ESD precautions to protect against ESD strikes.
- While applying bias, suppress instrument and bias supply transients. To minimize inductive pickup, use shielded signal and bias cables.
- Handle the HMC7229 along the edges with a vacuum collet or a sharp pair of bent tweezers. The surface of the chip has fragile air bridges and must not be touched with a vacuum collet, tweezers, or fingers.

MOUNTING
The HMC7229 is back metallized and can be die mounted onto a system with Au/Sn eutectic preforms or with electrically conductive epoxy. The mounting surface must be clean and flat.

**Eutectic Die Attach**
It is best to use an 80% Au/20% Sn preform with a work surface temperature of 255°C and a tool temperature of 265°C. When the work surface is 255°C and tool temperature is 265°C, 90% nitrogen/10% hydrogen gas is applied to the work surface, maintain the tool tip temperature at 290°C. Do not expose the HMC7229 to a temperature greater than 320°C for more than 20 sec. No more than 3 sec of scrubbing is required for attachment.

**Epoxy Die Attach**
The ABLETHERM 2600BT is recommended for chip attachment. Apply a minimum amount of epoxy to the mounting surface so a thin epoxy fillet is observed around the perimeter of the HMC7229 after placing the device into position on the surface. Cure the epoxy per the schedule provided by the manufacturer.

**Wire Bonding**
RF bonds made with 0.003 in. × 0.0005 in. Au ribbon are recommended for the RF ports. These bonds must be thermosonically bonded with a force of 40 g to 60 g. DC bonds of 1 mil (0.025 mm) diameter, thermosonically bonded, are recommended. Create ball bonds with a force of 40 g to 50 g and wedge bonds with a force of 18 g to 22 g. Create all bonds with a nominal stage temperature of 150°C. Apply a minimum amount of ultrasonic energy to achieve reliable bonds. Keep all bonds as short as possible, less than 12 mil (0.31 mm).

**BIASING PROCEDURES**
The basic connections for operating the HMC7229 are shown in the Typical Application Circuit section and the Theory of Operation section. The RF input and RF output are ac-coupled by internal dc block capacitors. Follow the recommended bias sequencing to avoid damaging the amplifier.

The amplifier gate bias can be supplied using either the VGG1 pin or VGG2 pin. Use the VDD1 to VDD8 pins while applying the drain bias to the amplifier. Testing to gather data for the HMC7229 data sheet used the VGG1 pin with the VDD1 to VDD8 pins connected together.

Use the following recommended bias sequence during power-up:
1. Connect GND to RF/dc ground.
2. Set VGG1 or VGG2 to −2 V.
3. Set VDD1 to VDD8 to 6 V.
4. Increase VGG1 or VGG2 to achieve a typical IDQ = 1200 mA.
5. Apply an RF signal the device.

Use the following recommended bias sequence during power-down:
1. Turn off the RF signal
2. Decrease VGG1 or VGG2 to ~2 V to achieve IDQ = 0 mA.
3. Decrease VDD1, VDD2, VDD3, and VDD4 to 0 V.
4. Increase VGG1 or VGG2 to 0 V.

The bias conditions listed at VDD = 6 V, IDQ = 1200 mA is a recommended operating point to receive optimum performance.
from the HMC7229. The data used in this data sheet is taken with the recommended bias conditions (see the Specifications section).

Using the HMC7229 in a different bias condition may provide different performance than the performance shown in the Typical Performance Characteristics section.

The V\text{DET} and V\text{REF} pins are the output pins for the internal power detector. The V\text{DET} pin is the dc voltage output pin representing the RF output power rectified by the internal diode, biased through an external resistor.

The V\text{REF} pin is the dc voltage output pin representing the reference diode voltage, which is biased through an external resistor. The reference diode voltage compensates the temperature variation effects on both the V\text{REF} and V\text{DET} diodes. Figure 36 shows a suggested circuit to read out the output voltage in correlation with the RF output power.
