Reference and Application Data for

Pressure and Force Sensors

Output Signal Adjustment and Temperature
Compensation for 24PC and FS Series

Application Note

INTRODUCTION

Many pressure and force sensor applications require close
control over performance parameters such as sensitivity,
linearity, hysteresis, and others. Using computer controlled
laser trimming on the 140/160PC and 240PC pressure
sensors, MICRO SWITCH™ provides this close control and
higher performance than can be achieved using discrete
circuitry. Temperature compensation circuitry is an integral
part of the device and is optimized on each unit as part of the
calibration procedure. Null offset and Span are similarly
controlled. No adjustment or recalibration by the user is
required.

26 and 176PC sensors provide interchangeability from unit to
unit and provide other limited temperature compensation. The
26 and 176PC are voltage excited.

The 24PC and FS feature a wider tolerance on null offset and
Span and do not include temperature compensation. The
following procedures can be used to set the null offset and
Span to desired output values (0-100 mV typically) and to
compensate for temperature shift.

OUTPUT SIGNAL ADJUSTMENT

Setting Null Offset to Zero

1. Measure null offset (lead 2 to 4).
2. For a negative null offset place a resistor from lead 1
   (supply) to lead 2 (positive output). Expect values around
   300K ohms **(Figure 1A)**.
3. For a positive null offset place a resistor from lead 1
   (supply) to lead 4 (negative output). Expect values around
   300K ohms **(Figure 1B)**.

Setting Span

1. Measure the bridge resistance (R_B) from lead 2 to 4
   (output).
2. Measure Span.
3. Calculate a shunt resistor (R_S) using the following
   equation:

$$R_S = \frac{R_B}{\frac{K_M}{K_D} - 1}$$

   Where:
   K_M = measured Span
   K_D = desired Span
   Generally: 5K < R_S < 20K ohms

4. Install shunt resistor from lead 2 to 4 (output) as in
   **Figure 2**.

Pressure and Force Sensors

TEMPERATURE COMPENSATION[1]

Introduction
The 24PC pressure and FS force sensors exhibit the following effects as temperature increases:
1. Pressure or force sensitivity decreases.[2]
2. The resistance of each piezoresistor increases.[2]

For illustration, consider the following piezoresistor model:
$R(P,T) = C_T(R_O + C_P k(25\ °C)P)$

Where:
R(P,T) is the value of the piezoresistance (ohm)

R_O is the unstressed (ambient) piezoresistance at 25°C

R_O = R(P = O, T = 25 °C)

C_T is the change in R(P,T) with temperature.

$$C_T = \frac{R(P = O, T)}{R_O} \quad \left(\frac{ohm}{ohm}\right)$$

k(25 °C) is the pressure or force sensitivity at 25 °C

$$k(25\ °C) = \frac{R(P, 25\ °C) + R_O}{P} \quad \left(\frac{ohm}{psi\ or\ g}\right)$$

k(T) is the pressure or force sensitivity at applied temperature.

C_P is the change in pressure or force sensitivity with temperature.

$$C_P = \frac{k(T)}{k(25\ °C)} \quad \frac{ohm/\ psi\ or\ g}{ohm/\ psi\ or\ g}$$

P is the applied pressure (psi)

F is the applied force (g)

Nominal Cp and CT characteristics are given in Figure 3.

Method #1
The circuit of **Figure 4** provides temperature compensation by combining a current source and positive feedback. Essentially, the change in CT is partially cancelled by an opposite change in Cp.

For a different supply voltage, vary the 24.9K resistor. Make sure that the common mode input voltage and output voltage swing limitations of the amplifiers are not exceeded.

24PC sensors are less sensitive to temperature when current excited. We strongly urge that current excitation be considered as a means of minimizing errors due to temperature changes. Feel free to contact the application center to get an update on this subject.

Temperature Compensation Method #1

Recommended Op Amps:
LM358—Dual Op Amp
LM124—Quad, military grade Op Amp

[1] Temperature Compensation Methods #1-2 affect the **sensitivity** of the sensor, not the null offset, in that the change in the slope of the output curve caused by temperature is minimized.
[2] Consistent from unit to unit within a narrow tolerance.

Method #2

C_P is inversely proportional to temperature. To compensate for this effect, the voltage applied to the sensor bridge must be proportional to temperature. One approach is to connect a thermistor with a negative temperature coefficient (resistance decreases with temperature) in series with the bridge, as shown in **Figure 5A.** Thermistors with the exact resistance vs. temperature characteristics to compensate the bridge may not be readily available. An alternate approach is the use of a thermistor-resistor network to meet the required characteristics. Standard 1% resistor values (with a standard thermistor) are shown in **Figure 5B.** This method provides temperature compensation to within ±2% Span over the range of -10 °C to 50 °C. The thermistor should be located close to the sensor, so they will experience the same thermal environment.

TEMPERATURE COMPENSATION TO CONTROL SHIFT OF NULL OFFSET

Null shift caused by temperature can be compensated using the circuit in **Figure 6.** However, it is required that the sensor first have sensitivity temperature compensation. In other words, you must use a 26 and 176 or a 24PC or FS employing one of Methods 1 or 2.

Null shift with temperature is unpredictable; therefore the sensors must be compensated individually.
1. Measure V2-3 and V2-4 at null over the temperature range of interest (room temperature (TR), and some other temperature (T)).
2. Measure R2-3 at room temperature.
3. Select R1 for Vn J V2-3 at room temperature.
4. Calculate the value of R2 necessary to compensate the measured null shift.

$$R_2 \;=\; R_{2\text{-}3} \left[\frac{V_{2\text{-}3(T)} - V_{2\text{-}3\,(TR)}}{V_{2\text{-}4(T)} - V_{2\text{-}4\,(TR)}} \right]$$

5. Connect R_2 to terminal 2 if $V_{2\text{-}4(T)} - V_{2\text{-}4\,(TR)}$ is positive. Connect it to terminal 4 if negative.
