

## EMI Filter Hints and Tips

2010

**Stephen Hopwood - Snr Engineer**

**Syfer Technology are a Dover CMP Company based in Norwich England. World leading manufacturers of ceramic passive components, their filter product range includes :-**

- **Multi Layer Chip Capacitors**
- **Feedthrough Chip Capacitors**
- **X2Y Chip and Panel Mount Filters**
- **Surface Mount C & Pi low pass Filters**
- **Discoidal and Planar Array capacitors and MOV Varistors**
- **Panel Mount C, L-C, Pi, T & multi-element low pass filters**
- **Very High Current Plastic Film based Panel Mount low pass filters**

# Today's Presentation

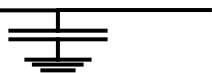

Filter hints and tips

Or

What we didn't realise our customers didn't realise about what we sold them

# Low Pass Filter Theory

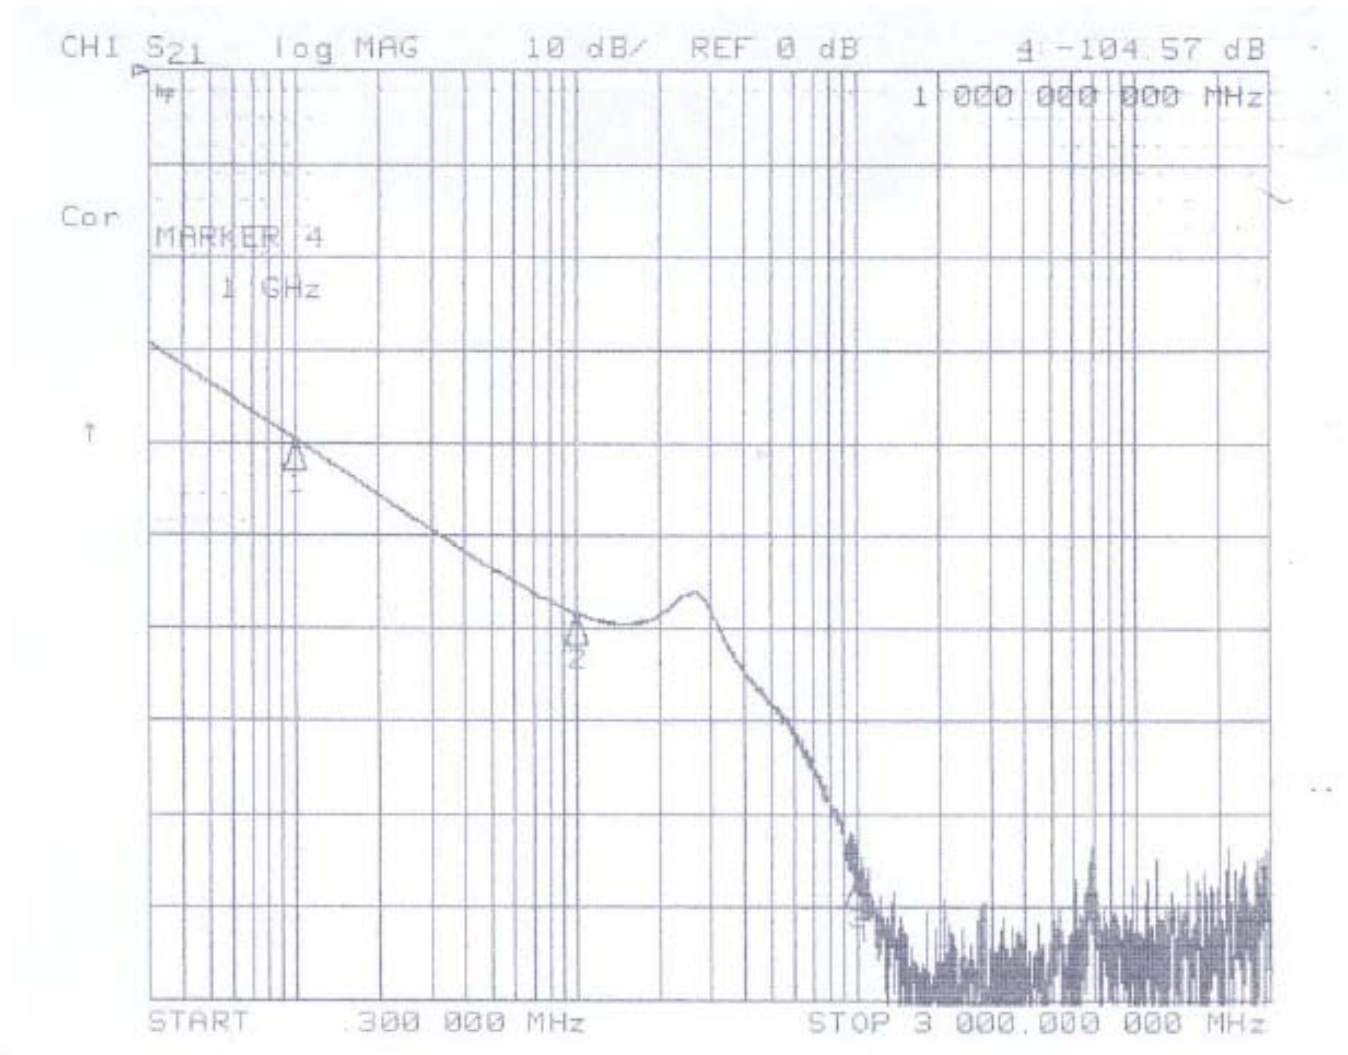

- A low pass filter is a network of capacitors to ground and inductors in series to filter unwanted signals
- As frequency increases, the capacitor becomes less resistive – 
- As frequency increases, the inductor becomes more resistive 
- A combination of the two elements shunts the high frequency noise to the ground
- Increasing the number of elements increases the filter performance

$$X_C = \frac{1}{2\pi fC}$$

$$X_L = 2\pi fL$$

# Low Pass Filter Response (Insertion Loss)

# Low Pass Filter Theory

- However, it is also important to remember that all capacitors have inherent inductance as well – reducing this improves the performance

# Filter Theory

- Self inductance is reduced by changing the architecture of the capacitor
- The longer and narrower the electrode path, the higher the inductance
- 3-terminal chips have lower inductance than conventional chips
- Discoidal capacitors have the lowest inductance.

# Important points to remember

- Filter performance is (generally) quoted at room temperature, no-load (0A flowing) and in a 50Ω system
- In real life the performance is unlikely to be as good
- Ceramic capacitors are affected by the application of voltage and temperature
- Ferrite bead inductors saturate at reasonably low currents
- The real life source and load impedance is unlikely to be 50Ω

# Types of Filter

## 'C' Filter

Capacitor between line and ground

## 'Pi' Filter

Capacitors between line and ground and Inductor in line

C & Pi filters are designed for applications with high source and load impedances and are the most common panel mount feedthrough filters

# Types of Filter

**'L-C' Filter**

**Capacitor between line and ground**

**Inductor in line**

**'T' Filter**

**Capacitor between line and ground**

**2x Inductors in line**

**L-C & T filters can offer performance improvements when the inductive elements 'face' a low impedance. If both source and load impedance are low then a 'T' filter is better than a Pi**

# Types of Filter

- Historically, panel mount filters tend to be 'C' or 'Pi' type.
- Surface mount filters tend to be 'C' or 'T' types
- This is purely due to historical manufacturing techniques – there is little or no technical reasoning behind it!
- Many applications are probably not using the optimum filter

# Panel Mounting Filters

# Surface Mount EMI filters

# Surface Mount EMI filters

- Filtering is simply one application of a capacitor – all MLCC's can be used as filters even simple chips
- For improved performance as a filter, changes to the basic architecture are made
- 'Low pass' filters use capacitors between line and ground to conduct high frequency noise to the ground or earth and, in some products, inductors in the signal line

# Surface Mount EMI filters

## Typical SM Chip Performance Curve

**100pF chip  
Insertion Loss  
shown**

# Surface Mount EMI filters

- Improved performance comes from using a 3-terminal feedthrough chip
- Same manufacturing techniques but allows for different internal architecture
- The signal lines pass through the chip architecture – the end terminations being shorted together

# Surface Mount EMI filters

## Ground inductance theory

### Basic Chip Capacitor Structure

Internal

Relatively high self inductance

# Surface Mount EMI filters

## Ground inductance theory – reduced inductance

### Feed Through Chip Capacitor Structure

External

Internal

### Lower self inductance

# Surface Mount EMI filters

## Typical Performance Curve

**100pF E01  
Insertion Loss  
shown**

# Surface Mount EMI filters

- Reducing the ground return inductance improves the performance so a 3-terminal chip offers an improvement over a conventional chip.
- The downside is that the signal must pass through the electrodes and is thus limited by the conductivity & architecture of the electrodes.
- The next improvement step is an X2Y™ chip which uses opposing current flow to cancel out internal inductances within the electrodes.
- The X2Y™ chip has 2 capacitors in a single ceramic block and is used as a bypass filter, so current does not flow through the chip and is not limited by the construction.

# X2Y

## X2Y Chip Capacitor Structure

External

Internal

Very low self inductance

# X2Y

## X2Y Capacitors

# Surface Mount Pi Filters

# Surface Mount EMI filters

- If we accept that we've reduced the ground inductance as much as possible the next step is to increase the filtering elements
- We can add an inductor in line, with capacitors to create a Pi or a T filter
- SM Pi filters use ferrite beads to add inductance between 2 capacitors

- SM T filters use 2x ferrite beads to add inductance either side of a small capacitor

# A note on Ferrite Beads

- All surface mount and small panel mount filters that have inductive elements use ferrite beads to form the inductance
- The inductance is very small – 50nH to 500nH
- Ferrites saturate with increasing current – typically the maximum before total saturation is about 6A flowing through the pin.
- Most filters quote the maximum operating current derived from the maximum the pin will carry (heating effects) and not the ferrite bead.
- When ferrites saturate, 'T' filters suffer more than Pi's due to the lower capacitance values involved
- Full load insertion loss approximates the performance of a C filter

# High Performance SMD Pi-Filters

## Generic Construction / Theory

# High Performance SMD Pi-Filters

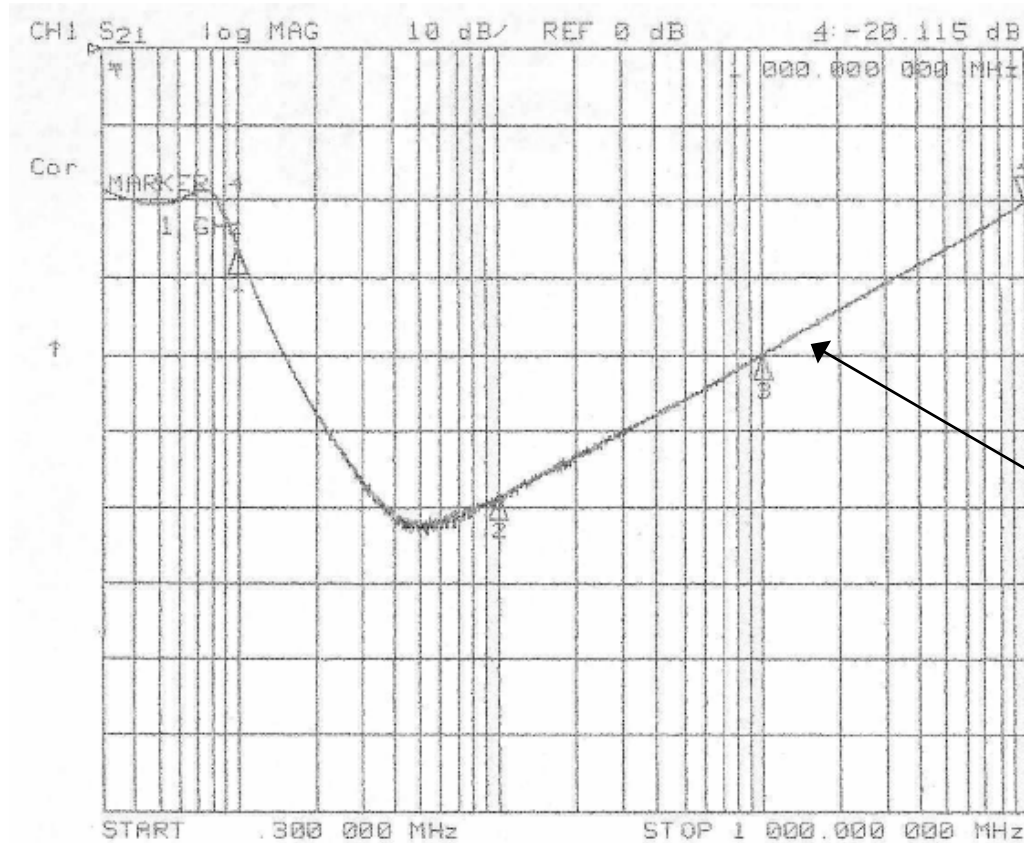

## Features

- Ferrite beads are used to add inductance in line
- High current 'C' filters are made the same way, but the ferrite bead is left out.
- An alternative option is to leave the board track under the feedthrough chip to handle the current

# High Performance SMD Pi-Filters

## Typical Performance Curve

**SBSGP 220nF  
Insertion Loss  
shown**

**Note the  
degradation with  
increasing  
frequency**

# Surface Mount EMI filters & High Frequency

All surface mount filters suffer at high frequencies

Insertion loss drops off as frequency increases

# Surface Mount EMI filters & High Frequency

- Insertion loss for surface mount types is lower at higher frequencies (100'sMHz to 1GHz) above the component resonance
- You can improve this by using a shielding can on the board to form a faraday cage, or by using a special track layout in conjunction with a multilayer board
- The high frequency performance can be improved, but it is difficult to get SM parts as good as panel mount components

# Surface Mount EMI filters & High Frequency

## High Frequency Improvement by Use of Shielded Can

Place shielding can over clean side of circuit to act as bulkhead and faraday cage

# Surface Mount EMI filters & High Frequency

## High Frequency Improvement by Use of Shielded Can

- Shielding can is grounded
- Can need not be attached to the filter
- Insertion loss performance is similar to that of a panel mounting type
- Best method of improving performance of SM filters
- Not very easy in practise – cost is relatively high

# Surface Mount EMI filters & High Frequency

High Frequency Improvement by Use of Buried Layer Board

*DIRTY AREA*

*CLEAN AREA*

# Surface Mount EMI filters & High Frequency

## High Frequency Improvement by Use of Buried Layer Board

- Much more common method
- Output track is on opposite side of the pcb to the input track
- A via connects the filter to the other side of the board
- An internal ground plane provides screening between the 2 tracks
- Assembly of the filter is then standard pick-and-place
- Benefit is ease of assembly for manufacturer

# Panel Mount EMI filters

# Panel Mount EMI filters

- Panel mount filters bolt or solder direct into a Faraday cage bulkhead to provide the ultimate in filtering performance at high frequencies
- These include filter connectors for multiple lines
- The heart of the filter is the disc or planar array - internal construction is as per standard MLCC's but the outside is shaped.
- The circular shape reduces self inductance and offers electrode interleaving giving optimum filtering performance
- Beware - some manufacturers use chip capacitors. These types of component have the same limitations as surface mount filters – poor high frequency performance

# Discoidal Capacitors

- Used for feedthrough filtering in panel mount filters and bulkheads.
- Ultimate in low inductance design
- Manufactured in the same way as chip capacitors and shaped prior to termination

# Planar Arrays

- Like many discoidals in one piece of ceramic
- Used for multi-way connectors

# Panel Mounting Filters

## Discoidal Capacitor Filter Construction

# Panel Mounting Filters

- Traditionally used tubular capacitors for low value filters
- Tubes are cheaper than discs, but only available in much lower capacitance (typically 20nF maximum)
- Often the low capacitance limitation is overcome by the use of very unstable dielectrics
- Ideal for Pi filters – hence these are often offered irrespective of best solution
- Have a reputation for cracking, particularly in applications where the tube is exposed

# Panel Mounting Filters

## Tubular Capacitor Filter Construction

# Panel Mount EMI filters

## Factors to consider in filter selection

- Ferrite bead inductors saturate with current – in high current applications it is better to use a high capacitance 'C' filter
- Some suppliers use very poor ceramic dielectrics such as Z5U, Y5V, X7W etc. which effect performance considerably
- The grounding is critical – mounting hole diameter and tightening torque must be checked
- Filter mounting pitch is determined by the head of the filter not the thread – often more expensive small thread filters are mistakenly specified

# Ceramic Dielectric Performance

## Example of different Dielectric Performance

Compare 2x 1nF filters :-

1) 500V rated X7R 10nF

@ 50V & 125°C

Actual capacitance  $\approx 8.6\text{nF}$

2) 50V rated Z5U 10nF

@ 50V & 125°C

Actual capacitance  $\approx 1.5\text{nF}$

Insertion loss of 8.6nF filter @ 1MHz  $\approx 3\text{dB}$

Insertion loss of 1.5nF filter @ 1MHz = 0dB

# Effect of Poor Grounding

Insertion Loss Plot 1 -  
680nF filter mounted in  
a standard test fixture  
with good grounding

(Tested IAW MIL-STD-  
220)

# Effect of Poor Grounding

**Insertion Loss Plot 2 -**  
the same filter as in  
plot 1, still in the  
same test can, but the  
filter mounting nut  
has been slackened  
by  $\frac{1}{4}$  turn

# Effect of Inadequate Shielding

**Insertion Loss Plot 3 - The same 680nF filter again, but this time mounted in a test fixture with too large a mounting hole meaning there's a gap which allows high frequency noise to radiate through the bulkhead to the output side**

# Panel Mounting Filters

- A note on the mechanical design for installing panel mount filters
- The body thread does not define the pitch – the head of the body does
- Smaller thread filters tend to be harder to make and therefore more expensive
- For closer pitch mounting use round body styles or consider an assembly

# Panel Mounting Filters

AND FINALLY

This is not possible

But it's amazing how often we see it tried

# Syfer Technology

**innovative  
world-class  
ceramic components**

THANK YOU
