Rev.2.20 Jan 2018

Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.
2. Renesas Electronics hereby expressly disclaims any warranties against and liability for infringement or any other claims involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawings, charts, programs, algorithms, and application examples.
3. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
4. You shall not alter, modify, copy, or reverse engineer any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copying or reverse engineering.
5. Renesas Electronics products are classified according to the following two quality grades: "Standard" and "High Quality". The intended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below.
   "Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; industrial robots; etc.
   "High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc.
   Unless expressly designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not intended or authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems; surgical implantations; etc.), or may cause serious property damage (space system; undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment; etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or any third parties arising from the use of any Renesas Electronics product that is inconsistent with any Renesas Electronics data sheet, user's manual or other Renesas Electronics document.
6. When using Renesas Electronics products, refer to the latest product information (data sheets, user's manuals, application notes, "General Notes for Handling and Using Semiconductor Devices" in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat dissipation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any malfunctions, failure or accident arising out of the use of Renesas Electronics products outside of such specified ranges.
7. Although Renesas Electronics endeavors to improve the quality and reliability of Renesas Electronics products, semiconductor products have specific characteristics, such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Unless designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not subject to radiation resistance design. You are responsible for implementing safety measures to guard against the possibility of bodily injury, injury or damage caused by fire, and/or danger to the public in the event of a failure or malfunction of Renesas Electronics products, such as safety design for hardware and software, including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult and impractical, you are responsible for evaluating the safety of the final products or systems manufactured by you.
8. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. You are responsible for carefully and sufficiently investigating applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive, and using Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
9. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall comply with any applicable export control laws and regulations promulgated and administered by the governments of any countries asserting jurisdiction over the parties or transactions.
10. It is the responsibility of the buyer or distributor of Renesas Electronics products, or any other party who distributes, disposes of, or otherwise sells or transfers the product to a third party, to notify such third party in advance of the contents and conditions set forth in this document.
11. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.
12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products.

(Note 1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its directly or indirectly controlled subsidiaries.

(Note 2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.

(Rev.4.0-1 November 2017)

General Precautions in the Handling of Microprocessing Unit and Microcontroller Unit Products

The following usage notes are applicable to all Microprocessing unit and Microcontroller unit products from Renesas. For detailed usage notes on the products covered by this document, refer to the relevant sections of the document as well as any technical updates that have been issued for the products.

1. Handling of Unused Pins

   Handle unused pins in accordance with the directions given under Handling of Unused Pins in the manual.

   — The input pins of CMOS products are generally in the high-impedance state. In operation with an unused pin in the open-circuit state, extra electromagnetic noise is induced in the vicinity of LSI, an associated shoot-through current flows internally, and malfunctions occur due to the false recognition of the pin state as an input signal become possible. Unused pins should be handled as described under Handling of Unused Pins in the manual.

2. Processing at Power-on

   The state of the product is undefined at the moment when power is supplied.

   — The states of internal circuits in the LSI are indeterminate and the states of register settings and pins are undefined at the moment when power is supplied.
   In a finished product where the reset signal is applied to the external reset pin, the states of pins are not guaranteed from the moment when power is supplied until the reset process is completed.
   In a similar way, the states of pins in a product that is reset by an on-chip power-on reset function are not guaranteed from the moment when power is supplied until the power reaches the level at which resetting has been specified.

3. Prohibition of Access to Reserved Addresses

   Access to reserved addresses is prohibited.

   — The reserved addresses are provided for the possible future expansion of functions. Do not access these addresses; the correct operation of LSI is not guaranteed if they are accessed.

4. Clock Signals

   After applying a reset, only release the reset line after the operating clock signal has become stable. When switching the clock signal during program execution, wait until the target clock signal has stabilized.

   — When the clock signal is generated with an external resonator (or from an external oscillator) during a reset, ensure that the reset line is only released after full stabilization of the clock signal. Moreover, when switching to a clock signal produced with an external resonator (or by an external oscillator) while program execution is in progress, wait until the target clock signal is stable.

5. Differences between Products

   Before changing from one product to another, i.e. to a product with a different part number, confirm that the change will not lead to problems.

   — The characteristics of Microprocessing unit or Microcontroller unit products in the same group but having a different part number may differ in terms of the internal memory capacity, layout pattern, and other factors, which can affect the ranges of electrical characteristics, such as characteristic values, operating margins, immunity to noise, and amount of radiated noise. When changing to a product with a different part number, implement a system-evaluation test for the given product.

How to Use This Manual

Readers This manual is intended for users who wish to understand the functions of the RH850/D1L/D1M and design application systems using the following RH850/D1L/D1M microcontrollers:

Purpose This manual is intended to give users an understanding of the hardware functions of the RH850/D1L/D1M shown in the *Organization* below.

Organization This manual is divided into two parts: Hardware (this manual) and Architecture (RH850 Family User's Manual: Software).

Hardware	Software
Pin functions	Overview
CPU function	Processor Model
On-chip peripheral functions	Register Reference
Flash memory programming	Exceptions and Interrupts
	Memory Management
	Instruction Reference
	Reset
	Appendix

How to read this manual It is assumed that the readers of this manual have general knowledge in the fields of electrical engineering, logic circuits, and microcontrollers.

To understand the overall functions of the RH850/D1L/D1M.

→ Read this manual according to the Contents.

To understand the details of an instruction function

→ See RH850 G3M User's Manual: Software (R01US0123EJ) available separately.

Product Naming To indicate the dedicated product in the "RH850/D1L/D1M Group", each product name is described as below:

D1L1, D1L2, D1L2H, D1L2(H), D1Lx

D1M1, D1M1H, D1M1(H), D1M2, D1M2H, D1M2(H), D1Mx, D1M1A, D1M1-V2

Conventions Data significance: Higher digits on the left and lower digits on the right

Active low representation: $\overline{xxx}$ (overscore over pin or signal name)

Memory map address: Higher addresses on the top and lower addresses on the bottom

Note: Footnote for item marked with Note in the text

Caution: Information requiring particular attention

Remark: Supplementary information

Numeric representation: Binary ... xxxx or $xxxx_B$

Decimal ... xxxx

Hexadecimal ... $xxxx_H$

Prefix indicating power of 2 (address space, memory capacity):

K (kilo): $2^{10} = 1,024$

M (mega): $2^{20} = 1,024^2$

G (giga): $2^{30} = 1,024^3$

Description of Registers

Each register description includes register access, register address, and register value after a reset, a bit chart, illustrating the arrangement of bits, and a table of bits, describing the meaning of the bit settings.

The standard format for bit charts and tables are described below.

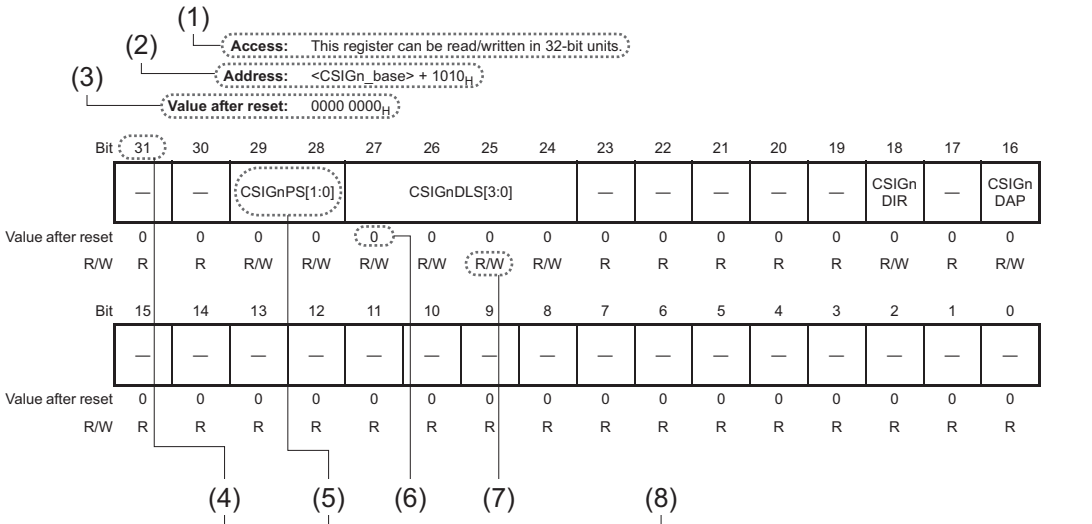

Table 14.19 CSIGnCFG0 register contents (1/2)

Bit Position	Bit Name	Function
31, 30	Reserved	The write value should always be the value after reset.
29, 28	CSIGnPS[1:0]	Specifies parity.
27 to 24	CSIGnDLS [3:0]	Specifies data length. 0: Data length is 16 bits 1: Data length is 1 bit 2: Data length is 2 bits ... 15: Data length is 15 bits **CAUTION** For a data length of less than 7 bits, do not set bits CSIGnCFG0.CSIGnDLS[3:0] for a value 1 to 6 when the extended data length function is disabled with bit CSIGnCTL1.CSIGnEDLE set to 0. It is forbidden to transmit two consecutive data with a data length of less than 7 bits.
23 to 19	Reserved	The write value should always be the value after reset.

CSIGn PS1	CSIGn PS0	Transmission	Reception
0	0	No parity transmitted	No parity is waited for.
0	1	Add parity bit fixed at 0	Parity bit is waited for but not judged.
1	0	Add odd parity	Odd parity bit is waited for.
1	1	Add even parity	Even parity bit is waited for.

(1) Access

The register can be accessed in the bit unit indicated here.

(2) Address

This is the register address.
For base address, see description of base address in each section.

(3) Value after a reset (in hexadecimal notation)

This is the value of all bits of the register after a reset. Values for bytes are given as numbers in the range from 0 to 9 and letters from A to F or as X where they are undefined.

(4) Bit position

This is the bit number.
The bits are numbered from 31 to 0 for 32-bit registers, 15 to 0 for 16-bit registers, and 7 to 0 for 8-bit registers.

(5) Bit name

Bit name or field name is indicated.
When clearly identifying the digits of a bit field is required, do so by using a form such as CSIGnDLS[3:0] above.
Indicate reserved bits by using a dash (—).

(6) Value after a reset (in binary notation)

This is the bit values after a reset.

0	:	The value after a reset is 0.
1	:	The value after a reset is 1.
—	:	The value after a reset is undefined.

(7) R/W

This is the bit attribute of all bits of the register.

R/W	:	The bit or field is readable and writable.
R	:	The bit or field is readable. Note that all reserved bits are indicated as R. When written, the value specified in the bit chart or the value after a reset should be written.
W	:	This bit or field is writable.When read, the value is undefined. If a value is indicated in the bit chart, the value is returned.

(8) Function

This is function of the bit.

Table of Contents

Section 1 Overview

1.1 Former products

CAUTION

For the new development project, please consider using "Replacement product" in the following table instead of "Former product".

Table 1.1 RH850/D1L/D1M former products

Former product		Replacement product	
Name	**Part number**	**Name**	**Part number**
D1M1_3.75M	R7F701404	D1M1-V2	R7F701442, R7F701462
D1M1_5M	R7F701405		
D1M1H_3.75M	R7F701406	D1M1A	R7F701441, R7F701461
D1M1H_5M	R7F701407		

1.2 RH850/D1L products overview

Table 1.2 RH850/D1L products overview (1/3)

Series name:			D1L1	D1L2	D1L2H
Memory	Code Flash		2 MB	4 MB	
	Local RAM (LRAM)		256 KB	512 KB	
	Retention RAM (RRAM)		16 KB		
	Data Flash		64 KB		
	Video RAM (VRAM) with Video RAM wrapper		–	144 KB	
External memory interfaces	Serial Flash Memory I/F (SFMA)	Bus width	4 bit	4 bit	8 bit
		Mode	SDR	SDR, DDR	SDR, DDR
		Max. clock	40 MHz	SDR: 120 MHz, DDR: 80 MHz	SDR: 120 MHz, DDR: 80 MHz
CPU	CPU System		G3M		
	CPU frequency		120 MHz		
	Floating Point Unit (FPU)		Provided		
	Memory Protection Unit (MPU)		Provided		
	Memory caches	Instruction cache	8 KB/4-way associative		
		Non-CPU system memories	–	16 KB/4-way associative	
DMA			16 channels		

Table 1.2 RH850/D1L products overview (2/3)

Series name:			D1L1	D1L2	D1L2H
Operating clock	Main Oscillator (MainOsc)		8 to 16 MHz		
	Low Speed Internal Oscillator (LS IntOsc)		typ. 240 kHz		
	High Speed Internal Oscillator (HS IntOsc)		typ. 8 MHz		
	Sub Oscillator (SubOsc)		typ. 32.768 kHz		
	Spread-spectrum PLL0		max. 480 MHz		
	PLL1		max. 480 MHz		
I/O port			103	103	126
A/D Converter (ADCE)			16 channels, 12 bit resolution		
Timer	Timer Array Unit B (TAUB)		3 units (16 bit resolution, 16 channels/unit)		
	Timer Array Unit J (TAUJ)		1 unit (32 bit resolution, 4 channels/unit)		
	Operating System Timer (OSTM)		2 units (32 bit resolution, 1 channel/unit)		
	Alway-On-Area Timer (AWOT)		1 unit (32 bit resolution, 1 channel/unit)		
	Real-Time Clock (RTCA)		Provided		
	Window Watchdog Timer A (WDTA)		2 units		
	PWM Generators with Diagnostic		1 unit (12 bit resolution, 24 PWM generators, 12 with diagnostic capability)		
Communi-cation interfaces	Clocked Serial Interface G (CSIG)		4 channels		
	Clocked Serial Interface H (CSIH)		2 channels		
	CAN Interface (RS-CAN)		3 channels (total 192 message buffers)*1		
	CAN Interface (RS-CANFD)		3 channels (total 192 message buffers)*1		
	LIN/UART Interface (RLIN3)		4 channels		
	I^2C Interface (RIIC)		2 channels		
External interrupts	Maskable		11		
	Non-maskable (NMI)		1		
Audio	Sound Generator (SG)		5 units		
	PCM-PWM Converter (PCMP)		1 unit		
	I^2S Interface (SSIF)		2 units (1 channel/unit)		
Video and Graphics	Video Output (VO)	Resolution	–	480 x 320 pixels	
		Color format	–	RGB666	
		Max. pixel clock	–	10 MHz	
		Layers	–	4	
		I/F	–	LVTTL	
		RLE decoding	–	Provided	
		Sprite layer	–	3 x 16 sprites for 3 output layers	
		Timing Controller (TCON)	–	3 programmable signals	7 programmable signals

Table 1.2 RH850/D1L products overview (3/3)

	Series name:		D1L1	D1L2	D1L2H
Other functions	LCD Bus I/F (LCBI)		18 bit output, max. 10 MHz		
	Clock Monitors (CLMA)		for MainOsc, LS IntOsc, HS IntOsc, PLL0, PLL1		
	Data CRC (DCRA)		Provided		
	Power-On-Clear (POC)		Provided		
	Intelligent Stepper Motor Driver (ISM), incl. zero point detection for each channel		1 unit, 6 channels		
	Error Correction Coding (ECC)		for Code Flash, Data Flash, Local RAM, Retention RAM, Video RAM, RS-CAN RAM, Caches tag/data RAMs		
	Error Control Module (ECM)		Master/Checker		
	Intelligent Cryptographic Unit (ICU-S2)		Provided		
	On-Chip debug (OCD)		Provided		
	Boundary Scan		Provided		
Voltage supply*2	Internal logic	AWO*3	3.3 V, 5 V via on-chip voltage regulator		
		ISO*3	3.3 V, 5 V via on-chip voltage regulator		
	I/O buffers	GPIO*3	3.3 V, 5 V		
	A/D Converter supplies		nominal 3.3 V, 5 V		
Package	Type		QFP	QFP	QFP
	Pins		144	144	176
	pin/ball pitch		0.5 mm	0.5 mm	0.5 mm

	Window Watchdog Timer A (WDTA)	2 units	
	PWM Generators with Diagnostic	1 unit (12 bit resolution, 24 PWM generators, 12 with diagnostic capability)	
Communi-cation interfaces	Clocked Serial Interface G (CSIG)	4 channels	
	Clocked Serial Interface H (CSIH)	2 channels	
	CAN Interface (RS-CAN)	3 channels (total 192 message buffers)*1	
	CAN Interface (RS-CANFD)	3 channels (total 192 message buffers)*1	
	LIN/UART Interface (RLIN3)	4 channels	
	I^2C Interface (RIIC)	2 channels	
	Ethernet AVB MAC (ETNB)	1 channel (Media Access Controller for up to 100 Mbps, with Audio Video Bridging)	
External interrupts	Maskable	11	
	Non-maskable (NMI)	1	
Audio	Sound Generator (SG)	5 units	
	PCM-PWM Converter (PCMP)	1 unit	
	I^2S Interface (SSIF)	2 units (1 channel/unit)	

Table 1.4 RH850/D1M1 development products overview (3/4)

			Series name: D1M1-V2	D1M1A
Video and Graphics	Video Output 0 (VO0)	Resolution	1024 x 1024 pixels	1280 x 1024 pixels
		Color format	RGB888	
		Max. pixel clock	30 MHz LVTTL, 40 MHz SerialRGB	48 MHz LVTTL, 34 MHz OpenLDI, 30 MHz VODDR
		Layers	4	
		I/F	LVTTL,SerialRGB	LVTTL, OpenLDI, VODDR *4
		Predistortion	Warping Engine (VOWE)	
		Timing Controller (TCON)	7 programmable signals	
		Video output data control	Video Output Checker (VOCA), 2 CRC checker (DISCOM)	
	Video Output 1 (VO1)	Resolution	–	1280 x 1024 pixels
		Color format	–	RGB888
		Max. pixel clock	–	40 MHz SerialRGB, 10 MHz VODDR
		Layers	–	4
		I/F	–	SerialRGB, VODDR
		Predistortion	–	–
		Timing Controller (TCON)	–	7 programmable signals
		Video output data control	–	Video Output Checker (VOCA) 2 CRC checker (DISCOM)
	Video Outputs shared features	RLE decoding	Provided for all layers	
		Sprite layer	4 x 16 sprites	
	Video Input (VI)	Channels	1 channel	
		Resolution	1024 x 1024 pixels	
		Pixel clock	30 MHz	
		Color formats	RGB666, ITU656	
		I/F	LVTTL	
	Graphics Processing Unit		2D Graphics Processing Unit (GPU2D), 80 MHz operation clock	2D Graphics Processing Unit (GPU2D), 120 MHz operation clock
	JPEG Unit (JCUA)		Provided	

Table 1.4 RH850/D1M1 development products overview (4/4)

Series name:			D1M1-V2	D1M1A
Other functions	LCD Bus I/F (LCBI)		18 bit output, max. 10 MHz	–
	Clock Monitors (CLMA)		for MainOsc, LS IntOsc, HS IntOsc, PLL0, PLL1, Video Input pixel clocks	
	Data CRC (DCRA)		Provided	
	Power-On-Clear (POC)		Provided	
	Intelligent Stepper Motor Driver (ISM), incl. zero point detection for each channel		1 unit, 6 channels	
	Error Correction Coding (ECC)		for Code Flash, Data Flash, Local RAM, Retention RAM, Video RAM, RS-CAN RAM, Caches tag/data RAMs	
	Error Control Module (ECM)		Master	
	Intelligent Cryptographic Unit (ICU-S2)		Provided	
	On-Chip debug (OCD)		Provided	
	Boundary Scan		Provided	
Voltage supply*2	Internal logic	AWO*3	3.3 V, 5 V via on-chip voltage regulator	
		ISO*3	3.3 V via on-chip voltage regulator	
	I/O buffers	GPIO*3	3.3 V, 5 V	
		SDR-SDRAM	–	3.3 V
	A/D Converter supplies		nominal 3.3 V, 5 V	
Package	Type		LQFP	BGA
	Pins		176	272
	pin/ball pitch		0.5 mm	1.0 mm

Note 1. Devices with RS-CAN or RS-CANFD interfaces have different product names, refer to **Section 1.5, Ordering Information**.

Note 2. The supply voltages are given as nominal values. Refer to the data sheet for detail specification of electrical values.

Note 3. AWO: Always-On-Area
ISO: Isolated-Area
GPIO: General purpose I/O port

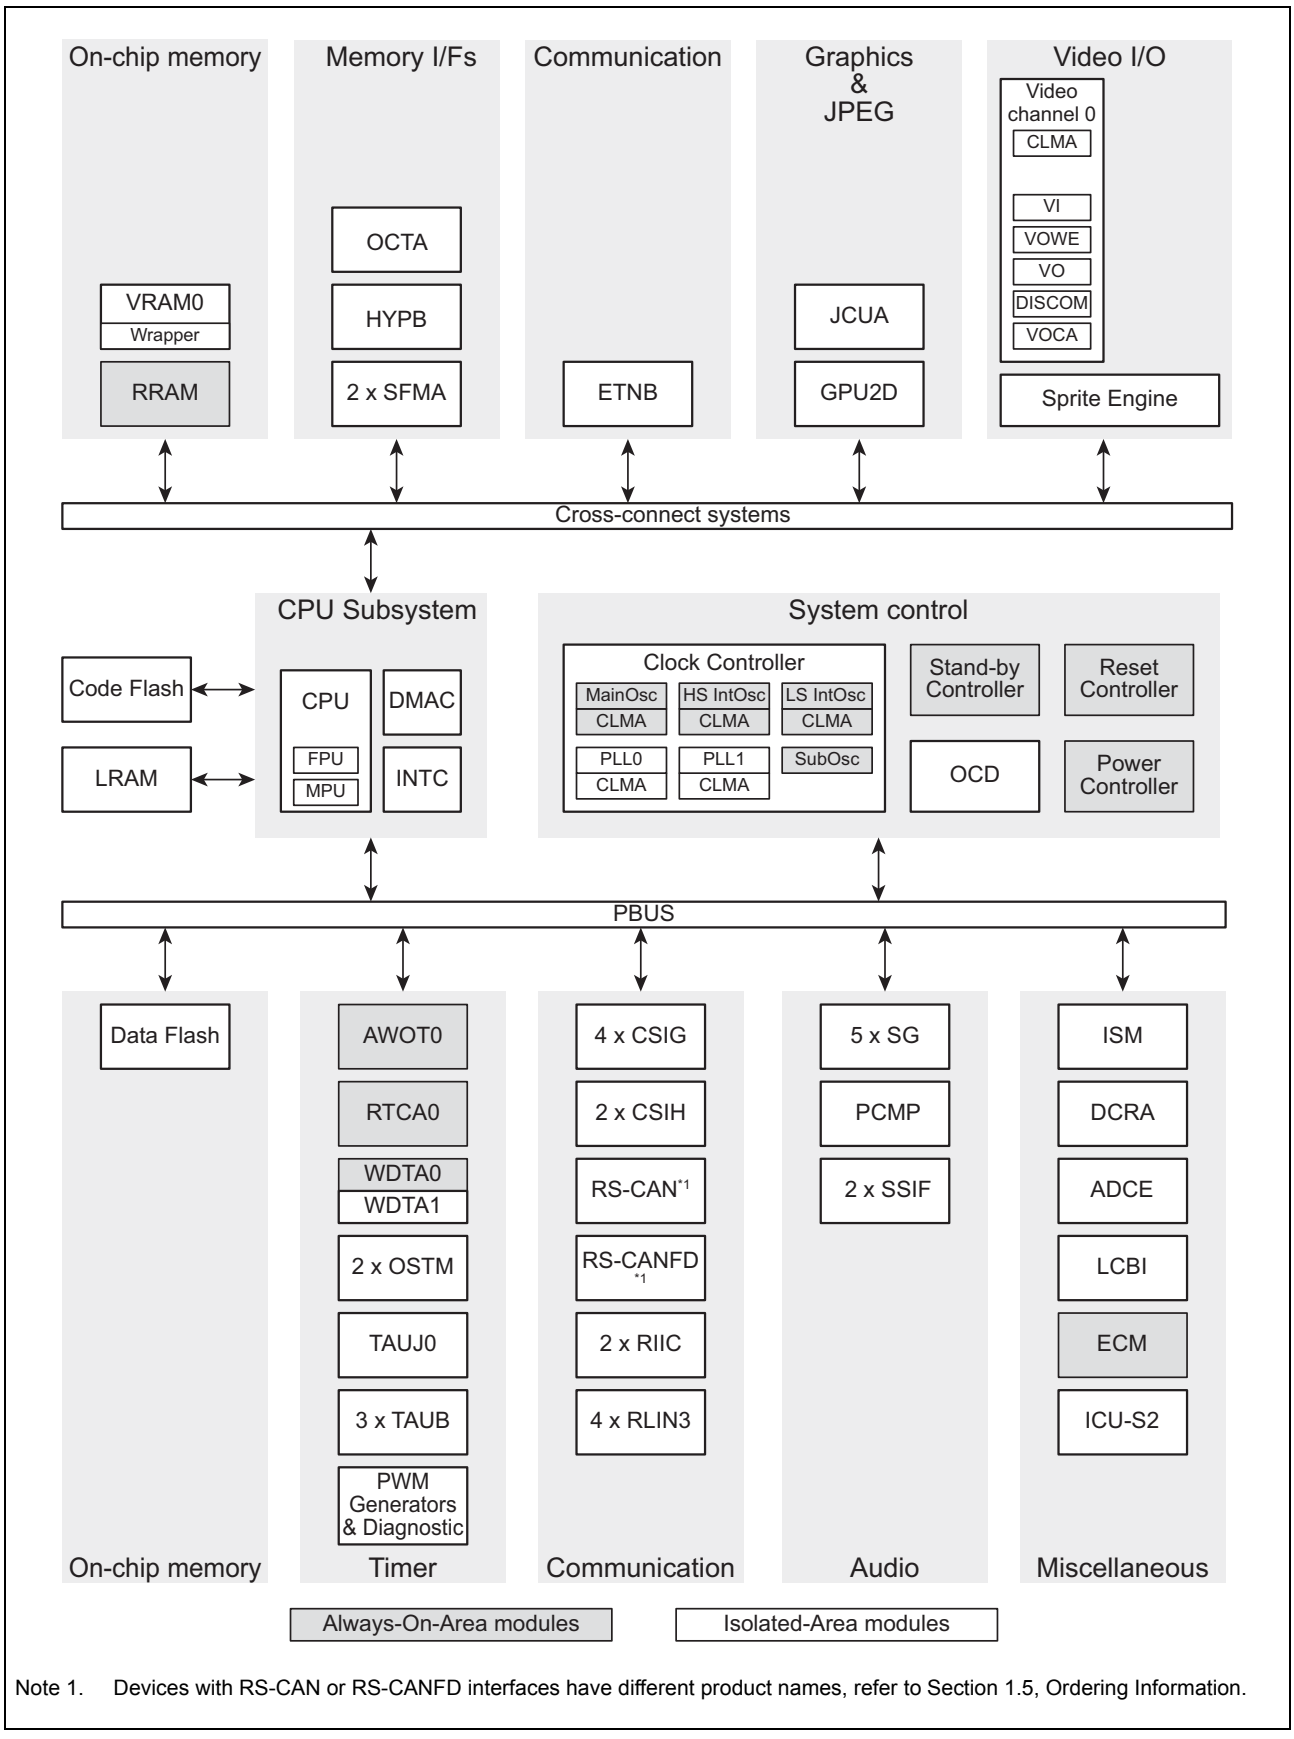
Note 4. Not all flash memory interfaces and all Video Output VO0 interfaces can be used in parallel. Refer to Table 1.5, Flash memory and Video output VO0 connection options for D1M1-V2 and D1M1A devices.

Table 1.5 Flash memory and Video output VO0 connection options for D1M1-V2 and D1M1A devices

Option	HYPB0	OCTA0	SFMA0	SFMA2	SFMA1	NFMA	VO0
	Port group P21			Port groups P21, P22, P45	Port group P42		Port group P45
1	HYPB0 or OCTA0 or SFMA0 (8 bit, 80 MHz)			–	–	8 bit, 20 MHz	All I/Fs *2
2 *1	–	–	4 bit, 80 MHz	4 bit, 80 MHz	–	8 bit, 20 MHz	OpenLDI
3	HYPB0 or OCTA0 or SFMA0 (8 bit, 80 MHz)			–	8 bit, 40 MHz	–	All I/Fs

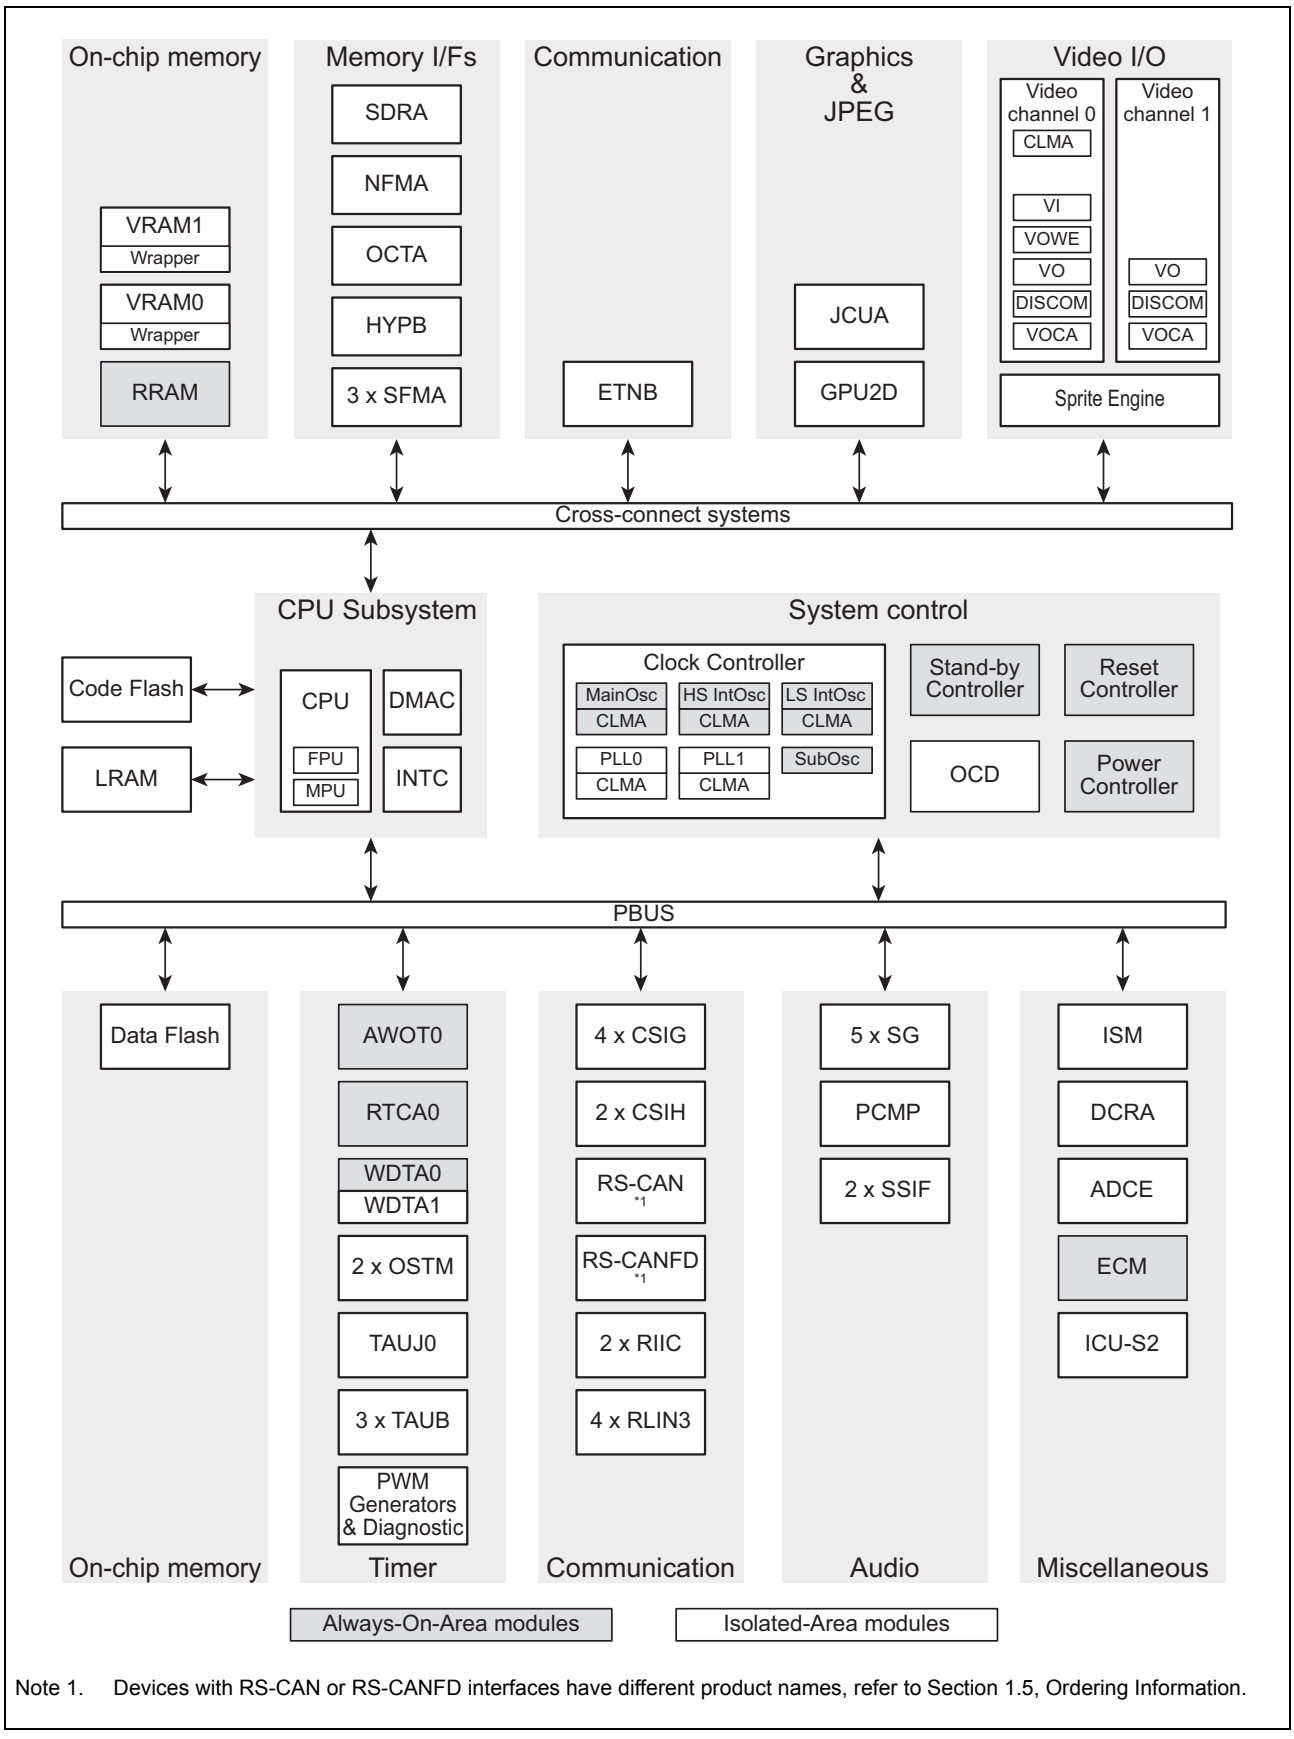
Note 1. This option is not available for D1M1-V2 devices.

Note 2. All interfaces means: LVTTL, OpenLDI, VODDR



Note 1. Devices with RS-CAN or RS-CANFD interfaces have different product names, refer to Section 1.5, Ordering Information.

Figure 1.4 D1M1-V2 block diagram



Note 1. Devices with RS-CAN or RS-CANFD interfaces have different product names, refer to Section 1.5, Ordering Information.

Figure 1.5 D1M1A block diagram

1.4 RH850/D1M2 products overview

Table 1.6 RH850/D1M2 products overview (1/4)

Series name:			D1M2_		D1M2H_	
			3.75M	5M	3.75M	5M
Memory	Code Flash		3.75 MB	5 MB	3.75 MB	5 MB
	Local RAM (LRAM)		512 KB			
	Retention RAM (RRAM)		16 KB			
	Data Flash		64 KB			
	Video RAM (VRAM) with Video RAM wrapper		2 x 1.55 MB			
External memory interfaces	SDRAM I/F	Bus width	16-bit		32-bit	
		Mode	DDR2-SDRAM I/F (SDRB)			
		Max. clock	240 MHz			
	Serial Flash Memory I/F 0 (SFMA0)	Bus width	8 bit			
		Mode	SDR, DDR			
		Max. clock	SDR: 120 MHz, DDR: 80 MHz			
CPU	CPU System		G3M			
	CPU frequency		240 MHz			
	Floating Point Unit (FPU)		Provided			
	Memory Protection Unit (MPU)		Provided			
	Memory caches	Instruction cache	8 KB/4-way associative			
		Non-CPU system memories	32 KB/4-way associative			
DMA			16 channels			
Operating clock	Main Oscillator (MainOsc)		8 to 16 MHz			
	Low Speed Internal Oscillator (LS IntOsc)		typ. 240 kHz			
	High Speed Internal Oscillator (HS IntOsc)		typ. 8 MHz			
	Sub Oscillator (SubOsc)		typ. 32.768 kHz			
	Spread-spectrum PLL0		max. 480 MHz			
	PLL1		max. 960 MHz			
	PLL2		max. 480 MHz			
I/O port			159		199	
A/D Converter (ADCE)			20 channels, 12 bit resolution			
Timer	Timer Array Unit B (TAUB)		3 units (16 bit resolution, 16 channels/unit)			
	Timer Array Unit J (TAUJ)		1 unit (32 bit resolution, 4 channels/unit)			
	Operating System Timer (OSTM)		2 units (32 bit resolution, 1 channel/unit)			
	Alway-On-Area Timer (AWOT)		1 unit (32 bit resolution, 1 channel/unit)			
	Real-Time Clock (RTCA)		Provided			
	Window Watchdog Timer A (WDTA)		2 units			
	PWM Generators with Diagnostic		1 unit (12 bit resolution, 24 PWM generators, 12 with diagnostic capability)			

Table 1.6 RH850/D1M2 products overview (2/4)

Series name:			D1M2_		D1M2H_	
			3.75M	5M	3.75M	5M
Communi-cation interfaces	Clocked Serial Interface G (CSIG)		4 channels			
	Clocked Serial Interface H (CSIH)		2 channels			
	CAN Interface (RS-CAN)		3 channels (total 192 message buffers)*1			
	CAN Interface (RS-CANFD)		3 channels (total 192 message buffers)*1			
	LIN/UART Interface (RLIN3)		4 channels			
	I^2C Interface (RIIC)		2 channels			
	Ethernet AVB MAC (ETNB)		1 channel (Media Access Controller for up to 100 Mbps, with Audio Video Bridging)			
	Media Local Bus (MLBB)		–		1 channel (50 Mbps)	
External interrupts	Maskable		11			
	Non-maskable (NMI)		1			
Audio	Sound Generator (SG)		5 units			
	PCM-PWM Converter (PCMP)		1 unit			
	I^2S Interface (SSIF)		2 units (1 channel/unit)			
Video and Graphics	Video Output 0 (VO0)	Resolution	1280 x 1024 pixels			
		Color format	RGB888			
		Max. pixel clock	48 MHz LVTTL, 48 MHz RSDS			
		Layers	4			
		I/F	LVTTL, single RSDS selectable for channel 0 or 1			
		Predistortion	Warping Engine (VOWE)			
		Timing Controller (TCON)	7 programmable signals			
		Video output data control	Video Output Checker (VOCA) 2 CRC checker (DISCOM)			

Table 1.6 RH850/D1M2 products overview (3/4)

Series name:			D1M2_		D1M2H_	
			3.75M	5M	3.75M	5M
Video and Graphics	Video Output 1 (VO1)	Resolution	1280 x 1024 pixels			
		Color format	RGB888			
		Max. pixel clock	48 MHz LVTTL, 48 MHz RSDS			
		Layers	4			
		I/F	LVTTL, single RSDS selectable for channel 0 or 1			
		Predistortion	–			
		Timing Controller (TCON)	7 programmable signals			
		Video output data control	Video Output Checker (VOCA) 2 CRC checker (DISCOM)			
	Video Outputs shared features	RLE decoding	Provided for background layers			
		Sprite layer	3 x 16 sprites			
	Video Input (VI)	Channels	1 channel		2 channels	
		Resolution	1024 x 1024 pixels			
		Pixel clock	48 MHz			
		Color formats	RGB888, ITU656			
		I/F	LVTTL for both channels, single MIPI CSI-2 for channel 0			
	Graphics Processing Unit		2D Graphics Processing Unit (GPU2D), 240 MHz operation clock			
	JPEG Unit (JCUA)		Provided			
Other functions	Clock Monitors (CLMA)		for MainOsc, LS IntOsc, HS IntOsc, PLL0, PLL1, Video Input pixel clocks			
	Data CRC (DCRA)		Provided			
	Power-On-Clear (POC)		Provided			
	Intelligent Stepper Motor Driver (ISM), incl. zero point detection for each channel		1 unit, 4 channels		1 unit, 6 channels	
	Error Correction Coding (ECC)		for Code Flash, Data Flash, Local RAM, Retention RAM, Video RAM, RS-CAN RAM, Caches tag/data RAMs			
	Error Control Module (ECM)		Master/Checker			
	Intelligent Cryptographic Unit (ICU-S2)		Provided			
	On-Chip debug (OCD)		Provided			
	Boundary Scan		Provided			

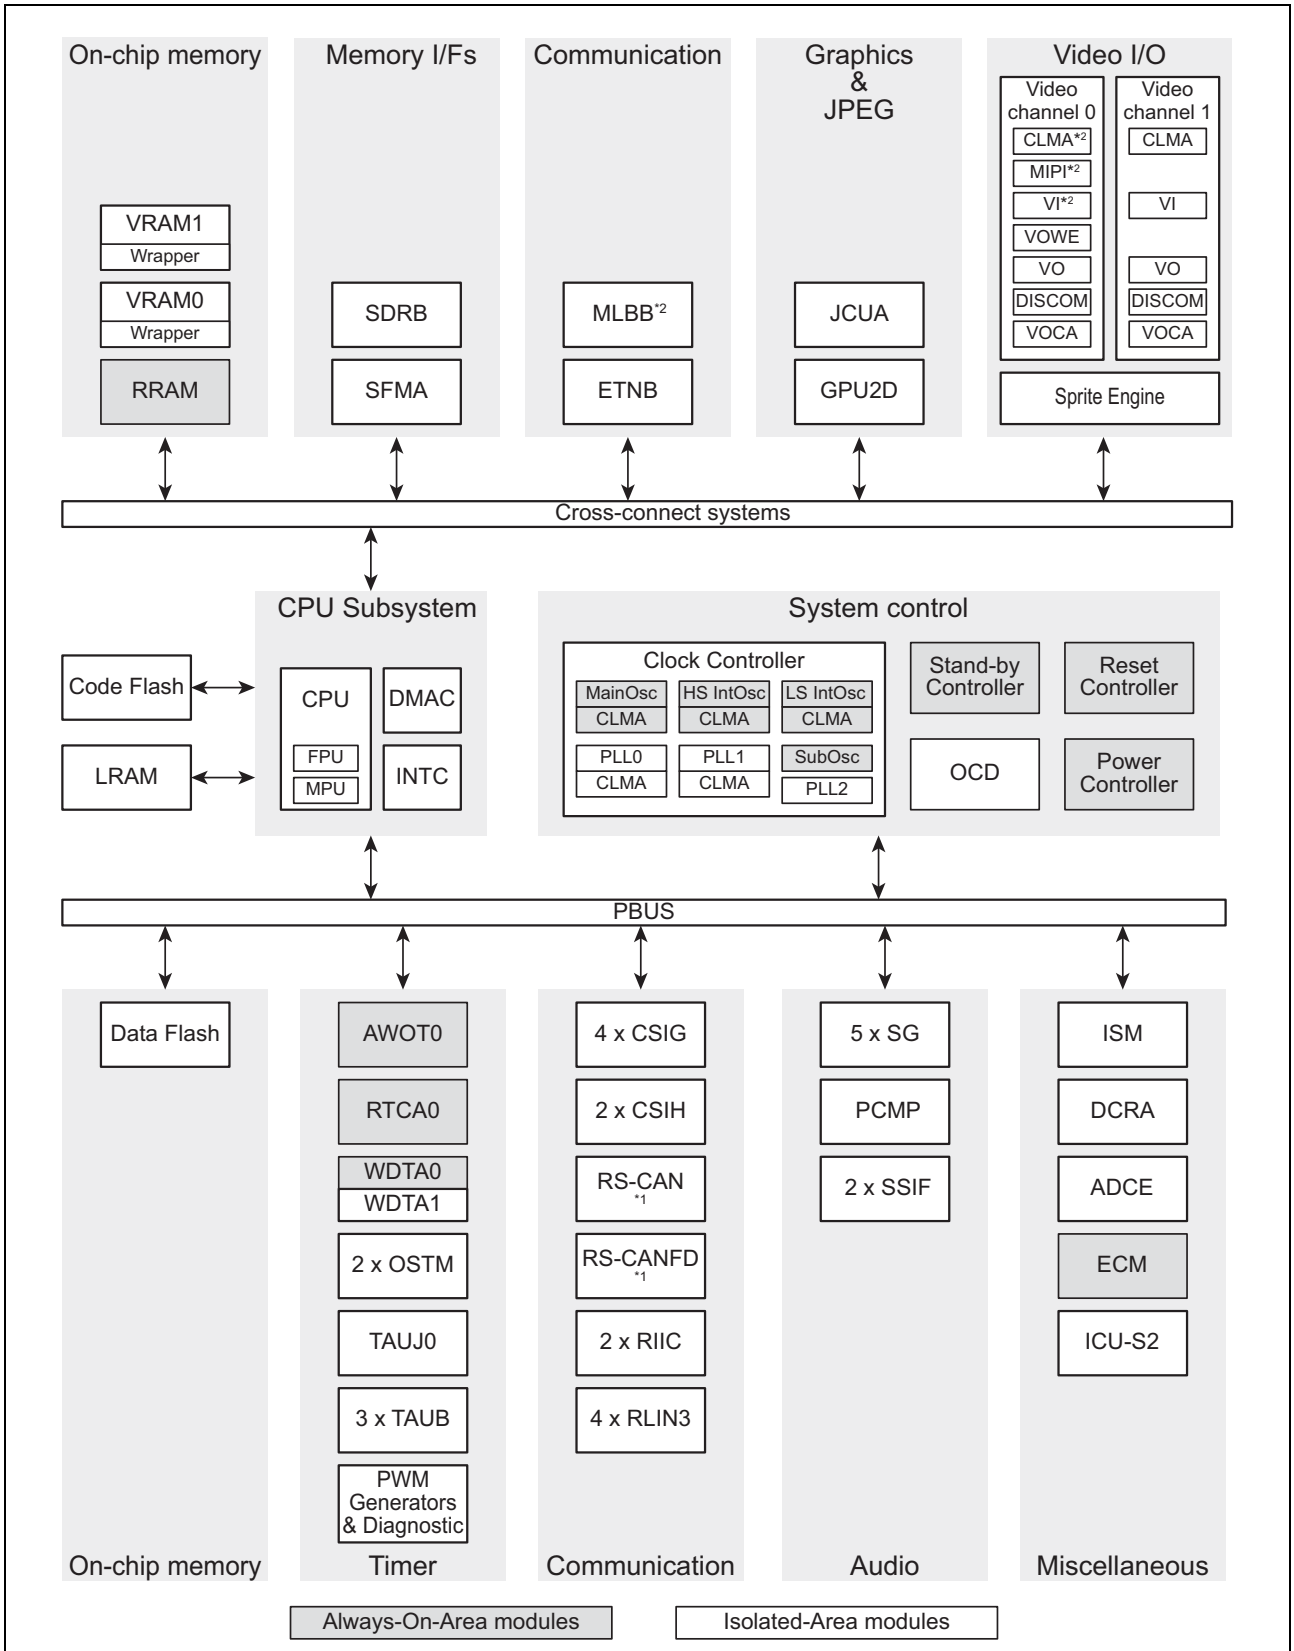
Table 1.6 RH850/D1M2 products overview (4/4)

Series name:			D1M2_		D1M2H_	
			3.75M	5M	3.75M	5M
Voltage supply*2	Internal logic	AWO*3	3.3 V, 5 V via on-chip voltage regulator			
		ISO*3	1.25 V			
	I/O buffers	GPIO*3	3.3 V, 5 V			
		SDR-SDRAM	–			
		DDR2-SDRAM	1.8 V			
	A/D Converter supplies		nominal 3.3 V, 5 V			
Package	Type		BGA			
	Pins		376		484	
	pin/ball pitch		1.0 mm			

Note 1. Devices with RS-CAN or RS-CANFD interfaces have different product names, refer to **Section 1.5, Ordering Information**.

Note 2. The supply voltages are given as nominal values. Refer to the data sheet for detail specification of electrical values.

Note 3. AWO: Always-On-Area
ISO: Isolated-Area
GPIO: General purpose I/O port



Note 1. Devices with RS-CAN or RS-CANFD interfaces have different product names, refer to Section 1.5, Ordering Information.
Note 2. These modules are not available for the D1M2 devices.

Figure 1.6 D1M2(H) block diagram

1.5 Ordering Information

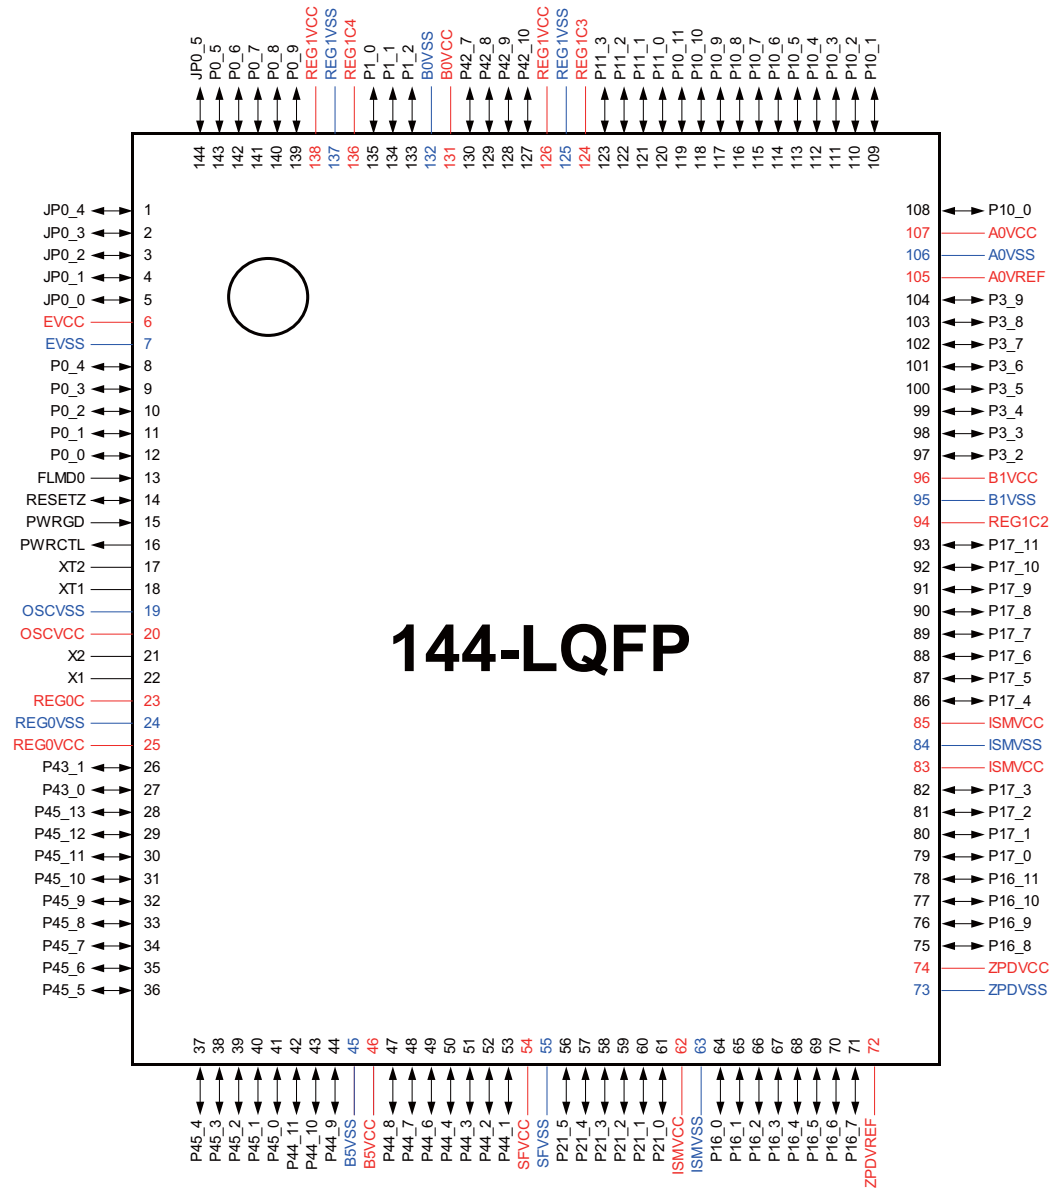
Table 1.7 Ordering information

Series name	Part number	Renesas order code	Remarks
D1L1	R7F701401		D1L1 with RS-CAN I/F
	R7F701421		D1L1 with RS-CANFD I/F
D1L2	R7F701402		D1L2 with RS-CAN I/F
	R7F701422		D1L2 with RS-CANFD I/F
D1L2H	R7F701403		D1L2H with RS-CAN I/F
	R7F701423		D1L2H with RS-CANFD I/F
D1M1_3.75M	R7F701404		D1M1 with 3.75 MB Code Flash and RS-CAN I/F
D1M1_5M	R7F701405		D1M1 with 5 MB Code Flash and RS-CAN I/F
D1M1H_3.75M	R7F701406		D1M1H with 3.75 MB Code Flash and RS-CAN I/F
D1M1H_5M	R7F701407		D1M1H with 5 MB Code Flash and RS-CAN I/F
D1M2_3.75M	R7F701408		D1M2 with 3.75 MB Code Flash and RS-CAN I/F
	R7F701428		D1M2 with 3.75 MB Code Flash and RS-CANFD I/F
D1M2_5M	R7F701410		D1M2 with 5 MB Code Flash and RS-CAN I/F
	R7F701430		D1M2 with 5 MB Code Flash and RS-CANFD I/F
D1M2H_3.75M	R7F701411		D1M2H with 3.75 MB Code Flash and RS-CAN I/F
	R7F701431		D1M2H with 3.75 MB Code Flash and RS-CANFD I/F
D1M2H_5M	R7F701412		D1M2H with 5 MB Code Flash and RS-CAN I/F
	R7F701432		D1M2H with 5 MB Code Flash and RS-CANFD I/F
D1M1-V2	R7F701442		D1M1-V2 with 4 MB Code Flash and RS-CAN I/F
	R7F701462		D1M1-V2 with 4 MB Code Flash and RS-CANFD I/F
D1M1A	R7F701441		D1M1A with 4 MB Code Flash and RS-CAN I/F
	R7F701461		D1M1A with 4 MB Code Flash and RS-CANFD I/F

Section 2 Pins

2.1 Pin Connection Diagrams

2.1.1 D1L1 and D1L2 pin connection



Note 1. Following signals are low level active and are denoted with overbars in this document:
– RESETZ → $\overline{\text{RESET}}$

2.2 Port Functions

2.2.1 Features

2.2.1.1 Port Group

This product has the following numbers of port groups:

Table 2.1 RH850/D1L/D1M Port Group

Product	Number of Group	Name of Group
D1L1	13	P0, P1, P3, P10, P11, P16, P17, P21, P42 to P45, JP0
D1L2	13	P0, P1, P3, P10, P11, P16, P17, P21, P42 to P45, JP0
D1L2H	13	P0, P1, P3, P10, P11, P16, P17, P21, P42 to P45, JP0
D1M1	13	P0, P1, P3, P10, P11, P16, P17, P21, P42 to P45, JP0
D1M1H	13	P0, P1, P3, P10, P11, P16, P17, P21, P42 to P45, JP0
D1M2	15	P0 to P3, P10, P11, P16, P17, P21, P43 to P47, JP0
D1M2H	17	P0 to P3, P10, P11, P16, P17, P21, P40, P42 to P47, JP0
D1M1A	14	P0, P1, P3, P10, P11, P16, P17, P21, P22, P42 to P45, JP0
D1M1-V2	14	P0, P1, P3, P10, P11, P16, P17, P21, P22, P42 to P45, JP0

Port Group Index n

Each port group is identified by its own index “n” (n = 0 to 3, 10, 11, 16, 17, 21, 22, 40, 42 to 47, JP0) throughout this section; e.g. PMCn for the port mode control register of the Pn pin.

2.2.1.2 Register Address

All port addresses are given as an offset from the individual base addresses, <PORTUn_Base>, <PORTOn_Base>, <JPORTUn_Base> and <JPORTOn_Base>.
These base addresses are listed in the following table.

Table 2.2 Port Base Address

Base address	Port group number	Address
<PORTUn_Base>	n = 0	FF61 8000$_H$
	n > 0	FF61 0000$_H$
<PORTOn_Base>	n = 0	FFC1 8000$_H$
	n > 0	FFC1 0000$_H$
<JPORTUn_Base>	n = 0	FF62 0000$_H$
<JPORTOn_Base>	n = 0	FFC2 0000$_H$

2.2.2 Overview

This product has various pins for input/output (I/O) functions, known as ports. The ports are organized in port groups.

This product also has several control registers to allocate the functions other than general I/O purpose to the corresponding pins.

For definitions of pin, port, and port group, see Section 2.2.2.1, Terms.

2.2.2.1 Terms

The terms described in this section are defined as follows.

- Pin:
  Denotes a physical pin. Every pin is denoted by a unique pin number. Most of pins can be used in multiple modes. Thus the pin name indicating its own function is assigned to each pin depending on the selected mode.
- Port group:
  Denotes a group of ports. The ports in the same port group have a common set of port mode control registers.
- Port mode / Port:
  A pin in port mode functions as a general purpose I/O pin. It is then called port.
  The corresponding name is Pn_m. For example, P0_7 denotes the port 7 of port group 0 and it is referred to as port P0_7.
- Alternative mode:
  In alternative mode, a pin can be used for various non-general purpose I/O functions; e.g. as the I/O pin of on-chip peripherals. Therefore, the corresponding pin name depends on the selected function. For example, the INTP0 pin denotes the pin for one of the external interrupt inputs.
  Note that two or more different names can refer to the same physical pin, e.g. for P0_2 and INTP0. Those different names indicate the function in which the pin is being operated.
- Port type:
  A control circuit depends on the assignment of a register to be set and a port type depends on the sort of the control circuit.

2.2.2.2 Overview of Pin Functions

The pin can operate in the following three different modes:

- Port mode (PMCn.PMCn_m = 0)
  The pin operates as a general purpose I/O port in port mode.
  PMn.PMn_m selects input or output.
- S/W I/O control alternative mode (PMCn.PMCn_m = 1, PIPCn.PIPCn_m = 0)
  The pin is operated by an alternative function in S/W I/O control alternative mode.
  The selection between input and output is made by S/W via the PMn.PMn_m control bits.
- Direct I/O control alternative mode (PMCn.PMCn_m = 1, PIPCn.PIPCn_m = 1)
  The pin is operated by an alternative function in direct I/O control alternative mode.
  In contrast to S/W I/O control alternative mode, input/out is directly controlled by the alternative function in this mode.

Table 2.3 shows the outline of the register settings.

Table 2.3 Pin Function Configuration (Outline)

Mode	Bit			I/O
	PMCn_m	PMn_m	PIPCn_m	
Port mode	0	0	X	O
		1*1		I
S/W I/O control alternative mode	1	0	0	O
		1*2	0	I
Direct I/O control alternative mode		X	1	Controlled by the alternative function

Note 1. The input buffer should be enabled (PIBCn_m = 1).
Note 2. The input buffer should be disabled (PIBCn_m = 0).

When a pin is operated in alternative mode (PMCn.PMCn_m = 1), one of six alternative functions can be selected by the PFCn, PFCEn and PFCAEn registers.

- S/W I/O control alternative functions (PIPCn.PIPCn_m = 0):
  - Outputs (PMn_m = 0): ALT-OUT1 to ALT-OUT6
  - Inputs (PMn_m = 1): ALT-IN1 to ALT-IN6
- Direct I/O control alternative functions (PIPCn.PIPCn_m = 1):
  - Input/Output of ALT-OUT1 to ALT-OUT6 and ALT-IN1 to ALT-IN6 is directly controlled by the alternative function.

Table 2.4 Outline of Alternative Mode Selection (PMCn.PMCn_m = 1)

Function	Register				I/O
	PFCAE	PFCE	PFC	PM*1	
Alternative output mode 1 (ALT-OUT1)	0	0	0	0	O
Alternative input mode 1 (ALT-IN1)	0	0	0	1	I
Alternative output mode 2 (ALT-OUT2)	0	0	1	0	O
Alternative input mode 2 (ALT-IN2)	0	0	1	1	I
Alternative output mode 3 (ALT-OUT3)	0	1	0	0	O
Alternative input mode 3 (ALT-IN3)	0	1	0	1	I
Alternative output mode 4 (ALT-OUT4)	0	1	1	0	O
Alternative input mode 4 (ALT-IN4)	0	1	1	1	I
Alternative output mode 5 (ALT-OUT5)	1	0	0	0	O
Alternative input mode 5 (ALT-IN5)	1	0	0	1	I
Alternative output mode 6 (ALT-OUT6)	1	0	1	0	O
Alternative input mode 6 (ALT-IN6)	1	0	1	1	I

Note 1. When PIPCn.PIPCn_m = 1, the I/O direction is directly controlled by the peripheral (alternative) function and PM is ignored.

When a pin is operated in alternative mode (PMCn.PMCn_m = 1), one of several alternative functions can be selected by the PFCn, PFCEn and PFCAEn registers.

2.2.2.3 Pin Data Input/Output

The registers used for data input and output are described below.

The source of the data to be read via the PPRn register depends on pin mode.

Output data

In port mode (PMCn.PMCn_m = 0), the value of Pn.Pn_m is output from the Pn_m pin.

Input data

A read operation of the PPRn register returns either the value of the Pn_m pin, the associated bit of the port register Pn.Pn_m, or the data output by an alternative function.

The source of the data read via PPRn depends on pin mode and setting of several control bits.

Table 2.5 summarizes the differences of PPRn read modes.

Table 2.5 PPRn_m Read Values

PMC n_m	PM n_m	PIBC n_m	PIPC n_m	PODC n_m	Mode	PPRn_m read value
0	1	0	X	X	Port input, input buffer disabled	Pn.Pn_m register
		1		X	Port input, input buffer enabled	Pn_m pin
	0	X		0	Port push-pull output	Pn.Pn_m register*1
				1	Port N-ch open-drain output	
1	1	0	0	X	S/W I/O control alternative input	Pn_m pin
	0	X		0	S/W I/O control alternative push-pull output	Alternative function internal output signal*1
				1	S/W I/O control alternative N-ch open-drain output	
	X		1	0	Direct I/O control alternative push-pull output	I/O port in alternative function mode: • Input: Pn_m pin • Output: Alternative function internal output signal*1
				1	Direct I/O control alternative N-ch open-drain output	

Note 1. When PBDCn_m = 1, Pn_m pin level is read via PPRn_m.

The control registers in **Table 2.5** have the following effects:

- PMCn.PMCn_m
  This bit selects either port mode (PMCn_m = 0) or alternative function mode (PMCn_m = 1).
- PMn.PMn_m
  This bit selects input (PMn_m = 1) or output (PMn_m = 0) in port mode (PMCn_m = 0) and S/W I/O control alternative function mode (PMCn_m = 1, PIPCn_m = 0).
- PIBCn.PIBCn_m
  This bit disables (PIBCn_m = 0) or enables (PIBCn_m = 1) the input buffer in input port mode (PMCn_m = 0 and PMn_m = 1). When the input buffer is disabled, PPRn_m reads the Pn.Pn_m bit, otherwise the Pn_m pin level is returned.
- PIPCn.PIPCn_m
  This bit selects either the S/W or direct I/O control alternative mode.
- PBDCn.PBDCn_m
  Setting this bit to 1 forces to read the Pn_m pin level via PPRn_m. Thus this enables a bidirectional mode, where the level of pin Pn_m can also be read back when the port is operated in an output mode.

- PODCn.PODCn_m bits
  These bits select push-pull output (PODCn_m bit = 0) or N-ch open-drain output (PODCn_m bit = 1).

Write to the Pn Register

The data to be output via port Pn_m in port mode (PMCn.PMCn_m = 0) is held in the port register Pn.

The Pn data can be rewritten in the following two different ways:

- Direct write to the Pn register
  New data can be directly written to the Pn register.
- Indirect operation to the Pn bit (set/reset/not)
  The indirect Pn operation is possible using the following two registers:
  - Port set/reset register: PSRn
    When the bit PSRn.PSRn(m+16) = 1, the value of bit PSRn.PSRn_m determines the value of Pn.Pn_m.
    Thus Pn_m can be set/reset without a direct write to Pn.
  - Port NOT register: PNOTn
    Setting PNOTn.PNOTn_m = 1 inverts the bit Pn.Pn_m without a direct write to Pn_m.
    Additionally, reading the level of the output pin can read the inverted value of the value that was initially set.

The indirect Pn set/reset/not operation provides access to single bits (not limited to one bit) of the Pn register while leaving all other Pn bits untouched.

2.2.3 Port Group Configuration Register

This section starts with an overview of all configuration registers and then presents all registers in detail. The configuration registers are classified as follows:

- 2.2.3.2 Pin Function Configuration
- 2.2.3.3 Pin Data Input/Output
- 2.2.3.4 Configuration of Electrical Characteristics

2.2.3.1 Outline

The following registers are used for the configuration of the individual pins of the port groups:

Table 2.6 Registers for Port Group Configuration (1/2)

Module Name				
n = 0	n > 0	Register Name	Symbol	Address
Pin function setting				
PORT_AWO	PORT_ISO	Port control register	PCRn_m*2	<PORTUn_base> + 2000_H + n × 40_H + m x 4

PORTJ_AWO	–		JPSRn	<JPORTU0_base> + 0004_H

Table 2.6 Registers for Port Group Configuration (2/2)

Module Name				
n = 0	n > 0	Register Name	Symbol	Address
PORT_AWO	PORT_ISO	Port output level inversion register	PINVn	<PORTUn_base> + 0030_H + n × 40_H
PORTJ_AWO	–		JPINVn	<JPORTU0_base> + 0030_H
Specifying electrical characteristics				
PORT_AWO	PORT_ISO	Pull-up option register	PUn	<PORTOn_base> + $400C_H$ + n × 40_H
PORTJ_AWO	–		JPUn	<JPORTO0_base> + $400C_H$
PORT_AWO	PORT_ISO	Pull-down option register	PDn	<PORTOn_base> + 4010_H + n × 40_H
PORTJ_AWO	–		JPDn	<JPORTO0_base> + 4010_H
PORT_AWO	PORT_ISO	Port drive strength control register	PDSCn	<PORTOn_base> + 4018_H + n × 40_H
PORTJ_AWO	–		JPDSCn	<JPORTO0_base> + 4018_H
PORT_AWO	PORT_ISO	Port open drain control register	PODCn	<PORTOn_base> + 4014_H + n × 40_H
PORTJ_AWO	–		JPODCn	<JPORTO0_base> + 4014_H
PORT_AWO	PORT_ISO	Port input buffer selection register	PISn	<PORTOn_base> + $401C_H$ + n × 40_H
PORTJ_AWO	–		JPISn	<JPORTO0_base> + $401C_H$
PORT_AWO	PORT_ISO	Port input buffer selection advanced register	PISAn	<PORTOn_base> + 4024_H + n × 40_H
PORTJ_AWO	–		JPISAn	<JPORTO0_base> + 4024_H
Port register protection				
For details about the registers for the port register protection refer to Section 4, Write-Protected Registers.				

Note 1. n: Port group number
m: Bit number in a port group

Note 2. In the header files the bit symbol of PCR0_m and JPCR0_m are different from others.
e.g. PCRn_0.PFC
– PORTn n > 0 PORT_ISOPFC
– PORTn n = 0 PORT_AWOPCR_PFC0_0
– JPORTn n = 0 PORTJ_AWOPCR_JPFC0_0

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> and <Symbol> are defined in the above table.

Base address

The PORTn base addresses <PORTUn_base>, <PORTOn_base>, <JPORTU0_base> and <JPORTO0_base> are defined in Register Addresses, Section 2.2.1.2, Register Address.

Register initial value

The initial values after reset release depend on the port, and are not described in the following register descriptions, but are given in Section 2.3.1, Port Registers.

2.2.3.2 Pin Function Configuration

(1) PMCn/JPMC0 — Port Mode Control Register

This register specifies whether the individual pins of port group n are in port mode or in alternative mode.

Access: The PMCn register can be read/written in 16-bit units.
The JPMC0 register can be read/written in 8-bit units.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMCn_15	PMCn_14	PMCn_13	PMCn_12	PMCn_11	PMCn_10	PMCn_9	PMCn_8	PMCn_7	PMCn_6	PMCn_5	PMCn_4	PMCn_3	PMCn_2	PMCn_1	PMCn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.7 PMCn register contents

Bit Position	Bit Name	Function
15 to 0	PMCn_[15:0]	Specifies the operation mode of the corresponding pin. 0: Port mode 1: Alternative mode

CAUTIONS

1. The I/O control is not performed by just setting alternative mode (PMCn.PMCn_m). When the alternative function performs direct I/O control, set also the PIPCn.PIPCn_m bit to 1.
2. When a port is used as an input pin in alternative mode, there is a pin that passes a noise filter. Such a pin might need FCLAnCTLm.DFNAnCTL and the DNFAnEN register to be set. For details, see Section 2.6, Noise Filter and Edge Level Detection Circuit, and Section 2.7, Description of Port Noise Filter & Edge/Level Detection.

NOTES

1. The control bits of the JTAG port mode control register (JPMC0) are JPMC0_[7:0].
2. For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

(2) PMCSRn/JPMCSR0 — Port Mode Control Set/Reset Register

This register provides an alternative method to write data to a bit in the PMCn register.

The upper 16 bits of PMCSRn_[31:16] specify whether the data is written to the PMCn.PMCn_m bit specified in the lower 16 bits of PMCSRn_[15:0]

Access: This register can be read/written in 32-bit units.
Bits 31 to 16 are always read as 0000_H. Reading bits 15 to 0 returns the value of the PMCn register.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PMCSRn_31	PMCSRn_30	PMCSRn_29	PMCSRn_28	PMCSRn_27	PMCSRn_26	PMCSRn_25	PMCSRn_24	PMCSRn_23	PMCSRn_22	PMCSRn_21	PMCSRn_20	PMCSRn_19	PMCSRn_18	PMCSRn_17	PMCSRn_16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMCSRn_15	PMCSRn_14	PMCSRn_13	PMCSRn_12	PMCSRn_11	PMCSRn_10	PMCSRn_9	PMCSRn_8	PMCSRn_7	PMCSRn_6	PMCSRn_5	PMCSRn_4	PMCSRn_3	PMCSRn_2	PMCSRn_1	PMCSRn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.8 PMCSRn register contents

Bit Position	Bit Name	Function
31 to 16	PMCSRn_ [31:16]	Specifies whether the value of the corresponding lower bit of PMCSRn_m is written to PMCn_m: 0: PMCn_m does not depend on PMCSRn_m. 1: The value of PMCn_m is the same as that of PMCSRn_m. Example: When PMCSRn.PMCSRn_31 = 1, the value of bit PMCSRn.PMCSRn_15 is written to bit PMCn.PMCn_15 and output.
15 to 0	PMCSRn_ [15:0]	Specifies the PMCn_m value when the corresponding upper bit PMCSRn_(m+16) is 1: 0: PMCn_m = 0 1: PMCn_m = 1

NOTES

1. The control bits of the JTAG port mode control set/reset register (JPMCSR0) are JPMCSR0_[31:0].
2. For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

(3) PIPCn — Port IP Control Register

This register specifies whether the I/O direction of pin Pn_m is controlled by the port mode register PMn.PMn_m or by an alternative function.

When the Pn_m pin is operated in alternative mode (PMCn.PMCn_m = 1) and the alternative function directly controls the I/O direction of Pn_m, PIPCn.PIPCn_m must be set to 1 as well. This hands over I/O control to the alternative function and overrules the PMn.PMn_m setting.

Access: This register can be read/written in 16-bit units.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPCn_15	PIPCn_14	PIPCn_13	PIPCn_12	PIPCn_11	PIPCn_10	PIPCn_9	PIPCn_8	PIPCn_7	PIPCn_6	PIPCn_5	PIPCn_4	PIPCn_3	PIPCn_2	PIPCn_1	PIPCn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.9 PIPCn register contents

Bit Position	Bit Name	Function
15 to 0	PIPCn_[15:0]	Specifies the I/O control mode. 0: I/O mode is selected by PMn.PMn_m (software I/O control). 1: I/O mode is selected by the peripheral function (direct I/O control).

NOTE

For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

(4) PMn/JPM0 — Port Mode Register

The PMn register specifies whether the individual pins of port group n are in input mode or in output mode.

Access: The PMn register can be read/written in 16-bit units.
The JPM0 register can be read/written in 8-bit units.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMn_15	PMn_14	PMn_13	PMn_12	PMn_11	PMn_10	PMn_9	PMn_8	PMn_7	PMn_6	PMn_5	PMn_4	PMn_3	PMn_2	PMn_1	PMn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.10 PMn register contents

Bit Position	Bit Name	Function
15 to 0	PMn_[15:0]	Specifies input/output mode of the corresponding pin. 0: Output mode (output enabled) 1: Input mode (output disabled)

NOTES

1. When a port is used in input port mode (PMCn.PMCn_m = 0 and PMn.PMn_m = 1), the input buffer needs to be enabled (PIBCn.PIBCn_m = 1).
2. After reset, PIPCn.PIPCn_m = 0 is set (I/O mode is controlled with PMn.PMn_m). Thus, PMn_m specifies the I/O direction of port mode (PMCn.PMCn_m = 0) and alternative mode (PMCn.PMCn_m = 1).
3. The control bits of the JTAG port mode register (JPM0) are JPM0_[7:0].
4. For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

(5) PMSRn/JPMSR0 — Port Mode Set/Reset Register n

This register provides an alternative method to write data to a bit in the PMn register.

The upper 16 bits of PMSRn_[31:16] specify whether the data is written to the PMn.PMn_m bit specified in the lower 16 bits of PMSRn_[15:0].

Access: This register can be read/written in 32-bit units.
Bits 31 to 16 are always read as 0000_H. Reading bits 15 to 0 returns the value of the PMn register.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PMSRn_31	PMSRn_30	PMSRn_29	PMSRn_28	PMSRn_27	PMSRn_26	PMSRn_25	PMSRn_24	PMSRn_23	PMSRn_22	PMSRn_21	PMSRn_20	PMSRn_19	PMSRn_18	PMSRn_17	PMSRn_16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMSRn_15	PMSRn_14	PMSRn_13	PMSRn_12	PMSRn_11	PMSRn_10	PMSRn_9	PMSRn_8	PMSRn_7	PMSRn_6	PMSRn_5	PMSRn_4	PMSRn_3	PMSRn_2	PMSRn_1	PMSRn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.11 PMSRn register contents

Bit Position	Bit Name	Function
31 to 16	PMSRn_[31:16]	Specifies whether the value of the corresponding lower bit of PMSRn_m is written to PMn_m: 0: PMn_m does not depend on PMSRn_m. 1: The value of PMn_m is the same as that of PMSRn_m. Example: When PMSRn.PMSRn_31 = 1, the value of bit PMSRn.PMSRn_15 is written to bit PMn.PMn_15 and output.
15 to 0	PMSRn_[15:0]	Specifies the PMn_m value when the corresponding upper bit PMSRn_(m+16) is 1: 0: PMn_m = 0 1: PMn_m = 1

NOTES

1. The control bits of the JTAG port mode set/reset register (JPMSR0) are JPMSR0_[7:0].
2. For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

(6) PIBCn/JPIBC0 — Port Input Buffer Control Register

This register enables and disables the input buffer of a port pin in input port mode (PMCn.PMCn_m = 0 and PMn.PMn_m = 1).

Additionally, when pins are in bidirectional mode (PBDCn.PBDCn_m = 1), it is capable of selecting shared output level loop-back function and pin output level-read function with the setting of PIBCn.PIBCn_m. For details, see (1) PBDCn/JPBDC0 — Port Bi-Direction Control Register in Section 2.2.3.3, Pin Data Input/Output.

Access: The PIBCn register can be read/written in 16-bit units.
The JPIBC0 register can be read/written in 8-bit units.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIBCn_15	PIBCn_14	PIBCn_13	PIBCn_12	PIBCn_11	PIBCn_10	PIBCn_9	PIBCn_8	PIBCn_7	PIBCn_6	PIBCn_5	PIBCn_4	PIBCn_3	PIBCn_2	PIBCn_1	PIBCn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.12 PIBCn register contents

Bit Position	Bit Name	Function
15 to 0	PIBCn_[15:0]	Enables/disables the input buffer: 0: Input buffer is disabled. 1: Input buffer is enabled.

NOTES

1. When the input buffer is disabled, it does not consume flow-through current even if the pin level is in Hi-Z state. Thus, the pin does not need to be fixed to a high or low level externally.
2. The control bits of the JTAG port input buffer control register (JPIBC0) are JPIBC0_[7:0].
3. For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.
4. When the S/W I/O control alternative input mode (PMCn_m = 1 and PMn_m = 1), PIBCn_m bit should be set to "0".

CAUTION

The setting of this register is not effective in bidirectional mode (PBDCn.PBDCn_m = 1).

(7) PFCn/JPFC0 — Port Function Control Register

This register, together with the PFCEn and PFCAEn registers, specifies an alternative function of the pins.

Some alternative functions require direct I/O control of pin Pn_m. For such alternative functions PIPCn.PIPCn_m must be set to 1 as well.

For other alternative functions, input/output must be specified by PMn.PMn_m.

Access: The PFCn register can be read/written in 16-bit units.
The JPFC0 register can be read/written in 8-bit units.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFCn_15	PFCn_14	PFCn_13	PFCn_12	PFCn_11	PFCn_10	PFCn_9	PFCn_8	PFCn_7	PFCn_6	PFCn_5	PFCn_4	PFCn_3	PFCn_2	PFCn_1	PFCn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.13 PFCn register contents

Bit Position	Bit Name	Function
15 to 0	PFCn_[15:0]	Specifies an alternative function of a pin. See Table 2.4, Outline of Alternative Mode Selection (PMCn.PMCn_m = 1).

NOTES

1. The control bits of the JTAG port function control register (JPFC0) are JPFC0_[7:0].
2. For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

CAUTION

With this product, the I/O of some functions is multiplexed in two pins, but only either one can be used as a pin function. Setting the same pin function in two pins is prohibited.

For example, if P0_1 pin is used as INTP0, JP0_0 pin cannot be used as INTP0. In this case, JP0_0 pin must be configured as the pin function other than INTP0.

(8) PFCEn / JPFCE0 — Port Function Control Expansion Register

This register, together with the PFCn and PFCAEn registers, specifies an alternative function of the pins.

Some alternative functions directly controls input/output of pin Pn_m. For such alternative functions PIPCn.PIPCn_m must be set to 1 as well.

For other alternative functions, input/output must be specified by PMn.PMn_m.

Access: The PFCEn register can be read/written in 16-bit units.
The JPFCE0 register can be read/written in 8-bit units.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFCEn_15	PFCEn_14	PFCEn_13	PFCEn_12	PFCEn_11	PFCEn_10	PFCEn_9	PFCEn_8	PFCEn_7	PFCEn_6	PFCEn_5	PFCEn_4	PFCEn_3	PFCEn_2	PFCEn_1	PFCEn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.14 PFCEn register contents

Bit Position	Bit Name	Function
15 to 0	PFCEn_[15:0]	Specifies an alternative function of a pin. See Table 2.4, Outline of Alternative Mode Selection (PMCn.PMCn_m = 1) for details.

Table 2.15 Setting alternative functions

PFCAEn_m	PFCEn_m	PFCn_m	PMn_m	Function
0	0	0	1	1st alternative function / Input
			0	1st alternative function / Output
		1	1	2nd alternative function / Input
			0	2nd alternative function / Output
	1	0	1	3rd alternative function / Input
			0	3rd alternative function / Output
		1	1	4th alternative function / Input
			0	4th alternative function / Output
1	0	0	1	5th alternative function / Input
			0	5th alternative function / Output
		1	1	6th alternative function / Input
			0	6th alternative function / Output

NOTES

1. The control bits of the JTAG port function control expansion register (JPFCE0) are JPFCE0_[7:0].
2. For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

CAUTION

With this product, the I/O of some functions is multiplexed in two pins, but only either one can be used as a pin function. Setting the same pin function in two pins is prohibited.

For example, if P0_1 pin is used as INTP0, JP0_0 pin cannot be used as INTP0. In this case, JP0_0 pin must be configured as the pin function other than INTP0.

(9) PFCAEn — Port Function Control Additional Expansion Register

This register, together with the PFCn and PFCEn registers, specifies an alternative function of the pins.

Some alternative functions directly controls input/output of pin Pn_m. For such alternative functions PIPCn.PIPCn_m must be set to 1 as well.

For other alternative functions, input/output must be specified by PMn.PMn_m.

Access: The PFCEn register can be read/written in 16-bit units.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFCAEn_15	PFCAEn_14	PFCAEn_13	PFCAEn_12	PFCAEn_11	PFCAEn_10	PFCAEn_9	PFCAEn_8	PFCAEn_7	PFCAEn_6	PFCAEn_5	PFCAEn_4	PFCAEn_3	PFCAEn_2	PFCAEn_1	PFCAEn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.16 PFCAEn register contents

Bit Position	Bit Name	Function
15 to 0	PFCAEn_[15:0]	Specifies an alternative function of a pin. See Table 2.4, Outline of Alternative Mode Selection (PMCn.PMCn_m = 1) for details.

2.2.3.3 Pin Data Input/Output

(1) PBDCn/JPBDC0 — Port Bi-Direction Control Register

This register enables the input buffer and sets the port to bi-direction mode. In bi-direction mode, PPRn.PPRn_m can read the level of the Pn_m pin.

The Pn_m pin level is read via PPRn.PPRn_m in bidirectional mode.

- Alternative output level loopback function
  When the Pn_m pin is used as the alternative output function, the actual pin output level based on the alternative output function can be looped back to the alternative input side by setting PBDCn.PBDCn_m = 1 and PIBCn.PIBCn_m= 0. For example, the pin output level based on the first alternative function can be looped back to the same alternative input side. Also the pin output level can be read via PPRn.PPRn_m.
- Pin output level read function
  When the Pn_m pin is used as the general output port function or the alternative output function, the actual pin output level can be read via PPRn.PPRn_m by setting PBDCn.PBDCn_m = 1 and PIBCn.PIBCn_m = 1. Under this setting, the pin output level will never be looped back to the alternative input side even in alternative output mode.

Access: The PBDCn register can be read/written in 16-bit units.
The JPBDC0 register can be read/written in 8-bit units.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PBDCn_15	PBDCn_14	PBDCn_13	PBDCn_12	PBDCn_11	PBDCn_10	PBDCn_9	PBDCn_8	PBDCn_7	PBDCn_6	PBDCn_5	PBDCn_4	PBDCn_3	PBDCn_2	PBDCn_1	PBDCn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.17 PBDCn register contents

Bit Position	Bit Name	Function
15 to 0	PBDCn_[15:0]	Enables/disables bi-direction mode of the corresponding pin. 0: Bi-direction mode disabled 1: Bi-direction mode enabled

CAUTION

When the Pn_m port is used as an alternative output function (PMCn.PMCn_m = 1, PMn.PMn_m = 0), if bidirectional mode is enabled (PBDCn.PBDCn_m = 1), the level of the Pn_m pin can be read with PPRn.PPRn_m.

However, the output of the alternative output function is input to the alternative input function of the same pin (the alternative input function that is set with PFCn.PFCn_m, PFCEn.PFCEn_m and PFCAEn_m). If this alternative input function is used in another pin, note that the output of the alternative output function and alternative input in other pins are input internally (OR input).

NOTES

1. The control bits of the JTAG port bi-direction control register (JPBDC0) are JPBDC0_[7:0].
2. For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

(2) PPRn/JPPR0 — Port Pin Read Register

This register reflects an actual Pn_m pin level, a Pn.Pn_m bit value, or an output level of the alternative function. The value to be read depends on various control settings as described in **Table 2.5, PPRn_m Read Values**.

Access: The PPRn register can be read/written in 16-bit units.
The JPPR0 register can be read/written in 8-bit units.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PPRn_15	PPRn_14	PPRn_13	PPRn_12	PPRn_11	PPRn_10	PPRn_9	PPRn_8	PPRn_7	PPRn_6	PPRn_5	PPRn_4	PPRn_3	PPRn_2	PPRn_1	PPRn_0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 2.18 PPRn register contents

Bit Position	Bit Name	Function
15 to 0	PPRn_[15:0]	Pin Pn_m, Pn.Pn_m value or alternative function output.

NOTES

1. For details about the read value of the PPRn register, see Section 2.2.2.3, Pin Data Input/Output.
2. The control bits of the JTAG port pin read register (JPPR0) are JPPR0_[7:0].
3. For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

(3) Pn/JP0 — Port Register

This register sets and holds the Pn.Pn_m data to be output via the related Pn_m port in output port mode (PMCn.PMCn_m = 0 and PMn.PMn_m = 0).

Access: The Pn register can be read/written in 16-bit units.
The JP0 register can be read/written in 8-bit units.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Pn_15	Pn_14	Pn_13	Pn_12	Pn_11	Pn_10	Pn_9	Pn_8	Pn_7	Pn_6	Pn_5	Pn_4	Pn_3	Pn_2	Pn_1	Pn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.19 Pn register contents

Bit Position	Bit Name	Function
15 to 0	Pn_[15:0]	Sets the output level of pin m (m = 0 to 15): 0: Low level output 1: High level output

NOTE

- The bits of this register can be manipulated by various means; refer to the subsection, Write to the Pn Register in Section 2.2.2.3, Pin Data Input/Output.
- The control bits of the JTAG port register (JP0) are JP0_[7:0].
- For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

(4) PNOTn/JPNOT0 — Port NOT Register

This register enables inverting the Pn_m bit of the port register without directly writing to Pn.

Access: The PNOTn register can be read/written in 16-bit units.
The JPNOT0 register can be read/written in 8-bit units.
The read value is always 0000_H.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PNOTn_15	PNOTn_14	PNOTn_13	PNOTn_12	PNOTn_11	PNOTn_10	PNOTn_9	PNOTn_8	PNOTn_7	PNOTn_6	PNOTn_5	PNOTn_4	PNOTn_3	PNOTn_2	PNOTn_1	PNOTn_0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 2.20 PNOTn register contents

Bit Position	Bit Name	Function
15 to 0	PNOTn_[15:0]	Specifies if Pn.Pn_m is inverted or not: 0: Pn.Pn_m is not inverted ($\overline{Pn\_m} \rightarrow Pn\_m$) 1: Pn.Pn_m is inverted ($Pn\_m \rightarrow Pn\_m$)

NOTES

1. The control bits of the JTAG port not register (JPNOT0) are JPNOT0_[7:0].
2. For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

(5) PSRn/JPSR0 — Port Set/Reset Register

This register provides an alternative method to write data to a bit in the Pn register.

The upper 16 bits of PSRn specify whether the data is written to the Pn.Pn_m bit specified in the lower 16 bits of PSRn.

Access: This register can be read/written in 32-bit units.
Bits 31 to 16 are always read as 0000_H. Reading bits 15 to 0 returns the value of the Pn register.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PSRn_31	PSRn_30	PSRn_29	PSRn_28	PSRn_27	PSRn_26	PSRn_25	PSRn_24	PSRn_23	PSRn_22	PSRn_21	PSRn_20	PSRn_19	PSRn_18	PSRn_17	PSRn_16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PSRn_15	PSRn_14	PSRn_13	PSRn_12	PSRn_11	PSRn_10	PSRn_9	PSRn_8	PSRn_7	PSRn_6	PSRn_5	PSRn_4	PSRn_3	PSRn_2	PSRn_1	PSRn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.21 PSRn register contents

Bit Position	Bit Name	Function
31 to 16	PSRn_[31:16]	Specifies whether the value of the corresponding lower bit of PSRn_m is written to Pn_m: 0: Pn_m does not depend on PSRn_m. 1: The value of Pn_m is the same as that of PSRn_m. Example: When PSRn.PSRn_31 = 1, the value of bit PSRn.PSRn_15 is written to bit Pn.Pn15.
15 to 0	PSRn_[15:0]	Specifies the Pn_m value when the corresponding upper bit PSRn_(m+16) is 1: 0: Pn_m = 0 1: Pn_m = 1

NOTES

1. The control bits of the JTAG port set/reset register (JPSR0) are JPSR0_[31:0].
2. For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

(6) PINVn/JPINV0 — Port Output Level Inversion Register

This register enables inverting the output level from a pin. It is effective when the pin is in output mode regardless of port output mode or alternative output mode.

Writing to this register is protected by a special sequence of instructions by using the protection command register PPCMDn.
For details, refer to **Section 4, Write-Protected Registers**.

Access: The PINVn register can be read/written in 16-bit units.
The JPINV0 register can be read/written in 8-bit units.
Writing to this register is protected by a specific instruction sequence. For details, see Section 2.2.3.5, Port Register Protection.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PINVn_15	PINVn_14	PINVn_13	PINVn_12	PINVn_11	PINVn_10	PINVn_9	PINVn_8	PINVn_7	PINVn_6	PINVn_5	PINVn_4	PINVn_3	PINVn_2	PINVn_1	PINVn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.22 PINVn register contents

Bit Position	Bit Name	Function
15 to 0	PINVn_[15:0]	Specifies whether the output level from a pin is inverted or not. 0: Pin output level is not inverted. 1: Pin output level is inverted.

NOTES

1. The control bits of the JTAG port output level inversion register (JPINV0) are JPINV0_[31:0].
2. For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

2.2.3.4 Configuration of Electrical Characteristics

(1) PUn/JPU0 — Pull-Up Option Register

This register specifies whether an on-chip pull-up resistor is connected to an input pin.

Access: The PUn register can be read/written in 16-bit units.
The JPU0 register can be read/written in 8-bit units.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PUn_15	PUn_14	PUn_13	PUn_12	PUn_11	PUn_10	PUn_9	PUn_8	PUn_7	PUn_6	PUn_5	PUn_4	PUn_3	PUn_2	PUn_1	PUn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.23 PUn register contents

Bit Position	Bit Name	Function
15 to 0	PUn_[15:0]	Specifies whether an on-chip pull-up resistor is connected to the corresponding pin: 0: No on-chip pull-up resistor is connected. 1: On-chip pull-up resistor is connected.

NOTES

1. Do not set PUn.PUn_m = 1 and PDn.PDn_m = 1 to a single pin.
2. The on-chip pull-up resistor has no effect when the pin is operated in output mode.
3. The control bits of the JTAG pull-up option register (JPU0) are JPU0_[7:0].
4. For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

(2) PDn/JPD0 — Pull-down option register

This register specifies whether an on-chip pull-down resistor is connected to an input pin.

Access: The PDn register can be read/written in 16-bit units.
The JPD0 register can be read/written in 8-bit units.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PDn_15	PDn_14	PDn_13	PDn_12	PDn_11	PDn_10	PDn_9	PDn_8	PDn_7	PDn_6	PDn_5	PDn_4	PDn_3	PDn_2	PDn_1	PDn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.24 PDn register contents

Bit Position	Bit Name	Function
15 to 0	PDn_[15:0]	Specifies whether a on-chip pull-down resistor is connected to the corresponding pin: 0: No on-chip pull-down resistor is connected. 1: On-chip pull-down resistor is connected.

NOTES

1. Do not set PUn.PUn_m = 1 and PDn.PDn_m = 1 to a single pin.
2. The on-chip pull-down resistor has no effect when the pin is operated in output mode.
3. The control bits of the JTAG pull-down option register (JPD0) are JPD0_[7:0].
4. For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

(3) PODCn/JPODC0 — Port Open-drain Control Register

This register selects push-pull or open-drain as the output buffer function.

Writing to this register is protected by a special sequence of instructions by using the protection command register PPCMDn.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units. Writing to this register is protected by a specific instruction sequence. For details, see Section 2.2.3.5, Port Register Protection.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	PODCn_15	PODCn_14	PODCn_13	PODCn_12	PODCn_11	PODCn_10	PODCn_9	PODCn_8	PODCn_7	PODCn_6	PODCn_5	PODCn_4	PODCn_3	PODCn_2	PODCn_1	PODCn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.25 PODCn register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When written, write the initial value.
15 to 0	PODCn_[15:0]	Specify the output circuit characteristics of pin m (m = 0 to 15). 0: push-pull 1: N-ch open-drain

(4) PDSCn/JPDSC0 — Port drive strength control register

This register specifies the output drive strength of a port pin. This function is related to fast or slow mode (high or low drive strength) of an output buffer.

Writing to this register is protected by a special sequence of instructions by using the protection command register PPCMDn.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.
Updating of this register needs a correct write sequence using the PPCMDn register.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

CAUTION

The upper 16 bits are also intended for the inverted value of a port register write sequence that is to be protected. See Section 2.2.3.5, Port Register Protection **for details.**

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.26 PDSCn register contents

Bit Position	Bit Name	Function
15 to 0	PDSCn_[15:0]	Specifies the output buffer characteristics of pin m (m = 0 to 15). 0: low drivability (pins supplied by ISMVCC) 1: high drivability (pins supplied by ISMVCC) 0: slow (other pins of relevant port groups) 1: fast (other pins of relevant port groups)

NOTE

For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

PDSC21 have to be set 0000 $03FF_H$ in D1M2(H).

NOTE

For D1M2 and D1M2H the initial value of the PDSC21 register have to be changed to PDSC21 = 0x03FF to select the output buffer type for the port P21.

- P21_[9:0] - HS Port Buffer for SFMA usage
- P21_[12:10] - MLB Port Buffer for MLBB usage

Because of this the use of the initial value for PDSC21 in D1M2 and D1M2(H) is restricted.

(5) PISn — Port Input Buffer Selection Register

This register specifies the input buffer characteristics together with the port input buffer selection advanced register PISAn.

Access: This register can be read/written in 16-bit units.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PISn_15	PISn_14	PISn_13	PISn_12	PISn_11	PISn_10	PISn_9	PISn_8	PISn_7	PISn_6	PISn_5	PISn_4	PISn_3	PISn_2	PISn_1	PISn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.27 PISn register contents

Bit Position	Bit Name	Function
15 to 0	PISn_[15:0]	Specifies the input buffer characteristics together with the PISAn register. See Section 2.2.5.4, Input buffer characteristics for details.

(6) PISAn — Port Input Buffer Selection Advanced Register

This register specifies the input buffer characteristics together with the port input buffer selection register PISn.

Access: This register can be read/written in 16-bit units.

Address: See Table 2.6, Registers for Port Group Configuration.

Initial value: See Section 2.3.1, Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PISAn_15	PISAn_14	PISAn_13	PISAn_12	PISAn_11	PISAn_10	PISAn_9	PISAn_8	PISAn_7	PISAn_6	PISAn_5	PISAn_4	PISAn_3	PISAn_2	PISAn_1	PISAn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.28 PISAn register contents

Bit Position	Bit Name	Function
15 to 0	PISAn_[15:0]	Specifies the input buffer characteristics together with the PISn register. See Section 2.2.5.4, Input buffer characteristics for details.

2.2.3.5 Port Register Protection

(1) Protection registers

For details about the registers for the port register protection refer to Section 4, Write-Protected Registers.

(2) Port Register to be Protected

- Port Output Level Inversion Register (PINVn, JPINV0)
- Port Open-drain Control Register (PODCn, JPODC0)
- Port Drive Strength Control Register (PDSCn, JPDSC0)

(3) Write Sequence of the Port Register to be Protected

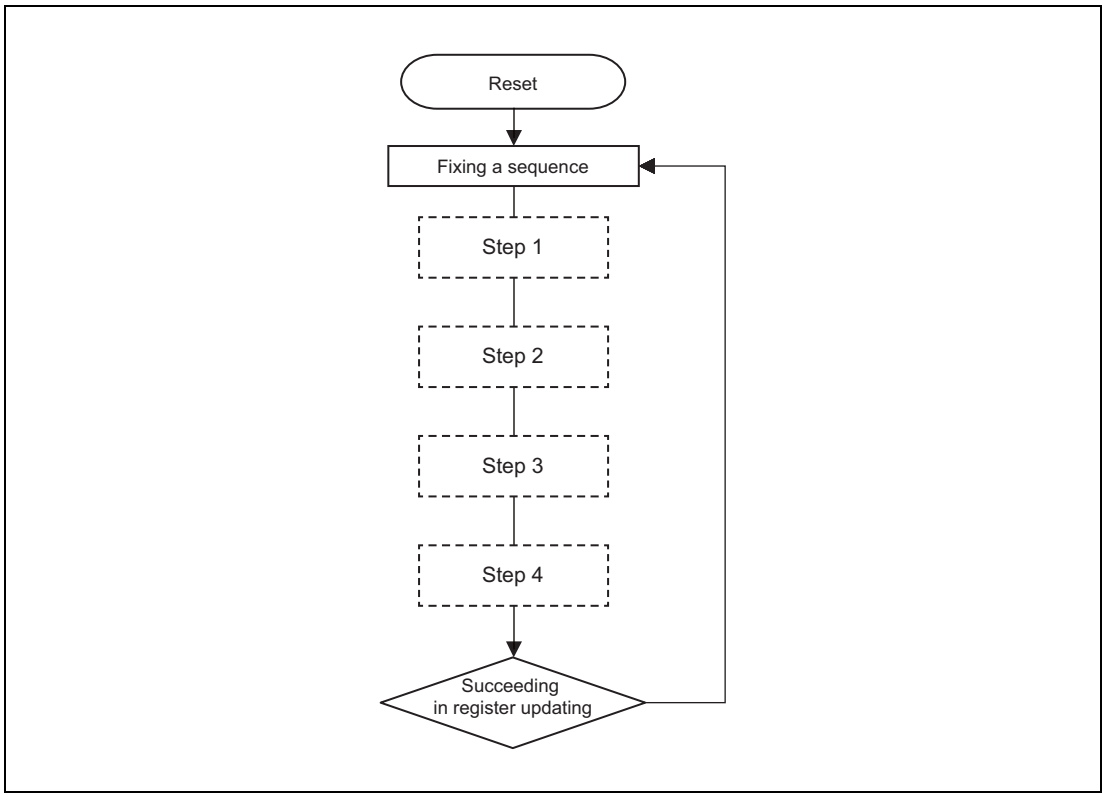

Figure 2.8 Write Sequence of the Port Register to be Protected

Step 1: Write $A5_H$ to the PPCMD register to initialize a write sequence.

Step 2: Write data to the register to be protected in accordance with each register's size (not updated).

Step 3: Write inverted data to the same register to be protected in accordance with each register's size (not updated).

Step 4: Write data to the same register to be protected in accordance with each register's size again (successfully updated). Verify successful write of the desired value to the protected register by reading the protected register written to.

2.2.3.6 Pin-unit Register

(1) Port Control Register (PCRn_m)

Each register of a port group can be accessed via this register and a PCR register can set all functions of a single pin. For example, setting bit 6 of the PCRn_m register to 1 sets bit m of the PMCn register to 1 also. Although writing to the PDSCn, PODCn and PINVn registers are protected, an access to them via the PCRn_m register does not require a protection release sequence.

CAUTIONS

1. **Multiple bits in the PCRn_m register can be batch-set within the ranges described in Section 2.2.4, Example of Port Configuration Flow, Section (2), Individual Setting.**
2. **If the bits are batch-set out of the range for setting of PCRn_m, the pin may output an unexpected signal level.**

Access: This register can be read/written in 32-bit units.

Initial value: See Section 2.3.1, Port Registers.

7	—	Reserved
6	PMC	Same function as bit m of the PMCn register
5	PIPC	Same function as bit m of the PIPCn register
4	PM	Same function as bit m of the PMn register
3	—	Reserved
2	PFCAE	Same function as bit m of the PFCAEn register
1	PFCE	Same function as bit m of the PFCEn register
0	PFC	Same function as bit m of the PFCn register

NOTE

For details about the relevant port groups and bits, see Section 2.3.1, Port Registers.

2.2.4 Example of Port Configuration Flow

The followings are examples of the port configuration flow.

CAUTION

Even if a port is used in S/W I/O control alternative mode, it may be temporarily switched to alternative input mode in the following port configuration flows. This may occur during the period from setting of PMCn_m = 1 to that of PMn_m = 0.

(1) Batch Setting

The following shows an example to collectively set a port group.

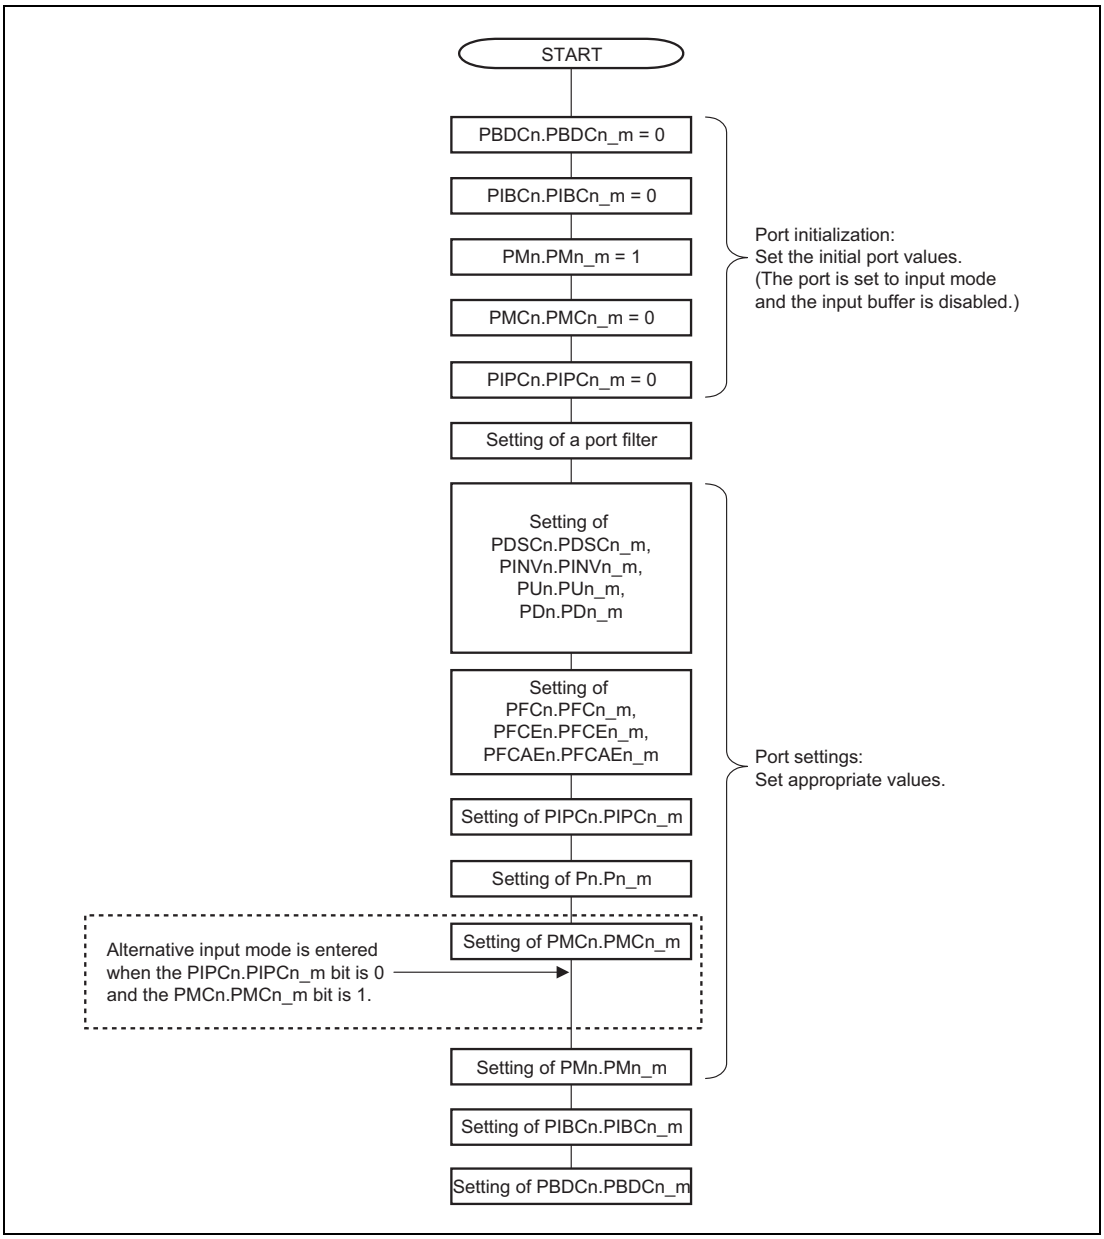

Figure 2.9 Example of Port Configuration Flow (batch setting)

(2) Individual Setting

The following shows an example to individually set a port group.

And it is capable of setting simultaneous bits at once within the Settable range described below by using PCRn_m register.

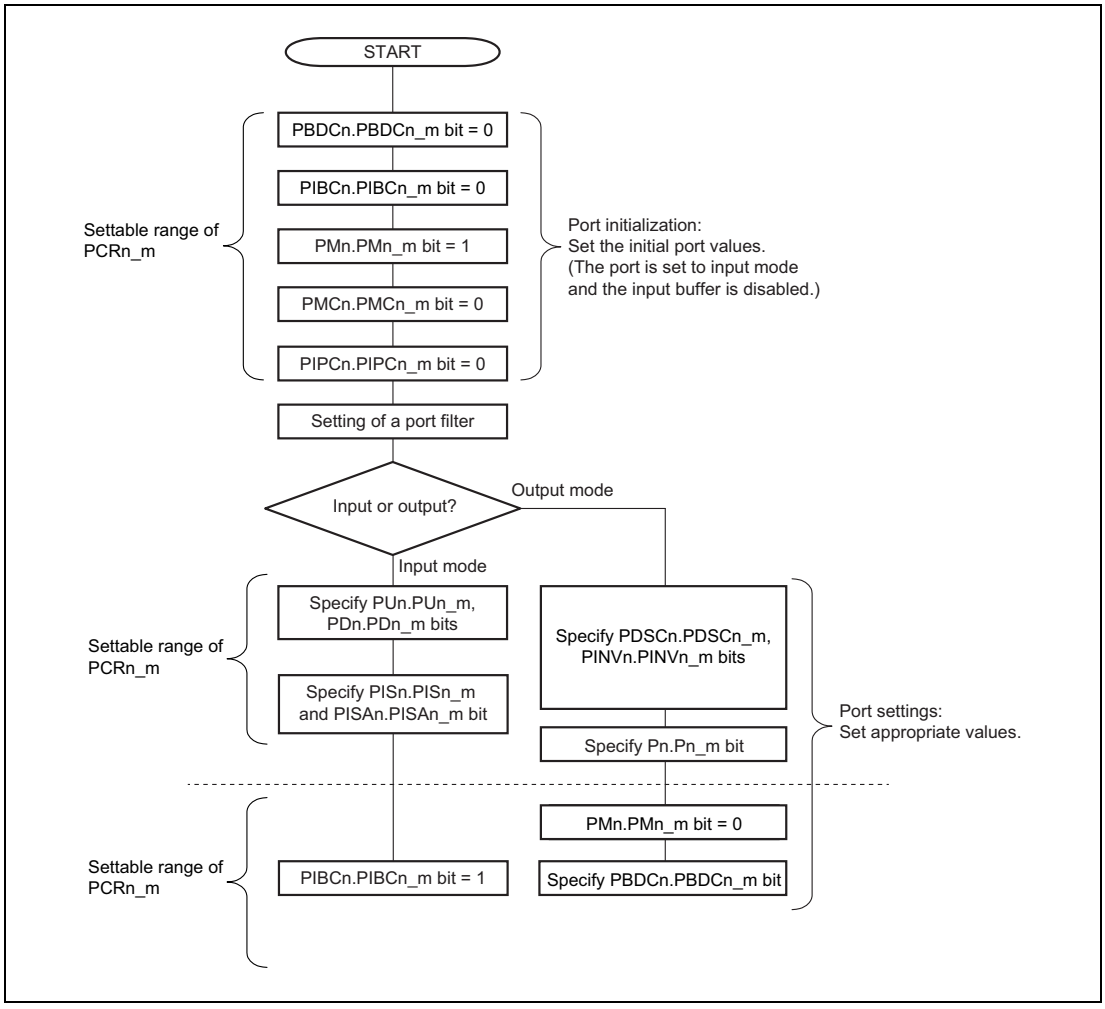

Figure 2.10 Example of Port Configuration Flow (in port mode)

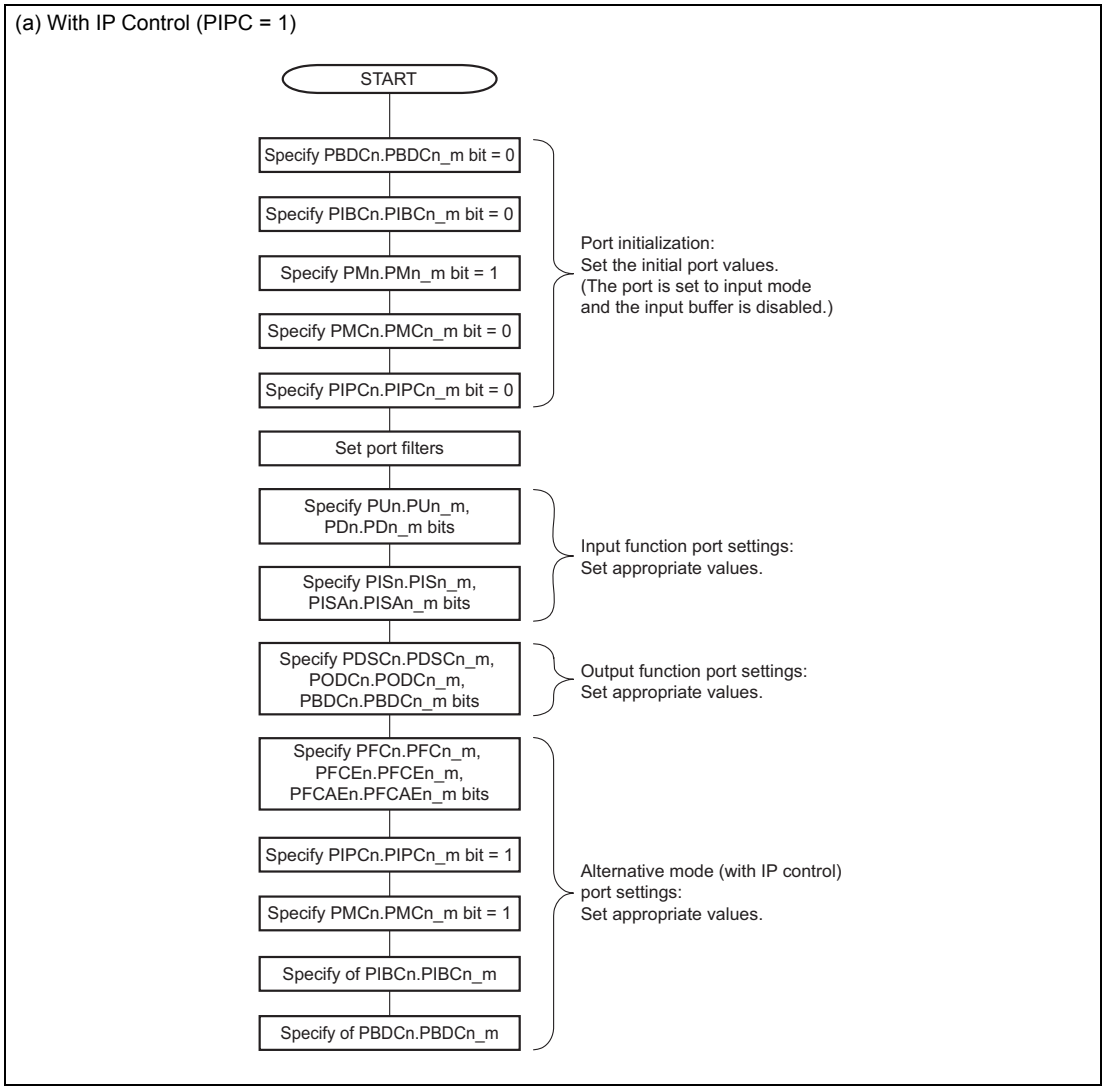

Figure 2.11 Example of Port Configuration Flow (in alternative mode) (1/2)

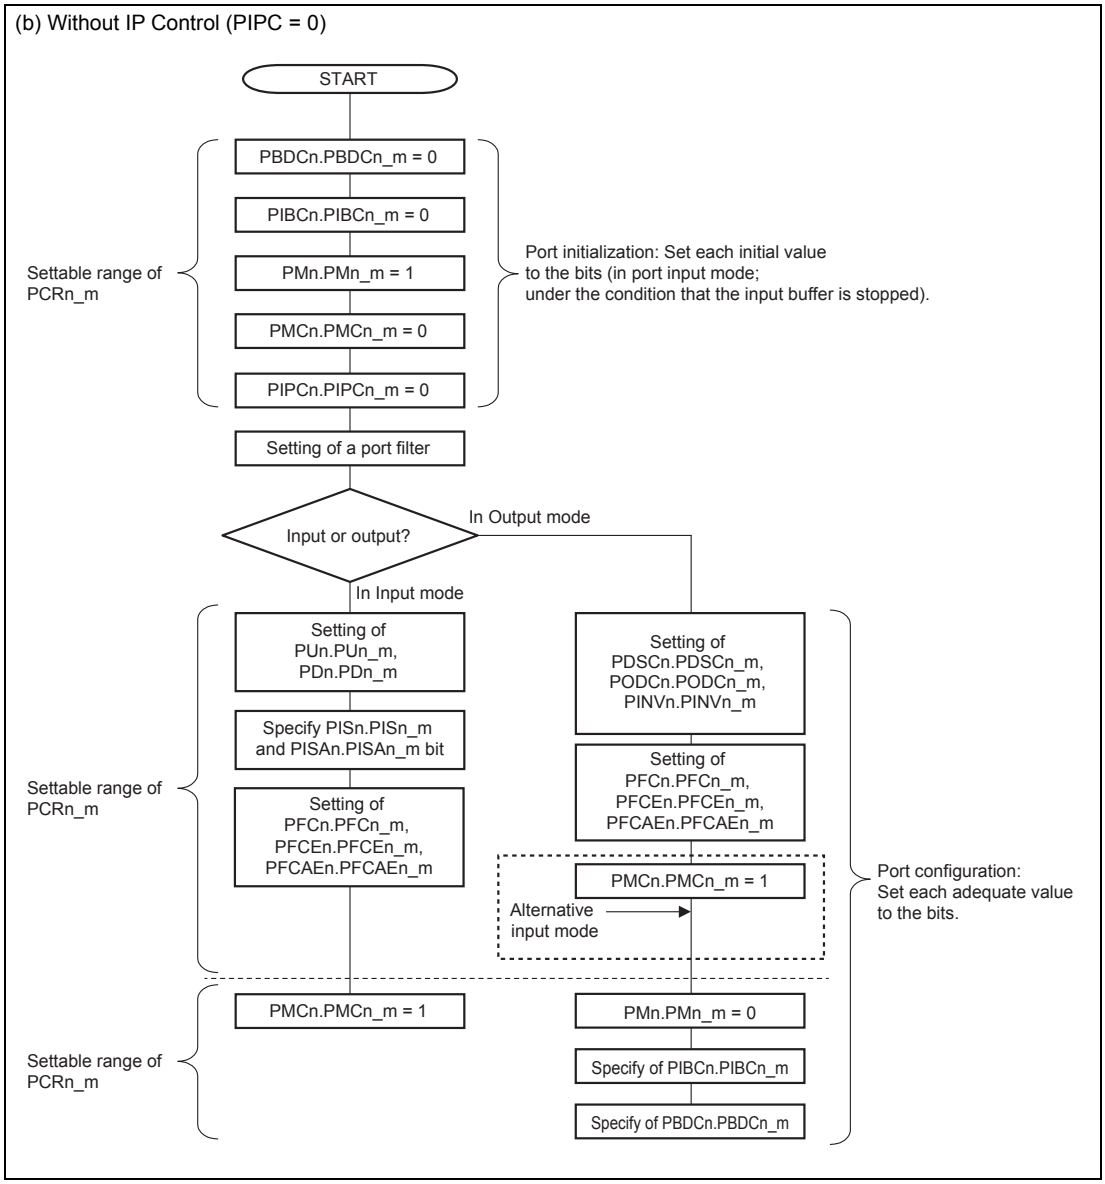

Figure 2.12 Example of Port Configuration Flow (in alternative mode) (2/2)

2.2.5 Functional Selection

2.2.5.1 Register Configuration in Use of the Alternative Function

When the pin alternative function is used, set PMCn_m = 1 and select the alternative numbers of PFCn_m, PFCEn_m and PFCAEn_m. In several peripheral functions, a single alternative I/O function is allocated to multiple pins. However, such an alternative function should not be enabled in multiple pins at the same time. For example, an external interrupt input, INTP7 is allocated to P0_6 and P44_11, but this alternative function can only be selected in either of them.

2.2.5.2 Alternative Function to be used in Direct I/O Control Alternative Mode

When the alternative functions described in **Table 2.30** are used, switch to direct I/O control alternative mode. When setting PIPCn_m = 1, the PMn_m value which has been set is ignored because the peripheral function enables or disables inputs and outputs of the buffer.

2.2.5.3 Register Setting in Use of an Analog Input Pin

Since ADCEnIm(SAR-A/D) for an analog input are always connected to the A/D converter, setting of a port register to select a pin function is not required.

2.2.5.4 Input buffer characteristics

The charateristic of most port input buffers is selectable via the PISn and PISAn registers.

The following tables show the selectable options.

Note that some port input buffers have a fixed charateristic, i.e. their default charateristic can not be changed.

(1) D1L1 input buffers characteristics

Table 2.31 D1L1 ports input buffer characteristics (1/3)

Port		PISAn_m = 1		PISAn_m = 0		Default
		PISn_m = 1	PISn_m = 0	PISn_m = 1	PISn_m = 0

For the electrical specification of the different input buffer types refer to the Data Sheet.

2.2.5.5 Output Buffer Control (PDSC)

For several ports the drive strength of an output buffer can be selected as

- PDSCn.PDSCn_m = 0: slow
- PDSCn.PDSCn_m = 1: fast

The applicable output ports can be identified by the exixtence of a PDSCn.PDSCn_m control bit in the port control register lists in Section 2.3.1, Port Registers.

For the electrical specification of the different output buffer types refer to the Data Sheet.

2.2.5.6 Output buffer drive strength control register (DSCTRL) (D1M1-V2, D1M1A only)

The output buffers of some ports feature a special output drive strength control register. This register can control the drive capability of the output buffer.

Access: This register can be read/written in 32-bit units.

Address: FFC0 6054_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

17, 16	P21_0_ DS[1:0]	Output drive strength of P21_0 00_B: target impedance 25 Ω 01_B: target impedance 33 Ω 10_B: target impedance 50 Ω 11_B: target impedance 100 Ω
15, 14	—	Reserved These bits are always read as 0. The write value should always be 0.
13, 12	SDRDSA[1:0]	Output drive strength of SDRAA[12:0], SDRABA[1:0], SDRACSZ, SDRARASZ, SDRACASZ, SDRAWEZ (D1M1A only) 00_B: target impedance 25 Ω 01_B: target impedance 33 Ω 10_B: target impedance 50 Ω 11_B: target impedance 100 Ω
11, 10	SDRDSD3[1:0]	Output drive strength of SDRADQ[31:24], SDRADM3 (D1M1A only) 00_B: target impedance 25 Ω 01_B: target impedance 33 Ω 10_B: target impedance 50 Ω 11_B: target impedance 100 Ω
9, 8	SDRDSD2[1:0]	Output drive strength of SDRADQ[23:16], SDRADM2 (D1M1A only) 00_B: target impedance 25 Ω 01_B: target impedance 33 Ω 10_B: target impedance 50 Ω 11_B: target impedance 100 Ω

Table 2.35 DSCTRL register contents (2/2)

Bit Position	Bit Name	Function
7, 6	SDRDSD1[1:0]	Output drive strength of SDRADQ[15:8], SDRADM1 (D1M1A only) 00_B: target impedance 25 Ω 01_B: target impedance 33 Ω 10_B: target impedance 50 Ω 11_B: target impedance 100 Ω
5, 4	SDRDSD0[1:0]	Output drive strength of SDRADQ[7:0], SDRADM0 (D1M1A only) 00_B: target impedance 25 Ω 01_B: target impedance 33 Ω 10_B: target impedance 50 Ω 11_B: target impedance 100 Ω
3, 2	SDRDSC[1:0]	Output drive strength of SDRACK, SDRACKE (D1M1A only) 00_B: target impedance 25 Ω 01_B: target impedance 33 Ω 10_B: target impedance 50 Ω 11_B: target impedance 100 Ω
1, 0	—	Reserved These bits are always read as 0. The write value should always be 0.

NOTE

In the header files the module name of the above register is defined as:

SELB.

2.3 Organization of Port Groups

2.3.1 Port Registers

The tables in this subsection show detailed bitmaps of control registers in each port group. In the bitmap field, "√" means an effective bit and "—" means a reserved one. Reserved areas are always read as initial values. The write value also should be an initial value.

2.3.1.1 List of D1L1, D1L2 Port Registers

2.3.2 List of Alternative Function Pins

The following sectiosn define the alternative functions of each port.

The first table in each section specifies all ports of the RH850/D1L/D1M devices with all possible alternative functions.

The following tables specify which signals and which ports are available for each device.

2.3.2.1 Port 0 (P0)

Table 2.96 Port 0 (P0)

Port mode (PMC0_m = 0)	Control Mode (PMC0_m = 1)								Dedicated function
	1st Alternative		2nd Alternative		3rd Alternative		4th Alternative		
	Input	Output	Input	Output	Input	Output	Input	Output	
P0_0	NMI	RLIN31TX	$\overline{\text{CSIH0SSI}}$	CSIH0CSS0	TAUJ0I0	TAUJ0O0	INTP5	OSTM0 TTOUT	MODE0
P0_1	RLIN31RX / INTP0			CSIH0SO	TAUJ0I1	TAUJ0O1		$\overline{\text{ERROROUT}}$	FLMD1
P0_2	INTP1	RLIN32TX	CSIH0SI		TAUJ0I3	TAUJ0O3		AWOT0 TOUT	MODE1
P0_3	RLIN32RX / INTP2		CSIH0SC		TAUJ0I2	TAUJ0O2		CAN0DREN	
P0_4	INTP5	OSTM1 TTOUT		TAUB1O3*1	TAUB1I3	CSCXFOUT		CAN0TX	
P0_5	TAUJ0I1	TAUJ0O1		TAUB1O5*1	TAUB1I5	RTCA0OUT	CAN0RX / INTP6		
P0_6	INTP7	RLIN30TX		TAUB1O7*1	TAUB1I7			CAN1TX	
P0_7	RLIN30RX / INTP8			TAUB1O9*1	TAUJ0I0	TAUJ0O0	CAN1RX / INTP8	CAN2DREN	
P0_8	INTP9	RLIN30TX			TAUJ0I1	TAUJ0O1		CAN2TX	
P0_9	RLIN30RX / INTP10				TAUJ0I0	TAUJ0O0	CAN2RX / INTP10	CAN1DREN	

Note 1. These ports are equipped with an XOR Compare Unit. Refer to Section 2.4.2, Port output check by XOR Compare Unit for details.

Table 2.97 P0 signals availability

2.4 Output ports check functions

Additionally to the capability of analyzing several PWM output signals, generated by the PWM Generators (refer to Section 32, PWM Generators and Diagnostic (PWM-Diag) for details), two other facilities allow to monitor output signals of further modules.

2.4.1 Port output check by timers

The PWM output signals of

- all Stepper Motor Controller/Driver (ISM) outputs
- the Sound Generators outputs
  - SG1: SG1FAO and SG1FAOL
  - SG2: SG2FAO and SG2FAOL
  - SG3: SG3FAO at port P3_5 and SG3FAOL at port P3_10
  - SG4: SG4FAO at port P3_6 and SG4FAOL at port P3_11

can be input to the capture inputs of some Timer Array Unit B (TAUB) channels.

This is possible due to the assignment of the ISM and SGn output signals and TAUB input signals to the same ports and concurrent activation of the output and input buffer of that port.

By this means the timing properties, e.g. cycle duration and duty factor, can be measured and pin short circuits can be detected.

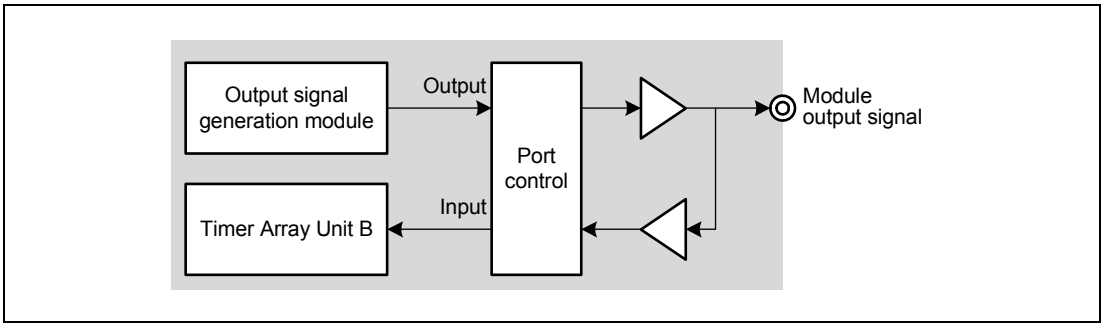

Figure 2.13 Port output check by timers

2.4.2 Port output check by XOR Compare Unit

Another way to detect a mismatch between the intended signal output and the real level at the output pin involves an XOR compare between the module output and the pin level.

The XOR Compare Unit can detect short-circuits of the pins.

Like with the output check by a timer, as described above, the output signal and the signal to compare are assigned to the same port with output and input buffers active.

A de-glitch filter suppresses possible spikes in the XOR output signal, which may occur due to signal propagation times and external capacitive load of the output buffer.
Refer to Section 2.6, Noise Filter and Edge Level Detection Circuit for details about the filter.

Since this port check can be permanently active - it does not require any CPU involvement - a mismatch between the output and input signal generates an error signals towards the Error Control Module and thus can assert interrupts or a reset.

XOR Compare Units are available for following modules, that generate output signals:

- Timer Array Unit B (TAUB) outputs:
  - TAUB0
    TAUB0O1, TAUB0O3, TAUB0O5, TAUB0O7, TAUB0O9, TAUB0O11, TAUB0O13
  - TAUB1
    TAUB1O1, TAUB1O3, TAUB1O5, TAUB1O7, TAUB1O9
- all PCM-PWM Convert (PCMP) outputs:
  PCMP0AP0, PCMP0AN0, PCMP0BP0, PCMP0BN0, PCMP0AP1, PCMP0AN1, PCMP0BP1, PCMP0BN1
- the Sound Generator SG0 outputs:
  SG0FAO, SG0FAOLat port P3_7, SG0AO at port P3_7

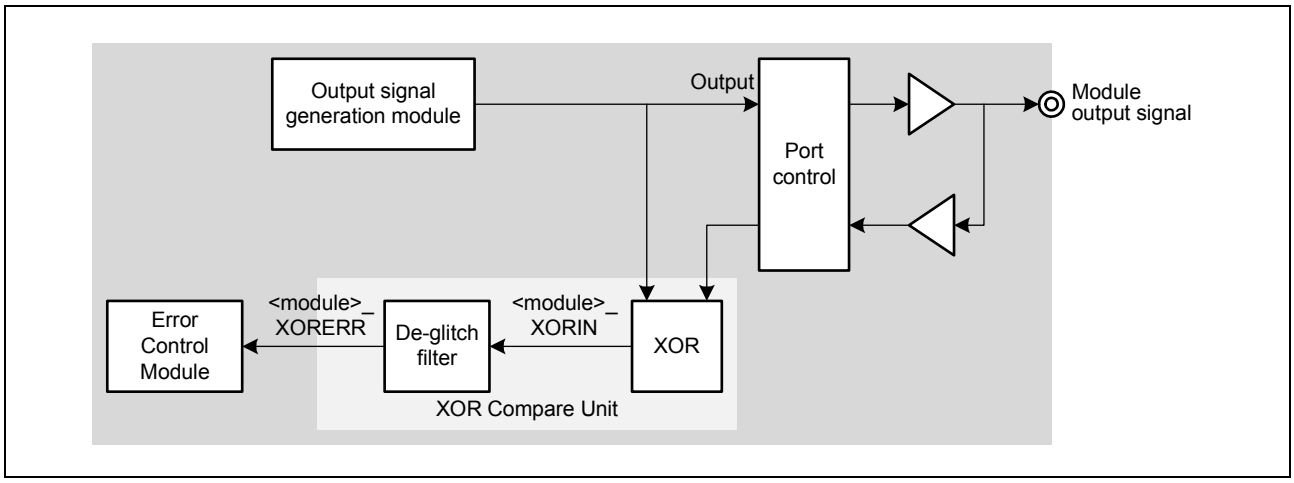

Figure 2.14 Port output check by XOR Compare Units

The XOR compare unit can be separately enabled or disabled for each signal by use of the following registers.

2.4.2.1 PRMR0CFG0 — Port XOR compare unit control register 0

This register controls the XOR compare units for Timer Array Unit B output signals.

Access: This register can be read/written in 32-bit units.

Address: FFC0 6000_H

Initial value: 0000 0000_H

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 2.154 PRMR0CFG2 register contents

Bit Position	Bit Name	Function
2	PRMR0XDPE 2	Enable XOR compare unit for SG0AO at port P3_7 0: XOR compare unit disabled 1: XOR compare unit enabled
1	PRMR0XDPE 1	Enable XOR compare unit for SG0FAOL at port P3_7 0: XOR compare unit disabled 1: XOR compare unit enabled
0	PRMR0XDPE 0	Enable XOR compare unit for SG0FAO 0: XOR compare unit disabled 1: XOR compare unit enabled

CAUTION

The XOR compare unit for SG0FAO (at port P3_2), SG0FAOL (at port P3_7) and SG0AO (at port P3_7) can be enabled for each of this functions here separately.

However the three functions share the same de-glitch filter (DNFA10NFEN8, refer to Table 2.156, List of XOR Compare Unit Filters). By that means the signal that is provided to the de-glitch filter is the logic OR-function of all activated XOR compare functions of SG0.

2.5 DNF

Digital Noise Filter (DNF) eliminates digital noise from external input signals. This product includes two sorts of DNF: peripheral function DNF and edge detection DNF.

2.5.1 Example of Noise Elimination

Figure 2.15 shows an example of noise elimination in peripheral function DNF and edge detection DNF. In this example, the sampling clock, the sampling count, and the current output level are set to 1/2 of the DNF input clock, two (twice), and low, respectively. "○" in the figure means that high level is detected.

In input examples 1, 2, and 3, the output level changes from low to high because the same level is detected twice in a row through sampling. In input examples 4, 5, and 6, on the other hand, the same level is not detected twice consecutively. Therefore, these inputs are regarded as noise and the input signal state is eliminated.

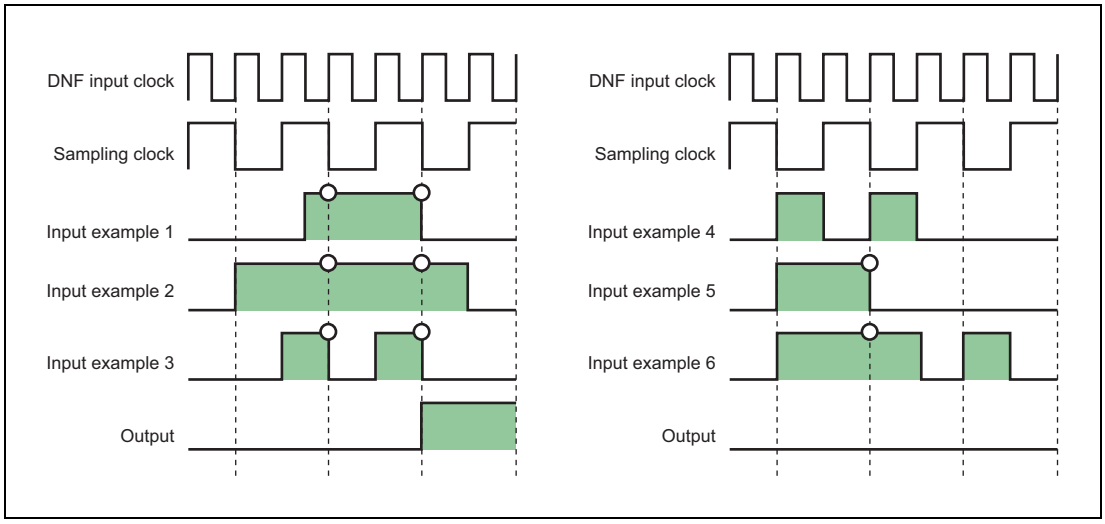

Figure 2.15 Timing Chart of Digital Noise Elimination

2.6 Noise Filter and Edge Level Detection Circuit

Some signals that are input to a pin pass the filter to eliminate noises and glitches. This product supports both analog filter and digital filter.

Additionally, the product also supports the function of detecting an edge or level after a pass through a filter.

The first section describes port input signals to which filters are allocated and the types of the filters, the noise filter and edge level detection control register and its control bits, and an overview of the register address and others.

For details about the digital/analog filter function and the noise filter and edge level detection control register, see Section 2.6.3.1, Analog Filter Type A Input Pin, Section 2.6.3.2, Analog Filter Type B Input Pin and Section 2.6.3.3, Digital Filter Type C (No Edge Detection) Input Pin.

2.6.1 Allocation of Port Filters

The following is a list of input pins that have analog filter or digital filter.

Table 2.155 List of Input Pins with a Noise Filter (1/3)

Input Pin	Filter Type	Digital Noise Elimination Control Register			Digital Noise Elimination Enable Register			Filter Control Register

2.6.2 XOR Compare Unit Filters

The XOR Compare Unit output signals are passed through a digital noise filter.

Refer to Section 2.4.2, Port output check by XOR Compare Unit for details.

Table 2.156 List of XOR Compare Unit Filters

XOR Comapre Unit output signal	Filter Type	Digital Noise Elimination Control Register			Digital Noise Elimination Enable Register			Filter Control Register

Note 1. ch8 of DNFA10 is for the logic OR-function of all activated XOR compare functions of SG0.

2.6.3 Filter Types

2.6.3.1 Analog Filter Type A Input Pin

The input pin of analog filter type A has only an analog filter.

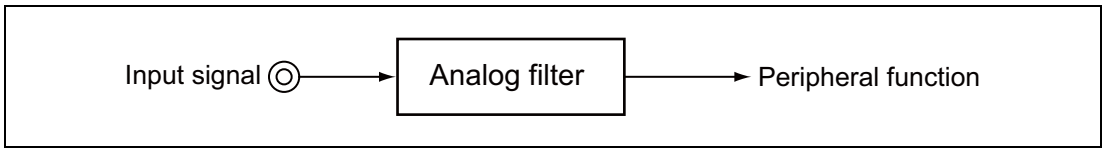

Figure 2.16 Block Diagram of Analog Filter Type A

2.6.3.2 Analog Filter Type B Input Pin

The input pin of analog filter type B has an analog filter, that is controlled with the following register.

- Filter control register FCLAnCTL
  Each FCLAnCTL control register controls filter processing.

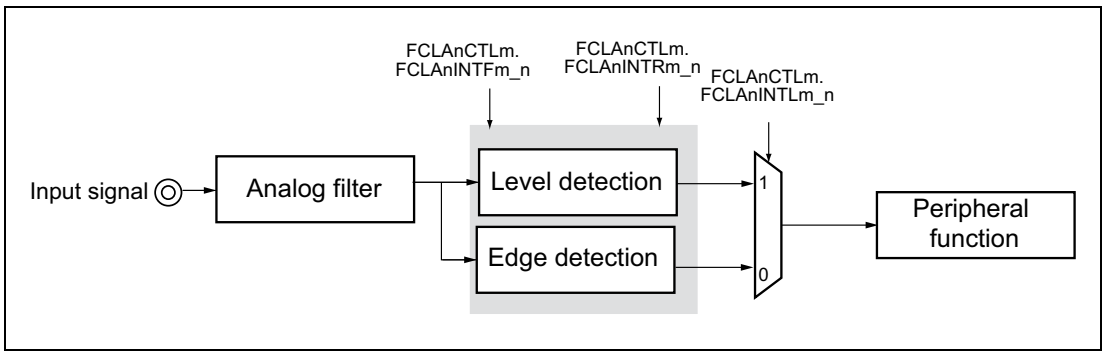

Figure 2.17 Block Diagram of Analog Filter Type B

2.6.3.3 Digital Filter Type C (No Edge Detection) Input Pin

The input pin of digital filter type C has a digital filter that is controlled with the following registers.

- Digital noise elimination control register DNFAnCTL
  Each DNFAnCTL control register controls digital filter processing.
- Digital noise elimination enable register DNFAnEN
  Each DNFAnEN enables digital filter processing.

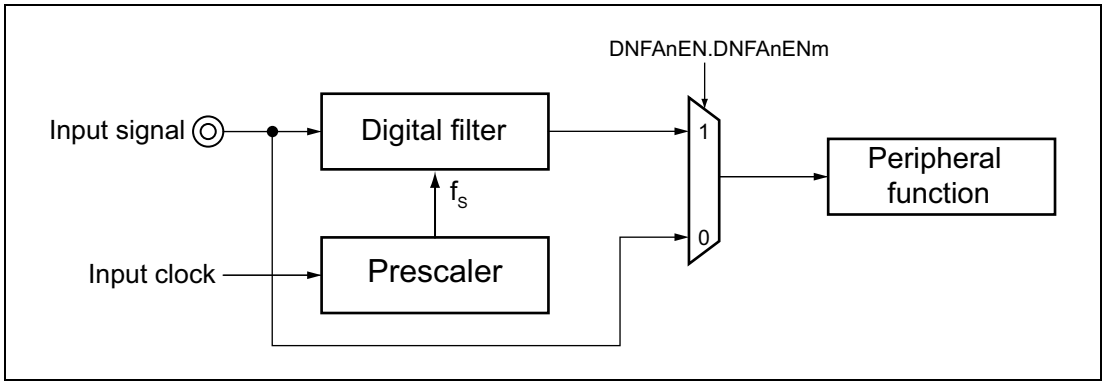

Figure 2.18 Block Diagram of Digital Filter Type C

CAUTIONS

1. **When the output signal from the digital filter is input to an alternative function, allow at least the following interval to elapse after the digital filter is enabled (DNFAnEN.DNFAnNFENm (m = 0 to 15) = 1) for the port pin to switch to the alternative function.**
   $s \times 1/fs + 2 \times 1/f_{DNFATCKI}$
   where
   s = DNFAnCTL.DNFAnNFSTS[1:0] + 2
   fs: sampling clock
   $f_{DNFATCKI}$: input clock
2. **When a digital filter's output signal is used as an interrupt signal, only enable the digital filter (DNFAnEN.DNFAnNFENm (m = 0 to 15) = 1) while interrupts are disabled. Furthermore, only enable interrupts after enabling the digital filter, waiting for the time below to elapse, and then clearing the interrupt request flag.**
   $s \times 1/fs + 3 \times 1/f_{DNFATCKI}$

2.6.4 Port Filter Registers

2.6.4.1 FCLAnCTLm — Filter Control Register

This register controls the analog filter operation.

Access: This register can be read or written in 8-bit units.

Address: The allocation of input signals to FCLAnCTLm registers and the address of each register are shown in the tables in Table 2.155, List of Input Pins with a Noise Filter and Table 2.156, List of XOR Compare Unit Filters..

Initial value: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	FCLAnINTLm	FCLAnINTFm	FCLAnINTRm
Initial value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 2.157 FCLAnCTLm register contents

Bit Position	Bit Name	Function
7 to 3	Reserved	When written, write the initial value.
2	FCLAnINTLm	Level detection control 0: Level detection disabled 1: Level detection enabled
1	FCLAnINTFm	Falling edge detection control 0: Falling edge detection disabled 1: Falling edge detection enabled
0	FCLAnINTRm	Rising edge detection control 0: Rising edge detection disabled 1: Rising edge detection enabled

Following table summarizes the correct register set-up for the various detection functions.

CAUTION

Before setting this register, make sure that the connected modules are disabled. Attempting to change

may lead to unexpected output from the filter.

Table 2.158 Register set-up for the various detection functions

FCLAnINTLm	FCLAnINTFm	FCLAnINTRm	Function
0	0	0	No detection
		1	Rising edge detection
	1	0	Falling edge detection
		1	Both edges detection
1	0	0	Low level detection
		1	High level detection
	1	0	Low level detection
		1	High level detection

NOTE

For details about the relevant port groups and bits, see Section 2.6.1, Allocation of Port Filters.

2.6.4.2 DNFAnCTL — Digital Noise Elimination Control Register

This register specifies characteristics of the digital noise elimination filter.

Access: This register can be read or written in 8-bit units.

Address: For the correspondence between the DNFAnCTL register and input signals, and the addresses of individual registers, see Table 2.155, List of Input Pins with a Noise Filter and Table 2.156, List of XOR Compare Unit Filters.

Initial value: 00_H

Bit	7	6	5	4	3	2	1	0
	—	DNFAnNFSTS[1:0]		—	—	DNFAnPRS[2:0]		
Initial value	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R	R	R/W	R/W	R/W

Table 2.159 DNFAnCTL register contents

Bit Position	Bit Name	Function
7	Reserved	When written, write the initial value.
6, 5	DNFAnNFSTS [1:0]	The DNFAnNFSTS[1:0] bits specify the number of samples used to judge whether an external signal pulse is valid. 00_B: 2 samples 01_B: 3 samples 10_B: 4 samples 11_B: 5 samples
4, 3	Reserved	When written, write the initial value.
2 to 0	DNFAnPRS [2:0]	Selects a digital filter sampling clock. The sampling clock depends on the input clock (see Table 2.155, List of Input Pins with a Noise Filter) and the DNFAnPRS[2:0] divider: sampling clock = input clock / $2^{DNFAnPRS[2:0]}$

NOTE

For details about the relevant port groups and bits, see Section 2.6.1, Allocation of Port Filters and Section 2.6.2, XOR Compare Unit Filters.

CAUTION

Before setting this register, make sure that the connected modules are disabled. Attempting to change may lead to unexpected output from the filter.

2.6.4.3 DNFAnEN — Digital Noise Elimination Enable Register

This register enables or disables digital noise elimination for an arbitrary input signal.

Access: This register can be read or written in 16-bit units.

Address: For the correspondence between the DNFAnEN register and input signals, and the addresses of individual registers, see Table 2.155, List of Input Pins with a Noise Filter and Table 2.156, List of XOR Compare Unit Filters.

Initial value: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DNFAn NFEN15	DNFAn NFEN14	DNFAn NFEN13	DNFAn NFEN12	DNFAn NFEN11	DNFAn NFEN10	DNFAn NFEN9	DNFAn NFEN8	DNFAn NFEN7	DNFAn NFEN6	DNFAn NFEN5	DNFAn NFEN4	DNFAn NFEN3	DNFAn NFEN2	DNFAn NFEN1	DNFAn NFEN0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.160 DNFAnEN register contents

Bit Position	Bit Name	Function
15 to 0	DNFAnNFEN [15:0]	Digital noise elimination control 0: Digital noise elimination disabled (filter is bypassed) 1: Digital noise elimination enabled

NOTE

For details about the relevant port groups and bits, see Section 2.6.1, Allocation of Port Filters and Section 2.6.2, XOR Compare Unit Filters.

CAUTION

Before setting this register, make sure that the connected modules are disabled. Attempting to change may lead to unexpected output from the filter.

2.7 Pin State

This section specifies the status of all pins in the different operating modes.

2.7.1 Pin state in normal operation mode

Table 2.161 Pin state in normal operation mode (1/2)

Port	Pin Category	$\overline{\text{DCUTRST}}$ = L			
		$\overline{\text{RESET}}$ pin = L		$\overline{\text{RESET}}$ pin = H	
		During power-up (POC0RES = H)	Internal reset active (POC0RES = L)	No reset active	During DEEPSTOP
Pn	P0	Hi-Z	Hi-Z	Operate	Hold/operate
	All D1x: P1, P2, P3, P42, P43, P46 and P47 D1L1, D1L2(H), D1M1(H): P44 and P45	Hi-Z	Hi-Z	Operate	Hold/Hi-Z
	All D1x: P10, P11, P21 and P40 D1M2(H) only: P44 and P45 D1M1A only: P22	Hi-Z	Hi-Z	Operate	Hi-Z
	P16, P17	L	L	Operate	Hold/L
JP0*3		Hi-Z	Hi-Z	Operate	Operate
$\overline{\text{RESET}}$ (open drain)		L	L → H input	H input	H input
FLMD0 (input with internal pull-down)		L	L	L	L
X1/X2		Stop	Stop *1	Operate	Operate
XT1/XT2		Stop	Stop *1	Operate	Operate
PWRGD		Operate	Operate	Operate	Operate
PWRCTL		L	H	H	L
ADCE0Im		Hi-Z	Hi-Z	Operate	Hi-Z
SDR-SDRAM I/F (SDRA)	SDRAA[12:11], SDRAA10, SDRAA[9:0]	L	L	Operate*2	Hi-Z
	SDRADQ[31:0]	Hi-Z	Hi-Z	Operate	Hi-Z
	SDRABA[1:0]	L	L	Operate*2	Hi-Z
	SDRACLK	L	L	Operate	Hi-Z
	SDRACKE	L	L	Operate	Hi-Z
	SDRADM[3:0]	L	H	Operate	Hi-Z
	$\overline{\text{SDRACS}}$, $\overline{\text{SDRACAS}}$, $\overline{\text{SDRARAS}}$, $\overline{\text{SDRAWE}}$	L	H	Operate	Hi-Z
DDR2-SDRAM I/F (SDRB)	SDRBA[13:11], SDRBA10, SDRBA[9:0]	L	L	Operate	Hi-Z
	SDRBDQ0	Hi-Z	Hi-Z	Operate	Hi-Z
	SDRBDQ1	H	H	Operate	Hi-Z
	SDRBDQ[31:2], $\overline{\text{SDRBDQS}}$[3:0], SDRBDQS[3:0]	Hi-Z	Hi-Z	Operate	Hi-Z

Table 2.161 Pin state in normal operation mode (2/2)

Port	Pin Category	DCUTRST = L			
		RESET pin = L		RESET pin = H	
		During power-up (POC0RES = H)	Internal reset active (POC0RES = L)	No reset active	During DEEPSTOP
DDR2-SDRAM I/F (SDRB)	SDRBBA[2:0]	L	L	Operate	Hi-Z
	SDRBCLK, SDRBCLK	L	L	Operate	Hi-Z
	SDRBCKE	L	L	Operate	Hi-Z
	SDRBDM[3:0]	L	H	Operate	Hi-Z
	SDRBODT	L	L	Operate	Hi-Z
	SDRBCS, SDRBCAS, SDRBRAS, SDRBWE	L	H	Operate	Hi-Z

Note 1. X1/X2 and XT1/XT2 are only affected by the Power-On-Clear 0 (POC0RES = H). Thus, once it starts operation, internal reset does not change the status of these pins.

Note 2. Unused pin of SDRAA[12:0] and SDRABA[1:0] are driven to low while the operation. Refer to Table 15.28, 1 x 16-bit SDRAM (DBCONF.BWIDTH[1:0] = 01B) and Table 15.29, 1 x 32-bit or 2 x 16-bit SDRAM (DBCONF.BWIDTH[1:0] = 10B) for their availability.

Note 3. JP0_4 should be pulled down on RESET pin = L state.
When SYSRES and the external RESET is active, an on-chip pull-down resistor is connected to JP0_4.

2.7.2 Pin state in debug mode

Table 2.162 Pin state in debug mode (1/2)

Port	Pin Category	DCUTRST = H			
		RESET pin = L		RESET pin = H	
		During power-up (POC0RES = H)	Internal reset active (POC0RES = L)	No reset active	During DEEPSTOP
Pn	P0	Hi-Z	Hi-Z	Operate	Hold/operate
	All D1x: P1, P2, P3, P42, P43, P46 and P47 D1L1, D1L2(H), D1M1(H): P44 and P45	Hi-Z	Hi-Z	Operate	Hold/Hi-Z
	All D1x: P10, P11, P21 and P40 D1M2(H) only: P44 and P45 D1M1A only: P22	Hi-Z	Hi-Z	Operate	Hi-Z
	P16, P17	L	L	Operate	Hold/L
JP0		Operate	Operate	Operate	Operate
RESET (open drain)		L	L → H input	H input	H input
FLMD0 (input with internal pull-down)		L	L	L	L

	SDRBDQ1	H	H	Operate	Hi-Z
	SDRBDQ[31:2], SDRBDQS[3:0], $\overline{\text{SDRBDQS[3:0]}}$	Hi-Z	Hi-Z	Operate	Hi-Z
	SDRBBA[2:0]	L	L	Operate	Hi-Z
	SDRBCLK, $\overline{\text{SDRBCLK}}$	L	L	Operate	Hi-Z
	SDRBCKE	L	L	Operate	Hi-Z
	SDRBDM[3:0]	L	H	Operate	Hi-Z
	SDRBODT	L	L	Operate	Hi-Z
	$\overline{\text{SDRBCS}}$, $\overline{\text{SDRBCAS}}$, $\overline{\text{SDRBRAS}}$, $\overline{\text{SDRBWE}}$	L	H	Operate	Hi-Z

Note 1. X1/X2 and XT1/XT2 are only affected by the Power-On-Clear 0 (POC0RES = H). Thus, once it starts operation, internal reset does not change the status of these pins.

Note 2. The X1/X2 pins are operating, if it is used for LPD 1-pin mode (OPJTAG[1:0] = 10_B).

Note 3. Unused pin of SDRAA[12:0] and SDRABA[1:0] are driven to low while the operation. Refer to Table 15.28, 1 x 16-bit SDRAM (DBCONF.BWIDTH[1:0] = 01B) and Table 15.29, 1 x 32-bit or 2 x 16-bit SDRAM (DBCONF.BWIDTH[1:0] = 10B) for their availability.

2.7.3 Pin state in serial programming mode

Table 2.163 Pin state in serial programming mode (1/2)

Port	Pin Category	$\overline{\text{DCUTRST}}$ = L

	$\overline{\text{SDRBCS}}$, $\overline{\text{SDRBCAS}}$, $\overline{\text{SDRBRAS}}$, $\overline{\text{SDRBWE}}$	L	H	Operate	Hi-Z

Note 1. Unused pin of SDRAA[12:0] and SDRABA[1:0] are driven to low while the operation. Refer to Table 15.28, 1 x 16-bit SDRAM (DBCONF.BWIDTH[1:0] = 01B) and Table 15.29, 1 x 32-bit or 2 x 16-bit SDRAM (DBCONF.BWIDTH[1:0] = 10B) for their availability.

Note 2. JP0_4 should be pulled down on RESET pin = L state.
When SYSRES and the external RESET is active, an on-chip pull-down resistor is connected to JP0_4.

2.8 Recommend connection of unused pins

This section specifies how to connect pins, which are not used in the application system.

Table 2.164 Recommended connection of unused pins (1/3)

Pin	Recommended connection, if not used	
X1	Must always be connected to oscillator	
X2		
XT1	Connect to OSCVSS	
XT2	Open or connect to OSCVSS	
FLMD0	Must always be connected	
P0_0/MODE0	The function of these pins depend on the operation mode.	
P0_1/FLMD1		
P0_2/MODE1		
PWRCTL	Open	
PWRGD	• D1Lx, D1M1(H), D1M1A: Connect to PWRCTL • D1M2(H): must always be connected	
$\overline{\text{RESET}}$	Pull-up resistor to EVCC	
Port group JP0	The function of these pins depend on the operation mode. When JP0_4 is unused, connect it to VSS through resistor.	Note: If the I/O ports reset configuration is changed, set • Hi-Z (input disabled, when PIBCn_m = 0 and PMCn_m = 0): leave open • input enabled (when PIBCn_m = 1 and PMCn_m = 1): connect to VSS through resistor. • output enabled (PMn_m = 0): leave open
Port group P0	Open	
Port group P1	Open	
Port group P2	Open	
Port group P3	Open	
Port group P10	Open	
Port group P11	Open

Section 3 CPU System

The RH850/D1L/D1M CPU is an RH850 CPU of the architecture class V850E3v5-V, as described in the

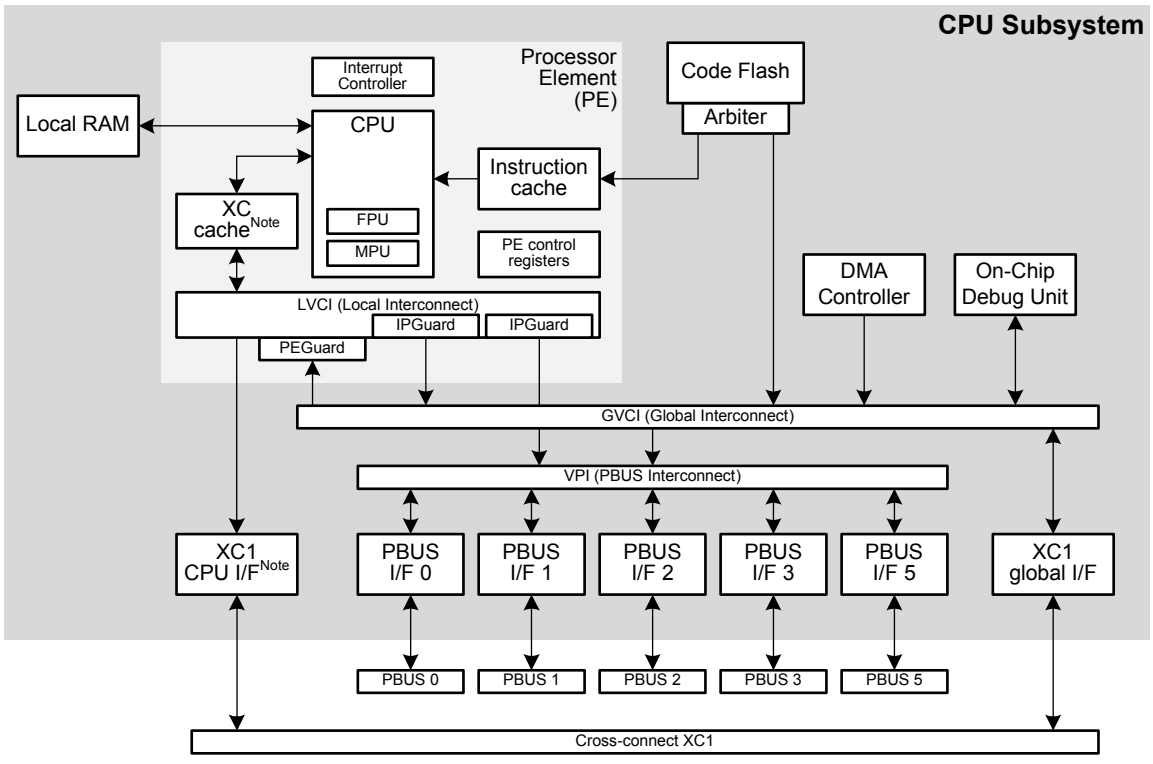
RH850 G3M
User's Manual: Software
Document number R01US0123EJxxxx (xxxx: revision number)

Of the functions as described in the above document the RH850/D1L/D1M products implement a subset as indicated in the following summary:

- MPU has 12 channels
- No MMU support
- No SIMD support

3.1 CPU Subsystem

The figure below shows the block diagram of the CPU Subsystem.



Note: The D1L1 devices do not have the XC cache and the XC1 CPU interface.

Figure 3.1 CPU Subsystem block diagram

3.1.1 Processor Element (PE) and CPU

The Processor Element (PE) comprises modules that are tightly coupled to the CPU. These modules operate with the CPU frequency and have dedicated protection facilities to prevent unwanted access.

The CPU features

- Single Processor Element with RH850G3M CPU core
- High performance 32-bit architecture for embedded control
- Separate 32-bit instruction and data bus
- 32-bit internal address bus: 4 GB linear space for both data and instructions
- 32 general-purpose registers, 32 bit wide
- Superscalar architecture with double 7 stage execution pipelines
- High speed branch structure with branch prediction and pre-fetch function
- Load/store units supports non-blocking load/store
- RISC type instruction set (backward compatible with V850, V850E1, and V850E2)
- Floating Point Unit (FPU)
  - Implemented as CPU coprocessor for execution of 32-bit single precision and 64-bit double precision floating-point operation instructions
  - Conforms to ANSI/IEEE standard 754 (IEEE binary floating-point operation standard)
- Code Flash cache
  - The cache resides in the instruction fetch pass of the CPU to the instruction flash memory
  - Size is 8 KB, 4-way associative, 128 lines for each way, with LRU replace algorithm
  - Cache operation is ECC protected
    - Double bit error detection, single bit error correction
- CPU protection functions:
  - supervisor and user mode
  - Memory Protection Unit (MPU)
- CPU snooze instruction:
  - Pauses CPU operation for 256 cycles per execution

Refer to Section 3.1.4, CPU protection functions for further details.

3.1.2 CPU Subsystem interfaces

All CPU Subsystem internal busses are multi-layered transaction based bus systems. Refer to Section 14.3.1, Transaction based busses for details.

3.1.2.1 XC1 interfaces

The CPU has access to all resources on the cross-connect XC1 via an exclusive CPU XC1 interface.

NOTE

This exclusive XC1 interface is not available for D1L1 devices.

The XC1 interfaces of following devices are equipped with a cache:

- D1L2(H), D1M1(H), D1M1-V2, D1M1A: 16 KB/4-way associative
- D1M2(H): 32 KB/4-way associative

All other CPU Subsystem master's XC1 accesses, e.g. the DMA Controller, are routed via the XC1 global interface.

A detailed description of the PBUS connections is given in Section 14.2, Cross-connect systems.

XC Cache

Refer to Section 3.3, XC Cache for description of the XC Cache.

3.1.2.2 PBUS interfaces

The PBUS is a single master bus, that is mainly used for accessing the control registers of most functional modules.

The PBUS modules are grouped into four functional segments, distributed to five separate PBUSes.

- System control PBUS segment
  connects modules to configure the system and the modules on the Always-On-Area, e.g.
  - System control: Interrupt Controller 2, Clock Controller, ICU-S, Error Control Module
  - Always-On-Area modules: Always-On-Area Timer, Real-Time Clock, Watchdog
- DMA PBUS segment
  connects modules mostly served by DMA e.g. like sound generator or IIS, e.g.
  - Audio interfaces: Sound Generator, I^2S interfaces, PCM-PWM Converter
  - LCD Bus Interface
- Graphics/communication PBUS segment
  connects to registers of modules, which are also attached to the cross-connections XC0, XC1, XC2, e.g.
  - video and graphics: Sprite Engine, Video Output Checker
  - advanced communication: Ethernet, Media Local Bus

- General PBUS segment
  connects all other modules, e.g.
  - timers: Timer Array Units, OS timers
  - standard communication: CAN, I2C, serial clocked and asynchronous interfaces (CSI, RLIN)
  - miscellaneous: A/D Converter, Stepper Motor Controller/Driver, PWM Generators and Diagnostic

Only the CPU and the DMA Controller can access the PBUS modules.

Each PBUS segment has its own guard, that allows to grant or prohibit certain access rights to dedicated PBUS masters.

A detailed description of the PBUS connections is given in Section 14.5, PBUS structure.

3.1.3 Bit manipulation

The RH850/G3M CPU core offers the following bit manipulation commands:

- CLR1, NOT1, SET1, TST1 → byte access used
- CAXI → word (32-bit) access used

Byte access can only be used if supported by

- the bus system
- the functional module

On bus level these commands result in a read-modify-write (RMW operation).

- Some buses can ensure this sequence is not interrupted by other access (bus is locked)
- If the bus or functional module cannot handle, the software needs to ensure that the register is not accessed in parallel by another master (e.g. CPU vs. DMA)

CAUTION

The application software must not use bit manipulation commands, if the register value can change as a result of operation of the functional module and read-modify-write access could overwrite such change.

Table 3.1 Bit manipulation support

	Target access via		
	PE internal buses*1	**APB**	**XC1 cross-connect**
Support of 8-bit, 16-bit access	Yes*2	Yes*2	Yes*2
Support of bus lock during RMW operations	Yes	Yes	No
Usage of SET1, CLR1, NOT1, TST1	Yes	Yes	No*3
Usage of CAXI	Yes	Yes	No*3

Note 1. All Processor Element internal buses.

Note 2. If the target register allows 8-bit/16-bit access.

Note 3. The usage of these commands is prohibited, when targeting registers via the XC1 cross-connect. The resulting read/write operations would be ignored.

CAUTION

The registers of the following modules are accessed via the XC1 cross-connect:

- **Serial Flash Memory Interface (SFMA)**
- **Video Data Controllers (VDCE)**
- **Video Output Warping Engine (VOWE)**
- **Display Output Comparators (DISCOM)**
- **JPEG Codec Unit A (JCUA)**
- **SDR-SDRAM Memory Controller (SDRA)**
- **HyperBus Controller (HYPB)**
- **OctaBus Controller (OCTA)**

Thus SET1, CLR1, NOT1, TST1 and CAXI operations must not be used for accessing the registers of these modules.

Note for memory access

The support of bit manipulation commands also affects data access in memory.

If the application software defines bit structures in memory, the compiler will access such data with bit manipulation. Consequently the bus connection of this memory must support bit manipulation commands.

In particular this means:

- Access to the Local RAM in the CPU Subsystem can use SET1, CLR1, TST1 and CAXI commands.
- Access to on-chip Video RAM (VRAM), Retention RAM (RRAM) and external SDRAM must not use SET1, CLR1, TST1 and CAXI commands. The read/write will be ignored.
  Note that no exception is issued in such case.

3.1.4 CPU protection functions

The CPU has the following means to protect the system against software malfunctions:

CPU Operating Modes

The CPU core provides three operating modes for the software:

- User mode
- Supervisor mode

The supervisor mode typically is granted to the operating system. Instructions required for modifications of the CPU core's system registers are only available in supervisor mode.

Applications managed by an operating system (or similar software instances) are run in user mode. Access to system resources or memory areas can be restricted. In case of a software malfunction non application related memory areas are protected against illegal access.

Memory Protection Unit (MPU)

The MPU is used to protect CPU memory regions against instruction fetches by illegal application software and or illegal data manipulation.

- The MPU supervises the whole address range of the CPU
  - Address range includes both memory and peripheral area
  - Allowed areas can be configured by software
  - Any unpermitted access will assert a MPU exception
- The MPU is integrated in the CPU core
  - Only CPU access (data and instruction) are supervised
  - Pipeline precise exceptions will be generated
  - Only if data/instruction are really used – i.e. speculative instructions fetch will not be handled if dropped
- MPU configuration
  - 12 protection windows configurable by CPU in supervisor mode
  - Granularity of windows is one word – areas may overlap

3.1.5 System Error Notification Control Function (SEG)

Errors due to an instruction fetch or data access can be the sources of system error exceptions. A SYSERR exception is an FE level exception from which return or recovery is not possible. SEG (SysErrGen) controls the notification and record of the error by the data access. Multiple error occurrence inputs are categorized according to error factors, and are processed sequentially from the highest-priority error factor, generating an FE-level asynchronous exception (SYSERR). The bit position of the SEGFLAG register becomes the priority of error factors. Error factors of lower bits take precedence over error factors of upper bits. Error information is recorded once regardless of error frequency. The error with the highest priority of error factor (in case errors occurred simultaneously) is valid. Recorded error information is not overwritten by subsequent errors.

NOTE

Be sure to place a SYNCP instruction at the start of handers for exceptions of set E.

- Exceptions of set E: FENMI, FEINT, EIINT (with the direct vector method), SYSERR, and FPI

For details, see "*RH850G3M User's Manual Software Edition*".

3.1.5.1 List of SEG Function Control Registers

Table 3.2 Base Address of SEG Register: FFFE E980$_H$

Address Offset	Size (Byte)	Register Name	Symbol	Right	R/W	OperableBit				Value after reset
						1	8	16	32	
0000_H	2	Errornotification control register	SEGCONT	—	R/W*1	—	—	√	—	0000_H
$+02_H$	2	Error occurrence retentionregister	SEGFLAG	—	R/W*1	—	—	√	—	0000_H
$+08_H$	4	Errorfactor retention register (address)	SEGADDR	—	R/W*1	—	—	√	√	Undefined (retained)

Note 1. Write accesses from other than the SV privilege (PSW.UM = 0) on the native machine are ignored.

NOTE

- If an access is made with an address offset or operable bits other than those specified above, an error response is returned.
- Write access is only possible in supervisor mode (UM = 0). Attempting to write in other modes leads to an error response being returned.
- No restriction is provided for read accesses.
- Read accesses to ranges permitted by other protection systems are enabled at any time.

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> is defined as “SEG” for the registers in the table above.

<Symbol> is defined in the above table

3.1.5.2 Register set

(1) SEGCONT — Error Notification Control Register

This register is used to enable (= 1) or disable (= 0) notification of SYSERR request in response to error flags that store error occurrence status according to factors.

Access: This register can be read/written in 16-bit units.

Address: $+00_H$

Initial value: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	VPGE	VCRE	—	TCME	ROME	VCIE	—	ICCE	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R	R

Table 3.3 SEGCONT register contents (1/2)

Bit Position	Bit Name	Function
15to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	VPGE	• This bit notifies of a response to an error in PBUS0-5. (excluding errors in readingfrom PBUS.) The error includes the followings: – When an unimplemented area is accessed – PBUS guard error(PBUS guarding also applies to the guarding of all registers in the modules for protection listed in Table 14.18)
8	VCRE	This bit notifies of IPG violation access detection and subsequent access blocking*2.
7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6	TCME	This bit notifies of an error during data accessing to its own local RAM. The error includes the following cases: • When an ECC error which cannot be corrected occurs • When an access to the RAM-unimplemented area in the local RAM is detected
5	ROME	This bit notifies of an error in access to the Code Flash when a table reference is read in response to a table reference interrupt. The error includes the following cases: • When an ECC error which cannot be corrected occurs

Table 3.3 SEGCONT register contents (2/2)

Bit Position	Bit Name	Function
4	VCIE	• This bit notifies of a response to an error in PBUS0-5.(excluding errors in writing to PBUS.) The error includes the following cases: – When an unimplemented areais accessed – PBUS guard error(PBUS guarding also applies to the guarding of all registers in the modules for protection listed in Table 14.18) • This bit notifies of a response to an error in the Code Flash The error includes the following cases: – When an ECC error which cannot be corrected occurs*1 • This bit notifies of a detection of access to an interconnect reserved area. – FFFF 0000_H to FFFF $4FFF_H$ – FFFE 0000_H to FFFE $BFFF_H$ – FB00 0000_H to FE9F $FFFF_H$ – F300 0000_H to F8FF $FFFF_H$ • This bit notifies of a IPG violation access detection and subsequent access blocking*2. • This bit notifies of an access privilege violation. – Read or write access to the IPG Protection Setting Registers by user mode (PSW.UM = 1) – Write access to the SEG Function Control Registers by user mode (PSW.UM = 1)
3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2	ICCE	Instruction cache error notification enable The error occurred in the instruction cache is handled when the instructioncache system register, ICCTRL.ICHEMK, is set to 0 (whose value after reset is 1): For instruction cache errors, see "*ICERR — Instruction Cache Error Register*" in "*RH850G3M User's Manual Software Edition*".
1 to 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

Note 1. While ECC error notification is enabled, an uncorrectable ECC error has occurred. Whether or not the error can be corrected depends on the ECC settings.

Note 2. For error factor address, see Section 14.6.3, PE's Internal Peripheral Guard (IPG), IPGADRUM register.

Table 3.4 Error Factor Codes and Handling of G3M Core SYSERR Exceptions

Factor Codes	Error Contents
10_H	Reserved
11_H	Instruction fetch errors (from code flash memory)
12_H	Errors in which their notification is enabled by the SEGCONT second bit
13_H	Instruction fetch errors (from other than code flash memory)
14_H	Errors in which their notification is enabled by the SEGCONT fourth bit
15_H	Errors in which their notification is enabled by the SEGCONT fifth bit
16_H	Errors in which their notification is enabled by the SEGCONT sixth bit
17_H	Reserved
18_H	Errors in which their notification is enabled by the SEGCONT eighth bit
19_H	Errors in which their notification is enabled by the SEGCONT ninth bit
$1A_H$	Reserved
$1B_H$	Reserved
$1C_H$	Reserved
$1D_H$	Reserved
$1E_H$	Reserved
$1F_H$	Reserved

3.1.5.3 SEGFLAG — Error Occurrence Retention Register

- This register sets the flags of error occurrence, that store each error occurrence status by factors. Those are not automatically cleared (return to 0).
- Writing to the register enables both setting and clearing.

Access: This register can be read/written in 16-bit units.

Address: $+02_H$

Initial value: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	VPGF	VCRF	—	TCMF	ROMF	VCIF	—	ICCF	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R	R

Table 3.5 SEGFLAG register contents

Bit Position	Bit Name	Function
15 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	VPGF	Flag corresponding to bit 9 of the SEGCONT register
8	VCRF	Flag corresponding to bit 8 of the SEGCONT register
7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6	TCMF	Flag corresponding to bit 6 of the SEGCONT register
5	ROMF	Flag corresponding to bit 5 of the SEGCONT register
4	VCIF	Flag corresponding to bit 4 of the SEGCONT register
3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2	ICCF	Flag corresponding to bit 2 of the SEGCONT register
1 to 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

3.1.5.4 SEGADDR — Error Factor Retention Register (Address)

This register records information of an error factor that notifies a SYSERR request (only one history is recorded).

It records the addresses where the error factors for the VCIF, ROMF and TCMF bits of the SEGFLAG register were found. The error factors except VCIF, ROMF and TCMF bits of the SEGFLAG register to be recorded as 00000000_H.

Access: This register can be read/written in 32-bit units.

Address: $+08_H$

Initial value: Undefined (retained)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note: ×: Undefined (retained)

Table 3.6 SEGADDR register contents

Bit Position	Bit Name	Function
31 to 0	ADDRESS[31:0]	These bits retain the address at which SYSERR source occurred. (If an error occurred by accessing to the local RAM area, the addresses of the 19 lower-order bits are retained and the addresses of the 13 higher-order bits are cleared to 0.)

CAUTION

This cannot be modified when the error occurrence flag to enable notification is set.

3.1.5.5 SEG Function

(1) SEG function: Notifying a SYSERR request due to an error flag

- Setting an error flag takes precedence over clearing the same flag.
  - Simultaneous clearing operation is ignored.
- Priority of error factors
  - The bit position of the notification-enabled SEGFLAG register becomes the priority of error factors. Error factors of lower bits take precedence over error factors of upper bits. Notification is made from the highest-priority error factor.
  - The bit position of error factors is notified as a “SYSERR factor code”.
- Conditions for starting SYSERR request notification

- Even if a notification-disabled flag is set to 1, notification is not made.
- Notification is made immediately after a notification-enabled flag is set to 1.
- After clearing, notification is made depending on the flag state (re-arbitration).

- Finishing notification at a SYSERR request response
  - Even after notification is finished, the flag is not cleared automatically.
  - Notification is not made until re-arbitration is performed by setting or clearing the flag.
  - If an error flag that is prioritized higher than with an upper SYSERR factor code.

(2) SEG function: Recording error factor information

- When notification-enabled error occurrence is input, the error address is retained in the above register.
  - No information is retained by setting or clearing an error flag described in "(1) SEG function: Notifying a SYSERR request due to an error flag in **Section 3.1.5.5, SEG Function**" above.
  - When multiple error occurrence inputs are present simultaneously, information other than the prioritized error factor is not retained.
- While the notification-enabled error flag described in "(1) SEG function: Notifying a SYSERR request due to an error flag in Section 3.1.5.5, SEG Function" above is set to 1, overwrite to the above register is inhibited
  - If error occurrence input continues, information of subsequent error factors is not retained.
  - To reset the inhibition of overwrite to the register, clear either SEGCONT or SEGFLAG register (or both of them).

(3) Supplementary information on SYSERR exception

- The PSW.EBV bit retains its value and the base address for the exception handler is not changed even when a SYSERR exception is generated.
- Detection of errors in the instruction cache

  Detection of an error in the instruction cache does not lead to a SYSERR exception of the type that requires re-execution by the origin of the instruction fetch. Execution of the instruction by the CPU still proceeds; the instruction cache automatically invalidates the entry which lead to the error and fetching is repeated, this time from the code flash memory. The SEG block will be informed that a cache error has occurred if the setting of the ICHEMK bit of the ICCTRL cache-control system register is 0.

3.1.6 Product dependent registers

Table 3.7 List of product dependent registers

Register No. (reg ID, sel ID)	Register name	Symbol	Access Permission
SR5, 1	Machine control register	MCTL	SV (PSW.UM = 0)
SR6, 1	Processor ID register	PID	SV (PSW.UM = 0)

3.1.6.1 MCTL — Machine Control Register

This register is used to control the CPU.

Access: —

Address: —

Initial value: 8000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 3.8 MCTL register contents

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
30 to 1	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	UIC	This bit is used to control the interrupt enable/disable operation in user mode. When this bit is set to 1, executing the EI/DI instructionbecomes possible in user mode.

3.1.6.2 PID — Processor ID Register

The PID register retains a processor identifier that is unique to the CPU. The PID register is a read-only register.

CAUTION

The PID register indicates information used to identify the incorporated CPU core and CPU core configuration. Usage such that the software behavior varies dynamically according to the PID register information is not assumed.

Access: —

Address: —

Initial value: 0580 0F12$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 24	PID	Architecture Identifier This identifier indicates the architecture of the processor.
23 to 8		Function Identifier This identifier indicates the functions of the processor. These bits indicate whether or not functions defined per bit are implemented (1: implemented, 0: not implemented). Bits 23 to 11:Reserved Bit 10: Double-precision floating-point operation function Bit 9: Single-precision floating-point operationfunction Bit 8: Memory protection unit function (MPU)
7to 0		Version Identifier This identifier indicates the version of the processor.

3.2 Instruction Cache ECC

The ECC of the Instruction Cache generates an interrupt request listed in the following table:

Table 3.10 Interrupt Request by ECC of Instruction Cache

Function	Connected to
Instruction cache data RAM ECC 2-bit error detection interrupt	These interrupts are logically OR combined and input to the Error Control Module INTECCI.
Instruction cache data RAM ECC 1-bit error detection interrupt	
Instruction cache tag RAM ECC 2-bit error detection interrupt	
Instruction cache tag RAM ECC 1-bit error detection interrupt	

Instruction caches ECC calculated following data size for each RAM.

- Instruction cache data RAM: The 8-bit ECC value is calculated for each 64-bit transfer.
- Instruction cache tag RAM: The 7-bit ECC value is calculated for each 32-bit transfer.

The ECC of the Instruction Cache and its registers are initialized by the following reset signal:

Table 3.11 Reset sources

ECC unit	Reset signal
Instruction Cache ECC	• Reset Controller SYSRES • reset upon wake-up from DEEPSTOP mode

3.2.1 Overview

The instruction cache ECC is summarized in the table below.

Item	Description
ECC error detection	ECC error detection and correction can be either enabled or disabled. When enabled, • For instruction cache data RAM, ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). • For instruction cache tag RAM, ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). When disabled, neither error detection nor correction is carried out. In the initial state, the ECC function is enabled, and notification are carried out.

Item	Description
Error notification	Upon occurrence of an ECC error, it is notified to the Error Control Module. **ECC Error:** • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. In the initial state, notification of the ECC 2-bit error is disabled, and notification of the ECC 1-bit error is disabled.
Error status	A status register is provided, which indicates the status of ECC 2-bit error detection and ECC 1-bit error detection. If an error occurs while no error status is set, the corresponding status is set. The error status can be cleared using the clear register.
Address capture	If an ECC error occurs while no error status is set, the address at which the associated error has occurred is captured. The address is captured when an ECC 2-bit error or an ECC 1-bit error is detected. The error status serves as the enable bit of the capture address.

3.2.2 List of Registers

Table 3.12 List of Registers

Address	Symbol	Register Name	R/W	Value after reset	Access Size
FFC6 0400$_H$	IDECCCTL_PE1_OS	Instruction cache data RAM ECC control register	R/W	0000 0000$_H$	16/32
FFC6 0404$_H$	IDERRINT_PE1_OS	Instruction cache data RAM error information control register	R/W	0000 0000$_H$	8/16/32
FFC6 0408$_H$	IDSTCLR_PE1_OS	Instruction cache data RAM error status clear register	W	0000 0000$_H$	8/16/32
FFC6 040C$_H$	IDOVFSTR_PE1	Instruction cache data RAM error count overflow status register	R	0000 0000$_H$	8/16/32
FFC6 0410$_H$	ID1STERSTR_PE1_OS	Instruction cache data RAM 1st error status register	R	0000 0000$_H$	8/16/32
FFC6 0450$_H$	ID1STEADR0_PE1_OS	Instruction cache data RAM (Bank0) 1st error address register	R	0000 0000$_H$	8/16/32
FFC6 0454$_H$	ID1STEADR1_PE1_OS	Instruction cache data RAM (Bank1) 1st error address register	R	0000 0000$_H$	8/16/32
FFC6 1400$_H$	ITECCCTL_PE1_OS	Instruction cache tag RAM ECC control register	R/W	0000 0000$_H$	16/32
FFC6 1404$_H$	ITERRINT_PE1_OS	Instruction cache tag RAM error information control register	R/W	0000 0003$_H$	8/16/32
FFC6 1408$_H$	ITSTCLR_PE1_OS	Instruction cache tag RAM error status clear register	W	0000 0000$_H$	8/16/32
FFC6 140C$_H$	ITOVFSTR_PE1_OS	Instruction cache tag RAM error count overflow status	R	0000 0000$_H$	8/16/32
FFC6 1410$_H$	IT1STERSTR_PE1_OS	Instruction cache tag RAM 1st error status clear register	R	0000 0000$_H$	8/16/32
FFC6 1450$_H$	IT1STEADR0_PE1_OS	Instruction cache tag RAM (Bank0) 1st error address register	R	0000 0000$_H$	8/16/32

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> is defined as “ECCIC1” for the registers in the table above.

<Symbol> is defined in the above table.

3.2.3 Details of Registers

3.2.3.1 IDECCCTL_PE1_OS — Instruction cache data RAM data ECC control register

IDECCCTL enables or disables ECC error detection and correction and 1-bit error correction for cache data RAM. Set PROT[1:0] bits to 01_B when writing to IDECCCTL.

IDECCCTL is initialized by an internal reset or an external reset.

Access: This register can be read/written in 16-bit and 32-bit units.

Address: FFC6 0400_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PROT[1:0]		—	—	—	—	—	—	—	—	—	—	—	—	—	ECC DIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 3.13 IDECCCTL_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, these bits are always read as 0. When writing, always write 0.
15, 14	PROT[1:0]	Enables or disables modification of the ECCDIS bits. The value written is not retained. These bits are always read as 0. Set PROT[1:0] = 01_B when writing to IDECCCTL.
13 to 1	Reserved	When read, these bits are always read as 0. When writing, always write 0.
0	ECCDIS	ECC disable bit Setting ECC error detection to enable/disable. 0:ECC error detection is enable 1:ECC error detection is disable

3.2.3.2 IDERRINT_PE1_OS — Instruction cache data RAM error information control register

IDERRINT enables or disables generation of the error notification signal to the ECM upon detection of an ECC 2-bit error or an ECC 1-bit error in cache data RAM.

IDERRINT is initialized by an internal reset or an external reset.

Access: This register can be read/written in 8-bit, 16-bit and 32-bit units.

Address: FFC6 0404_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DEDIE	SEDIE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 3.14 IDERRINT_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, these bits are always read as 0. When writing, always write 0.
1	DEDIE	ECC 2-bit error Notification Enable Enables or disables generation of the error notification signal upon detection of a 2-bit error when ECC error detection and correction are enabled. 0: Disables notification of the ECC 2-bit error. 1: Enables notification of the ECC 2-bit error.
0	SEDIE	ECC 1-bit error Notification Enable Enables or disables generation of the error notification signal upon detection of a 1-bit error when ECC error detection and correction are enabled. 0: Disables notification of the ECC 1-bit error. 1: Enables notification of the ECC 1-bit error.

3.2.3.3 IDSTCLR_PE1_OS — Instruction cache data RAM error status clear register

IDSTCLR clears the error flags in the error status register (ID1STERSTR), the overflow flag in the error overflow status register (IDOVFSTR), and the error address register (ID1STEADR). IDSTCLR is a write-only register and is always read as 0.

Access: This register can be written in 8-bit, 16-bit and 32-bit units.

Address: FFC6 0408$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SST CLR1	SST CLR0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W	W

Table 3.15 IDSTCLR_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, these bits are always read as 0. When writing, always write 0.
1	SSTCLR1	Error Overflow Flag Clear (for bank 1) Writing 1 to this bit clears the DEDF1and SEDF1 flags in ID1STERSTR; ERROVF1 flag in IDOVFSTR; and ID1STEADR1.
0	SSTCLR0	Error Overflow Flag Clear (for bank 0) Writing 1 to this bit clears the DEDF0and SEDF0 flags in ID1STERSTR; ERROVF0 flag in IDOVFSTR; and ID1STEADR0.

3.2.3.4 IDOVFSTR_PE1_OS — Instruction cache data RAM error count overflow status register

IDOVFSTR monitors occurrence of error overflow in cache data RAM. If the second error occurs after the first error (= while any of the error flags in the error status register is set), the flag in this register is set. However, if the second error is identical to the first error (both the source and address are same), this flag is not set. ERROVF is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in IDSTCLR.

Access: This register can be read in 8-bit, 16-bit and 32-bit units.

Address: FFC6 040C$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 3.16 IDOVFSTR_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, these bits are always read as 0. When writing, always write 0.
1	ERROVF1	Error Overflow Flag (for bank 1) ERROVF1 is set if the second error occurs while any of the error flags (DEDF1 and SEDF1) in the error status register is set, except when both of the error address and source of the second error are the same as those of the first error.
0	ERROVF0	Error Overflow Flag (for bank 0) ERROVF0 is set if the second error occurs while any of the error flags (DEDF0 and SEDF0) in the error status register is set, except when both of the error address and source of the second error are the same as those of the first error.

3.2.3.5 ID1STERSTR_PE1_OS — Instruction cache data RAM 1st error status register

ID1STERSTR monitors occurrence of the first error in cache data RAM. The error status is set if an error occurs while all the error flags for the relevant banks are 0. The error flag is overwritten if an ECC 2-bit error occurs while the ECC 1-bit error monitor flag is set.

ID1STERSTR is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in IDSTCLR.

Access: This register can be read in 8-bit, 16-bit and 32-bit units.

Address: FFC6 0410$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 3.17 ID1STERSTR_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, these bits are always read as 0. When writing, always write 0.
9	DEDF1	ECC 2-bit error Monitor Flag (for bank 1) 0: Cleared to 0 by setting the STCLR1 bit to 1 in IDSTCLR. 1: Indicates that an ECC 2-bit error has occurred while the error flag DEDF1 is 0.
8	SEDF1	ECC 1-bit error Monitor Flag (for bank 1) 0: Cleared to 0 by setting the STCLR1 bit to 1 in IDSTCLR. 1: Indicates that an ECC 1-bit error has occurred while the error flags DEDF1 and SEDF1 are 0.
7 to 2	Reserved	When read, these bits are always read as 0. When writing, always write 0.
1	DEDF0	ECC 2-bit error Monitor Flag (for bank 0) 0: Cleared to 0 by setting the STCLR0 bit to 1 in IDSTCLR. 1: Indicates that an ECC 2-bit error has occurred while the error flag DEDF0 is 0.
0	SEDF0	ECC 1-bit error Monitor Flag (for bank 0) 0: Cleared to 0 by setting the STCLR0 bit to 1 in IDSTCLR. 1: Indicates that an ECC 1-bit error has occurred while the error flags DEDF0 and SEDF0 are 0.

3.2.3.6 ID1STEADRn_PE1_OS — Instruction cache data RAM (bank n) 1st error address register (n = 0, 1)

ID1STEADR holds the address at which an error has occurred in cache data RAM. The error address is set if an error occurs while all the error flags for the relevant banks are 0 in ID1STERSTR. The address is updated if an ECC 2-bit error occurs while the ECC 1-bit error flag is set as the first error. Once an ECC 2-bit error occurs, the address is not updated.

Since this register holds the internal address, add the base address of the associated memory to transform the internal address to the real address. ID1STEADR is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in IDSTCLR.

Access: This register can be read in 8-bit, 16-bit and 32-bit units.

Address: ID1STEADR0_PE1_OS: FFC6 0450$_H$
ID1STEADR1_PE1_OS: FFC6 0454$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 3.18 ID1STEADRn_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, these bits are always read as 0. When writing, always write 0.
8 to 0	EADRn[8:0]	1st Error Address (for bank n) Monitors the address of the first error. The error address is set if an error occurs while all the error flags for bank n are 0 in ID1STERSTR. The address is updated if an ECC 2-bit error occurs while the ECC 1-bit error flag is set as the first error. Once an ECC 2-bit error occurs, the address is not updated.

3.2.3.7 ITECCCTL_PE1_OS — Instruction cache tag RAM ECC control register

ITECCCTL enables or disables ECC error detection in cache tag RAM. Set PROT[1:0] to 01_B when writing to ITECCCTL.

ITECCCTL is initialized by an internal reset or an external reset.

Access: This register can be read/written in 16-bit and 32-bit units.

Address: FFC6 1400_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 3.19 ITECCCTL_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, these bits are always read as 0. When writing, always write 0.
15, 14	PROT[1:0]	Enables or disables modification of the ECCDIS bit. The value written is not retained. These bits are always read as 0. Set PROT[1:0] = 01_B when writing to ITECCCTL.
13 to 1	Reserved	When read, these bits are always read as 0. When writing, always write 0.
0	ECCDIS	ECC Disable Enables or disables ECC error detection and correction. Write a value to this bit simultaneously with setting PROT[1:0] = 01_B. 0: Enables ECC error detection. 1: Disables ECC error detection.

3.2.3.8 ITERRINT_PE1_OS — Instruction cache tag RAM error information control register

ITERRINT enables or disables generation of the error notification signal to the ECM upon detection of an ECC 2-bit error or an ECC 1-bit error in cache tag RAM.

ITERRINT is initialized by an internal reset or an external reset.

Access: This register can be read/written in 8-bit, 16-bit and 32-bit units.

Address: FFC6 1404_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 3.20 ITERRINT_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, these bits are always read as 0. When writing, always write 0.
1	DEDIE	ECC 2-bit error Notification Enable Enables or disables generation of the error notification signal upon detection of a 2-bit error when ECC error detection and correction are enabled. 0: Disables notification of the ECC 2-bit error. 1: Enables notification of the ECC 2-bit error.
0	SEDIE	ECC 1-bit error Notification Enable Enables or disables generation of the error notification signal upon detection of a 1-bit error when ECC error detection and correction are enabled. 0: Disables notification of the ECC 1-bit error. 1: Enables notification of the ECC 1-bit error.

3.2.3.9 ITSTCLR_PE1_OS — Instruction cache tag RAM error status clear register

ITSTCLR clears the error flags in the error status register (IT1STERSTR), the overflow flag in the error overflow status register (ITOVFSTR), and the error address register (IT1STEADR). ITSTCLR is a write-only register and is always read as 0.

Access: This register can be written in 8-bit, 16-bit and 32-bit units.

Address: FFC6 1408_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 3.21 ITSTCLR_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, these bits are always read as 0. When writing, always write 0.
0	STCLR0	Error Overflow Flag Clear Writing 1 to this bit clears the DEDF0 and SEDF0 flags in IT1STERSTR; ERROVF0 flag in ITOVFSTR; and IT1STEADR0.

3.2.3.10 ITOVFSTR_PE1_OS — Instruction cache tag RAM error count overflow status register

ITOVFSTR monitors occurrence of error overflow in cache tag RAM. If the second error occurs after the first error (= while any of the error flags in the error status register is set), the flag in this register is set. However, if the second error is identical to the first error (both the source and address are same), this flag is not set. ERROVF is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in ITSTCLR.

Access: This register can be read in 8-bit, 16-bit and 32-bit units.

Address: FFC6 140C$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 3.22 ITOVFSTR_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, these bits are always read as 0. When writing, always write 0.
0	ERROVF0	Error Overflow Flag ERROVF0 is set if the second error occurs while any of the error flags (DEDF0 and SEDF0) in the error status register is set, except when both of the error address and source of the second error are the same as those of the first error.

3.2.3.11 IT1STERSTR_PE1_OS — Instruction cache tag RAM 1st error status register

IT1STERSTR monitors occurrence of the first error in cache tag RAM.

The error flag is overwritten if an ECC 2-bit error occurs while the error flag is 0.

IT1STERSTR is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in ITSTCLR.

Access: This register can be read in 8-bit, 16-bit and 32-bit units.

Address: FFC6 1410$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 3.23 IT1STERSTR_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, these bits are always read as 0. When writing, always write 0.
1	DEDF0	ECC 2-bit error Monitor Flag 0: Cleared to 0 by setting the STCLR0 bit to 1 in ITSTCLR. 1: Indicates that an ECC 2-bit error has occurred while the error flag DEDF0 is 0.
0	SEDF0	ECC 1-bit error Monitor Flag 0: Cleared to 0 by setting the STCLR0 bit to 1 in ITSTCLR. 1: Indicates that an ECC 1-bit error has occurred while the error flags DEDF0 and SEDF0 are 0.

3.2.3.12 IT1STEADR0_PE1_OS — Instruction cache tag RAM 1st error address register

IT1STEADR holds the address at which an error has occurred in cache tag RAM. The error address is set if an error occurs while all the error flags for the relevant banks are 0 in IT1STERSTR. The address is updated if an ECC 1-bit error occurs while the ECC 1-bit error flag is set as the first error. Once an ECC 2-bit error occurs, the address is not updated. Since this register holds the internal address, add the base address of the associated memory to transform the internal address to the real address.

IT1STEADR is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in ITSTCLR.

Access: This register can be read in 8-bit, 16-bit and 32-bit units.

Address: FFC6 1450$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	EADR[8:0]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 3.24 IT1STEADR0_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, these bits are always read as 0. When writing, always write 0.
8 to 0	EADR[8:0]	1st Error Address Monitors the address of the first error. The error address is set if an error occurs while all the error flags are 0 in IT1STERSTR. The address is updated if an ECC 2-bit error occurs while the ECC 1-bit error flag is set as the first error. Once an ECC 2-bit error occurs, the address is not updated.

3.3 XC Cache

CPU access to the on-chip and external memories can be performed directly (un-cached) or via the XC Cache.

Therefore the

- Retention RAM (RRAM)
- on-chip Video RAMs (VRAM0 and VRAM1)
- external serial flash memory devices via the Serial Flash Memory Interface A (SFMA)
- external SDRAM memory devices via the SDR-SDRAM Memory Controller (SDRA) or DDR2-SDRAM Memory Controller (SDRB)
- external serial flash/RAM memory devices via the HyperBus (HYPB) Controller

can be accessed through different address windows.

For details about the direct and mirrored access areas refer to Section 5.3, Cross-connect address map and Section 54.5, Video RAM and SDRAM memory map.

3.3.1 XC Cache features summary

- The XC cache is not implemented in the D1L1 devices.
  - Unified cache i.e. both instruction and data cache
  - It allows caching of memories on the XC1 cross-connect, i.e. Video RAM (VRAM), external SDRAM, external serial flash
- Cache size:
  - D1L2(H), D1M1(H), D1M1-V2, D1M1A: 16 KB
  - D1M2(H): 32 KB
  - All: 4-way associative, 32 byte line size
- Least recently used (LRU) and write-back policy
- Cache operation is ECC protected
  - Double bit error detection, single bit error correction
  - XC caches ECC calculated following data size for each RAM.
    XC cache data RAM: The 7-bit ECC value is calculated for each 32-bit transfer.
    XC cache tag RAM: The 7-bit ECC value is calculated for each 19-bit transfer.

Item	Description
ECC error detection	ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected. • ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). When disabled, neither error detection nor correction is carried out. In the initial state, the ECC function is enabled, and 1-bit error detection and correction and 2-bit error detection and notification are carried out.
Error notification	Upon occurrence of an ECC error, it is notified to the Error Control Module. **ECC Error:** • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. In the initial state, notification of the ECC 1-bit and 2-bit errors is disabled.
Error status	A status register is provided, which indicates the statuses of ECC 2-bit error detection and ECC 1-bit error detection. If an error occurs while no error status is set, the corresponding status is set. The error status can be cleared using the clear register.
Address capture	If an ECC error occurs while no error status is set, the address at which the associated error has occurred is captured. The address is captured when an ECC 2-bit error or an ECC 1-bit error is detected. The error status serves as the enable bit of the capture address.

- Cached access configuration
  - Default mode is direct (un-cached) access
  - Two address windows can be defined for cached access
  - Minimum granularity is 1 MB
- Buffered mode available
  - Buffer area and Cache area cannot set to same address area. If address area are overlapped, XC cache issue the error response.
  - Read buffer: 64 bit x 8 entries
  - Write buffer: 64 bit x 2 entries
  - Buffer flash function available
- Cache operation commands available (by register access)

3.3.2 Cache/Buffer window set-up

- Base address of cached window = AXCCABASEn
- Window size of cached window = AXCCAMASKn

Example:

Window for cached access from address 2000 0000_H to 3FFF $FFFF_H$ (512 MByte window size):

- AXCCABASE0 = 2000 0000_H
- AXCCAMASK0 = 3FFF $FFFF_H$

Window for buffered access from address 4000 0000_H to 400F $FFFF_H$ (1 MByte window size):

- AXCBFBASE0 = 4000 0000_H
- AXCBFMASK0 = 000F $FFFF_H$

3.3.3 Cache initialization

After Power-On reset the cache needs to be reset as follows:

1. Cache RAM for data and tag initialization

- clear data and tag RAM by issuing cache commands for all index of the cache

2. Initialization sequence for error control registers AXCSYSERR, AXCERRCNT, AXCERRADR

- 1 st step (lock clear)
  - Write AXCSYSERR.SE = 0
  - Write AXCERRCNT.ERR = 0
- 2 nd step (initialize)
  - Write all zero to AXCSYSERR
  - Write all zero to AXCERRCNT
  - Write all zero to AXCERRADR

3.3.4 XC Cache latency

XC Cache latency is different in the hit case and miss case.

When a cache miss occure, XC cache fills the data from XC slaves to own cache. Therefore, the latency in the miss case depends on the latency to XC bus and slaves.

Cache latency

- Cache hit : 8 CPU clocks
- Cache miss : 25 CPU clocks (This is general value including XC bus latency.)

3.3.5 XC Cache control registers (D1L2(H), D1M1(H), D1M2(H), D1M1A, D1M1-V2)

CAUTION

Write access to the XC Cache registers is only available in supervisor mode.

In user mode the registers can only be read.

Table 3.25 List of XC Cache control registers

Register name	Symbol	Address
Cache configuration register		
Configuration register	AXCCFG	FFFE EE00$_H$
Cache error handling registers		
System error register	AXCSYSERR	FFFE EE0C$_H$
Error control register	AXCERRCNT	FFFE EE10$_H$
Error address register	AXCERRADR	FFFE EE14$_H$
Direct handling of cache tag and data content registers		
Cache synchronize register	AXCREQSYNC	FFFE EE18$_H$
Buffer flush register	AXCBUFFLUSH	FFFE EE1C$_H$
Cache command register	AXCCACHECMD	FFFE EE20$_H$
TAGLO register	AXCTAGLO	FFFE EE24$_H$
LRU register	AXCLRU	FFFE EE28$_H$
DATALO register	AXCDATALO	FFFE EE2C$_H$
DATAHI register	AXCDATAHI	FFFE EE30$_H$
TAGECC register	AXCTAGECC	FFFE EE34$_H$
DATAECC register	AXCDATAECC	FFFE EE38$_H$
Direct window handling registers		
Cache base 0 register	AXCCABASE0	FFFE EE40$_H$
Cache mask 0 register	AXCCAMASK0	FFFE EE44$_H$
Cache base 1 register	AXCCABASE1	FFFE EE48$_H$
Cache mask 1 register	AXCCAMASK1	FFFE EE4C$_H$
Buffer base 0 register	AXCBFBASE0	FFFE EE60$_H$
Buffer mask 0 register	AXCBFMASK0	FFFE EE64$_H$
Buffer base 1 register	AXCBFBASE1	FFFE EE68$_H$
Buffer mask 1 register	AXCBFMASK1	FFFE EE6C$_H$

NOTE

XC cache registers are reserved on D1L1.

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> is defined as “AXC” for the registers in the table above.

<Symbol> is defined in the above table

3.3.5.1 AXCCFG — Configuration register

Access: This register can be read/written in 32-bit units.

Address: FFFE EE00$_H$

Initial value: 0002 030F$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	DW	AUT
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 3.26 AXCCFG register contents

Bit Position	Bit Name	Function
31 to 18	Reserved	When written, write the initial value.
17	DW	Direct area WAW (write after write) Wait 0: no wait 1: wait
16	AUT	SEC (ECC single bit error correction) auto re-write enable 0: disable 1: enable
15 to 10	Reserved	When written, write the initial value.
9	BF1	Buffer area 1 enable 0: disable 1: enable
8	BF0	Buffer area 0 enable 0: disable 1: enable
7 to 2	Reserved	When written, write the initial value.
3	CA1	Cache area 1 enable 0: disable 1: enable
2	CA0	Cache area 0 enable 0: disable 1: enable
1 to 0	Reserved	When written, write the initial value.

3.3.5.2 AXCSYSERR — System error register

Access: This register can be read/written in 32-bit units.

Address: FFFE EE0C$_H$

Initial value: After power-up reset PURES: 0000 0000 0000 0000 0XXX XXXX 0000 000X$_B$
Any other reset does not change the value.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W

Table 3.27 AXCSYSERR register contents

Bit Position	Bit Name	Function
31 to 15	Reserved	When written, write the initial value.
14 to 8	ETYPE[14:8]	Error type (write mask by SE = 1) ETYPE14: cross-connect error response ETYPE13: direct control error ETYPE12: cache multi hit error ETYPE11: read buffer control error ETYPE10: read buffer ID error ETYPE9: write buffer ID error ETYPE8: write buffer post error
7 to 1	Reserved	When written, write the initial value.
0	SE	System error 0: no error 1: error

3.3.5.3 AXCERRCNT — Error control register

Access: This register can be read/written in 32-bit units.

Address: FFFE EE10$_H$

Initial value: After power-up reset PURES: 0000 0000 0000 0000 0000 XXXX 000X XXXX$_B$
Any other reset does not change the value.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	DV	TV	WAY[1:0]		0	0	0	DD	DS	TD	TS	ERR

Table 3.28 AXCERRCNT register contents

Bit Position	Bit Name	Function
31 to 12	Reserved	When written, write the initial value.
11	DV	DRAM SEC log overflow. Overwrite masked by AXCERRCNT.ERR=1
10	TV	TRAM SEC log overflow. Overwrite masked by AXCERRCNT.ERR=1
9 to 8	WAY[1:0]	Error Way. Overwrite masked by AXCERRCNT.ERR=1
7 to 5	Reserved	When written, write the initial value.
4	DD	DRAM Uncorrectable Error. Overwrite masked by AXCERRCNT.ERR=1
3	DS	DRAM Correctable Error. Overwrite masked by AXCERRCNT.ERR=1
2	TD	TRAM Uncorrectable Error. Overwrite masked by AXCERRCNT.ERR=1
1	TS	TRAM Correctable Error. Overwrite masked by AXCERRCNT.ERR=1
0	ERR	Error Status 0: no error detect 1: error detect

An error reported in AXCERRCNT will assert INTECCACC connected to the Error Control Module (ECM), see Section 48, Error Control Module (ECM).

3.3.5.4 AXCERRADR — Error address register

Access: This register can be read/written in 32-bit units.

Address: FFFE EE14$_H$

Initial value: After power-up reset PURES: XXXX XXXX$_H$.
Any other reset does not change the value.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 3.29 AXCERRADR register contents

Bit Position	Bit Name	Function
31 to 0	ADR[31:0]	XC1 slave device error address. Overwrite masked by AXCERRCNT.ERR=1 **Note:** The AXCERRADR.ADR[31:0] register stores the address that the CPU side was accessing to through the XC Cache when an access error occur. Means the address stored is the address of the slave device in the XC1 Cross-connect area (SFMA, DDR2, SDRAM, VRAM0/1).

3.3.5.5 AXCREQSYNC — Cache synchronize register

Access: This register can be read in 32-bit units.

Address: FFFE EE18$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 3.30 AXCREQSYNC register contents

Bit Position	Bit Name	Function
31 to 0	–	Read access to this register will synchronize/write back of buffer of the XBUS cache bus interface.*1

Note 1. The cache RAM content is not written back - please use a suitable cache command for this purpose.

3.3.5.6 AXCBUFFLUSH — Buffer flush register

Access: This register can be read in 32-bit units.

Address: FFFE EE1C$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 3.31 AXCBUFFLUSH register contents

Bit Position	Bit Name	Function
31 to 0	–	Buffered domain all flush. Read buffer entries are all cleared. Write buffer entries are all written to XC cross-connect and invalidated.

Note 1. The cache RAM content is not written back - please use a suitable cache command for this purpose.

3.3.5.7 AXCCACHECMD — Cache command register

Access: This register can be read/written in 32-bit units.

Address: FFFE EE20$_H$

Initial value: 0000 0000$_H$

(1) Index type (IDX_*, CLEAR) format

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	BLK[1:0]		WAY[1:0]	
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	IDX[7:0]								TYP[3:0]				VLD
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 3.32 AXCCACHECMD register contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When written, write the initial value.
19 to 18	BLK[1:0]	DRAM block. Valid only IDX_ST_DATA. 00=DW0, 01=DW1, 10=DW2, 11=DW3.
17 to 16	WAY[1:0]	Cache way. 00=Way0, 01=Way1, 10=Way2, 11=Way3.
15 to 13	Reserved	When written, write the initial value.
12 to 5	IDX[7:0]	Cache logical index. Hardware automatically compensates corkscrew allocation.
4 to 1	TYP[3:0]	Command type.
0	VLD	Cache command valid. Automatically cleared to 0 when command done. In case of writing with VLD=0, operates as APB write. So cache command doesn't activate.

(2) Hit Type (HIT_WB_INV, FILL, CREATE_DIRTY) format

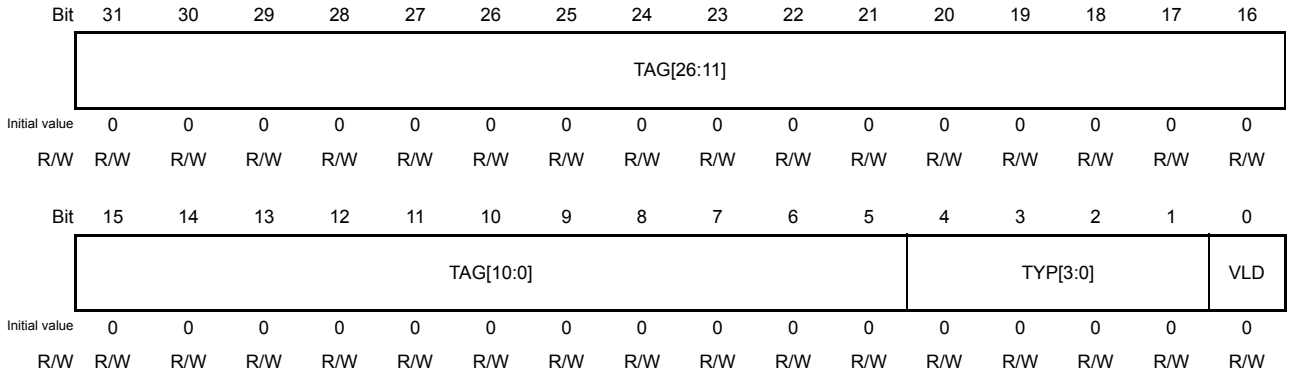

Table 3.33 AXCCACHECMD register contents

Bit Position	Bit Name	Function
31 to 5	TAG[26:0]	Physical cache tag. It is limited in cached domain. Access to other domain arises slave error.
4 to 1	TYP[3:0]	Command type.
0	VLD	Cache command valid. Automatically cleared to 0 when command done. In case of writing with VLD=0, operates as APB write. So cache command doesn't activate.

Table 3.34 Code assignment and permission of execution (1/2)

TYP[3:0]	Command	ECC detect	Note
0000_B	IDX_LD_TAG	ON(@TE=1) OFF(@TE=0)	Read from TRAM/Status-FF/LRU-FF of specified index/way. Write to AXCTAGLO, AXCLRU registers. Case of TE=0: write tag under ECC=Off. AXCTAGECC holds previous value. Case of TE=1 & TC=0: write tag/checkbits before correction. Case of TE=1 & TC=1: write tag/checkbits after correction.
0001_B	IDX_ST_TAG	No read	Read AXCTAGLO, AXCLRU registers. Case of AXCTAGECC.TE=0: Tag check bits are generated automatically. Case of AXCTAGECC.TE=1: AXCTAGECC.TAGECC[6:0] is used. Write to TRAM/Status-FF/LRU-FF of specified index/way.
0010_B	IDX_LD_DATA	ON(@TE=1) OFF(@TE=0)	Read from DRAM of specified index/double word. Write to AXCDATALO/AXCDATAHI/AXCECC registers. Case of DE=0: write data under ECC=Off. AXCDATAECC holds previous value. Case of DE=1 & DC=0 : write data/checkbits before correction. Case of DE=1 & DC=1 : write data/checkbits after correction. Hardware automatically compensates corkscrew allocation.
0011_B	IDX_ST_DATA	No read	Read from AXCDATALO/AXCDATAHI/AXCECC registers. Case of AXCDATAECC.DE=0 : Data check bits are generated automatically. Case of AXCDATAECC.DE=1 : AXCDATAECC.DATAECC{0/1} are used. Write to DRAM of specified index/doubleword. Hardware automatically compensates corkscrew allocation.
0100_B	IDX_WB_INV	ON	Check status of specified index/way. Case of Valid=1 & Dirty=1 : Writeback & Invalidate specified entry.
0101_B	FILL	ON	Fill data to cache way specified by LRU.

Table 3.34 Code assignment and permission of execution (2/2)

TYP[3:0]	Command	ECC detect	Note
0110_B	HIT_WB_INV	ON	Check status of specified address. Case of Hit & Dirty=1 : Writeback & Invalidate specified entry. Case of Hit & Dirty=0 : Invalidate specified entry Case of Miss : No operation.
0111_B	CREATE_DIRTY	OFF	Create dirty status. Case of Hit : Set D=1 Case of Miss : Write specified address to TRAM. Case of V=0 : Write 0 to DRAM Case of V=1 & D=1 : with writeback.
$1xxx_B$	CLEAR	No read	Clear target : All of {Valid, Dirty, LRU} bits.

3.3.5.8 AXCTAGLO — TAGLO register

Access: This register can be read/written in 32-bit units.

Address: FFFE $EE24_H$

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TAG[18:3]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TAG[2:0]			0	0	0	0	0	0	0	0	0	0	0	D	V
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 3.35 AXCTAGLO register contents

Bit Position	Bit Name	Function
31 to 13	TAG[18:0]	TAG
12 to 2	Reserved	When written, write the initial value.
1	D	Dirty
0	V	Valid

3.3.5.9 AXCLRU — LRU register

Access: This register can be read/written in 32-bit units.

Address: FFFE EE28$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	LRU
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 3.36 AXCLRU register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When written, write the initial value.
0	LRU	LRU

3.3.5.10 AXCDATALO — DATALO register

Access: This register can be read/written in 32-bit units.

Address: FFFE EE2C$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DATALO[31:16]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DATALO[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 3.37 AXCDATALO register contents

Bit Position	Bit Name	Function
31 to 0	DATALO[31:0]	Write data[31:0] for IDX_ST_DATA.

3.3.5.11 AXCDATAHI — DATAHI register

Access: This register can be read/written in 32-bit units.

Address: FFFE EE30$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DATAHI[63:48]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DATAHI[47:32]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 3.38 AXCDATAHI register contents

Bit Position	Bit Name	Function
31 to 0	DATAHI[63:32]	Write data[63:32] for IDX_ST_DATA.

3.3.5.12 AXCTAGECC — TAGECC register

Access: This register can be read/written in 32-bit units.

Address: FFFE EE34$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	TAGECC[6:0]							0	0	0	0	0	0	TC	TE
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Table 3.39 AXCTAGECC register contents

Bit Position	Bit Name	Function
31 to 15	Reserved	When written, write the initial value.
14 to 8	TAGECC[6:0]	Tag ECC for IDX_ST_TAG/IDX_LD_TAG. TE=1 : Use TAGECC field TE=0 : Use generated syndrome
7 to 2	Reserved	When written, write the initial value.
1	TC	Tag Read Capture 0: before correction 1: after correction
0	TE	Error Syndrome Enable.

3.3.5.13 AXCDATAECC — DATAECC register

Access: This register can be read/written in 32-bit units.

Address: FFFE EE38$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	DATAECC1[6:0]						
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	DATAECC0[6:0]							0	0	0	0	0	0	DC	DE
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Note 1. The initial value “0” of bit 16 must be changed to “1” and must not be changed afterwards.

Table 3.40 AXCDATAECC register contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When written, write the initial value.
22 to 16	DATAECC1[6:0]	Higher word Data ECC for IDX_ST_DATA/IDX_LD_DATA. DE=1 : Use DATAECC field, DE=0 : Use generated syndrome
15	Reserved	When written, write the initial value.
14 to 8	DATAECC0[6:0]	Lower word Data ECC for IDX_ST_DATA/IDX_LD_DATA. DE=1 : Use DATAECC field, DE=0 : Use generated syndrome
1	DC	Data Read Capture 0: before correction 1: after correction.
0	DE	Error Syndrome Enable

3.3.5.14 AXCCABASEn — Cache base n register (n = 0, 1)

Access: This register can be read/written in 32-bit units.

Address: AXCCABASE0: FFFE EE40$_H$
AXCCABASE1: FFFE EE48$_H$

Initial value: AXCCABASE0: E400 0000$_H$
AXCCABASE1: 2200 0000$_H$

AXCCABASE0:

XC cache tag RAM 1st Error Status Register 0	AXCT1STERSTR_PE1_OS	FFC6 7410$_H$
XC cache tag RAM (Bank 0) 1st Error Address Register 0	AXCT1STEADR0_PE1_OS	FFC6 7450$_H$
XC cache tag RAM (Bank 1) 1st Error Address Register 1	AXCT1STEADR1_PE1_OS	FFC6 7454$_H$

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> is defined as “ECCAXC” for the registers in the table above.

<Symbol> is defined in the above table

3.3.6.1 AXCDECCCTL_PE1_OS – XC cache data/tag RAM ECC control register

AXCDECCCTL enables or disables ECC error detection and correction and 1-bit error correction for cache data RAM and tag RAM. Set PROT[1:0] bits to 01B when writing to AXCDECCCTL.

AXCDECCCTL is initialized by an internal reset or an external reset.

Access: This register can be read/written in 16-bit and 32-bit units.

Address: FFC6 6400$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	PROT[1:0]		–	–	–	–	–	–	–	–	–	–	–	–	–	ECCDIS
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 3.47 AXCDECCCTL_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, these bits are always read as 0. When writing, always write 0.
15, 14	PROT[1:0]	Enables or disables modification of the ECCDIS bits. The value written is not retained. These bits are always read as 0. Set PROT[1:0] = 01$_B$ when writing to AXCDECCCTL.
13 to 1	Reserved	When read, these bits are always read as 0. When writing, always write 0.
0	ECCDIS	ECC disable bit Setting ECC error detection to enable/disable. 0: ECC error detection is enable 1: ECC error detection is disable

3.3.6.2 AXCDERRINT_PE1_OS – XC cache data RAM error information control register

AXCDERRINT enables or disables generation of the error notification signal to the ECM upon detection of an ECC 2-bit error or an ECC 1-bit error in cache data RAM.

AXCDERRINT is initialized by an internal reset or an external reset.

Access: This register can be read/written in 8-bit, 16-bit and 32-bit units.

Address: FFC6 6404_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 3.48 AXCDERRINT_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, these bits are always read as 0. When writing, always write 0.
1	DEDIE	ECC 2-bit error Notification Enable Enables or disables generation of the error notification signal upon detection of a 2-bit error when ECC error detection and correction are enabled. 0: Disables notification of the ECC 2-bit error. 1: Enables notification of the ECC 2-bit error.
0	SEDIE	ECC 1-bit error Notification Enable Enables or disables generation of the error notification signal upon detection of a 1-bit error when ECC error detection and correction are enabled. 0: Disables notification of the ECC 1-bit error. 1: Enables notification of the ECC 1-bit error.

3.3.6.3 AXCDSTCLR_PE1_OS – XC cache data RAM error status clear register

AXCDSTCLR clears the error flags in the error status register (AXCD1STERSTRm, m = 0 to 3), the overflow flag in the error overflow status register (AXCDOVFSTR), and the error address register (AXCD1STEADRn, n = 0 to 15). AXCDSTCLR is a write-only register and is always read as 0.

Access: This register can be read/written in 8-bit, 16-bit and 32-bit units.

Address: FFC6 6408$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 3.49 AXCDSTCLR_PE1_OS register contents (1/2)

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, these bits are always read as 0. When writing, always write 0.
15	SSTCLR15	Error Overflow Flag Clear (for bank 15) Writing 1 to this bit clears the DEDF15 and SEDF15 flags in AXCD1STERSTR3 and ERROVF15 flag in AXCDOVFSTR and AXCD1STEADR15.
14	SSTCLR14	Error Overflow Flag Clear (for bank 14) Writing 1 to this bit clears the DEDF14 and SEDF14 flags in AXCD1STERSTR3 and ERROVF14 flag in AXCDOVFSTR and AXCD1STEADR14.
13	SSTCLR13	Error Overflow Flag Clear (for bank 13) Writing 1 to this bit clears the DEDF13 and SEDF13 flags in AXCD1STERSTR3 and ERROVF13 flag in AXCDOVFSTR and AXCD1STEADR13.
12	SSTCLR12	Error Overflow Flag Clear (for bank 12) Writing 1 to this bit clears the DEDF12 and SEDF12 flags in AXCD1STERSTR3 and ERROVF12 flag in AXCDOVFSTR and AXCD1STEADR12.
11	SSTCLR11	Error Overflow Flag Clear (for bank 11) Writing 1 to this bit clears the DEDF11 and SEDF11 flags in AXCD1STERSTR2 and ERROVF11 flag in AXCDOVFSTR and AXCD1STEADR11.
10	SSTCLR10	Error Overflow Flag Clear (for bank 10) Writing 1 to this bit clears the DEDF10 and SEDF10 flags in AXCD1STERSTR2 and ERROVF10 flag in AXCDOVFSTR and AXCD1STEADR10.
9	SSTCLR9	Error Overflow Flag Clear (for bank 9) Writing 1 to this bit clears the DEDF9 and SEDF9 flags in AXCD1STERSTR2 and ERROVF9 flag in AXCDOVFSTR and AXCD1STEADR9.
8	SSTCLR8	Error Overflow Flag Clear (for bank 8) Writing 1 to this bit clears the DEDF8 and SEDF8 flags in AXCD1STERSTR2 and ERROVF8 flag in AXCDOVFSTR and AXCD1STEADR8.
7	SSTCLR7	Error Overflow Flag Clear (for bank 7) Writing 1 to this bit clears the DEDF7 and SEDF7 flags in AXCD1STERSTR1 and ERROVF7 flag in AXCDOVFSTR and AXCD1STEADR7.
6	SSTCLR6	Error Overflow Flag Clear (for bank 6) Writing 1 to this bit clears the DEDF6 and SEDF6 flags in AXCD1STERSTR1 and ERROVF6 flag in AXCDOVFSTR and AXCD1STEADR6.

Table 3.49 AXCDSTCLR_PE1_OS register contents (2/2)

Bit Position	Bit Name	Function
5	SSTCLR5	Error Overflow Flag Clear (for bank 5) Writing 1 to this bit clears the DEDF5 and SEDF5 flags in AXCD1STERSTR1 and ERROVF5 flag in AXCDOVFSTR and AXCD1STEADR5.
4	SSTCLR4	Error Overflow Flag Clear (for bank 4) Writing 1 to this bit clears the DEDF4 and SEDF4 flags in AXCD1STERSTR1 and ERROVF4 flag in AXCDOVFSTR and AXCD1STEADR4.
3	SSTCLR3	Error Overflow Flag Clear (for bank 3) Writing 1 to this bit clears the DEDF3 and SEDF3 flags in AXCD1STERSTR0 and ERROVF3 flag in AXCDOVFSTR and AXCD1STEADR3.
2	SSTCLR2	Error Overflow Flag Clear (for bank 2) Writing 1 to this bit clears the DEDF2 and SEDF2 flags in AXCD1STERSTR0 and ERROVF2 flag in AXCDOVFSTR and AXCD1STEADR2.
1	SSTCLR1	Error Overflow Flag Clear (for bank 1) Writing 1 to this bit clears the DEDF1 and SEDF1 flags in AXCD1STERSTR0 and ERROVF1 flag in AXCDOVFSTR and AXCD1STEADR1.
0	SSTCLR0	Error Overflow Flag Clear (for bank 0) Writing 1 to this bit clears the DEDF0 and SEDF0 flags in AXCD1STERSTR0 and ERROVF0 flag in AXCDOVFSTR and AXCD1STEADR0.

3.3.6.4 AXCDOVFSTR_PE1_OS – XC cache data RAM error count overflow status

AXCDOVFSTR monitors occurrence of error overflow in cache data RAM. If the second error occurs after the first error (= while any of the error flags in the error status register is set), the flag in this register is set. However, if the second error is identical to the first error (both the source and address are same), this flag is not set. ERROVFn is cleared by an internal reset, an external reset, or setting the STCLRn bit to 1 in AXCDSTCLR.

Access: This register can be read in 8-bit, 16-bit and 32-bit units.

Address: FFC6 640C$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

Table 3.50 AXCDOVFSTR_PE1_OS register contents (1/2)

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, these bits are always read as 0. When writing, always write 0.
15	ERROVF15	Error Overflow Flag (for bank 15) ERROVF15 is set if the second error occurs while any of the error flags (DEDF15 and SEDF15) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.
14	ERROVF14	Error Overflow Flag (for bank 14) ERROVF14 is set if the second error occurs while any of the error flags (DEDF14 and SEDF14) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.
13	ERROVF13	Error Overflow Flag (for bank 13) ERROVF13 is set if the second error occurs while any of the error flags (DEDF13 and SEDF13) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.
12	ERROVF12	Error Overflow Flag (for bank 12) ERROVF12 is set if the second error occurs while any of the error flags (DEDF12 and SEDF12) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.
11	ERROVF11	Error Overflow Flag (for bank 11) ERROVF11 is set if the second error occurs while any of the error flags (DEDF11 and SEDF11) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.
10	ERROVF10	Error Overflow Flag (for bank 10) ERROVF10 is set if the second error occurs while any of the error flags (DEDF10 and SEDF10) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.

Table 3.50 AXCDOVFSTR_PE1_OS register contents (2/2)

Bit Position	Bit Name	Function
9	ERROVF9	Error Overflow Flag (for bank 9) ERROVF9 is set if the second error occurs while any of the error flags (DEDF9 and SEDF9) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.
8	ERROVF8	Error Overflow Flag (for bank 8) ERROVF8 is set if the second error occurs while any of the error flags (DEDF8 and SEDF8) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.
7	ERROVF7	Error Overflow Flag (for bank 7) ERROVF7 is set if the second error occurs while any of the error flags (DEDF7 and SEDF7) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.
6	ERROVF6	Error Overflow Flag (for bank 6) ERROVF6 is set if the second error occurs while any of the error flags (DEDF6 and SEDF6) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.
5	ERROVF5	Error Overflow Flag (for bank 5) ERROVF5 is set if the second error occurs while any of the error flags (DEDF5 and SEDF5) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.
4	ERROVF4	Error Overflow Flag (for bank 4) ERROVF4 is set if the second error occurs while any of the error flags (DEDF4 and SEDF4) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.
3	ERROVF3	Error Overflow Flag (for bank 3) ERROVF3 is set if the second error occurs while any of the error flags (DEDF3 and SEDF3) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.
2	ERROVF2	Error Overflow Flag (for bank 2) ERROVF2 is set if the second error occurs while any of the error flags (DEDF2 and SEDF2) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.
1	ERROVF1	Error Overflow Flag (for bank 1) ERROVF1 is set if the second error occurs while any of the error flags (DEDF1 and SEDF1) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.
0	ERROVF0	Error Overflow Flag (for bank 0) ERROVF0 is set if the second error occurs while any of the error flags (DEDF0 and SEDF0) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.

3.3.6.5 AXCD1STERSTRn_PE1_OS – XC cache data RAM 1st error status register (n = 0 - 3)

AXCD1STERSTRn monitors occurrence of the first error in cache data RAM. The error status is set if an error occurs while all the error flags for the relevant banks are 0. The error flag is overwritten if an ECC 2-bit error occurs while the ECC 1-bit error monitor flag is set.

SEDFn and DEDFn is cleared by an internal reset, an external reset, or setting the STCLRn bit to 1 in AXCDSTCLR.

Access: This register can be read in 8-bit, 16-bit and 32-bit units.

Address: FFC6 6410$_H$ + 4 × n

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 3.51 AXCD1STERSTRn_PE1_OS register contents (1/2)

Bit Position	Bit Name	Function
31 to 26	Reserved	When read, these bits are always read as 0. When writing, always write 0.
25	DEDF4n+3	ECC 2-bit error Monitor Flag (for bank 4n+3) 0: Cleared to 0 by setting the STCLR4n+3 bit to 1 in AXCDSTCLR. 1: Indicates that an ECC 2-bit error has occurred while the error flag DEDF4n+3 is 0.
24	SEDF4n+3	ECC 1-bit error Monitor Flag (for bank 4n+3) 0: Cleared to 0 by setting the STCLR4n+3 bit to 1 in AXCDSTCLR. 1: Indicates that an ECC 1-bit error has occurred while the error flags DEDF4n+3 and SEDF4n+3 are 0.
23 to 18	Reserved	When read, these bits are always read as 0. When writing, always write 0.
17	DEDF4n+2	ECC 2-bit error Monitor Flag (for bank 4n+2) 0: Cleared to 0 by setting the STCLR4n+2 bit to 1 in AXCDSTCLR. 1: Indicates that an ECC 2-bit error has occurred while the error flag DEDF4n+2 is 0.
16	SEDF4n+2	ECC 1-bit error Monitor Flag (for bank 4n+2) 0: Cleared to 0 by setting the STCLR4n+2 bit to 1 in AXCDSTCLR. 1: Indicates that an ECC 1-bit error has occurred while the error flags DEDF4n+2 and SEDF4n+2 are 0.
16 to 10	Reserved	When read, these bits are always read as 0. When writing, always write 0.
9	DEDF4n+1	ECC 2-bit error Monitor Flag (for bank 4n+1) 0: Cleared to 0 by setting the STCLR4n+1 bit to 1 in AXCDSTCLR. 1: Indicates that an ECC 2-bit error has occurred while the error flag DEDF4n+1 is 0.
8	SEDF4n+1	ECC 1-bit error Monitor Flag (for bank 4n+1) 0: Cleared to 0 by setting the STCLR4n+1 bit to 1 in AXCDSTCLR. 1: Indicates that an ECC 1-bit error has occurred while the error flags DEDF4n+1 and SEDF4n+1 are 0.
7 to 2	Reserved	When read, these bits are always read as 0. When writing, always write 0.

Table 3.51 AXCD1STERSTRn_PE1_OS register contents (2/2)

Bit Position	Bit Name	Function
1	DEDF4n	ECC 2-bit error Monitor Flag (for bank 4n) 0: Cleared to 0 by setting the STCLR4n bit to 1 in AXCDSTCLR. 1: Indicates that an ECC 2-bit error has occurred while the error flag DEDF4n is 0.
0	SEDF4n	ECC 1-bit error Monitor Flag (for bank 4n) 0: Cleared to 0 by setting the STCLR4n bit to 1 in AXCDSTCLR. 1: Indicates that an ECC 1-bit error has occurred while the error flags DEDF4n and SEDF4n are 0.

3.3.6.6 AXCD1STEADRn_PE1_OS – XC cache data RAM (bank n) 1st error address register (n = 0 - 15)

AXCD1STEADR holds the address at which an error has occurred in cache data RAM. The error address is set if an error occurs while all the error flags for the relevant banks are 0 in AXCD1STERSTRm (m = 0 to 3). The address is updated if an ECC 2-bit error occurs while the ECC 1-bit error flag is set as the first error. Once an ECC 2-bit error occurs, the address is not updated.

Since this register holds the internal address, add the base address of the associated memory to transform the internal address to the real address. AXCD1STEADRn is cleared by an internal reset, an external reset, or setting the STCLRn bit to 1 in AXCDSTCLR.

Access: This register can be read in 8-bit, 16-bit and 32-bit units.

Address: FFC6 6450_H + 4 × n

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 3.52 AXCD1STEADRn_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 0	EADRn[31:0]	1st Error Address (for bank n) Monitors the address of the first error. The error address is set if an error occurs while all the error flags for bank n are 0 in AXCD1STERSTRm. The address is updated if an ECC 2-bit error occurs while the ECC 1-bit error flag is set as the first error. Once an ECC 2-bit error occurs, the address is not updated.

3.3.6.7 AXCTERRINT_PE1_OS – XC cache tag RAM error information control register

AXCTERRINT enables or disables generation of the error notification signal to the ECM upon detection of an ECC 2-bit error or an ECC 1-bit error in cache tag RAM.

AXCTERRINT is initialized by an internal reset or an external reset.

Access: This register can be read/written in 8-bit, 16-bit and 32-bit units.

Address: FFC6 7404$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, these bits are always read as 0. When writing, always write 0.
1	DEDIE	ECC 2-bit error Notification Enable Enables or disables generation of the error notification signal upon detection of a 2-bit error when ECC error detection and correction are enabled. 0: Disables notification of the ECC 2-bit error. 1: Enables notification of the ECC 2-bit error.
0	SEDIE	ECC 1-bit error Notification Enable Enables or disables generation of the error notification signal upon detection of a 1-bit error when ECC error detection and correction are enabled. 0: Disables notification of the ECC 1-bit error. 1: Enables notification of the ECC 1-bit error.

3.3.6.8 AXCTSTCLR_PE1_OS – XC cache tag RAM error status clear register

AXCTSTCLR clears the error flags in the error status register (AXCT1STERSTR), the overflow flag in the error overflow status register (AXCTOVFSTR), and the error address register (AXCT1STEADRn, n = 0, 1). AXCTSTCLR is a write-only register and is always read as 0.

Access: This register can be read/written in 8-bit, 16-bit and 32-bit units.

Address: FFC6 7408$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 3.54 AXCTSTCLR_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, these bits are always read as 0. When writing, always write 0.
1	STCLR1	Error Overflow Flag Clear (for bank 1) Writing 1 to this bit clears the DEDF1 and SEDF1 flags in AXCT1STERSTR and ERROVF1 flag in AXCTOVFSTR and AXCT1STEADR1.
0	STCLR0	Error Overflow Flag Clear (for bank 0) Writing 1 to this bit clears the DEDF0 and SEDF0 flags in AXCT1STERSTR and ERROVF0 flag in AXCTOVFSTR and AXCT1STEADR0.

3.3.6.9 AXCTOVFSTR_PE1_OS – XC cache tag RAM error count overflow status register

AXCTOVFSTR monitors occurrence of error overflow in cache tag RAM. If the second error occurs after the first error (= while any of the error flags in the error status register is set), the flag in this register is set. However, if the second error is identical to the first error (both the source and address are same), this flag is not set. ERROVFn is cleared by an internal reset, an external reset, or setting the STCLRn bit to 1 in AXCTSTCLR.

Access: This register can be read in 8-bit, 16-bit and 32-bit units.

Address: FFC6 740C$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

Table 3.55 AXCTOVFSTR_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, these bits are always read as 0. When writing, always write 0.
1	ERROVF1	Error Overflow Flag (for bank 1) ERROVF1 is set if the second error occurs while any of the error flags (DEDF1 and SEDF1) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.
0	ERROVF0	Error Overflow Flag (for bank 0) ERROVF0 is set if the second error occurs while any of the error flags (DEDF0 and SEDF0) in the error status register is set,except when both of the error address and source of the second error are the same as those of the first error.

3.3.6.10 AXCT1STERSTR_PE1_OS – XC cache tag RAM 1st error status register

AXCT1STERSTR monitors occurrence of the first error in cache tag RAM.

The error flag is overwritten if an ECC 2-bit error occurs while the error flag is 0.

AXCT1STERSTR is cleared by an internal reset, an external reset, or setting the STCLRn bit to 1 in AXCTSTCLR.

Access: This register can be read in 8-bit, 16-bit and 32-bit units.

Address: FFC6 7410$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 3.56 AXCT1STERSTR_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, these bits are always read as 0. When writing, always write 0.
9	DEDF1	ECC 2-bit error Monitor Flag (for bank 1) 0: Cleared to 0 by setting the STCLR1 bit to 1 in AXCTSTCLR. 1: Indicates that an ECC 2-bit error has occurred while the error flag DEDF1 is 0.
8	SEDF1	ECC 1-bit error Monitor Flag (for bank 1) 0: Cleared to 0 by setting the STCLR1 bit to 1 in AXCTSTCLR. 1: Indicates that an ECC 1-bit error has occurred while the error flags DEDF1 and SEDF1 are 0.
7 to 2	Reserved	When read, these bits are always read as 0. When writing, always write 0.
1	DEDF0	ECC 2-bit error Monitor Flag (for bank 0) 0: Cleared to 0 by setting the STCLR0 bit to 1 in AXCTSTCLR. 1: Indicates that an ECC 2-bit error has occurred while the error flag DEDF0 is 0.
0	SEDF0	ECC 1-bit error Monitor Flag (for bank 0) 0: Cleared to 0 by setting the STCLR0 bit to 1 in AXCTSTCLR. 1: Indicates that an ECC 1-bit error has occurred while the error flags DEDF0 and SEDF0 are 0.

3.3.6.11 AXCT1STEADRn_PE1_OS – XC cache tag RAM 1st error address register (n = 0, 1)

AXCT1STEADRn holds the address at which an error has occurred in cache tag RAM. The error address is set if an error occurs while all the error flags for the relevant banks are 0 in AXCT1STERSTR. The address is updated if an ECC 1-bit error occurs while the ECC 1-bit error flag is set as the first error. Once an ECC 2-bit error occurs, the address is not updated. Since this register holds the internal address, add the base address of the associated memory to transform the internal address to the real address.

AXCT1STEADRn is cleared by an internal reset, an external reset, or setting the STCLRn bit to 1 in AXCTSTCLR.

Access: This register can be read in 8-bit, 16-bit and 32-bit units.

Address: FFC6 7450_H + 4 × n

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	EADRn[31:16]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EADRn[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 3.57 AXCD1STEADRn_PE1_OS register contents

Bit Position	Bit Name	Function
31 to 0	EADRn[31:0]	1st Error Address (for bank n) Monitors the address of the first error. The error address is set if an error occurs while all the error flags for bank n are 0 in AXCT1STESTR. The address is updated if an ECC 2-bit error occurs while the ECC 1-bit error flag is set as the first error. Once an ECC 2-bit error occurs, the address is not updated.

3.4 Usage Notes

3.4.1 Synchronization of Store Instruction Completion and Subsequent Instruction Generation

When a control register is updated by a store instruction, there is a time lag between CPU implementation of the store instruction and actual updating of the control register. Therefore, adequate synchronization processing is needed to ensure the control register reflects updated contents before generation of a subsequent instruction. How to perform synchronization processing is shown below.

Regarding the procedure of system register update by LDSR instruction and synchronizing subsequent instruction generation, see

APPENDIX A HAZARD RESOLUTION PROCEDURE FOR SYSTEM REGISTERS
in RH850G3M User's Manual: Software.

When updated results in the control registers are reflected in the implementation of a subsequent instruction:

Example1: an interrupt is enabled by implementation of an EI instruction after an interrupt request is cleared by access from the control register in the INTC2 and the peripheral circuits. Proceed as follows in this case.

(1) Store instruction to update a control register (ST.W, etc.)

(2) Dummy read of the above-mentioned control register (LD.W etc.)

(3) SYNCP

(4) Subsequent instruction (EI)

Example 2: Implement the same processing even when the access required after waiting to secure the updating of a given control register (register A) is to another control register (register B). This includes the following cases: the interlinked operation of different peripheral modules and when releasing the interrupt mask in INTC after making peripheral module settings.

However, this processing is unnecessary if control registers A and B are in the same PBUS group.

(1) Issue the instruction for storage to update control register A (ST.W, etc.)

(2) Dummy-read the above control register (LD.W, etc.)

(3) Issue SYNCP.

(4) Issue the instruction to access control register B (ST.W, LD.W, etc.)

The same processing is also required when access to control registers and memory within the scope of protection starts after waiting for the completion of settings for safety functions such as memory protection, ECC checking, and so on.

When the updated results in the control registers and memories are reflected in the instruction fetch of a subsequent instruction:

(Case a) After writing an instruction in a RAM, CPU fetch the written instruction from the same RAM. Proceed as follows.

(1) Store instruction to update a memory (ST.W, etc.)

(2) Dummy read of the above-mentioned memory (LD.W, etc.)

(3) SYNCP

(4) SYNCI

(5) Subsequent instruction (branch instruction, etc.)

(Case b) After completion of MPU function or ECC register updating, CPU fetch the instruction from the same RAM.
Proceed as follows.

(1) Store instruction to update a memory (ST.W, etc.)

(2) Dummy read of the above-mentioned memory (LD.W, etc.)

(3) SYNCP

(4) SYNCI

(5) Subsequent instruction (branch instruction, etc.)

When switching Code Flash area:

In this case, see (7) Update of FCUFAREA register in the RH850/D1x Flash Memory User's Manual: Hardware Interface

3.4.2 Accesses to Registers by Bit-Manipulation Instructions

Processing of a bit-manipulation instruction takes the form of atomic reading, modification, and writing of an eight-bit unit. Therefore, registers which enable reading and writing in 8 bits can be basically accessed by bit-manipulation instructions. However, take care in the cases of registers that contain multiple flag bits, since the read-modify-write cycle may also clear flags other than that which was the target for clearing.

NOTE

Bit-manipulation instructions cannot be used for VDCE, DISCOM, JCUA, SFMA, SDRA, VOWE.

3.4.3 Ensuring Coherency after Code Flash Programming

The CPU has an efficient instruction cache and data buffer for the code flash area.

Therefore, after using self-programming to program the code flash memory, clear the instruction cache and data buffer to ensure coherency. The instruction cache and data buffer can be cleared by using the ICCTRL register and the CDBCR register, respectively.

3.4.4 Overwriting Context when Acknowledging Multiple Exceptions

Exceptions may be acknowledged regardless of the states of the ID and NP bits of the PSW register. This depends on the type of exception. When multiple exceptions occur, the contents of the system registers which hold the context information are overwritten. Regarding the conditions for acknowledging exceptions from each source and the possibility of return and recovery, see the list of exception sources in the *RH850G3M User's Manual:Software*.

3.4.5 Usage Notes on Prefetching

CPU executes speculative instruction fetching from locations later than the current value of the program counter to retain maintain the throughput of instruction fetches. Reading from memory due to such prefetching may proceed even from locations to which instruction codes have not been assigned (note 1 in **Figure 3.2**). Please note the following. The CPU does not execute values read in such cases.

These notes apply to instruction fetching from memory in general.

- Occurrence of ECC errors due to values in memory being undefined
  This prefetching may lead to an ECC error in case of reading from the code flash memory after it has been erased or from the local RAM before initialization. When instruction codes are assigned to memory, initialize said area with values as desired (note 1 in **Figure 3.2**).
- Detection of illegal access by the IPG
  The IPG may detect such prefetching as illegal access. To prevent prefetching being detected as an illegal access, do not allow any region of overlap area with said areas (note 1 in **Figure 3.2**) and areas to which access is prohibited by the IPG. Reading from an area protected by the MPU does not cause a memory protection exception.
- Access to Access Prohibited Area
  Assign instruction codes to memory without allowing any overlap between said area (note 1 in **Figure 3.2**) and an access-prohibited area.

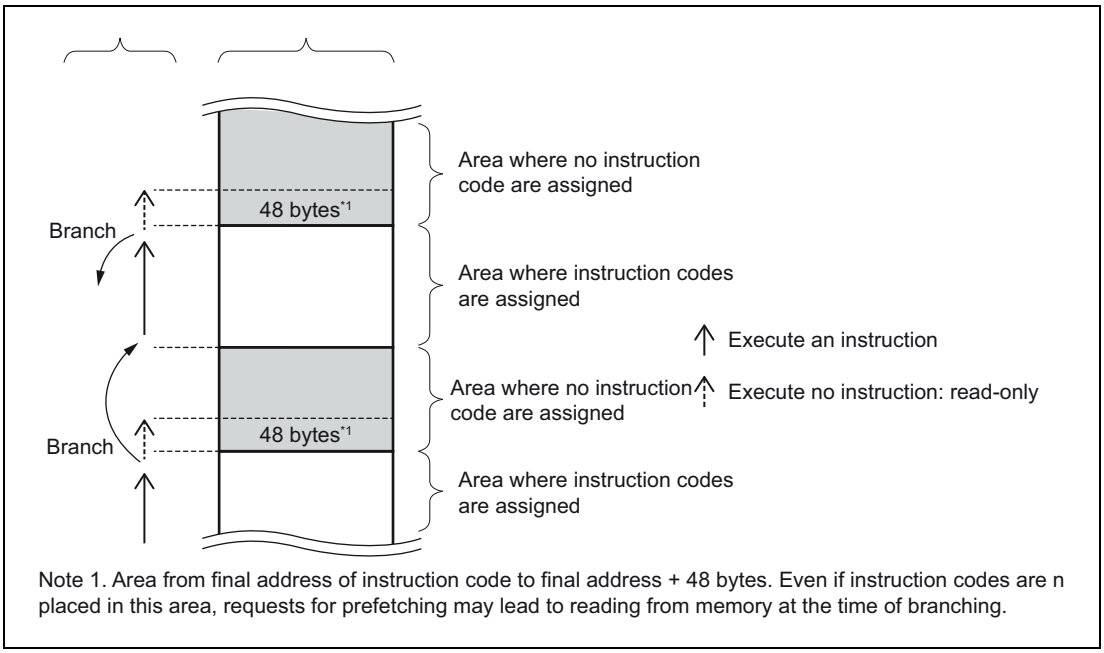

Figure 3.2 Area that Requires Attention Regarding Prefetching

3.4.6 Initialization of Register Set

For a register in the register set, which contains an undefined value after reset, write a value and then read it.

Section 4 Write-Protected Registers

Write-protected registers are protected from inadvertent write access due to erroneous program execution, etc.

Writing to a write-protected register requires a special register protection unlock sequence.

4.1 Register protection clusters

Protected registers are bundled in some register protection clusters.

The protection equipment treats all registers in the same cluster as a single protection unit.

If the protection unlock sequence for a register is initiated, no access to any other register of the same protection cluster is allowed. Otherwise the unlock sequence is disrupted and the register write fails. The diagram below shows a disruption of the unlock sequence by an access to the same cluster within an interrupt service routine.

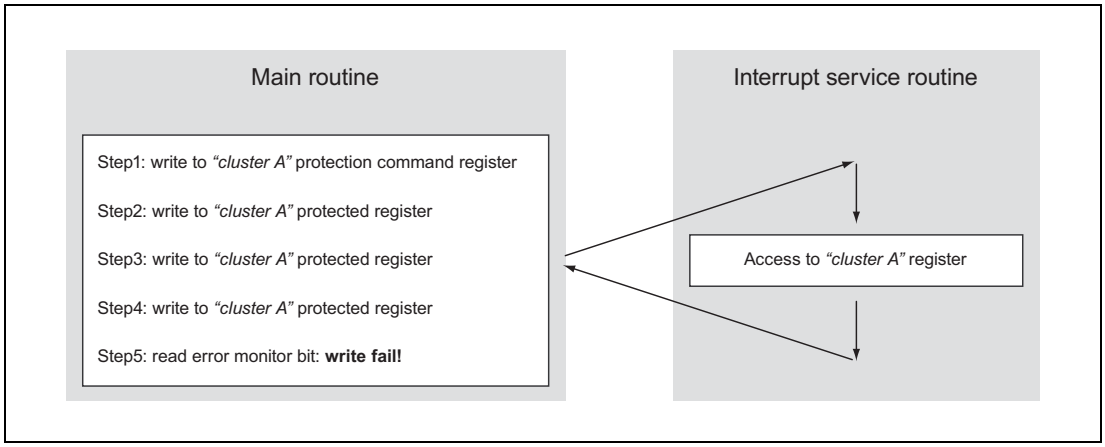

Figure 4.1 Interruption of Register Protection Unlock Sequence

Access to a register of another protection cluster during the unlock sequence does not disrupt the unlock sequence and the register write can be completed successfully.
The following diagram below shows such situation.

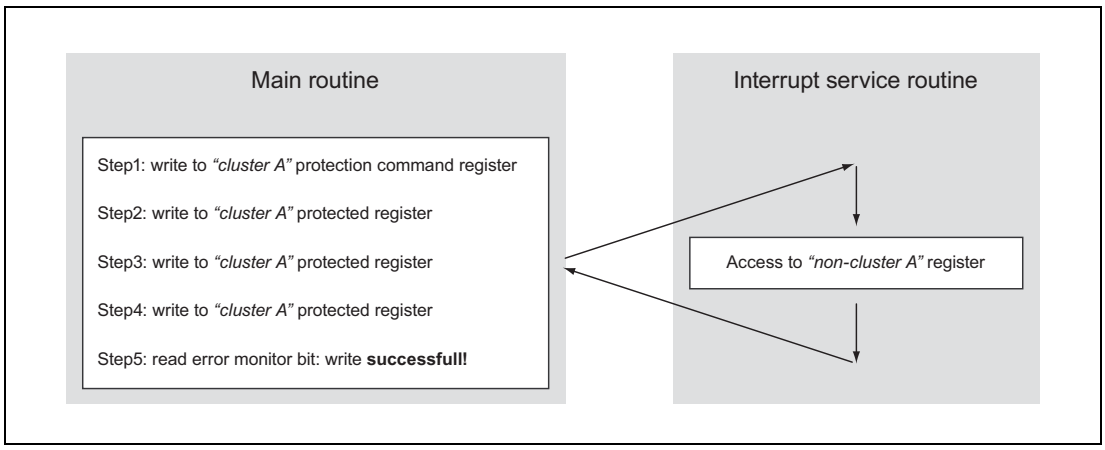

Figure 4.2 Example of Successful Protection Unlock Sequence

For more information on registers of RH850/D1L/D1M register protection clusters, see Section 4.2, RH850/D1L/D1M write-protected registers.

4.1.1 Register protection unlock sequence

Write access to a write protected register is enabled by using a special protection unlock sequence:

1. Write the fixed value 0000 $00A5_H$ to the protection command register
2. Write the desired value to the protected register.
3. Write the bit-wise inversion of the desired value to the protected register.
   (To the reserved bits, write the bit-wise inversion of the initial value.)
4. Write the desired value to the protected register.
5. Verify successful write of the desired value to the protected register by verifying that the error monitor bit in the protection status register is “0”.
   In case the write was not successful, indicated by the error monitor bit set to “1”, the entire sequence has to be restarted at step 1.

In case of any access to another register between step 1 to step 4 of the above sequence, the protection mechanism behaves as follows:

- If the second register belongs to the same cluster, the write to the protected register fails (the error monitor bit set to “1”). The entire sequence has to be restarted at step 1.
- If the second register does not belong to the same cluster, the protection unlock sequence is not disrupted and the write to the first register can be completed successfully.

For the port regisetr protection sequence, see Section 2.2.3.5, Port Register Protection.

4.1.2 Register protection and interrupt/emulation break

If an interrupt/emulation break occurs during the protection unlock sequence, the protection mechanism behaves as follows:

(1) Interrupt during the protection unlock sequence

If an interrupt is acknowledged during the above protection unlock sequence and the interrupt service routine does not access any register of the same register protection cluster, the protection unlock sequence is not disrupted and the write to the protected register can be successfully completed after returning from the interrupt service routine.

(2) Emulation break during the protection unlock sequence

If an emulation break occurs during the above protection unlock sequence, e.g. because of a breakpoint hit, the debugger does not access any register of the same register protection cluster, the protection unlock sequence is not disrupted and the write to the protected register can be successfully completed after returning from the break.

4.2 RH850/D1L/D1M write-protected registers

The following table lists the RH850/D1L/D1M write-protected registers.

Table 4.1 Write-Protection Target Registers (1/2)

Protection Target	Protected Register	Protection Register		Protection Cluster
		Command Register	Status Register	
Clock Controller	MOSCE	PROTCMD0	PROTS0	Control protection cluster 0
	SOSCE

On-Chip Debug control	IDMODI	PROTCMDIDMODI	PROTSIDMODI	
Port control*1	PINVn, PODCn, PDSCn of AWO ports	PPCMDn	PPROTSn	Port control protection clusters
	PINVn, PODCn, PDSCn of ISO ports	PPCMDn	PPROTSn	
	JPINVn, JPODCn, JPDSCn of JP0 ports	JPPCMDn	JPPROTSn	
Self-programming function	FLMDCNT	FLMDPCMD	FLMDPS	Self-programming protection clusters

Note 1. Each port group has its own protection command register and status register. For details, see **Section 4.2.1, Port protection clusters** on the next page.

4.2.1 Port protection clusters

The following port control registers have write protection:

- Port output level inversion register (PINVn, JPINV0)
- Port open drain control registers (PODCn, JPODC0)
- Port drive strength control registers (PDSCn)

For the port regisetr protection sequence, see Section 2.2.3.5, Port Register Protection.

4.2.2 Overview of RH850/D1L/D1M protection registers

Register write protection is controlled and operated by using the following registers.

Table 4.2 Overview of Protection Command Registers (1/2)

Module Name	Register Name	Symbol	Address
Control protection clusters			
SYS	Protection command register 0	PROTCMD0	FFF8 0000$_H$
SYS	Protection status register 0	PROTS0	FFF8 0004$_H$
Isolated-Area clock control protection clusters			
SYS	Protection command register 1	PROTCMD1	FFF8 8000$_H$
SYS	Protection status register 1	PROTS1	FFF8 8004$_H$
SYS	Protection command register	PROTCMDD1	FFF8 7000$_H$
SYS	Protection status register	PROTSD1	FFF8 7004$_H$
Clock Monitors control protection cluster			
	Protection command register 0	CLMA0PCMD	FFF8 C010$_H$
	Protection status register 0	CLMA0PS	FFF8 C014$_H$
	Protection command register 1	CLMA1PCMD	FFF8 F010$_H$
	Protection status register 1	CLMA1PS	FFF8 F014$_H$
	Protection command register 2	CLMA2PCMD	FFF8 F090$_H$
	Protection status register 2	CLMA2PS	FFF8 F094$_H$
	Protection command register 3	CLMA3PCMD	FFF8 F110$_H$

	Protection command register	FLMDPCMD	FFA0 0004$_H$
	Protection status register	FLMDPS	FFA0 0008$_H$

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> and <Symbol> are defined in the above table.

4.2.3 Control protection cluster registers

4.2.3.1 PROTCMD0 — Protection command register

This register is used to initiate the write protection unlock sequence for write-protected registers.

Access: This register can be written in 32-bit units.

Address: See Table 4.2, Overview of Protection Command Registers.

Initial value: Reading this register returns 0000 0000_H.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit Position	Bit Name	Function
7 to 0	PCMD0[7:0]	Protection commands to enable writing to control protection cluster registers

4.2.3.2 PROTS0 — Protection status register

This register indicates the status of the protection unlock sequence performed by PROTCMD0.

Access: This register is a read-only register that can be read in 32-bit units.
Write operation is ignored.

Address: See Table 4.2, Overview of Protection Command Registers.

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	PROTERR	Protection write sequence error monitor 0: No protection error 1: Protection error occurred

4.2.4 Isolated-Area clock control protection clusters

4.2.4.1 PROTCMD1 — Protection command register

This register is used to initiate the write protection unlock sequence for write-protected registers.

Access: This register can be written in 32-bit units.

Address: See Table 4.2, Overview of Protection Command Registers.

Initial value: Reading this register returns 0000 0000_H.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 4.5 PROTCMD1 Register Contents

Bit Position	Bit Name	Function
7 to 0	PCMD1[7:0]	Protection commands to enable writing to control protection cluster registers

4.2.4.2 PROTS1 — Protection status register

This register indicates the status of the protection unlock sequence performed by PROTCMD1.

Access: This register is a read-only register that can be read in 32-bit units.
Write operation is ignored.

Address: See Table 4.2, Overview of Protection Command Registers.

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 4.6 PROTCMD1 Register Contents

Bit Position	Bit Name	Function
0	PROTERR	Protection write sequence error monitor 0: No protection error 1: Protection error occurred

4.2.4.3 PROTCMDD1 — Protection command register

This register is used to initiate the write protection unlock sequence for write-protected registers.

Access: This register can be written in 32-bit units.

Address: See Table 4.2, Overview of Protection Command Registers.

Initial value: Reading this register returns 0000 0000_H.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

4.2.4.4 PROTSD1 — Protection status register

This register indicates the status of the protection unlock sequence performed by PROTCMDn.

Access: This register is a read-only register that can be read in 32-bit units.
Write operation is ignored.

Address: See Table 4.2, Overview of Protection Command Registers.

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	PROTD ERR	Protection write sequence error monitor 0: No protection error 1: Protection error occurred

4.2.5 Clock Monitors protection cluster registers

4.2.5.1 CLMAnPCMD — CLMAn protection command register

This register is a protection command register for the CLMAnCTL0 register.

Index n

An index “n” denotes the number of protection command registers. For details, see Table 4.1, Write-Protection Target Registers.

Access: This register can be written in 8-bit units.
Address: See Table 4.2, Overview of Protection Command Registers.
Initial value: Reading this register returns an undefined value.

Bit	7	6	5	4	3	2	1	0
	CLMAnREG[7:0]							
Initial value								
R/W	W	W	W	W	W	W	W	W

Table 4.9 CLMAnPCMD Register Contents

Bit Position	Bit Name	Function
7 to 0	CLMAn REG[7:0]	Protection command that enables writing to the CLMAnCTL0 register

4.2.5.2 CLMAnPS — CLMAn protection status register

This register is used to verify whether the write-protected register (CLMAnCTL0) has been successfully written or not.

Index n

An index “n” denotes the number of protection command registers. For details, see Table 4.1, Write-Protection Target Registers.

Access: This register can be read in 8-bit units.
Address: See Table 4.2, Overview of Protection Command Registers.
Initial value: 00_H

Bit	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	CLMAnPRERR
Initial value	0	0	0	0	0	0	0	0

Bit Position	Bit Name	Function
0	CLMAn PRERR	Protection write sequence error monitor 0: No protection error 1: Protection error occurred

4.2.5.3 PROTCMDCLMA — Clock monitor test protection command register

This register is a protection command register for the CLMATEST register.

Access: This register can be written in 32-bit units.

Address: See Table 4.2, Overview of Protection Command Registers.

Initial value: Reading this register returns an undefined value.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	CLMATPRERR	Protection write sequence error monitor 0: No protection error 1: Protection error occurred

4.2.5.5 PROTCMDCLMA2 — Clock monitor test protection command register 2

This register is a protection command register for the CLMATEST2 register.

Access: This register can be written in 32-bit units.

Address: See Table 4.2, Overview of Protection Command Registers.

Initial value: Reading this register returns an undefined value.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

4.2.5.7 PROTCMDCLMA3 — Clock monitor test protection command register3

This register is a protection command register for the CLMATEST3 register.

Access: This register can be written in 32-bit units.

Address: See Table 4.2, Overview of Protection Command Registers.

Initial value: Reading this register returns an undefined value.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
0	CLMATPRERR3	Protection write sequence error monitor 0: No protection error 1: Protection error occurred

4.2.6 System control protection register

4.2.6.1 PROTCMDMRST — Reset control protection command register

This register is a protection command register for the MRSTC register.

Access: This register can be written in 32-bit units.

Address: See Table 4.2, Overview of Protection Command Registers.

Initial value: Reading this register returns an undefined value.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

4.2.6.2 PROTSMRST — Reset protection status register

This register is used to verify whether the write-protected register (MRSTC) has been successfully written or not.

Access: This register can be read in 32-bit units.

Address: See Table 4.2, Overview of Protection Command Registers.

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

4.2.6.3 PROTCMDPWRGD — PWR_GD protection command register

This register is a protection command register for the PWR_GD and APB_CLK_RATIO register.

Access: This register can be written in 32-bit units.

Address: See Table 4.2, Overview of Protection Command Registers.

Initial value: Reading this register returns an undefined value.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

4.2.7 Port protection cluster registers

4.2.7.1 PPCMDn — Port protection command register

PPCMDn is a protection command register for port group n.

Index n

An index “n” denotes the number of protection command registers. For details, see Table 4.1, Write-Protection Target Registers.

Access: This register is a write-only register that can be written in 32-bit units.

Address: See Table 4.2, Overview of Protection Command Registers.

Initial value: Reading this register returns 0000 0000_H.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

NOTE

The protection command register for port group JP0 is JPPCMD0. Its bits are JPPCMD0[7:0].

Table 4.23 PPCMDn Register Contents

Bit Position	Bit Name	Function
7 to 0	PPCMDn[7:0]	Protection command that enables writing to port protection cluster registers

4.2.7.2 PPROTSn — Port protection status register

PPROTSn is a protection status register for write-protected registers of port group n. It indicates the status of the protection sequence operated by PPCMDn.

Index n

An index “n” denotes the number of protection command registers. For details, see Table 4.1, Write-Protection Target Registers.

Access: This register is a read-only register that can be read in 32-bit units.

Address: See Table 4.2, Overview of Protection Command Registers.

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

4.2.8 Details of self-programming protection cluster registers

4.2.8.1 FLMDPCMD — FLMD protection command register

FLMDPCMD is a protection command register for the FLMDCNT register.

Access: This register is a write-only register that can be written in 32-bit units.

Address: See Table 4.2, Overview of Protection Command Registers.

Initial value: Reading this register returns 0000 0000_H.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

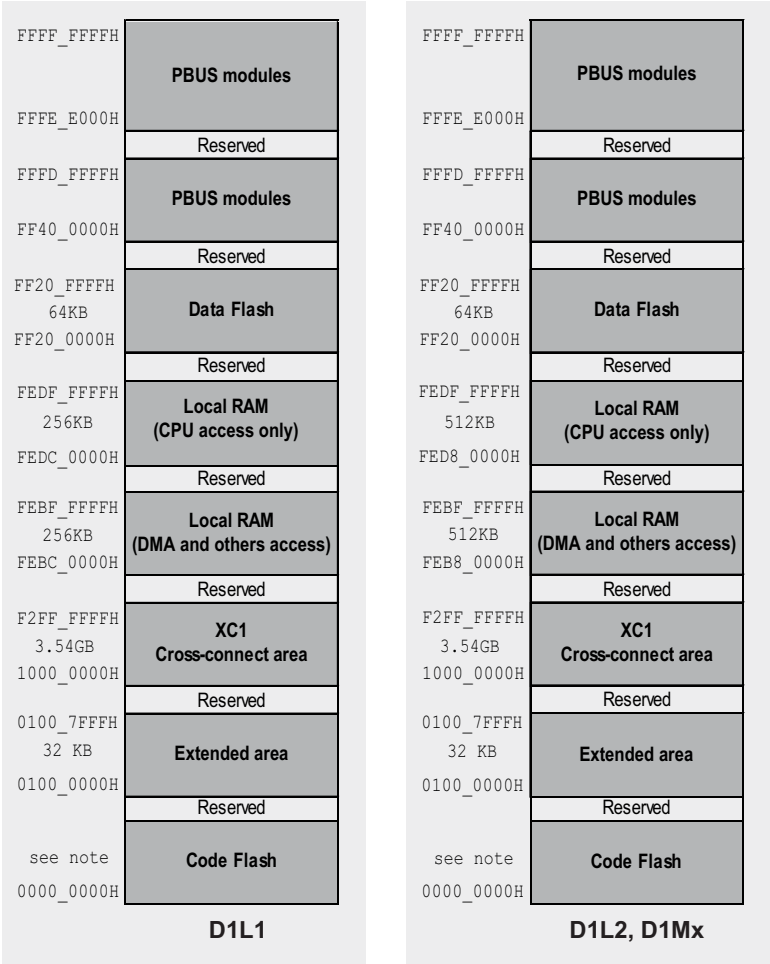
Section 5 Address Spaces

CAUTION

When making an access to the on-chip I/O register space, access the addresses shown in this manual. Do not access an address that is reserved or not specified in this manual. Otherwise, operation is not guaranteed.

5.1 CPU address map

The following diagram shows the address map from the CPU's perspective.



Note: The Code Flash memory is device dependent:

- D1L1: 2 MB, address space 0000 0000_H to 001F $FFFF_H$
- D1L2(H), D1M1-V2, D1M1A: 4 MB, address space 0000 0000_H to 003F $FFFF_H$
- D1M1(H)_3.75MB, D1M2(H)_3.75MB: 3.75 MB, address space 0000 0000_H to 003B $FFFF_H$
- D1M1(H)_5MB, D1M2(H)_5MB: 5 MB, address space 0000 0000_H to 004F $FFFF_H$

NOTE

Initial value of CPU reset vector

Reset vector is depended RBASE register settings. And, RBASE initial value is 0000 0000H.

RBASE register is described by "RH850 Family User's Manual: Software".

Figure 5.1 CPU address map

Local RAM

The Local RAM is accessible through two address areas in the CPU address map:

- The Local RAM area starting from address FEDC 0000_H (D1L1) or FED8 0000_H (D1L2, D1Mx) is accessible only by the CPU.
- The Local RAM area starting from address FEBC 0000_H (D1L1) or FEB8 0000_H (D1L2, D1Mx) is accessible also by all other masters, like the DMA Controller and all bus masters of the cross-connect system.

NOTE

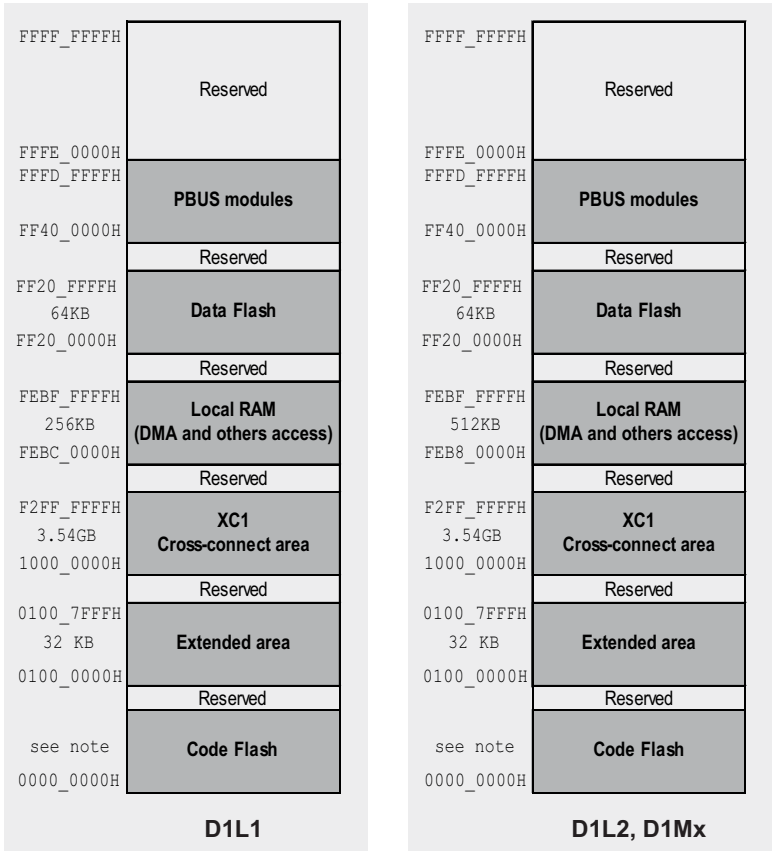
Though the CPU can access the Local RAM via both address areas, it is highly recommended to use the exclusive area at FEDC 0000_H (D1L1) or FED8 0000_H (D1L2, D1Mx).

CPU access to on-chip and external memories

The CPU can access the video RAMs and all external memories via the 3.54 GB large memory window to the XC1 cross-connect.

5.2 DMA and XC1 master's address map for the CPU Subsystem

The following diagram shows the address map of the CPU Subsystem from the DMA Controllers and the other XC1 cross-connect master's perspective.



Note: The Code Flash memory is device dependent:

- D1L1: 2 MB, address space 0000 0000_H to 001F $FFFF_H$
- D1L2(H), D1M1-V2, D1M1A: 4 MB, address space 0000 0000_H to 003F $FFFF_H$
- D1M1(H)_3.75MB, D1M2(H)_3.75MB: 3.75 MB, address space 0000 0000_H to 003B $FFFF_H$
- D1M1(H)_5MB, D1M2(H)_5MB: 5 MB, address space 0000 0000_H to 004F $FFFF_H$

Figure 5.2 DMA address map

5.3 Cross-connect address map

The following diagram shows the address map of the cross-connect bus system from all master's perspective.

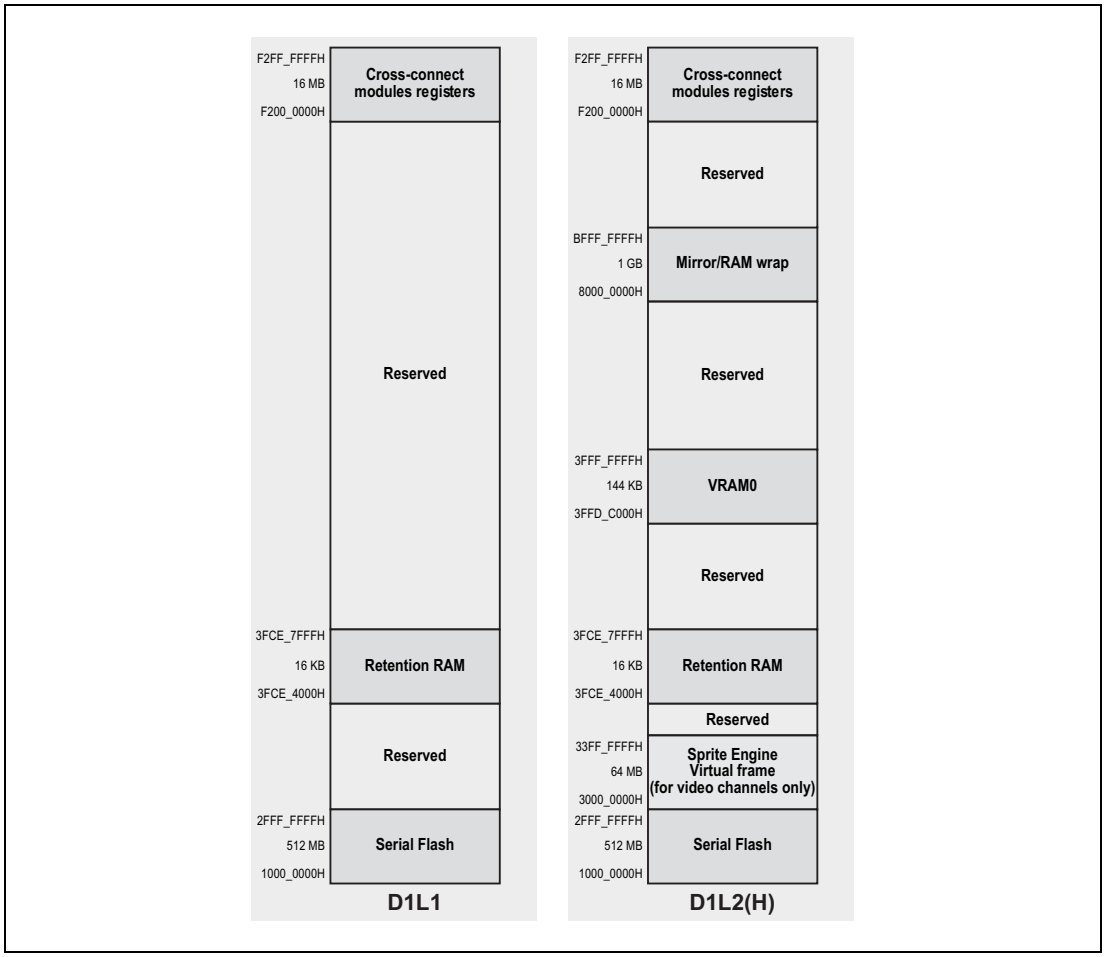


Figure 5.3 D1Lx cross-connect address map

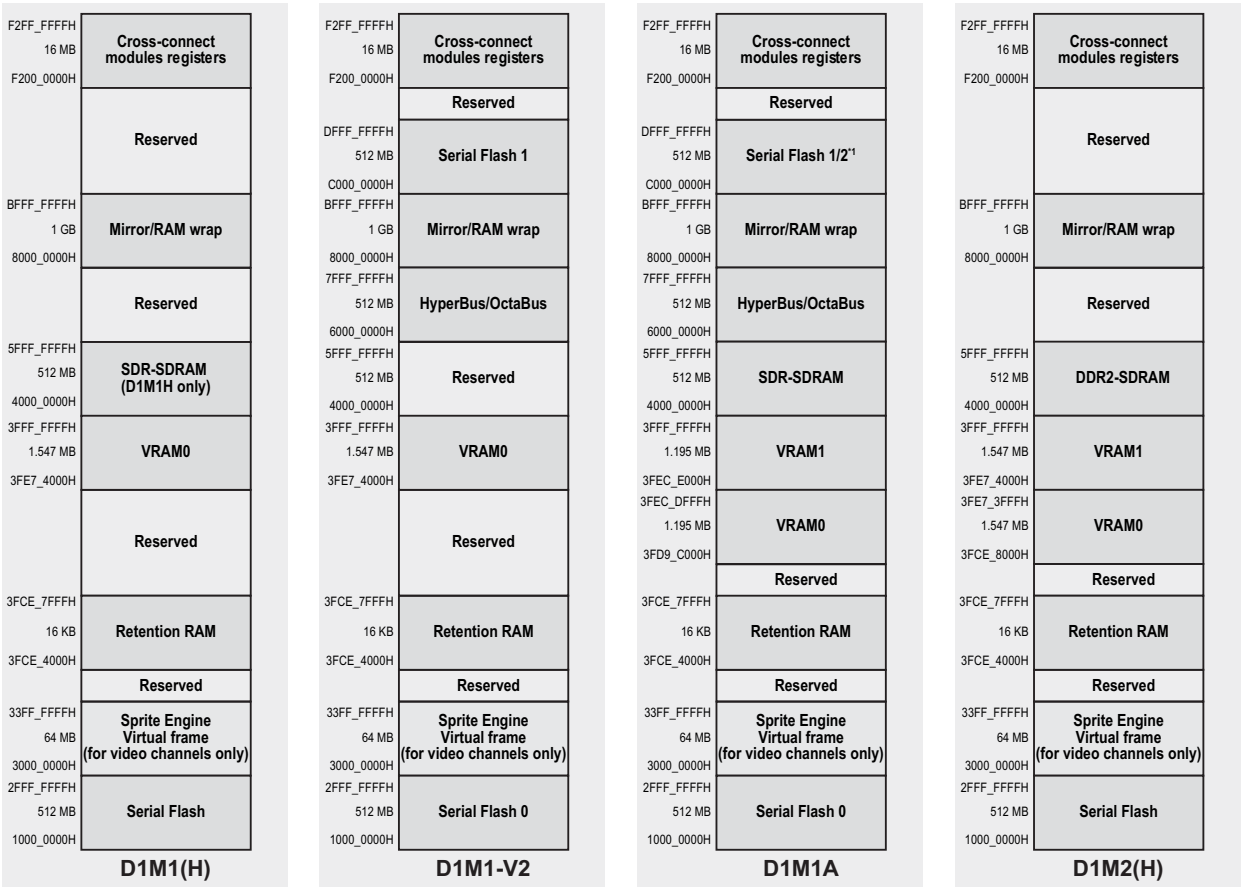

Note 1. SFMA1 and SFMA2 cannot be used concurrently. One of them must be selected by XCRAMCFG0.SFMASEL. Refer to Section 14.4, Bus Switch for external memory interfaces (D1M1-V2, D1M1A only) for details.

Figure 5.4 D1Mx cross-connect address map

The Mirror/RAM wrap area contains different address mapping images of the Video RAMs VRAM0/VRAM1, the SDRAM and the serial flash area.

Purpose of the mirrored areas are

- optimized memory mapping for different colour modes
- possibility for cached/uncached access from CPU.

Refer to Section 54, Video RAM and Video RAM Wrapper (VRAM) for details.

Section 6 Operating Modes

This section describes the operating mode and mode selection of the RH850/D1L/D1M.

The RH850/D1L/D1M has the operating modes as shown below.

Operating modes

- Normal operating mode

  This mode is for execution of application software. The on-chip debug capabilities also use this mode. If FLMD0 is activated while the operation is in this mode, writing to the code flash memory through self programming is enabled.

- Flash serial programming mode

  The flash programmer enables erasing/writing to the on-chip flash memory.

- Boundary scan mode

  This mode allows boundary scan tests compliant with IEEE Standard 1149.1.

When an external reset or power-on reset *1 is generated, RH850/D1L/D1M latches the state of the FLMD0, FLMD1, MODE0, and MODE1 pins and decides the operating mode after the reset is canceled. **Table 6.1** lists the relationship between the pin settings and the operating mode.

Note 1. The external reset includes all SYSRES in normal operation mode because RESET output is available.

Table 6.1 Selection of Operating Modes

Pins				
FLMD0*1	FLMD1 (P0_1)	MODE0 (P0_0)	MODE1 (P0_2)	Operating Mode
0	x	x	x	Normal operation mode*2
1	0	x	x	Flash programming mode
1	1	0	1	Boundary scan mode
Other than above				Settings are prohibited

Note 1. FLMD0 is not allowed to change its state during operation.
Note 2. Except the case using self-programming function.

CAUTION

To change operating mode, restart from POC0RES (remove the power supply once and apply it again). In the case of only by the external reset, some functions are not initialized after the mode transitions. For details of functions not initialized by the external reset, see Section 9.2.2, Reset sources and targets.

Section 7 Interrupt

The interrupt controller (INTC) determines priority of interrupt sources and controls interrupt requests to the CPU. The INTC has a register to set priority of each interrupt. Interrupt requests are processed according to the priority set in this register.

7.1 Overview

- One non-maskable interrupts (FENMI), one FE level interrupt (FEINT), and 256 EI level interrupts
  - FENMI interrupt: FE level non-maskable interrupt from ECM
  - FEINT interrupt: FE level maskable interrupt from ECM
  - Maskable interrupts: 256
    – 32 high-speed interrupts
    – 224 low-speed interrupts
    Refer to Section 7.6, Interrupt Response Times for details concerning the different interrupt response times.
- Sixteen interrupt priority levels can be set for the EI level interrupts.
  Up to 16 priority levels of the EI level interrupts can be set in EI level interrupt control registers.
- Three detection methods
  A method of detecting the pin NMI interrupt and external interrupt can be selected from rising edge, falling edge, and both edges.
- Direct branching method or table referencing method is selectable by setting two types of interrupt handler address setting registers.

7.2 Register Specifications

The INTC has registers listed in tables below. These registers are mainly used to set interrupt priority and to control detection of external interrupt input signals.

Table 7.1 Index

Index	Meaning
n	Indicating EI level interrupt source number (n = 0 - 255)
m	Indicating EI level interrupt mask register number (m = 0 - 7)
x	Indicating INTP number (x = 0 - 10)

7.2.1 Register Configuration

Table 7.2 Interrupt Control

Address	Symbol	Register Name	R/W	Initial Value	Access Size
FFFE EA00$_H$ - FFFE EA3E$_H$	EIC0 to EIC31	EI level interrupt control register	R/W	008F$_H$*1 808F$_H$*2	8 bit, 16 bit
FFFF B040$_H$ - FFFF B1FE$_H$	EIC32 to EIC255				
FFFE EAF0$_H$	IMR0	EI level interrupt mask register	R/W	FFFF FFFF$_H$	8 bit, 16 bit, 32 bit
FFFF B404$_H$ - FFFF B41C$_H$	IMR1 to IMR7				
FFFE EA78$_H$	FNC	FE level NMI status register	R	0000$_H$	8 bit, 16 bit
FFFE EA7A$_H$	FIC	FE level interrupt status register	R	0000$_H$	8 bit, 16 bit

Note 1. When a synchronous edge is detected.
Note 2. When a high-level signal is detected.

INTC1 registers

Among the registers shown in **Table 7.2**, the EIC0 to 31, IMR0, FNC, and FIC are located in INTC1 of the CPU-specific Peripheral. Each of these registers only can be accessed from the CPU which includes it.Writing is only possible in supervisor mode (PSW.UM = 0).

INTC2 registers

Of the registers listed in **Table 7.2**, EIC32 to EIC255, and IMR1 to IMR7 are located in INTC2, the controller for interrupts from peripheral IP group 0. Writing to these registers is only possible for the PE in supervisor mode. When writing to IMR1 to IMR7, only the bits corresponding to the conditions described above are overwritten; other bits are not updated.

CAUTION

The INTC2 registers are not accessible per default as these registers are guarded by the PBUS Guard PBG0B.

Before accessing any of these registers the PBG0B protection register FSGD0BPROT0 has to be set to 07FF FFFF$_H$.

See Section 14.6.4, PBUS Guards (PBG) for further details.

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> is defined as "INTC1" or “INTC2” for the registers in the table above.

<Symbol> is defined in the above table.

7.2.2 EI Level Interrupt Control Registers 0 to 255 (EIC0 - EIC255)

These registers are used to set interrupt control conditions for each EI level interrupt source. One register is provided for each source of this type. Writing to these registers requires care when a register is set for detection in synchronous edge mode. If 0 is written to the EIRFn bit immediately after a peripheral module generates the corresponding interrupt request, the request may be inadvertently lost. On the other hand, writing 1 to the EIRFn bit immediately after an interrupt is accepted by the CPU may lead to incorrect re-issuing of the request. Writing to any of these registers, therefore, should only proceed while peripheral modules are not generating interrupt requests and the CPU has not accepted any interrupt.

Writing to an EICn register includes writing by using the bit operation instructions (set1, clr1, and not1). The bit operation instructions proceed in the following sequence (1) reading the register, (2) processing the specified bit, and (3) writing the new value back to the register. When a bit operation instruction has a bit other than EIRFn as the operand, the value read in step (1) will be written back in step (3). Accordingly, the issuance of interrupt requests from peripheral modules or the acceptance of an interrupt request by the CPU between steps (1) and (3) may lead to the problems described above.

The addresses of the registers corresponding to the interrupt channels that are listed as reserved in the tables in 7.4, Interrupt Exception Handler and Priority Operations, are also reserved. Therefore, access to these addresses is prohibited. Operation cannot be guaranteed if they are accessed.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EICTn	—	—	EIRFn	—	—	—	—	EIMKn	EITBn	—	—	EIP3n	EIP2n	EIP1n	EIP0n

Note 1. 0: Synchronous edge detection, 1: High-level detection

Table 7.3 EIC0 - EIC255 register contents (1/2)

Bit Position	Bit Name	Function
15	EICTn	Interrupt Channel Type The following values are read according to the interrupt input interface. This is a read-only bit. 0: Synchronous edge detection 1: High-level detection
14, 13	—	Reserved These bits are always read as 0. The write value should always be 0.
12	EIRFn	Interrupt Request Flag Operation varies with the interrupt input interface. 0: No interrupt request (Initial value) 1: Interrupt request present • Synchronous edge detection This flag is automatically cleared to 0 when an interrupt request of the self-channel is accepted by the CPU core. This bit can be set or cleared by the software. • High level detection This bit cannot be set or cleared by the software. This is a read-only bit.
11 to 8	—	Reserved These bits are always read as 0. The write value should always be 0.

Table 7.3 EIC0 - EIC255 register contents (2/2)

Bit Position	Bit Name	Function
7	EIMKn	Interrupt Mask While this bit is set to 1, interrupt requests set in the interrupt request flag (EIRFn) are masked to inhibit interrupt requests from the channel to the CPU core. Notification of presence of unprocessed interrupts is not made and the PMEI bit in ICSR is not set from channels for which this bit is set to 1. Even when interrupt processing is disabled by the setting of this bit, an input of interrupt signal is not masked and the interrupt request flag is set. Setting this bit is also reflected in the setting of corresponding bit of the interrupt mask register (IMR). 0: Interrupt processing is enabled. 1: Interrupt processing is disabled. (Initial value)
6	EITBn	Interrupt Vector Method Select 0: Direct branching method based on priority 1: Table referencing method
5, 4	—	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	EIP3n-0n	These bits specify 16 interrupt priority levels (0: highest priority, 15: lowest priority). If two or more EI level interrupt requests are generated simultaneously, a source with higher priority specified by these bits is selected and is sent to the CPU core. If the priority specified by these bits is equal, a source of smaller channel number is selected as fixed priority.

Note: n = 0 to 255

7.2.3 EI Level Interrupt Mask Registers 0 to 7 (IMR0 - IMR7)

These registers are aggregation of the EIMK bit in the EIC register. Setting of the corresponding EIMK bit is reflected in each bit in the IMRm register. Furthermore, setting of the IMRm register is reflected in the corresponding EIMK bit.

The bits corresponding to the interrupt channels that are listed as reserved in in the tables in **7.4, Interrupt Exception Handler and Priority Operations**, are also reserved. When read, an initial value is returned. When written, write an initial value.

7.2.4 FE Level NMI Status Register (FNC)

This register indicates the status of FE level NMI conditions.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	FNRF	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.4 FNC register contents

Bit Position	Bit Name	Function
15 to 13	—	Reserved. The write value should always be 0.
12	FNRF	Interrupt Request Flag 0: No interrupt request (Initial value) 1: An interrupt request present This bit is automatically cleared to 0 when an FE level NMI interrupt request is accepted by the CPU core.
11 to 0	—	Reserved. The write value should always be 0.

7.2.5 FE Level Interrupt Status Register (FIC)

This register indicates the status of FE level interrupt conditions.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	FIRF	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.5 FIC register contents

Bit Position	Bit Name	Function
15 to 13	—	Reserved. The write value should always be 0.
12	FIRF	Interrupt Request Flag 0: No interrupt request (Initial value) 1: An interrupt request present This bit is automatically cleared to 0 when an FE level interrupt request is accepted by the CPU core.
11 to 0	—	Reserved. The write value should always be 0.

7.3 Interrupt Sources

Interrupt sources are grouped into three: NMI, INTPx, and on-chip peripheral modules. Priority of each interrupt is represented by an interrupt priority level value between 0 (highest level) and 15 (lowest level).

7.3.1 NMI Interrupts

NMI interrupts are input from the Error Control Module. For details see Section 48, Error Control Module (ECM).

7.3.2 INTPx Interrupts

INTPx interrupts are input from INTPx pins. A method of detecting the INTPx interrupt can be selected from rising edge, falling edge, and both edges. For details on the detection method, see Section 2, Pins.

Furthermore, interrupt priority levels 0 to 15 can be set for each pin in the interrupt control register (EICn).

When an interrupt request is detected by a change in the INTPx pin, and an interrupt request signal is sent to the INTC. The INTPx interrupt request detection result is retained until the interrupt request is accepted. Whether an INTPx interrupt request has been detected or not can be checked by reading the EIRFn bit in the corresponding EI level interrupt control register n (EICn) for INTPx. Writing 0 clears the INTPx interrupt request detection result.

When exiting the INTPx interrupt exception handler, confirm that the EIRFn bit has been cleared in the corresponding EI level interrupt control register n (EICn) for INTPx to prevent re-acceptance by mistake, and then issue an instruction to return from interrupt.

7.3.3 On-Chip Peripheral Module Interrupts

For the on-chip peripheral module that generates an interrupt, see 7.4, Interrupt Exception Handler and Priority Operations.

Since different interrupt vectors are assigned to each source, the interrupt exception handler need not decide sources. Priority can be set within priority levels 0 to 15 for each interrupt source.

7.4 Interrupt Exception Handler and Priority Operations

The following tables list interrupt sources, source codes, exception handler offset addresses, and interrupt priority.

There are two specifications for exception handler addresses: (1) standard specifications where exception handler addresses are determined by the PSW.EBV bit in the CPU core, RBASE register, and EBASE register and (2) extended specifications where exception handler addresses for interrupts are specified individually for each channel.

In the standard specifications, an offset address is added to the base address (RBASE register /EBASE register) in the CPU core to generate an exception handler address. The following two methods are provided for giving an interrupt offset address. For channels other than the interrupt channel, the specified offset address is given.

- An offset address is determined within a range of +100H to +1F0H according to the priority level (0 to 15) specified for each channel, regardless of interrupt channels.
- Every offset address is +100H regardless of the priority level. This is a function to reduce the memory occupation size of the exception handler. To utilize this function, set the RINT bit in the RBASE/EBASE register to 1. The initial value of RINT is 0.

In the extended specifications, a table for reading exception handler addresses for each interrupt channel is provided. The handler address is extracted by referencing the table. The table reference position is obtained by the following calculation formula. The INTBP register exists in the CPU core.

Exception handler address read position = INTBP + channel number * 4-byte

For details of handler addresses, refer to "*RH850G3M User's Manual Software Edition*."

Priority levels 0 to 15 (0: highest) of INTPx (external interrupts) and on-chip peripheral module interrupts can be set for each channel. If specified priority levels are equal, an interrupt source of smaller channel number is selected as fixed priority.

NOTE

Be sure to place a SYNCP instruction at the start of handers for exceptions of set E.

- Exceptions of set E: FENMI, FEINT, EIINT (with the direct vector method), SYSERR, and FPI

For details, see "*RH850G3M User's Manual Software Edition*".

7.4.1 D1L1 Interrupt Exception Handler and Priority

Table 7.6 D1L1 Interrupt Exception Handler and Priority (1/7)

Functional Module	Interrupt Source Name	Level Interrupt *1	Number of Interrupt Channel (EIINT)	Source Code	Offset Address: Direct Branch RINT = 0	Offset Address: Direct Branch RINT = 1	Offset Address: Table Reference	Interrupt Priority (Initial Value)	Default Priority
Non-maskable interrupt			(FENMI)	$E0_H$	$+0E0_H$	$+0E0_H$	—		High
FE level interrupt			(FEINT)	$F0_H$	$+0F0_H$	$+0F0_H$	—		
WDTA0	75 % interrupt (INTWDTA0)		0	1000	The offset address is the same in all channels and is determined between $+100_H$ and $+1F0_H$ according to priority.	The offset address is always $+100_H$ regardless of priority to reduce the offset address.	$+000_H$	0 to 15 (15)	
WDTA1	75 % interrupt (INTWDTA1)		1	1001			$+004_H$	0 to 15 (15)	
RTCA0	1 second interrupt (INTRTCA01S)		2	1002			$+008_H$	0 to 15 (15)	
	Alarm interrupt (INTRTCA0AL)		3	1003			$+00C_H$	0 to 15 (15)	
	Fixed interval interrupt (INTRTCA0R)		4	1004			$+010_H$	0 to 15 (15)	
AWOT0	Timer interrupt (INTAWOT0)		5	1005			$+014_H$	0 to 15 (15)	
Port	External interrupt 0 (INTP0)		6	1006			$+018_H$	0 to 15 (15)

Internal bus errors	This interrupt is a logical OR combination of various internal bus error indications. The exact cause of this error interrupt can be evaluated by use of the bus error status registers. Refer to Section 7.4.9, Bus error status registers for details.		255	10FF			$+3FC_H$	0 to 15 (15)	

Note 1. For a level interrupt, the status register in each module should be cleared during interrupt processing by software. The EICTn bit in EICn is set to 1. The EIRFn bit in EICn cannot be cleared by software.

7.4.2 D1L2(H) Interrupt Exception Handler and Priority

Table 7.7 D1L2(H) Interrupt Exception Handler and Priority (1/7)

Functional Module	Interrupt Source Name	Level Interrupt *1	Number of Interrupt Channel (EIINT)	Source Code	Offset Address: Direct Branch RINT = 0	Offset Address: Direct Branch RINT = 1	Offset Address: Table Reference	Interrupt Priority (Initial Value)	Default Priority
Non-maskable interrupt			(FENMI)	$E0_H$	$+0E0_H$	$+0E0_H$	—		High
FE level interrupt			(FEINT)	$F0_H$	$+0F0_H$	$+0F0_H$	—		
WDTA0	75 % interrupt (INTWDTA0)		0	1000	The offset address is the same in all channels and is determined between $+100_H$ and $+1F0_H$ according to priority.	The offset address is always $+100_H$ regardless of priority to reduce the offset address.	$+000_H$	0 to 15 (15)

Internal bus errors	This interrupt is a logical OR combination of various internal bus error indications. The exact cause of this error interrupt can be evaluated by use of the bus error status registers. Refer to Section 7.4.9, Bus error status registers for details.		255	10FF			$+3FC_H$	0 to 15 (15)	

Note 1. For a level interrupt, the status register in each module should be cleared during interrupt processing by software. The EICTn bit in EICn is set to 1. The EIRFn bit in EICn cannot be cleared by software.

7.4.3 D1M1 Interrupt Exception Handler and Priority

Table 7.8 D1M1 Interrupt Exception Handler and Priority (1/7)

Functional Module	Interrupt Source Name	Level Interrupt *1	Number of Interrupt Channel (EIINT)	Source Code	Offset Address: Direct Branch RINT = 0	Offset Address: Direct Branch RINT = 1	Offset Address: Table Reference	Interrupt Priority (Initial Value)	Default Priority
Non-maskable interrupt			(FENMI)	$E0_H$	$+0E0_H$	$+0E0_H$	—		High
FE level interrupt			(FEINT)	$F0_H$	$+0F0_H$	$+0F0_H$	—		
WDTA0	75 % interrupt (INTWDTA0)		0	1000	The offset address is the same in all channels and is determined between $+100_H$ and $+1F0_H$ according to priority.	The offset address is always $+100_H$ regardless of priority to reduce the offset address.	$+000_H$	0 to 15 (15)	
WDTA1	75 % interrupt (INTWDTA1)		1	1001			$+004_H$	0 to 15 (15)

Internal bus errors	This interrupt is a logical OR combination of various internal bus error indications. The exact cause of this error interrupt can be evaluated by use of the bus error status registers. Refer to Section 7.4.9, Bus error status registers for details.		255	10FF			$+3FC_H$	0 to 15 (15)	

Note 1. For a level interrupt, the status register in each module should be cleared during interrupt processing by software. The EICTn bit in EICn is set to 1. The EIRFn bit in EICn cannot be cleared by software.

7.4.4 D1M1H Interrupt Exception Handler and Priority

Table 7.9 D1M1H Interrupt Exception Handler and Priority (1/7)

Functional Module	Interrupt Source Name	Level Interrupt *1	Number of Interrupt Channel (EIINT)	Source Code	Offset Address: Direct Branch RINT = 0	Offset Address: Direct Branch RINT = 1	Offset Address: Table Reference	Interrupt Priority (Initial Value)	Default Priority
Non-maskable interrupt			(FENMI)	$E0_H$	$+0E0_H$	$+0E0_H$	—		High
FE level interrupt			(FEINT)	$F0_H$	$+0F0_H$	$+0F0_H$	—

Internal bus errors	This interrupt is a logical OR combination of various internal bus error indications. The exact cause of this error interrupt can be evaluated by use of the bus error status registers. Refer to Section 7.4.9, Bus error status registers for details.		255	10FF			$+3FC_H$	0 to 15 (15)	

Note 1. For a level interrupt, the status register in each module should be cleared during interrupt processing by software. The EICTn bit in EICn is set to 1. The EIRFn bit in EICn cannot be cleared by software.

7.4.5 D1M2 Interrupt Exception Handler and Priority

Table 7.10 D1M2 Interrupt Exception Handler and Priority (1/7)

Functional Module	Interrupt Source Name	Level Interrupt *1	Number of Interrupt Channel (EIINT)	Source Code	Offset Address: Direct Branch RINT = 0	Offset Address: Direct Branch RINT = 1	Offset Address: Table Reference	Interrupt Priority (Initial Value)	Default Priority
Non-maskable interrupt			(FENMI)	$E0_H$	$+0E0_H$	$+0E0_H$	—		High
FE level interrupt			(FEINT)	$F0_H$	$+0F0_H$	$+0F0_H$	—		
WDTA0	75 % interrupt (INTWDTA0)		0	1000	The offset address is the same in all channels and is determined between $+100_H$ and $+1F0_H$ according to priority.	The offset address is always $+100_H$ regardless of priority to reduce the offset address.	$+000_H$	0 to 15 (15)	
WDTA1	75 % interrupt (INTWDTA1)		1	1001			$+004_H$	0 to 15 (15)

Internal bus errors	This interrupt is a logical OR combination of various internal bus error indications. The exact cause of this error interrupt can be evaluated by use of the bus error status registers. Refer to Section 7.4.9, Bus error status registers for details.		255	10FF			$+3FC_H$	0 to 15 (15)	

Note 1. For a level interrupt, the status register in each module should be cleared during interrupt processing by software. The EICTn bit in EICn is set to 1. The EIRFn bit in EICn cannot be cleared by software.

7.4.6 D1M2H Interrupt Exception Handler and Priority

Table 7.11 D1M2H Interrupt Exception Handler and Priority (1/7)

Functional Module	Interrupt Source Name	Level Interrupt *1	Number of Interrupt Channel (EIINT)	Source Code	Offset Address: Direct Branch RINT = 0	Offset Address: Direct Branch RINT = 1	Offset Address: Table Reference	Interrupt Priority (Initial Value)	Default Priority
Non-maskable interrupt			(FENMI)	$E0_H$	$+0E0_H$	$+0E0_H$	—		High
FE level interrupt			(FEINT)	$F0_H$	$+0F0_H$	$+0F0_H$	—		
WDTA0	75 % interrupt (INTWDTA0)		0	1000	The offset address is the same in all channels and is determined between $+100_H$ and $+1F0_H$ according to priority.	The offset address is always $+100_H$ regardless of priority to reduce the offset address.	$+000_H$	0 to 15 (15)	
WDTA1	75 % interrupt (INTWDTA1)		1	1001			$+004_H$	0 to 15 (15)	
RTCA0	1 second interrupt (INTRTCA01S)		2	1002			$+008_H$	0 to 15 (15)	
	Alarm interrupt (INTRTCA0AL)		3	1003			$+00C_H$	0 to 15 (15)	
	Fixed interval interrupt (INTRTCA0R)		4	1004			$+010_H$	0 to 15 (15)	
AWOT0	Timer interrupt (INTAWOT0)		5	1005			$+014_H$	0 to 15 (15)	
Port	External interrupt 0 (INTP0)		6	1006			$+018_H$	0 to 15 (15)	
	External interrupt 1 (INTP1)		7	1007			$+01C_H$	0 to 15 (15)	
	External interrupt 2 (INTP2)		8	1008			$+020_H$	0 to 15 (15)	
	External interrupt 3 (INTP3)		9	1009			$+024_H$	0 to 15 (15)	
	External interrupt 4 (INTP4)		10	100A			$+028_H$	0 to 15 (15)	
	External interrupt 5 (INTP5)		11	100B			$+02C_H$	0 to 15 (15)	
	External interrupt 6 (INTP6)		12	100C			$+030_H$	0 to 15 (15)	
	External interrupt 7 (INTP7)		13	100D			$+034_H$	0 to 15 (15)	
	External interrupt 8 (INTP8)		14	100E			$+038_H$	0 to 15 (15)	
	External interrupt 9 (INTP9)		15	100F			$+03C_H$	0 to 15 (15)	
	External interrupt 10 (INTP10)		16	1010			$+040_H$	0 to 15 (15)	
TAUB0	Channel 0 interrupt (INTTAUB0I0)		17	1011			$+044_H$	0 to 15 (15)	
	Channel 1 interrupt (INTTAUB0I1)		18	1012			$+048_H$	0 to 15 (15)	
	Channel 2 interrupt (INTTAUB0I2)		19	1013			$+04C_H$	0 to 15 (15)	
	Channel 3 interrupt (INTTAUB0I3)		20	1014			$+050_H$	0 to 15 (15)	
	Channel 4 interrupt (INTTAUB0I4)		21	1015			$+054_H$	0 to 15 (15)	
	Channel 5 interrupt (INTTAUB0I5)		22	1016			$+058_H$	0 to 15 (15)	
	Channel 6 interrupt (INTTAUB0I6)		23	1017			$+05C_H$	0 to 15 (15)	
	Channel 7 interrupt (INTTAUB0I7)		24	1018			$+060_H$	0 to 15 (15)	
	Channel 8 interrupt (INTTAUB0I8)		25	1019			$+064_H$	0 to 15 (15)	
	Channel 9 interrupt (INTTAUB0I9)		26	101A			$+068_H$	0 to 15 (15)	
	Channel 10 interrupt (INTTAUB0I10)		27	101B			$+06C_H$	0 to 15 (15)	
	Channel 11 interrupt (INTTAUB0I11)		28	101C			$+070_H$	0 to 15 (15)	
	Channel 12 interrupt (INTTAUB0I12)		29	101D			$+074_H$	0 to 15 (15)	
	Channel 13 interrupt (INTTAUB0I13)		30	101E			$+078_H$	0 to 15 (15)	
	Channel 14 interrupt (INTTAUB0I14)		31	101F			$+07C_H$	0 to 15 (15)	
	Channel 15 interrupt (INTTAUB0I15)		32	1020			$+080_H$	0 to 15 (15)	

Table 7.11 D1M2H Interrupt Exception Handler and Priority (2/7)

Functional Module	Interrupt Source Name	Level Interrupt *1	Number of Interrupt Channel (EIINT)	Source Code	Offset Address: Direct Branch RINT = 0	Offset Address: Direct Branch RINT = 1	Offset Address: Table Reference	Interrupt Priority (Initial Value)	Default Priority
TAUB1	Channel 0 interrupt (INTTAUB1I0)		33	1021	The offset address is the same in all channels and is determined between $+100_H$ and $+1F0_H$ according to priority.	The offset address is always $+100_H$ regardless of priority to reduce the offset address.	$+084_H$	0 to 15 (15)	High
	Channel 1 interrupt (INTTAUB1I1)		34	1022			$+088_H$	0 to 15 (15)

Internal bus errors	This interrupt is a logical OR combination of various internal bus error indications. The exact cause of this error interrupt can be evaluated by use of the bus error status registers. Refer to Section 7.4.9, Bus error status registers for details.		255	10FF			$+3FC_H$	0 to 15 (15)	

Note 1. For a level interrupt, the status register in each module should be cleared during interrupt processing by software. The EICTn bit in EICn is set to 1. The EIRFn bit in EICn cannot be cleared by software.

7.4.7 D1M1A Interrupt Exception Handler and Priority

Table 7.12 D1M1A Interrupt Exception Handler and Priority (1/7)

Functional Module	Interrupt Source Name	Level Interrupt *1	Number of Interrupt Channel (EIINT)	Source Code	Offset Address: Direct Branch RINT = 0	Offset Address: Direct Branch RINT = 1	Offset Address: Table Reference	Interrupt Priority (Initial Value)	Default Priority
Non-maskable interrupt			(FENMI)	$E0_H$	$+0E0_H$	$+0E0_H$	—		High
FE level interrupt			(FEINT)	$F0_H$	$+0F0_H$	$+0F0_H$	—		
WDTA0	75 % interrupt (INTWDTA0)		0	1000	The offset address is the same in all channels and is determined between $+100_H$ and $+1F0_H$ according to priority.	The offset address is always $+100_H$ regardless of priority to reduce the offset address.	$+000_H$	0 to 15 (15)	
WDTA1	75 % interrupt (INTWDTA1)		1	1001			$+004_H$	0 to 15 (15)

Internal bus errors	This interrupt is a logical OR combination of various internal bus error indications. The exact cause of this error interrupt can be evaluated by use of the bus error status registers. Refer to Section 7.4.9, Bus error status registers for details.		255	10FF			$+3FC_H$	0 to 15 (15)	

Note 1. For a level interrupt, the status register in each module should be cleared during interrupt processing by software. The EICTn bit in EICn is set to 1. The EIRFn bit in EICn cannot be cleared by software.

7.4.8 D1M1-V2 Interrupt Exception Handler and Priority

Table 7.13 D1M1-V2 Interrupt Exception Handler and Priority (1/7)

Functional Module	Interrupt Source Name	Level Interrupt *1	Number of Interrupt Channel (EIINT)	Source Code	Offset Address: Direct Branch RINT = 0	Offset Address: Direct Branch RINT = 1	Offset Address: Table Reference	Interrupt Priority (Initial Value)	Default Priority
Non-maskable interrupt			(FENMI)	$E0_H$	$+0E0_H$	$+0E0_H$	—		High
FE level interrupt			(FEINT)	$F0_H$	$+0F0_H$	$+0F0_H$	—		
WDTA0	75 % interrupt (INTWDTA0)		0	1000	The offset address is the same in all channels and is determined between $+100_H$ and $+1F0_H$ according to priority.	The offset address is always $+100_H$ regardless of priority to reduce the offset address.	$+000_H$	0 to 15 (15)	
WDTA1	75 % interrupt (INTWDTA1)		1	1001			$+004_H$	0 to 15 (15)	
RTCA0	1 second interrupt (INTRTCA01S)		2	1002			$+008_H$	0 to 15 (15)	
	Alarm interrupt (INTRTCA0AL)		3	1003			$+00C_H$	0 to 15 (15)	
	Fixed interval interrupt (INTRTCA0R)		4	1004			$+010_H$	0 to 15 (15)	
AWOT0	Timer interrupt (INTAWOT0)		5	1005			$+014_H$	0 to 15 (15)	
Port	External interrupt 0 (INTP0)		6	1006			$+018_H$	0 to 15 (15)

Internal bus errors	This interrupt is a logical OR combination of various internal bus error indications. The exact cause of this error interrupt can be evaluated by use of the bus error status registers. Refer to Section 7.4.9, Bus error status registers for details.		255	10FF			$+3FC_H$	0 to 15 (15)	

Note 1. For a level interrupt, the status register in each module should be cleared during interrupt processing by software. The EICTn bit in EICn is set to 1. The EIRFn bit in EICn cannot be cleared by software.

7.4.9 Bus error status registers

7.4.9.1 BERR0ST0 — Bus error status register 0

This register holds error flags, that indicated the cause of an assertion of the internal bus error interrupt (EIINT channel number 255).
Other bus errors are indicated in the bus error staus register 1 BERR0ST1.

The error flags of this register can be cleared by use of the bus error status clear register 0 BERR0STC0.

Access: This register can be accessed in 32-bit units.
Address: FFC0 7000_H
Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	BERR0 SSF018	0	BERR0 SSF016
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	BERR0 SSF008	BERR0 SSF007	BERR0 SSF006	BERR0 SSF005	BERR0 SSF004	BERR0 SSF003	BERR0 SSF002	BERR0 SSF001	BERR0 SSF000
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

All error flags in this register indicate the following:

- BERR0SSF0x = 0: respective error has not occured
- BERR0SSF0x = 1: respective error has occured

Table 7.14 BERR0ST0 register contents

Bit position	Bit name	Function
31 to 19	Reserved	Reading returns 0. When written, write the initial value.
18	BERR0SSF018	HBUS Error (BRG_GFX)
17	Reserved	Reading returns 0. When written, write the initial value.
16	BERR0SSF016	Media Local Bus module (MLBB) cross-connect error An error occurred during an MLBB transaction via the XC1 cross-connect.
15 to 9	Reserved	Reading returns 0. When written, write the initial value.
8	BERR0SSF008	PBUS Slave Error (PBUSBUSIP_EEP)
7	BERR0SSF007	PBUS Slave Error (PBUSBUSIP3)
6	BERR0SSF006	PBUS Slave Error (PBUSBUSIP2)

2	BERR0SSF002	PBUS Slave Error (PBUSBUSIP_COM)
1	BERR0SSF001	PBUS Slave Error (PBUSBUSIP_PWM)
0	BERR0SSF000	PBUS Slave Error (PBUSBUSIP_AWO)

7.4.9.2 BERR0ST1 — Bus error status register 1

This register holds error flags, that indicated the cause of an assertion of the internal bus error interrupt (EIINT channel number 255).
Other bus errors are indicated in the bus error staus register 0 BERR0ST0.

The error flags of this register can be cleared by use of the bus error status clear register 1 BERR0STC1.

Access: This register can be accessed in 32-bit units.

Address: FFC0 7004_H

Initial value: 0000 00xx 0000 0000 0000 0000 0000 0000_B

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7.4.9.3 BERR0STC0 — Bus error status clear register 0

This register is used to clear the bus error flags of BERR0ST0.

Access: This register can be accessed in 32-bit units.

Address: FFC0 7010_H

Initial value: Reading this register returns always 0000 0000_H.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

All clear bits in this register effect the following, when written:

- BERR0CL0x = 0: no function
- BERR0CL0x = 1: respective error flag in the bus error status register 0 is cleared

Table 7.16 BERR0STC0 register contents

Bit position	Bit name	Function
31 to 19	Reserved	Reading returns 0. When written, write the initial value.
18	BERR0CL018	BERR0ST0.BERR0SSF018 error flag clear
17	Reserved	Reading returns 0. When written, write the initial value.
16	BERR0CL016	BERR0ST0.BERR0SSF016 error flag clear
15 to 9	Reserved	Reading returns 0. When written, write the initial value.
8	BERR0CL008	BERR0ST0.BERR0SSF008 error flag clear
7	BERR0CL007	BERR0ST0.BERR0SSF007 error flag clear
6	BERR0CL006	BERR0ST0.BERR0SSF006 error flag clear
5	BERR0CL005	BERR0ST0.BERR0SSF005 error flag clear
4	BERR0CL004	BERR0ST0.BERR0SSF004 error flag clear
3	BERR0CL003	BERR0ST0.BERR0SSF003 error flag clear
2	BERR0CL002	BERR0ST0.BERR0SSF002 error flag clear
1	BERR0CL001	BERR0ST0.BERR0SSF001 error flag clear
0	BERR0CL000	BERR0ST0.BERR0SSF000 error flag clear

7.4.9.4 BERR0STC1 — Bus error status clear register 1

This register is used to clear the bus error flags of BERR0ST1.

Access: This register can be accessed in 32-bit units.

Address: FFC0 7014_H

Initial value: Reading this register returns always 0000 0000_H.

7.4.10 DMA Bus Error Control Module (BECM)

The Bus Error Control Module detects error responses during DMA Controller tranaction attempts via the cross-connect.

In case of an transaction error detection an interrupt is generated.

Following errors can be detected:

- illegal ID error response from cross-connect
- error response from targetted cross-connect slave module

Table 7.18 DMA bus error status registers overview

Register Name	Symbol	Address
Access protect control for BECM registers	BECMBUSERRKEYCODE	FFFF 7400$_H$
DMAC bus error mask register	BECMBUSERRMASK	FFFF 7404$_H$
DMAC bus error flag register	BECMBUSERRFLAG	FFFF 7408$_H$
DMAC bus error clear register	BECMBUSERRCLEAR	FFFF 740C$_H$
DMAC bus error index register	BECMBUSERRINDEX	FFFF 7410$_H$
DMAC bus error info register 0	BECMBUSERRINFO0	FFFF 7414$_H$
DMAC bus error info register 1	BECMBUSERRINFO1	FFFF 7418$_H$

7.4.10.1 BECMBUSERRKEYCODE — Access protect control for BECM registers

This register enables write access to the BECM registers.

Access: This register can be accessed in 32-bit units.

Address: FFFF 7400$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	BECMKEY[7:0]							
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 7.19 BECMBUSERRKEYCODE register contents

Bit position	Bit name	Function
31 to 8	Reserved	Reading returns 0. When written, write the initial value.
7 to 0	BECMKEY[7:0]	When AA$_H$ is written, write access to the BECM registers is enabled. BECMKEY[0] will become 0. Writing any other value than AA$_H$ prohibits write access to the BECM registers. BECMKEY[0] will become 1. When access is prohibited, write access to the BECM registers is invalid and reading of the BECM registers returns 0000 0000$_H$. Reading this register returns 0 of the bits 31 to 1 and bit 0 (BECMKEY[0]) indicates BECM registers access status: 1: BECM registers access prohibited 0: BECM registers access enabled

7.4.10.2 BECMBUSERRMASK — DMAC bus error mask register

This register controls the generation of interrupts in case of error detections.

Access: This register can be accessed in 32-bit units.

Address: FFFF 7404_H

Initial value: 0000 $FFA6_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 7.20 BECMBUSERRMASK register contents

Bit position	Bit name	Function
31 to 13	Reserved	Reading returns the initial value. When written, write the initial value.
12	BECMMASK12	DMA Controller post write response error interrupt generation control 0: interrupt upon post write response error generated 1: no interrupt upon post write response error generated
11	BECMMASK11	DMA Controller response error interrupt generation control 0: interrupt upon response error generated 1: no interrupt upon response error generated
10 to 0	Reserved	Reading returns the initial value. When written, write the initial value.

7.4.10.3 BECMBUSERRFLAG — DMAC bus error flag register

This register holds error flags, that indicated the cause of an assertion of the internal bus error interrupt (EIINT channel number 255).

The error flags of this register can be cleared via the DMAC bus error clear register BECMBUSERRCLEAR.

The settings of the DMAC bus error mask register BECMBUSERRMASK does not affect this register.

Access: This register can be accessed in 32-bit units.

Address: FFFF 7408$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	Bit name	Function
31 to 13	Reserved	Reading returns the initial value. When written, write the initial value.
12	BECMFLG12	DMA Controller post write response status flag 0: DMA Controller post write response error not detected 1: DMA Controller post write response error detected
11	BECMFLG11	DMA Controller response error status flag 0: DMA Controller response error not detected 1: DMA Controller response error detected
10 to 0	Reserved	Reading returns the initial value. When written, write the initial value.

7.4.10.4 BECMBUSERRCLEAR — DMAC bus error clear register

This register is used to clear the error flags of the DMA Controller bus error flag register BECMBUSERRFLAG.

For clearing an error flag BECMFLGx in the BECMBUSERRFLAG register, proceed as follows:

1. set BECMBUSERRCLEAR.BECMCLRx = 1
2. set BECMBUSERRCLEAR.BECMCLRx = 0
3. set BECMBUSERRFLAG.BECMFLGx = 0

Access: This register can be accessed in 32-bit units.

Address: FFFF 740C$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7.5 Operation

7.5.1 External Interrupts (NMI / INTP)

NMI and INTP interrupts are input from external devices.

The NMI is input to the Error Control Module. For details see Section 48, Error Control Module (ECM).

The INTP interrupts are can directly generate EI level interrupts.

Figure 7.1 shows an IRQ (external interrupt) detection flow.

- Select an IRQ detecting method (rising edge, falling edge, and both edges) by setting the FCLAnCTLm register.
- After an IRQ has been detected, an interrupt request is sent to the INTC.

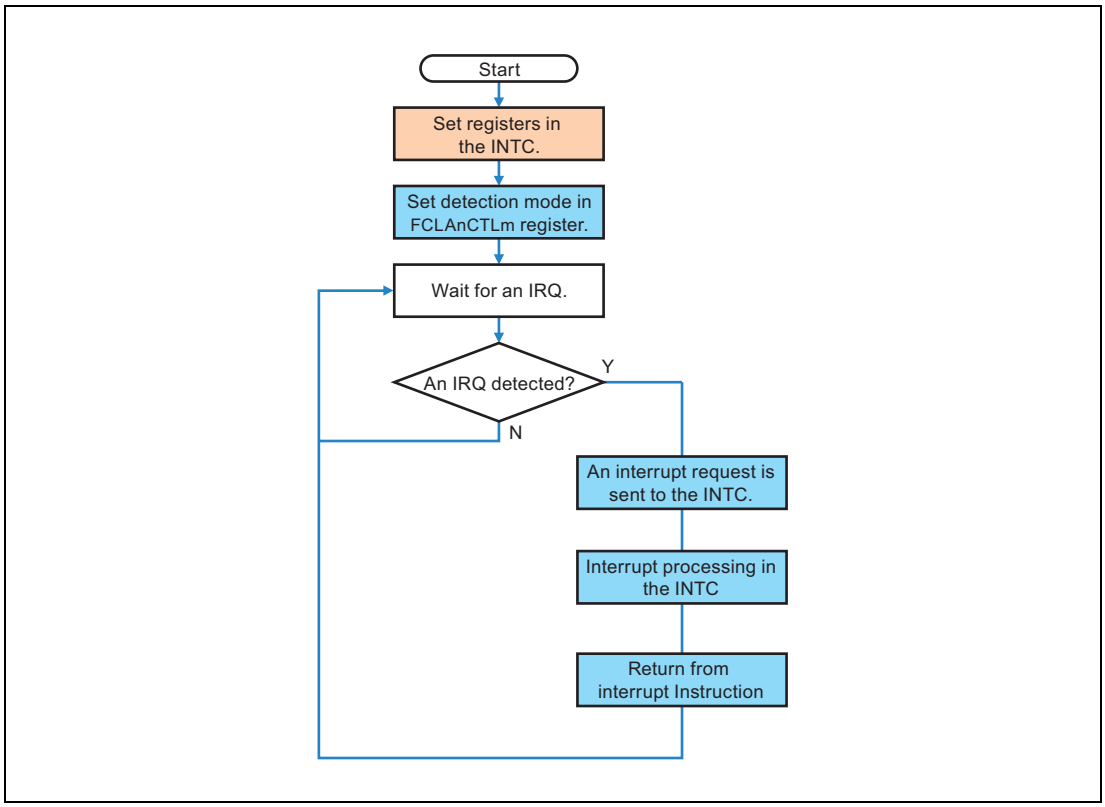

Figure 7.1 External Interrupt Processing Flow

7.6 Interrupt Response Times

Table 7.26 Minimum interrupt Response Times to be Considered

Interrupt Request Source	Number of Cycles for Processing			
INTC Connection	INTC2	INTC1	in CPU	Total (in the case of edge detection by fixed vector method a)
Directly input to INTC1	—	2 x CPUCLK <1 x CPUCLK>	Refer to the description under CPU below	7 x CPUCLK
Input via INTC2	3 x XCCLK + 1 x CPUCLK <2 x XCCLK + 1 x CPUCLK>	—		3 x XCCLK + 6 x CPUCLK

Note 1. The numbers in < > indicate the numbers of cycles in the case of level detection.

Vector method	Cache HIT/MISS	in CPU		Vector method
		D1M2(H), D1M1A	Other devices	
Fixed vector method	a) ISR entry is hit	5 x CPUCLK		a) Fixed vector method
	b) ISR entry is missed	10 x CPUCLK	8 x CPUCLK	
Vector table reference method	c) Vector code Flash assigned, ISR entry is hit	14 x CPUCLK	12 x CPUCLK	b) Vector table reference method Code flash assigned
	d) Vector code Flash assigned, ISR entry is missed	19 x CPUCLK	15 x CPUCLK	
	e) Vector Local RAM assigned, ISR entry is hit	9 x CPUCLK		c) Vector table reference method Local RAM assigned
	f) Vector Local RAM assigned, ISR entry is missed	14 x CPUCLK	12 x CPUCLK	

7.7 Using Interrupt Request Signals to Initiate Data Transfer

An interrupt request signal activates the DMAC to perform data transfer. For details, see **Section 8, DMA**.

Section 8 DMA

8.1 Overview

8.1.1 Overview

Direct memory access (DMA) is used to access data without going through the CPU.

A DMAC includes registers for storing transfer information. DMA has two 8-channel DMAC modules.

In this manual, DTFR denotes the function to select among hardware DMA transfer sources for a DMAC and retain the DMA transfer request. The DTFR can handle 128 types of hardware DMA transfer sources.

The address space that can be used for DMA transfer is a 4 GB address space represented by a 32-bit address. For information about which resource is assigned to a particular area in the 4 GB address space and which area is accessible from DMA, see Section 5, Address Spaces.

8.1.2 Term Definition

Table 8.1 shows the terms used in this section.

Table 8.1 List of Term Definitions

Term	Meaning
DMA transfer	A general term for data transfer carried out by DMA.
DMA cycle	A series of actions that consist of reading an amount of data specified by the transfer size (8/16/32/64/128 bits) from the address specified by the source address and writing it to the address specified by the destination address. The first half of the DMA cycle (reading part) is called a read cycle, and the second half (writing part) is called a write cycle.
Hardware DMA transfer source	A trigger for a DMA transfer request given by an internal peripheral device.
Hardware DMA transfer request	A DMA transfer request generated by a hardware DMA transfer source
Software DMA transfer request	A DMA transfer request generated by software writing to a register.
DMA transfer request	A trigger to start DMA transfer with a DMAC.
Single transfer	DMA transfer consisting of one DMA cycle started by one DMA transfer request.
Block transfer 1	DMA transfer consisting of a number of DMA cycles specified by the transfer count in the transfer information, started by one DMA transfer request.
Block transfer 2	DMA transfer consisting of a number of DMA cycles specified by the address reload count in the transfer information, started by one DMA transfer request.
Block transfer	A general term for both block transfer 1 and block transfer 2.
Last transfer	The DMA cycle carried out when the transfer count in the transfer information is 1.
Address reload transfer	The DMA cycle carried out when the address reload count in the transfer information is 1 if the reload function 2 is used.
Suspension	An action of pausing DMA transfer during block transfer. You can resume DMA transfer after suspension.
Resume	An action of resuming suspended DMA transfer.
Transfer abort	An action of aborting DMA transfer in the middle. You cannot resume DMA transfer after that.

8.2 DMA Function

8.2.1 Basic Operation of DMA Transfer

8.2.1.1 Transfer Mode

DMA has three transfer modes.

Single Transfer

One DMA cycle is executed when a DMA transfer request is accepted.

Block Transfer 1

A number of DMA cycles specified in the transfer count register are executed when a DMA transfer request is accepted.

Block Transfer 2

A number of DMA cycles specified by the address reload count are executed when a DMA transfer request is accepted. If the address reload count is larger than the value in the transfer count register, a number of DMA cycles specified in the transfer count register are executed.

8.2.1.2 Executing a DMA Cycle

Dual-address (2-cycle) transfer operation is adopted to DMA cycle.

DMA always executes a write cycle after a read cycle is complete. For example, if the transfer data size is 128 bits, a write cycle is executed after a read cycle for the 128-bit data is finished. A write cycle never starts in the middle of a read cycle.

8.2.1.3 Updating Transfer Information

When a DMA cycle is executed, DMA updates transfer information as follows.

Source Address and Destination Address

Transfer information will be updated as described in **Table 8.2** according to the settings for the source address and destination address and the settings in the transfer control register such as the count directions of source address and destination address and transfer data size.

Table 8.2 Updating the Source Address and the Destination Address (1/2)

Direction of Count	Transfer Data Size	Address after Update
Increment	8 bit	(address before update) + 0000 0001_H
	16 bit	(address before update) + 0000 0002_H
	32 bit	(address before update) + 0000 0004_H
	64 bit	(address before update) + 0000 0008_H
	128 bit	(address before update) + 0000 0010_H

Table 8.2 Updating the Source Address and the Destination Address (2/2)

Direction of Count	Transfer Data Size	Address after Update
Decrement	8 bit	(address before update) – 0000 0001_H
	16 bit	(address before update) – 0000 0002_H
	32 bit	(address before update) – 0000 0004_H
	64 bit	(address before update) – 0000 0008_H
	128 bit	(address before update) – 0000 0010_H
Fixed	—	Same as the address before update.

When you use the reload function, a special update rule other than the one described in **Table 8.2** is applied for the last transfer and the address reload transfer. For details, see Section 8.2.3, Reload Function.

Transfer Count/Address Reload Count

The transfer count is decremented by one for every DMA cycle.

The address reload count is decremented by one for every DMA cycle when the reload function 2 or block transfer 2 is used. When the reload function 2 or block transfer 2 is not used, it is not updated.

When you use the reload function, a special update rule is applied for the last transfer and the address reload transfer. For details, see Section 8.2.3, Reload Function.

Other transfer information

Other transfer information is not updated during execution of a DMA cycle.

8.2.1.4 Last Transfer and Address Reload Transfer

The last transfer means a DMA cycle executed when the value in the transfer count register, which shows the remaining number of transfers, is one. The last transfer differs in operation compared to other DMA cycles as follows.

- The transfer completion flag (DCSTn.TC) is set when the last transfer is complete. (Only applicable for a DMAC)
- The channel operation enable (DCENn.DTE) bit is cleared when the last transfer is complete. (Only applicable for a DMAC. When the continuous transfer is disabled.)
- When the transfer completion interrupt output enable is set, a transfer completion interrupt is output when the last transfer is complete.
- When the reload function 1 is enabled, the reload function 1 is executed at the timing of the last transfer. For details, see Section 8.2.3, Reload Function.

The address reload transfer means a DMA cycle executed when the reload function 2 is enabled and the address reload count is one. The reload function 2 is executed during the address reload transfer. For details, see Section 8.2.3, Reload Function.

8.2.1.5 Transfer Completion Interrupt and Transfer Count Match Interrupt Outputs

DMA can output a transfer completion interrupt and a transfer count match interrupt to external devices.

Transfer Completion Interrupt Output

When the transfer completion interrupt output enable (DTCTn.TCE) is set in the transfer control register, a DMAC requests a transfer completion interrupt when the last transfer is complete.

Transfer Count Match Interrupt Output

When the transfer count match interrupt enable (DTCTn.CCE) is set in the transfer control register, a DMAC requests a DMAC transfer count match interrupt when the DMA cycle in which the transfer count compare register and the transfer count have the same value is complete.

Figure 8.1 shows the operation of the transfer completion interrupt and the transfer count match interrupt.

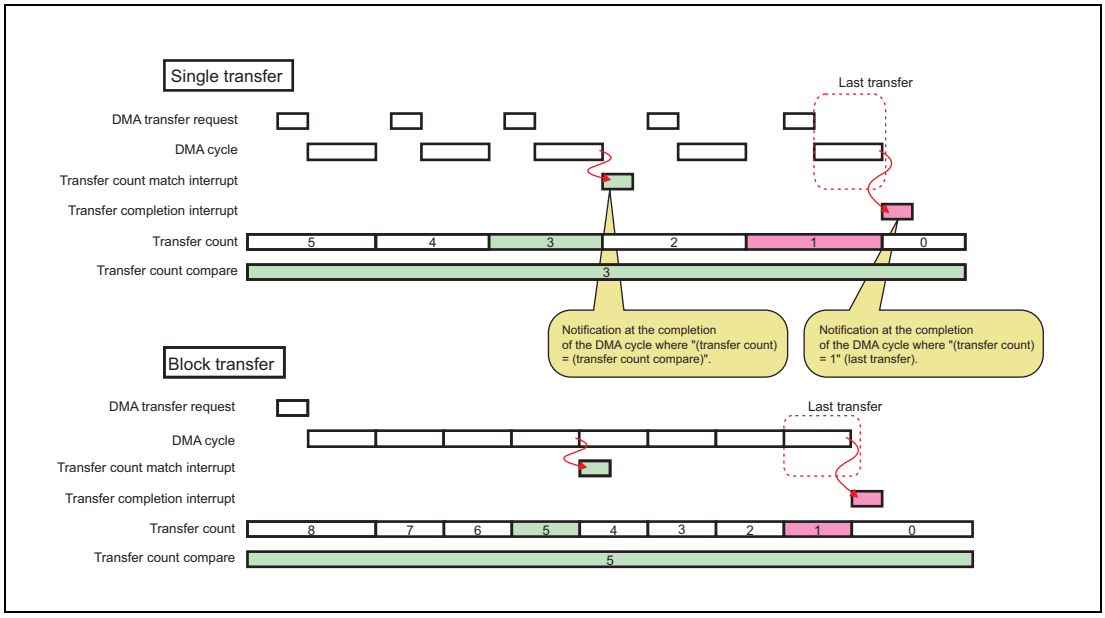

Figure 8.1 Transfer Completion Interrupt and Transfer Count Match Interrupt

8.2.1.6 Continuous Transfer

If the continuous transfer is not used, a DMAC sets the transfer completion flag (DCSTn.TC) and clears the channel operation enable (DCENn.DTE) bit when the last transfer is complete. In this case, a DMA transfer request is not accepted when the request is generated after the completion of the last transfer.

If the continuous transfer is used, the channel operation enable (DCENn.DTE) bit is not cleared when the last transfer is complete, and a DMA transfer request can be accepted even when the transfer completion flag is set. If DMA is used for a case where a specified number of DMA transfers are executed repetitively, software overhead associated with clearing the transfer completion flag and setting the channel operation enable bit after the completion of the last transfer can be reduced by using the continuous transfer.

The continuous transfer is enabled by setting the continuous transfer enable (DTCTn.MLE) in the DMAC transfer control register.

The continuous transfer is designed to work with the reload function 1. The continuous transfer function itself does not update the source address register, destination address register, and transfer count register. If, after the last transfer is complete, you want to restore the source address register, destination address register, and transfer count register to their state before the DMA transfer started, use the reload function 1 and set the values of the source address register, destination address register,

and the transfer count register before the DMA transfer starts to the reload source address register, reload destination address register, and reload transfer count register respectively.

Figure 8.2 shows an operation of continuous transfer by a DMAC.

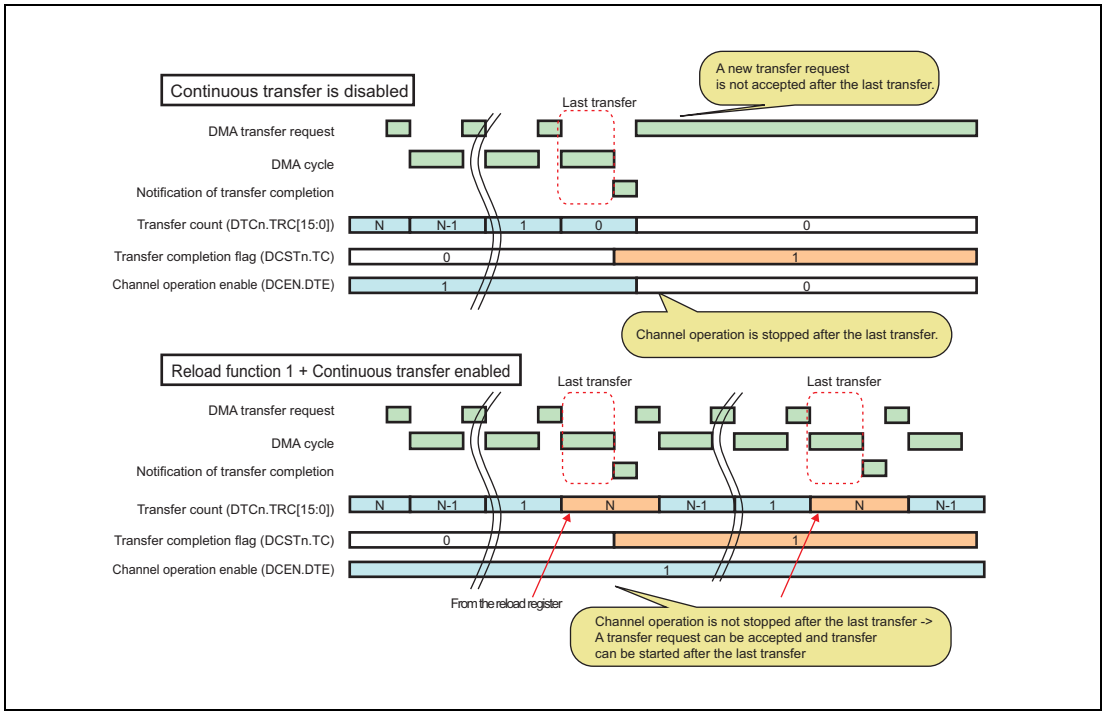

Figure 8.2 Operation of Continuous Transfer by a DMAC

8.2.2 Channel Priority Order

This subsection explains arbitration between multiple DMA channels.

8.2.2.1 DMAC Channel Arbitration

A DMAC selects one channel out of eight channels by arbitration. Arbitration is done according to a fixed priority order. The priority order is “channel 0 > channel 1 > channel 2 > channel 3 > channel 4 > channel 5 > channel 6 > channel 7” for DMAC0, and “channel 8 > channel 9 > channel 10 > channel 11 > channel 12 > channel 13 > channel 14 > channel 15” for DMAC1.

Arbitration is done for every DMA cycle. No arbitration occurs between the read and write of a DMA cycle.

If, at the time when one DMA cycle in the middle of a block transfer of a channel is complete, there is a DMA transfer request from a channel with a higher priority than the channel, a DMA cycle of the channel with the higher priority will be executed next as the result of arbitration.

If a DMAC executes the block transfer 1 or block transfer 2, DMAC channel arbitration is done for every DMA cycle, and possibly a DMA cycle of another DMAC channel with a higher priority can cut in.

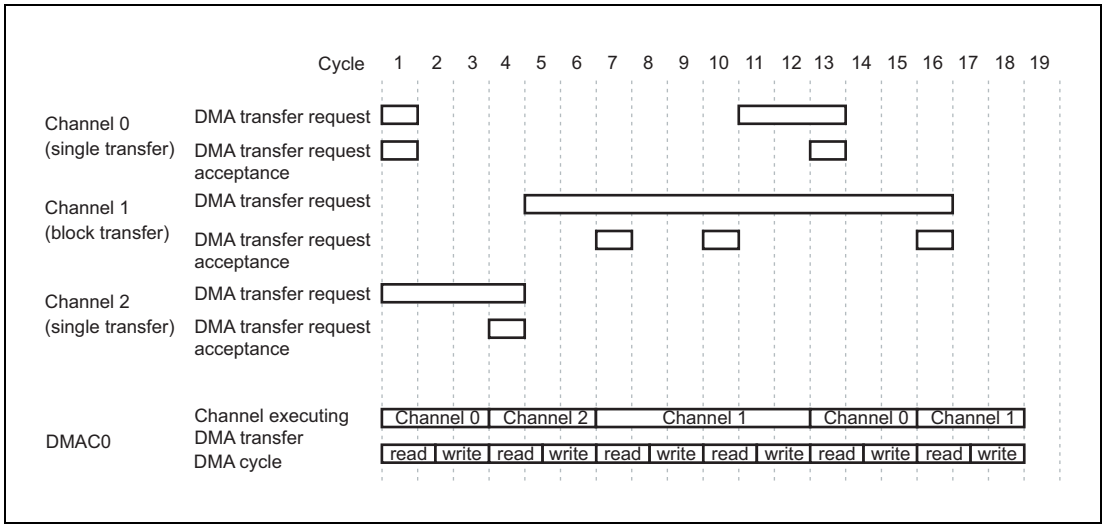

Figure 8.3 DMAC Channel Arbitration

Cycle numbers shown in **Figure 8.3** are for explanation purpose only. They do not indicate an actual number of cycles necessary for executing DMA transfer.

In **Figure 8.3**, DMA transfer requests for channels 0 and 2 are generated at Cycle 1. As a result of arbitration, a DMA cycle for channel 0 starts because its priority is higher. At Cycle 4, a DMA cycle for channel 2 starts. At Cycle 5, a DMA transfer request for channel 1 is generated. The DMA cycle for channel 2 is still ongoing and no arbitration is done at this point. At Cycle 7, a DMA cycle for channel 1 starts. Channel 1 uses block transfer. Another DMA cycle continues at Cycle 10 because there are no DMA transfer requests from other channels. At Cycle 11, a DMA transfer request for channel 0 is generated. The DMA cycle for channel 1 is still ongoing and no arbitration is done at this point. At Cycle 12, the DMA cycle for channel 1 is complete. At Cycle 13, a DMA cycle for channel 0 starts as a result of arbitration between DMA channels 0 and 1.

It should be noted that, even though a block transfer of channel 1 has been already started, a DMA cycle of not channel 1 but channel 0 is executed at Cycle 13 because the priority of the latter is higher. At Cycle 15, the DMA cycle for channel 0 is complete. At Cycle 16, a DMA cycle for channel 1 starts again. At Cycle 18, the last DMA cycle of the block transfer of channel 1 is complete.

8.2.2.2 Interface Arbitration

The DMA units DMAC0 and DMAC1 execute DMA transfer independently.
That means, two DMA transactions, one on each DMA unit, can be processed concurrently.

Each channel of DMAC0 and DMAC1 has the capability to store one DMA transfer request, while it is already processing the previous request of that channel.

CAUTION

If a DMA transfer request occurs, while the previous one is pending, the new request gets lost.

8.2.3 Reload Function

8.2.3.1 Overview of the Reload Function

The reload function updates a portion of transfer information, more specifically, the source address, destination address, transfer count, and address reload count, to the predefined values during DMA transfer.

The reload function has two types of functions: reload function 1 and reload function 2.

8.2.3.2 Operation of Reload Function 1

When the reload function 1 is enabled, actions described in **Table 8.3** are executed at the time of the last transfer according to the reload function 1 setting.

If the last transfer is generated at the same time as the address reload transfer is generated, reload is executed according to the reload function 1 setting.

Table 8.3 Operation of Reload Function 1

Reload Function 1 Setting (DTCTn.RLD1M[1:0])	Register	Action at the Last Transfer
00 (Reload function 1 disabled.)	Source address	Not reloaded.
	Destination address	Not reloaded.
	Transfer count	Not reloaded.
	Address reload count	Not reloaded.
01 (Reload function 1 enabled. Reloading source address and transfer count.)	Source address	The reload source address is copied to this.
	Destination address	Not reloaded.
	Transfer count	The reload transfer count is copied to this.
	Address reload count	• If the reload function 2 is disable: Not reloaded. • If the reload function 2 is enabled: The reload address reload count is copied to this.
10 (Reload function 1 enabled. Reloading destination address and transfer count.)	Source address	Not reloaded.
	Destination address	The reload destination address is copied to this.
	Transfer count	The reload transfer count is copied to this.
	Address reload count	• If the reload function 2 is disable: Not reloaded. • If the reload function 2 is enabled: The reload address reload count is copied to this.
11 (Reload function 1 enabled. Reloading source address, destination address, and transfer count.)	Source address	The reload source address is copied to this.
	Destination address	The reload destination address is copied to this.
	Transfer count	The reload transfer count is copied to this.
	Address reload count	• If the reload function 2 is disable: Not reloaded • If the reload function 2 is enabled: The reload address reload count is copied to this.

Figure 8.4 shows an operation of the reload function 1.

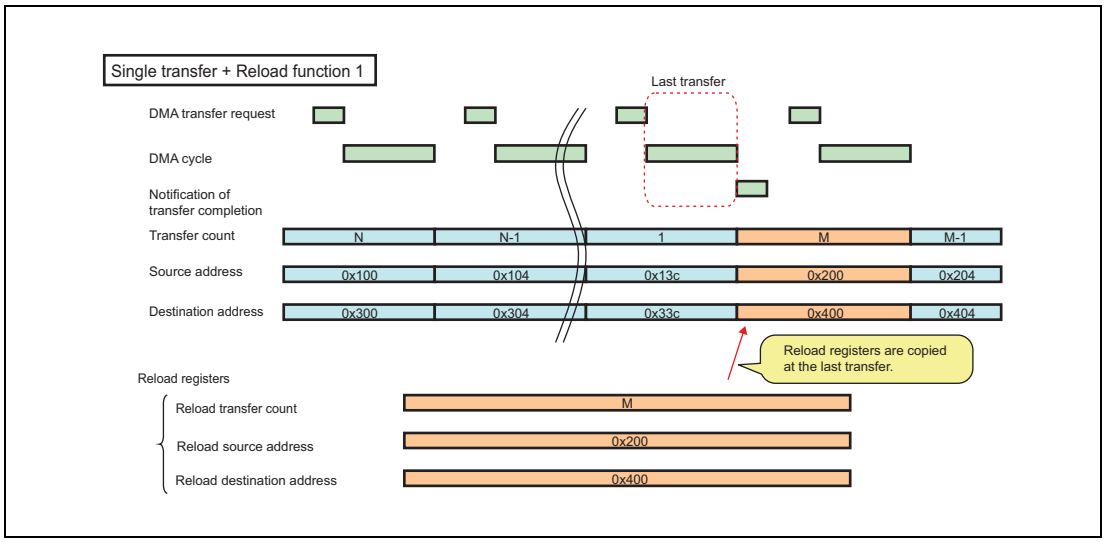

Figure 8.4 Operation of Reload Function 1

8.2.3.3 Reload Function 2

When the reload function 2 is enabled, actions described in **Table 8.4** are executed at the time of the address reload transfer according to the reload function 2 setting.

Table 8.4 Operation of Reload Function 2

Reload Function 2 Setting (DTCTn.RLD2M[1:0])	Register	Action at the Address Reload Transfer
00 (Reload function 2 disabled.)	Source address	Not reloaded.
	Destination address	Not reloaded.
	Address reload count	Not reloaded.
01 (Reload function 2 enabled. Reloading source address.)	Source address	The reload source address is copied to this.
	Destination address	Not reloaded.
	Address reload count	The reload address reload count is copied to this.
10 (Reload function 2 enabled. Reloading destination address.)	Source address	Not reloaded.
	Destination address	The reload destination address is copied to this.
	Address reload count	The reload address reload count is copied to this.
11 (Reload function 2 enabled. Reloading source address and destination address.)	Source address	The reload source address is copied to this.
	Destination address	The reload destination address is copied to this.
	Address reload count	The reload address reload count is copied to this.

Figure 8.5 shows an operation of the reload function 2.

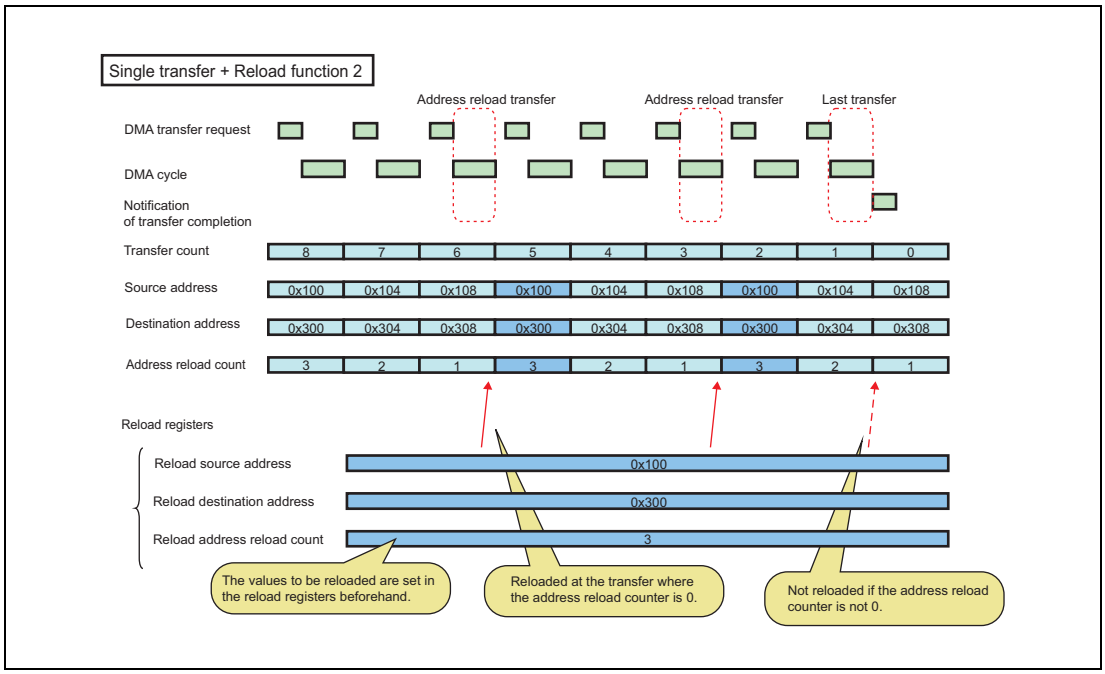

Figure 8.5 Operation of Reload Function 2

Figure 8.6 shows an operation when both the reload function 1 and the reload function 2 are used simultaneously.

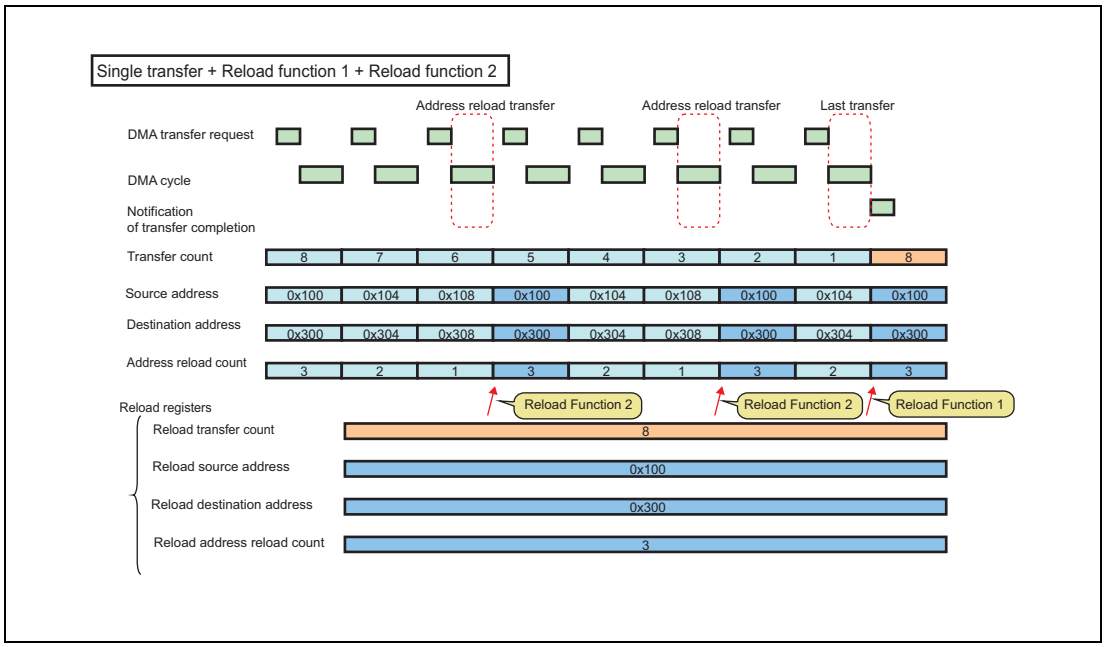

Figure 8.6 Operation when combining the reload function 1 and the reload function 2

8.2.3.4 Timing of Setting DMAC Reload Registers

You can set up the reload source address register, reload destination address register, and reload transfer count register any time (even during DMA transfer). As an exception, if you update the reload source address register, reload destination address register, and reload transfer count register during DMA transfer, there may be a conflict between reloading at the last transfer or address reload transfer and updating the reload register. In order to avoid this conflict, setting of reload registers must be completed before the last transfer or address reload transfer starts.

If you need to update the reload source address register, reload destination address register, and reload transfer count register during DMA transfer, one way to know the right timing to update is to use a DMA transfer count match interrupt. In this case, you must set up the DMA transfer count compare register (DTCCn) so that you can have enough margin for the time necessary to update the reload registers.

8.2.4 Chain Function

8.2.4.1 Overview

DMA offers a function called chain function. If you use the chain function, the completion of the DMA cycle or last transfer for one channel can trigger a DMA transfer request for another channel. A DMA transfer request for another channel initiated by the chain function is called a chain request.

You can select the condition for generating a chain request from the following two options.

- Always chain: A chain request is generated at the completion of every DMA cycle.
- Chain at the last transfer: A chain request is generated at the completion of the last transfer.

Figure 8.7 shows a case of “always chain” operation.

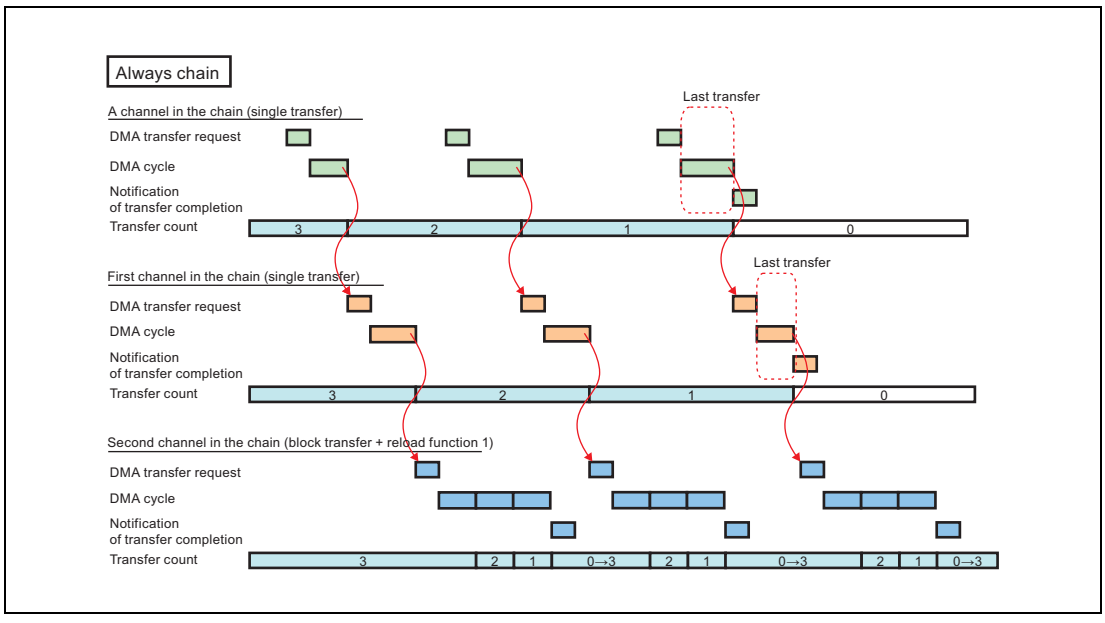

Figure 8.7 Operation of “Always Chain”

Figure 8.8 shows a care of "chain at the last transfer" operation.

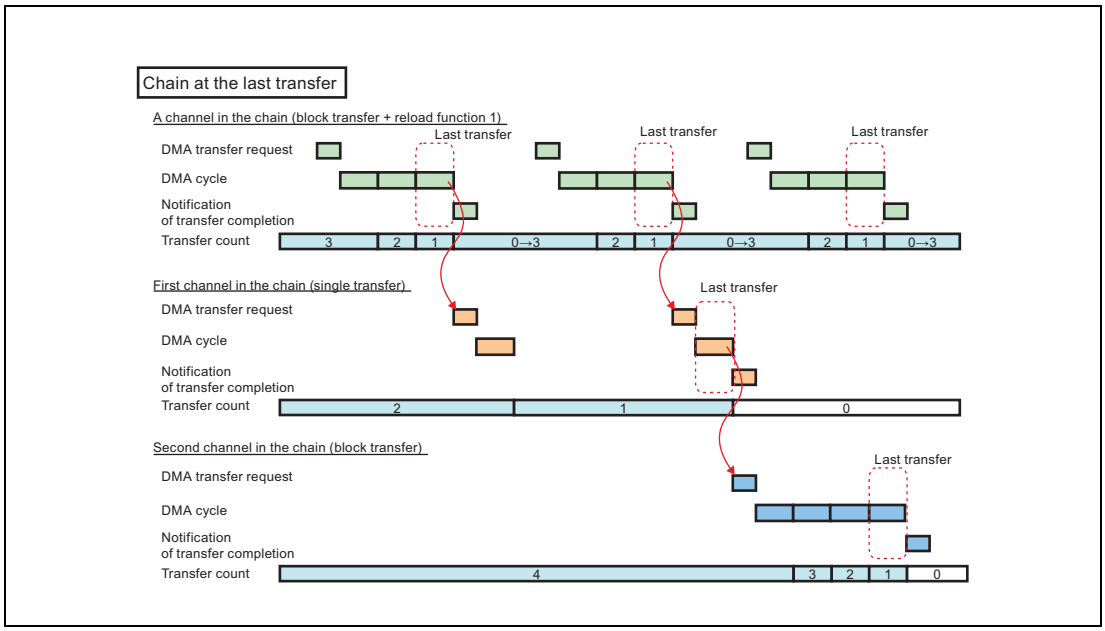

Figure 8.8 Operation of "Chain at the Last Transfer"

8.2.4.2 Setting Up the Chain Function

For a DMAC, you need to write to the chain enable (DTCTn.CHNE[1:0]) and the next channel in the chain selection (DTCTn.CHNSEL[2:0]) in the DMAC transfer control register in order to set up the type of chain function and the next channel number in the chain.

8.2.4.3 Caution for Using the Chain Function

The chain function sets the software DMA transfer request flag of the next channel in the chain as a part of its function. Therefore, you need to set up the channel settings of the next channel in the chain in the same way as when the software DMA transfer request is used. If you specify a channel using the hardware DMA transfer request for the next channel in the chain, the chain function does not work.

A channel and its next channel in the chain must belong to the same module (DMAC0 and DMAC1). You cannot specify a channel in another module for its next channel in the chain.

8.2.5 DMAC Operation

8.2.5.1 Types of DMA Transfer Requests and Assigning DMA Transfer Requests

A DMAC starts DMA transfer by accepting a hardware DMA transfer request or software DMA transfer request. The DMA transfer request selection assignment (DRS) bit in the DMAC transfer control register (DTCTn) determines whether a hardware DMA transfer request or a software DMA transfer request is used.

In the case of a hardware DMA transfer request for a DMAC, one out of 128 hardware DMA transfer sources is selected and assigned for each channel of the DMAC in the DTFR. This assignment is configured in the DTFR setting registers.

8.2.5.2 Generating and Accepting a Software DMA Transfer Request

By setting the software DMA transfer request flag (SR) in the DMAC transfer status register (DCSTn) using the DMAC transfer status set register (DCSTSn), a software DMA transfer request can be generated.

The software DMA transfer request flag is automatically cleared when the DMAC processes the DMA transfer request. The timing at which the software DMA transfer request flag is automatically cleared differs depending on the transfer mode of the DMA transfer to be executed.

- In the single transfer mode, the software DMA transfer request flag is cleared whenever the software DMA transfer request is accepted.
- In the block transfer 1 mode, the software DMA transfer request flag is cleared when the last transfer starts.
- In the block transfer 2 mode, the software DMA transfer request flag is cleared when the last transfer or address reload transfer starts.

The software DMA transfer request flag can also be cleared by software using the DMAC transfer status clear register (DCSTCn). When you abort a DMA transfer of a DMAC channel, you must clear the software DMA transfer request flag.

8.2.5.3 Generating and Accepting a Hardware DMA Transfer Request

Upon detection of a rising edge on the configured DMA transfer source a DMA transfer request is generated, indicated by the hardware DMA transfer request flag DCSTn.DR = 1.

The hardware DMA transfer request flag is automatically cleared when the DMAC processes the DMA transfer request. The timing at which the hardware DMA transfer request flag is automatically cleared differs depending on the transfer mode of the DMA transfer to be executed.

- In the single transfer mode, the hardware DMA transfer request flag is cleared whenever the hardware DMA transfer request is accepted.
- In the block transfer 1 mode, the hardware DMA transfer request flag is cleared when the last transfer starts.
- In the block transfer 2 mode, the hardware DMA transfer request flag is cleared when the address reload transfer starts.

8.2.5.4 Execution time of DMA transfers

A DMA cycle is triggered by the detection of a transfer request (hardware or software). The DMA cycle starts one DMA clock later. The read request is issued 2 DMA clocks later and the read data is provided after the latency time of the read bus has expired. After the read data has been provided in a read response, the DMAC needs two more DMA clock cycles to issue a write request. The whole DMA cycle is completed after expiration of the write latency time.

8.3 Suspension, Resume, Transfer Abort, and Clearing a DMA Transfer Request

8.3.1 DMA Suspension and Resume by Software Control

The DMA control register (DMACTL) is used to suspend DMA transfer for all channels.

When the DMA suspension bit (DMASPD) in the DMA control register is set, DMA puts all channels into the suspended state, If all channels are in the suspended state and the DMA suspension bit (DMASPD) in the DMA control register is cleared, DMA restores all channels from the suspended state to the normal state and resumes the DMA transfer of the suspended channel.

When all channels are put into the suspended state, DMA transfer is suspended for all channels without changing the value of the DTE bit of each DMAC channel.

8.3.2 Suspension, Resume, and Transfer Abort of a DMAC Channel

You can suspend the DMA transfer of a DMAC channel by clearing the channel operation enable bit (DCENn.DTE) in the DMAC channel operation enable setting register for the channel. If a DMA cycle is ongoing, the DMA transfer of a channel is suspended after the currently ongoing DMA cycle is finished. If you set the DTE bit for a channel while the DMA transfer of the channel is suspended, the DMA transfer of the channel is resumed.

If you want to abort the currently ongoing DMA transfer of a DMAC channel, similarly clear the channel operation enable bit (DCENn.DTE) in the DMAC channel operation enable setting register, and then clear the hardware DMA transfer request in the DTFR in the case of a hardware DMA transfer request, and clear the software DMA transfer request flag (DCSTn.SR) using the DMAC transfer request flag clear bit (DCSTCn.SRC) in the DMAC transfer status clear register in the case of a software DMA transfer request.

In case that the continuous transfer enable bit (DTCTn.MLE) is set, the channel operation enable bit (DCENn.DTE) is kept to be set. Even though the channel operation enable bit (DCENn.DTE) is cleared by software during a DMA cycle in a last transfer, the function of the continuous transfer enable bit (DTCTn.MLE) is given high priority and the channel operation enable bit (DCENn.DTE) is set after completion of the last transfer. If you want to abort an ongoing DMA transfer of a DMAC channel when continuous transfer function is enabled, please clear the continuous transfer enable bit (DTCTn.MLE) first and then clear the channel operation enable bit (DCENn.DTE) to abort DMA transfer of the DMAC channel. Only for the operation, DMAC Transfer Control Register (DTCTn) can be written under the channel operation is enabled (DCENn.DTE = 1).

Figure 8.9 shows an example of suspension, resume, and transfer abort of a DMAC channel.

In **Figure 8.9**, both channels 0 and 1 are executing block transfer. At time tick 1, DMA transfer of channel 1 starts. At time tick 2, a DMA transfer request for channel 0 is accepted. As a result of DMAC channel arbitration, DMA transfer of channel 0 starts because channel 0 has a higher priority than channel 1. At time tick 3, the last transfer of channel 0 is complete, and the remaining DMA transfer in the block transfer of channel 1 starts. At time tick 4, the last transfer of channel 1 is complete. After time tick 5, DMA transfer of channel 0 and DMA transfer of channel 1 are executed similarly. At time tick 7, the DMA transfer of channel 0 is suspended and, as a result of DMAC channel arbitration, the DMA transfer of channel 1 starts. At time tick 8, the last transfer of channel 1 is complete, and then, at time tick 9, the DMA transfer of channel 0 resumes. At time tick 10, the last transfer of channel 0 is suspended again, and then, at time tick 11, the DMA transfer of channel 0 is aborted. At time tick 12, the suspended state for channel 0 is cleared, but DMA transfer is not executed because the DMA transfer is aborted at time tick 11.

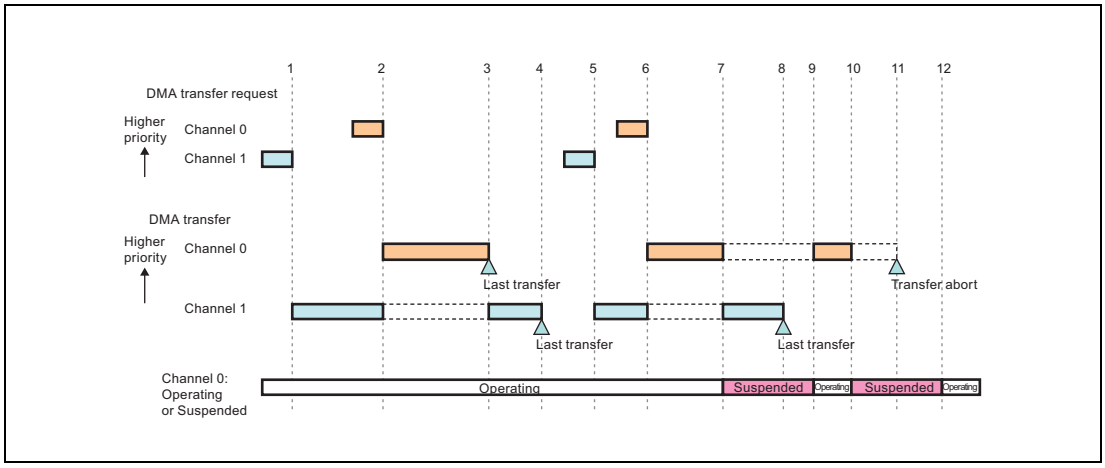

Figure 8.9 Example of Suspension, Resume, and Transfer Abort of a DMAC Channel

8.3.3 Masking and Clearing a Hardware DMA Transfer Request by the DTFR

If a DMAC uses a hardware DMA transfer request, you can temporarily disable (mask) the hardware DMA transfer request output from the DTFR to the DMAC by clearing the hardware DMA transfer source selection enable bit (DTFRn.REQEN) in the DTFR setting register.

Also, if a hardware DMA transfer source is used, you can clear a hardware DMA transfer request retained in the DTFR by using the hardware DMA transfer request clear (DTFRRQCn.DRQC) bit in the DTFR transfer request clear register.

Even if you suspend or abort DMA transfer of a DMAC channel, the hardware DMA transfer request selection/hold circuit of the DTFR is still running, and consequently, the DTFR may retain a hardware DMA transfer request that came to the DTFR during the suspension or transfer abort period of the DMAC channel. When you resume or start DMA transfer of a DMAC channel, clear the hardware DMA transfer request retained in the DTFR as required.

8.3.4 List of Suspend, Resume, and Transfer Abort Functions

Table 8.5 List of Suspend, Resume, and Transfer Abort Functions

Function	How to execute the function	Operation	Possibility of DMA transfer abort	Master that can execute the function (See Section 8.5, Reliability Function.)
DMA suspension and resume by software control	Setting and clearing the DMACTL.DMASPD.	All channels are in the suspended state.	Not possible*1	Special master
Suspension and resume of a DMAC channel	Clearing and setting the DCENn.DTE in each channel register.*2	DMA transfer of a channel is suspended.	Possible (by clearing the DMA transfer request flag during suspension)	Special master, and general master assigned to the channel.

Note 1. In order to abort DMA transfer, you need to abort transfer for the DMAC channel.

Note 2. In case that the continuous transfer enable bit (DTCTm.MLE) is set, please clear (or set) the continuous transfer enable bit (DTCTm.MLE) first.

8.4 Error Control

8.4.1 Type of Error

DMA can generate the following error.

- DMA Transfer Error
  This error is generated when error is detected in the read cycle or write cycle in a DMA cycle.
  This error can be generated in all DMAC channels during execution of DMA transfer.

8.4.2 DMA Transfer Error

When a DMA transfer error occurs, DMA asserts the DMA Transfer Error (INTDMAERR).

8.4.2.1 Operation of a DMAC When DMA Transfer Error Occurs

When DMA transfer error occurs in a DMAC, the transfer error flag (DCSTn.ER) in the DMAC transfer status register of the channel with the DMA transfer error. The DMAC error register (DMACER) shows the transfer error flags of all 16 DMAC channels.

While the transfer error flag of a channel is set, a new DMA cycle is not executed if the transfer error case DMA transfer disable setting (DTCTn.ESE) bit is set. On the other hand, a DMA cycle is executed regardless of the value of the transfer error flag if the transfer error case DMA transfer disable setting (DTCTn.ESE) bit is cleared.

If you want to abort the DMA transfer of a channel with DMA transfer error, follow the procedure to abort DMA transfer of the DMAC channel.

If DMA transfer error occurs during the read cycle of a DMA cycle, the write cycle is not executed. If DMA transfer error occurs during the write cycle of a DMA cycle, the validity of the write is not guaranteed.

Regardless of whether DMA transfer error occurs in the read cycle or write cycle of a DMA cycle, the source address, destination address, transfer count, and address reload count registers are updated.

8.5 Reliability Function

8.5.1 Overview

In this product, DMA offers the following reliability functions.

- Register access protection function
- Master information inherit function

8.5.2 Register Access Protection Function

The register access protection function allows access to the transfer information of each DMA channel from the master assigned to the channel but prohibits access from other masters.

The register access protection function enables you, for example, to prevent the settings of the channel from being read or updated by masters other than the one assigned to the channel.

8.5.2.1 Identifying the Accessing Master

DMA identifies a master based on the ID of the accessing CPU (PEID) and whether the CPU is in the supervisor mode (PSW.UM = 0) or the user mode (PSW.UM = 1).

8.5.2.2 Special Master Access

DMA treats access from the CPU supervisor mode as special master access.

8.5.2.3 General Master Access

DMA treats accesses except special master access as general master access.

In general master access, access to the following registers is allowed.

- The DMACER global registers
- Channel registers of the channels assigned by the channel assignment. (For details, see Section 8.5.2.4, Channel Assignment.)

In general master access, access to registers other than the above is not allowed.

8.5.2.4 Channel Assignment

To each channel, DMA can assign a master so that the master is allowed to use the channel. Channel assignment is configured in the channel master setting register (DMnnCM) by the CPU in the supervisor mode.

In general master access, the master assigned to a channel by channel assignment is allowed to access the channel registers of the channel. If the channel registers of a channel is accessed by a master other than the master assigned to the channel, the access is called illegal access. For information about illegal access, see Section 8.5.2.5, Illegal Access.

8.5.2.5 Illegal Access

DMA handles the following access as illegal access.

(a) General master access to the global registers
Except the DMACER register

(b) General master access to the channel registers of a channel by a master other than the master assigned to the channel

DMA's actions against illegal access are as follows.

For both cases (a) and (b),

- Write access is ignored.
- Read access returns 0 as read data.

Only for case (b),

- The information about the illegal access is stored in a register access protection violation register. The DMAC0 and DMAC1 have their own register access protection violation registers (DM0CMV and DM1CMV respectively).
- A generation of illegal access is notified to ECM.

Only the special master can access the register access protection violation registers. The special master can check whether illegal access has occurred by checking the register access protection violation registers periodically.

In addition, it is recommended that, when a master tries to use DMA and configures transfer information in the channel registers, the master should check whether the configuration has been successfully completed without illegal access by, for example, reading back the settings.

8.5.3 Master Information Inherit Function

In this product, DMA access inherits master information that is equivalent to the master information of the CPU assigned to the DMA channel.

The master information that is output from DMA is as in **Table 8.6**.

Table 8.6 Master Information That Is Output from DMA

Item	Value that is output from DMA
UM	Same as the UM bit value in the channel master setting register
SPID	Same as the SPID[1:0] bit value in the channel master setting register
PEID	Same as the PEID[2:0] bit value in the channel master setting register
DMA access	1

8.5.4 Other Reliability Functions

8.5.4.1 Restriction on the Next Channel in the Chain

The reliability function limits the channels you can select as the next channel in the chain.

When you use the chain function, the channel master settings of a channel and its next channel in the chain must be the same.

The chain function is designed so that a channel and its next channel in the chain are managed by the same master.

When DMA detects that different masters are assigned to a channel and its next channel in the chain, it is deemed illegal and the chain function is suppressed. More specifically, when DMA tries to execute the chain function, DMA compares the chain master settings of the channel and its next channel in the chain, and if the settings are the same for both PEID and UM, the chain function is allowed and a chain request is sent to the next channel. If the settings are not the same for either PEID or UM, a chain request is not sent.

8.6 Setting Up DMA Transfer

8.6.1 Overview of Setting Up DMA

Table 8.7 Channel Assignment

No.	Master that configures the setting	Description	Register		Necessity of the setting
1	Special master (CPU in the supervisor mode)	Overall DMA operation setting	DM00CM to DM07CM, DM10CM to DM17CM	DMAC channel master setting	Mandatory (if a DMAC is used)
2		Status clear	CMVC	Channel protection violation clear register	Recommended
3	Master assigned to the DMAC channel	Channel setting	DSAn	DMAC source address	Mandatory
4			DDAn	DMAC destination address	Mandatory
5			DTCn	DMAC transfer count	Mandatory
6			DTCTn	DMAC transfer control	Mandatory
7			DRSAn	DMAC reload source address	Mandatory if the reload function is used
8			DRDAn	DMAC reload destination address	Mandatory if the reload function is used
9			DRTCn	DMAC reload transfer count	Mandatory if the reload function is used
10			DTCCn	DMAC transfer count compare	Mandatory if the transfer count match interrupt is used
11			DTFRn	DTFR setting register	Mandatory
12		Status clear	DCSTCn	DMAC transfer status clear	Mandatory
13			DTFRRQCn	DTFR transfer request clear	Recommended
14		Channel operation enable	DCENn	DMAC channel operation enable setting	Mandatory

8.6.2 Setting Up the Overall DMA Operation

You need to set up the overall DMA operation before you start using DMA.

To configure the overall DMA operation, the special master (a CPU in the supervisor mode) needs to set up global registers. Global registers can be set up only by special master access. For details, see Section 8.5, Reliability Function.

The following register must be set up to configure the overall DMA operation.

- DMAC channel master setting registers (DMnnCM)

If the DMAC channel master setting registers are not properly set, DMA channel setting and DMA transfer cannot be executed properly.

Also, if errors are detected in the following registers while the overall DMA operation is set up, clearing the errors is recommended.

- DMAC0 register access protection violation register (DM0CMV)
- DMAC1 register access protection violation register (DM1CMV)

8.6.3 Setting Up the DMA Channel Setting

The DMA channel setting defines the transfer information and transfer source for each DMAC channel.

To configure the DMA channel setting, the master assigned to each channel by the channel assignment needs to set up channel registers.

Follow the procedure below to set up the DMAC channel setting and use the DMAC.

(1) Disabling the DMAC Channel Operation

If the channel operation enable (DTE) in the DMAC channel operation enable setting register (DCENn) is set, clear the DTE bit to disable the channel operation.

(2) Setting Up the Transfer Information

When you set up the transfer information of the DMAC, the following registers need to be set up.

- DMAC source address register (DSAn)
- DMAC destination address register (DDAn)
- DMAC transfer count register (DTCn)
- DMAC transfer control register (DTCTn)
- DMAC reload source address register (DRSAn)
- DMAC reload destination address register (DRDAn)
- DMAC reload transfer count register (DRTCn)
- DMAC transfer count compare register (DTCCn)

(3) Setting Up the DMA Transfer Request

While setting the transfer information, you need to set up the DMA transfer request selection assignment (DTCTn.DRS) bit in the DMAC transfer control register (DTCTn) to define whether the hardware or software DMA transfer request is used.

You cannot use both the hardware and software DMA transfer requests for the same channel at the same time.

If you use the hardware DMA transfer request, you need to select one source used as the hardware DMA transfer request out of 128 hardware DMA transfer sources using the hardware DMA transfer source selection (DTFRn.REQSEL[6:0]) in the DTFR setting register. Also, you need to enable the hardware DMA transfer source selection (DTFRn.REQEN) in the same register.

The DTFR may retain a hardware DMA transfer request that came before the hardware DMA transfer source is selected. Clear the hardware DMA transfer request (DTFRRQn.DRQ) retained in the DTFR using the DTFR transfer request clear register (DTFRRQCn) if necessary.

If you use the software DMA transfer request, disable the hardware DMA transfer source selection (DTFRn.REQEN) in the DTFR setting register.

(4) Clearing the Transfer Status

The DMAC transfer status register (DCSTn) may retain the result of the previous DMA transfer. You need to clear the flags in the DMAC transfer status register using the DMAC transfer status clear register (DCSTCn).

(5) Enabling the DMAC Channel Operation

Set the channel operation enable (DCENn.DTE) bit in the DMAC channel operation enable setting register to enable the channel operation.

After the channel operation enable bit is set, the DMAC can accept a DMA transfer request and start DMA transfer.

8.7 DMA Trigger Source

The DMA trigger source ID assignment for DMA channel n is set in the DTFR setting register (DTFRn).

Table 8.8 List of DMA Trigger Sources (1/4)

DMA trigger ID	DMA trigger factor	Module	DMA Trigger Source
0	INTP0	Port	External interrupts
1	INTP1		
2	INTP2		
3	INTP3		
4	INTP4		
5	INTP5		
6	INTP6		
7	INTP7		
8	INTP8		
9	INTP9		
10	INTP10		
11	Reserved	–	–
12	INTLCBI0RDY	LCBI0	Read data ready interrupt
13	INTLCBI0EMPTY		Write buffer empty interrupt
14	INTLCBI0HALF		Write buffer half full interrupt
15	INTLCBI0FULL		Write buffer full interrupt
16	INTLCBI0QTR		Write buffer quarter full interrupt
17	INTLCBI03QTR		Write buffer three quarters full interrupt

Table 8.8 List of DMA Trigger Sources (2/4)

DMA trigger ID	DMA trigger factor	Module	DMA Trigger Source
18	INTPWGA0	PWGA	PWM Generator 0 interrupt
19	INTPWGA1		PWM Generator 1 interrupt
20	INTPWGA2		PWM Generator 2 interrupt
21	INTPWGA3		PWM Generator 3 interrupt
22	INTPWGA4		PWM Generator 4 interrupt
23	INTPWGA5		PWM Generator 5 interrupt
24	INTPWGA6		PWM Generator 6 interrupt
25	INTPWGA7		PWM Generator 7 interrupt
26	INTPWGA8		PWM Generator 8 interrupt

8.8 Global Register

CAUTION

The DMA global registers are not accessible per default as these registers are guarded by the PBUS Guard PBG0B.

Before accessing any DMA global register the PBG0B protection register FSGD0BPROT1 has to be set to 07FF FFFF$_H$.

See Section 14.6.4, PBUS Guards (PBG) for further details.

8.8.1 List of Global Register Addresses

Address = Base address "FFFF 8000$_H$" + Offset address

Table 8.9 List of Global Register Addresses

Module Name	Offset Address	Symbol	Meaning	Access	
				Special Master	General Master
PDMA	0000$_H$	DMACTL	DMA control register	Allowed	Not allowed
PDMA	0020$_H$	DMACER	DMAC error register	Allowed	Allowed
PDMA	0030$_H$	DM0CMV	DMAC0 register access protection violation register	Allowed	Not allowed
PDMA	0034$_H$	DM1CMV	DMAC1 register access protection violation	Allowed	Not allowed
PDMA	003C$_H$	CMVC	Register access protection violation clear register	Allowed	Not allowed
PDMA	0100$_H$	DM00CM	DMAC0 channel 0 channel master setting	Allowed	Not allowed
PDMA	0104$_H$	DM01CM	DMAC0 channel 1 channel master setting	Allowed	Not allowed
PDMA	0108$_H$	DM02CM	DMAC0 channel 2 channel master setting	Allowed	Not allowed
PDMA	010C$_H$	DM03CM	DMAC0 channel 3 channel master setting	Allowed	Not allowed
PDMA	0110$_H$	DM04CM	DMAC0 channel 4 channel master setting	Allowed	Not allowed
PDMA	0114$_H$	DM05CM	DMAC0 channel 5 channel master setting	Allowed	Not allowed
PDMA	0118$_H$	DM06CM	DMAC0 channel 6 channel master setting	Allowed	Not allowed
PDMA	011C$_H$	DM07CM	DMAC0 channel 7 channel master setting	Allowed	Not allowed
PDMA	0120$_H$	DM10CM	DMAC1 channel 0 channel master setting	Allowed	Not allowed
PDMA	0124$_H$	DM11CM	DMAC1 channel 1 channel master setting	Allowed	Not allowed
PDMA	0128$_H$	DM12CM	DMAC1 channel 2 channel master setting	Allowed	Not allowed
PDMA	012C$_H$	DM13CM	DMAC1 channel 3 channel master setting	Allowed	Not allowed
PDMA	0130$_H$	DM14CM	DMAC1 channel 4 channel master setting	Allowed	Not allowed
PDMA	0134$_H$	DM15CM	DMAC1 channel 5 channel master setting	Allowed	Not allowed
PDMA	0138$_H$	DM16CM	DMAC1 channel 6 channel master setting	Allowed	Not allowed
PDMA	013C$_H$	DM17CM	DMAC1 channel 7 channel master setting	Allowed	Not allowed

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> and <Symbol> are defined in the above table.

8.8.2 Details of Global Registers

8.8.2.1 DMA Control Register (DMACTL)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8000_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMA SPD
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 8.10 DMACTL register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the initial value is read. When written, write the initial value.
0	DMASPD	DMA suspension This bit shows whether DMA transfer for all channels is suspended. If a user writes 1 to this bit, DMA transfer for all channels can be suspended. If a user writes 0 to this bit, suspension of DMA transfer for all channels can be cleared. The suspension controlled by this bit is independent from the suspension controlled by the transfer enable bit (DTE) of each DMAC channel. That means, if this bit is 1, all DMA transfers are suspended regardless of the values of the DTE bit of each channel. Writing to this bit does not affect the DTE bit of each channel. 0: DMA suspension cleared 1: DMA suspension request/DMA suspension ongoing

8.8.2.2 DMAC Error Register (DMACER)

Access: This register can be read in 32-bit units.

Address: FFFF 8020_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DM1 ER7	DM1 ER6	DM1 ER5	DM1 ER4	DM1 ER3	DM1 ER2	DM1 ER1	DM1 ER0	DM0 ER7	DM0 ER6	DM0 ER5	DM0 ER4	DM0 ER3	DM0 ER2	DM0 ER1	DM0 ER0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 8.11 DMACER register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the initial value is read. When written, write the initial value.
15 to 8	DM1ER[7:0]	DMAC1 DMA transfer error status These bits show the DMA transfer error status of channels 0 through 7 of the DMAC1. Each bit is mapped from the DCSTn.ER bit of each channel of the DMAC1 and is read-only. 0: DMA transfer error is not generated 1: DMA transfer error is generated
7 to 0	DM0ER[7:0]	DMAC0 DMA transfer error status These bits show the DMA transfer error status of channels 0 through 7 of the DMAC0. Each bit is mapped from the DCSTn.ER bit of each channel of the DMAC0 and is read-only. 0: DMA transfer error is not generated 1: DMA transfer error is generated

8.8.2.3 DMAC0 Register Access Protection Violation Register (DM0CMV)

Access: This register can be read in 32-bit units.

Address: FFFF 8030_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	MINF[6:4]			MINF[3:2]		MINF1	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	VCH2	VCH1	VCH0	—	—	—	VF
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 8.12 DM0CMV register contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the initial value is read. When written, write the initial value.
22 to 17	MINF[6:1]	Illegal access master information These bits show the accessing master information of the first illegal access after the VF bit is cleared to 0. If illegal access occurs while the VF bit is 1, these bits do not change. These bits are read-only and cannot be cleared. MINF6-4 retains the PEID of the accessing master, MINF3-2 retains the SPID of the accessing master, and MINF1 retains the UM of the accessing master.
16 to 7	Reserved	When read, the initial value is read. When written, write the initial value.
6 to 4	VCH[2:0]	Illegal access channel These bits show the channel number (0-7) of the first illegal access after the VF bit is cleared to 0. If illegal access occurs while the VF bit is 1, these bits do not change. These bits are read-only and cannot be cleared.
3 to 1	Reserved	When read, the initial value is read. When written, write the initial value.
0	VF	Illegal access flag This bit shows whether illegal access occurs in the DMAC0. 0: No illegal access has occurred in the DMAC0 1: Illegal access has occurred in the DMAC0 If illegal access occurs in the DMAC0 while this bit is 0, this bit is set, and MINF6 to 1 and VCH2 to 0 store their respective information. If illegal access occurs in the DMAC0 while this bit is 1, this bit remains 1, and MINF6 to 1 and VCH2 to 0 do not change. This bit can be cleared by using the CMVC register.

8.8.2.4 DMAC1 Register Access Protection Violation Register (DM1CMV)

Access: This register can be read in 32-bit units.

Address: FFFF 8034_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	MINF[6:4]			MINF[3:2]		MINF1	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	VCH2	VCH1	VCH0	—	—	—	VF
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 8.13 DM1CMV register contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the initial value is read. When written, write the initial value.
22 to 17	MINF[6:1]	Illegal access master information These bits show the accessing master information of the first illegal access after the VF bit is cleared to 0. If illegal access occurs while the VF bit is 1, these bits do not change. These bits are read-only and cannot be cleared. MINF6-4 retains the PEID of the accessing master, MINF3-2 retains the SPID of the accessing master, and MINF1 retains the UM of the accessing master.
16 to 7	Reserved	When read, the initial value is read. When written, write the initial value.
6 to 4	VCH[2:0]	Illegal access channel These bits show the channel number (0-7) of the first illegal access after the VF bit is cleared to 0. If illegal access occurs while the VF bit is 1, these bits do not change. These bits are read-only and cannot be cleared.
3 to 1	Reserved	When read, the initial value is read. When written, write the initial value.
0	VF	Illegal access flag This bit shows whether illegal access occurs in the DMAC1. 0: No illegal access has occurred in the DMAC1 1: Illegal access has occurred in the DMAC1 If illegal access occurs in the DMAC1 while this bit is 0, this bit is set, and MINF 6 to 1 and VCH2 to 0 store their respective information. If illegal access occurs in the DMAC1 while this bit is 1, this bit remains 1, and MINF6 to 1 and VCH2 to 0 do not change. This bit can be cleared by using the CMVC register.

8.8.2.5 Register Access Protection Violation Clear Register (CMVC)

Access: This register can be read/written in 32-bit units.

Address: FFFF 803C$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DM1VC	DM0VC
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 8.14 CMVC register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the initial value is read. When written, write the initial value.
1	DM1VC	DMAC1 illegal access flag clear The DMAC1 illegal access flag (DM1CMV.VF) can be cleared by writing 1 to this bit. The read value of this bit is always 0.
0	DM0VC	DMAC0 illegal access flag clear The DMAC0 illegal access flag (DM0CMV.VF) can be cleared by writing 1 to this bit. The read value of this bit is always 0.

8.8.2.6 DMAC Channel Master Setting (DMnnCM) (nn = 00 - 07, 10 - 17)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8100_H + 4 × Ch. No. n (n = 0 to 7)
FFFF 8120_H + 4 × Ch. No. n - 10 (n = 10 to 17)

Initial value: 0000 0010_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	PEID2	PEID1	PEID0	SPID1	SPID0	UM	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 8.15 DMnnCM register contents

Bit Position	Bit Name	Function ion
31 to 7	Reserved	When read, the initial value is read. When written, write the initial value.
6 to 4	PEID[2:0]	Channel master PEID setting Specifies the PEID information of the master assigned to the channel. This register must be set to a value other than 0.
3, 2	SPID[1:0]	Channel master SPID setting Specifies the SPID information used by the master assigned to the channel.
1	UM	Channel master UM setting Specifies the UM information of the master assigned to the channel.
0	Reserved	When read, the initial value is read. When written, write the initial value.

CAUTION

DM00CM - DM07CM configure the channel master information of the DMAC0 channel 0-7 respectively.
DM10CM - DM17CM configure the channel master information of the DMAC1 channel 0-7 respectively.

For information about the functions this register offers, see Section 8.5, Reliability Function.

8.9 DMAC Channel Register

CAUTION

The DMA channel registers are not accessible per default as these registers are guarded by the PBUS Guard PBG0B.

Before accessing any DMA channel register the PBG0B protection register FSGD0BPROT1 has to be set to 07FF FFFF$_H$.

See Section 14.6.4, PBUS Guards (PBG) for further details.

8.9.1 DMAC Channel Register Address

Address = Base address "FFFF 8000$_H$" + Offset address

Table 8.16 DMAC Channel Register Address

Module Name	Offset Address	Symbol	Meaning	Access	
				Special Master	General Master
PDMA	0400$_H$ + 40$_H$ × [channel number]	DSAn	DMAC source address	Allowed	Allowed
PDMA	0404$_H$ + 40$_H$ × [channel number]	DDAn	DMAC destination address	Allowed	Allowed
PDMA	0408$_H$ + 40$_H$ × [channel number]	DTCn	DMAC transfer count	Allowed	Allowed
PDMA	040C$_H$ + 40$_H$ × [channel number]	DTCTn	DMAC transfer control	Allowed	Allowed
PDMA	0410$_H$ + 40$_H$ × [channel number]	DRSAn	DMAC reload source address	Allowed	Allowed
PDMA	0414$_H$ + 40$_H$ × [channel number]	DRDAn	DMAC reload destination address	Allowed	Allowed
PDMA	0418$_H$ + 40$_H$ × [channel number]	DRTCn	DMAC reload transfer count	Allowed	Allowed
PDMA	041C$_H$ + 40$_H$ × [channel number]	DTCCn	DMAC transfer count compare	Allowed	Allowed
PDMA	0420$_H$ + 40$_H$ × [channel number]	DCENn	DMAC channel operation enable setting	Allowed	Allowed
PDMA	0424$_H$ + 40$_H$ × [channel number]	DCSTn	DMAC transfer status	Allowed	Allowed
PDMA	0428$_H$ + 40$_H$ × [channel number]	DCSTSn	DMAC transfer status set	Allowed	Allowed
PDMA	042C$_H$ + 40$_H$ × [channel number]	DCSTCn	DMAC transfer status clear	Allowed	Allowed
PDMA	0430$_H$ + 40$_H$ × [channel number]	DTFRn	DTFR setting	Allowed	Allowed
PDMA	0434$_H$ + 40$_H$ × [channel number]	DTFRRQn	DTFR transfer request status	Allowed	Allowed
PDMA	0438$_H$ + 40$_H$ × [channel number]	DTFRRQCn	DTFR transfer request clear	Allowed	Allowed

Note 1. The [channel number] in the offset addresses and "n" in the register symbols are numbers in the range from 0 to 15, and the correspondence between the channel number n and the channel is as follows.

Channel number n	Channel
0	DMAC0 channel 0
1	DMAC0 channel 1
2	DMAC0 channel 2
3	DMAC0 channel 3
4	DMAC0 channel 4
5	DMAC0 channel 5
6	DMAC0 channel 6
7	DMAC0 channel 7
8	DMAC1 channel 0
9	DMAC1 channel 1
10	DMAC1 channel 2

Channel number n	Channel
11	DMAC1 channel 3
12	DMAC1 channel 4
13	DMAC1 channel 5
14	DMAC1 channel 6
15	DMAC1 channel 7

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> and <Symbol> are defined in the above table.

8.9.2 Details of DMAC Channel Registers

The “n” in the register symbols indicates the DMAC channel number (n = 0 to 15).

8.9.2.1 DMAC Source Address Register (DSAn)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8400_H + 40_H × Ch. No. n (n = 0 to 15)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SA31	SA30	SA29	SA28	SA27	SA26	SA25	SA24	SA23	SA22	SA21	SA20	SA19	SA18	SA17	SA16
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SA15	SA14	SA13	SA12	SA11	SA10	SA9	SA8	SA7	SA6	SA5	SA4	SA3	SA2	SA1	SA0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8.17 DSAn register contents

Bit Position	Bit Name	Function
31 to 0	SA[31:0]	Source address Specifies the DMA transfer source address. Those bits are updated whenever a DMA cycle is executed. If you read from those bits, the transfer source address for the next DMA cycle is read.

CAUTIONS

1. It is forbidden to write to those bits when the channel operation is enabled (DTE bit = 1). If you do, the correct operation is not guaranteed.
2. The address must be set up while the DTE bit is 0.
3. DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (× denotes an arbitrary one bit.)
   The correct operation is not guaranteed if you select any other setting.

Data Size	SA3	SA2	SA1	SA0
8 bits	×	×	×	×
16 bits	×	×	×	0
32 bits	×	×	0	0
64 bits	×	0	0	0
128 bits	0	0	0	0

8.9.2.2 DMAC Destination Address Register (DDAn)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8404_H + 40_H × Ch. No. n (n = 0 to 15)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DA31	DA30	DA29	DA28	DA27	DA26	DA25	DA24	DA23	DA22	DA21	DA20	DA19	DA18	DA17	DA16
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DA15	DA14	DA13	DA12	DA11	DA10	DA9	DA8	DA7	DA6	DA5	DA4	DA3	DA2	DA1	DA0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8.18 DDAn register contents

Bit Position	Bit Name	Function
31 to 0	DA[31:0]	Destination address Specifies the DMA transfer destination address. Those bits are updated whenever a DMA cycle is executed. If you read from those bits, the transfer destination address for the next DMA cycle is read.

CAUTIONS

1. It is forbidden to write to those bits when the channel operation is enabled (DTE bit = 1). If you do, the correct operation is not guaranteed.
2. The address must be set up while the DTE bit is 0.
3. If transfer error is generated in the read cycle of DMA transfer, the write cycle is not executed, but the destination address is updated.
4. DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (× denotes an arbitrary one bit.)
   The correct operation is not guaranteed if you select any other setting.

Data Size	DA3	DA2	DA1	DA0
8 bits	×	×	×	×
16 bits	×	×	×	0
32 bits	×	×	0	0
64 bits	×	0	0	0
128 bits	0	0	0	0

8.9.2.3 DMAC Transfer Count Register (DTCn)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8408_H + 40_H × Ch. No. n (n = 0 to 15)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ARC15	ARC14	ARC13	ARC12	ARC11	ARC10	ARC9	ARC8	ARC7	ARC6	ARC5	ARC4	ARC3	ARC2	ARC1	ARC0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TRC15	TRC14	TRC13	TRC12	TRC11	TRC10	TRC9	TRC8	TRC7	TRC6	TRC5	TRC4	TRC3	TRC2	TRC1	TRC0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8.19 DTCn register contents

Bit Position	Bit Name	Function
31 to 16	ARC[15:0]	Address reload count Specifies the number of transfers until the address reload when the reload function 2 is used, and also specifies the number of transfers when the block transfer 2 is used. If you read from those bits during DMA transfer, the address reload count for the next DMA cycle is read. When the reload function 2 or block transfer 2 is used, ARC[15:0] is decremented by one for every DMA cycle. When the reload function 2 or block transfer 2 is not used, ARC[15:0] is not updated. If the value is 0000_H, it means that the number of transfers until the address reload when the reload function 2 is used and the number of transfers when the block transfer 2 is used are 65536.
15 to 0	TRC[15:0]	Transfer count Configures the number of transfers. TRC[15:0] is decremented by one whenever a DMA cycle is executed. If you read from those bits, the remaining number of transfers for the next DMA cycle is read. If the reload function is not used, after the last transfer is complete, the value at the completion (0000_H) is retained.

TRC15-0	Operation
0000_H	The number of transfers is 65536, or the transfer is complete.
0001_H	The number of transfers or remaining transfers is 1.
:	:
$FFFF_H$	The number of transfers or remaining transfers is 65535.

CAUTIONS

1. It is forbidden to write to those bits when the channel operation is enabled (DTE bit = 1). If you do, the correct operation is not guaranteed.
2. If transfer error is generated in the read cycle of DMA transfer, the write cycle is not executed, but the transfer count and the address reload count are updated.

8.9.2.4 DMAC Transfer Control Register (DTCTn)

Access: This register can be read/written in 32-bit units.

Address: FFFF 840C$_H$ + 40$_H$ × Ch. No. n (n = 0 to 15)

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	ESE	DRS	—	—	—	—	—	CHNSEL2	CHNSEL1	CHNSEL0	CHNE1	CHNE0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8.20 DTCTn register contents (1/3)

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the initial value is read. When written, write the initial value.
27	ESE	Transfer error case DMA transfer disable setting Configures whether a DMA cycle is executed when the DCSTn.ER bit is set due to DMA transfer error. If this bit is cleared to 0, even when the DCSTn.ER bit is set due to DMA transfer error, the following DMA cycles can be executed. If this bit is set to 1, the following DMA cycles are not executed when the DCSTn.ER bit is set due to DMA transfer error. 0: DMA cycles are executed while the DCSTn.ER bit is set. 1: DMA cycles are not executed while the DCSTn.ER bit is set.
26	DRS	DMA transfer request selection assignment Selects the type of DMA transfer requests to be accepted. 0: Software DMA transfer request 1: Hardware DMA transfer request
25 to 21	Reserved	When read, the initial value is read. When written, write the initial value.
20 to 18	CHNSEL[2:0]	Next channel in the chain Specifies the next channel in the chain. The next channel must be another channel in the same DMAC. You cannot specify a channel in the different DMAC. You cannot specify the same channel for the next channel. (If you do, the correct operation is not guaranteed.)
17, 16	CHNE[1:0]	Chain enable Selects the chain function. 00: Disabled 01: Chain at the last transfer A chain request is generated at the completion of the DMA cycle in which the remaining transfer count is one. 10: (Forbidden. No guarantee of operation) 11: Always chain A chain request is generated at the completion of every DMA cycle.
15	CCE	Transfer count match interrupt enable If this bit is set, a transfer count match interrupt is generated at the completion of the DMA cycle in which the transfer count compare register and the remaining transfer count have the same value.
14	TCE	Transfer completion interrupt enable If this bit is set, a transfer completion interrupt is generated at the completion of the last transfer. A transfer completion notification interrupt is also generated at the completion of the last transfer when DCSTn.TC = 1.

Table 8.20 DTCTn register contents (2/3)

Bit Position	Bit Name	Function
13	MLE	Continuous transfer enable If this bit is set, the DTE bit is not cleared at the completion of DMA transfer. In addition, even if the TC bit is not cleared, DMA transfer starts when there is a DMA transfer request. 0: The DTE bit is cleared at the completion of DMA transfer. In addition, the next DMA transfer can start only after the TC bit is cleared. 1: The DTE bit is not cleared at the completion of DMA transfer. In addition, even if the TC bit is not cleared, DMA transfer starts when there is a DMA transfer request.
12, 11	RLD2M[1:0]	Reload function 2 setting Configures the reload function 2. 00: Reload function 2 is disabled. 01: Reload function 2 is enabled. The source address and address reload count are reloaded at the completion of the DMA cycle in which the address reload count is 1. 10: Reload function 2 is enabled. The destination address and address reload count are reloaded at the completion of the DMA cycle in which the address reload count is 1. 11: Reload function 2 is enabled. The source address, destination address, and address reload count are reloaded at the completion of the DMA cycle in which the address reload count is 1.
10, 9	RLD1M[1:0]	Reload function 1 setting Configures the reload function 1. 00: Reload function 1 is disabled. 01: Reload function 1 is enabled. The source address and transfer count are reloaded at the completion of the DMA cycle in which the remaining transfer count is 1. (If the reload function 2 is enabled, the address reload count is also reloaded.) 10: Reload function 1 is enabled. The destination address and transfer count are reloaded at the completion of the DMA cycle in which the remaining transfer count is 1. (If the reload function 2 is enabled, the address reload count is also reloaded.) 11: Reload function 1 is enabled. The source address, destination address, and transfer count are reloaded at the completion of the DMA cycle in which the remaining transfer count is 1. (If the reload function 2 is enabled, the address reload count is also reloaded.)
8, 7	DACM[1:0]	Destination address count direction Specifies the count direction of the destination address.

DACM1	DACM0	Direction of Count
0	0	Increment
0	1	Decrement
1	0	Fixed
1	1	Forbidden (No guarantee of operation)

6, 5	SACM[1:0]	Source address count direction Specifies the count direction of the source address.

SACM1	SACM0	Direction of Count
0	0	Increment
0	1	Decrement
1	0	Fixed
1	1	Forbidden (No guarantee of operation)

Table 8.20 DTCTn register contents (3/3)

Bit Position	Bit Name	Function
4 to 2	DS[2:0]	Transfer data size Specifies the transfer data size.
1, 0	TRM[1:0]	Transfer mode Specifies the DMA transfer mode. 00: Single transfer 01: Block transfer 1 (The number of transfers is specified by the transfer count.) 10: Block transfer 2 (The number of transfers is specified by the address reload count.) 11: Forbidden (No guarantee of operation)

DS2	DS1	DS0	Transfer Data Size
0	0	0	8 bits
0	0	1	16 bits
0	1	0	32 bits
0	1	1	64 bits
1	0	0	128 bits
Other than the above			Forbidden (No guarantee of operation)

CAUTIONS

1. It is forbidden to write to those bits when the channel operation is enabled (DTE bit = 1), only MLE bit can be changed '1' to '0'. (If other setting done, the correct operation is not guaranteed.)
2. If forbidden settings are used for some of the bits, the correct operation is not guaranteed.

8.9.2.5 DMAC Reload Source Address Register (DRSAn)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8410_H + 40_H × Ch. No. n (n = 0 to 15)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RSA31	RSA30	RSA29	RSA28	RSA27	RSA26	RSA25	RSA24	RSA23	RSA22	RSA21	RSA20	RSA19	RSA18	RSA17	RSA16
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RSA15	RSA14	RSA13	RSA12	RSA11	RSA10	RSA9	RSA8	RSA7	RSA6	RSA5	RSA4	RSA3	RSA2	RSA1	RSA0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8.21 DRSAn register contents

Bit Position	Bit Name	Function
31 to 0	RSA[31:0]	Reload source address Specifies the source address to be reloaded to the DMA source address register when the reload function 1 or reload function 2 is used.

CAUTION

DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (× denotes an arbitrary one bit.) The correct operation is not guaranteed if you select any other setting.

Data Size	RSA3	RSA2	RSA1	RSA0
8 bits	×	×	×	×
16 bits	×	×	×	0
32 bits	×	×	0	0
64 bits	×	0	0	0
128 bits	0	0	0	0

8.9.2.6 DMAC Reload Destination Address Register (DRDAn)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8414_H + 40_H × Ch. No. n (n = 0 to 15)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RDA31	RDA30	RDA29	RDA28	RDA27	RDA26	RDA25	RDA24	RDA23	RDA22	RDA21	RDA20	RDA19	RDA18	RDA17	RDA16
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RDA15	RDA14	RDA13	RDA12	RDA11	RDA10	RDA9	RDA8	RDA7	RDA6	RDA5	RDA4	RDA3	RDA2	RDA1	RDA0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8.22 DRDAn register contents

Bit Position	Bit Name	Function
31 to 0	RDA[31:0]	Reload destination address Specifies the destination address to be reloaded to the DMA destination address register when the reload function 1 or reload function 2 is used.

CAUTION

DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (× denotes an arbitrary one bit.) The correct operation is not guaranteed if you select any other setting.

Data Size	RDA3	RDA2	RDA1	RDA0
8 bits	×	×	×	×
16 bits	×	×	×	0
32 bits	×	×	0	0
64 bits	×	0	0	0
128 bits	0	0	0	0

8.9.2.7 DMAC Reload Transfer Count Register (DRTCn)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8418_H + 40_H × Ch. No. n (n = 0 to 15)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RARC15	RARC14	RARC13	RARC12	RARC11	RARC10	RARC9	RARC8	RARC7	RARC6	RARC5	RARC4	RARC3	RARC2	RARC1	RARC0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RTRC15	RTRC14	RTRC13	RTRC12	RTRC11	RTRC10	RTRC9	RTRC8	RTRC7	RTRC6	RTRC5	RTRC4	RTRC3	RTRC2	RTRC1	RTRC0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8.23 DRTCn register contents

Bit Position	Bit Name	Function
31 to 16	RARC[15:0]	Reload address reload count Specifies the value to be loaded to the address reload count in the transfer count register at the time of reload when the reload function 2 is used.
15 to 0	RTRC[15:0]	Reload transfer count Specifies the value to be loaded to the transfer count in the transfer count register at the time of reload when the reload function 1 or reload function 2 is used.

8.9.2.8 DMAC Transfer Count Compare Register (DTCCn)

Access: This register can be read/written in 32-bit units.

Address: FFFF 841C$_H$ + 40$_H$ × Ch. No. n (n = 0 to 15)

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMC15	CMC14	CMC13	CMC12	CMC11	CMC10	CMC9	CMC8	CMC7	CMC6	CMC5	CMC4	CMC3	CMC2	CMC1	CMC0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8.24 DTCCn register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the initial value is read. When written, write the initial value.
15 to 0	CMC[15:0]	Transfer count compare Configures the transfer count to be compared to the transfer count register. At the completion of the DMA cycle in which the remaining transfer count is the same as the value in this register, the transfer count match flag (DCSTn.CC) in the DMAC transfer status register is set. Furthermore, if the transfer count match interrupt enable (DTCTn.CCE) bit is 1, a transfer count match interrupt is generated. If 0000$_H$ is set, comparison with the transfer count is disabled. In this case, the transfer count match flag in the DMAC transfer status register is never set, and a transfer count match interrupt is never generated.

CAUTION

It is forbidden to write to those bits when the channel operation is enabled (DTE bit = 1). If you do, the correct operation is not guaranteed.

8.9.2.9 DMAC Channel Operation Enable Setting Register (DCENn)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8420_H + 40_H × Ch. No. n (n = 0 to 15)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DTE
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 8.25 DCENn register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the initial value is read. When written, write the initial value.
0	DTE	Channel operation enable Specifies whether to enable or disable the transfer operation of the channel. If the DTE bit is 1, DMA transfer starts when there is a DMA transfer request. If the MLE bit is 0, the DTE bit is cleared automatically at the completion of the DMA transfer. In addition, if 0 is written to the DTE bit during DMA transfer, the DMA transfer is suspended. If 1 is written to the DTE bit during suspension, the suspension is cleared and the DMA transfer resumes. 0: Channel operation is disabled/Channel suspended 1: Channel operation is enabled/Channel suspension cleared

8.9.2.10 DMAC Transfer Status Register (DCSTn)

Access: This register can be read in 32-bit units.

Address: FFFF 8424_H + 40_H × Ch. No. n (n = 0 to 15)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	ERWR	—	—	CY	ER	—	CC	TC	—	—	DR	SR
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 8.26 DCSTn register contents (1/2)

Bit Position	Bit Name	Function
31 to 12	Reserved	When read, the initial value is read. When written, write the initial value.
11	ERWR	DMA Transfer Error occurring cycle This bit is updated at the same time as setting of the DMA transfer error flag (ER), indicating which cycle of read or write the DMA transfer error occurs in. This bit is not updated when a new DMA transfer error occurs after the ER bit has been set. If the ER bit is cleared, this bit is also cleared to 0. 0: DMA transfer error occurs in read cycle. 1: DMA transfer error occurs in write cycle.
10, 9	Reserved	When read, the initial value is read. When written, write the initial value.
8	CY	DMA cycle execution state This bit shows whether a DMA cycle is ongoing in this channel. 0: DMA cycle is not ongoing. 1: DMA cycle is ongoing.
7	ER	Transfer error flag This bit is set when DMA transfer error is generated. If this bit is 1 and the DTCTn.ESE bit is set, a DMA cycle is not executed when a DMA transfer request is generated. 0: No DMA transfer error is generated 1: DMA transfer error is generated
6	Reserved	When read, the initial value is read. When written, write the initial value.
5	CC	Transfer count match flag This bit is set at the completion of the DMA cycle in which the remaining transfer count is the same as the value set in the transfer compare register. 0: No compare match has occurred with the transfer count compare register. 1: Compare match has occurred with the transfer count compare register.
4	TC	Transfer completion flag This bit is set at the completion of the last transfer and shows whether the DMA transfer is complete. If the MLE bit is 0 and this bit is 1, a DMA cycle is not executed when a DMA transfer request is generated. 0: DMA transfer incomplete 1: DMA transfer complete
3, 2	Reserved	When read, the initial value is read. When written, write the initial value.

Table 8.26 DCSTn register contents (2/2)

Bit Position	Bit Name	Function
1	DR	Hardware DMA transfer request status This bit shows whether there is a hardware DMA transfer request (DMARQ) from the DTFR. This bit changes regardless of the value of the DTE bit when a hardware DMA transfer request from the DTFR is generated. If the software DMA transfer request is selected by the transfer request selection bit (DRS) in the DMAC transfer control register, this bit is not set even when a hardware DMA transfer request is input from the DTFR. 0: There is no hardware DMA transfer request 1: There is a hardware DMA transfer request
0	SR	Software DMA transfer request flag This bit shows whether there is a software DMA transfer request (DMARQ). This bit is automatically cleared at the completion of the last transfer. A user can set this bit by writing 1 to the SRS bit in the DMAC transfer status set register. In addition, a user can clear this bit by writing 1 to the SRC bit in the DMAC transfer status clear register, but if this is done, the ongoing DMA transfer is aborted and cannot be resumed. 0: There is no software DMA transfer request 1: There is a software DMA transfer request

8.9.2.11 DMAC Transfer Status Set Register (DCSTSn)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8428_H + 40_H × Ch. No. n (n = 0 to 15)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SRS
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 8.27 DCSTSn Set register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the initial value is read. When written, write the initial value.
0	SRS	Software DMA transfer request flag A user can set the software DMA transfer request flag (SR) by writing 1 to this bit. 0 is always read from this bit.

8.9.2.12 DMAC Transfer Status Clear Register (DCSTCn)

Access: This register can be read/written in 32-bit units.

Address: FFFF 842C$_H$ + 40$_H$ × Ch. No. n (n = 0 to 15)

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 8.28 DCSTCn register contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the initial value is read. When written, write the initial value.
7	ERC	Transfer error flag clear The DMA transfer error flag (ER) can be cleared by writing 1 to this bit. The read value of this bit is always 0.
6	Reserved	When read, the initial value is read. When written, write the initial value.
5	CCC	Transfer count match flag clear The transfer count match flag (CC) can be cleared by writing 1 to this bit. The read value of this bit is always 0.
4	TCC	Transfer completion flag clear The transfer completion flag (TC) can be cleared by writing 1 to this bit. The read value of this bit is always 0.
3 to 1	Reserved	When read, the initial value is read. When written, write the initial value.
0	SRC	Software DMA transfer request flag clear The software DMA transfer request flag (SR) can be cleared by writing 1 to this bit. The read value of this bit is always 0.

8.9.2.13 DTFR Setting Register (DTFRn)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8430_H + 40_H × Ch. No. n (n = 0 to 15)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8.29 DTFRn register contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the initial value is read. When written, write the initial value.
7 to 1	REQSEL[6:0]	Hardware DMA transfer source selection Selects one out of 128 hardware DMA transfer sources as the hardware DMA transfer request. 000_0000: Selecting the DMACTRG[0] input : 111_1111: Selecting the DMACTRG[127] input
0	REQEN	Hardware DMA transfer source selection enable This bit enables/disables the hardware DMA transfer source selection. 0: Hardware DMA transfer source selection is disabled. 1: Hardware DMA transfer source selection is enabled. If this bit is 0, even when the hardware DMA transfer source selected by the REQSEL6-0 bits is activated, it is not recognized as a hardware DMA transfer request, and a hardware DMA transfer request is not generated.

8.9.2.14 DTFR Transfer Request Status Register (DTFRRQn)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8434_H + 40_H × Ch. No. n (n = 0 to 15)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DRQ
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 8.30 DTFRRQn register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the initial value is read. When written, write the initial value.
0	DRQ	Hardware DMA transfer request status If this bit is set, it means that a hardware DMA transfer request exists or is retained. • If the hardware DMA transfer request is an edge detection type*1 This bit shows whether a hardware DMA transfer request generated by edge detection is retained. When the DMA transfer request acceptance signal (DMAAKn) from the DMAC is asserted, this bit is automatically cleared. A user can clear this bit by writing 1 to the DTFRRQCn.DRQC bit. • If the hardware DMA transfer request is a level input type*1 This bit shows whether there is a hardware DMA transfer request input from the outside. Even when the DMA transfer request acceptance signal (DMAAKn) from the DMAC is asserted, this bit is not automatically cleared. In addition, this bit is not cleared even when a user writes to the DTFRRQCn.DRQC bit. This bit changes regardless of the value of the DTFRn.REQEN bit when a hardware DMA transfer request from the outside is generated. 0: There is no hardware DMA transfer request 1: There is a hardware DMA transfer request

Note 1. Whether the hardware DMA transfer request is an edge detection type or level input type depends on the hardware DMA transfer source selected by DTFRn.REQSEL[6:0]. This product's hardware DMA transfer request is only an edge detection type.

8.9.2.15 DTFR Transfer Request Clear Register (DTFRRQCn)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8438_H + 40_H × Ch. No. n (n = 0 to 15)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DRQC
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 8.31 DTFRRQCn register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the initial value is read. When written, write the initial value.
0	DRQC	Hardware DMA transfer request clear If the hardware DMA transfer request is an edge detection type*1, a user can clear the DTFRRQn.DRQ bit by writing 1 to this bit. If the hardware DMA transfer request is a level input type*1, the DTFRRQn.DRQ bit cannot be cleared by writing to this bit. The read value of this bit is always 0.

Note 1. Whether the hardware DMA transfer request is an edge detection type or level input type depends on the hardware DMA transfer source selected by DTFRn.REQSEL[6:0]. This product's hardware DMA transfer request is only an edge detection type.

Section 9 Reset Controller

9.1 Overview

Several system reset functions are provided in order to initialize the microcontroller hardware and its registers.

A reset can be caused by the following events:

- External reset signal $\overline{\text{RESET}}$
  Noise in the external reset signal is eliminated by an analog filter.
- Power-On-Clear 0 (POC0RES)
- Power-On-Clear 1 (POC1RES) (not for D1M2(H))
- External power-good indicator signal (PWRGD)
- Overflow of the Watchdog Timers (WDTA0RES, WDTA1RES)
- Clock Monitor 0 reset ($\overline{\text{CLMA0RES}}$)
- Error Control Module reset output (ECMRES)
- Software reset (SWRES)
- Debugger reset ($\overline{\text{DBRES}}$)
- DEEPSTOP mode (ISORES)

9.1.1 Clock Supply

The Reset Controller clock supply is shown in the following table.

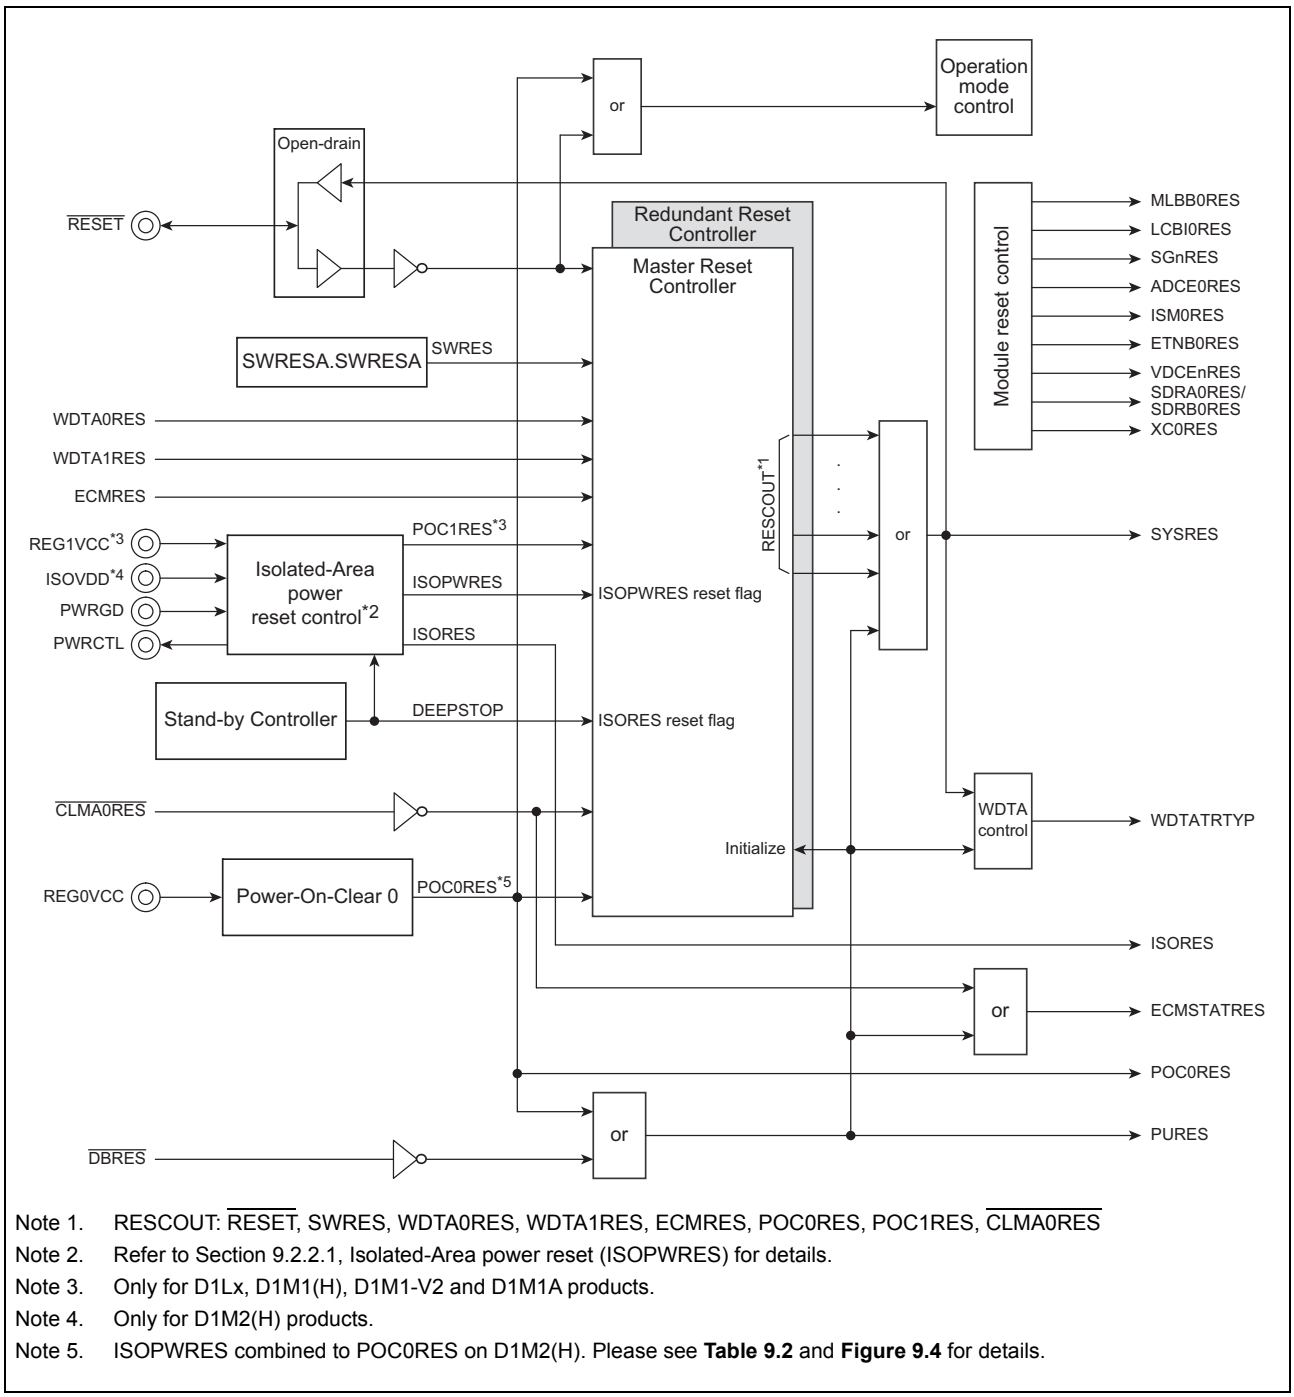
Table 9.1 Clock Supply

Module	Clock	Connected to
Reset Controller	Register access clock	Clock Controller • C_ISO_PCLK in RUN mode • EMCLK in DEEPSTOP mode

9.2 Configuration

9.2.1 Block Diagram

The block diagram of reset circuitry is shown below.



Note 1. RESCOUT: $\overline{\text{RESET}}$, SWRES, WDTA0RES, WDTA1RES, ECMRES, POC0RES, POC1RES, $\overline{\text{CLMA0RES}}$

Note 2. Refer to Section 9.2.2.1, Isolated-Area power reset (ISOPWRES) for details.

Note 3. Only for D1Lx, D1M1(H), D1M1-V2 and D1M1A products.

Note 4. Only for D1M2(H) products.

Note 5. ISOPWRES combined to POC0RES on D1M2(H). Please see **Table 9.2** and **Figure 9.4** for details.

Figure 9.1 Block diagram of the Reset Controller

9.2.2 Reset sources and targets

Table 9.2 Reset sources and targets overview

Power domain	Reset target	Reset source				
		Reset level 1 (PURES)		Reset level 2 (SYSRES)		Reset level 3 (ISORES)
		POC0RES, ISOPWRES*3	$\overline{\text{DBRES}}$	$\overline{\text{CLMA0RES}}$	POC1RES*2, $\overline{\text{RESET}}$, WDTAnRES, ECMRES, SWRES, ISOPWRES*4	ISORES
AWO	Watchdog Timer WDTA0	reset	reset	reset	reset	not reset
	Real-Time Clock RTCA0	reset	reset	reset	reset	not reset
	Always-On-Area Timer AWOT0	reset	reset	reset	reset	not reset

	Low Speed IntOsc	reset	reset	not reset	not reset	not reset
	High Speed IntOsc	reset	reset	reset	not reset	not reset
	MainOsc, SubOsc	reset	reset	not reset	not reset	not reset
	Always-On-Area ports	reset	reset	reset	reset	not reset
	RRAM content	not reset	not reset	not reset	not reset	not reset
ISO	All Isolated-Area modules*1	reset	reset*5	reset*5	reset*5	reset*5
	Isolated-Area ports	reset	reset	reset	reset	reset

Note 1. Including CPU Subsystem, PLL clock generators.
Note 2. If POC1RES is asserted during DEEPSTOP mode (i.e. because REG1VCC was switched off), it has no effect.
Note 3. In D1M2(H)
Note 4. In D1Lx, D1M1-V2, D1M1(H) and D1M1A
Note 5. LRAM content keep in this reset (except POC1RES and ISOPWRES)

The various reset sources are assigned to different hierarchical reset levels.
The reset sources of each reset level affect different reset targets:

- Reset level 1: power-up reset PURES
  Level 1 resets initialize basically the entire microcontroller.
- Reset level 2: system reset SYSRES
  Level 2 resets initialize all microcontroller modules and ports, except the oscillator circuits. This ensures fast return to normal operation, since no waiting for oscillators stabilization necessary after level 2 reset release.
  A level 2 reset also retains the content of the Error Control Module's error status register.
- Reset level 3: Isolated-Area reset ISORES
  A level 3 resets is asserted during DEEPSTOP mode and initialization the entire Isolated-Area.

9.2.2.1 Isolated-Area power reset (ISOPWRES)

The Isolated-Area power reset is asserted, when the power supply of the Isolated-Area fails.

Since switch-off of the Isolated-Area power supply during DEEPSTOP stand-by mode is a regular operation condition, ISOPWRES is never asserted during DEEPSTOP, i.e. while the Stand-by Controller activates the Isolated-Area reset ISORES. Refer also to the figures below.

(1) D1Lx, D1M1(H), D1M1-V2 and D1M1A Isolated-Area reset

If the device is not in DEEPSTOP mode (DEEPSTOP = 0) an Isolated-Area power reset (i.e. ISOPWRES = 1) is asserted if

- or POC1RES is active (POC1RES = 1) due to a fail of REG1VCC
- or the power-good signal PWRGD is externally set to low level, indicating unstable REG1VCC

Assertion and de-assertion of ISORES is managed by the Isolated-Area reset control, refer to Section (4), Isolated-Area reset control (D1L1, D1L2(H), D1M1(H), D1M1-V2, D1M1A) for details.

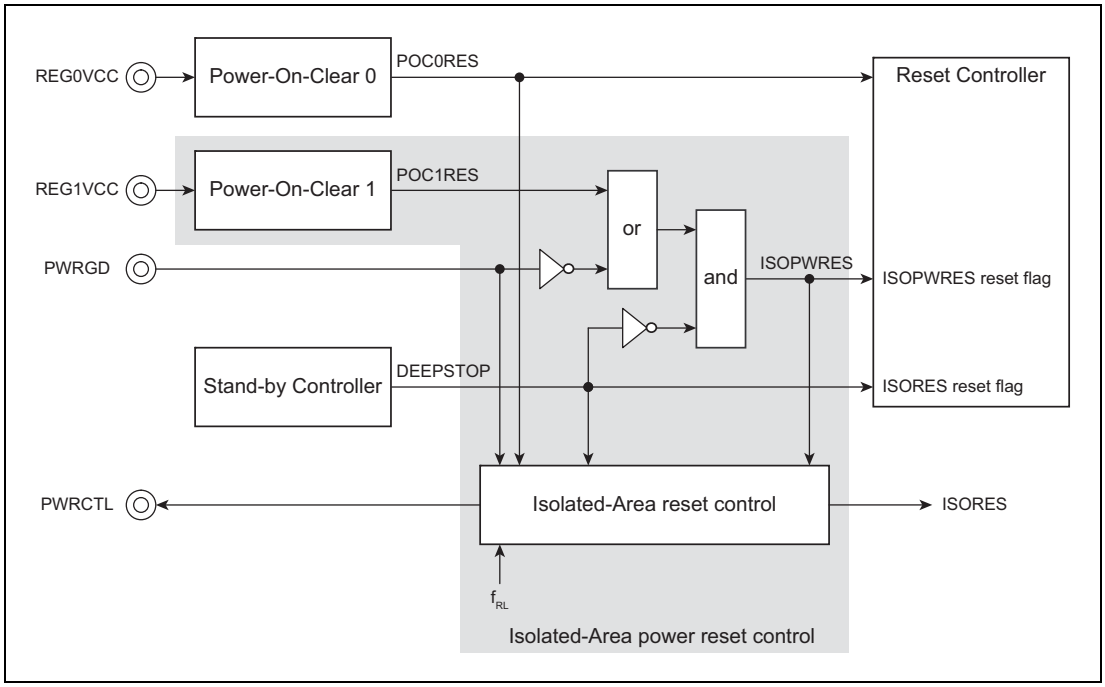

Figure 9.2 D1Lx, D1M1(H), D1M1-V2 and D1M1A Isolated-Area power reset

(2) D1M2(H) Isolated-Area power reset

If the device is not in DEEPSTOP mode (ISORES = 0) and D1M2(H) issues POC0RES when PWRGD signals set to low before PWRCTL change from high to low.

Assertion and de-assertion of ISORES is managed by the Isolated-Area reset control, refer to Section (3), Isolated-Area reset control (D1M2(H)) for details.

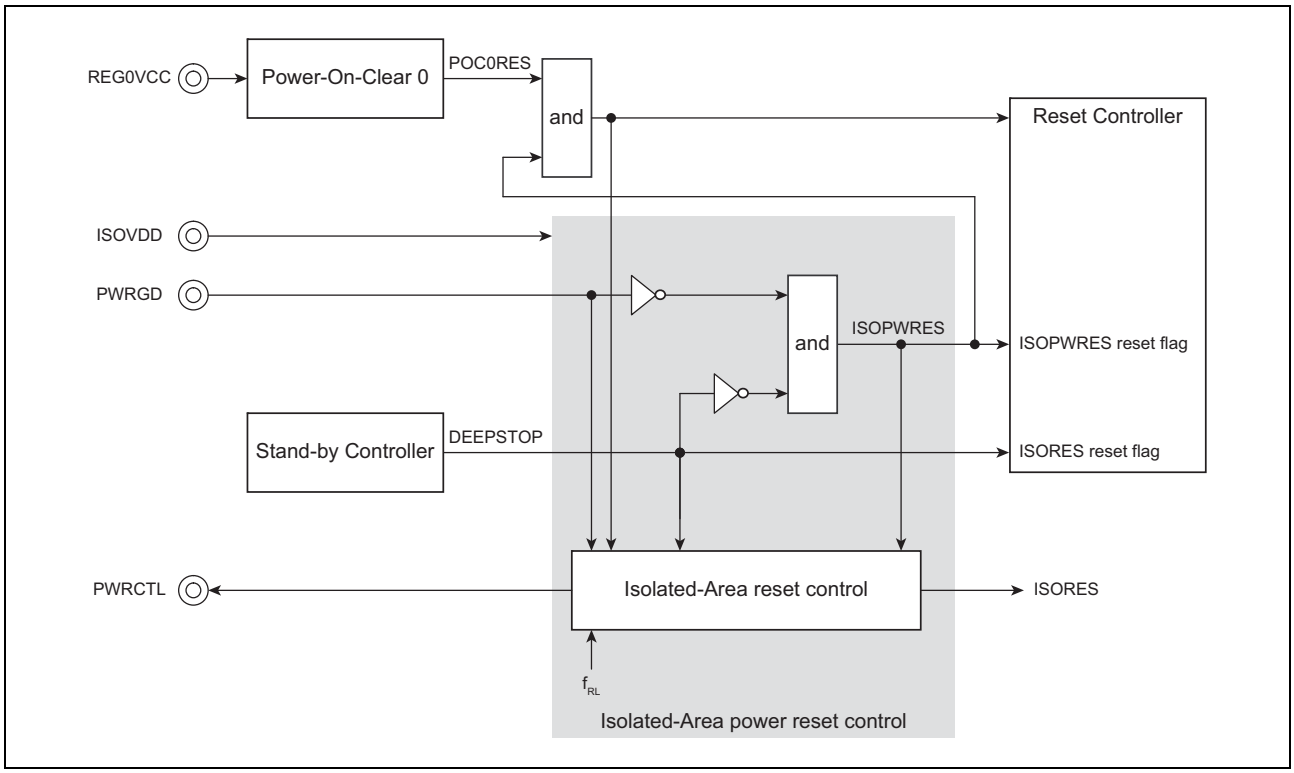

Figure 9.3 D1M2(H) Isolated-Area power reset

(3) Isolated-Area reset control (D1M2(H))

The Isolated-Area reset ISORES is release if

- the external REG1VCC/ISOVDD power supply sets PWRGD = H to confirm stable voltage
- the PWRGD_CNT counter has elapsed

The PWGD counter is used to ensure a minimum delay time from power supply switch on until ISORES release. It counts Low Speed IntOsc clocks f_{RL}.
The start value of the PWGD counter is defined by the PWRGD_CNT register.
The default value of the PWRGD counter after initial power-up is FFF_H, thus the initial ISORES release delay is nominal 4095 x 1/100 kHz = 41 ms.
In order to shorten the wake-up time from DEEPSTOP mode PWRGD_CNT can be set to the lowest acceptable value.

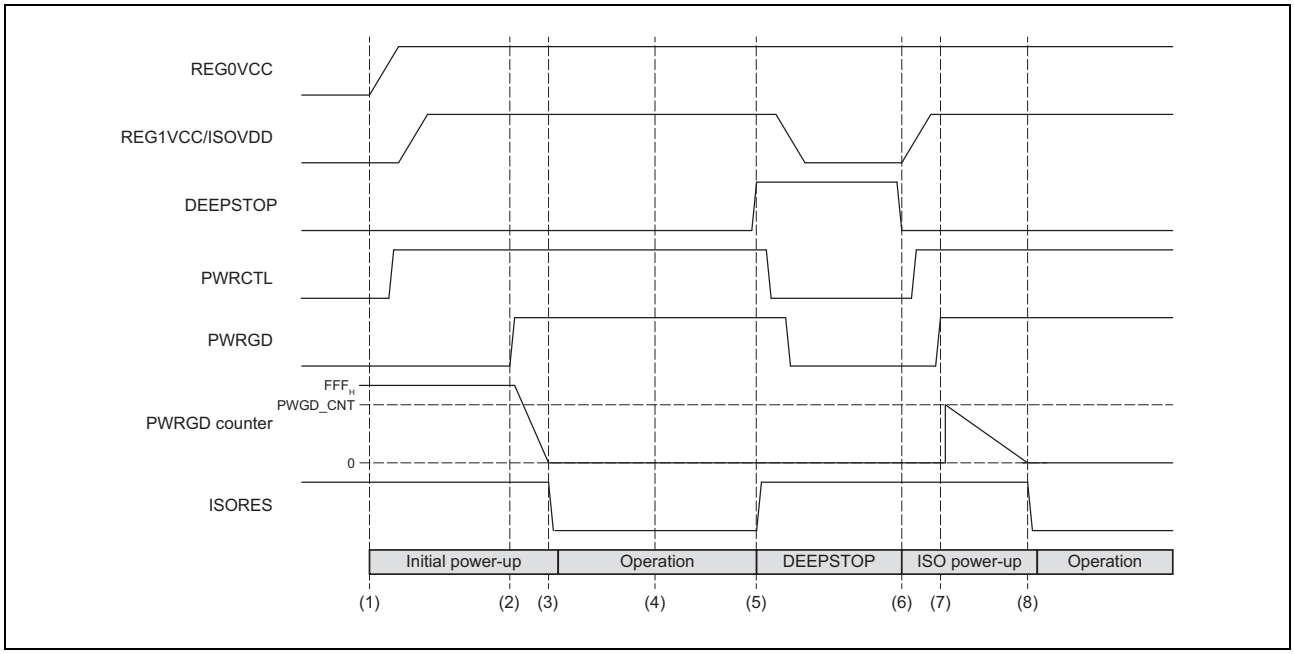

Figure 9.4 Isolated-Area reset control (D1M2(H))

(1) Initial power-up REG0VCC for Always-On-Area starts.
PWRCTL = H signals to external REG1VCC/ISOVDD supply to switch on.

(2) Stable REG1VCC/ISOVDD is signalled by PWRGD = H.
PWRGD counter starts count down from default counter value FFF_H.

NOTE

If PWRGD pin transits H → L → H during PWRGD counter is counting, the counter value is cleared and restarts counting.

(3) PWRGD counter has elapsed. Thus ISORES is released.

(4) New PWRGD_CNT < FFF_H is set up to minimize wake-up time.

(5) Transition to DEEPSTOP mode is entered, thus ISORES is asserted and PWRCTL = L signals to external REG1VCC/ISOVDD supply to switch off.
If REG1VCC/ISOVDD is switched during DEEPSTOP, PWRGD turns to L.

(6) Wake-up from DEEPSTOP
PWRCTL = H signals to external REG1VCC/ISOVDD supply to switch on again.

(7) Stable REG1VCC/ISOVDD is signalled by PWRGD = H.
PWRGD counter starts count down from new counter value < FFF_H.

(8) PWRGD counter has elapsed and ISORES is released.

(4) Isolated-Area reset control (D1L1, D1L2(H), D1M1(H), D1M1-V2, D1M1A)

The Isolated-Area reset ISORES is release after a fixed time*1, if the external REG1VCC power supply is confirmed stable by POC1RES = L and externally set PWRGD = H.

Note 1. – 0.8 ms, when High Speed IntOsc clock f_{RH} is running
– 1.2 ms, when High Speed IntOsc clock f_{RH} is stopping

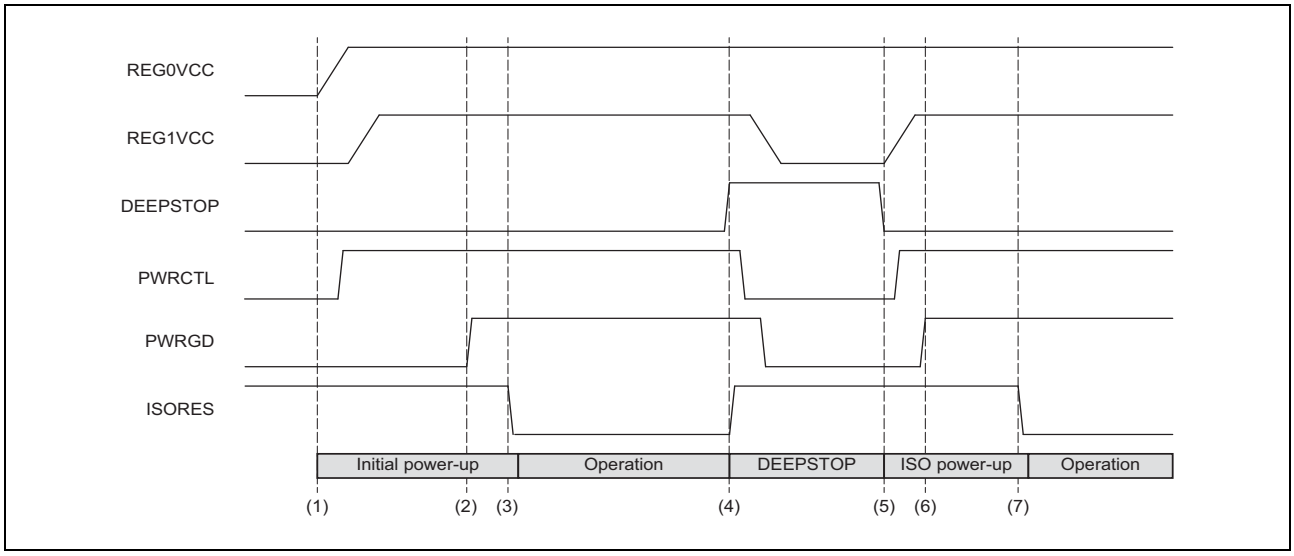

Figure 9.5 Isolated-Area reset control (D1L1, D1L2(H), D1M1(H), D1M1-V2, D1M1A)

(1) Initial power-up REG0VCC for Always-On-Area starts.
PWRCTL = H signals to external REG1VCC supply to switch on.

(2) Stable REG1VCC is signalled by POC1RES = L and PWRGD = H.

(3) ISORES is released after fixed time.

(4) Transition to DEEPSTOP mode is entered, thus ISORES is asserted and PWRCTL = L signals to external REG1VCC supply to switch off.
If REG1VCC is switched during DEEPSTOP, PWRGD turns to L.

(5) Wake-up from DEEPSTOP
PWRCTL = H signals to external REG1VCC supply to switch on again.

(6) Stable REG1VCC is signalled by POC1RES=L and PWRGD = H.
A Low → High signal transition at PWRGD pin is necessary to start the PWRGD counter after PWRCTL = H

(7) ISORES is released after fixed time.

NOTE

In D1M1(H) and D1Lx products, ISOPWRES occurs when REG1VCC is lower than 3.1 V after DEEPSTOP, under following conditions:

- PWRGD is high level before REG1VCC reached 3.1 V.
- Slew rate of REG1VCC is slow and noise is present on REG1VCC

To avoid unintended reset, adapt one of following workarounds.

1. Keep REG1VCC supplied during DEEPSTOP.
2. Rise PWRGD signal after REG1VCC is higher than 3.1 V.
3. Increase slew rate of REG1VCC to meet eliminable noise level.
4. Reduce noise on REG1VCC to meet slew rate.

Eliminable noise level is shown below.

Table 9.3 Eliminable noise level by slew rate

Slew rate for REG1VCC [V/ms]	Eliminable maximum peak to peak of noise on REG1VCC [mV]
≥ 20	220
≥ 10	110
≥ 5	70
≥ 3.3	70
≥ 2.5	50

9.2.2.2 Reset Controller reset output signals

The Reset Controller manages the generation of five reset signals upon occurrence of reset signals from various reset sources:

- Power-up reset PURES
  PURES is generated by the Power-On-Clear 0 circuit POC0RES or the debugger reset $\overline{\text{DBRES}}$.
  It basically initializes all microcontroller modules and ports.
- Power-On-Clear 0 reset POC0RES
  POC0RES is generated by the Power-On-Clear 0 circuit.
- System reset SYSRES
  SYSRES is generated by all reset sources except
  – ISORES, i.e. except during DEEPSTOP mode
  – POC1RES during DEEPSTOP mode
  At the generation of SYSRES, all the clock generation circuits operating up to that time continue to operate.
- ISO area reset ISORES
  ISORES is generated during DEEPSTOP mode and resets all modules in the Isolated-Area.
- Error Control Modules status reset ECMSTATRES
  ECMSTATRES is generated by the power-up PURES and the Clock Monitor 0 reset $\overline{\text{CLMA0RES}}$.
  It clears the error status registers of the Error Control Module.

9.2.2.3 External $\overline{\text{RESET}}$ input/output

Any assertion of a microcontroller reset is signalled via a reset output signal, that can be used to reset external devices concurrently to a microcontroller internal reset.

The internal SYSRES is combined with the external reset input via an open-drain buffer.
Thus any internal SYSRES or external reset sets the microcontroller as well as all other external devices, which are connected to $\overline{\text{RESET}}$, into reset state.

- POC RESET: output low
- Internal reset cause: output low
- External reset inputs: disable output enable

NOTE

In the self programming mode, reset output function can not be used.

9.2.2.4 Watchdog Timers start-up control WDTATRTYP

The Watchdog Timers can be started automatically or remain stopped after reset release. This is controlled by the WDTATRTYP signal and other Watchdog Timers start-up options.

For further information concerning the Watchdog Timers start-up options refer to **Section 26, Window Watchdog Timer (WDTA)**.

9.2.2.5 Operation mode control

The microcontroller's operation mode is determined upon release of the Power-On-Clear reset POC0RES or the external $\overline{\text{RESET}}$*1.

Note 1. The external reset includes all SYSRES in normal operation mode because RESET output is available.

Refer to Section 6, Operating Modes for details about the operation modes.

9.2.2.6 Module reset control

Following modules can be separately set into reset state by use of the reset control register MRSTC:

- MLBB0RES = 0 sets the Media Local Bus MLBB0 into reset
- LCBI0RES = 0 sets the LCD Bus I/F LCBI0 into reset
- SGnRES = 0 sets the Sound Generator SGn into reset
- ADCE0RES = 0 sets the A/D Converter ADCE0 into reset
- ISM0RES = 0 sets the Stepper Motor Driver ISM0 into reset
- ETNB0RES = 0 sets the Ethernet AVB MAC ETNB0 into reset
- VDCEnRES = 0 sets the Video Data Controller VDCEn into reset
- SDRB0RES = 0 sets the DDR2-SDRAM Memory Controller SDRB0 PHY into reset
  Note: In D1M1H and D1M1A, SDRB0RES bit corresponds to SDRA0RES signal, that reset SDR-SDRAM Memory Controller SDRA0.
- XC0RES = 0 sets XC0 cross-connect into reset

CAUTION

By default, i.e. after release of the system reset SYSRES, the above module resets are active.
Thus before accessing any of these modules its reset must be released by setting the respective reset bit to 1.

9.2.3 Reset Controller redundancy

For functional safety reasons two identical Reset Controllers are provided to ensure that a reset event performs the microcontroller initialization even in case of a Reset Controller failure. Both, the master and the redundant Reset Controller, have identical reset inputs. Their respective outputs are combined by a logical OR. Thus if one controller fails, the other still generates the reset.

Both Reset Controllers have an identical set of registers:

- master Reset Controller registers: reset factor RESF and reset factor clear RESFC
- redundant Reset Controller registers: reset factor RESFR and reset factor clear RESFCR

9.2.4 Masking of reset source in debugging mode

The following table informs, which reset sources can be masked, i.e. deactivated in debug mode. The reset mask is configurable via the debugger.

Table 9.4 Enabled or disabled reset sources in debug mode

Reset Source	Maskable
Power-On-Clear 0 reset (POC0RES)	no
Debugger reset ($\overline{\text{DBRES}}$)	no
Power-On-Clear 1 reset (POC1RES)	no
Isolated-Area reset (ISORES)	no
External reset ($\overline{\text{RESET}}$)	yes
Error Control Module reset (ECMRES)	yes
Clock Monitor 0 reset ($\overline{\text{CLMA0RES}}$)	yes
Watchdog Timer overflow (WDTA0RES, WDTA1RES)	yes
Software reset (SWRES)	yes

9.3 Registers

This section contains a description of all registers of the Reset Controller.

9.3.1 Reset Controller registers overview

The Reset Controller is controlled and operated by the following registers:

Table 9.5 Reset Controller registers overview

Module Name	Register Name	Symbol	Address
General reset flags registers			
SYS	Reset factor register	RESF	FFF8 0760$_H$
SYS	Reset factor clear register	RESFC	FFF8 0768$_H$
SYS	Redundant reset factor register	RESFR	FFF8 0860$_H$
SYS	Redundant reset factor clear register	RESFCR	FFF8 0868$_H$
Software reset control registers			
SYS	Software reset register	SWRESA	FFF8 0A04$_H$
SYS	Module reset control register	MRSTC	FFF8 F400$_H$
Isolated-Area reset control register			
PWRG	PWRGD counter register	PWRGD_CNT	FFF8 F500$_H$
Write protection registers			
SYS	Protection command register	PROTCMD0	FFF8 0000$_H$
SYS	Protection status register	PROTS0	FFF8 0004$_H$
SYS	MRSTC protection command register	PROTCMDMRST	FFF8 F480$_H$
SYS	MRSTC protection status register	PROTSMRST	FFF8 F484$_H$
PWRG	Protection command register	PROTCMDPWRGD	FFF8 F580$_H$
PWRG	Protection status register	PROTSPWRGD	FFF8 F584$_H$

NOTE

As for the protection registers, see Section 4, Write-Protected Registers.

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> and <Symbol> is defined are the above table.

9.3.2 General reset flag registers details

9.3.2.1 RESF, RESFR — Reset factor register

These registers contain information about which type of resets occurred since the last power-up reset PURES.

RESF is the reset factor register of the Master Reset Controller.
RESFR is the reset factor register of the Redundant Reset Controller.

NOTES

1. The following description refers only to the RESF bits.
   The corresponding bits of the RESFR register are named RESFRx.
2. For details, see Figure 9.7, When RESET is Released before the Flash Sequence is Completed.

In accordance with the setting conditions for each bit in the reset factor register, the same bits are set in this register.

Access: This register can be read in 32-bit units.

Address: RESF: FFF8 0760_H
RESFR: FFF8 0860_H

Initial value: 0000 0200_H/0000 0300_H *1 This register is initialized by a power-up reset PURES.

Note 1. For details, see Figure 9.7, When RESET is Released before the Flash Sequence is Completed.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. For details, see Figure 9.7, When RESET is Released before the Flash Sequence is Completed.

NOTE

The corresponding bits of the RESFR register are named RESFRx.

Table 9.6 RESF, RESFR register contents (1/2)

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, an initial value is returned. The write value should be 0.
15	RESF15	Isolated-Area power reset (ISOPWRES) reset flag 0: No reset occurred 1: Reset has occurred
14	RESF14	Error Control Module (ECMRES) reset flag 0: No reset occurred 1: Reset has occurred
13 to 11	Reserved	When read, an initial value is returned. The write value should be 0.

Table 9.6 RESF, RESFR register contents (2/2)

Bit Position	Bit Name	Function
10	RESF10	Isolated-Area (ISORES) reset flag 0: No reset occurred 1: Reset has occurred
9	RESF9	Power-On-Clear 0 (POC0RES) reset flag 0: No reset occurred 1: Reset has occurred
8	RESF8	External reset ($\overline{\text{RESET}}$) flag 0: No reset occurred 1: Reset has occurred
7 to 4	Reserved	When read, an initial value is returned. The write value should be 0.
3	RESF3	CLMA0 ($\overline{\text{CLMA0RES}}$) reset flag 0: No reset occurred 1: Reset has occurred
2	RESF2	WDTA1 (WDTA1RES) reset flag 0: No reset occurred 1: Reset has occurred
1	RESF1	WDTA0 (WDTA0RES) reset flag 0: No reset occurred 1: Reset has occurred
0	RESF0	Software (SWRES) reset flag 0: No reset occurred 1: Reset has occurred

NOTE

In normal operation mode, reset factors (except for ISORES) are noticed with external $\overline{\text{RESET}}$ flag (RESF8). See Section 9.2.2.3, External RESET input/output for details.

9.3.2.2 RESFC, RESFCR — Reset factor clear register

RESFC is the reset factor clear register of the Master Reset Controller. This register clears the reset flags of the RESF register.

RESFCR is the reset factor clear register of the Redundant Reset Controller. This register clears the reset flags of the RESFR register.

NOTE

The following description refers only to the RESFC bits.
The corresponding bits of the RESFCR register are named RESFCRx.

Access: This register can be written in 32-bit units.

Address: RESFC: FFF8 0768_H
RESFCR: FFF8 0868_H

Initial value: Reading this register always returns 0000 0000_H.

9.3.3 Software reset control registers details

9.3.3.1 SWRESA — Software reset register

This register is used to generate a software reset SWRES.

Access: This register can be written in 32-bit units.
Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMD0. For details, refer to Section 4, Write-Protected Registers.

Address: FFF8 0A04$_H$

Initial value: Reading this register always returns 0000 0000$_H$.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

0	SWRESA	Software reset trigger 0: no function 1: Generate software reset SWRES

9.3.3.2 MRSTC — Module reset control register

This register is used to generate separate resets for various modules.

CAUTION

By default, i.e. after release of the power-up reset PURES, the system reset SYSRES and the Isolated-Area reset ISORES, the module resets are active.

Thus before accessing any of these modules its reset must be released by setting the respective reset bit to 1.

NOTE

Reset bits of unused modules should remain in reset state with exception of XC0RES and ETNB0RES.
Refer to Section 12.4, Clock Controller set-up for details.

Access: This register can be read/written in 32-bit units.
Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMDMRST. For details, refer to Section 4, Write-Protected Registers.

Address: FFF8 F400$_H$

Initial value: 0000 0000$_H$. This register is initialized by a system reset SYSRES.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

0	VDCE0RES	Software reset of Video Data Controller VDCE0 (D1L2(H), D1M1(H), D1M1-V2, D1M2(H), D1M1Aonly) 0: reset is active 1: reset is inactive

9.3.4 Isolated-Area reset control registers details

9.3.4.1 PWRGD_CNT — PWRGD counter register

This register is used to set PWRGD counter value.
It determines a minimum waiting period for PLLVDD and REG1VCC available after PWRGD is high.

Access: This register can be read/written in 32-bit units.
Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMDPWRGD. For details, refer to Section 4, Write-Protected Registers.

Address: FFF8 F500$_H$

Initial value: 0000 0FFF$_H$. This register is initialized by POC0RES only.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 9.10 PWRGD_CNT register contents

Bit Position	Bit Name	Function
31 to 12	Reserved	When read, an initial value is returned. The write value should be 0.
11 to 0	PWRGD_ CNT[11:0]	PWR_GD counter value PWR_GD delay time = (PWRGD_CNT[11:0] + 1) x T_{RL} T_{RL} denotes the cycle duration of the Low Speed IntOsc frequency f_{RL}.

NOTE

This register can be written in D1M2(H).
For D1L1, D1L2(H), D1M1(H), D1M1-V2, D1M1A, this register can not be written. (Fixed to initial value.)

9.4 Functional Description

All descriptions refer only to the master Reset Controller.
However they are valid also for the redundant Reset Controller, since both Reset Controllers behave identical.

9.4.1 Reset flags

The reset factor register (RESF) provides reset flags for each reset source.

If a reset has occurred, the assigned flag is set. This way the source of the reset can be evaluated.

RESF is initialized by a power-up reset PURES (POC0RES or $\overline{\text{DBRES}}$).

In addition, the flags in RESF can be cleared by the reset factor clear register (RESFC).

RESF8 and RESF9 is set when PURES is generated.

9.4.2 Power-On-Clear Resets (POC0RES, POC1RES)

NOTE

The RH850/D1L/D1M devices provide following Power-On-Clear circuits:

- All devices: Power-On-Clear circuit 0 supervises the external REG0VCC voltage
- D1Lx, D1M1(H), D1M1-V2 and D1M1A: Power-On-Clear circuit 1 supervises the external REG1VCC voltage

The following description refers to both Power-On-Clear circuits, denoted as POC, supervising the REGVCC voltage and generating the POCRES reset.

The Power-On-Clear circuit (POC) permanently compares the power supply voltage REGVCC with the internal reference voltage VPOC. It ensures that the microcontroller only operates as long as the power supply exceeds a well-defined limit.

If REGVCC falls below the internal reference voltage (REGVCC < VPOC),

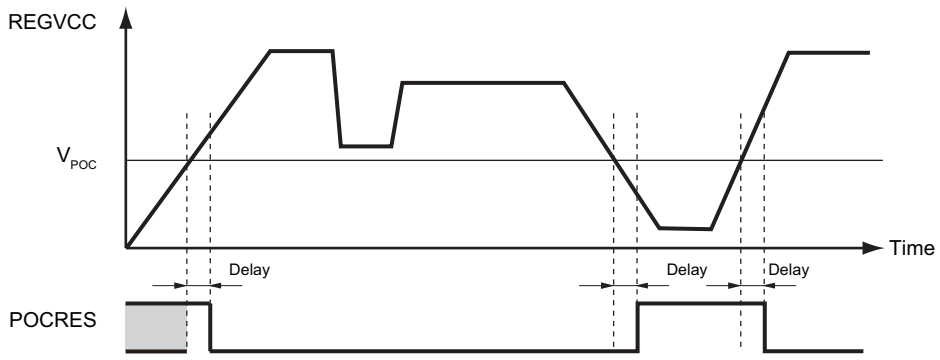
- POC0RES: Isolated-Area reset ISORES, system reset SYSRES, and a power-up reset PURES are generated.
- POC1RES: Isolated-Area reset ISORES and system reset SYSRES are generated.

For details on the specification of the internal voltage reference level VPOC, refer to the Data Sheet.

The reset factor register (RESF) is cleared by the power-on clear reset PURES.
RESF8 and RESF9 are set to 1 after the initialization.

The Power-On-Clear function holds the microcontroller in reset state as long as the power supply voltage does not exceed the threshold level VPOC.

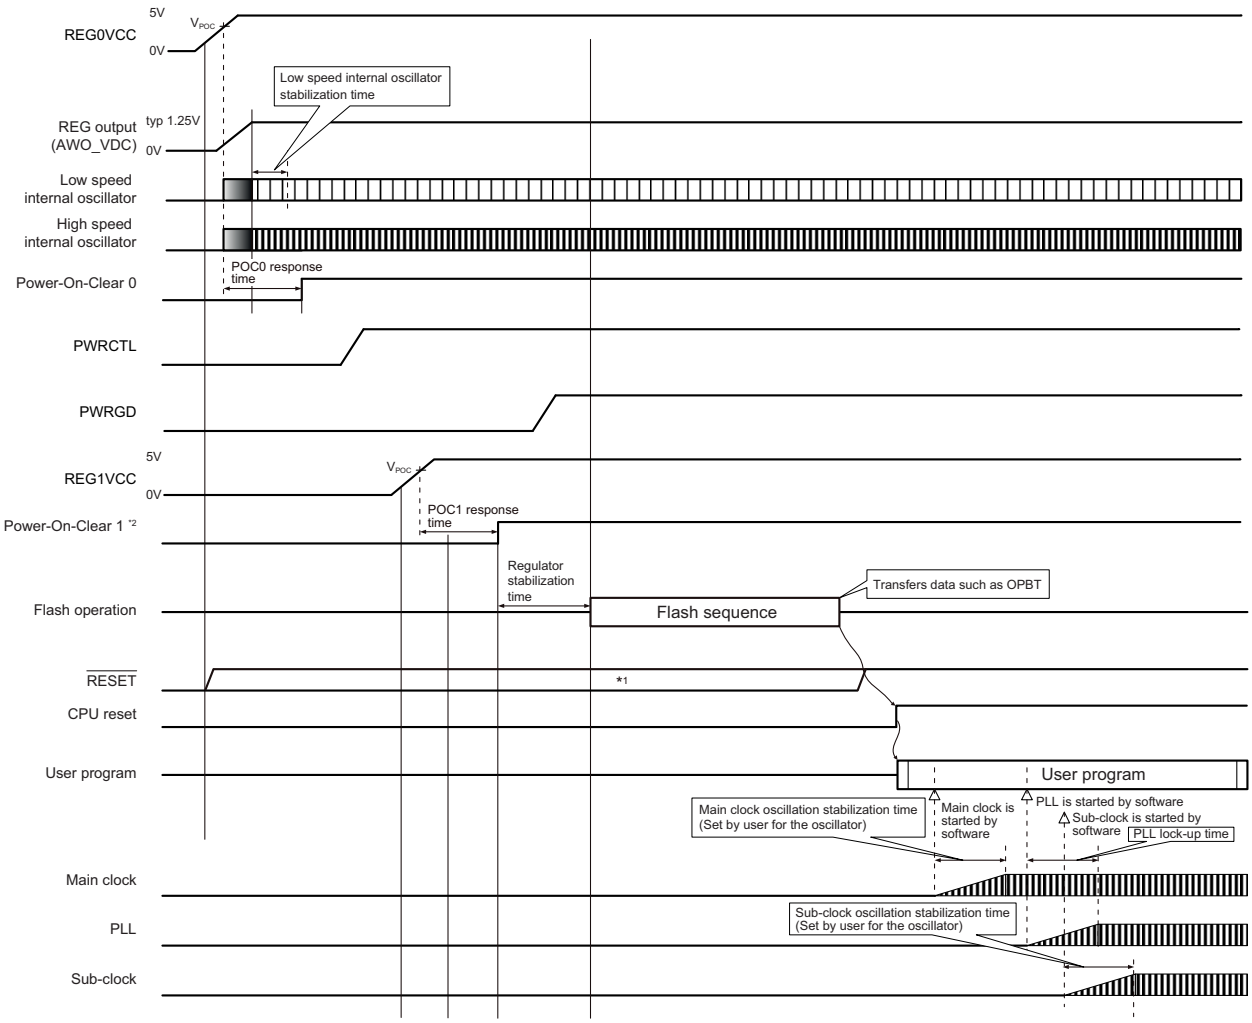
The following figure illustrates the timing of a POCRES.



Note: Delay:
When the REGVCC exceeds the VPOC, the POCRES is released after certain delay. When the REGVCC falls below the VPOC, the POCRES is asserted after certain delay.
See the Data Sheet for the delay time.

Figure 9.6 POC reset timing

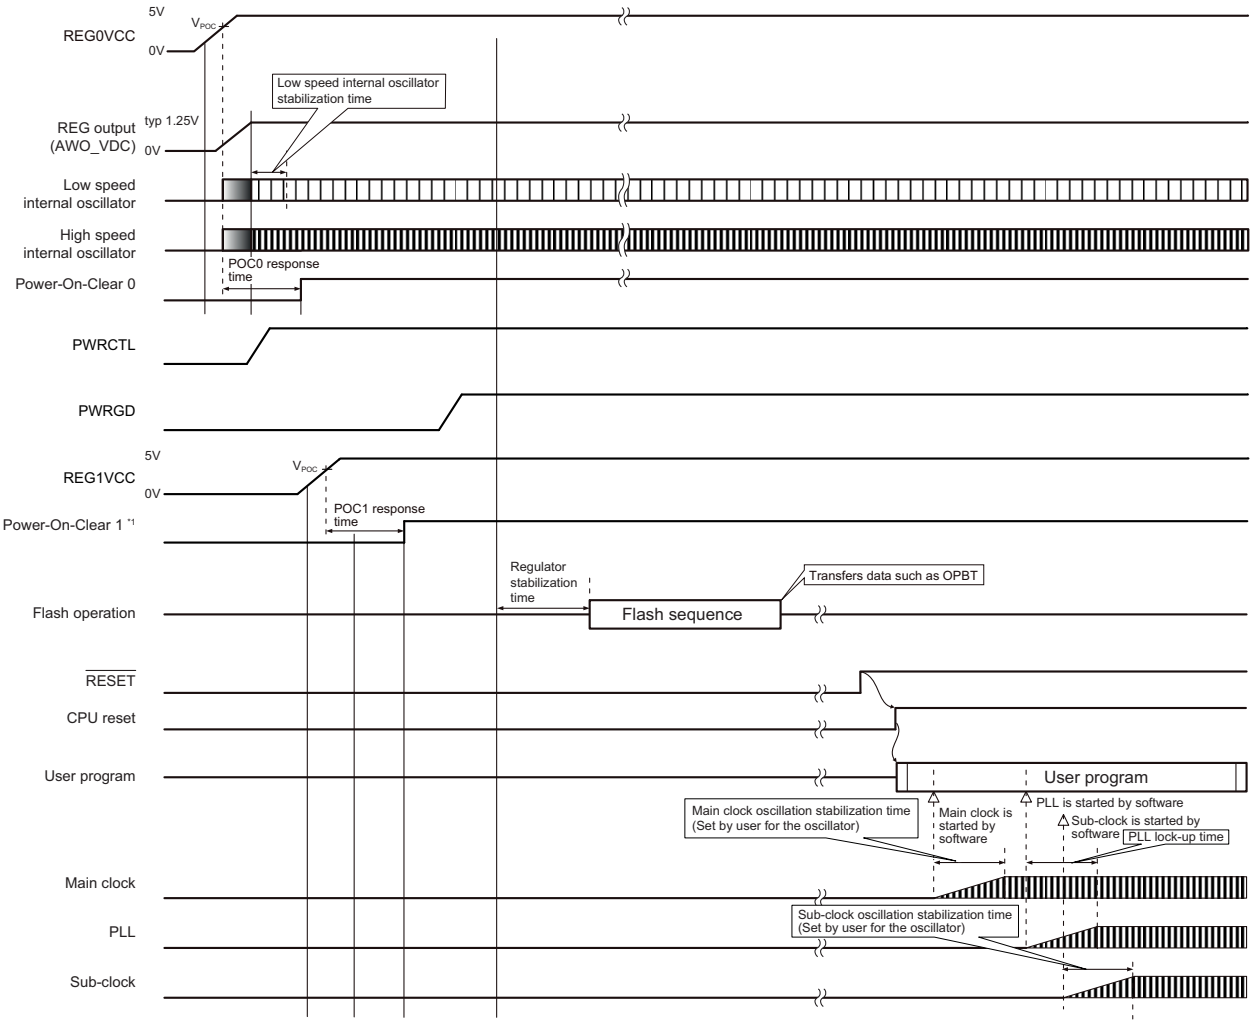
(1) Overview of CPU System Startup after Power-On-Clear



Note 1. After a power-on clear reset, the on-chip pull-down resistors are enabled until the flash sequence is completed. The timing of release from the reset state due to the $\overline{\text{RESET}}$ signal depends on the external circuit of the microcomputer.
If the $\overline{\text{RESET}}$ pin is at the low level, the values of both RESF8.RESF8 and RESFR.RESFR8 are set to 1. If the $\overline{\text{RESET}}$ pin is high level, the initial values of both RESF8.RESF8 and RESFR.RESFR8 are set to 0.

Note 2. In D1M2(H) Power-On-Clear 1 is not available.

Figure 9.7 When $\overline{\text{RESET}}$ is Released before the Flash Sequence is Completed



Note 1. In D1M2(H) Power-On-Clear 1 is not available.

Figure 9.8 When $\overline{\text{RESET}}$ is Released after the Flash Sequence is Completed

9.4.3 External Reset Signal ($\overline{\text{RESET}}$)

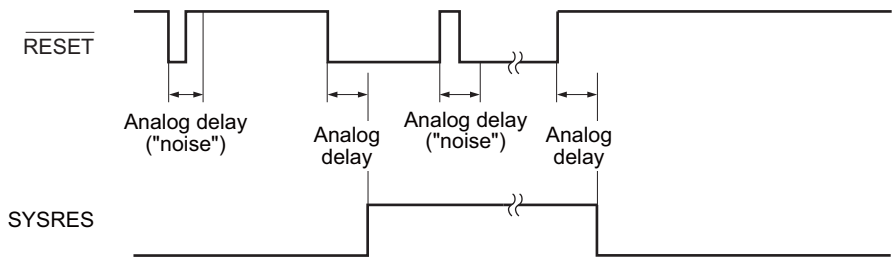
A reset is performed when a low level signal is applied to the $\overline{\text{RESET}}$ pin and the bit RESF.RESF8 is set.

After that, the bit RESF.RESF8 and RESFR.RESFR8 are not cleared automatically, even if the low-level input to the $\overline{\text{RESET}}$ pin is released. The bit RESF.RESF8 is cleared by

- setting the RESFC.RESFC8 bit to 1.
- power-up reset PURES (POCRES or $\overline{\text{DBRES}}$)

The $\overline{\text{RESET}}$ signal is passed through an analog noise filter to prevent erroneous resets due to noise.

The following figure shows the timing when SYSRES is generated by an external reset. This figure also shows the effect of the noise filter.



Note: The analog delay is caused by the analog filter. The filter regards pulses up to a certain width as noise and suppresses them.
For the minimum $\overline{\text{RESET}}$ pulse width refer to the Data Sheet.

Figure 9.9 External reset signal ($\overline{\text{RESET}}$)

9.4.4 Watchdog Timer Resets (WDTAnRES)

The Watchdog Timers can be configured to generate a reset if the watchdog time expires. After watchdog reset, the corresponding watchdog timer reset flag (the RESF.RESF1 bit for WDTA0RES, and the RESF.RESF2 bit for WDTA1RES, respectively) are set.

After that, the bit RESF.RESF1 (or the bit RESF.RESF2) is not cleared automatically, if WDTA0RES (or WDTA1RES) is stopped.

The bit RESF.RESF1 and the bit RESF.RESF2 are cleared by

- WDTA0RES:
  Setting the RESFC.RESFC1 bit to 1 clears the RESF.RESF1 bit.
- WDTA1RES:
  Setting the RESFC.RESFC2 bit to 1 clears the RESF.RESF2 bit.
- power-up reset PURES (POCRES or $\overline{\text{DBRES}}$)

9.4.5 Error Control Module Reset (ECMRES)

The Error Control Module can be configured to generate the reset ECMRES upon various error events. Refer to Section 48, Error Control Module (ECM) for details about the possible error events.

After ECMRES reset, the corresponding Error Control Module reset flag (RESF.RESF14 bit) is set.

After that, the bit RESF.RESF14 is not cleared automatically, if ECMRES is stopped.

The bit RESF.RESF14 is cleared by

- setting the RESFC.RESFC14 bit to 1
- power-up reset PURES (POCRES or $\overline{\text{DBRES}}$)

9.4.6 Software reset (SWRES)

The software reset SWRES can be asserted by setting

SWRESA.SWRESA = 1.

SWRES sets the reset flag RESF.RESF0 bit.

RESF.RESF0 is not cleared automatically. RESF.RESF0 is cleared by

- setting the RESFC.RESFC0 bit to 1
- power-up reset PURES (POCRES or $\overline{\text{DBRES}}$)

9.4.7 Clock Monitor 0 Reset ($\overline{\text{CLMA0RES}}$)

The Clock Monitor 0 generates the reset $\overline{\text{CLMA0RES}}$, when a fail of the High Speed IntOsc is detected.

In addition, flag CLMA0RES is set.

This flag is not cleared automatically. It is cleared by

- setting the RESFC.RESFC3 bit to 1
- power-up reset PURES (POCRES or $\overline{\text{DBRES}}$)

9.4.8 Debugger reset ($\overline{\text{DBRES}}$)

Debugger reset ($\overline{\text{DBRES}}$) is generated via a debugger command. $\overline{\text{DBRES}}$ activates PURES, thus operates in the similar way like the Power-On-Clear reset POC0RES:

- It resets the MainOsc and SubOsc clock generators. Hence these clock generators stop operation and must be restarted.
- The reset factor register RESF is cleared (bit RESF9 is set to 1 after initialization.).
- It does not reset the Low Speed IntOsc and High Speed IntOsc clock generators.

Section 10 Power Supply and Power Domains

This section describes the power supply and power domains of the RH850/D1L/D1M.

10.1 Function

The device is separated into two independent power domains for internal circuits, the Always-On-Area (AWO) and the Isolated-Area (ISO).
The power supply of the Always-On-Area remains powered in all operating modes.
The power supply of the Isolated-Area can be turned off in DEEPSTOP mode, reducing the overall device power consumption.
The digital logic of the power domains is supplied by a nominal voltage of 1.25 V.
This voltage is generated by dedicated on-chip voltage regulators for the Always-On-Area and the Isolated-Area of the D1L1, D1L2(H), D1M1(H) and D1M1A devices.
The voltage for the Isolated-Area's digital logic of the D1M2(H) devices is supplied from external.

10.1.1 Power Supply Pins

For operation of the devices the following voltages need to be provided:

Table 10.1 Power Supply Pins Overview (1/2)

Power supply pins	D1L1	D1L2(H)	D1M1(H), D1M1-V2, D1M1A	D1M2(H)
Always-On-Area:				
REG0VCC REG0VSS	AWO digital circuits via on-chip voltage regulator; nominal 3.3 V and 5 V			
OSCVCC OSCVSS	MainOsc and SubOsc; nominal 3.3 V and 5 V			
EVCC EVSS	$\overline{\text{RESET}}$, FLMD0, PWRGD, PWRCTL, port buffers P0 and JP0; nominal 3.3 V and 5 V			
Isolated-Area:				
REG1VCC REG1VSS	ISO digital circuits via on-chip voltage regulator, flash memory and PLL circuits; nominal 3.3 V and 5 V		ISO digital circuits via on-chip voltage regulator, flash memory and PLL circuits; nominal 3.3 V	Flash memory, nominal 3.3 V and 5 V
ISOVDD ISOVSS	–	–	–	ISO digital circuits, nominal 1.25 V
PLLVCC PLLVSS	–	–	–	PLL circuits; nominal 3.3 V and 5 V
B0VCC B0VSS	Port buffers port group P1; nominal 3.3 V and 5 V Port buffers ports P42_7 to P42_10; nominal 3.3 V and 5 V	Port buffers port group P1; nominal 3.3 V and 5 V • D1L2: Port buffers port group P42_7 to P42_10; nominal 3.3 V and 5 V	Port buffers port group P1; nominal 3.3 V and 5 V	Port buffers port groups P1, P2; nominal 3.3 V and 5 V
B1VCC B1VSS	Port buffers port group P3; nominal 3.3 V and 5 V			
B2VCC B2VSS	–	–	–	Port buffers ports P43_0 to P43_6, port groups P46, P47; nominal 3.3 V and 5 V
B3VCC B3VSS	–	–	–	Port buffers ports P43_7 to P43_12; nominal 3.3 V and 5 V

Table 10.1 Power Supply Pins Overview (2/2)

Power supply pins	D1L1	D1L2(H)	D1M1(H), D1M1-V2, D1M1A	D1M2(H)
B4VCC B4VSS	–	• D1L2: – • D1L2H: Port buffers port group P42; nominal 3.3 V and 5 V	Port buffers port group P42; nominal 3.3 V and 5 V	• D1M2: – • D1M2H port buffers port group P42; nominal 3.3 V and 5 V
B5VCC B5VSS	Port buffers port groups P44, P45; nominal 3.3 V and 5 V Port buffers ports P43_0, P43_1; nominal 3.3 V and 5 V • D1M1A : Port buffers port group P45 (OpenLDI); nominal 3.3V			–
RVCC RVSS	–	–	–	Port buffers port groups P44, P45 (VO0 RSDS); nominal 3.3 V
MVCC MVSS	–	–	–	• D1M2: – • D1M2H: port buffers port group P40 (VI0 MIPI I/F); nominal 3.3 V
SFVCC SFVSS	Port buffers port group P21 (Serial Flash I/F); nominal 3.3 V and 5 V	Port buffers port group P21 (Serial Flash I/F); nominal 3.3 V • D1M1-V2, D1M1A: Port buffers port group P22 (Serial Flash I/F); nominal 3.3 V		Port buffers port group • D1M2(H): P21 (Serial Flash I/F) • D1M2H: P21 (Media Local Bus) nominal 3.3 V
ISMVCC ISMVSS	Port buffers port groups P16 and P17 (Stepper Motor Controller/Driver); • nominal 5 V when used for stepper motor operation • nominal 3.3 V and 5 V when not used for stepper motor operation			
ZPDVCC ZPDVSS	Zero point detection circuit; nominal 5 V			
ZPDVREF	Zero point detection external reference voltage; maximum ZPDVCC

A0VREF	A/D Converter reference voltage; maximum A0VCC			

NOTE

For the exact voltage ranges, refer to the data sheet for the Electrical Characteristics.

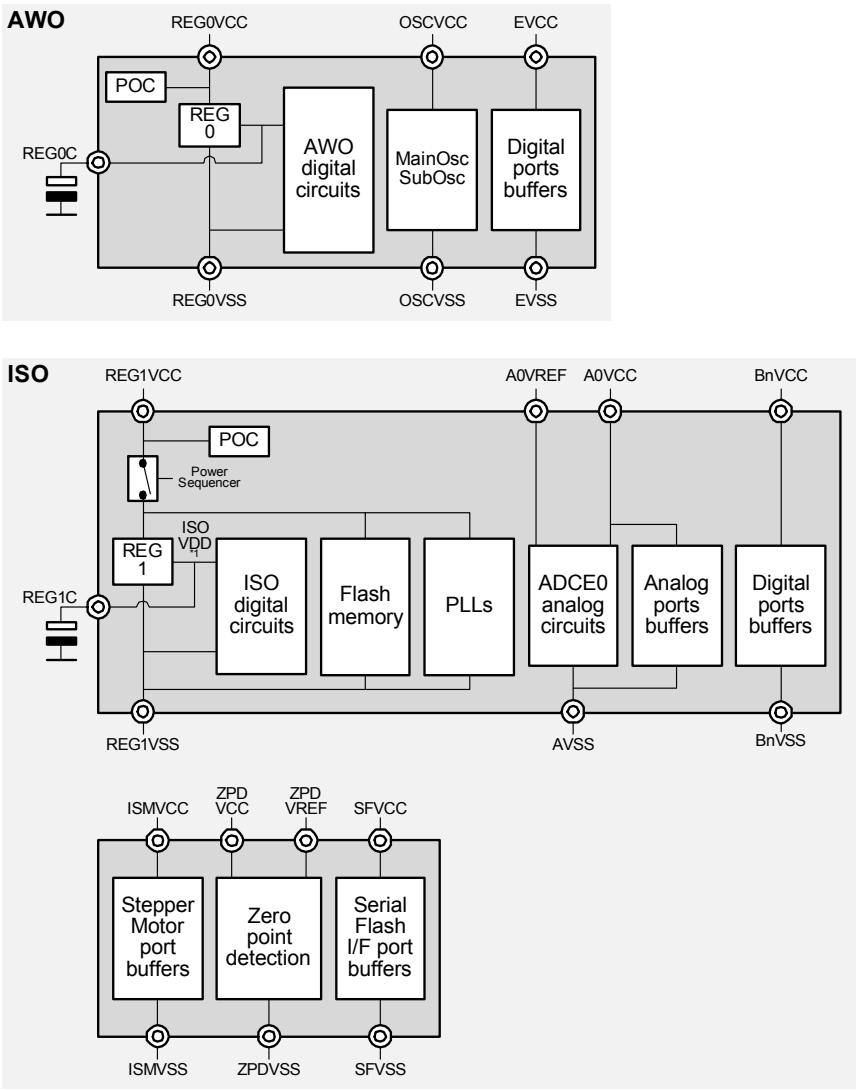
10.1.2 Power-On-Clear

The external power supplies

- REG0VCC
- REG1VCC of the D1L1, D1L2(H), D1M1(H), D1M1-V2 and D1M1A devices

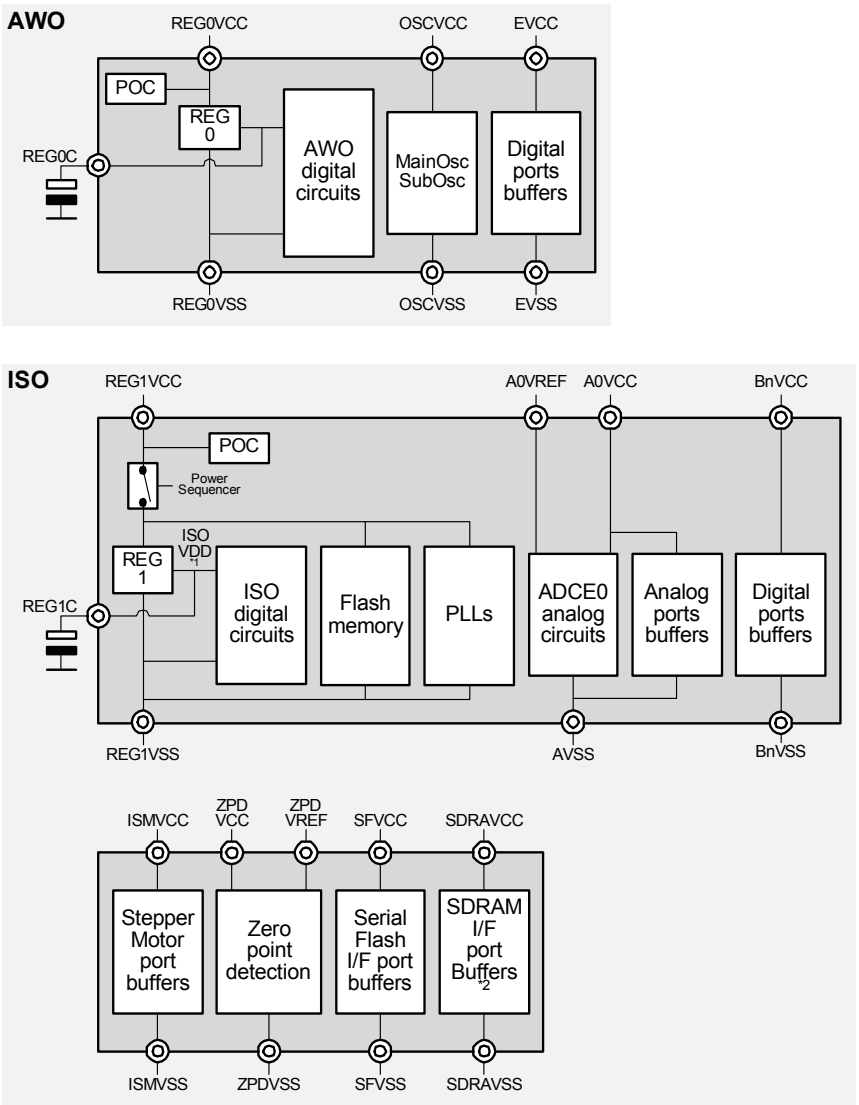
are monitored internally by Power-On-Clear circuits in order to secure the device operation. Refer to Section 9, Reset Controller for details.

10.1.3 Block Diagram of Power Domains



Note 1. ISOVDD is also input to the A/D Converter channel 20 for supply voltage monitoring purposes.

Figure 10.1 D1L1, D1L2(H) power supply overview



Note 1. ISOVDD is also input to the A/D Converter channel 20 for supply voltage monitoring purposes.
Note 2. Only for D1M1H and D1M1A

Note 1. ISOVDD is also input to the A/D Converter channel 20 for supply voltage monitoring purposes.
Note 2. Only for D1M2H.

Figure 10.3 D1M2(H) power supply overview

Section 11 Temperature Measurement

The temperature measurement facility measures the on-chip temperature by use of an on-chip Temperature Sensor (TSN). The output signal TSNOUT of the sensor is converted by the A/D Converter into a temperature representative value, which is checked to be in a configurable value range. In case it crosses that range the error interrupt INTADCE0ERR is generated.
The temperature out-of-range detection interrupt INTADCE0ERR is forwarded to the Error Control Module and thus can initiate interrupts and a reset.

A selectable Timer Array Unit B (TAUB) channel is used to trigger the A/D conversion - i.e. control of the temperature - periodically.

The temperature measurement is conducted by the CPU, which

- enables the Temperature Sensor
- sets up the selected TAUB channel as interval timer with the desired cycle duration
- starts the TAUB interval timer, when the start-up time of the sensor has passed and the Temperature Sensor output signal TSNOUT is stable.

Afterwards continuous temperature control is running without any CPU involvement.

In order to ensure sufficient start-up time to stabilize the sensor output TSNOUT a programmable start-up counter is provided , that is operated with the C_ISO_PCLK clock. The start-up time is minimum 200 µs.
The counter is automatically started with enabling the Temperature Sensor and indicates a stable TSNOUT signal by setting the ready flag TSNSTAT.TSNRDY = 1.

The A/D Converter provides a dedicated conversion channel, assigned to a dedicated scan group, for the temperature signal TSNOUT conversion, that allows to chose long sampling times for the Sample & Hold circuit of the A/D Converter in order to cope with voltage drops due to the capacitive load during sampling.

Temperature Measurement functions summary

- Temperature sensor is available with the analog channel 37of A/D converter unit 0 (ADCE0).
- Tj = Between -40°C to 25°C: ±10°C
  Tj = Between 25°C to 150°C: ±5°C
- Minimum Temperature measurement time: 6.55 µs (with 40 MHz CLKAD)
- start-up time: 200 µs
- Temperature alarm error is generated when temperature reaches to the upper/lower limit.
- Temperature measurement mode
  Continuous temperature measurement mode
- Self-diagnosis function
  Supporting self-diagnosis function by inserting high temperature error.
- Error notification function
  ADCE0 interrupt and TSN error are generated when the result of temperature measurement exceeded the value set in ADCEmULLMTBR0 to ADCEmULLMTBR2 registers.
- Supporting error reduction by calibration between two measurement points of temperature (Tj = 25°C and Tj = 150°C).

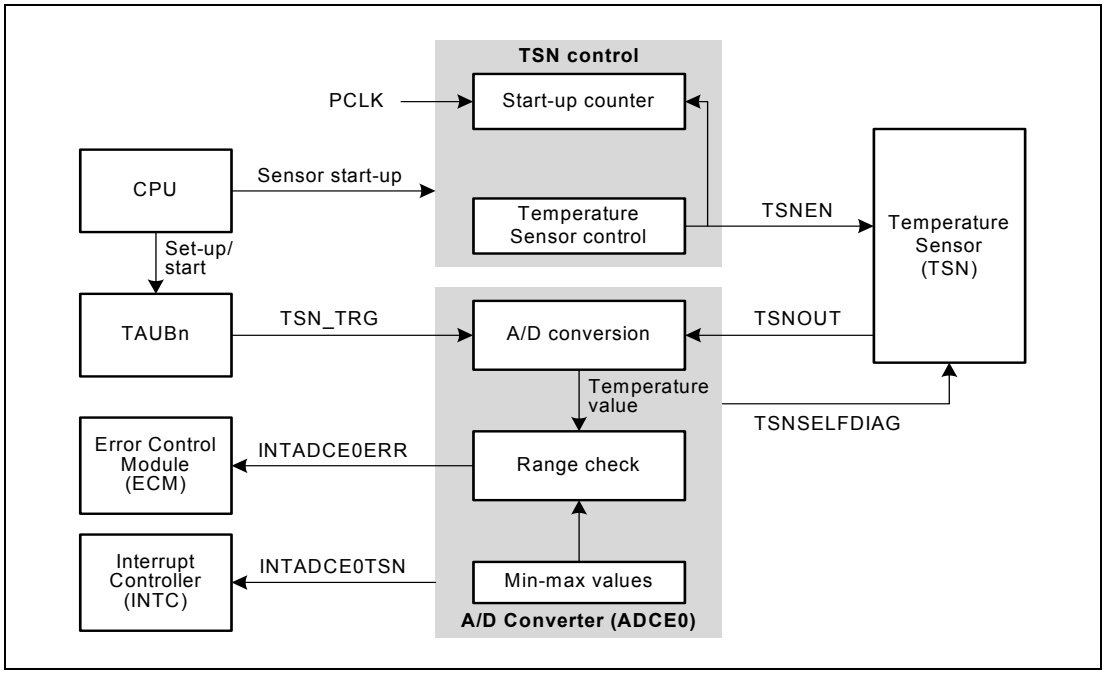

Figure 11.1 Temperature measurement set-up

11.1 Temperature calculation

The current temperature T_c can be calculated with the following formular:

$$T_c = \frac{150 - 25}{R_{150} - R_{25}} \times (R - R_{25}) + 25$$

T_c:	Current temperature in °C
R:	A/D conversion result of current measurement
R_{25}:	A/D conversion reference value for 25 °C for A0VREF = 5V
R_{150}:	A/D conversion reference value for 150 °C for A0VREF = 5V

The reference values read from the flash mask option bytes:

- OPBT10.TSNREFDH[11:0]: R_{150} value for A0VREF = 5V
- OPBT10.TSNREFDL[11:0]: R_{25} value for A0VREF = 5V

11.2 Temperature measurement initialization

The flow of AD conversion for temperature sensor is as follows.

(1) Select and set up the TAUBn channel to be used for triggering the temperature measurement A/D conversion. The TAUBn channel must not be started at this stage, but after the Temperature Sensor output signal is stable, i.e. after **(5)**.

(2) Set up all A/D Converter registers, related to temperature measurement:

- Temperature Sensor output limits by an upper/lower limit table register ADCE0ULLMTBR0 to 2

- Temperature measurement virtual channel register ADCE0TSNVCR:
  - upper/lower limit selection by TSNULS[1:0]
  - physical channel selection by TSNGCTRL[5:0] = 37
- Temperature measurement sampling control register ADCE0TSNSMPCR:
  - sampling time TSNSMPT[7:0]. The sampling time must be set to 6 µs. The correct TSNSMPT[7:0] value depends on the A/D Converter clock CLKAD.
- Temperature measurement trigger select control register ADCE0TSNSGTSEL
  - TTSNSEL[15:0] selects the A/D conversion trigger, i.e. the TAUBn channel, selected for triggering the A/D conversion in **(1)**.
- Temperature measurement scan group control register ADCE0TSNSGCR
  - TSNTRGMD = 1 enables the trigger to perform A/D conversion of the Temperature Sensor output signal

(3) Temperature Sensor start-up time by setting the TSNCNTCMP counter register.
The counter counts C_ISO_PCLK clocks. TSNCNTCMP has to be set to pass the minimum start-up time of 200 µs.

(4) Enable the Temperature Sensor by setting TSNCR.TSNEN = 1.
This starts also the Temperature Sensor start-up counter.

(5) Wait until the Temperature Sensor output TSNOUT is stable.
Stable output is indicated by TSNSTAT.TSNRDY = 1.

(6) Start the TAUBn channel, selected as the trigger in **(1)**.

(7) The TAUBn channel generates the conversion triggers TSN_TRG periodically and initiates A/D conversion of the Temperature Sensor output signal.

(8) The A/D Converter asserts the INTADCE0TSN interrupt, each time the conversion is completed.

(9) In case the A/D conversion result of the Temperature Sensor output exceeds the upper/lower limits, the A/D Converter asserts the error interrupt INTADCE0ERR and sets the upper limit/lower limit error register ADCE0ULER accordingly:
  - UE = 1 indicates Temperature Sensor output above upper limit
  - LE = 1 indicates Temperature Sensor output below lower limit
  - ULSG[1:0] = 0 indicates temperature measurement scan group number
  - ULECAP[5:0] = 37 indicated temperature measurement physical channel.

NOTES

1. All general A/D Converter settings, like e.g. resolution and alignment control via the A/D control register ADCE0ADCR and error control settings via the safety control register ADCEnSFTCR, are also valid for the temperature measurement.
2. For a detailed description of the A/D Converter registers refer to Section 45, A/D Converter (ADCE).

11.2.1 Stopping the temperature measurement

In order to stop the temperature measurement, disable temperature measurement scan group trigger via the control register ADCE0TSNSGCR:

– TSNTRGMD = 0 disables further A/D conversion triggers

11.2.2 Temperature measurement self-diagnostic

A temperature measurement self-diagnostic function allows to check proper operation of the Temperature Sensor.

The self-diagnostic mode is selected via the TSNSELFDIAG control bit of the A/D converter control register ADCEnADCR:

- TSNSELFDIAG = 0: self-diagnostic disabled
- TSNSELFDIAG = 1: self-diagnostic enabled

If self-diagnostic is enabled the Temperature Sensor outputs TSNOUT = 0 V.

During Temperature Sensor self-diagnostic the A/D Converter remains in normal operation mode.

In self-diagnostic mode it is expected that the maximum allowed temperature is exceeded.
Thus the lower limit ADCEnULLMTBRx.LLMTB[11:0], that represents the maximum allowed temperature T_{cmax}, has to be set for a temperature of

$T_{cmax} = T_{jmax} + 10\ °C$

By rearranging the formula for the temperature calculation, as given in Section 11.1, Temperature calculation, the lower limit value ADCEnULLMTBRx.LLMTB[11:0] = Rmin can be calculated by

$$R_{min} = \frac{(R_{150} - R_{25}) \times (T_{cmax} - 25)}{150 - 25} + R_{25}$$

T_{cmax}:	Maximum allowed temperature in °C
R_{min}:	A/D conversion result, representing the maximum allowed temperature T_
R_{25}:	A/D conversion reference value for 25 °C for A0VREF = 5V
R_{150}:	A/D conversion reference value for 150 °C for A0VREF = 5V

NOTE

ADCEnULLMTBRx with x = 0 to 2 in denotes the upper/lower limit pair, selected for the temperature measurement.

11.3 List of Registers

Following registers are used to operate the Temperature Sensor:

Table 11.1 Temperature Sensor registers

Module Name	Register Name	Symbol	Address
SELB	Temperature Sensor control register	TSNCR	FFC0 6034_H
SELB	Temperature Sensor status register	TSNSTAT	FFC0 6038_H
SELB	Compare match timer compare register	TSNCNTCMP	FFC0 $604C_H$

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> and <Symbol> are defined in the above table.

11.3.1 TSNCR — Temperature Sensor control register

This register enables or disables the Temperature Sensor.

Access: This register can be read or written in 32-bit units.

Address: FFC0 6034_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Section 12 Clock Controller

This section describes the Clock Controller functions of the RH850/D1L/D1M microcontrollers.

12.1 Clock Controller Overview

Features summary

The Clock Controller has the following functions:

- six clock sources:
  - Low Speed Internal Oscillator (LS IntOsc) with a nominal frequency of 240 kHz
  - High Speed Internal Oscillator (HS IntOsc) with a nominal frequency of 8 MHz
  - Sub Oscillator (SubOsc) with a nominal frequency of 32.768 kHz
  - Main Oscillator (MainOsc) 8 to 16 MHz
  - D1L1, D1L2(H), D1M1(H), D1M2(H):
    Spread Spectrum Phase Locked Loop (PLL0) with a nominal frequency of 320 MHz, 400 MHz, 480 MHz
  - D1M1-V2, D1M1A:
    Spread Spectrum Phase Locked Loop (PLL0) with a nominal frequency of 800 MHz, 960 MHz
  - D1L1, D1L2(H), D1M1(H), D1M1-V2, D1M1A:
    Fixed frequency Phase Locked Loop (PLL1) with a nominal frequency of up to 480 MHz
  - D1M2(H):
    Fixed frequency Phase Locked Loop (PLL1) with a nominal frequency of up to 960 MHz
  - D1M2(H) only: Phase Locked Loop (PLL2) for the video output channels pixel clock generation
    Refer to Section 37.5, Video channels clock generation for details.
- five Clock Monitors (CLMA0 to CLMA4) for
  - CLMA0 monitors the High Speed Internal Oscillator (HS IntOsc) f_{RH}
  - CLMA1 monitors the Low Speed Internal Oscillator (LS IntOsc) f_{RL}
  - CLMA2 monitors the Main Oscillator (MainOsc) f_X
  - CLMA3 monitors the PLL0 clock PLL0CLK
  - CLMA4 monitors the PLL1 clock PLL1CLK

  The additional two clock monitors CLMA5 and CLMA6 monitor the Video Input Interfaces pixel clocks at the ports VDCE0_VI_CLK and VDCE1_VI_CLK.
  Refer to Section 37.5.8, Video Input Pixel Clock Monitoring for details.

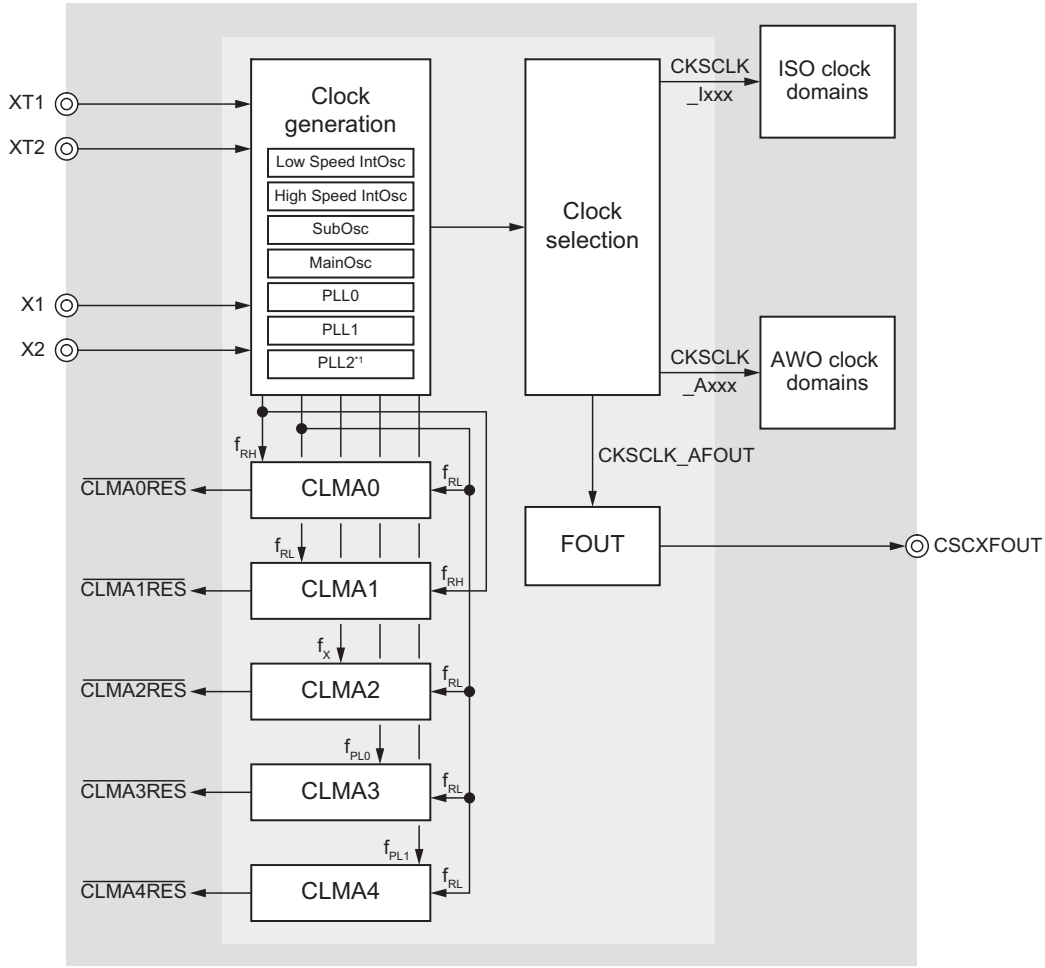
  If a Clock Monitor detects a failure of the monitored clock, it generates a signal towards the reset Controller or the Error Control Module (ECM).
- selectable and adjustable frequency output (CSCXFOUT)

For the specifications of the frequencies, acceptable variation, and other parameters of the clock generators, refer to the Data Sheet.

PLL index k

Throughout this section, the individual units of the PLL circuits are identified by the index "k" (k = 0 to 2). PLL2 is only available for D1M2(H) devices.

The following figure shows the main components of the Clock Controller.



Note 1. PLL2 is only available for D1M2(H) devices.

Figure 12.1 Clock Controller overview

12.1.1 Naming conventions

The clock signals, their control registers, etc. follow a defined naming convention, that reflects their membership to a certain power domain and clock domain.

Clock domain placeholder “xxx”

The placeholder “xxx” is used to identify the clock domain name, according to following naming convention:

- Clock domain names:
  - C_AWO_xxx: Always-On-Area clock domain
  - C_ISO_xxx: Isolated-Area clock domain
- Domain clock names:
  - CKSCLK_Axxx: Always-On-Area domain clock
  - CKSCLK_Ixxx: Isolated-Area domain clock
- Clock selector names:
  - CKSC_Axxx: clock selector for Always-On-Area clock selectors
  - CKSC_Ixxx: clock selector for Isolated-Area clock selectors
- Clock selector registers:
  - CKSC_AxxxS_CTL: Always-On-Area source clock selector registers
  - CKSC_AxxxD_CTL, CKDV_AxxxD_CTL: Always-On-Area source clock divider registers
  - CKSC_IxxxS_CTL: Isolated-Area source clock selector registers
  - CKSC_IxxxD_CTL, CKDV_IxxxD_CTL: Isolated-Area source clock divider registers

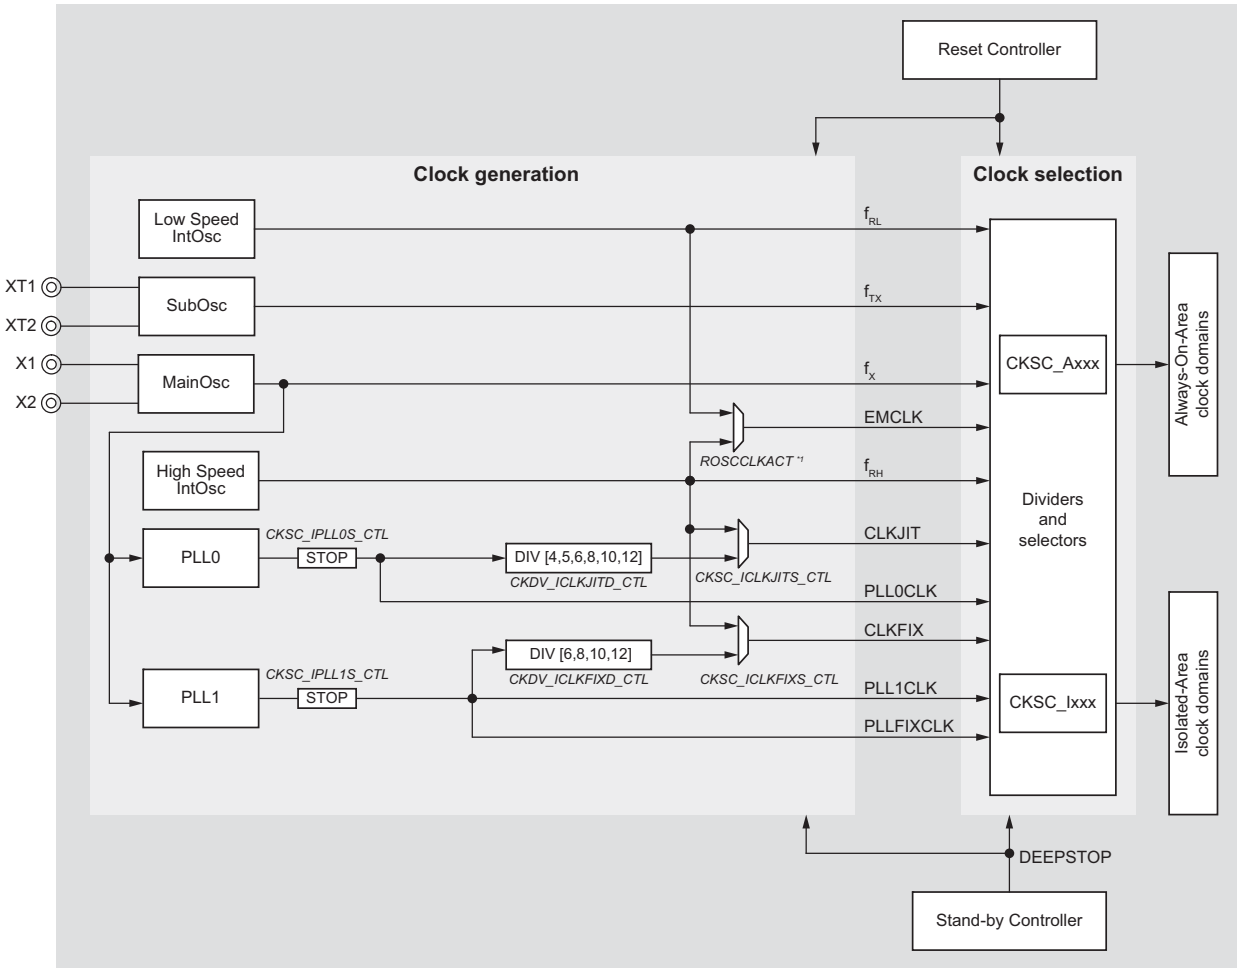
Example

The clock signal CKSCLK_ARTCA (placeholder xxx = RTCA) is the clock supplied to the clock domain C_AWO_RTCA in the Always-On-Area. This clock is selected by the clock selector register CKSC_ARTCAS_CTL.

12.1.2 Clock Controllers Block Diagrams

The following figure outlines the basic structure of the Clock Controller.

12.1.2.1 D1L1, D1L2(H) and D1M1 Clock Controller block diagram

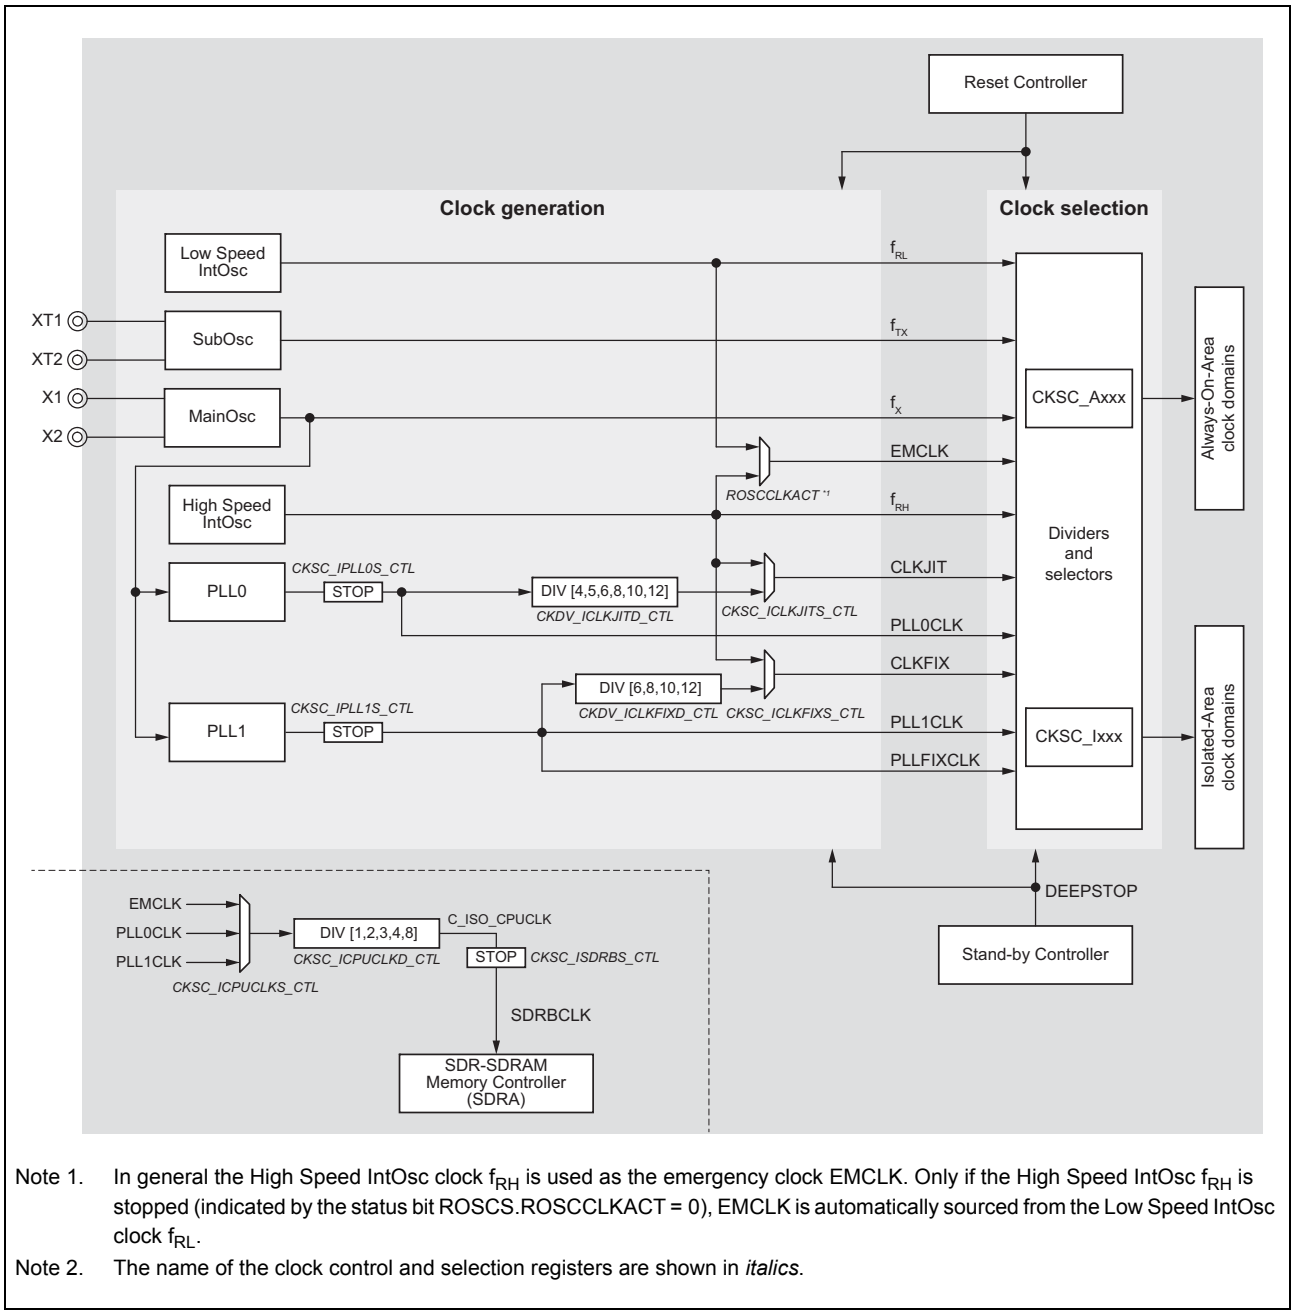


Note 1. In general the High Speed IntOsc clock f_{RH} is used as the emergency clock EMCLK. Only if the High Speed IntOsc clock f_{RH} is stopped (indicated by the status bit ROSCS.ROSCCLKACT = 0), EMCLK is automatically sourced from the Low Speed IntOsc clock f_{RL}.

Note 2. The name of the clock control and selection registers are shown in *italics*.

Figure 12.2 D1L1, D1L2(H) and D1M1 Clock Controller block diagram

12.1.2.2 D1M1H Clock Controller block diagram

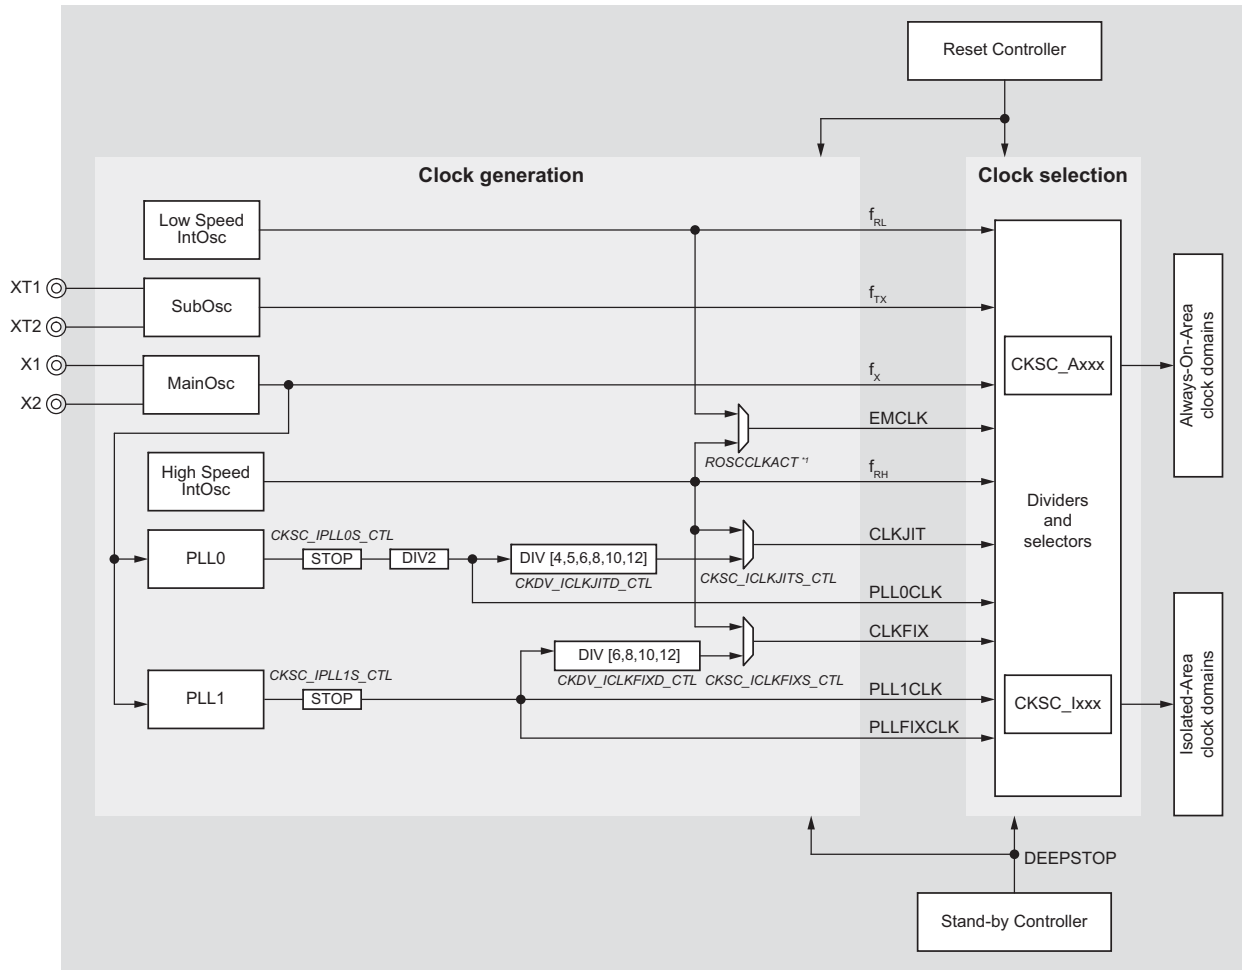


Note 1. In general the High Speed IntOsc clock f_{RH} is used as the emergency clock EMCLK. Only if the High Speed IntOsc f_{RH} is stopped (indicated by the status bit ROSCS.ROSCCLKACT = 0), EMCLK is automatically sourced from the Low Speed IntOsc clock f_{RL}.

Note 2. The name of the clock control and selection registers are shown in *italics*.

Figure 12.3 D1M1H Clock Controller block diagram

12.1.2.3 D1M1-V2 Clock Controller block diagram

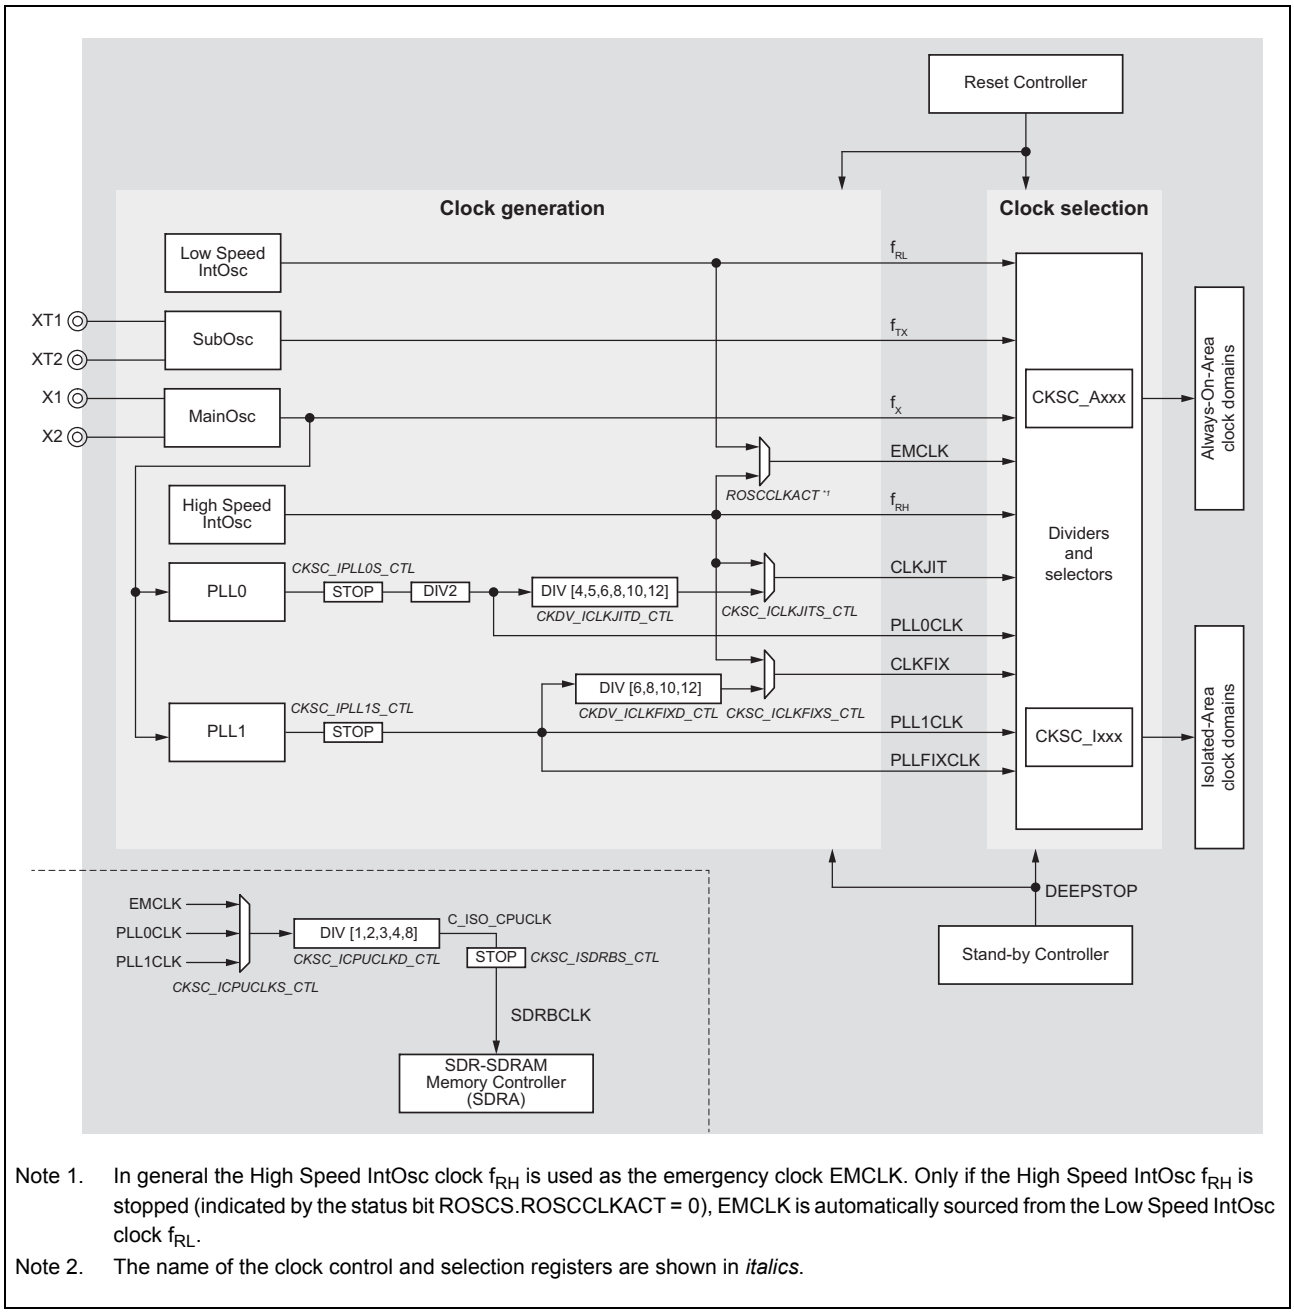


Note 1. In general the High Speed IntOsc clock f_{RH} is used as the emergency clock EMCLK. Only if the High Speed IntOsc clock f_{RH} is stopped (indicated by the status bit ROSCS.ROSCCLKACT = 0), EMCLK is automatically sourced from the Low Speed IntOsc clock f_{RL}.

Note 2. The name of the clock control and selection registers are shown in *italics*.

Figure 12.4 D1M1-V2 Clock Controller block diagram

12.1.2.4 D1M1A Clock Controller block diagram

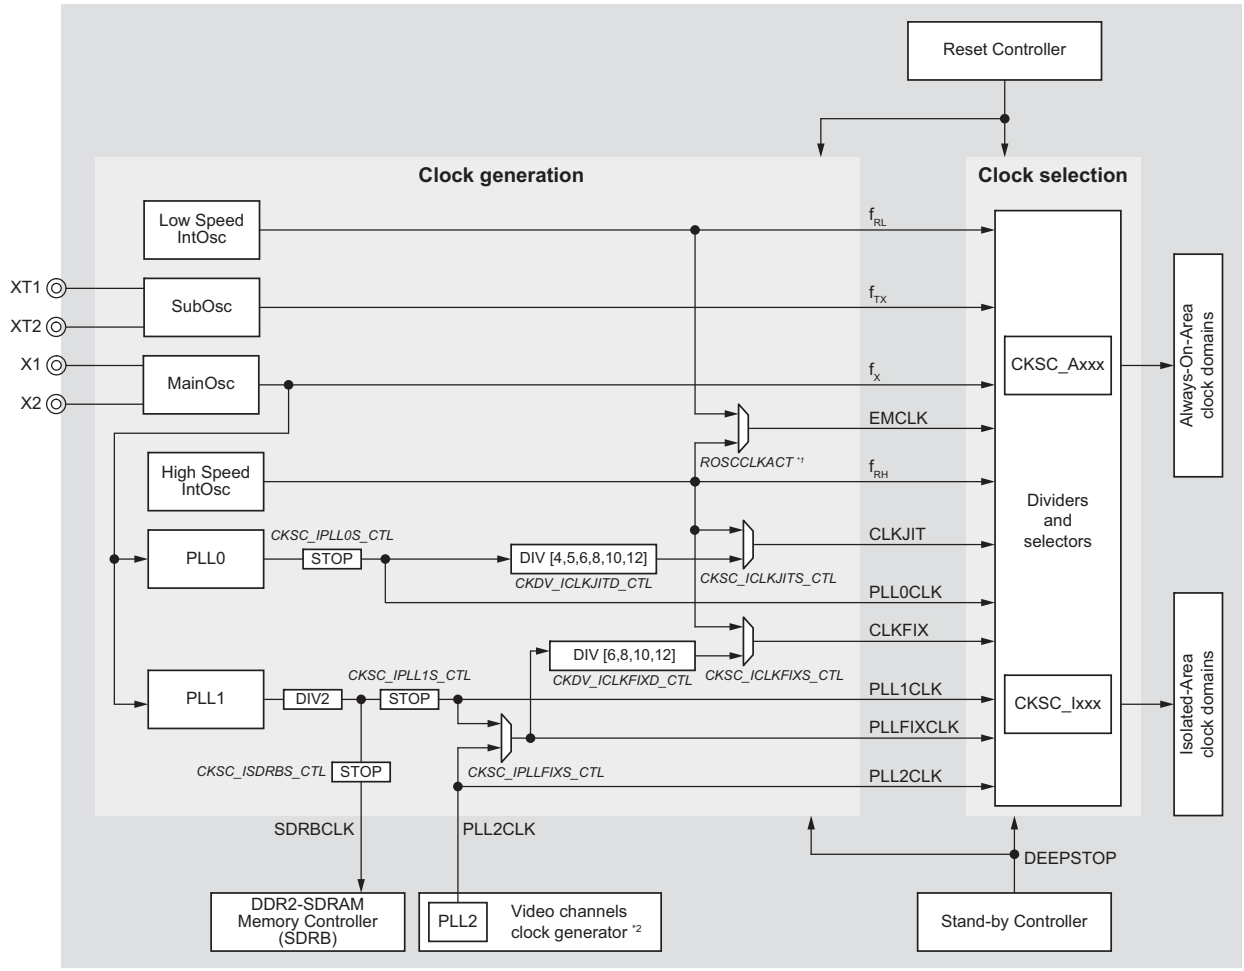


Note 1. In general the High Speed IntOsc clock f_{RH} is used as the emergency clock EMCLK. Only if the High Speed IntOsc f_{RH} is stopped (indicated by the status bit ROSCS.ROSCCLKACT = 0), EMCLK is automatically sourced from the Low Speed IntOsc clock f_{RL}.

Note 2. The name of the clock control and selection registers are shown in *italics*.

Figure 12.5 D1M1A Clock Controller block diagram

12.1.2.5 D1M2(H) Clock Controller block diagram



Note 1. In general the High Speed IntOsc clock f_{RH} is used as the emergency clock EMCLK. Only if the High Speed IntOsc f_{RH} is stopped (indicated by the status bit ROSCS.ROSCCLKACT = 0), EMCLK is automatically sourced from the Low Speed IntOsc clock f_{RL}.

Note 2. PLL2 is included in the video channels clock generator. Refer to Section 37.5, Video channels clock generation for details.

Note 3. The name of the clock control and selection registers are shown in *italics*.

Figure 12.6 D1M2(H) Clock Controller block diagram

NOTES

1. The control registers of the oscillators and PLL circuits in **Figure 12.2** to **Figure 12.6** are described in Section 12.3.2, Clock oscillators and PLL control registers.
2. The clock selection and control registers of the clock generation part in **Figure 12.2** to **Figure 12.6** are described in Section 12.3.3, Clock generator selection registers.
3. The clock selection and control registers of the clock selection part in **Figure 12.2** to **Figure 12.6** are described in Section 12.3.5, Always-On-Area clock domain selection registers and Section 12.3.6, Isolated-Area clock domain selection registers.

12.1.2.6 CPU Subsystem and bus clock domains

The base clock for the CPU Subsystem and all buses can be selected from various sources.

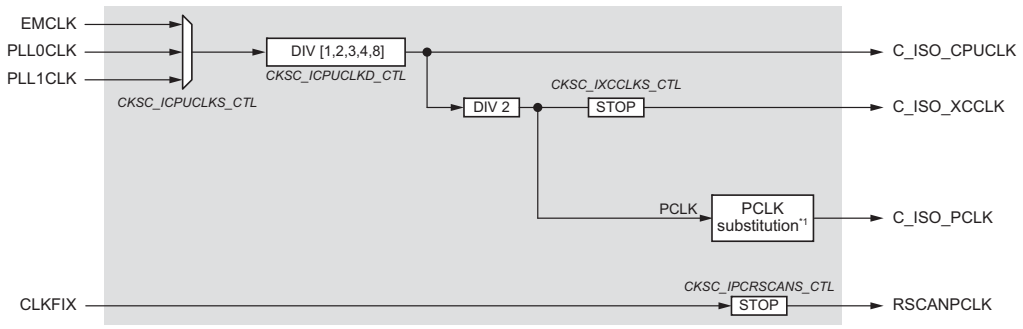
All bus clocks (C_ISO_XCCLK for Cross-connects, C_ISO_PCLK for PBUS) are derived from the CPU Subsystem clock domain C_ISO_CPUCLK.

Several bus clocks can be stopped individually, as shown in the figure below.

NOTE

The clock selection and control registers of the CPU and bus subsystems clock domains are described in Section 12.3.4, CPU Subsystems and bus clock domains selection registers.

(1) D1L1, D1L2(H) CPU and bus subsystems clock domains

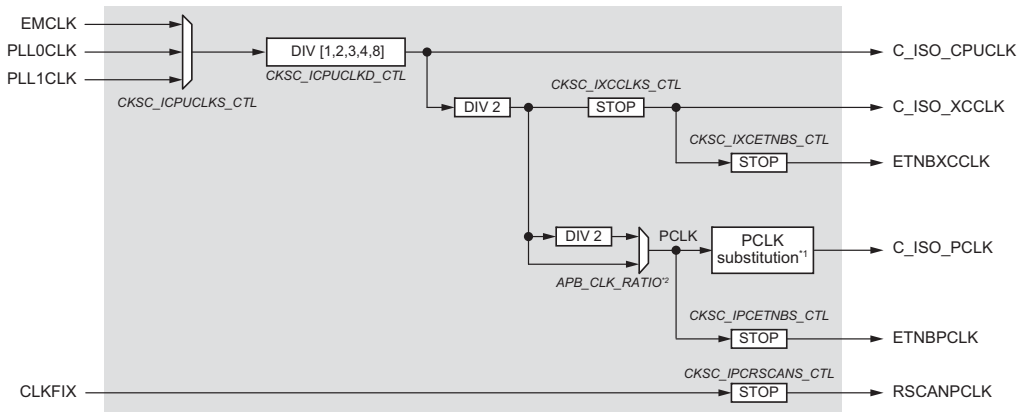


Note 1. Refer to Section 12.1.2.7, PCLK substitution for details.

Note: The name of the clock control and selection registers are shown in *italics*.

Figure 12.7 D1L1, D1L2(H) CPU and bus subsystems clock domains

(2) D1M1(H), D1M1-V2, D1M1A CPU and bus subsystems clock domains



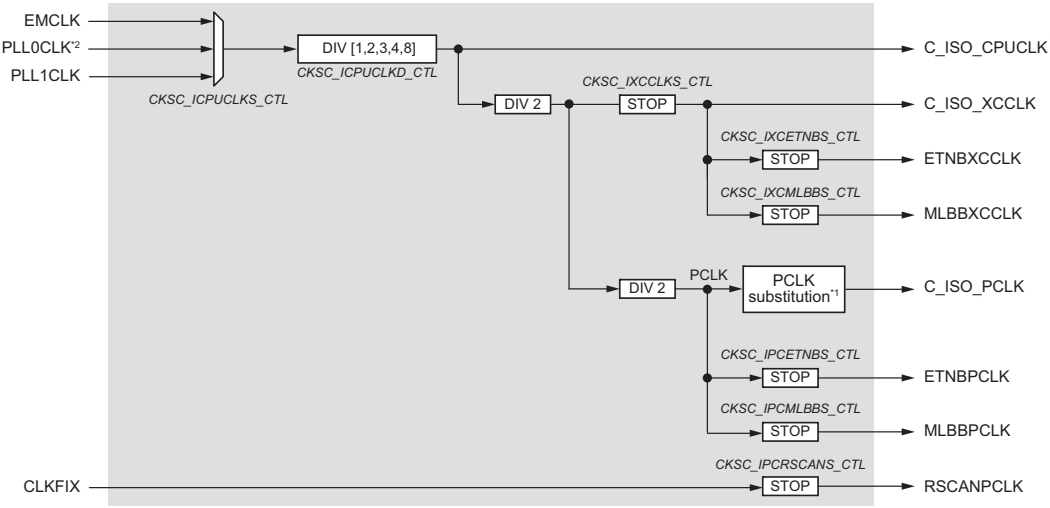
Note 1. Refer to Section 12.1.2.7, PCLK substitution for details.

Note 2. APB_CLK_RATIO selection register not available in D1M1-V2 and D1M1A.
D1M1-V2 implements fixed selection C_ISO_PCLK = C_ISO_XCCLK.
D1M1A implements fixed selection C_ISO_PCLK = C_ISO_XCCLK / 2.

Note: The name of the clock control and selection registers are shown in *italics*.

Figure 12.8 D1M1(H), D1M1-V2, D1M1A CPU and bus subsystems clock domains

(3) D1M2(H) CPU and bus subsystems clock domains



Note 1. Refer to Section 12.1.2.7, PCLK substitution for details.

Note 2. Selection of PLL0CLK for the C_ISO_CPUCLK clock domain is not allowed, when the DDR2-SDRAM Memory Controller (SDRB) is used.

Note: The name of the clock control and selection registers are shown in *italics*.

Figure 12.9 D1M2(H) CPU and bus subsystems clock domains

12.1.2.7 PCLK substitution

The Error Control Module is supplied by the C_ISO_PCLK clock. Since the Error Control Module's operation clock is also C_ISO_PCLK, the PCLK clock substitution ensures clock supply even if the selected source for C_ISO_PCLK fails to operate.

In the following situation the C_ISO_PCLK clock is switched to the High Speed IntOsc clock f_{RH}:

- The source of C_ISO_PCLK is the PLL0CLK or PLL1CLK:
  - CKSC_ICPUCLKS_CTL.CPUCLKSCSID[2:0] = 011_B for PLL0CLK
  - CKSC_ICPUCLKS_CTL.CPUCLKSCSID[2:0] = 100_B for PLL1CLK
- The selected PLL clock fails, which leads to an error detection of the respective Clock Monitor, thus
  - INTCLMA3TI is asserted, if PLL0CLK fails
  - INTCLMA4TI is asserted, if PLL1CLK fails
- CLMAOTCTL1.CLMA3CNT[3:0] cycles of the High Speed IntOsc clock f_{RH} have passed.

Since the Error Control Module is operating now with the f_{RH} clock, it handles the Clock Monitor error INTCLMA3TI or INTCLMA4TI.

The time between a Clock Monitor error detection and the switch of C_ISO_PCLK to f_{RH} is programmable via the CLMAOTCTL1 register.

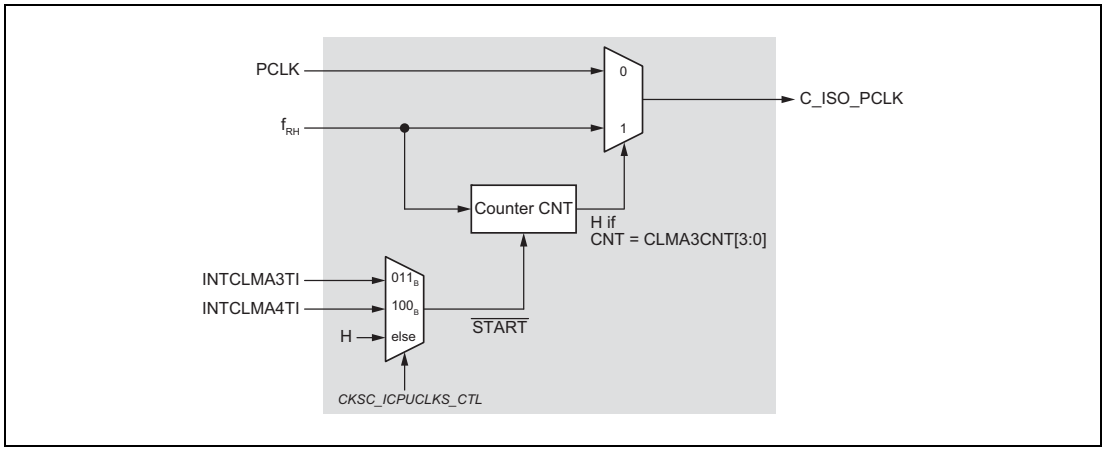


Figure 12.10 PCLK substitution

(1) CLMAOTCTL1 - PCLK substitution timing register

Access: This register is readable/writable in 8-bit units.

Address: FFF8 F2C4$_H$

Initial value: 0F$_H$

Table 12.1 CLMAOTCTL1 Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When written, write the initial value.
3 to 0	CLMA3CNT[3:0]	Number of f_{RH} cycles between INTCLMA3TI or INTCLMA4TI Clock Monitor error detection and switch of C_ISO_PCLK to f_{RH}. **CAUTION** These bits must be written with more than 01$_H$.

NOTE

In the header files the module name of the above register is defined as:

CLMAC

12.1.3 Clock generators

Four clock generators are located on the Always-On-Area (AWO).
PLL0, PLL1 and PLL2 (for D1M2(H) only) are located on the Isolated-Area (ISO).

Low Speed Internal Oscillator (Low Speed IntOsc)

This oscillator generates the clock f_{RL}, which runs at a frequency of 240 kHz (Typ.). It starts operation after power up and can not be stopped, hence it is always operating.

High Speed Internal Oscillator (High Speed IntOsc)

The High Speed IntOsc generates a clock f_{RH}, which runs at a frequency of 8 MHz (Typ.).
It is automatically started after power up. It can be automatically stopped during DEEPSTOP mode and re-started after wake-up.

Sub Oscillator (SubOsc)

The SubOsc generates the sub-clock f_{TX}, which runs at a frequency of typical 32.768 kHz. Generation of the sub clock f_{TX} requires the connection of an external resonator to XT1 and XT2.
This clock is mainly used for real-time clock applications.

Main Oscillator (MainOsc)

The MainOsc generates the clock f_X.
Generation of the clock f_X requires the connection of an external resonator to X1 and X2.
The clock f_X is used as the reference clock for PLL0 and PLL1.

PLL0

The Spread Spectrum Phase Locked Loop (PLL0) generates the clock PLL0CLK. It is the main clock source for CPU and all busses. It is also the clock for jitter tolerant functional modules.

PLL1

PLL1 generates the PLL1CLK clock. It is the main clock for functional modules that need a fixed frequency.

PLL2 (D1M2(H) only)

PLL2 provides additional options for generating the video output pixel clocks of the D1M2(H) devices.

12.1.3.1 Clock generators reset

The clock generators on the Always-On-Area are reset by the PURES signal and the clock generator on the Isolated-Area is reset by the SYSRES signal or the ISORES signal.

NOTE

For the specifications of the frequencies, acceptable variation, and other parameters of the clock generators, refer to the Data Sheet.

12.1.4 Clock selectors

The clocks, generated by the clock generators, are input to the clock selectors CKSC_Axxx/CKSC_Ixxx.

Domain clocks CKSCLK_A<name>/CKSCLK_I<name> are selected by dedicated clock selectors from clocks directly input from the oscillators, or in some cases from clocks that have been divided by clock dividers.

- CKSC_IxxxS_CTL/CKSC_IxxxD_CTL registers: determine the clock for the Isolated-Area clock domains.
- CKSC_AxxxS_CTL/CKSC_AxxxD_CTL registers: determine the clock for the Always-On-Area clock domains.

Clock selectors reset

The clock selectors are reset by the SYSRES signal, which is asserted by all reset sources of the microcontroller. Hence after any reset the supply of all clock domains are set to their default configuration.

Clock stop request in DEEPSTOP mode

The Always-On-Area domain clocks can optionally be stopped in DEEPSTOP mode.

Continuation of stop of these clocks can be selected by use of individual stop mask registers.

CAUTION

Changing of one or all of this clock tree registers below must not be done again within a period of 20 µs after last change.

- **clock selector change of CKSC_IPLL0S_CTL**
- **clock selector change of CKSC_IPLL1S_CTL**
- **clock selector change of CKSC_ISDRBS_CTL**
- **clock selector change of CKSC_ICPUCLKS_CTL**
- **clock divider change of CKSC_ICPUCLKD_CTL**
- **PLL0 enable register PLL0E**
- **PLL1 enable register PLL1E**

CAUTION

You have to make sure that a clock source is active before you can change a clock selector already assigned to it.

Example:
CKSC_IDOTCLK0S_CTL defaults to PLL0PIXCLK which is stopped after reset. The PLL0PIXCLK must be started before the CKSC_IDOTCLK0S_CTL can be changed.

12.2 Clock Generators

12.2.1 Main Oscillator (MainOsc)

The Main Oscillator generates the clock f_X. f_X is also used as the PLL0 and PLL1 input clock PLL0CLKIN and PLL1CLKIN.

The following figure shows the basic structure and signals of the MainOsc.

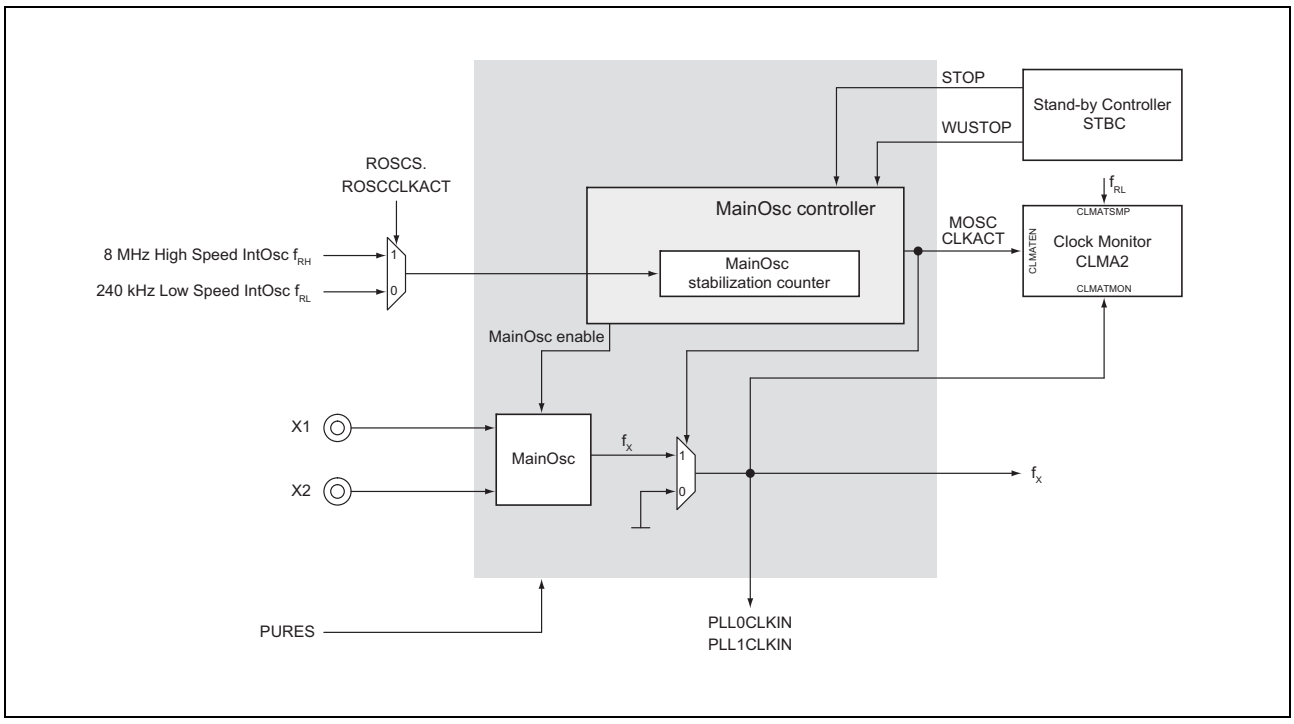

Figure 12.11 Main Oscillator (MainOsc)

The MainOsc is disabled after release from the power-up reset PURES state, and so must be enabled by setting the MainOsc enable trigger MOSCE.MOSCENTRG = 1.

MainOsc stabilization

The MOSCST.MOSCCLKST[16:0] bits set the MainOsc oscillation stabilization time.
The MainOsc stabilization counter counts the oscillation stabilization time with EMCLK as the clock source for counting. The range of settings is from 2^2 to (2^{17} –1), and is in cycles of EMCLK.
As long as the MainOsc is not stable, the MOSCCLKACT signal disables the f_X output.
If the MainOsc stabilization counter has reached the value, defined by MOSCST.MOSCCLKST[16:0], f_X is judged as stable and the change of MOSCCLKACT from 0 to 1 makes f_X available when a waveform is output from the MainOsc.

Stable and active f_X clock is indicated by MOSCS.MOSCCLKACT = 1.

MainOsc amplification gain

By using MOSCC.MOSCAMPSEL[1:0], the MainOsc's input frequency, determined by the external resonator, can be selected in the range from 8 MHz to 16 MHz.

MainOsc STOP requests in DEEPSTOP mode

The STOP signal from the Stand-by Controller requests the MainOsc Controller to switch off the f_X clock in DEEPSTOP mode.

The stop request mask bit MOSCSTPM.MOSCSTPMSK controls whether the MainOsc is stopped during DEEPSTOP or continues operation:

- MOSCSTPM.MOSCSTPMSK = 0:
  The STOP request signal is not masked, so the MainOsc is stopped in DEEPSTOP.
  If the MainOsc was in operation before DEEPSTOP, it is automatically re-started after wake-up from DEEPSTOP and the oscillation stabilization time is counted.
- MOSCSTPM.MOSCSTPMSK = 1:
  The STOP request signal is masked, so the MainOsc continues to operate in DEEPSTOP.

Clock Monitor control

The MainOsc activity signal MOSCCLKACT enables or disables supervision by the Clock Monitor CLMA2. In case the MainOsc is inactive (MOSCCLKACT = 0), supervision of its output clock f_X by CLMA2 is also deactivated.

MainOsc enable/disable trigger

The MainOsc can be enabled and disabled by the enable and disable trigger control bits:

- enable trigger MOSCE.MOSCENTRG = 1 starts the MainOsc
  Note that setting the enable trigger is only effective if the MainOsc is inactive, i.e. if MOSCS.MOSCCLKACT = 0.
- disable trigger MOSCE.MOSCDISTRG = 1 stops the MainOsc
  Note that setting the disable trigger is only effective if the MainOsc is active, i.e. if MOSCCLKACT = 1.

12.2.2 Sub Oscillator (SubOsc)

The Sub Oscillator generates the sub clock f_{TX}. f_{TX} has usually a frequency of 32.768 kHz and is used for the Real-time Clock.

The following figure shows the basic structure and signals of the SubOsc.

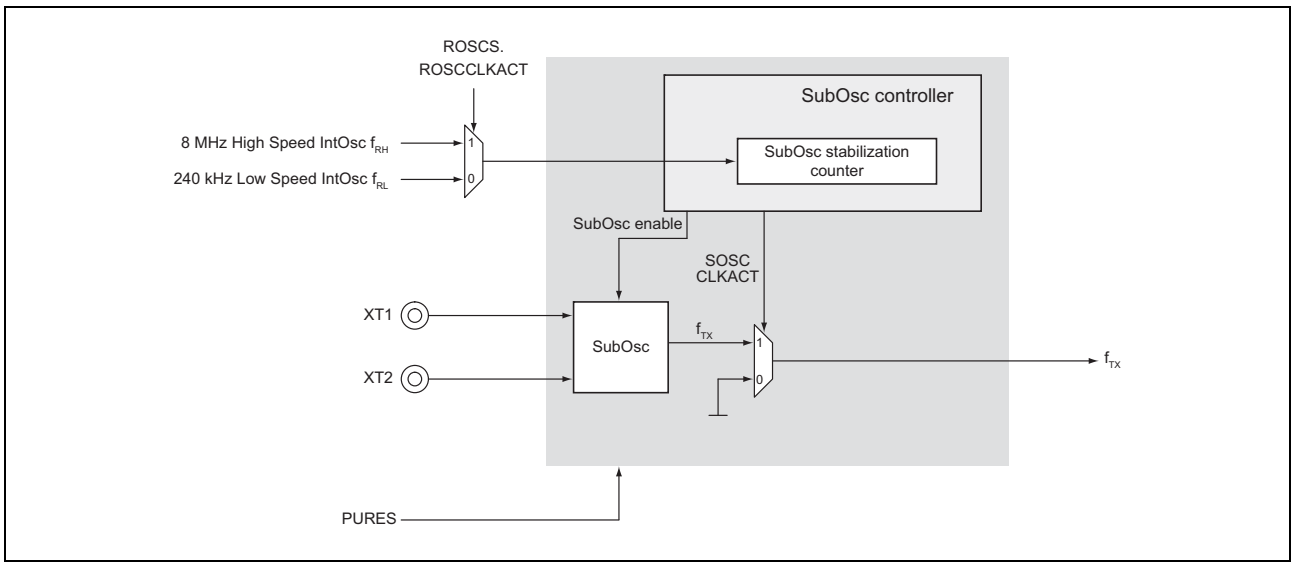

Figure 12.12 Sub Oscillator (SubOsc)

The SubOsc is disabled after release from the power-up reset PURES state, and so must be enabled by setting the SubOsc enable trigger SOSCE.SOSCENTRG = 1.

SubOsc stabilization

The SOSCST.SOSCCLKST[29:0] bits set the SubOsc oscillation stabilization time.

The SubOsc stabilization counter counts the oscillation stabilization time with EMCLK as the clock source for counting.

As long as the SubOsc is not stable, the SOSCCLKACT signal disables the f_{TX} output.

If the SubOsc stabilization counter has reached the value, defined by SOSCST.SOSCCLKST[29:0] bits, f_{TX} is judged as stable and the change of SOSCCLKACT from 0 to 1 makes f_{TX} available.

Secure the stabilization time longer than 2 seconds.

Stable and active f_{TX} clock is indicated by SOSCS.SOSCCLKACT = 1.

NOTE

The stabilization time of the SubOsc is specified in the Data Sheet.

SubOsc input frequencies

The SubOsc input frequency is typically 32.768 kHz.

SubOsc enable trigger/disable trigger

The SubOsc can be enabled or disabled by using the enable/disable trigger control bit.

- Enable trigger SOSCE.SOSCENTRG = 1 starts the SubOsc.
  Note that setting the enable trigger is only effective if the SubOsc is inactive, i.e. if SOSCS.SOSCCLKACT = 0.
- Disable trigger SOSCE.SOSCDISTRG = 1 stops the SubOSC.
  Note that setting the disable trigger is only effective if the SubOSC is active; that is, if SOSCS.SOSCCLKACT = 1.

12.2.3 High Speed Internal Oscillator (High Speed IntOsc)

The High Speed Internal Oscillator generates the clock f_{RH}. f_{RH} has a nominal frequency of 8 MHz.

The following figure shows the basic structure and signals of the High Speed IntOsc.

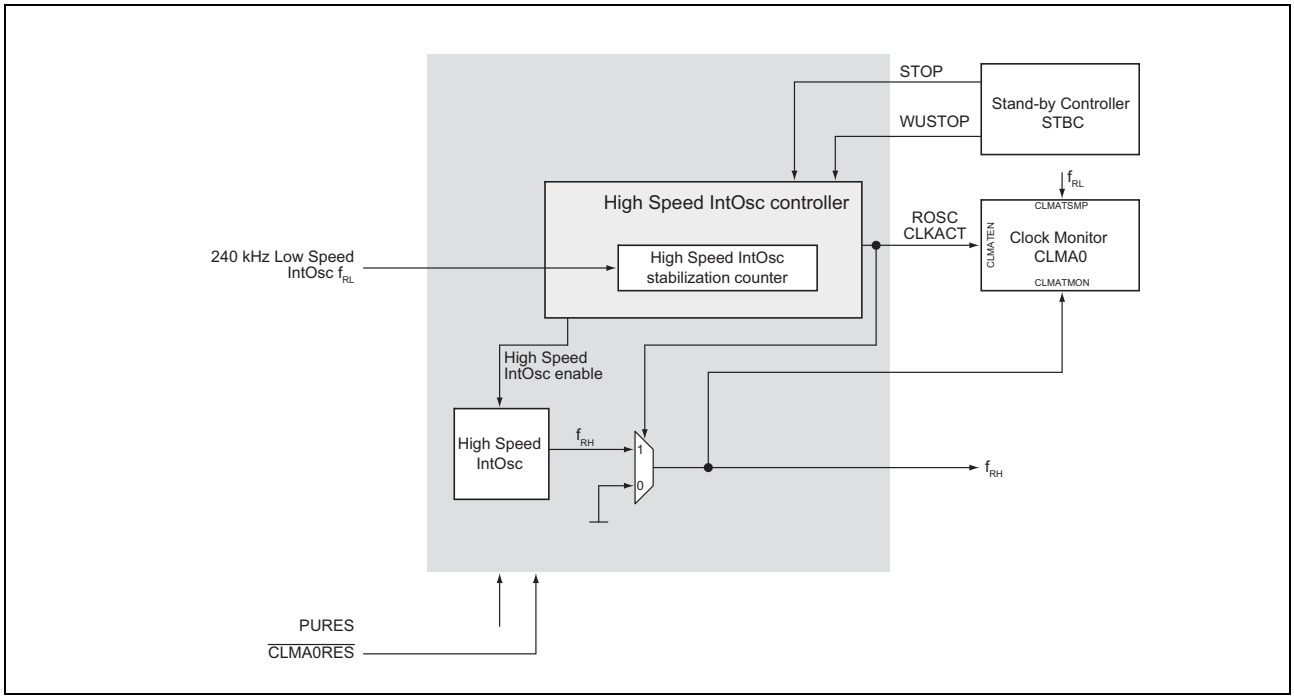

Figure 12.13 High Speed Internal Oscillator (High Speed IntOsc)

After reset release from the Power-up reset (PURES) or Clock Monitor 0 reset ($\overline{\text{CLMA0RES}}$) state the High Speed IntOsc starts operation.

NOTE

The High Speed IntOsc may only be stopped by software (using ROSCE.ROSCDISTRG = 1) after a CLMA0 reset. Thus CLMA0 reset indicates a High Speed IntOsc malfunction. In order to remain operable and to perform some emergency tasks, the software may stop the High Speed IntOsc and continue operation based on the Low Speed IntOsc.

High Speed IntOsc stabilization

Stable and active f_{RH} clock is indicated by ROSCS.ROSCCLKACT = 1.

NOTE

The stabilization time of the High Speed IntOsc is specified in the Data Sheet.

High Speed IntOsc STOP requests in DEEPSTOP mode

The STOP signal from the Stand-by Controller requests the High Speed IntOsc Controller to switch off the f_{RH} clock in DEEPSTOP mode.
The stop request mask bit ROSCSTPM.ROSCSTPMSK controls whether the High Speed IntOsc is stopped during DEEPSTOP or continues operation:

- ROSCSTPM.ROSCSTPMSK = 0:
  The STOP request signal is not masked, so the High Speed IntOsc is stopped in DEEPSTOP and automatically restarted after wake-up from DEEPSTOP.
- ROSCSTPM.ROSCSTPMSK = 1:
  The STOP request signal is masked, so the High Speed IntOsc continues to operate in DEEPSTOP.

Clock Monitor control

The High Speed IntOsc activity signal ROSCCLKACT enables or disables supervision by the Clock Monitor CLMA0. In case the High Speed IntOsc is inactive (ROSCCLKACT = 0), supervision of its output clock f_{RH} by CLMA0 is also deactivated.

The High Speed IntOsc clock f_{RH} is used as the sampling clock for Clock Monitor CLMA1.

12.2.4 Low Speed Internal Oscillator (Low Speed IntOsc)

The Low Speed Internal Oscillator generates the clock f_{RL}. f_{RL} has a nominal frequency of 240 kHz.

The following figure shows the basic structure and signals of the Low Speed IntOsc.

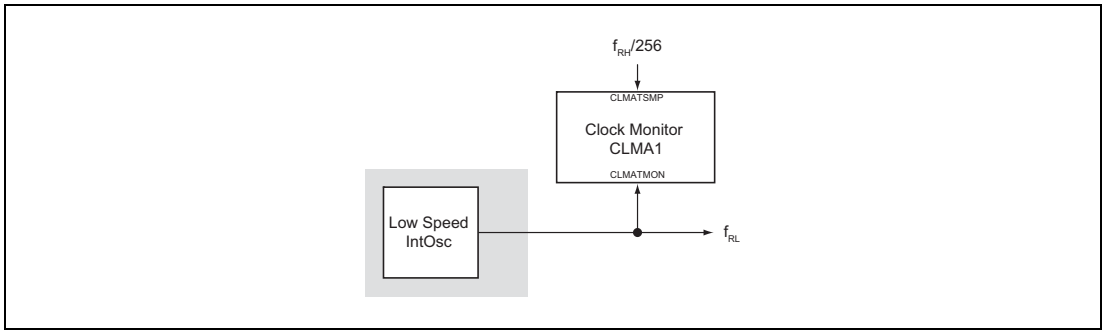

Figure 12.14 Low Speed Internal Oscillator (Low Speed IntOsc)

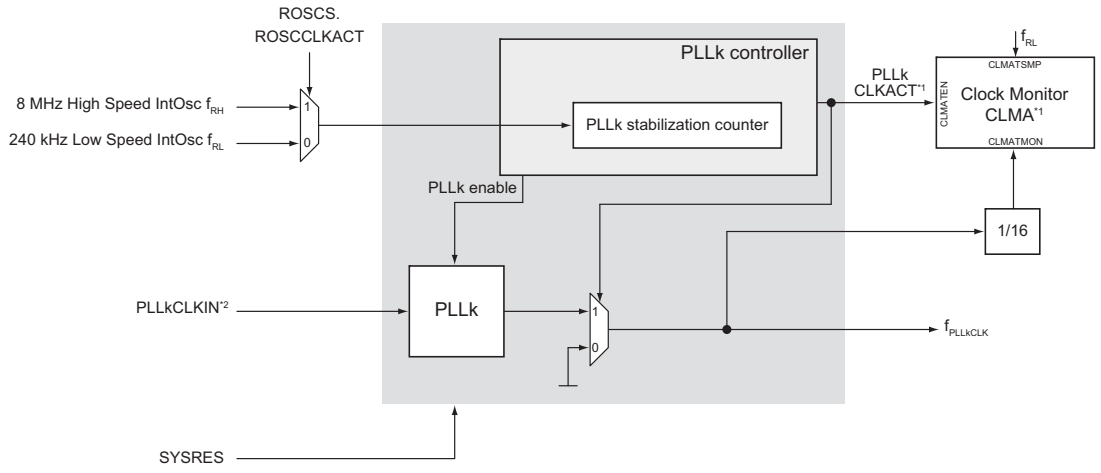
After reset release the Low Speed IntOsc starts operation. It can not be stopped.

The Low Speed IntOsc clock f_{RL} is used as the sampling clock for all Clock Monitors, except CLMA1.

12.2.5 PLLs

The RH850/D1L/D1M microcontrollers incorporate up to three PLL circuits.
PLLk with k = 0 to 2 identifies an individual unit. PLL2 is available only for D1M2(H) devices.

The following figure shows the basic structure and signals of the PLLk circuits.



Note 1. PLL0 output clock $f_{PLL0CLK}$/16 is monitored by Clock Monitor CLMA3.
PLL1 output clock $f_{PLL1CLK}$/16 is monitored by Clock Monitor CLMA4.
PLL2 output clock $f_{PLL2CLK}$ is not monitored.

Note 2. PLL0CLKIN = MainOsc clock f_X
PLL1CLKIN = MainOsc clock f_X
As for PLL2CLKIN refer Section 37.5, Video channels clock generation.

Figure 12.15 PLLk

All PLLs are disabled after release from the reset state, and so must be enabled by setting PLLkE.PLLkENTRG to 1.

PLL stabilization

The PLLk stabilization counter starts counting the stabilization time.
As long as the PLLk is not stable, the PLLkCLKACT signal disables the $f_{PLLkCLK}$ output.
If the PLLk stabilization counter has reached a predefined value, $f_{PLLkCLK}$ is judged as stable and the change of PLLkCLKACT from 0 to 1 makes $f_{PLLkCLK}$ available.

The stable and active state of the $f_{PLLkCLK}$ clock is indicated by PLLkS.PLLkCLKACT = 1.

NOTE

The stabilization time of the PLLs is specified in the Data Sheet.

PLLk in DEEPSTOP mode

Since all PLLk reside on the Isolated-Area, their power supply is switch off in DEEPSTOP mode.

Clock Monitor control

The PLL0 and PLL1 output clocks $f_{PLL0CLK}$ and $f_{PLL1CLK}$ are supervised by Clock Monitors.
The PLL0 and PLL1 activity signals PLL0CLKACT and PLL1CLKACT enable or disable supervision by the Clock Monitor CLMA3 and CLMA4. In case the PLL0 or PLL1 is inactive (PLL0CLKACT = 0 or PLL1CLKACT = 0), supervision of the output clocks $f_{PLL0CLK}$ or $f_{PLL1CLK}$ by CLMA3 or CLMA4 is also deactivated.

PLLk enable/disable trigger

The PLLk can be enabled and disabled by the enable and disable trigger control bits:

- enable trigger PLLkE.PLLkENTRG = 1 starts the PLLk
  Note that setting the enable trigger is only effective if the PLLk is inactive, i.e. if PLLkS.PLLkCLKACT = 0.
- disable trigger PLLkE.PLLkDISTRG = 0 stops the PLLk
  Note that setting the disable trigger is only effective if the PLLk is active, i.e. if PLLkS.PLLkCLKACT = 1.

12.2.6 PLLk parameters

The PLLk (k = 0 to 2) are configured by a set of parameters, derived from the control register PLLkC.

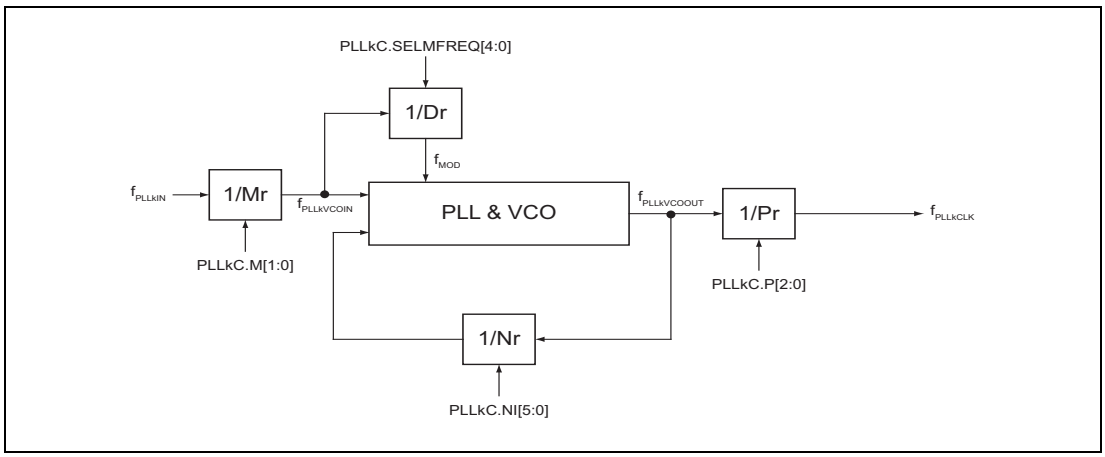


Figure 12.16 PLLk circuit

12.2.6.1 PLLk input clocks

- PLL0: f_{PLL0IN} = MainOsc f_X
- PLL1: f_{PLL1IN} = MainOsc f_X
- PLL2: f_{PLL2IN} is the frequency of the PLL2INCLK and depends on the setting of the CKSC_IPLL2INS_CTL clock selector and CKDV_IPLL2IND_CTL clock divider. Refer to Section 37.5, Video channels clock generation for details.

12.2.6.2 PLL0 modes

The PLL0 can used as a Spread Spectrum Clock Generator (SSCG) with dithering output clock:

• PLLkC.SSMODE[1:0] = $0x_H$: PLL mode with fixed output frequency, i.e. dithering disabled

• PLLkC.SSMODE[1:0] = 10_H: Down spread dithering mode

• PLLkC.SSMODE[1:0] = 11_H: Center spread dithering mode

NOTES

1. PLL1 and PLL2 can not be used in any dithering mode.
2. The output clock of PLL2 can be dithered, if PLL0 is operated in dithering mode and its output clock is selected as the PLL2 input clock via the CKSC_IPLL2INS_CTL clock selector.

12.2.6.3 PLLk output frequency

The PLLk output frequency $f_{PLLkCLK}$ is calculated as follows:

$$f_{PLLkCLK} = f_{PLLkIN} \bullet \frac{Nr}{Mr \bullet Pr}$$

The values Nr, Mr and Pr are derived from PLLkC register bits:

(1) Nr value

The Nr value is determined by

Nr = PLLkC.NI[5:0] + 1.

- PLL0:
  - D1L1, D1L2(H), D1M1(H), D1M2(H):
    Nr = PLL0C.NI[6:0] + 1
    Allowed range:
    $12 \le Nr \le 80$ thus PLL0C.NI[6:0] = $0B_H$ to $4F_H$
  - D1M1A, D1M1-V2:
    Nr = PLL0C.NI[6:0] + 1
    Allowed range:
    $24 \le Nr \le 160$ thus PLL0C.NI[6:0] = $0B_H$ to $4F_H$
- PLL1:
  - D1L1, D1L2(H), D1M1(H), D1M1A, D1M1-V2:
    Nr = PLL1C.NI[5:0] + 1
    Allowed range:
    $20 \le Nr \le 60$ thus PLL1C.NI[5:0] = 13_H to $3B_H$
  - D1M2(H):
    Nr = (PLL1C.NI[6:0] + 1) × 2
    Allowed range:
    $24 \le Nr \le 160$ thus PLL1C.NI[6:0] = $0B_H$ to $4F_H$
- PLL2: Nr = PLL2C.NI[5:0] + 1
  Allowed range:
  $20 \le Nr \le 60$ thus PLL2C.NI[5:0] = 13_H to $3B_H$

(2) Mr value

Mr is determined by PLLkC.M[1:0]:

Mr = PLLkC.M[1:0] + 1

Allowed range: $1 \le Mr \le 3$, thus PLLkC.M[1:0] = 0, 1, 2

(3) Pr value

Pr is determined by PLLkC.P[2:0] according to the following table:

	PLL0 output frequency			
PLL0C.P[2:0]	**Pr**	**D1L1, D1L2(H), D1M1(H), D1M2(H)**	**Pr**	**D1M1A, D1M1-V2**
000_B	1	320 MHz ≤ $f_{PLL0CLK}$ ≤ 480 MHz	1	533 MHz ≤ $f_{PLL0CLK}$ ≤ 960 MHz
001_B	2	160 MHz ≤ $f_{PLL0CLK}$ ≤ 320 MHz	2	266 MHz ≤ $f_{PLL0CLK}$ ≤ 533 MHz
010_B	4	80 MHz ≤ $f_{PLL0CLK}$ ≤ 160 MHz	4	160 MHz ≤ $f_{PLL0CLK}$ ≤ 266 MHz
011_B	8	40 MHz ≤ $f_{PLL0CLK}$ ≤ 80 MHz	8	66.6 MHz ≤ $f_{PLL0CLK}$ ≤ 160 MHz
100	16	20 MHz ≤ $f_{PLL0CLK}$ ≤ 40 MHz	16	40 MHz ≤ $f_{PLL0CLK}$ ≤ 66.6 MHz
101_B	–	Invalid	–	Invalid
110_B				
111_B				

	PLL1 output frequency			
PLL1C.P[2:0]	**Pr**	**D1L1, D1L2(H), D1M1(H), D1M1-V2, D1M1A**	**Pr**	**D1M2(H)**
000_B	1	240 MHz ≤ $f_{PLL1CLK}$ ≤ 480 MHz	1	533 MHz ≤ $f_{PLL1CLK}$ ≤ 960 MHz
001_B	2	120 MHz ≤ $f_{PLL1CLK}$ ≤ 240 MHz	2	266 MHz ≤ $f_{PLL1CLK}$ ≤ 533 MHz
010_B	4	60 MHz ≤ $f_{PLL1CLK}$ ≤ 120 MHz	4	160 MHz ≤ $f_{PLL1CLK}$ ≤ 266 MHz
011_B	6	40 MHz ≤ $f_{PLL1CLK}$ ≤ 80 MHz	8	66.6 MHz ≤ $f_{PLL1CLK}$ ≤ 133 MHz
100	8	30 MHz ≤ $f_{PLL1CLK}$ ≤ 40 MHz	16	40 MHz ≤ $f_{PLL1CLK}$ ≤ 66.6 MHz
101_B	16	20 MHz ≤ $f_{PLL1CLK}$ ≤ 30 MHz	–	Invalid
110_B	–	Invalid		
111_B				

PLL2C.P[2:0]	**Pr**	**PLL2 output frequency (D1M2(H))**
000_B	1	240 MHz ≤ $f_{PLL2CLK}$ ≤ 480 MHz
001_B	2	120 MHz ≤ $f_{PLL2CLK}$ ≤ 240 MHz
010_B	4	60 MHz ≤ $f_{PLL2CLK}$ ≤ 120 MHz
011_B	6	40 MHz ≤ $f_{PLL2CLK}$ ≤ 80 MHz
100	8	30 MHz ≤ $f_{PLL2CLK}$ ≤ 60 MHz
101_B	16	20 MHz ≤ $f_{PLL2CLK}$ ≤ 30 MHz
110_B	–	Invalid
111_B		

12.2.6.4 PLL0 frequency dithering parameters

If frequency dithering of the PLL0 is enabled (PLL0C.SSMODE[1:0] = $1x_H$), additional parameters must be set in PLL0C in order to specify the modulation frequency and range:

(1) PLL0C.SELMFREQ[4:0]: modulation frequency selection

The modulation frequency f_{MOD} is calculated as follows:

$$f_{MOD} = f_{PLL0VCOIN} / (4 \times Dr)$$

The factor Dr is determined by PLL0C.SELMFREQ[4:0].
Refer to Section 12.3.2.14, PLL0C — PLL0 control register for the relation between Dr and SELMFREQ[4:0].

The allowed range of f_{MOD} is 20 kHz ≤ f_{MOD} ≤ 100 kHz.

(2) PLLkC.SELMPERCENT[2:0]: dithering frequency range

The dithering frequency range is given in % of the PLL0 output clock frequency $f_{PLL0CLK}$.

- Down spread mode: - 1 % to -10 % of $f_{PLL0CLK}$
- Center spread mode: ± 1 % to ± 5 % of $f_{PLL0CLK}$

12.3 Registers

This section contains a description of all registers of the Clock Controller.

12.3.1 Clock Controller registers overview

The Clock Controller is controlled and operated by means of the following registers:

Table 12.2 List of Clock Controller registers (1/3)

Module Name	Register Name	Symbol	Address
Clock oscillators and PLL control registers:			
SYS	MainOsc enable register	MOSCE	FFF8 1100$_H$
SYS	MainOsc status register	MOSCS	FFF8 1104$_H$

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> and <Symbol> is defined in the above table.

12.3.2 Clock oscillators and PLL control registers

12.3.2.1 MOSCE — MainOsc enable register

This register is used to start and stop the MainOsc.

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMD0.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.

Address: FFF8 1100$_H$

Initial value: 0000 0000$_H$ This register is initialized by the power-up reset PURES.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MOSC DISTRG	MOSC ENTRG
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 12.3 MOSCE register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When written, write the initial value.
1	MOSCDISTRG	MainOsc disable trigger*1 0: no function 1: stops the MainOsc
0	MOSCENTRG	MainOsc enable trigger 0: no function 1: starts the MainOsc

Note 1. <Recommended procedure for stopping operations when MainOsc is stopped by MOSCDISTRG>
1. Check that there is no clock domain for which MainOsc is selected.
   If MainOsc is selected for a clock domain, disable the setting or select a clock source other than MainOsc.
2. Stop the MainOsc (MOSCE.MOSCDISTRG = 1)
3. Confirm that the MainOsc has been stopped (MOSCS.MOSCCLKACT = 0)

12.3.2.2 MOSCS — MainOsc status register

This register provides activity status information about the MainOsc.

Access: This register can be read in 32-bit units.

Address: FFF8 1104$_H$

Initial value: 0000 0000$_H$ This register is initialized by the power-up reset PURES.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	MOSCCLKACT	—*1	—*1
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. The values of bit 1 and 0 are undefined.
After masking bit 1 and 0, check only bit 2 to verify the status.

Table 12.4 MOSCS register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When written, write the initial value.
2	MOSCCLKACT	MainOsc activation status 0: MainOsc is inactive 1: MainOsc is active
1, 0	Reserved	When written, write the initial value.

12.3.2.3 MOSCC — MainOsc control register

This register is used to specify amplification gain of the MainOsc.

This register can only be written, if the MainOsc is disabled.

Access: This register can be read/written in 32-bit units.

Address: FFF8 1108_H

Initial value: 0000 0004_H This register is initialized by the power-up reset PURES.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—*1	MOSCAMPSEL [1:0]	
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Note 1. Do not change the default value “1” of this bit.

Table 12.5 MOSCC register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When written, write the initial value.
2	–	**CAUTION** The default value “1” of this bit must not be changed.
1, 0	MOSC AMPSEL[1:0]	MainOsc frequency selection

AMPSEL[1:0]	MainOsc frequency
00_B	8 MHz < $f_X \leq$ 16 MHz
01_B	8 MHz
10_B	8 MHz Low Power Mode
11_B	8 MHz Very Low Power Mode

NOTE

Standard oscillator circuits usually do not support Low Power Modes or Very Low Power Modes. Please ask your oscillator circuit supplier for special oscillators to support these modes.

12.3.2.4 MOSCST — MainOsc stabilization time register

This register determines the MainOsc stabilization time.

This register can only be written, if the MainOsc is disabled.

Access: This register can be read/written in 32-bit units.

Address: FFF8 110C$_H$

Initial value: 0000 44C0$_H$ This register is initialized by the power-up reset PURES.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MOSCCLKST16
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MOSCCLKST[15:0]															
Initial value	0	1	0	0	0	1	0	0	1	1	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 12.6 MOSCST register contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When written, write the initial value.
16 to 0	MOSC CLKST[16:0]	MOSCCLKST[16:0] defines the number EMCLK cycles, used as the MainOsc stabilization time. • If High Speed IntOsc active (ROSCS.ROSCCLKACT = 1): Stabilization time = MOSCCLKST[16:0] / f_{RH} • If High Speed IntOsc inactive (ROSCS.ROSCCLKACT = 0): Stabilization time = MOSCCLKST[16:0] / f_{RL}

NOTE

Refer to the Data Sheet for information about the MainOsc stabilization time.

12.3.2.5 MOSCSTPM — MainOsc Stop Mask Register

Access: This register can be read/written in 32-bit units.

Address: FFF8 1118$_H$

Initial value: 0000 0002$_H$. This register is initialized by the power-up reset PURES.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MOSCSTPMSK
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 12.7 MOSCSTPM register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When written, write the initial value.
0	MOSCSTPMSK	MainOsc stop request mask 0: MainOsc stops operation in DEEPSTOP mode. 1: MainOsc continues operation in DEEPSTOP mode

12.3.2.6 SOSCE — SubOsc enable register

This register is used to start and stop the SubOsc.

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMD0.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.

Address: FFF8 1200_H

Initial value: $0000\ 0000_H$. This register is initialized by the power-up reset PURES.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 12.8 SOSCE register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When written, write the initial value.
1	SOSCDISTRG	SubOsc disable trigger*1 0: No function 1: Stop SubOsc
0	SOSCENTRG	SubOsc enable trigger 0: no function 1: starts SubOsc

Note 1. <Recommended procedure for stopping operations when SubOsc is stopped by SOSCDISTRG>
1. Check that there is no clock domain for which SubOsc is selected.
   If SubOsc is selected for a clock domain, disable the setting or select a clock source other than SubOsc.
2. Stop the SubOsc (SOSCE.SOSCDISTRG = 1)
3. Confirm that the SubOsc has been stopped (SOSCS.SOSCCLKACT = 0)

12.3.2.7 SOSCS — SubOsc status register

This register provides activity status information about the SubOsc.

Access: This register can be read in 32-bit units.

Address: FFF8 1204_H

Initial value: 0000 0000_H This register is initialized by the power-up reset PURES.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	SOSCCLKACT	—*1	—*1
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. The values of bit 1 and 0 are undefined.
After masking bit 1 and 0, check only bit 2 to verify the status.

Table 12.9 SOSCS register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When written, write the initial value.
2	SOSCCLKACT	SubOsc activation status 0: SubOsc is inactive 1: SubOsc is active
1, 0	Reserved	When written, write the initial value.

12.3.2.8 SOSCST — SubOsc stabilization time register

This register determines the SubOsc stabilization time.

This register can only be written, if the SubOsc is disabled.

Access: This register can be read/written in 32-bit units.

Address: FFF8 120C$_H$

Initial value: 010C 8E00$_H$. This register is initialized by the power-up reset PURES.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	SOSCCLKST[29:16]													
Initial value	0	0	0	0	0	0	0	1	0	0	0	0	1	1	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SOSCCLKST[15:0]															
Initial value	1	0	0	0	1	1	1	0	0	0	0	0	0	0	0	0

Table 12.10 SOSCST register contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
29 to 0	SOSC CLKST[29:0]	The SOSCCLKST[29:0] bits specify the count for the SubOsc stabilization time counter. • If HS IntOsc is active (ROSCS.ROSCCLKACT = 1): stabilization time = SOSCCLKST[29:0] / f_{RH} • If HS IntOsc is inactive (ROSCS.ROSCCLKACT = 0): stabilization time = SOSCCLKST[29:0] / f_{RL}

NOTE

Refer to the Data Sheet for information about the SubOsc stabilization time.

CAUTION

Set this register when SubOsc has been stopped.

12.3.2.9 ROSCE — High Speed IntOsc enable register

This register is used to stop the High Speed IntOsc operation.

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMD0.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.

Address: FFF8 1000_H

Initial value: $0000\ 0000_H$. This register is initialized by the power-up reset PURES and the Clock Monitor 0 reset CLMA0RES.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ROSC DISTRG	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R

Table 12.11 ROSCE register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When written, write the initial value.
1	ROSCDISTRG	High Speed IntOsc disable trigger*1 0: no function 1: High Speed IntOsc stopped
0	Reserved	When written, write the initial value.

Note 1. <Recommended procedure for stopping operations when High-Speed IntOsc is stopped by ROSCDISTRG>
1. Check that there is no clock domain for which High-Speed IntOsc is selected.
   If High-Speed IntOsc is selected for a clock domain, disable the setting or select a clock source other than High-Speed IntOsc.
2. Stop the High-Speed IntOsc (ROSCE.ROSCDISTRG = 1)
3. Confirm that the High-Speed IntOsc has been stopped (ROSCS.ROSCCLKACT = 0).

12.3.2.10 ROSCS — High Speed IntOsc status register

This register provides activity status information about the High Speed IntOsc.

Access: This register can be read in 32-bit units.

Address: FFF8 1004_H

Initial value: $\overline{0000\ 0007_H}$. This register is initialized by the power-up reset PURES and the Clock Monitor 0 reset $\overline{CLMA0RES}$.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	—	ROSCCLKACT	—*1	—*1
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. The values of bit 1 and 0 are undefined.
After masking bit 1 and 0, check only bit 2 to verify the status.

Table 12.12 ROSCS register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When written, write the initial value.
2	ROSCCLKACT	High Speed IntOsc activation status 0: High Speed IntOsc is inactive 1: High Speed IntOsc is active
1, 0	Reserved	When written, write the initial value.

12.3.2.11 ROSCSTPM — High Speed IntOsc Stop Mask Register

Access: This register can be read/written in 32-bit units.

Address: FFF8 1018_H

Initial value: $0000\ 0002_H$. This register is initialized by the power-up reset PURES and the Clock Monitor 0 reset $\overline{CLMA0RES}$.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ROSCSTPMSK
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 12.13 ROSCSTPM register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When written, write the initial value.
0	ROSCSTPMSK	High Speed IntOsc stop request mask in DEEPSTOP mode 0: High Speed IntOsc stops operation in DEEPSTOP mode. 1: High Speed IntOsc continues operation in DEEPSTOP mode Note that the High Speed IntOSC can be stopped in the case the High Speed IntOSC disable trigger ROSCE.ROSCDISTRG is set to 1 regardless of the setting of this bit.

NOTE

Except in D1M1A and D1M1-V2, there are possibility that MCU does not wake-up. When using the interrupt signals INTP0 to INTP10 for wake-up factor, set the input pulse width long enough or configure that high speed internal oscillator does not stop in DEEPSTOP (ROSCSTPM.ROSCSTPMSK = 1). To refer the sufficient value, see RH850/D1L/D1M Group DATASHEET.

12.3.2.12 PLL0E — PLL0 enable register

This register is used to start and stop the PLL0.

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMD1.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.

Address: FFF8 9000_H

Initial value: $0000\ 0000_H$. This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 12.14 PLL0E register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When written, write the initial value.
1	PLL0DISTRG	PLL0 disable trigger*1 0: no function 1: stops PLL0
0	PLL0ENTRG	PLL0 enable trigger*2 0: no function 1: starts PLL0

Note 1. <Recommended procedure for stopping operations when PLL0 is stopped by PLL0EDISTRG>
1. Check that there is no clock domain for which PLL0 is selected.
If PLL0 is selected for a clock domain, disable the setting or select a clock source other than PLL0.
2. Stop the PLL0 (PLL0E.PLL0DISTRG = 1)
3. Confirm that the PLL0 has been stopped (PLL0S.PLL0CLKACT = 0).

Note 2. Before enabling the PLL0 by PLL0ENTRG, confirm that the MainOsc is active.

12.3.2.13 PLL0S — PLL0 status register

This register provides activity status information about the PLL0.

Access: This register can be read in 32-bit units.

Address: FFF8 9004$_H$

Initial value: 0000 0000$_H$. This register is initialized by any reset.

Note 1. The values of bit 1 and 0 are undefined.
After masking bit 1 and 0, check only bit 2 to verify the status.

Table 12.15 PLL0S register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When written, write the initial value.
2	PLL0CLKACT	PLL0 activation status 0: PLL0 is inactive 1: PLL0 is active
1, 0	Reserved	When written, write the initial value.

12.3.2.14 PLL0C — PLL0 control register

This register is used to specify the PLL0 output clock frequencies $f_{PLL0CLK}$.

This register can only be written, if the PLL0 is disabled.

Access: This register can be read/written in 32-bit units.

Address: FFF8 9008_H

Initial value: 6000 $003B_H$. This register is initialized by any reset.

12.3.2.15 PLL1E — PLL1 enable register

This register is used to start and stop the PLL1.

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMD1.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.

Address: FFF8 9100_H

Initial value: $0000\ 0000_H$. This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 12.17 PLL1E register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When written, write the initial value.
1	PLL1DISTRG	PLL1 disable trigger*1 0: no function 1: stops PLL1
0	PLL1ENTRG	PLL1 enable trigger*2 0: no function 1: starts PLL1

Note 1. Before stopping the PLL1 by PLL1DISTRG, confirm that the PLL1 output clock is not used as the source clock for any clock domain.

Note 2. Before enabling the PLL1 by PLL1ENTRG, confirm that the MainOsc is active.

12.3.2.16 PLL1S — PLL1 status register

This register provides activity status information about the PLL1.

Access: This register can be read in 32-bit units.

Address: FFF8 9104$_H$

Initial value: 0000 0000$_H$. This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	—	PLL1CLKACT	—*1	—*1
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. The values of bit 1 and 0 are undefined.
After masking bit 1 and 0, check only bit 2 to verify the status.

Table 12.18 PLL1S register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When written, write the initial value.
2	PLL1CLKACT	PLL1 activation status 0: PLL1 is inactive 1: PLL1 is active
1, 0	Reserved	When written, write the initial value.

12.3.2.17 PLL1C — PLL1 control register

This register is used to specify the PLL1 output clock frequencies $f_{PLL1CLK}$.

This register can only be written, if the PLL1 is disabled.

Access: This register can be read/written in 32-bit units.

Address: FFF8 9108_H

Initial value:
- D1L1, D1L2(H), D1M1(H), D1M1-V2, D1M1A: 0000 $003B_H$.
- D1M2(H): 6000 $001D_H$.

This register is initialized by any reset.

12.3.2.18 PLL2E — PLL2 enable register (D1M2(H) only)

This register is used to start and stop the PLL2.

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMDD1.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.

Address: FFF8 50C0$_H$

Initial value: 0000 0000$_H$. This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 12.20 PLL2E register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When written, write the initial value.
1	PLL2DISTRG	PLL2 disable trigger*1 0: no function 1: stops PLL2
0	PLL2ENTRG	PLL2 enable trigger*2 0: no function 1: starts PLL2

Note 1. Before stopping the PLL2 by PLL2DISTRG, confirm that the PLL2 output clock is not used as the source clock for any clock domain.

Note 2. Before enabling the PLL2 by PLL2ENTRG, confirm that the selected PLL2 input clock is active. Refer to Section 37.5, Video channels clock generation for details about the PLL2 clock input selections.

12.3.2.19 PLL2S — PLL2 status register (D1M2(H) only)

This register provides activity status information about the PLL2.

Access: This register can be read in 32-bit units.

Address: FFF8 50C4$_H$

Initial value: 0000 0000$_H$. This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note 1. The values of bit 1 and 0 are undefined.
After masking bit 1 and 0, check only bit 2 to verify the status.

Table 12.21 PLL2S register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When written, write the initial value.
2	PLL2CLKACT	PLL2 activation status 0: PLL2 is inactive 1: PLL2 is active
1, 0	Reserved	When written, write the initial value.

12.3.2.20 PLL2C — PLL2 control register (D1M2(H) only)

This register is used to specify the PLL2 output clock frequencies $f_{PLL2CLK}$.

This register can only be written, if the PLL2 is disabled.

Access: This register can be read/written in 32-bit units.

Address: FFF8 50C8$_H$

Initial value: 0001 002F$_H$. This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

12.3.3 Clock generator selection registers

12.3.3.1 CKSC_IPLL0S_CTL — PLL0CLK clock control register

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMD1.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.
Address: FFF8 9200$_H$
Initial value: 0000 0001$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PLL0S STP
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 12.23 CKSC_IPLL0S_CTL register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When written, write the initial value.
0	PLL0S STP	PLL0CLK stop control 0: Stop PLL0CLK 1: Activate PLL0CLK (default)

NOTE

PLL0SSTP = 0 does not stop the operation of the PLL0. It just switches off the forwarding of the PLL0 output clock.

12.3.3.2 CKSC_IPLL0S_ACT — PLL0CLK clock active register

Access: This register can be read in 32-bit units.

Address: FFF8 9208$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PLL0S ACT
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 12.24 CKSC_IPLL0S_ACT register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When written, write the initial value.
0	PLL0S ACT	PLL0CLK status 0: PLL0CLK is stopped 1: PLL0CLK is active

NOTE

As long as the clock, selected by the source clock selection register, is not active, this source clock active register remains 0.

Its shows the correct value, when the selected clock becomes active.

12.3.3.3 CKSC_IPLL1S_CTL — PLL1CLK clock control register

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMD1.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.
Address: FFF8 9300$_H$
Initial value: 0000 0001$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PLL1S STP
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 12.25 CKSC_IPLL1S_CTL register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When written, write the initial value.
0	PLL1S STP	PLL1CLK stop control 0: Stop PLL1CLK 1: Activate PLL1CLK (default)

NOTES

1. PLL1SSTP = 0 does not stop the operation of the PLL1 clock generator. It just switches off the forwarding of the PLL1 output clock.
2. For D1M2(H) devices:
   The direct PLL1 output clock is used as the clock supply for the DDR2-SDRAM Memory Controller (SDRB). Thus the SDRB clock supply is not stopped by PLL1SSTP = 0.

12.3.3.4 CKSC_IPLL1S_ACT — PLL1CLK clock active register

Access: This register can be read in 32-bit units.

Address: FFF8 9308$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PLL1S ACT
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 12.26 CKSC_IPLL1S_ACT register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When written, write the initial value.
0	PLL1S ACT	PLL1CLK status 0: PLL1CLK is stopped 1: PLL1CLK is active

NOTE

As long as the clock, selected by the source clock selection register, is not active, this source clock active register remains 0.

Its shows the correct value, when the selected clock becomes active.

12.3.3.5 CKDV_ICLKJITD_CTL — CLKJIT clock divider register

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMDD1.

For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.

Address: FFF8 53C0$_H$

Initial value: 0000 0006$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 12.34 CKSC_ICLKFIXS_ACT register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When written, write the initial value.
1 to 0	CLKFIXS ACT[1:0]	Current active CLKFIXS source clock selection 0: selected clock inactive All others: selected and active clock

NOTE

As long as the clock, selected by the source clock selection register, is not active, this source clock active register remains 0.
Its shows the correct value, when the selected clock becomes active.

12.3.3.13 CKSC_IPLLFIXS_CTL — PLLFIXCLK source clock selection register (D1M2(H) only)

The selection of the PLLFIXCLK clock is only available for the D1M2(H) devices.
For all other devices the PLLFIXCLK clock is always the PLL1CLK.

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMDD1.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.

Address: FFF8 5000$_H$

Initial value: 0000 0001$_H$

Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 12.36 CKSC_IPLLFIXS_ACT register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When written, write the initial value.
1 to 0	PLLFIXS ACT[1:0]	Current active PLLFIXS source clock selection 0: selected clock inactive All others: selected and active clock

NOTE

As long as the clock, selected by the source clock selection register, is not active, this source clock active register remains 0.
Its shows the correct value, when the selected clock becomes active.

12.3.3.15 CKSC_ISDRBS_CTL — SDRBCLK clock control register (D1M2(H), D1M1H, D1M1Aonly)

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMDD1.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.

Address: FFF8 5140$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 12.39 CKSC_ICPUCLKS_CTL register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When written, write the initial value.
2 to 0	CPUCLKS CSID[2:0]*1	Source clock selection for C_ISO_CPUCLK 001$_B$: EMCLK (default) 011$_B$: PLL0CLK 100$_B$: PLL1CLK All others: Setting prohibited

Note 1. For D1L1 products only:
After changing the value of CPUCLKSCSID[2:0] a waiting time of 1 µsec must pass by inserting an appropriate number of NOP operations before continuing with the application program.

CAUTION

The clock source selected for the C_ISO_CPUCLK clock domain should not be stopped by software.

12.3.4.2 CKSC_ICPUCLKS_ACT — C_ISO_CPUCLK source clock active register

Access: This register can be read in 32-bit units.

Address: FFF8 A008$_H$

Initial value: 0000 0001$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 12.54 CKSC_IPCRSCANS_ACT register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When written, write the initial value.
0	PCRSCANSACT	PCRSCANCLK status 0: RSCANPCLK is stopped 1: RSCANPCLK is active

12.3.4.17 APB_CLK_RATIO — PBUS clock ration selection register (D1M1(H) only)

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMDPWRGD.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.
Address: FFF8 F510$_H$
Initial value: 0000 0001$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	APB_CLK_RATIO
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 12.55 APB_CLK_RATIO register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When written, write the initial value.
0	APB_CLK_RATIO	PBUS clock ratio selection 0: C_ISO_PCLK = C_ISO_CPUCLK / 2 1: C_ISO_PCLK = C_ISO_CPUCLK / 4 (default)

NOTE

- APB_CLK_RATIO only can change on High Speed IntOsc operation of CPU (except PLL operation of CPU).
- If software change the APB_CLK_RATIO settings, software should confirm the reflected correct setting by read access. After then, software can go forward next steps.
- APB_CLK_RATIO only can change from 1 to 0. The change from 0 to 1 is not permitted.

12.3.5 Always-On-Area clock domain selection registers

12.3.5.1 CKSC_AAWOTS_CTL — C_AWO_AWOT source clock selection register

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMD0.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.
Address: FFF8 2100_H
Initial value: 0000 0001_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	AWOTD STP MSK
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

CAUTION

The initial value “1” of bit 1 must not be changed.

Table 12.60 CKSC_AAWOTD_STPM register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When written, write the initial value.
0	AWOTD STPMSK	0: Clock domain C_AWO_AWOT is stopped in DEEPSTOP mode Clock domain C_AWO_AWOT is stopped by disabling the C_AWO_AWOT source clock selection register (CKSC_AAWOTS_CTL = 0000 0000$_H$). 1: Clock domain C_AWO_AWOT is not stopped in DEEPSTOP mode Clock domain C_AWO_AWOT is not stopped by disabling the C_AWO_AWOT source clock selection register (CKSC_AAWOTS_CTL = 0000 0000$_H$).

12.3.5.6 CKSC_AWDTA0D_CTL — C_AWO_WDTA0 clock divider register

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMD0.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.

Address: FFF8 2000_H

Initial value: 0000 0001_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	—	WDTA0DACT[2:0]		
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 12.62 CKSC_AWDTA0D_ACT register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When written, write the initial value.
2 to 0	WDTA0D ACT[2:0]	Current active WDTA0D clock divider

12.3.5.8 CKSC_ARTCAS_CTL — C_AWO_RTCA source clock selection register

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMD0.

For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.

Address: FFF8 2300_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	RTCASCSID[2:0]		
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 12.63 CKSC_ARTCAS_CTL register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When written, write the initial value.
2 to 0	RTCAS CSID[2:0]	Source clock selection for C_AWO_RTCA 000_B: Disable (default) 001_B: SubOsc f_{TX} 010_B: MainOsc f_X 011_B: Low Speed IntOsc f_{RL} 100_B: High Speed IntOsc f_{RH} All others: Setting prohibited

NOTE

To avoid supplying a clock signal at a frequency of higher than 4 MHz to the C_AWO_RTCA clock domain due to the CKSC_ARTCAS_CTL register setting, check that CKSC_ARTCAD_ACT = 0000 0000_H (disabled) when the setting of CKSC_ARTCAS_CTL is 010_B (MainOsc f_X) or 100_B (High Speed IntOsc f_{RH}).

CAUTION

Always make sure that the source clock is operating before assigning it (writing to this register). The source clock assignment cannot be changed afterwards if the assigned source clock is not running.

This register is only reset by POC0RES, ISOPWRES and $\overline{\text{DBRES}}$.

12.3.5.9 CKSC_ARTCAS_ACT — C_AWO_RTCA source clock active register

Access: This register can be read in 32-bit units.

Address: FFF8 2308$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

CAUTION

The initial value “1” of bit 1 must not be changed.

Table 12.67 CKSC_ARTCAD_STPM register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When written, write the initial value.
0	RTCAD STPMSK	0: Clock domain C_AWO_RTCA is stopped in DEEPSTOP mode Clock domain C_AWO_RTCA is stopped by disabling the C_AWO_RTCA source clock selection register (CKSC_ARTCAS_CTL = 0000 0000$_H$). 1: Clock domain C_AWO_RTCA is not stopped in DEEPSTOP mode Clock domain C_AWO_RTCA is not stopped by disabling the C_AWO_RTCA source clock selection register (CKSC_ARTCAS_CTL = 0000 0000$_H$).

12.3.5.13 CKSC_AFOUTS_CTL — C_AWO_FOUT source clock selection register

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMD0.

For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.

Address: FFF8 2700_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 12.93 CKSC_IADCED_CTL register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When written, write the initial value.
1, 0	ADCED CSID[1:0]	Clock divider setting for C_ISO_ADCE 01_B: CLKJIT /2 (default) 10_B: CLKJIT /4 All others: Setting prohibited

CAUTIONS

1. **The A/D Converter (ADCE) requires a minimum operating frequency of 8 MHz. Make sure that C_ISO_ADCE is not below 8 MHz. Refer to the Data Sheet for details.**
2. **The CKSC_IADCED_CTL register must be set so that the relationship between frequency of the C_ISO_PCLK and C_ISO_ADCE clocks is retained within the range of "C_ISO_PCLK/C_ISO_ADCE = 1 to 2.4".**

12.3.6.24 CKSC_IADCED_ACT — C_ISO_ADCE clock divider active register

Access: This register can be read in 32-bit units.

Address: FFF8 5488$_H$

Initial value: 0000 0001$_H$

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 12.94 CKSC_IADCED_ACT register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When written, write the initial value.
1, 0	ADCED ACT[1:0]	Current active ADCED clock divider

NOTE

As long as the clock, selected by the source clock selection register, is not active, this source clock active register remains 0.

Its shows the correct value, when the selected clock becomes active.

12.3.6.25 CKSC_IISMS_CTL — C_ISO_ISM source clock selection register

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMDD1.

For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.

Address: FFF8 5440$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 12.96 CKSC_IISMS_ACT register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When written, write the initial value.
0	ISMS ACT0	Current active ISMS source clock selection 0: selected clock inactive 1: selected and active clock

NOTE

As long as the clock, selected by the source clock selection register, is not active, this source clock active register remains 0.
Its shows the correct value, when the selected clock becomes active.

12.3.6.27 CKSC_IRLINS_CTL — C_ISO_RLIN source clock selection register

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMDD1.
For details, refer to **Section 4, Write-Protected Registers**.

Access: This register can be read/written in 32-bit units.

Address: FFF8 5500$_H$

Initial value:
- D1M1(H), D1M1-V2, D1M1A: 0000 0003$_H$
- All other devices: 0000 0002$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RLINS ACT[1:0]	
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1*1	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. In D1M1(H), D1M1-V2, D1M1A, initial value of this bit is 0.

Table 12.98 CKSC_IRLINS_ACT register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When written, write the initial value.
1, 0	RLINS ACT[1:0]	Current active RLINS source clock selection 0: selected clock inactive All others: selected and active clock

NOTE

As long as the clock, selected by the source clock selection register, is not active, this source clock active register remains 0.
Its shows the correct value, when the selected clock becomes active.

12.4 Clock Controller set-up

The following procedure shows an initial set-up of the Clock Controller to activate the CPU Subsystem and the cross-connects.

(1) Configure the MainOsc
- Select the MainOsc frequency via the MOSCC register.
- Select the correct MainOsc stabilization time via the MOSCST register.
- Start the MainOsc by MOSCE.MOSCENTRG = 1.
- Wait until MOSCS.MOSCCLKACT = 1 indicates MainOsc active.

(2) Configure the PLLk clock generators
- Define the PLLk parameters via the PLLkC register.
- Start the PLLs by PLLkE.PLLkENTRG = 1.
- Wait until PLLkS.PLLkCLKACT = 1 indicates PLLk active.
- Enable the PLLkCLK clock by CKSC_IPLLkS_CTL.PLLkSSTP = 1.
- Wait until CKSC_IPLLkS_ACT = 1 indicates PLLkCLK active.

(3) Configure the SubOsc
- Select correct SubOsc stabilization time via SOSCST register.
- Start the SubOsc by SOSCE.SOSCENTRG = 1.
- Wait until SOSCS.SOSCCLKACT = 1 indicates SubOsc active.

(4) Activate the C_ISO_CPUCLK clock domain to supply the CPU Subsystem with its operation clock
- Select the C_ISO_CPUCLK clock divider via the CKSC_ICPUCLKD_CTL register.
- Wait until CKSC_ICPUCLKD_ACT = 1 indicates the selected divider.
- Select the C_ISO_CPUCLK clock source via the CKSC_ICPUCLKS_CTL register.
- Wait until CKSC_ICPUCLKS_ACT = 1 indicates C_ISO_CPUCLK active.

NOTE

In order to prevent supplying unintentional clocks to the CPU Subsystem, it is necessary to set CKSC_CPUCLKS_CTL after selecting the divider by CKSC_ICPUCLKD_CTL.

(5) Activate C_ISO_XCCLK clock domain to supply the cross-connects with its operation clocks
- Release the Ethernet AVB Mac (ETNB0) reset by MRSTC.ETNB0RES = 1.
- Enable the ETNBPCLK clock by CKSC_IPCETNBS_CTL.IPCETNBSSTP = 1.
- Wait until CKSC_IPCETNBS_ACT = 1 indicates ETNBPCLK active.
- Release the XC0 cross-connect reset by MRSTC.XC0RES = 1.
- Enable the C_ISO_XCCLK clock by CKSC_IXCCLKS_CTL.XCCLKSSTP = 1.
- Wait until CKSC_IXCCLKS_ACT = 1 indicates C_ISO_XCCLK active.

NOTE

For stopping the C_ISO_XCCLK clock, follow the procedure shown below.
- Make sure that ETNBPCLK is active, i.e. CKSC_IPCETNBS_ACT = 1.

- Make sure that XC0 cross-connect reset is inactive, i.e. MRSTC.XC0RES = 1.
- Make sure that the Ethernet AVB MAC (ETNB0) reset is inactive, i.e. MRSTC.ETNB0RES = 1.
- Stop the C_ISO_XCCLK clock by CKSC_IXCCLKS_CTL.XCCLKSSTP = 0.
- Wait until CKSC_IXCCLKS_ACT = 0 indicates C_ISO_XCCLK inactive.

12.5 Clock Selection

The base clocks, generated by the clock generators, are distributed to the functional modules by several clock domains. The tables below show the various clock domains, their possible clock sources, clock dividers and control options.
Note that various functional modules provide additional internal prescalers and dividers.

NOTE

The default value of the clock selector and divider registers are denoted in *italics*.

CAUTIONS

1. **When changing the source clock by a clock selector, the selected clock source before changing the selector must not be stopped until the new source was selected. Otherwise the clock selector will not be able to perform the new assignment.**
2. **The register access clock for each module must be supplied when the registers of the module are accessed.**
   The module can't receive request from CPU if register access clock for modules is not supplied.

12.5.1 Base clocks

The following table shows the selection and control options for the generation of the clock controller base clocks.

Refer also to Section 12.1.2, Clock Controllers Block Diagrams for figures of the clock controller.

Table 12.99 Clock controller base clocks selection and control (1/2)

	Clock selection		Clock divider	
Base clock	**Register**	**Selections**	**Register**	**Divisors**
PLL0CLK	CKSC_IPLL0S_CTL	Stop	–	–
		PLL0CLK		
PLL1CLK	CKSC_IPLL1S_CTL	Stop	–	–
		PLL1CLK		
CLKJIT	–	PLL0CLK	CKDV_ICLKJITD_CTL	Disable, 4, 5, *6*, 8, 10, 12
	CKSC_ICLKJITS_CTL	CKDV_ICLKJITD_CTL selection	–	–
		HS IntOsc f_{RH}		
CLKFIX	–	PLLFIXCLK	CKDV_ICLKFIXD_CTL	Disable, *6*, 8, 10, 12
	CKSC_ICLKFIXS_CTL	CKDV_ICLKFIXD_CTL selection	–	–
		HS IntOsc f_{RH}		

Table 12.99 Clock controller base clocks selection and control (2/2)

Base clock	Clock selection		Clock divider	
	Register	Selections	Register	Divisors
PLLFIXCLK	CKSC_IPLLFIXS_CTL (D1M2(H) only)*2	*PLL1CLK*	–	–
		PLL2CLK		
SDRBCLK (D1M2(H), D1M1H and D1M1A only)	CKSC_ISDRBS_CTL	*Stop*	–	–
		SDRBCLK		

Note 1. The default value of the clock selector and divider registers are denoted in *italics*.
Note 2. For all other devices: PLLFIXCLK = PLL1CLK.

Table 12.100 Base clocks maximum frequencies

Base clock	Maximum frequency								
	D1L1	D1L2	D1L2H	D1M1	D1M1H	D1M1-V2	D1M1A	D1M2	D1M2H

PLLFIXCLK	480 MHz								
SDRBCLK	–				200 MHz	–	240 MHz	480 MHz	

12.5.2 CPU and buses subsystems clocks

The following table shows the selection and control options for the generation of the CPU and buses subsystem clocks.

Refer also to Section 12.1.2.6, CPU Subsystem and bus clock domains for figures of the clock controller.

Table 12.101 CPU Subsystems and bus clock domains selection (1/2)

Clock domain	Clock selection		Clock divider		Module
	Register	Selections	Register	Divisors	
C_ISO_CPUCLK	CKSC_ICPUCLKS_CTL	*EMCLK*	CKSC_ICPUCLKD_CTL	*1*, 2, 4, 8, 3	CPU Subsystem
		PLL0CLK			
		PLL1CLK			
C_ISO_XCCLK	CKSC_IXCCLKS_CTL	*Stop*	–	–	Cross-connect systems
		C_ISO_XCCLK			
ETNBPCLK	CKSC_IPCETNBS_CTL	*Stop*	–	–	ETNB0
		ETNBPCLK			
ETNBXCCLK (D1M2(H), D1M1(H), D1M1-V2 and D1M1A)	CKSC_IXCETNBS_CTL	*Stop*	–	–	
		ETNBXCCLK			

Table 12.101 CPU Subsystems and bus clock domains selection (2/2)

Clock domain	Clock selection		Clock divider		Module
	Register	Selections	Register	Divisors	
MLBBPCLK (D1M2H)	CKSC_IPCMLBBS_CTL	*Stop*	–	–	MLBB0
		MLBBPCLK			
MLBBXCCLK (D1M2H)	CKSC_IXCMLBBS_CTL	*Stop*	–	–	
		MLBBXCCLK			
RSCANPCLK	CKSC_IPCRSCANS_CTL	Stop	–	–	RSCAN0
		RSCANPCLK			

Note 1. The default value of the clock selector and divider registers are denoted in *italics*.

Table 12.102 CPU and buses subsystems clocks maximum frequencies

Base clock	Maximum frequency								
	D1L1	D1L2	D1L2H	D1M1	D1M1H	D1M1-V2	D1M1A	D1M2	D1M2H
C_ISO_CPUCLK	120 MHz			160 MHz	200 MHz	160 MHz	240 MHz		
C_ISO_XCCLK	60 MHz			80 MHz	100 MHz	80 MHz	120 MHz		
C_ISO_PCLK	60 MHz			80 MHz	50 MHz	80 MHz	60 MHz		
ETNBPCLK	–			80 MHz	50 MHz	80 MHz	60 MHz		
ETNBXCCLK	–			80 MHz	100 MHz	80 MHz	120 MHz		
MLBBPCLK	–								60 MHz
MLBBXCCLK	–								120 MHz
RSCANPCLK	80 MHz								

12.5.3 Always-On-Area clock domains

The following table shows the selection and control options for the generation of the Always-On-Area clock domains.

AWO clock domains stop

Each AWO clock domain except for C_AWO_WDTA0 is equipped with a stop mask register, that allows to select either stop or continuation of the clock domain in DEEPSTOP mode.

Table 12.103 Always-On-Area clock domains selections (1/2)

Clock domain	Clock selection		Clock divider		Module
	Register	Selections	Register	Divisors	
C_AWO_AWOT	CKSC_AAWOTS_CTL	Disabled	CKSC_AAWOTD_CTL	*1*, 2, 4, 8, 16	AWOT0
		HS IntOsc f_{RH}			
		MainOsc f_X			
		LS IntOsc f_{RL}			
C_AWO_WDTA0	–	LS IntOsc f_{RL}	CKSC_AWDTA0D_CTL	*128*, 1, 256, 512, 1024, 2048	WDTA0

Table 12.103 Always-On-Area clock domains selections (2/2)

Clock domain	Clock selection		Clock divider		Module
	Register	Selections	Register	Divisors	
C_AWO_RTCA	CKSC_ARTCAS_CTL	*Disabled*	CKSC_ARTCAD_CTL	*Disabled*, 1, 2, 4, 8, 16	RTCA0
		LS IntOsc f_{RL}			
		HS IntOsc f_{RH}			
		MainOsc f_X			
		SubOsc f_{TX}			
C_AWO_FOUT	CKSC_AFOUTS_CTL	*Disabled*	–	–	FOUT
		MainOsc f_X			
		HS IntOsc f_{RH}			
		LS IntOsc f_{RL}			
		SubOsc f_{TX}			
		PLL0CLK/4			
		PLL1CLK/4			
		PLL2CLK/4 (D1M2(H) only)			

Note 1. The default value of the clock selector and divider registers are denoted in *italics*.

Table 12.104 Always-On-Area clock domain clocks maximum frequencies

Base clock	Maximum frequency								
	D1L1	D1L2	D1L2H	D1M1	D1M1H	D1M1-V2	D1M1A	D1M2	D1M2H
C_AWO_AWOT	8 MHz								
C_AWO_WDTA0	240 kHz								
C_AWO_RTCA	4 MHz								
C_AWO_FOUT	20 MHz								

12.5.4 Isolated-Area clock domains

The following table shows the selection and control options for the generation of the Isolated-Area clock domains.

Table 12.105 Isolated-Area clock domains selections (1/2)

Clock domain	Clock selection		Clock divider		Module
	Register	Selections	Register	Divisors	
C_ISO_MLBB	CKSC_IMLBBS_CTL	*Disabled*	–	–	MLBB0
		PLL0CLK/2			
		PLL0CLK/4			
C_ISO_SFMA	CKSC_ISFMAS_CTL	PLL0CLK	CKSC_ISFMAD_CTL	*Disabled*, 2, 3, 4, 6*3	SFMA0 SFMA1 SFMA2
		PLL1CLK			

Table 12.105 Isolated-Area clock domains selections (2/2)

Clock domain	Clock selection		Clock divider		Module
	Register	Selections	Register	Divisors	
C_ISO_RSCAN	–	PLLFIXCLK	CKSC_IRSCAND_CTL	Disabled 30, 40, 60, *12*, 24	RSCAN0

C_ISO_ADCE	40 MHz								
C_ISO_ISM	80 MHz								
C_ISO_RLIN	48 MHz			24 MHz*1		48 MHz			

Note 1. When used 50 MHz for PCLK

12.5.5 Video output channels clock domains

The video output channels have additional pixel clock generators.
Refer to Section 37.5, Video channels clock generation for details.

12.6 Frequency Output Function (FOUT)

The Frequency Output function allows to output the CKSCLK_AFOUT as the external signal CSCXFOUT.

Furthermore, the frequency of CKSCLK_AFOUT can be divided by the FOUT clock divider before it is output.

The figure below outlines the Frequency Output function.

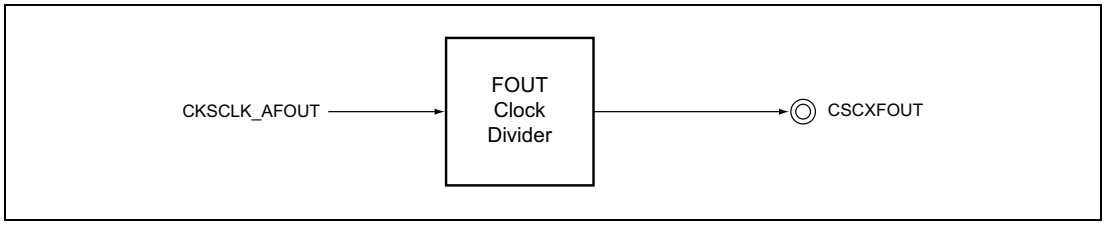

Figure 12.17 Frequency Output function

12.6.1 CSCXFOUT Clock Divider

The CSCXFOUT Clock Divider divides its input clock CKSCLK_AFOUT by 1 to 512 and thus provides a variable CSCXFOUT clock.

The divisor value N is defined by FOUTDIV.FOUTDIV[9:0], where

N = FOUTDIV.FOUTDIV[9:0]

Note that the clock output is stopped if FOUTDIV.FOUTDIV[9:0] = 000_H.

The frequency $f_{CSCXFOUT}$ of the output clock is calculated by

$f_{CSCXFOUT}$ = CKSCLK_AFOUT / N

When a new clock divisor is written to the FOUTDIV.FOUTDIV[9:0] bits, it becomes effective in synchronization with the CSCXFOUT output clock. Accordingly, the clock divisor can be changed even while the CSCXFOUT clock is operating.

12.6.2 Clock supply

FOUT provides one clock input:

Table 12.107 FOUT clock supply

Module	Clock	Connect to
FOUT	CKSCLK_AFOUT	Clock domain C_AWO_FOUT

12.6.3 Register of the CSCXFOUT Clock Divider

The CSCXFOUT Clock Divider is controlled and operated by the following register.

Table 12.108 Register of the CSCXFOUT Clock Divider

Module Name	Register Name	Symbol	Address
SYS	Clock divider register	FOUTDIV	FFF8 2800_H
SYS	Clock divider status register	FOUTSTAT	FFF8 2804_H

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> and <Symbol> are defined in the above table.

12.6.4 CSCXFOUT Clock Divider Control Register Details

12.6.4.1 FOUTDIV — Clock divider register

This register defines the clock divisor.

Access: This register can be read/written in 32-bit units.

Address: FFF8 2800_H

Initial value: 0000 0000_H This register is initialized by SYSRES.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 12.109 FOUTDIV register contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When written, write the initial value.
9 to 0	FOUTDIV[9:0]	Clock divisor N 000_H: Clock output is stopped (default) 001_H: N = 1 002_H: N = 2 ... $1FF_H$: N = 511 200_H: N = 512 All others: Setting prohibited

12.6.4.2 FOUTSTAT — Clock divider status register

This register defines the clock divider status.

Access: This register can be read in 32-bit units.

Address: FFF8 2804_H

Initial value: 0000 0001_H This register is initialized by SYSRES.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 12.110 FOUTSTAT register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When written, write the initial value.
1	FOUTCLKACT	Divider clock active bit 0: CLKOUT inactive 1: CLKOUT active
0	FOUTSYNC	Divider clock synchronized 0: CLKOUT does not correspond to the actual divisor setting in FOUTDIV 1: CLKOUT corresponds to the actual divisor setting in FOUTDIV

12.7 Clock Monitor A (CLMA)

This section contains a generic description of the Clock Monitor A (CLMA).

The first section describes all properties specific to the RH850/D1L/D1M, such as units, register base addresses, input/output signal names, etc.

The subsequent sections describe the features that apply to all implementations.

12.7.1 Overview of RH850/D1L/D1M CLMA

12.7.1.1 Units

This microcontroller has the following numbers of Units of the Clock Monitor A.

Table 12.111 Units

Clock Monitor A	D1L1	D1L2(H)	D1M1(H)	D1M1-V2	D1M1A	D1M2	D1M2H
Units	5	5	6	6	6	6	7
Names	CLMAn (n = 0 to 4)	CLMAn (n = 0 to 4)	CLMAn (n = 0 to 5)	CLMAn (n = 0 to 5)	CLMAn (n = 0 to 5)	CLMAn (n = 0 to 4, 6)	CLMAn (n = 0 to 6)

Index n

Throughout this section, the individual units of a Clock Monitor A are identified by the index “n” (n = 0 to 6), for example, CLMAnCTL0 for the control register 0 of CLMAn.

12.7.1.2 Register addresses

All CLMAn register addresses are given as address offsets from the individual base address <CLMAn_base>.

The base address <CLMAn_base> of each CLMAn is listed in the following table.

Table 12.112 Register base addresses <CLMAn_base>

CLMAn	<CLMAn_base> address
CLMA0	FFF8 C000$_H$
CLMA1	FFF8 F000$_H$
CLMA2	FFF8 F080$_H$
CLMA3	FFF8 F100$_H$
CLMA4	FFF8 F180$_H$
CLMA5	FFF8 F200$_H$
CLMA6	FFF8 F280$_H$

12.7.1.3 Clock supply

The monitored and the sampling clocks of all Clock Monitors A are listed in the following table.

Table 12.113 CLMAn clock supply (1/2)

Module	Clock	Connected to
CLMA0	Register access clock	Clock Controller • C_ISO_PCLK in RUN mode • EMCLK in DEEPSTOP mode
	CLMATSMP	Low Speed IntOsc f_{RL} (240 kHz)
	CLMATMON	High Speed IntOsc f_{RH} (8 MHz)

Table 12.113 CLMAn clock supply (2/2)

Module	Clock	Connected to
CLMA1	Register access clock	Clock Controller • C_ISO_PCLK in RUN mode • EMCLK in DEEPSTOP mode
	CLMATSMP	High Speed IntOsc f_{RH}/256 (31.25 kHz)
	CLMATMON	Low Speed IntOsc f_{RL} (240 kHz)
CLMA2	Register access clock	Clock Controller • C_ISO_PCLK in RUN mode • EMCLK in DEEPSTOP mode
	CLMATSMP	Low Speed IntOsc f_{RL} (240 kHz)
	CLMATMON	MainOsc
CLMA3	Register access clock	Clock Controller C_ISO_PCLK
	CLMATSMP	Low Speed IntOsc f_{RL} (240 kHz)
	CLMATMON	$f_{PLL0CLK}$ / 16
CLMA4	Register access clock	Clock Controller C_ISO_PCLK
	CLMATSMP	Low Speed IntOsc f_{RL} (240 kHz)
	CLMATMON	$f_{PLL1CLK}$ / 16
CLMA5	Register access clock	Clock Controller C_ISO_PCLK
	CLMATSMP	Low Speed IntOsc f_{RL} (240 kHz)
	CLMATMON	Port VDCE0_VI_CLK (Video Input Interface 0 pixel clock)
CLMA6	Register access clock	Clock Controller C_ISO_PCLK
	CLMATSMP	Low Speed IntOsc f_{RL} (240 kHz)
	CLMATMON	Port VDCE1_VI_CLK (Video Input Interface 1 pixel clock)

12.7.1.4 CLMAn internal signal connections

The following table shows the connection of the CLMAn signals to other microcontroller internal modules.

Table 12.114 CLMAn internal signal connections

CLMAn signals	Function	Connected to
CLMA0:		
$\overline{\text{CLMATRES}}$	CLMA0 error reset	Reset Controller $\overline{\text{CLMA0RES}}$
CLMA1:		
CLMATINT	CLMA1 error reset	Error Control Module INTCLMATI1
CLMA2:		
CLMATINT	CLMA2 error reset	Error Control Module INTCLMATI2
CLMA3:		
CLMATINT	CLMA3 error reset	Error Control Module INTCLMATI3
CLMA4:		
CLMATINT	CLMA4 error reset	Error Control Module INTCLMATI4
CLMA5:		
CLMATINT	CLMA5 error reset	Error Control Module INTCLMATI5
CLMA6:		
CLMATINT	CLMA6 error reset	Error Control Module INTCLMATI6

12.7.2 CLMA Enabling

Clock monitoring is started by the clock monitor when CLMAnCTL0.CLMAnCLME = 1.

When the monitored clock is stopped by register operation or standby mode, the corresponding clock monitor is automatically disabled. After the monitored clock starts oscillation again and becomes stable, the clock monitor also starts operation.

A CLMAn that is enabled can be only disabled by reset.
Thus writing CLMAnCTL0.CLMAnCLME = 0 cannot disable the CLMAn.

12.7.3 Start and stop of video input clock monitors CLMA5 and CLMA6

If a clock monitor is enabled by CLMAnCTL0.CLMAnCLME = 1, it can not be stopped by the application program afterwards. Only a reset would stop the clock monitors.

In order to stop the clock monitors CLMA5 and CLMA6, which monitor the external video input clocks of the video channels without applying a reset, the Video input clock monitors control register CLMAOTCTL0 is provided to enable and disable these clock monitors, if required.

Enabling and starting the video input clock monitor (n = 5, 6)

1. Activate the external video input clock.
2. Enable the respective clock monitor CLMAn by CLMAnCTL0.CLMAnCLME = 1.
3. Start video input clock monitoring by CLMAOTCTL0.CLMAnEN = 1.

Stopping the video input clock monitor (n = 5, 6)

1. Stop video input clock monitoring by CLMAOTCTL0.CLMAnEN = 0.
2. The respective external video input clock can be stopped.

12.7.3.1 CLMAOTCTL0 - Video input clock monitors control register (D1M2(H), D1M1(H), D1M1-V2, D1M1A only)

This register controls monitoring of the video clocks by the clock monitors CLMA5 and CLMA6.

Access: This register is readable/writable in 8-bit units.

Address: FFF8 F2C0$_H$

Initial value: 00$_H$

Bit	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	CLMA6EN	CLMA5EN
Initial value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 12.115 CLMAOTCTL0 Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When written, write the initial value.
1	CLMA6EN	Controls monitoring of the video input clock of video channel 1 by CLMA6 0: video input clock VDCE1_VI_CLK monitoring stopped 1: video input clock VDCE1_VI_CLK monitoring active
0	CLMA5EN	Controls monitoring of the video input clock of video channel 0 by CLMA5 0: video input clock VDCE0_VI_CLK monitoring stopped 1: video input clock VDCE0_VI_CLK monitoring active

NOTE

In the header files the module name of the above register is defined as:
CLMAC

12.7.4 CLMA Function

The clock monitor CLMAn detects an abnormal frequency of the monitored clock.

Overview of CLMA Features

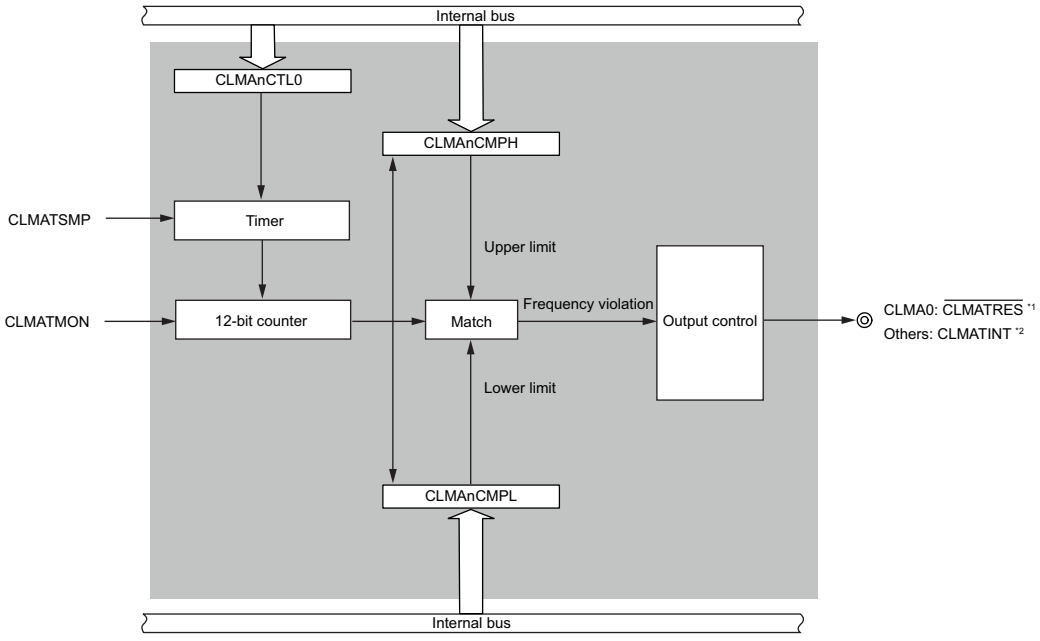
The clock monitor has the following features:

- Monitors the frequency of the input clock CLMATMON by using the sampling clock CLMATSMP.
- Outputs a reset request signal when an abnormal clock frequency is detected.

NOTE

Once enabled, only a reset can disable the CLMAn.

The following figure shows the main components of the Clock Monitor.



Note 1. $\overline{\text{CLMATRES}}$ is connected to Reset Controller.
Note 2. CLMATINT is connected to Error Control Module.

Figure 12.18 Block diagram of the Clock Monitor A

12.7.5 Description of Functions

The Clock Monitor CLMAn is used to verify whether the frequency of a clock (CLMATMON) is within the specified range.

12.7.5.1 Detection of Abnormal Clock Frequencies

Detection Method

1. CLMAn counts the rising edges of the monitored clock CLMATMON within 16 cycles of the sampling clock CLMATSMP and then compares the counter value with the specified thresholds:
   - CLMAnCMPL.CLMAnCMPL[11:0] defines the lower threshold.
   - CLMAnCMPH.CLMAnCMPH[11:0] defines the upper threshold.
2. When CLMATMON's frequency is lower than the limit*, the counter falls below CLMAnCMPL.CLMAnCMPL[11:0].
3. When the frequency of CLMATMON is higher than the limit, the counter exceeds CLMAnCMPH.CLMAnCMPH[11:0].

NOTE*

There is a case that the abnormal state is not detected when the CLMATMON completely stops.

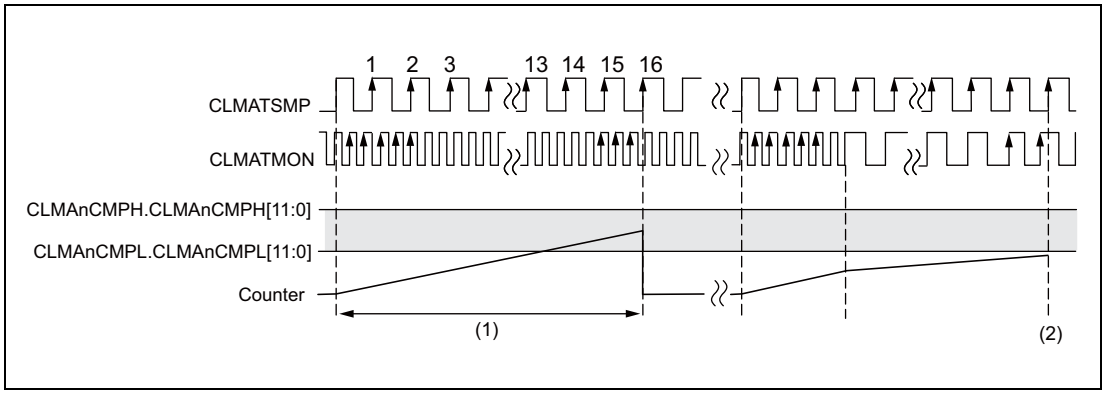


Figure 12.19 Example: $f_{CLMATMON}$ is lower than the specified limit.

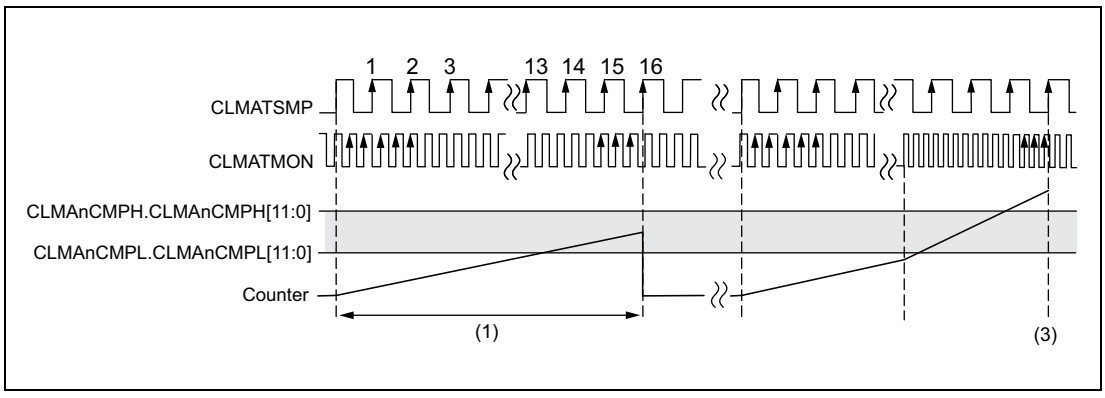

Figure 12.20 Example: $f_{CLMATMON}$ is higher than the specified limit.

NOTE

Even if $f_{CLMATMON}$ exceeds or falls below the specified limits during a sampling interval, the counter might be within the valid range.

Abnormal $f_{CLMATMON}$ is detected after one sampling interval.

(1) Calculation method of the thresholds CLMAnCMPL.CLMAnCMPL[11:0] and CLMAnCMPH.CLMAnCMPH[11:0]

The compare registers CLMAnCMPL and CLMAnCMPH are configured with the minimum and maximum number of clock cycles of CLMATMON that are assumed to be valid within 16 cycles of the sampling clock CLMATSMP.

The expected number of clock cycles is denoted by N.

$$\frac{16}{f_{CLMATSMP}} = \frac{N}{f_{CLMATMON}}$$

$$N = \frac{f_{CLMATMON}}{f_{CLMATSMP}} \times 16$$

Considering the allowed frequency deviations of CLMATMON and CLMATSMP, the threshold values can be calculated by the following formulas:

$$\text{Lower threshold} = N_{min} = \frac{f_{CLMATMON(min)}}{f_{CLMATSMP(max)}} \times 16 - 1$$

$$\text{Upper threshold} = N_{max} = \frac{f_{CLMATMON(max)}}{f_{CLMATSMP(min)}} \times 16 + 1$$

NOTE

The jitter of the PLL is covered by "+1" and "-1" in the formulae.

Example:

When $f_{CLMATSMP}$ = 240 kHz (±8%) and $f_{CLMATMON}$ = 16 MHz (±5%), the recommended threshold values are the followings:

N_{min} = 15,200 / 259.2 × 16 - 1
= 937.27
CLMAnCMPL = 937 = $03A9_H$

N_{max} = 16,800 / 220.8 × 16 + 1
= 1218.39
CLMAnCMPH = 1219 = $04C3_H$

Minimum thresholds

The following restrictions must be taken into account:

- CLMAnCMPL ≥ 0001_H
- CLMAnCMPH ≥ CLMAnCMPL + 0003_H

(2) Definition of the initial value input to the threshold registers

The initial and reset values of the threshold registers are set so that the maximum frequency deviation of the monitored clock is allowed:

- CLMAnCMPL[11:0] = 0001_H
- CLMAnCMPH[11:0] = $03FF_H$

12.7.5.2 Notification of Abnormal Clock Frequency

In case that $f_{CLMATMON}$ is higher than the upper or lower than the lower threshold:

- in case of CLMA0:
  - The reset request signal $\overline{\text{CLMATRES}}$ is set to low level.
  - The system reset SYSRES is generated and CLMAn is reset.
- In case of others (CLMAn: n = 1 to 6)
  - The error signal CLMATINT is stored to error status register in Error Control Module.

12.7.5.3 CLMAn Enable (Write to CLMAnCTL0)

Writing to this register (CLMAnCTL0) is protected by a special sequence of instructions by using the protection command register CLMAnPCMD. Refer to Section 4, Write-Protected Registers.

NOTE

CLMAn can be only disabled by reset. Writing to CLMAnCTL0 cannot disable CLMAn.

12.7.6 Clock Monitor Registers

The Clock Monitor is controlled and operated by the following registers.

Table 12.116 List of Clock Monitor Registers

Module Name	Register Name	Symbol	Address
	CLMAn control register 0	CLMAnCTL0	<CLMAn_base> + 00_H
	CLMAn compare register L	CLMAnCMPL	<CLMAn_base> + 08_H
	CLMAn compare register H	CLMAnCMPH	<CLMAn_base> + $0C_H$
CLMAC	CLMA test register	CLMATEST	FFF8 $C100_H$
CLMAC	CLMA test status register	CLMATESTS	FFF8 $C104_H$
CLMAC	CLMA test register 2	CLMATEST2	FFF8 $F600_H$
CLMAC	CLMA test status register 2	CLMATESTS2	FFF8 $F604_H$
CLMAC	CLMA test register 3	CLMATEST3	FFF8 $F300_H$
CLMAC	CLMA test status register 3	CLMATESTS3	FFF8 $F304_H$
	CLMAn emulation register 0	CLMAnEMU0	<CLMAn_base> + 18_H
Write protection registers			
	CLMA0CTL0 protection command register	CLMA0PCMD	FFF8 $C010_H$
	CLMA0CTL0 protection status register	CLMA0PS	FFF8 $C014_H$
	CLMA1CTL0 protection command register	CLMA1PCMD	FFF8 $F010_H$

	CLMA4CTL0 protection command register	CLMA4PCMD	FFF8 $F190_H$
	CLMA4CTL0 protection status register	CLMA4PS	FFF8 $F194_H$
	CLMA5CTL0 protection command register	CLMA5PCMD	FFF8 $F210_H$
	CLMA5CTL0 protection status register	CLMA5PS	FFF8 $F214_H$
	CLMA6CTL0 protection command register	CLMA6PCMD	FFF8 $F290_H$
	CLMA6CTL0 protection status register	CLMA6PS	FFF8 $F294_H$
CLMAC	CLMATEST protection command register	PROTCMDCLMA	FFF8 $C200_H$

<CLMAn_base>

The base addresses <CLMAn_base> of the CLMAn are defined in “Register addresses” of the first part in Section 12.7.1.2, Register addresses.

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> and <Symbol> are defined in the above table.

12.7.6.1 CLMAnCTL0 - CLMAn control register 0

This register enables the clock monitor CLMAn.

Writing to this register is protected by a special sequence of instructions by using the protection command register CLMAnPCMD. For details, see Section 4, Write-Protected Registers.

Access: This register is read/written in 8-bit units.

Address: <CLMAn_base> + 00_H

Initial value: 00_H. This register can be initialized by any reset source.*1

Note 1. CLMAnCTL (n = 0 to 2) can be initialized only by PURES and SYSRES.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CLMAnCLME
Initial value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 12.117 CLMAnCTL0 Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When written, write the initial value.
0	CLMAnCLME	Enables the clock monitor. 0: CLMAn is disabled.*1 1: Enable the CLMAn.

Note 1. After the CLMAnCTL0.CLMAnCLME bit is set to 1, writing 0 to this bit is ignored. The only condition for clearing the bit is a reset (PURES, SYSRES). In addition, the bit is cleared when CLMATEST.RESCLM bit is set to 1 during self-test of CLMAn.

CAUTION

Write 0 in bit 7 to 1.

12.7.6.2 CLMAnCMPH - CLMAn compare register H

This register specifies the upper limit of frequency.

Refer to **12.7.5.1** (1), Calculation method of the thresholds CLMAnCMPL.CLMAnCMPL[11:0] and CLMAnCMPH.CLMAnCMPH[11:0] for details.

Access: This register is read/written in 16-bit units.
It can only be written, when CLMAn is disabled (CLMAnCTL0.CLMAnCLME = 0).

Address: <CLMAn_base> + $0C_H$

Initial value: $03FF_H$. This register can be initialized by any reset source.*1

Note 1. CLMAnCTL (n = 0 to 2) can be initialized only by PURES and SYSRES.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	CLMAnCMPH[11:0]

R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 12.118 CLMAnCMPH Register Contents

Bit Position	Bit Name	Function
15 to 12	Reserved	When written, write the initial value.
11 to 0	CLMAnCMPH [11:0]	Specifies the upper threshold. • The recommended value is $f_{CLMATMON\ (max)}$ / $f_{CLMATSMP\ (min)}$ × 16 + 1. • The minimum value is CLMAnCMPL + 0003_H.

CAUTION

Write 0 in bit 15 to 12.

12.7.6.3 CLMAnCMPL - CLMAn compare register L

This register specifies the lower limit of frequency.

Refer to **12.7.5.1** (1), Calculation method of the thresholds CLMAnCMPL.CLMAnCMPL[11:0] and CLMAnCMPH.CLMAnCMPH[11:0] for details.

Access: This register is read/written in 16-bit units.
It can only be written, when CLMAn is disabled (CLMAnCTL0.CLMAnCLME=0).

Address: <CLMAn_base> + 08_H

Initial value: 0001_H. This register can be initialized by any reset source.*1

Note 1. CLMAnCTL (n = 0 to 2) can be initialized only by PURES and SYSRES.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit Position	Bit Name	Function
15 to 12	Reserved	When written, write the initial value.
11 to 0	CLMAnCMPL [11:0]	Specifies the lower threshold. • The recommended value is $f_{CLMATMON\ (min)}$ / $f_{CLMATSMP\ (max)}$ × 16 - 1 • The minimum value is 0001_H.

CAUTION

Write 0 in bit 15 to 12.

12.7.6.4 CLMATEST — CLMA Test Register

This register is used to test CLMA0.

Writing to this register is protected by the special sequence of command register PROTCMDCLMA. For details, see Section 4, Write-Protected Registers.

Access: This register can be read/written in 32-bit units.

Address: FFF8 $C100_H$

Value after reset: $0000\ 0000_H$ This register is initialized by PURES and SYSRES.

12.7.6.6 CLMATEST2 — CLMA Test Register 2

This register is used to test CLMA1 and CLMA2.

Writing to this register is protected by the special sequence of command register PROTCMDCLMA2. For details, see Section 4, Write-Protected Registers.

Access: This register can be read/written in 32-bit units.

Address: FFF8 F600$_H$

Value after reset: 0000 0000$_H$ This register is initialized by PURES and SYSRES.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note 1. This bit is enabled when the CLMAnTESEN bit is 1.

12.7.6.7 CLMATESTS2 — CLMA Test Status Register 2

This register is used to test CLMA1 and CLMA2.

Access: This register can only be read 32-bit units.

Address: FFF8 F604$_H$

Value after reset: 0000 0000$_H$ This register is initialized by PURES and SYSRES.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

12.7.6.8 CLMATEST3 — CLMA Test Register 3

This register is used to test CLMA3 to CLMA6.

Writing to this register is protected by the special sequence of command register PROTCMDCLMA3. For details, see Section 4, Write-Protected Registers.

Access: This register can be read/written in 32-bit units.

Address: FFF8 F300$_H$

Value after reset: 0000 0000$_H$ This register is initialized by any reset source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 12.125 CLMATESTS3 Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is returned.
3	CLMA6ERRS	CLMA6 Error Status (D1M2(H) only) 0: Errors are not detected 1: Errors are detected
2	CLMA5ERRS	CLMA5 Error Status (D1M2(H), D1M1(H), D1M1-V2, D1M1A only) 0: Errors are not detected 1: Errors are detected
1	CLMA4ERRS	CLMA4 Error Status 0: Errors are not detected 1: Errors are detected
0	CLMA3ERRS	CLMA3 Error Status 0: Errors are not detected 1: Errors are detected

12.7.6.10 CLMAnEMU0 - CLMAn emulation register 0

This register provides the bits to emulate a frequency deviation while the microcontroller is set in break mode during debugging.

Access: This register is read/written in 8-bit units.

Address: <CLMAn_base> + 18_H

Initial value: 00_H. This register can be initialized by any reset source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	CLMAnSLFST	CLMAnSLSLW
Initial value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 12.126 CLMAnEMU0 Register Contents

Bit Position	Bit Name	Function
1	CLMAnSLFST	Specifies the higher value of $f_{CLMATMON}$ during emulation: 0: CLMATMON is assumed to be within the normal frequency range 1: CLMATMON is assumed to exceed the upper threshold.
0	CLMAnSLSLW	Specifies the lower value of $f_{CLMATMON}$ during emulation: 0: CLMATMON is assumed to be within the normal frequency range 1: CLMATMON is assumed to fall below the lower threshold.

CAUTIONS

1. It is prohibited to emulate a too low and too high CLMATMON at the same time. Thus CLMAnEMU0 must not be set to 03_H.
2. Write 0 in bit 7 to 2.

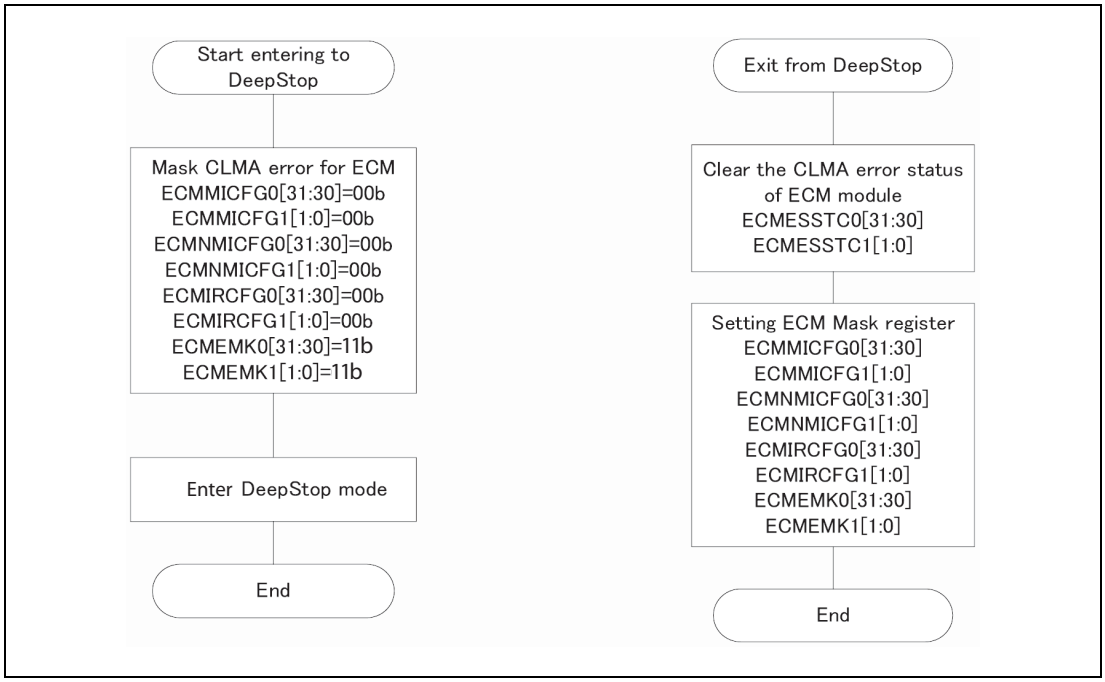
12.7.7 Usage Notes

12.7.7.1 ECM detects false error signals from CLMA at resuming DEEPSTOP

ECM sometimes detects false error signals from CLMA3 to CLMA6 at resuming from DEEPSTOP.

Before entering DEEPSTOP, mask error signals of CLMA3 to CLMA6 on ECM.

And after resuming from DEEPSTOP, clear error status flags of CLMA3 to CLMA6 and set expected mask setting of ECM again.
Details are shown below.



Section 13 Stand-by Controller (STBC)

This section describes the functions of the stand-by controller (STBC), the registers, and various standby modes.

13.1 Functions

The RH850/D1L/D1M supports the following power-save modes:

- HALT mode

  HALT mode can be entered from normal RUN mode by performing the CPU instruction “HALT”. This stops the CPU operation, while all clocks other than the CPU clock continue to operate and all areas remain under power.
  For details, refer to “*RH850 Family User’s Manual: Software*”.

- DEEPSTOP mode

  In order to reduce power consumption, the power supply of the Isolated-Area can be switched off. DEEPSTOP mode is entered when the STBC0PSC.STBC0DISTRG is set to 1.

NOTE

The mode in which the CPU is operating is called RUN mode.

13.1.1 Clock Supply

The Stand-by Controller clock supply is shown in the following table.

Table 13.1 Clock Supply

Module	Unit Clock Name	Connected to
Stand-by Controller	Register access clock	Clock Controller • C_ISO_PCLK in RUN mode • EMCLK in DEEPSTOP mode

13.1.2 Wake-up

13.1.2.1 Wake-up factors

The wake-up events for terminating a power save mode are controlled and monitored by the following Stand-by Controller registers:

- WUF0, WUFMSK0, WUFC0

The assignment of the wake-up events to the wake-up control and status register bits is given in the table below.

For details about the wake-up control and status registers, refer to Section 13.2.2.2, WUF0 — Wake-up factor register, Section 13.2.2.3, WUFMSK0 — Wake-up factor mask register, and Section 13.2.2.4, WUFC0 — Wake-up factor clear registers.

Table 13.2 Wake-up factors Registers Assignments

Name	Assignment of WUFm/WUFMSKm/ WUFCm Register Bits			Function
INTDCUTDI	WUF0[0]	WUFMSK0[0]	WUFC0[0]	OCD
INTP0 (RLIN31RX)	WUF0[1]	WUFMSK0[1]	WUFC0[1]	Port
INTP1	WUF0[2]	WUFMSK0[2]	WUFC0[2]	Port
INTP2 (RLIN32RX)	WUF0[3]	WUFMSK0[3]	WUFC0[3]	Port
INTP3	WUF0[4]	WUFMSK0[4]	WUFC0[4]	Port
INTP4 (RLIN33RX)	WUF0[5]	WUFMSK0[5]	WUFC0[5]	Port
INTP5	WUF0[6]	WUFMSK0[6]	WUFC0[6]	Port
INTP6 (CAN0RX)	WUF0[7]	WUFMSK0[7]	WUFC0[7]	Port
INTP7	WUF0[8]	WUFMSK0[8]	WUFC0[8]	Port
INTP8 (CAN1RX/RLIN30RX)	WUF0[9]	WUFMSK0[9]	WUFC0[9]	Port
INTP9	WUF0[10]	WUFMSK0[10]	WUFC0[10]	Port
INTP10 (CAN2RX/RLIN30RX)	WUF0[11]	WUFMSK0[11]	WUFC0[11]	Port
INTWDTA0	WUF0[12]	WUFMSK0[12]	WUFC0[12]	WDTA0
INTRTCA01S	WUF0[13]	WUFMSK0[13]	WUFC0[13]	RTCA0
INTRTCA0AL	WUF0[14]	WUFMSK0[14]	WUFC0[14]	RTCA0
INTRTCA0R	WUF0[15]	WUFMSK0[15]	WUFC0[15]	RTCA0
INTAWOT0	WUF0[16]	WUFMSK0[16]	WUFC0[16]	AWOT0
ECMTI	WUF0[17]	WUFMSK0[17]	WUFC0[17]	ECM
ECMTNMI	WUF0[18]	WUFMSK0[18]	WUFC0[18]	ECM

CAUTIONS

1. **The interrupt signals INTP0 to INTP10 can not be used for wake-up from DEEPSTOP mode, when the interrupts are connected to ISO area port groups such as P42 or P44. INTP interrupt signals are only wake-up capable when used on AWO port groups JP0 and P0.**
2. **When an external RS-CAN CANnRX or RLIN3 RLIN3nRX signal is to be used for wake up, the corresponding external interrupt INTPx must be configured for the falling edge detection.**
3. **Except in D1M1A and D1M1-V2, CPU clock must be changed to EMCLK when the interrupt signals INTP0 to INTP10 are used for wake-up factor from DEEPSTOP mode. Refer to Figure 13.3, Example of DEEPSTOP mode transition (except for D1M1A, D1M1-V2) for details.**
4. **Except in D1M1A and D1M1-V2, there are possibility that MCU does not wake-up. When using the interrupt signals INTP0 to INTP10 for wake-up factor, set the input pulse width long enough or configure that high speed internal oscillator does not stop in DEEPSTOP (ROSCSTPM.ROSCSTPMSK = 1). To refer the sufficient value, see RH850/D1L/D1M Group DATASHEET.**

On-Chip Debug wake-up

The On-Chip Debug unit (OCD) is generating a wake-up event while the microcontroller runs the application program in the following cases:

- the debugger issues a stop request
- a breakpoint is hit
  Note: A breakpoint hit occurs only in normal mode.

In either case any stand-by mode is terminated, provided the OCD debug event is enabled as a wake-up factor via the WUFMSK0 register.

CAUTION

If the OCD wake-up event is disabled, it is not possible to wake-up the microcontroller from stand-by mode by a manual stop via the debugger.

Thus it is recommended to enable the OCD wake-up for terminating the DEEPSTOP mode by setting WUFMSK0[0] = 0.

When the hot plug-in function is used, make sure to enable this factor. The INTDCUTDI interrupt is required to return from power save mode as the wake-up handling.

13.1.2.2 Wake-up control

Wake-up factors are selected by the wake-up factors control registers:

- Wake-up mask register WUFMSK0
  Each bit of this register is assigned to a certain wake-up event. Wake-up by this event is enabled if its mask bit is set to 0.
- Wake-up factor register WUF0
  Upon occurrence of an unmasked wake-up event, the associated wake-up factor flag is set to 1. By use of this register the application program can identify the wake-up factor.
- Wake-up factor clear register WUFC0
  In order to clear a wake-up factor flag of the wake-up factor register (WUF0), its assigned bit has to be set to 1.

NOTE

The wake-up factor flags in the wake-up factors register (WUF0) indicate only the occurrence of a wake-up factor. Thus an asserted wake-up factor flag does not mean that the transition from DEEPSTOP to normal operation mode is already accomplished.
This means that wake-up factor bits could be set during normal operation mode.

13.1.3 I/O buffer control

This section describes the behavior of the I/O buffers during various DEEPSTOP modes.

13.1.3.1 I/O buffer hold state

During the I/O buffer hold state, the I/O buffer maintains the state it was in before entering this state. Therefore, no external or internal signal can change the state of the I/O buffer until the I/O buffer hold state is terminated.

The port buffers on the Isolated-Area, that are supplied with BnVCC and ISMVCC can be set into or released from IOHOLD state by the application program via the IOHOLD register.
Further the P0 port buffers on the Always-On-Area, that are supplied with EVCC can be set into or released from IOHOLD state by the application program via the IOHOLD register.
The IOHOLD register has a separate bit IOHOLDn for certain groups of the buffers, which are supplied by power supply B0VCC to B5VCC, EVCC and ISMVCC.

13.1.3.2 I/O buffers during DEEPSTOP mode

Before entering DEEPSTOP mode the Isolated-Area buffers can be set into IOHOLD as long as port buffers kept power supplied during DEEPSTOP mode. If power supply of port buffer is expected to stop during DEEPSTOP mode, the corresponding IOHOLD register must be set to 0.

Also the Always-On-Area port buffers of P0 may be set into IOHOLD before entering DEEPSTOP mode. In case P0 is not set into IOHOLD, the port buffers of P0 remain operational in DEEPSTOP mode.

In DEEPSTOP mode, the I/O buffers of port groups transition to I/O buffer hold state.

After wake-up from DeepSTOP, the I/O buffers remain in I/O buffer hold state until canceling the state by software. To cancel I/O buffer hold state, follow the steps shown below.

1. Re-configure the peripheral or port function.
2. Set the corresponding IOHOLD.IOHOLDn = 0

NOTES

1. The output level of the port buffers of the DDR2-SDRAM I/F for D1M2(H) become undefined in DEEPSTOP mode. Thus the DDR2-SDRAM I/F supply SDRBVCC must be switched off.
2. The output level of the port buffers of the
   – MIPI video input interface port group (P40)
   – RSDS video output interface port groups (P44 and P45)
   – Serial Flash Memory and Media Local Bus interface port group (P21)
   – SDR-SDRAM I/F port buffers for D1M1H and D1M1A
   become undefined in DEEPSTOP mode. Thus it is recommended to connect these pins to the respective ground or voltage supply via pull-up or -down resistors.

13.1.4 Clock supply in DEEPSTOP mode

Some clock generators and the clock domain of the Always-On-Area can optionally be stopped in DEEPSTOP mode and restarted automatically after wake-up, provided they are operating at DEEPSTOP entry.

The clock generator's and domain's DEEPSTOP behavior is selected via a stop mask register, that is available for each clock generator and domain, that allows to select stop/continue in DEEPSTOP:

- stop mask = 1: clock generator or domain status does not change in DEEPSTOP
- stop mask = 0: clock generator or domain stops in DEEPSTOP and returns to status as before DEEPSTOP (restarted when operating before DEEPSTOP or remains stopped)

Following clock generators and clock domains feature stop mask registers for stop/continue selection:

- MOSCSTPM: MainOsc
  If the MainOsc is stopped in DEEPSTOP mode (MOSCSTPM.MOSCSTPMSK = 0) the Clock Monitor CLMA2 is also stopped in DEEPSTOP.
- ROSCSTPM: High Speed IntOsc
  If the High Speed IntOsc is stopped in DEEPSTOP mode (ROSCSTPM.ROSCSTPMSK = 0) the Clock Monitor CLMA0 is also stopped in DEEPSTOP mode. Further when the High Speed IntOsc is stopped in DEEPSTOP mode (ROSCSTPM.ROSCSTPMSK = 0) the Clock Monitor CLMA1 must not be used.
- CKSC_AAWOTD_STPM: C_AWO_AWOT domain for the Always-On-Area Timer (AWOT)
- CKSC_ARTCAD_STPM: C_AWO_RTCA domain for the Real-Time Clock (RTCA)
- CKSC_AFOUTS_STPM: C_AWO_FOUT domain for the Frequency Output Function (FOUT)

NOTES

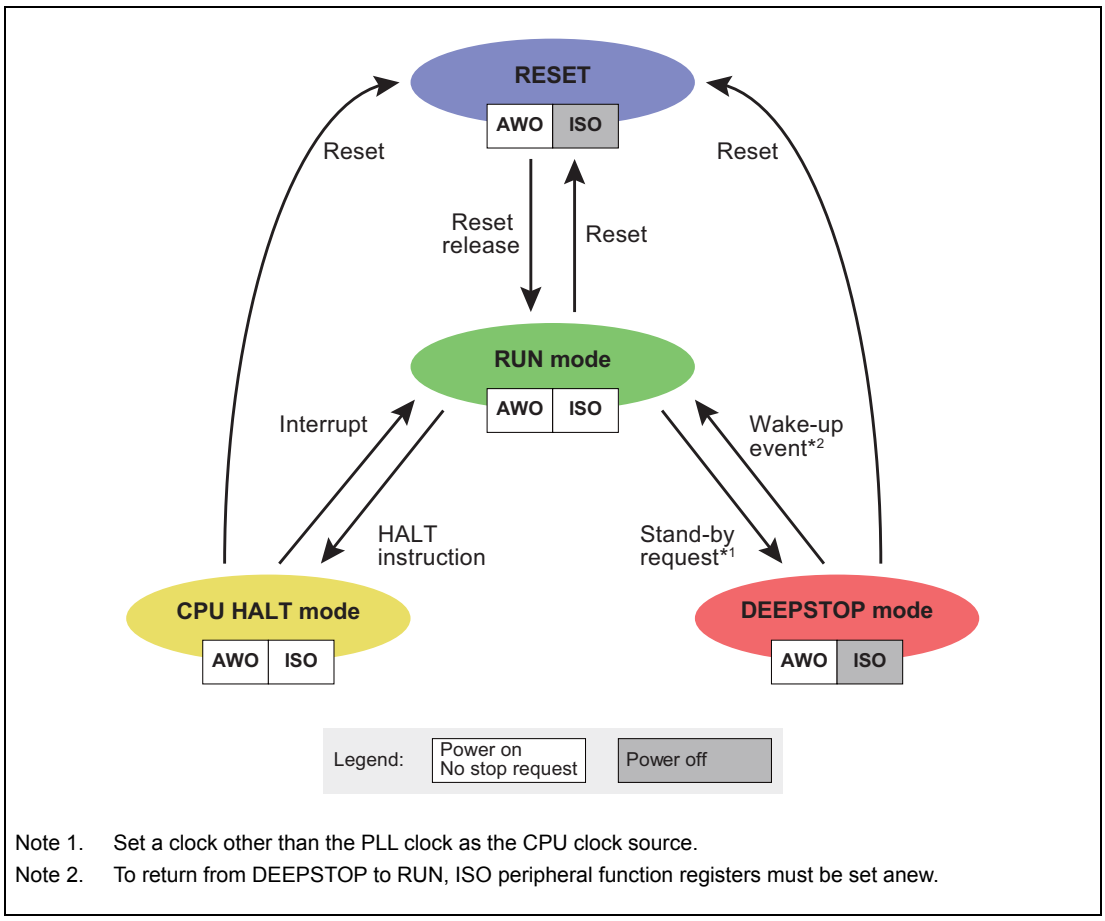
1. The Low Speed IntOsc is always operating and can not be stopped.
   If the High Speed IntOsc is stopped in DEEPSTOP mode (ROSCSTPM.ROSCSTPMSK = 0), the Low Speed IntOsc Clock Monitor CLMA1 must not be used. That means CLMA1 must never be enabled (keep CLMAnCTL0.CLMAnCLME = 0). The failing of Low Speed IntOsc can be detected by CLMA0 and CLMA2 to CLMA6 in this case.
2. The Watchdog Timer on the Always-On-Area (WDTA0) operates with the Low Speed IntOsc clock and thus remains in operation even in DEEPSTOP mode.
3. All PLL circuits reside on the Isolated-Area, thus are completely switched off in DEEPSTOP and must be configured and restarted after wake-up by the application program. The respective Clock Monitors CLMA3 and CLMA4 are also stopped in DEEPSTOP mode.
4. All Isolated-Area clock domains C_ISO_xxx and their selection registers reside on the Isolated-Area, thus are completely switched off in DEEPSTOP and must be configured and restarted after wake-up by the application program.
5. The Video Input Interfaces pixel Clock Monitors CLMA5 and CLMA6 must be stopped by the application software by setting CLMAOTCTL0.CLMA5EN = 0 and CLMAOTCTL0.CLMA6EN = 0 (refer to Section 12.7.3, Start and stop of video input clock monitors CLMA5 and CLMA6 for details).
6. The clock supply does not stop even if clock generator's stop request is not masked (stop mask = 0), while stop masks of clock domains are set to 1. Be sure to set stop mask bit of each domain register (CKSC_AAWOTD_STPM, CKSC_ARTCAD_STPM, CKSC_AFOUTS_STPM) to 0 before entering DEEPSTOP mode.

   [example – clock supply for RTCA]
   (Case-1)
   1. Select MainOSC by RTCA (CKSC_ARTCAS_CTL = 2_H)
   2. Enable "stop mask" of RTCA (CKSC_ARTCAD_STPM = 3_H)
   3. Disable "stop mask" of MainOSC (MOSCSTPM = 2_H)
   4. Transit to DEEPSTOP
   5. Both of MainOSC and RTCATCKI "do not stop"

   (Case-2)
   1. Select MainOSC by RTCA (CKSC_ARTCAS_CTL = 2_H)
   2. Disable "stop mask" of RTCA (CKSC_ARTCAD_STPM = 2_H)
   3. Disable "stop mask" of MainOSC (MOSCSTPM = 2_H)
   4. Transit to DEEPSTOP
   5. Both of MainOSC and RTCATCKI "stop"

13.1.5 Transition to power save mode

The figure below shows the transition between RUN mode, HALT mode and DEEPSTOP mode.



Note 1. Set a clock other than the PLL clock as the CPU clock source.
Note 2. To return from DEEPSTOP to RUN, ISO peripheral function registers must be set anew.

Figure 13.1 State transition diagram of stand-by mode

13.2 Registers

13.2.1 Overview of Stand-by Controller Registers

The Stand-by Controller is controlled and operated by the following registers.

Table 13.3 Overview of Stand-by Controller Registers

Module Name	Symbol	Initial Value	Attribute	Address
SYS	STBC0PSC	0000 0000$_H$	R/W	FFF8 0100$_H$
SYS	WUF0	0000 0000$_H$	R	FFF8 0400$_H$
SYS	WUFMSK0	FFFF FFFF$_H$	R/W	FFF8 0404$_H$
SYS	WUFC0	—	W	FFF8 0408$_H$
SYS	IOHOLD	0000 0000$_H$	R/W	FFF8 0B00$_H$

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> and <Symbol> are defined in the above table.

13.2.2 Stand-by controller control registers details

13.2.2.1 STBC0PSC — Stand-by control register

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMD0.
For details, refer to **Section 4, Write-Protected Registers**.

This register is initialized by all reset sources except the transition to DeepSTOP mode (ISORES).

Access: This register can be read/written in 32-bit units.

Address: FFF8 0100$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R

Table 13.4 STBC0PSC Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When written, write the initial value.
1	STBC0DISTRG	0: Writing “0” has no effect. 1: DEEPSTOP mode is entered
0	Reserved	When written, write the initial value.

13.2.2.2 WUF0 — Wake-up factor register

This register informs of a wake-up event in the isolated area.

WUF0 is initialized by all reset sources except the transition to DeepSTOP mode (ISORES).

Access: This register can be read in 32-bit units.

Address: FFF8 0400_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	WUF18	WUF17	WUF16
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 13.5 WUF0 Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When written, write the initial value.
18 to 0	WUFy	Indicates the generation of a wake-up event. 0: Wake-up event is not generated 1: Wake-up event is generated

NOTE

While the WUFMSKy bit in the wake-up factor mask register is 1, WUFy is not set to 1 at the generation of a wake-up event.

Wake-up factor

As for the assignment of a wake-up event to the wake-up factor register bit, refer to **Table 13.2, Wake-up factors Registers Assignments**.

The bit to which a wake-up event is not assigned is read as the value “0”.

13.2.2.3 WUFMSK0 — Wake-up factor mask register

This register enables a wake-up event in the isolated area.

WUF0 is initialized by all reset sources except the transition to DeepSTOP mode (ISORES).

Access: This register can be read/written in 32-bit units.

Address: FFF8 0404$_H$

Initial value: FFFF FFFF$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	WUFMSK18	WUFMSK17	WUFMSK16

Table 13.6 WUFMSK0 Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When written, write the initial value.
18 to 0	WUFMSKy	Enables/disables a wake-up event. 0: Wake-up event is enabled 1: Wake-up event is disabled

NOTE

While the WUFMSKy bit is 1, WUFy of the wake-up factor register is not set to 1 at the generation of a wake-up event.

Wake-up factor

As for the assignment of a wake-up event to the wake-up factor register bit, refer to **Table 13.2, Wake-up factors Registers Assignments**.

13.2.2.4 WUFC0 — Wake-up factor clear registers

This register clears the WUFy bit in the wake-up factor register.

Access: This register can be written in 32-bit units.

Address: FFF8 0408$_H$

Initial value: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	WUFC 18	WUFC 17	WUFC 16

Table 13.7 WUFC0 Register Contents

Bit Position	Bit Name	Function
31 to19	Reserved	When read, an undefined value is returned.
18 to 0	WUFCy	Clear the wake-up factor WUFy in the wake-up factor register. 0: WUFy is not modified 1: WUFy is cleared

Wake-up factor

As for the assignment of a wake-up event to the wake-up factor register bit, refer to **Table 13.2, Wake-up factors Registers Assignments**.

13.2.2.5 IOHOLD — Port IOHOLD control register

This register controls the IOHOLD state of the I/O buffer.

Writing to this register is protected by a special sequence of instructions by using the protection command register PROTCMD0.
For details, refer to **Section 4, Write-Protected Registers**.

This register is initialized by all reset sources except the transition to DeepSTOP mode (ISORES).

Access: This register can be read/written in 32-bit units.

Address: FFF8 0B00$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 13.8 IOHOLD Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 7	Reserved	When written, write the initial value.
6	IOHOLD6	This bit controls the IOHOLD function of the port groups P16 and P17 ports. 0: I/O hold state of the respective ports is released 1: I/O hold state of the respective ports is activated
5	IOHOLD5	This bit controls the IOHOLD function of the port group P42 ports. 0: I/O hold state of the respective ports is released 1: I/O hold state of the respective ports is activated
4	IOHOLD4	This bit controls the IOHOLD function of the ports P43_7 to P43_12. 0: I/O hold state of the respective ports is released 1: I/O hold state of the respective ports is activated
3	IOHOLD3	• D1L1, D1L2: This bit controls the IOHOLD function of the ports – P43_0, P43_1 – P44_1 to P44_4, P44_6 to P44_11 – P45_0 to P45_13. • D1L2H, D1M1(H), D1M1-V2, D1M1A: This bit controls the IOHOLD function of the ports – P43_0, P43_1 – P44_0 to P44_11 – P45_0 to P45_13. • D1M2(H): This bit controls the IOHOLD function of the ports P43_0 to P43_6 and of the port groups P46 and P47 ports. 0: I/O hold state of the respective ports is released 1: I/O hold state of the respective ports is activated
2	IOHOLD2	This bit controls the IOHOLD function of the port group P3 ports. 0: I/O hold state of the respective ports is released 1: I/O hold state of the respective ports is activated

Table 13.8 IOHOLD Register Contents (2/2)

Bit Position	Bit Name	Function
1	IOHOLD1	This bit controls the IOHOLD function of the port groups P1 and P2 ports. 0: I/O hold state of the respective ports is released 1: I/O hold state of the respective ports is activated
0	IOHOLD0	This bit controls the IOHOLD function of the port group P0 ports. 0: I/O hold state of the respective ports is released 1: I/O hold state of the respective ports is activated

13.3 DEEPSTOP Mode

In DEEPSTOP mode, the clock and power supply of the Isolated-Area is stopped.
Some clock generators and Always-On-Area clock domains can optionally be stopped.

The transition procedure (example) to DEEPSTOP mode is shown below.

Preparation for DEEPSTOP

- Stop all of the modules, connected to a clock that will be stopped.
- Set the port buffer of the Isolated-Area into hold state via the IOHOLD register.
  Note: Unless the power of corresponding port buffers are kept supplied during DEEPSTOP mode, IOHOLD register must not be set to 1.
- Disable the interrupt handling by the CPU instruction “DI”.
- (In D1M1A and D1M1-V2)
  Set the interrupt control registers.
  - Clear the interrupt flag (ICxxx.RFxxx = 0).
  - Mask the interrupt of non-wake-up factor (ICxxx.MKxxx = 1).
  - Unmask the interrupt of wake-up factors (ICxxx.MKxxx = 0).
- Set the wake-up related registers.
  - Clear the wake-up factor flag (the WUFC0 register).
  - Mask the non-wake-up factors (the WUFMSK0 register).
  - Unmask the wake-up factors (the WUFMSK0 register).
- (Except in D1M1A and D1M1-V2)
  Change CPU clock to EMCLK
- (Except in D1M1A and D1M1-V2)
  Abort entering DEEPSTOP mode if interrupt requests’ flags to abort entering DEEPSTOP mode set.
- Set the clock stop mask and select the clock domains to be stopped and to continue operating. (Set by the CKSC_xxx_STPM.xxxxSTPMSK bit.)
- Designate each clock source for oscillation or for stopping. In addition, set the clock mask and select which clock source is to stop and which clock source is to continue operation. Refer to Section 13.1.4, Clock supply in DEEPSTOP mode for information about these clock generators and domains.
- Stop all active PLLs (set PLLkE.PLLkDISTRG = 1)
- Clear the RESF register.

Start of DEEPSTOP

Set the STBC0DISTRG bit in the STBC0PSC register to 1 to shift to DEEPSTOP mode.

End of DEEPSTOP

When a wake-up event is generated, the microcontroller returns from DEEPSTOP mode.

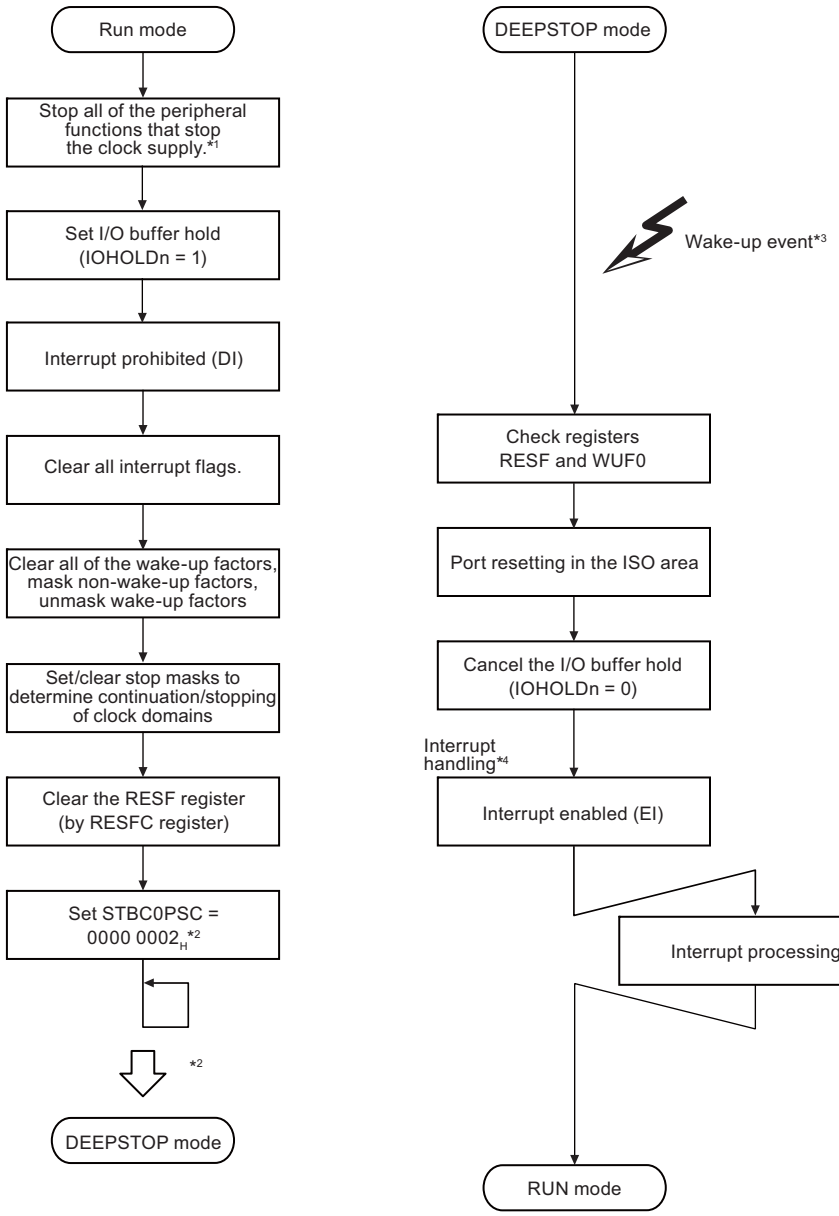
Wake-up handling

- Make sure that all BnVCC supplies are switched on.
- When returned from DEEPSTOP mode due to wake-up factor, the microcontroller starts the operation from the reset address.
- The wake-up factor is determined by the wake-up factor flag (WUF0).
- The ports in the Isolated-Area maintain the I/O buffer hold state.
- Release the I/O buffer hold state in the following order.

  1. Re-configure the modules and port functions.

  2. Release the I/O buffers from hold state by IOHOLD.IOHOLDn = 0

- To execute an interrupt of the wake-up factor after the wake-up, evaluate the information of wake-up factor flag by software and set the interrupt request flag in the interrupt control register. Then, when an interrupt is enabled by the CPU instruction “EI”, the generated wake-up interrupt is to be executed.



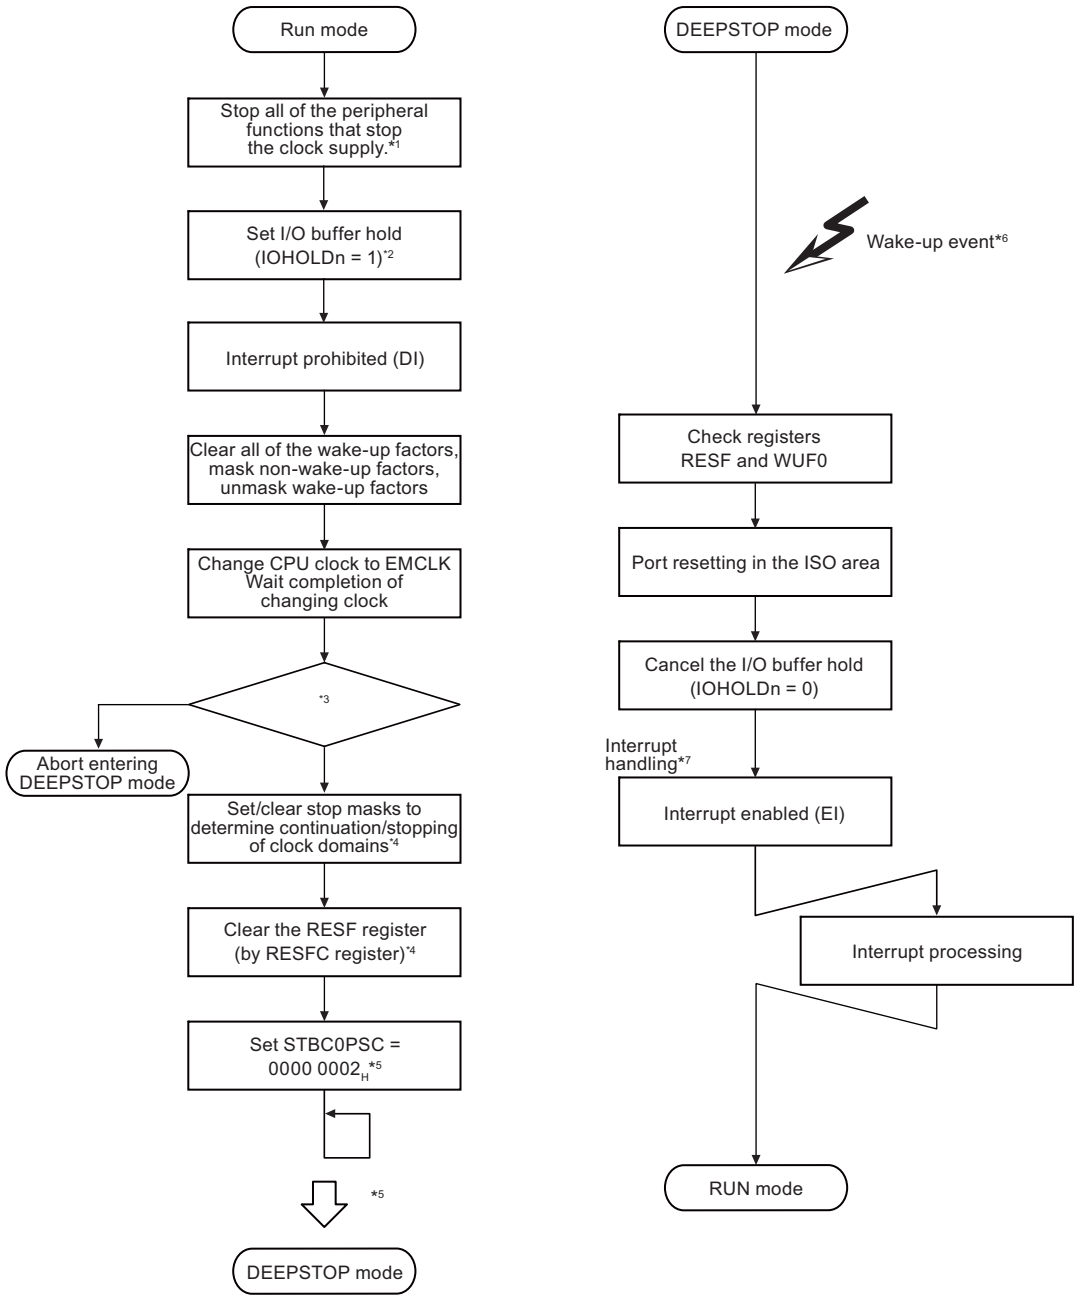
Note 1. When the operation of the peripheral function is stopped during operating due to the transition to the DEEPSTOP mode, the operation of the peripheral function may be incorrect. Before the transition to the DEEPSTOP mode, stop all of the peripheral functions that stop the clock supply.

Note 2. After setting STBC0PSC = 0000 0002_H, wait for the transition to the DEEPSTOP mode by the unconditional loop.

Note 3. The CPU starts the program from the reset vector after the generation of a wake-up event. The return from the DEEPSTOP mode by a reset can be checked by the RESF register. In addition, the generated wake-up event can be checked by the WUF0 register.

Note 4. This processing is optional. It is required to execute the interrupt handling after the wake-up.

Figure 13.2 Example of DEEPSTOP mode transition (D1M1A, D1M1-V2)



Note 1. When the operation of the peripheral function is stopped during operating due to the transition to the DEEPSTOP mode, the operation of the peripheral function may be incorrect. Before the transition to the DEEPSTOP mode, stop all of the peripheral functions that stop the clock supply.

Note 2. Unless the power of corresponding port buffers are kept supplied during DEEPSTOP mode, IOHOLD register must not be set to 1.

Note 3. Are interrupt requests' flags to abort entering DEEPSTOP mode set?

Note 4. These steps can execute before setting wake-up factors.

Note 5. After setting STBC0PSC = 0000 0002_H, wait for the transition to the DEEPSTOP mode by the unconditional loop.

Note 6. The CPU starts the program from the reset vector after the generation of a wake-up event. The return from the DEEPSTOP mode by a reset can be checked by the RESF register. In addition, the generated wake-up event can be checked by the WUF0 register.

Note 7. This processing is optional. It is required to execute the interrupt handling after the wake-up.

Figure 13.3 Example of DEEPSTOP mode transition (except for D1M1A, D1M1-V2)

13.4 Writing to the protected registers

The Stand-by Controller registers shown below are write-protected registers.

- STBC0PSC register
- IOHOLD register

The write-protected registers are protected against the illegal writing due to the error programming operation.

For details on the write-protected sequence, refer to Section 4, Write-Protected Registers.

Section 14 Bus Architecture

14.1 Bus Systems Clock Supply

The clock supply of the bus systems is shown in the following table.

Table 14.1 Bus Systems Clock Supply

Bus System	Clock for the Bus System
PBUS	C_ISO_PCLK
Cross-connects XC	C_ISO_XCCLK

14.2 Cross-connect systems

The cross-connect systems are multilayered, transaction based multi-master connections and allow parallel access to different targets (refer to Section 14.3.1, Transaction based busses for more information).

Several cross-connect systems establish the data transfer paths between the bus masters and the slaves.

In order to cope with different demands in terms of data transfer bandwidth and real-time constrains different groups of masters and slaves are connected via different cross-connect systems:

- “Streaming data access masters” with high bandwidth demand of the video channels is centralized via the XC2 cross-connect and passed over the Sprite Engine to the XC0 cross-connect.
- “Random data access masters”, that mostly access data randomly or have no priority on high bandwidth (CPU Subsystem, Ethernet AVB MAC, Medial Local Bus Interface, JPEG Coding Unit), utilize the XC1 cross-connect, that hosts also the on-chip memories (CPU Subsystem’s local RAM and Code Flash, Retention RAM, Video RAMs) and the interface to external serial flash memory.
- SDRAM interfaces
  The bandwidth demand to external SDRAM varies with the device type:
  - D1M1H and D1M1A: an interface to single data rate SDRAM (SDR-SDRAM) is connected to the XC1 cross-connect
  - D1M2(H): can address double data rate SDRAM (DDR2-SDRAM) and provides several 128-bit wide ports to supply high data rates for the video and graphics masters.
- The connection of the 2D Graphics Processing Unit (GPU2D), that acts also as a bus master, depends on the device:
  - D1M1(H), D1M1-V2 and D1M1A: GPU2D is also a XC1 master
  - D1M2(H): GPU2D can act as a master to the XC1 cross-connect for accessing on-chip memories, but has also a dedicated 128-bit port to the DDR2-SDRAM interface, that boosts the drawing performance in conjunction with the external DDR2-SDRAM.

Multilayered topology

Since the cross-connect systems represent a multilayer topology, masters accessing different slaves do not interfere.

Access of masters accessing the same slave concurrently is regulated by an arbiter. Refer to Section 14.3, Arbitration, bandwidth and latencies for details.

14.2.1 XC0 and XC1 cross-connects and XC Guards

The access to all XC0 and XC1 cross-connect slaves is guarded by the XC Guards. These can be configured to permit or prohibit write or read access to the slave by the various cross-connect masters.

The XC Guards XCGn identify a master by its master ID MSTIDk. The XC0 and XC1 cross-connects form a single master ID domain.
The IDs of all XC0 and XC1 masters are given in the following table.

Table 14.2 XC0 and XC1 cross-connect master IDs

Cross-connect	Master		Master ID k	Symbol
XC1	Debug unit		0	MSTID0
	CPU		1	MSTID1
	DMA Controller		2	MSTID2
	2D Graphics Processing Unit (GPU2D)		4	MSTID4
	JPEG Codec Unit A (JCUA)		5	MSTID5
	Ethernet AVB MAC (ETNB)		6	MSTID6
	Media Local Bus I/F (MLBB) or NAND Flash Controller (NFMA)		7	MSTID7
XC0 for D1L2(H), D1M1(H), D1M2(H)	Sprite Engine (SPEA)	RLE Units	8	MSTID8
		Sprite Unit 0	9	MSTID9
		Sprite Unit 1	10	MSTID10
		Sprite Unit 2	11	MSTID11
XC0 for D1M1-V2, D1M1A	Sprite Engine (SPEA)	RLE Unit 0, Sprite Unit 3	8	MSTID8
		RLE Unit 1, Sprite Unit 0	9	MSTID9
		RLE Unit 2, Sprite Unit 1	10	MSTID10
		RLE Unit 3, Sprite Unit 2	11	MSTID11

The XC0 cross-connect has two layers XC0_0 and XC0_1.

NOTE

The D1L1 devices do not have an XC0 cross-connect.

14.2.1.1 List of XC1 QoS Registers (D1M1(H), D1M1-V2, D1M1A only)

Table 14.3 List of XC1 QoS registers

Master Name XXX	Master number n	Description
CPU0	0	Debug master and DMA
CPU1	1	CPU master
VACC0	2	Cross-connect XC0_0
VACC1	3	Cross-connect XC0_1
JCUA	4	JCUA master
GPU2D	5	GPU2D master
ETNB	6	ETNB master

Base address

The register addresses in the table below are given as offset addresses to the

<base_addr> = FFCD 2300_H.

Table 14.4 List of XC1 QoS registers

Register name	Symbol	Address
XC1 QoS mode	QOS_MODE	<base_addr>
XC1 XXX QoS cycle count max value	XXX_MAX_COUNT	<base_addr> + 4_H + $10_H \times n$
XC1 XXX QoS read access permit count designation	XXX_MAX_RACC	<base_addr> + 8_H + $10_H \times n$
XC1 XXX QoS write access permit count designation	XXX_MAX_WACC	<base_addr> + C_H + $10_H \times n$

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> is defined as “SD_ISO_VDD" for the registers in the table above.

<Symbol> is defined in the above table

(1) QOS_MODE – XC1 QoS mode register (D1M1(H), D1M1-V2, D1M1A only)

This register is used to select QoS mode of XC1.

CAUTION

This register must only be changed while XC1 is not used.

Access: This register can be read/written in 32-bit units.

Address: <base_addr>

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

Table 14.5 QOS_MODE register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, these bits are always read as 0. When writing, always write 0.
2 to 0	QOS_ MODE[2:0]	XC QoS mode selection 000_B : Qos off 010_B : Interval mode 011_B: Threshold mode others : Setting prohibited

NOTE

- XXX indicates the master name
- n indicates the master number

(2) XXX_MAX_COUNT – XC1 XXX QoS cycle count max value register (D1M1(H), D1M1-V2, D1M1A only)

This register sets the initial value of the QoS cycle counter.

CAUTION

This register must only be changed while XC1 is not used.

Access: This register can be read/written in 32-bit units.

Address: <base_addr> + 4_H + 10_H × n

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 14.6 XXX_MAX_COUNT register contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, these bits are always read as 0. When writing, always write 0.
8 to 0	XXX_MAX_ COUNT[8:0]	QoS cycle counter initial value for XXX master. This register is enabled in interval mode and threshold mode. In other modes, setting value of this register is ignored. Interval mode: This register is set the number of interval cycles after accepting one access. Threshold mode : This register is set to the initial value of the cycle counter. XXX_MAX_RACC / XXX_MAX_WACC times of read / write access are permitted within the period that is set in this register.

NOTE

- XXX indicates the master name
- n indicates the master number

(3) XXX_MAX_RACC – XC1 XXX QoS read access permit count designation register (D1M1(H), D1M1-V2, D1M1A only)

This register sets the number of read access that are permitted in threshold mode.

CAUTION

This register must only be changed while XC1 is not used.

Access: This register can be read/written in 32-bit units.

Address: <base_addr> + 8_H + 10_H × n

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 14.7 XXX_MAX_RACC register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, these bits are always read as 0. When writing, always write 0.
2 to 0	XXX_MAX_ RACC[2:0]	The number of read accesses that are permitted in threshold mode This register is enabled in threshold mode. In other modes, setting value of this register is ignored. This register sets the number of read accesses that can be accepted within the period specified in the XXX_MAX_COUNT.

NOTE

- XXX indicates the master name
- n indicates the master number

(4) XXX_MAX_WACC – XC1 XXX QoS write access permit count designation register (D1M1(H), D1M1-V2, D1M1A only)

This register sets the number of write access that are permitted in threshold mode.

CAUTION

This register must only be changed while XC1 is not used.

Access: This register can be read/written in 32-bit units.

Address: <base_addr> + C_H + $10_H \times n$

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 14.8 XXX_MAX_WACC register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, these bits are always read as 0. When writing, always write 0.
2 to 0	XXX_MAX_ WACC[2:0]	The number of write accesses that are permitted in threshold mode This register is enabled in threshold mode. In other modes, setting value of this register is ignored. This register sets the number of write accesses that can be accepted within the period specified in the XXX_MAX_COUNT.

NOTE

- XXX indicates the master name
- n indicates the master number

14.2.2 XC2 cross-connect

The XC2 cross-connect forms an own master ID domain. Accesses of the XC2 masters are performed via the XC0 master ports of the Sprite Engine. Thus their XC2 master IDs are not visible on the XC0 and XC1 cross-connects.

The XC2 cross-connect has four layers XC2_0 to XC2_3.

NOTE

The D1L1 devices do not have an XC2 cross-connect.

14.2.3 Cross-connect details

This section gives details about each cross-connect.

NOTES

1. The arrows in the diagrams indicate the data transfer direction.
2. The assignment of the XC Guards XCGn to the cross-connect slaves are given in Table 14.40, Register base addresses <XCGn_base> in Section 14.6.5, Cross-connect Guards (XCG).
3. The indicators in the connection matrix table, provided for each device have the following meaning:

R:	The master can read from the slave.
W:	The master can write to the slave.
R/W;	The master can read from and write to the slave.
–:	The master has no access to the slave.

14.2.3.1 D1L1 bus architecture

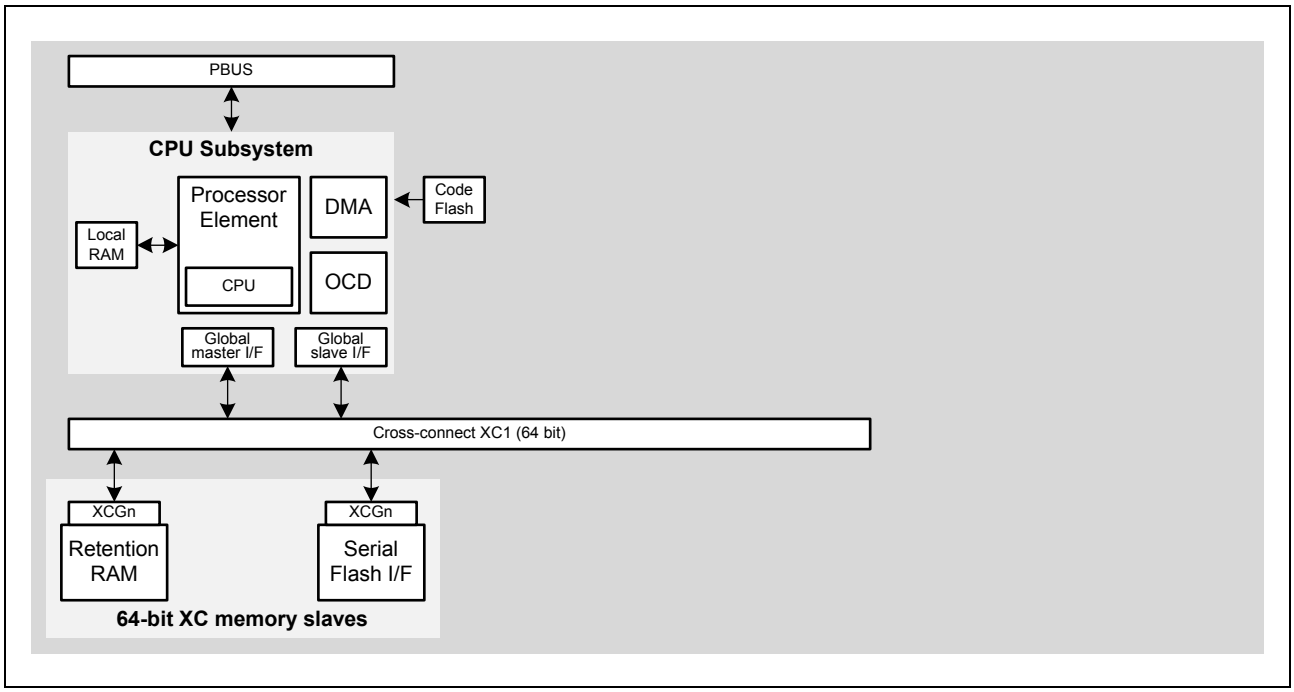

Figure 14.1 D1L1 bus architecture overview

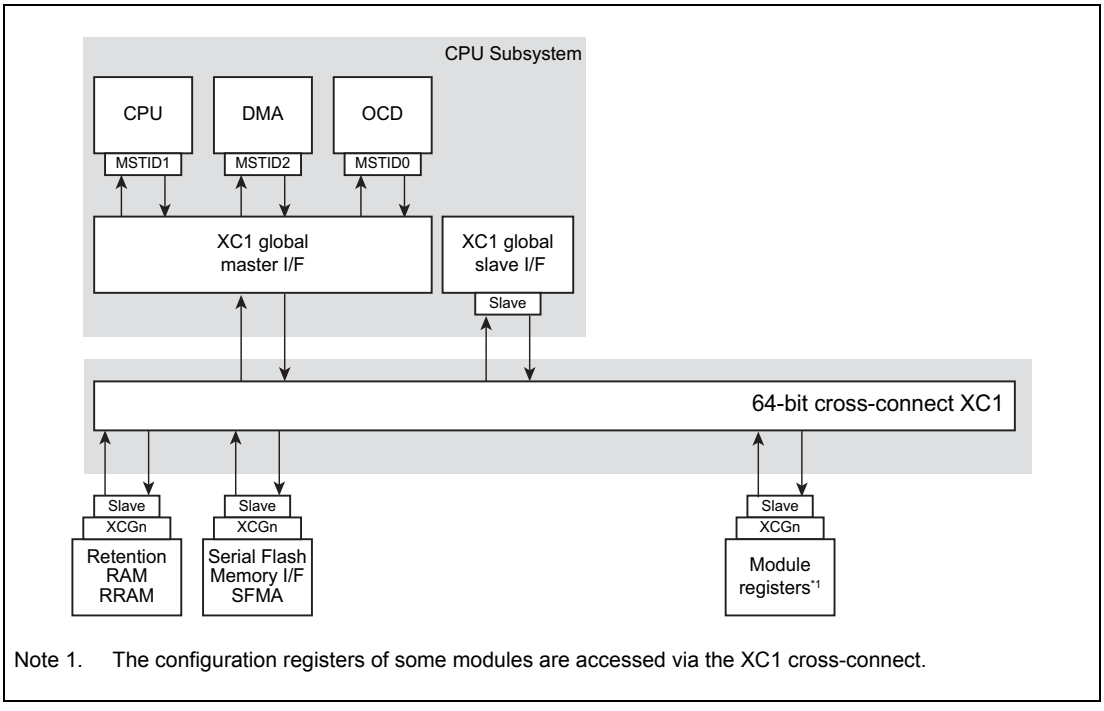
(a) D1L1 cross-connect XC1



Note 1. The configuration registers of some modules are accessed via the XC1 cross-connect.

Figure 14.2 D1L1 cross-connect XC1

14.2.3.6 D1M2(H) bus architecture

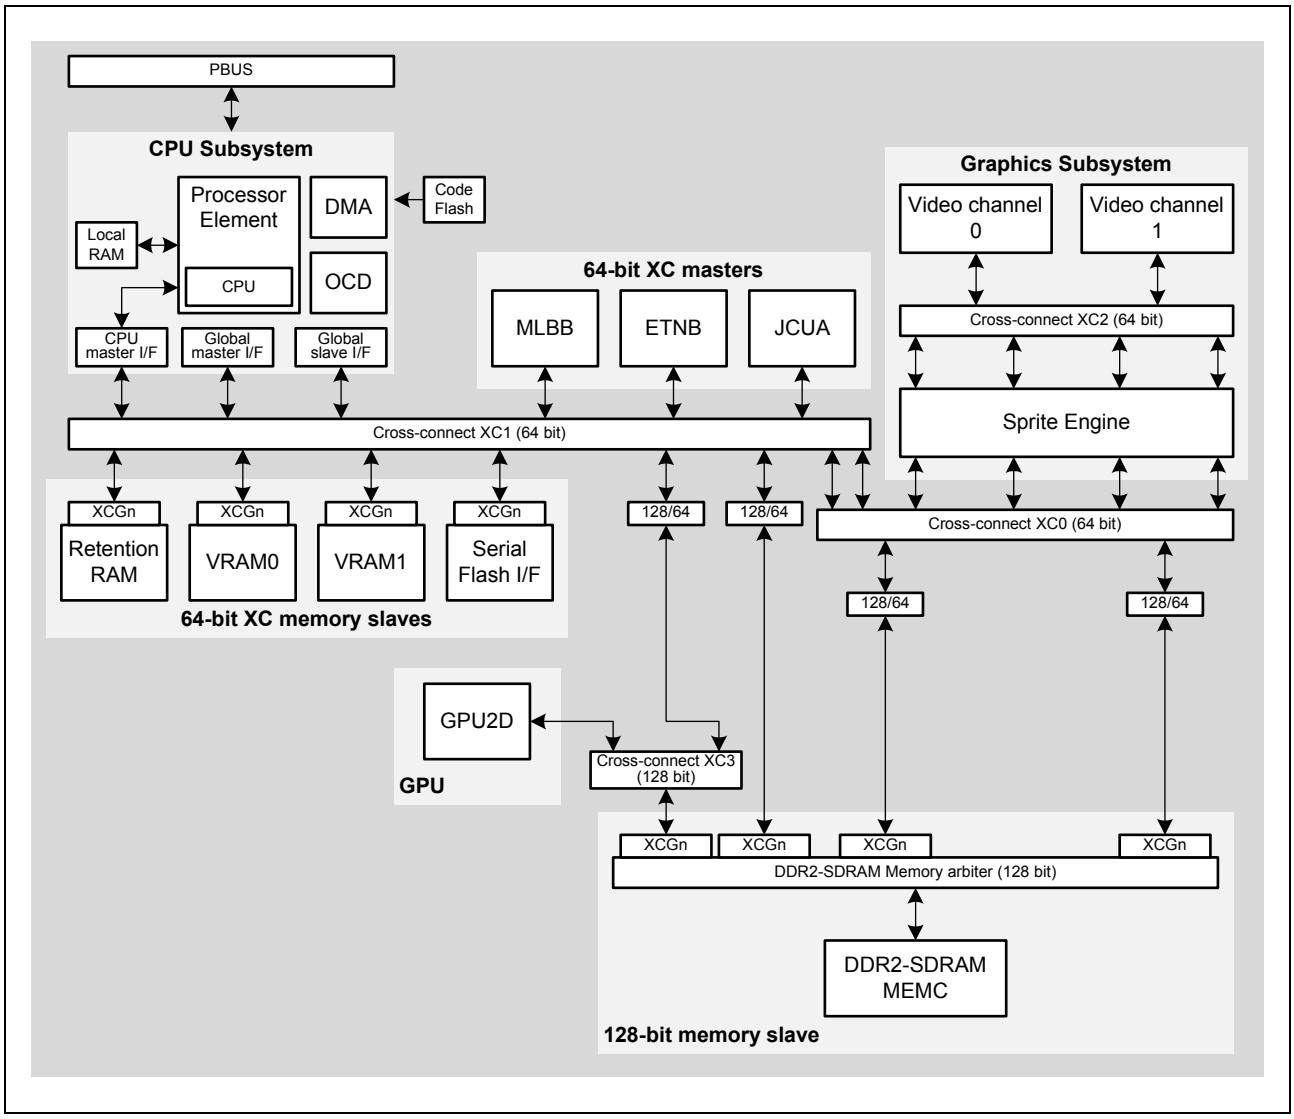

Figure 14.19 D1M2(H) bus architecture overview

DDR2-SDRAM interface

The DDR2-SDRAM Memory Controller (SDRB) provides four 128-bit wide ports to supply high data rates for the video and graphics masters. Refer to Section 14.3.4, D1M2(H) DDR2-SDRAM interface arbitration and bandwidth for further details.

D1M2(H) 2D Graphics Processing Unit GPU2D

The 2D Graphics Processing Unit (GPU2D) of the D1M2(H) devices acts as a master on the XC3 cross-connect towards two slaves:

- 128-bit port to the DDR2-SDRAM port 1, that boosts the drawing performance in conjunction with the external DDR2-SDRAM
- 64-bit port to the XC1 cross-connect for accessing on-chip memories.

(a) D1M2(H) cross-connect XC0

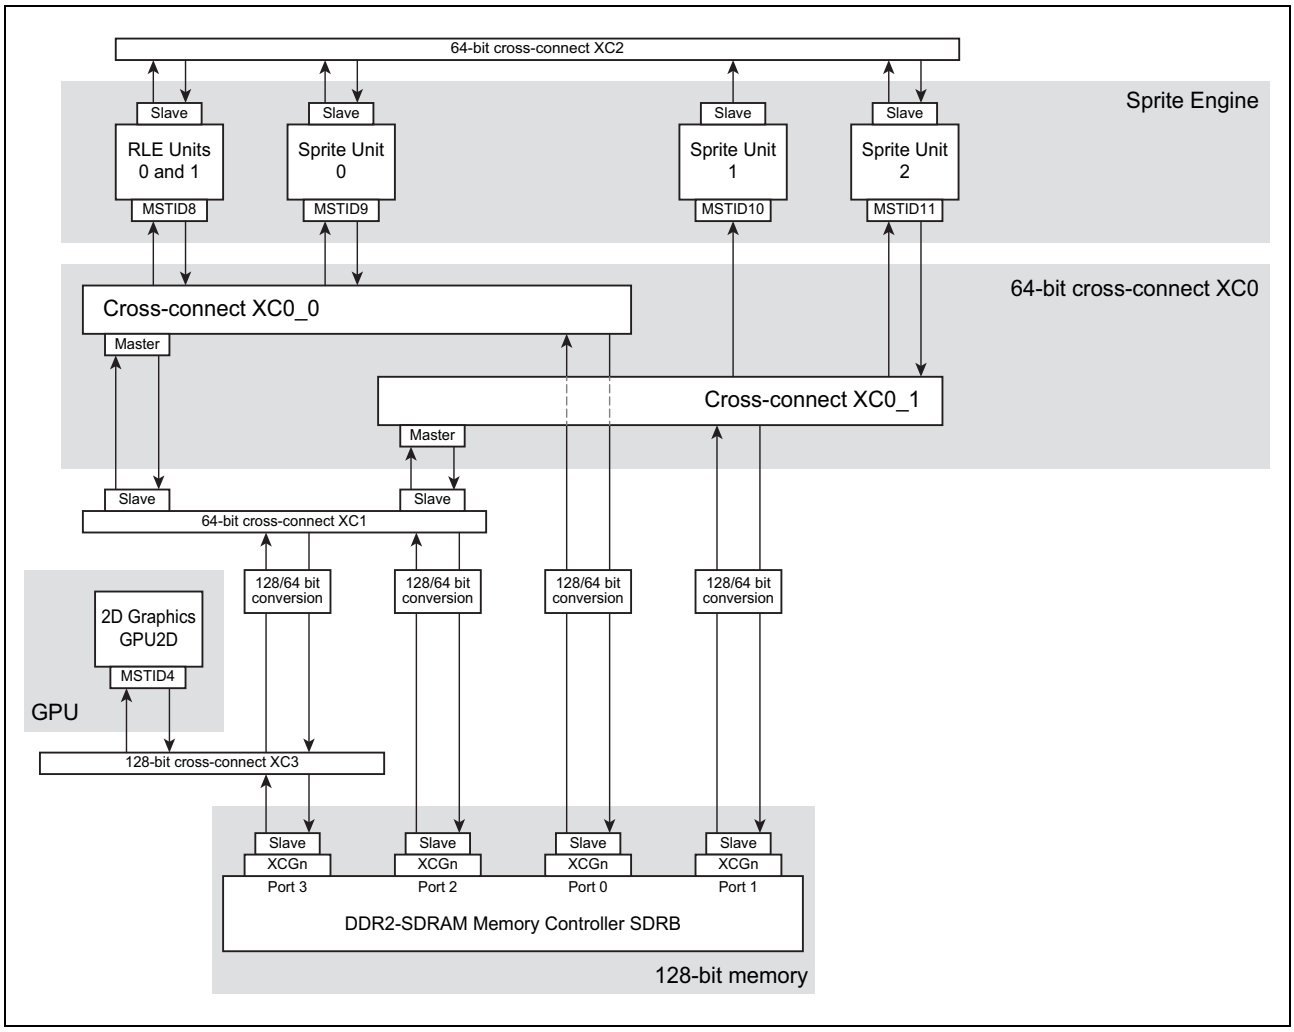

Figure 14.20 D1M2(H) cross-connect XC0

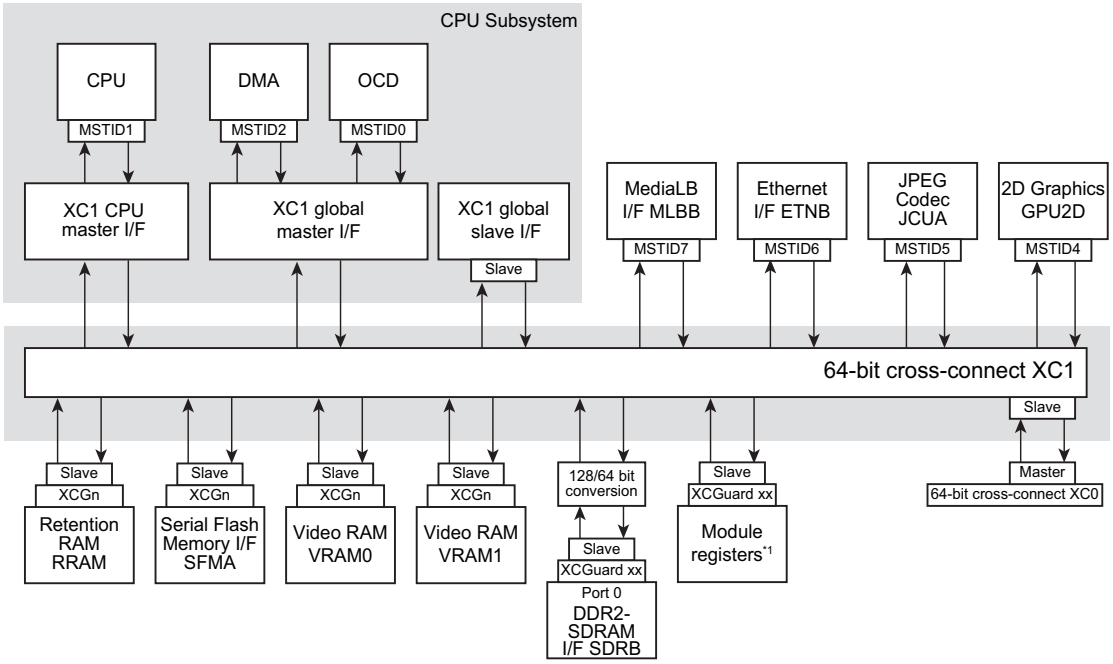
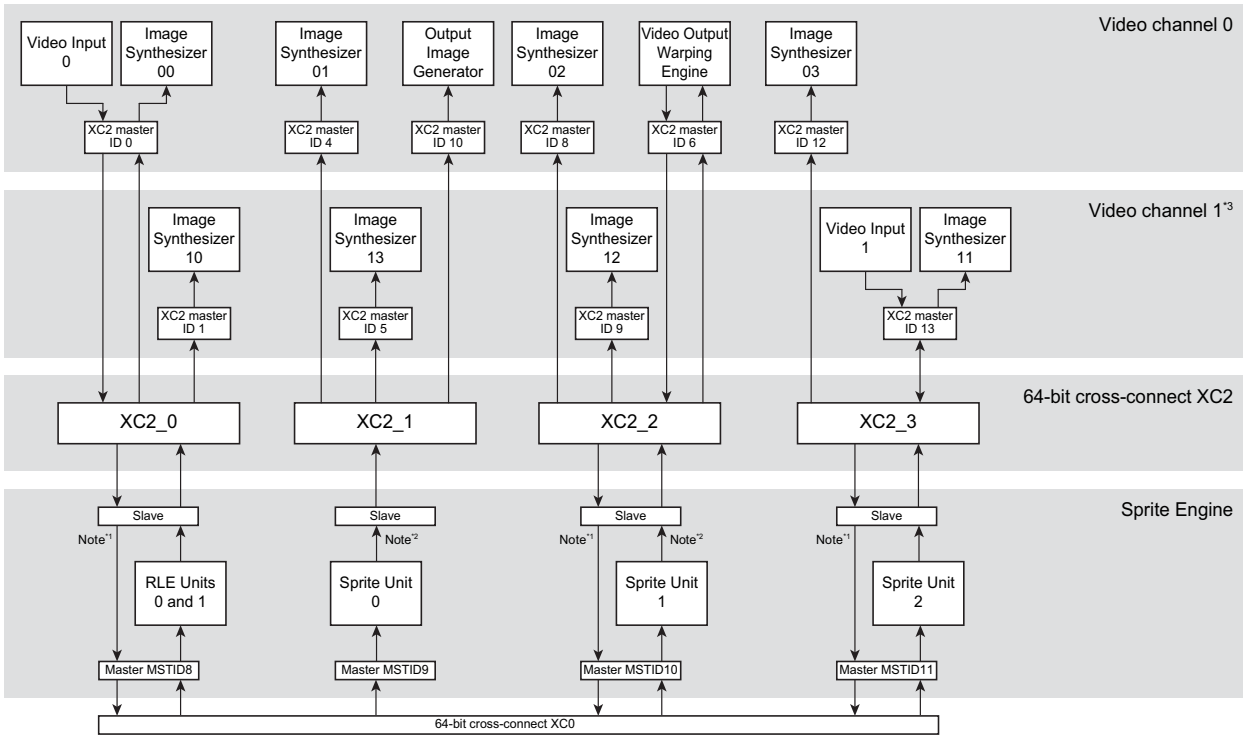
(b) D1M2(H) cross-connect XC1



Note 1. The configuration registers of some modules are accessed via the XC1 cross-connect.

Figure 14.21 D1M2(H) cross-connect XC1

(c) D1M2(H) cross-connect XC2



Note 1. All write accesses of the video channel masters are passed through the Sprite Engine to the XC0 cross-connect.

Note 2. Read accesses of the Warping Engine via Sprite Unit 0 and the Output Image Generator via Sprite Unit 1 must not read from addresses, covered by the Sprite Engine's virtual frame (refer to Section 43, Sprite Engine (SPEA) for details about the virtual frame). This way the Sprite Unit passes the master's read access through to the XC0 cross-connect.

Note 3. The video channel 1 is only available for D1M2(H) devices.

Note 7. Write access to SFMA registers only.

14.3 Arbitration, bandwidth and latencies

This section describes the arbitration policies of the slave interfaces, the data transfer bandwidth, provided to the masters, and defines the latencies needs to be taken into account, when a master initiates an access to a slave.

14.3.1 Transaction based busses

The cross-connect systems and the CPU Subsystem internal busses operate transactions based in order to avoid blocked busses due to not completed data transfers.

The diagram below shows the handling of transfers.
While the “classical” bus is blocked until the slave responses (“T1 response 001”) to a master request (“M1 request 001”), the “transaction bus” handles several master requests (“M1 request 001”, “M2 request 002”, “M1 request 003”) concurrently and routes the slave responses (“T2 response 002”, “T1 response 001”, “T1 response 003”) to the requesting masters.

Since bus blocking times are avoided, the bus effective bandwidth increases.

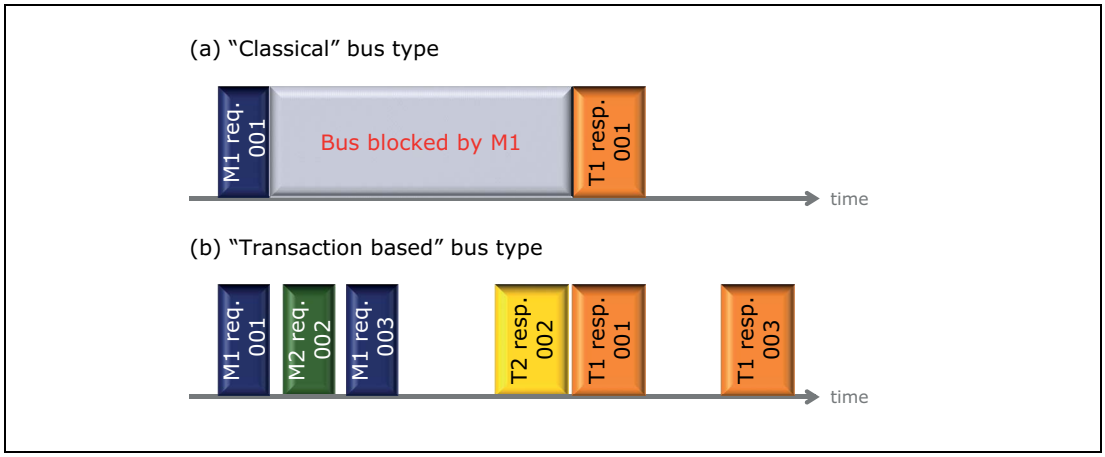

Figure 14.23 “Classical” vs. “transaction based” bus types

14.3.2 Cross-connects arbitration and bandwidth

Cross-connect arbitration

The slave modules of the cross-connect system arbitrate accesses of the masters according to a fair round robin scheme. This ensures an equal minimum bandwidth assigned to each master.

Cross-connect bandwidth

The maximum total bandwidth, a slave can provide, is determined by the cross-connect system’s bus width and clock frequency. All cross-connect systems operate with 64 data bits, the maximum slave bandwidth depends on the device:

- D1L2(H): 64 bit x 60 MHz = 480 MB/sec
- D1M1: 64 bit x 80 MHz = 640 MB/sec
- D1M1H: 64 bit x 100 MHz = 800 MB/sec
- D1M1-V2: 64 bit x 80 MHz = 640 MB/sec
- D1M1A: 64 bit x 120 MHz = 960 MB/sec

- D1M2(H): 64 bit x 120 MHz = 960 MB/sec

14.3.3 Cross-connect access latencies

In the following minimum access latencies are specified, when a cross-connect master writes or reads data from a cross-connect slave.

Explanation to the latency tables

- The numbers given in the table refer to the number clock cycles of the cross-connect operation clock C_ISO_XCCLK.
- The cycle numbers specify the minimum number of clock cycles under the condition that no additional arbitration takes place, because of several master acting on the same slave.
- JCUA: JPEG Codec Unit performs non-blocking data write to memory via a buffer. This means a memory write from the JCUA's perspective is always performed in 1 XCCLK cycle, provided the buffer is not full, while the real transfer from the buffer to the memory needs more cycles.
  The JCUA write cycle indicators in the Table 14.15, Minimum write access latency*1 mean:
  (latency cycle for JCUA) / (transfer cycles from buffer to target)
- VIn: Video Input of video channel n, writing data to memory through the Sprite Engine
- ISn: Image Synthesizers of the video channel n, i.e.
  - video channel 0 Image Synthesizers 00 to 03
  - video channel 1 Image Synthesizers 10 to 13

  reading data from memory through the Sprite Engine
- VOWE: Video Output Warping Engine of video channel 0, reading/writing data from/to memory through the Sprite Engine

14.3.3.1 Minimum write access latency

14.3.4 D1M2(H) DDR2-SDRAM interface arbitration and bandwidth

The DDR2-SDRAM internal bus interface is 128-bit wide and operates with 120 MHz, thus provides a total bandwidth of 1.92 GB/s.
The external DDR2-SDRAM interface is 32-bit wide and can operate with 480 MHz.

It features four read/write ports. Arbitration is ruled by a programmable priority generator, that allows to dynamically adjust priorities of the ports.

Refer to Section 16, DDR2-SDRAM Memory Controller (SDRB) for details.

14.4 Bus Switch for external memory interfaces (D1M1-V2, D1M1A only)

The HYPBSEL selects HyperBus or OctaBus usage and the SFMASEL selects SFMA1 or SFMA2.

These interfaces are configurable via the bus switch control register XCRAMCFG0.

The HyperBus and OctaBus interface share also the ports P21_[9:0] and P22_10.

The SFMA1 and SFMA2 interface share also the ports P21_[9:6].

The related ports are also selected by the bus switch control register XCRAMCFG0.

(1) XCRAMCFG0 – Bus switch control register

Access: This register can be read/written in 32-bit units.

Address: FFC0 6050_H

Initial value: 0000 0000_H

Bit Position	Bit Name	Function
31 to 22	Reserved	When read, these bits are always read as 0. When writing, always write 0.
21	CSSEL2	Select P45_1 4th alternative function (D1M1A only) 0: VDCE0_VO_TCON3 1: SFMA2SSL, which is selected by XCRAMCFG0.CSSEL
20	CSSEL	Select P45_13 5th alternative function (D1M1A only) 0: SFMA2SSL 1: OCTA0 MCS1
19 to 10	Reserved	When read, these bits are always read as 0. When writing, always write 0.
9	SFMASEL	Bus type selection at cross-connect XC1 (D1M1A only) 0: SFMA1 1: SFMA2
8	HYPBSEL	Bus type selection at cross-connect XC1 0: HyperBus 1: OctaBus
7 to 0	Reserved	When read, these bits are always read as 0. When writing, always write 0.

CAUTION

XCRAMCFG0 must be set according to the HyperBus or OctaBus and SFMA1 or SFMA2 selection before the XC0 cross-connect is released from reset, i.e. before MRSTC.XC0RES = 1 is set.

14.6 Bus Guards

Several bus guards allow to grant or prohibit certain access rights to certain bus masters for accessing particular busses and their attached modules.

- Processor Element Guard (PEG)
  regulates access of all master, except the CPU, to CPU's local RAM
- PE's Internal Peripheral Guard (IPG)
  protects the Processor Element's control and configuration registers against illegal access
- PBUS guards (PBG)
  regulates access to all PBUS modules
- Cross-connect guards (XCG)
  regulates access to all cross-connect slave modules

In case a bus guard detects an access violation, error notifications are forwarded to the Error Control Module, and thus can generate interrupts or a reset.

14.6.1 SPID and PEID assignment

Table 14.19 SPID and PEID assignment

		Device
SPID[1:0] SPID is set by the CPU system.	0 to 3*1	CPU
	0 to 3*2	DMA
	0	Cross-connect XC1 master (via XC1 global I/F)
PEID[2:0]	0	Debug master*3
	1	CPU
	1 to 7*2	DMA
	4	Cross-connect XC1 master (via XC1 global I/F)

Note 1. SPID from CPU is set in the MCFG0 register of the CPU Subsystem. Default SPID is 01_B.
Refer to the RH850 Family User's Manual: Software

Note 2. In the case of DMA access, PEID/SPID is the value in the DMnnCM register of the DMA Controller.

Note 3. PEG does not protect access from debug master that PEID is set to 0.

14.6.2 PE Guard (PEG)

PE Guard error signals

Table 14.20 PE Guard error signals

CFG signal	Function	Connected to
PE1_PEG_RDERR	Guard error during Processor Element read access from Global Interconnect (GVCI)	Error Control Module INTPEGRD*1
PE1_PEG_WRERR	Guard error during Processor Element write access from Global Interconnect (GVCI)	

Note 1. This Error Control Module input signal is a logical OR of both error signals.
Refer to Section 48, Error Control Module (ECM) for details.

14.6.2.1 Overview of the PEG Function

The PEG is a constituent of the slave guard system to prevent unauthorized access to the resources in the PE from the external master. This function protects access to the local RAM in the PE. In the initial state after a reset, all access by masters other than the PE itself is disabled. Setting the registers listed in Section 14.6.2.3, List of PEG Protection Setting Registers, enables access by masters other than the PE itself.

(1) Detecting PE guard violation
If the external master outside the PE makes an unauthorized access to the resource area in the PE for which PE guard is set, the access is detected as a PE guard violation.

(2) Blocking unauthorized accesses
When a PE guard violation is detected, unauthorized accesses to the internal resources of the PE are blocked to prevent the contents of PE resources from being modified illegally.

(3) Notifying occurrence of violation
An error response to an unauthorized access is sent to the request source of external master.

When the DMAC makes an unauthorized access, a DMA transfer error occurs due to an error response.

NOTE

PEG does not protect access from debug master that PEID is set to 0.

14.6.2.2 Protection Made by SPID

NOTE

For a list of SPID numbers refer to Section 14.6.1, SPID and PEID assignment.

- Setting PEG Protection
  - Up to four areas can be set depending on the Local RAM address of the own PE.
  - The area range is specified by the base address and the mask bit (4 Kbytes to 4 Gbytes).
  - “Read enable” and “write enable” can be set for each area.
  - “Enable” or “disable” can be selected on each system protection identifier (SPID) basis for each area.
- Access permission by the system protection identifier (SPID) (see Figure 14.28)

1. When the Local RAM area is to be accessed, go to step 2.
   Otherwise, return an error response.
2. When any of enabled area 0 to area 3 is to be accessed, go to step 3.
   Otherwise, return an error response.
3. Are all the conditions below for the relevant area met?
   - The system protection identifier (SPID) is enabled.
   - Required operations (read/write) are enabled.
     Otherwise, return an error response.

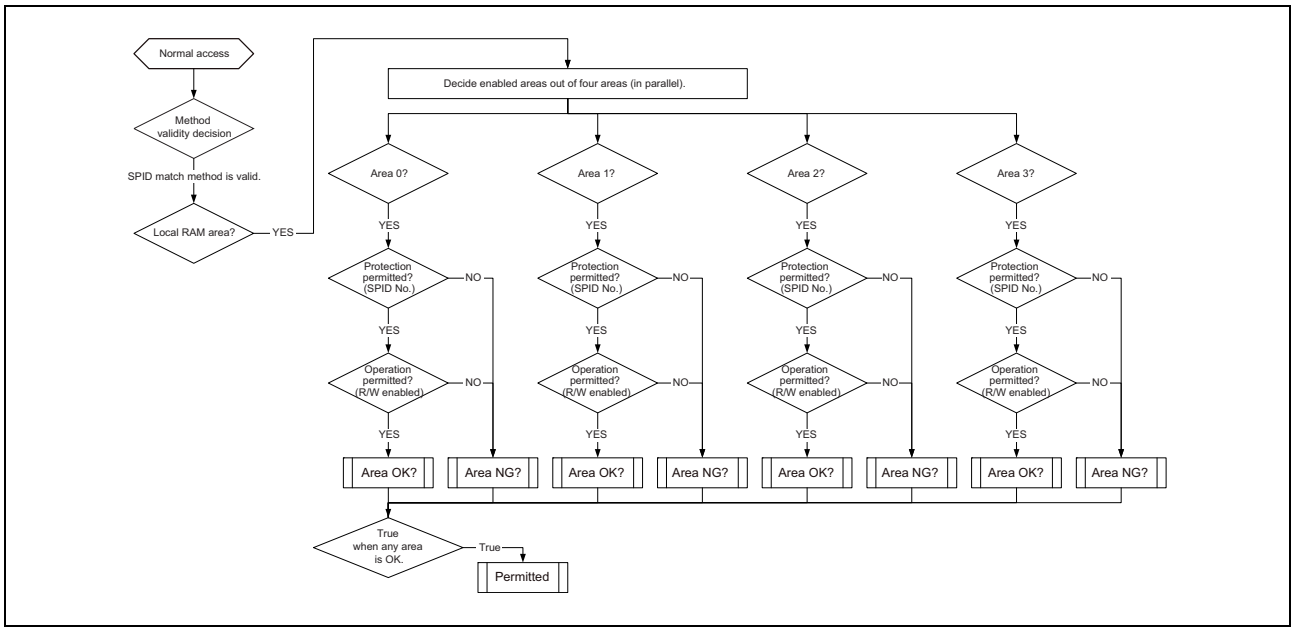

Figure 14.28 Access Permission by the System Protection Identifier (SPID)

14.6.2.3 List of PEG Protection Setting Registers

Make necessary settings for the following registers to protect PE resources from unauthorized accesses by the external master.

Accesses to registers listed in Table 14.21 are not protected by the PEG. Make access protection settings by the MPU or IPG as needed.

Table 14.21 Base Address of PEG Register: FFFE E600$_H$

Address Offset	Size (Byte)	Register Name	Symbol	Right	R/W	Operable Bit				Initial Value
						1	8	16	32	
+00C$_H$	2	PE guard SPID master decision control register	PEGSP	—	R/W	—	√	√	—	0000$_H$
+080$_H$	4	PE guard area 0 mask setting register	PEGG0MK	—	R/W	—	√	√	√	0000 0000$_H$
+084$_H$	4	PE guard area 0 base setting register	PEGG0BA	—	R/W	—	√	√	√	0000 0000$_H$
+090$_H$	4	PE guard area 1 mask setting register	PEGG1MK	—	R/W	—	√	√	√	0000 0000$_H$
+094$_H$	4	PE guard area 1 base setting register	PEGG1BA	—	R/W	—	√	√	√	0000 0000$_H$
+0A0$_H$	4	PE guard area 2 mask setting register	PEGG2MK	—	R/W	—	√	√	√	0000 0000$_H$
+0A4$_H$	4	PE guard area 2 base setting register	PEGG2BA	—	R/W	—	√	√	√	0000 0000$_H$
+0B0$_H$	4	PE guard area 3 mask setting register	PEGG3MK	—	R/W	—	√	√	√	0000 0000$_H$
+0B4$_H$	4	PE guard area 3 base setting register	PEGG3BA	—	R/W	—	√	√	√	0000 0000$_H$

To set PEG Protection, register setting order as described below must be followed.

1. Set PEGGnMK(mask setting register)
2. Set PEGGnBA(base setting register)

14.6.2.4 Register Set

(1) PE Guard SPID Master Decision Control Register (PEGSP)

This register is used to enable or disable access by an external master to the resources in the PE. The initial value of the SPEN bit is 0, which disables access to PE resources by an external master. Setting the SPEN bit to 1 enables access by an external master under the conditions set by PEGGnMK and PEGGnBA.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SPEN
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 14.22 PEGSP register contents

Bit Position	Bit Name	Function
15 to 1	—	Reserved. These bits are always read as 0. The write value should always be 0.
0	SPEN	This bit enables or disables detection of accesses by the external master having SPID. 0: Detection of accesses by the external master having SPID is disabled. 1: Detection of accesses by the external master having SPID is enabled.

(2) PE Guard Area n Mask Setting Register (PEGGnMK)

In combination with the PEGGnBA register, this register specifies a range or ranges within PE guard protection area n. Setting a GnMASK bit to 1 masks the corresponding address bit and places the address bit outside the range of address comparison target in the PE guard protection area n. The minimum unit of setting the PE guard protection area n is 4 Kbytes.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GnMASK															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GnMASK				—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 14.23 PEGGnMK register contents

Bit Position	Bit Name	Function
31 to 12	GnMASK	These bits determine whether to mask upper bits of the address that specifies the range of PE guard protection area n. 0: Target address bits are compared when determining the PE guard area. 1: Target address bits are not compared when determining the PE guard area.
11 to 0	—	Reserved. These bits are always read as 0. The write value should always be 0.

(3) PE Guard Area n Base Setting Register (PEGGnBA)

In combination with the PEGGnMK register, this register specifies a range or ranges within PE guard protection area n. Setting the GnEN bit to 1 brings the address enable conditions specified by this register and the PEGGnMK register into effect.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GnBASE															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GnBASE				—	—	—	—	GnSP3	GnSP2	GnSP1	GnSP0	—	GnWR	GnRD	GnEN
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 14.24 PEGGnBA register contents

Bit Position	Bit Name	Function
31 to 12	GnBASE	Base address that specifies PE guard protection area n
11 to 8	—	Reserved. These bits are always read as 0. The write value should always be 0.
7	GnSP3	Enables accesses to PE guard protection area n by the external master. 0: Access by an external master having SPID = 3 is disabled. 1: Access by an external master having SPID = 3 is enabled.
6	GnSP2	Enables accesses to PE guard protection area n by the external master. 0: Access by an external master having SPID = 2 is disabled. 1: Access by an external master having SPID = 2 is enabled.
5	GnSP1	Enables accesses to PE guard protection area n by the external master. 0: Access by an external master having SPID = 1 is disabled. 1: Access by an external master having SPID = 1 is enabled.
4	GnSP0	Enables accesses to PE guard protection area n by the external master. 0: Access by an external master having SPID = 0 is disabled. 1: Access by an external master having SPID = 0 is enabled.
3	—	Reserved. This bit is always read as 0. The write value should always be 0.
2	GnWR	Enables write access to PE guard protection area n. 0: Write access is disabled. 1: Write access is enabled.
1	GnRD	Enables read access to PE guard protection area n. 0: Read access is disabled. 1: Read access is enabled.
0	GnEN	PE guard protection area n enable 0: Settings for access enable conditions are disabled 1: Settings for access enable conditions are enabled

NOTE

PEGGnBA is cleared when PEGGnMK is written.

14.6.3 PE's Internal Peripheral Guard (IPG)

14.6.3.1 Overview of the IPG Function

The IPG is a system to prevent unauthorized accesses to peripheral devices from the CPU core equipped with the IPG. The IPG achieves the following functions. The IPG covers accesses to resources except the ROM and the local RAM.

(1) Detecting violation of peripheral device protection
If the CPU makes an unauthorized access to an area (peripheral device) for which peripheral device protection is set, the access is detected as "violation of peripheral device protection."

(2) Storing unauthorized-access information
When a violation of peripheral device protection is detected, the unauthorized-access information is stored in the IPG's internal register.

(3) Blocking unauthorized accesses
When a violation of peripheral device protection is detected, unauthorized accesses to peripheral devices are blocked to prevent contents of peripheral devices from being modified illegally.

(4) Notifying violation
When a violation of peripheral device protection is detected, an exception is generated.

NOTE

The RH850G3M makes a request for generating a SYSERR (asynchronous) exception via SysErrGen.

(5) Invalidating subsequent accesses
When a violation of peripheral device protection is detected, subsequent accesses (regardless of authorized or unauthorized accesses) are blocked until the error flag is cleared.

NOTE

Even if a request for generating an exception is immediately sent to the CPU in step (4) above, a subsequent access issued by the CPU before receiving a request from the IPG may illegally modify contents of peripheral devices. (If an access after a violation has occurred is also a violation, access protection is made.)

14.6.3.2 IPG Function

(1) This function invalidates accesses according to their attributes (including address, transfer type, and access right).

(2) After an access right violation is detected until the error flag (described later) is cleared by writing by the software, subsequent accesses are invalidated. However, invalidation is applied only to accesses from the CPU and is not applied to accesses from outside the CPU. Invalidation is performed for accesses within the IPG protection range regardless of the IPG protection setting.

(3) When a request for accessing different peripheral devices simultaneously is made due to misalignment or double-word access, the access is executed when all such accesses are enabled.

14.6.3.3 IPG Protection Setting Registers for Illegal Users

To protect peripheral devices from unauthorized accesses by programs in user mode, necessary settings are required for the registers listed below.

- Accesses in user mode are to be detected.
- This register set is intended for IPG settings related to user mode and reading the IPG settings.

Table 14.25 Base Address of IPG Register: FFFE E000$_H$

Address Offset	Size (Byte)	Register Name	Symbol	Right *1	R/W	Operable Bit 1	8	16	32	Initial Value

+020$_H$	1	Peripheral device protection setting register 0	IPGPMTUM0	SV	R/W	√	√	–	–	00$_H$
+022$_H$	1	Peripheral device protection setting register 2	IPGPMTUM2	SV	R/W	√	√	–	–	00$_H$
+023$_H$	1	Peripheral device protection setting register 3	IPGPMTUM3	SV	R/W	√	√	–	–	00$_H$
+024$_H$	1	Peripheral device protection setting register 4	IPGPMTUM4	SV	R/W	√	√	–	–	00$_H$

Note 1. Registers for which “SV” is described are accessible by accesses with SV right (PSW.UM = 0).

14.6.3.4 Register Set

(1) Peripheral Device Protection Violation Access Information Register (IPGECRUM)

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DS[3:0]				EX	WR	RD	VD
Initial value	0	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

×: Undefined (retained)

Table 14.26 IPGECRUM register contents

Bit Position	Bit Name	Function
15 to 8	—	Reserved. These bits are always read as 0. The write value should always be 0.
7 to 4	DS[3:0]	These bits store the data size of access that made a violation. 1000: Double-word (8 bytes) 0100: Word (4 bytes) 0010: Half-word (2 bytes) 0001: Byte Other than above: RFU
3	EX	This bit is set to 1 when a violation occurred in an instruction fetch read access. In other cases, this bit is cleared to 0.
2	WR	This bit is set to 1 when a violation occurred in a write access or bit operation or CAXI. In other cases, this bit is cleared to 0.
1	RD	This bit is set to 1 when a violation occurred in a read access or bit operation or CAXI. In other cases, this bit is cleared to 0.
0	VD	This bit is set to 1 when a violation of peripheral device protection is detected by a program with the relevant right. If another violation of peripheral device protection is detected, data of this IPGECRUM register and the IPGADRUM register is updated.

NOTE

When the IRE bit value of the IPGENUM register (described later) is 0 and violation of peripheral device protection by a program operating in user mode is an instruction fetch read access, no bit of this register is updated.

(2) Peripheral Device Protection Violation Access Address Register (IPGADRUM)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	EADR[31:16]															
Initial value	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EADR[15:0]															
Initial value	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

×: Undefined (retained)

Table 14.27 IPGADRUM register contents

Bit Position	Bit Name	Function
31 to 0	EADR[31:0]	These bits store the address of the access in which a violation occurred.

NOTE

When the IRE bit value of the IPGENUM register (described later) is 0 and violation of peripheral device protection by a program operating in user mode is an instruction fetch read access, no bit of this register is updated.

(3) Peripheral Device Protection Enable Register (IPGENUM)

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	IRE	E
Initial value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 14.28 IPGENUM register contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved. These bits are always read as 0. The write value should always be 0.
1	IRE	This bit sets whether to store the access information in the peripheral device protection violation access address register and the peripheral device protection violation access information register when a violation of peripheral device protection occurred in an instruction fetch access. 0: Instruction fetch access information is not stored. (Initial value) 1: Instruction fetch access information is stored. **CAUTION** If you do not want to detect speculative instruction fetches (no instruction is executed in some cases), clear this bit to 0.
0	E	This bit enables or disables the peripheral devices protection function against accesses by the relevant access right. 0: The peripheral device protection function is disabled. (Initial value) 1: The peripheral device protection function is enabled.

(4) Peripheral Device Protection Setting Register 0 (IPGPMTUM0)

Bit	7	6	5	4	3	2	1	0
	—	X1	W1	R1	—	—	—	—
Initial value	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R	R	R	R

Table 14.29 IPGPMTUM0 register contents

Bit Position	Bit Name	Function
7	—	Reserved. This bit is always read as 0. The write value should always be 0.
6	X1	This bit sets whether to enable instruction fetch read access to peripheral devices to be connected to the PBUS and Data Flash. 0: Instruction fetch read access to peripheral devices to be connected to the PBUS and Data Flash is treated as violation. (Initial value) 1: Instruction fetch read access to peripheral devices to be connected to the PBUS and Data Flash is not restricted.
5	W1	This bit sets whether to enable write access to peripheral devices to be connected to the PBUS and Data Flash. 0: Write access to peripheral devices to be connected to the PBUS and Data Flash is treated as violation. (Initial value) 1: Write access to peripheral devices to be connected to the PBUS and Data Flash is not restricted.
4	R1	This bit sets whether to enable read access to peripheral devices to be connected to the PBUS and Data Flash. 0: Read access to peripheral devices to be connected to the PBUS and Data Flash is treated as violation. (Initial value) 1: Read access to peripheral devices to be connected to the PBUS and Data Flash is not restricted.
3 to 0	—	Reserved. This bit is always read as 0. The write value should always be 0.

(5) Peripheral Device Protection Setting Register 2 (IPGPMTUM2)

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	X0	W0	R0
Initial value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 14.30 IPGPMTUM2 register contents

Bit Position	Bit Name	Function
7 to 3	—	Reserved. This bit is always read as 0. The write value should always be 0.
2	X0	This bit sets whether to enable instruction fetch read access to INTC1. 0: Instruction fetch read access to INTC1 is treated as violation. (Initial value) 1: Instruction fetch read access to INTC1 is not restricted.
1	W0	This bit sets whether to enable write access to INTC1. 0: Write access to INTC1 is treated as violation. (Initial value) 1: Write access to INTC1 is not restricted.
0	R0	This bit sets whether to enable read access to INTC1. 0: Read access to INTC1 is treated as violation. (Initial value) 1: Read access to INTC1 is not restricted.

(6) Peripheral Device Protection Setting Register 3 (IPGPMTUM3)

Bit	7	6	5	4	3	2	1	0
	—	X1	W1	R1	—	—	—	—
Initial value	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R	R	R	R

Table 14.31 IPGPMTUM3 register contents

Bit Position	Bit Name	Function
7	—	Reserved. This bit is always read as 0. The write value should always be 0.
6	X1	This bit sets whether to enable instruction fetch read access to SysErrGen. 0: Instruction fetch read access to SysErrGen is treated as violation. (Initial value) 1: Instruction fetch read access to SysErrGen is not restricted.
5	W1	This bit sets whether to enable write access to SysErrGen. 0: Write access to SysErrGen is treated as violation. (Initial value) 1: Write access to SysErrGen is not restricted.
4	R1	This bit sets whether to enable read access to SysErrGen. 0: Read access to SysErrGen is treated as violation. (Initial value) 1: Read access to SysErrGen is not restricted
3 to 0	—	Reserved. These bits are always read as 0. The write value should always be 0.

(7) Peripheral Device Protection Setting Register 4 (IPGPMTUM4)

Bit	7	6	5	4	3	2	1	0
	—	X1	W1	R1	—	—	W0	R0
Initial value	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R	R	R/W	R/W

Table 14.32 IPGPMTUM4 register contents

Bit Position	Bit Name	Function
7	—	Reserved. These bits are always read as 0. The write value should always be 0.
6	X1	This bit sets whether to enable instruction fetch read access to peripheral devices to be connected to the cross-connect XC1. 0: Instruction fetch read access to peripheral devices to be connected to the cross-connect XC1 is treated as violation. (Initial value) 1: Instruction fetch read access to peripheral devices to be connected to the cross-connect XC1 is not restricted.
5	W1	This bit sets whether to enable write access to peripheral devices to be connected to the cross-connect XC1. 0: Write access to peripheral devices to be connected to the cross-connect XC1 is treated as violation. (Initial value) 1: Write access to peripheral devices to be connected to the cross-connect XC1 is not restricted.
4	R1	This bit sets whether to enable read access to peripheral devices to be connected to the cross-connect XC1. 0: Read access to peripheral devices to be connected to the cross-connect XC1 is treated as violation. (Initial value) 1: Read access to peripheral devices to be connected to the cross-connect XC1 is not restricted.
3, 2	—	Reserved. This bit is always read as 0. The write value should always be 0.
1	W0	This bit sets whether to enable write access to PEG. 0: Write access to PEG is treated as violation. (Initial value) 1: Write access to PEG is not restricted.
0	R0	This bit sets whether to enable read access PEG. 0: Read access to PEG is treated as violation. (Initial value) 1: Read access to PEG is not restricted

14.6.4 PBUS Guards (PBG)

The PBG module is divided into several PBG groups, each of which is provided with a maximum of 16 protection channels. A single PBG channel can designate the access against which a single peripheral circuit should be protected. Each PBG group can hold the information of the access that has been rejected.

The PBG groups are defined in Section 14.5, PBUS structure.

14.6.4.1 List of Registers

The following table lists the register provided for each PBG channel.

Module Name	Symbol	Register Name	R/W	Initial Value	Address	Access Size
PBG	FSGDxxPROTn	PBGxx protection register n	R/W	07FF FFFF$_H$	<base_addr0> + 4*n	8/16/32

NOTE

The content and the initial value of the FSGD0BPROTn registers are different to all other FSGDxxPROTn registers. For details, please refer to Section 14.6.4.2, Details of Registers.

The following table lists the registers provided for each PBG group.

Module Name	Symbol	Register Name	R/W	Initial Value	Address	Access Size
PBG	ERRSLVxxCTL	PBGxx error control register	W	0000 0000$_H$	<base_addr1> + 0$_H$	8/16/32
PBG	ERRSLVxxSTAT	PBGxx error status register	R	0000 0000$_H$	<base_addr1> + 4$_H$	8/16/32
PBG	ERRSLVxxADDR	PBGxx error address register	R	0000 0000$_H$	<base_addr1> + 8$_H$	8/16/32
PBG	ERRSLVxxTYPE	PBGxx error type register	R	0000 0000$_H$	<base_addr1> + C$_H$	8/16/32

NOTE

In the header files the names of the above registers are defined in the following format:
<ModuleName> + <Symbol>.
<ModuleName> and <Symbol> are defined in the above tables.

The availability of each PBG register depends on corresponding module availability for each product. See the overview part of each module chapter, for details.
ex) All corresponding registers for PBUS2 are not available in D1L1.

In the above tables, “xx” and “n” in the register names and symbols represents the PBG group numbers and PBG channel numbers, respectively. The table below shows the base address values <base_addr0> and <base_addr1>, which correspond to each of the PBG group numbers and PBG channel numbers.

PBG Group	PBG Group Number xx	PBG Channel Number n	<base_addr0>	<base_addr1>
PBG0A	0A	0 to 4, 6, 7	FFF9 4000_H	FFF9 5000_H
PBG0B	0B	0, 1	FFC4 $C000_H$	FFC4 $C800_H$
PBG1A	1A	0 to 2, 4 to 6	FFF9 $B000_H$	FFF9 $C000_H$
PBG10A	10A	0 to 6	FFF9 $D000_H$	FFF9 $E000_H$
PBG2A	2A	0 to 9	FFFC 7000_H	FFFC 8000_H
PBG2B	2B	1 to 5, 7, 11 to 13	FFFC 9000_H	FFFC $A000_H$
PBG3A	3A	1, 3 to 8	FFDC 0000_H	FFDC 1000_H
PBG3B	3B	0 to 8, 10, 11	FFDC 2000_H	FFDC 3000_H
PBG30A	30A	0 to 15	FFDC 8000_H	FFDC 9000_H
PBG30B	30B	0, 1	FFDC $A000_H$	FFDC $B000_H$
PBG5A	5A	2, 3, 6 to 15	FFF9 0000_H	FFF9 0400_H
PBG5B	5B	0 to 3, 5 to 10, 12	FFF9 0800_H	FFF9 $0C00_H$
PBG5C	5C	0 to 12, 14, 15	FFF9 1000_H	FFF9 1400_H
PBG32A	32A	0 to 15	FFDC 4000_H	FFDC 5000_H
PBG32B	32B	0 to 3	FFDC 6000_H	FFDC 7000_H

14.6.4.2 Details of Registers

(1) FSGDxxPROTn — PBGxx protection register n

FSGDxxPROTn designates the access to be rejected against which the peripheral circuit control registers and RAM should be protected. Any access that is disabled using any of the identifiers is rejected as an illegal access.

NOTE

The content and the initial value of the FSGD0BPROTn registers are different to all other FSGDxxPROTn registers.

(a) FSGD0BPROTn

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PROTLOCK	—	—	—	—	—	PROTUM	PROTPEID[7:0]								VCID7
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0
R/W	R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VCID[6:0]							PROTSPID[3:0]				PROTDEB	PROTRDPDEF	PROTWRPDEF	PROTRD	PROTWR
Initial value	0	0	0	0	0	0	1	0	0	0	1	1	0	1	0	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

(b) All other FSGDxxPROTn (xx ≠ 0B):

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PROTLOCK	—	—	—	—	—	PROTUM	PROTPEID[7:0]								VCID7
Initial value	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VCID[6:0]							PROTSPID[3:0]				PROTDEB	PROTRDPDEF	PROTWRPDEF	PROTRD	PROTWR
Initial value	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 14.33 FSGDxxPROTn register contents (1/2)

Bit Position	Bit Name	Function
31	PROTLOCK	Lock of register The PROTLOCK bit allows to block any further change of the register. 0 : Register can be re-written 1 : Any further write to this register is ignored. This bit can only be cleared by reset.
30 to 27	—	Reserved. These bits are always read as 0. The write value should also be 0.
26	—	Reserved. When read, the initial value is read. When written, write the initial value.

Table 14.33 FSGDxxPROTn register contents (2/2)

Bit Position	Bit Name	Function
25	PROTUM	User Mode Access 0: Enables access in supervisor mode. 1: Enables access in user mode and supervisor mode. **Note:** Enabling User Mode Access by FSGDxxPROTn.PROTUM is only useful, if the protected register is accessible in User Mode. For example enabled User Mode Access by PBG0B group to DMA registers may not be useful, because all DMA registers, with exception of DMACER, are not accessible in User Mode (PSW.UM=1).
24 to 17	PROTPEID[7:0]	PEID Access The PROTnPEID field is a bit list, in which one bit corresponds to one PEID value. Setting multiple bits enables the multiple ID values simultaneously. For example, setting the PROTnPEID field to 0101B enables access with PEID = 0 and PEID = 2. 0: Disables access with PEIDn. 1: Enables access with PEIDn. For the PEID assignment refer to Section 14.6.1, SPID and PEID assignment.
16 to 9	VCID[7:0]	VCID Access The PROTnVCID field is a bit list, in which one bit corresponds to one VCID value. Setting multiple bits enables the multiple ID values simultaneously. For example, setting the PROTnVCID field to 0101B enables access with VCID = 0 and VCID = 2. 0: Disables access with VCIDn. 1: Enables access with VCIDn.
8 to 5	PROTSPID[3:0]	SPID Access The PROTnSPID field is a bit list, in which one bit corresponds to one SPID value. Setting multiple bits enables the multiple SPID values simultaneously. For example, setting the PROTnSPID field to 0101B enables access with SPID = 0 and SPID = 2. 0: Disables access with SPIDn. 1: Enables access with SPIDn. For the SPID assignment refer to Section 14.6.1, SPID and PEID assignment.
4	PROTDEB	Debug Access 0: Disables access from the debug master. 1: Enables access from the debug master.
3	PROTRDPDEF	Default Read Protection 0: Enables read access from any master. 1: Only enables read access from the master having permitted access.
2	PROTWRPDEF	Default Write Protection 0: Enables write access from any master. 1: Only enables write access from the master having permitted access.
1	PROTRD	Read Permission 0: Disables read access from any master. 1: Only enables read access from the master having permitted access.
0	PROTWR	Write Permission 0: Disables write access from any master. 1: Only enables write access from the master having permitted access.

(2) ERRSLVxxCTL — PBGxx error control register

ERRSLVxxCTL clears the status in the error status register.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLRO	CLRE
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W	W

Table 14.34 ERRSLVxxCTL register contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved. These bits are always read as 0. The write value should also be 0.
1	CLRO	Writing 1 to this bit clears the OVF flag in ERRSLVxxSTAT. Always read as 0 when read.
0	CLRE	Writing 1 to this bit clears the ERR flag in ERRSLVxxSTAT. Always read as 0 when read.

(3) ERRSLVxxSTAT — PBGxx error status register

ERRSLVxxSTAT holds the status of the illegal access rejected with the PBGxx.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OVF	ERR
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 14.35 ERRSLVxxSTAT register contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved. These bits are always read as 0. The write value should also be 0.
1	OVF	0: When ERR = 1, PBG protection violation has not been detected. 1: When ERR = 1, PBG protection violation has been detected.
0	ERR	0: PBG protection violation has not been detected. 1: PBG protection violation has been detected.

(4) ERRSLVxxADDR — PBGxx error address register

ERRSLVxxADDR holds the address of the illegal access rejected with the PBGxx.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADDR[31:16]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADDR[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 14.36 ERRSLVxxADDR register contents

Bit Position	Bit Name	Function
31 to 0	ADDR[31:0]	Access Address when PBG Protection Violation is Detected ADDR[1:0] are always fixed to 0.

(5) ERRSLVxxTYPE — PBGxx error type register

ERRSLVxxTYPE holds the type of the illegal access rejected with the PBGxx.

NOTE

The content of the ERRSLV0BTYPE register is different to all other ERRSLVxxTYPE registers.

(a) ERRSLV0BTYPE

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PEID[2:0]			VCID[2:0]			SPID[1:0]		—	UM	—	STRB[3:0]				WRITE
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 14.37 ERRSLV0BTYPE register contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved. These bits are always read as 0.
15 to 13	PEID[2:0]	PEID of the access source from which the PBG protection violation is generated.
12 to 10	VCID[2:0]	VCID of the access source from which the PBG protection violation is generated.
9 to 8	SPID[1:0]	SPID of the access source from which the PBG protection violation is generated.
7	—	Reserved. This bit is always read as 0.
6	UM	User mode of the access source from which the PBG protection violation is generated.
5	—	Reserved. This bit is always read as 0.
4 to 1	STRB[3:0]	STRB of the access source from which the PBG protection violation is generated.
0	WRITE	This bit is set to 1 when an access that has generated PBG protection violation is the write.

(b) All other ERRSLVxxTYPE (xx ≠ 0B):

Table 14.38 ERRSLVxxTYPE (xx ≠ 0B) register contents

Bit Position	Bit Name	Function
31 to 21	—	Reserved. These bits are always read as 0.
20 to 16	SPID[4:0]	SPID of the access source from which the PBG protection violation is generated.
15 to 13	PEID[2:0]	PEID of the access source from which the PBG protection violation is generated.
12 to 10	VCID[2:0]	VCID of the access source from which the PBG protection violation is generated.
9 to 7	—	Reserved. These bits are always read as 0.
6	UM	User mode of the access source from which the PBG protection violation is generated.
5	—	Reserved. This bit is always read as 0.
4 to 1	STRB[3:0]	STRB of the access source from which the PBG protection violation is generated.
0	WRITE	This bit is set to 1 when an access that has generated PBG protection violation is the write.

14.6.5 Cross-connect Guards (XCG)

This microcontroller has the following number of units of the Cross-connect Guards XCGn.

Table 14.39 Units

Cross-connect Guard (XCGn)	
Units	13
Names	XCG3 to XCG15

Unit index n

Throughout this section, the individual units of the Cross-connect Guards are identified by the index "n" (n = 3 to 15), for example XCGnCTL for guard n function control register.

Window index i

Each Cross-connect Guard has eight protection windows. Each individual window is identified by the index "i" (i = 1 to 8), for example XCGnCMPi for guard n window i compare register.

Cross-connect Guard to XC slave assignment and register addresses

All Cross-connect Guards register addresses are given as address offsets from the individual base addresses <XCGn_base>.
The <XCGn_base> addresses of each XCGn and its assignment to an individual Cross-connect slave I/F are listed in the following table:

Table 14.40 Register base addresses <XCGn_base>

XCGn unit	<XCGn_base> address	Cross-connect slave
XCG3	FFFC 0000$_H$	Retention RAM (RRAM)
XCG4	FFFC 1000$_H$	Video RAM 0 (VRAM0)
XCG5	FFFC 2000$_H$	Video RAM 1 (VRAM1)
XCG6	FFFC 3000$_H$	Serial Flash Memory I/F 0 (SFMA0)
XCG7	FFFC 4000$_H$	DDR2-SDRAM Memory Controller (SDRB) port 3 (2D Drawing Engine port)
XCG8	FFFC 6000$_H$	Cross-connect XC1 module registers bridge*1
XCG9	FFFC 4400$_H$	DDR2-SDRAM Memory Controller (SDRB) port 2 (XC1 cross-connect port)*2
XCG10	FFFC 4800$_H$	DDR2-SDRAM Memory Controller (SDRB) port 0 (XC0_0 cross-connect port)
XCG11	FFFC 4C00$_H$	DDR2-SDRAM Memory Controller (SDRB) port 1 (XC0_1 cross-connect port)
XCG12	Reserved	
XCG13	FFFC 5400$_H$	Serial Flash Memory I/F 1 (SFMA1)*3
XCG14	FFFC 5800$_H$	HyperBus (HYPB0)*3
XCG15	FFFC 5C00$_H$	OctaBus (OCTA0)*3

Note 1. The configuration registers of some modules are accessed via the XC1 cross-connect.
Note 2. In D1M1H and D1M1A, this channel is used for SDR-SDRAM Memory Controller (SDRA).
Note 3. Only for D1M1-V2, D1M1A.

Cross-connect Guards error signals

Each cross-connect guard can generate two error signals:

- WINTn: guard error during write to the cross-connect slave
- RINTn: guard error during read from the cross-connect slave

Table 14.41 Cross-connect Guards error signals

XCG unit n	Slave	WINTn/RINTn connected to
XCG30 to XCG15	WINT3 to WINT15	Error Control Module INTPERIGRD*1
	RINT3 to RINT15	

Note 1. This Error Control Module input signal is a logical OR combination of various error signals. Refer to Section 48, Error Control Module (ECM) for details.

Reset sources

The Cross-connect Guards and their registers are initialized by the following reset signal:

Table 14.42 Reset sources

XCGn unit	Reset signal
XCGn	• Reset Controller SYSRES • reset upon wake-up from DEEPSTOP mode

14.6.5.1 XC Guards function

(1) Enabling the XC Guard

The function of the entire XC Guard XCGn can be enabled via the compare control register:

- XCGnCTL.EN = 1: XCGn enabled

NOTE

Once the XCGn is enabled, it can not be disabled by the application software. Disabling the XCGn is only possible via a reset.

(2) Guard window i set-up

The XC Guard allows to define up to eight windows (i = 1 to 8).
Each guard window i is defined by its address area and access rights. These parameters can be defined separately for each guard window i.

Enabling guard window i

Each guard window i can be separately enable/disabled via the address compare register:

- XCGnCMPi.WINENi = 0: guard window i disabled
- XCGnCMPi.WINENi = 1: guard window i enabled

NOTE

If any of the window i set-up registers shall be changed, the window i must be disabled by XCGnCMPi.WINENi = 0.

CAUTION

Before enabling or disabling the a window i make sure that no master accesses are performed to the window address area.

Definition of the guard window address

An address window is defined by a base address and an address mask.

The base address is defined by the XCGnCMP[31:1] address in the compare register XCGnCMPi. The base address must be aligned to 4 KB, thus the lower 12 address bits must be set to 000_H.

The size of the window is defined by the XCGnVLDi[31:0] in the address valid register XCGnVLDi. The size must be a power of 2, i.e. the respective number of lower bits of XCGnVLDi must all be 0. The address valid register must be set up with the bit-inverted size value, i.e. XCGnVLDi = not Size.

The window addresses are calculated as follows:

- Window start address = XCGnCMPi[31:1], XCGnCMPi[0] = 0
- Window end address = (window start address) or (not XCGnVLDi[31:0])

Following an example for a 32 KB window at address F3F2 0000_H to F3F2 $7FFF_H$:

- XCGnCMPi[31:1] = F3F2 0000_H, (XCGnCMPi[0] = 0)
- XCGnVLDi = not Size = not 0000 $7FFF_H$ = FFFF 8000_H
- Window start address = F3F2 0000_H and FFFF 8000_H = F3F2 0000_H
- Window end address = F3F2 0000_H or (not FFFF 8000_H)
  = F3F2 0000_H or 0000 $7FFF_H$ = F3F2 $7FFF_H$

(3) Access rights setup

All windows i of a guard XCGn can be setup to allow access exclusively in supervisor mode via the compare control register:

- XCGnCTL.UM = 0: access allowed only in supervisor mode
- XCGnCTL.UM = 1: access allowed in supervisor and user mode

Other access rights can be defined separately for each guard window i via the window control register:

- Master access permission

  Each master is identified by its master ID MSTIDk. Refer to Table 14.2, XC0 and XC1 cross-connect master IDs for the IDs of the various masters.
  Each of the MSTIDSEL[11:0] bits in the window control register XCGnCTLWi corresponds to a certain master ID, i.e.

  - MSTIDSEL0 corresponds to MSTID0
  - MSTIDSEL1 corresponds to MSTID1
  - ...

  Each MSTIDSELx bit determines the access right of the respective master:

  - XCGnCTLWi.MSTIDSELx = 0: master with MSTIDx access prohibited
  - XCGnCTLWi.MSTIDSELx = 1: master with MSTIDx access permitted

- Write access permission

– XCGnCTLWi.WMSK = 0:
write access permitted
– XCGnCTLWi.WMSK = 1:
write access prohibited for master IDs set to prohibited by MSTIDSELx

- Read access permission
  – XCGnCTLWi.RMSK = 0:
  read access permitted
  – XCGnCTLWi.RMSK = 1:
  read access prohibited for master IDs set to prohibited by MSTIDSELx

(4) Access violation

Upon detection of an access violation interrupts can be generated:

– XCGnINTL1.WINTEN = 0/1: interrupt WINTn generation disabled/enabled upon write access violation
– XCGnINTL1.RINTEN = 0/1: interrupt RINTn generation disabled/enabled upon read access violation

Assertion of a write or read access violation interrupt can also be monitored by use of interrupt status bits:

– reading XCGnINTL1.WINTSTAT = 1: interrupt WINTn is asserted
– reading XCGnINTL1.RINTSTAT = 1: interrupt RINTn is asserted

Once asserted, an interrupt needs to be de-asserted by the application software:

– writing XCGnINTL1.WINTSTAT = 1: de-assertion of WINTn
– writing XCGnINTL1.RINTSTAT = 1: de-assertion of RINTn

The access address, that led to an access violation, is saved in a register:

– Write error address register XCGnERRWADDR holds the address of the write access violation
– Read error address register XCGnERRRADDR holds the address of the read access violation

Additional information about the access violation is provided by the registers XCGnERRRTYPE for read violation and XCGnERRWTYPE for write violation, which indicates the master, that has caused the violation, and whether it has occurred in super visor or user mode

In case a read or write access violation is detected while the respective interrupt RINTn or WINTn is already asserted (overflow condition) an overflow flag bit is set in the overflow information register XCGnOVF:

– WOVF = 1 indicates a write access violation overflow
writing XCGnOVF.WOVF = 1 clears WOVF
– ROVF = 1 indicates a read access violation overflow
writing XCGnOVF.ROVF = 1 clears ROVF

Note that the address and the additional information of the overflow access violation is not stored in the error address register.

If write access is guarded, the write data of this access will not be written to the slave, and WINTn will be asserted.

If read access is guarded, the read data from the slave will be read out, and RINTn will be asserted.

If the prohibited area overlapped by multiple windows, either one will be valid, and the access will be guarded.

NOTE

When XCGnCTL.EN = 0 the access is to any address area is not guarded.
In the case XCGnCTL.EN = 1 the access is guarded even if the address does not match to any window.

Table 14.43 Guard function matrix

XCGn CTL.EN	XCGn CTL.UM	Access mode	Comparison result of access address for window i	Access permission for window i (XCGnCTLWi. R/WMSK)	Master permission for window i (XCGnCTLWi. MSTIDSEL)	Decision
0	Don't care	Don't care	Don't care	Don't care	Don't care	Through
1	0	User mode	Don't care	Don't care	Don't care	Guard
1	0	Supervisor mode	Match to window 1	0 (permitted)	Don't care	Through
				1 (prohibited to master set for not allowed)	not allowed	Guard
					allowed	Through
1	0	Supervisor mode	Match to window 2	0 (permitted)	Don't care	Through
				1 (prohibited to master set for not allowed)	not allowed	Guard
					allowed	Through
1	0	Supervisor mode	...			
1	0	Supervisor mode	Match to window 8	0 (permitted)	Don't care	Through
				1 (prohibited to master set for not allowed)	not allowed	Guard
					allowed	Through
1	0	Supervisor mode	No match to all windows	Don't care	Don't care	Guard
1	1	User or supervisor mode	Match to window 1	0 (permitted)	Don't care	Through
				1 (prohibited to master set for not allowed)	not allowed	Guard
					allowed	Through
1	1	User or supervisor mode	Match to window 2	0 (permitted)	Don't care	Through
				1 (prohibited to master set for not allowed)	not allowed	Guard
					allowed	Through
1	1	User or supervisor mode	...			
1	1	User or supervisor mode	Match to window 8	0 (permitted)	Don't care	Through
				1 (prohibited to master set for not allowed)	not allowed	Guard
					allowed	Through
1	1	User or supervisor mode	No match to all windows	Don't care	Don't care	Guard

(5) Set-up flow example

(1) Set up the base address in XCGnCMPi.CMP[31:1].

(2) Enable the window i by XCGnCMPi.WINEN = 1.

(3) Set up the window size in the XCGnVLDi.

(4) Grant access to the masters by setting the respective XCGnCTLWi.MSTIDSEL[11:0] bits.

(5) Grant write and/or read access by setting XCGnCTLWi.WMSK = 1 and/or XCGnCTLWi.RMSK = 1.

(6) Enable the generation of write and/or read access violation interrupts WINTn and RINTn by setting XCGnINTL1.WINTEN = 1 and/or XCGnINTL1.RINTEN = 1.

(7) Select whether the XCGn shall guard accesses in only in supervisor or also in user mode by XCGnCTL.UM.

(8) Enable the XCGn by setting XCGnCTL.EN = 1.

14.6.5.2 XC Guards registers overview

The XC Guards are controlled and operated by the following registers:

Table 14.44 XC Guards registers overview

Register name	Shortcut	Address
Address compare registers	XCGnCMPi	<XCGn_base> + (i-1) x 4_H
Address valid registers	XCGnVLDi	<XCGn_base> + 20_H + (i-1) x 4_H
Compare control register	XCGnCTL	<XCGn_base> + 40_H
Window control registers	XCGnCTLWi	<XCGn_base> + 44_H + (i-1) x 4_H
Interrupt control register	XCGnINTL1	<XCGn_base> + 64_H
Overflow condition register	XCGnOVF	<XCGn_base> + 68_H
Read error address register	XCGnERRRADDR	<XCGn_base> + $6C_H$
Write error address register	XCGnERRWADDR	<XCGn_base> + 70_H
Read error type register	XCGnERRRTYPE	<XCGn_base> + 74_H
Write error type register	XCGnERRWTYPE	<XCGn_base> + 78_H

<XCGn_base>

The base addresses <XCGn_base> of the XCGn is defined in the first subsection of this section under the key word “Register addresses”.

NOTE

Memory access right after register access has possibility to cause the racing between two accesses via different routes.
Therefore, the last accessed register value must be confirmed at least before memory access. Refer to Section 3.4.1, Synchronization of Store Instruction Completion and Subsequent Instruction Generation for details.

14.6.5.3 XC Guard registers details

(1) XCGnCMPi - Address compare registers

This register enables the guard window i and defines its base address.

CAUTIONS

1. **Before enabling or disabling the a window i make sure that no master accesses are performed to the window address area.**
2. **Before changing XCGnCMPi.CMP[31:1] the window i must be disabled by XCGnCMPi.WINENi = 0.**

Access: This register can be accessed in 32-bit units.

Address: <XCGn_base> + (i-1) x 4_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CMP[31:16]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMP[15:1]															WINEN
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 14.45 XCGnCMPi register contents

Bit position	Bit name	Function
31 to 1	CMP[31:1]	Upper 31 bit of the window i base address. **CAUTION** The window base address must be aligned to 4 KB, thus the lower 11 address bits must be set to 000_H.
0	WINEN	Enable/disable guard window i. 0: window i disabled 1: window i enabled

(2) XCGnVLDi - Address valid registers

This register defines the size of the guard window i.

CAUTION

Before changing this register the window i must be disabled by XCGnCMPi.WINENi = 0.

Access: This register can be accessed in 32-bit units.

Address: <XCGn_base> + 20_H + (i-1) x 4_H

Initial value: FFFF $FFFE_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VLD[31:16]															
Initial value	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 14.46 XCGnVLDi register contents

Bit position	Bit name	Function
31 to 1	VLD[31:1]	VLD[31:1] determines of the size of the guard window i. The lowest address bit VLD0 is always 0. It must be set to the bit-inversion of the size value, i.e. VLD[31:0] = not (size - 1). **CAUTION** The minimum window size is 4 KB, thus VLD[11:0] must be set to 000_H.
0	Reserved	When read, the value after reset is returned. When written, write the value after reset.

(3) XCGnCTL - Compare control register

This register is used to enable/disable the XCGn and to define supervisor/user mode access rights.

Access: This register can be accessed in 32-bit units.

Address: <XCGn_base> + 40_H

Initial value: 8000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	UM	EN	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 14.47 XCGnCTL register contents

Bit position	Bit name	Function
31	UM	User and supervisor mode control 0: Access allowed only in supervisor mode 1: Access allowed in supervisor and user mode
30	EN	XC Guard enable/disable • At EN bit read: XCGn status 0: XCGn is disabled 1: XCGn is enabled • At EN write: enable XCGn 0: no function 1: enable XCGn **CAUTION** Once the XCGn is enabled, it can not be disabled by the application software. Disabling the XCGn is only possible via a reset.
29 to 0	Reserved	When read, the value after reset is returned. When written, write the value after reset.

(4) XCGnCTLWi - Window control register

This register is used to define window specific access rights.

CAUTION

Before changing this register the window i must be disabled by XCGnCMPi.WINENi = 0.

Access: This register can be accessed in 32-bit units.

Address: <XCGn_base> + 44_H + (i-1) x 4_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 14.48 XCGnCTLWi register contents

Bit position	Bit name	Function
31 to 28	Reserved	When read, the value after reset is returned. When written, write the value after reset.
27 to 16	MSTIDSEL[11:0]	Master ID selection for access permission Each MSTIDSELx bit corresponds to a certain master, i.e. MSTIDSEL0: Controls access with master ID MSTID0 MSTIDSEL1: Controls access with master ID MSTID1 ... MSTIDSEL11: Controls access with master ID MSTID11 0: Access by MSTID[11:0] not allowed 1: Access by MSTID[11:0] allowed
15 to 2	Reserved	When read, the value after reset is returned. When written, write the value after reset.
1	WMSK	Write access permission 0: write permitted 1: write prohibited for master IDs set to not allowed by MSTIDSELx
0	RMSK	Read access permission 0: read permitted 1: read prohibited for master IDs set to not allowed by MSTIDSELx

(5) XCGnINTL1 - Interrupt control register

This register is used to control access violation interrupt generation and holds information flags about these interrupts.

Access: This register can be accessed in 32-bit units.

Address: <XCGn_base> + 64_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	WINT EN	WINT STAT	RINT EN	RINT STAT
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 14.49 XCGnINTL1 register contents

Bit position	Bit name	Function
31 to 4	Reserved	When read, the value after reset is returned. When written, write the value after reset.
3	WINTEN	Write guard interrupt WINTn enable bit. 0: WINTn disabled 1: WINTn enabled
2	WINTSTAT	Write guard interrupt WINTn status and clear bit. • At XCGnINTL1 register read: WINTn status 0: WINTn has not occurred 1: WINTn has occurred • At XCGnINTL1 register write: WINTn clear 0: no function 1: clear this bit and WINTn de-assert interrupt
1	RINTEN	Read guard interrupt RINTn enable bit. 0: RINTn disabled 1: RINTn enabled
0	RINTSTAT	Read guard interrupt RINTn status and clear bit. • At XCGnINTL1 register read: RINTn status 0: RINTn has not occurred 1: RINTn has occurred • At XCGnINTL1 register write: RINTn clear 0: no function 1: clear this bit and RINTn de-assert interrupt

(6) XCGnOVF - Overflow information register

This register indicates occurrence of access violation overflows.

Access: This register can be accessed in 32-bit units.

Address: <XCGn_base> + 68_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	0	0	0	0	0	0	0	0	0	0	0	0	0	0	WOVF	ROVF
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 14.50 XCGnOVF register contents

Bit position	Bit name	Function
31 to 2	Reserved	When read, the value after reset is returned. When written, write the value after reset.
1	WOVF	Write access violation overflow flag • At read: 0: write access violation did not occur during WINTn assertion 1: write access violation occurred during WINTn assertion • At write: 0: no function 1: clear WOVF
0	ROVF	Read access violation overflow flag • At read: 0: read access violation did not occur during RINTn assertion 1: read access violation occurred during RINTn assertion • At write: 0: no function 1: clear ROVF

(7) XCGnERRRADDR - Read error address register

This register stores the address during a read access violation.

Access: This register can be accessed in 32-bit units.

Address: <XCGn_base> + $6C_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ERRRADDR[31:16]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ERRRADDR[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 14.51 XCGnERRRADDR register contents

Bit position	Bit name	Function
31 to 0	ERRRADDR[31:0]	Address of the read access violation. ERRRADDR[31:0] does not change when a read access violation overflow occurs. Thus it holds always the address of the first access violation, until the read access violation interrupt RINTn is de-asserted by setting XCGnINTL1.RINTSTAT = 1.

(8) XCGnERRWADDR - Write error address register

This register stores the address during a write access violation.

Access: This register can be accessed in 32-bit units.

Address: <XCGn_base> + 70_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ERRWADDR[31:16]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ERRWADDR[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 14.52 XCGnERRWADDR register contents

Bit position	Bit name	Function
31 to 0	ERRWADDR[31:0]	Address of the write access violation. ERRWADDR[31:0] does not change when a write access violation overflow occurs. Thus it holds always the address of the first access violation, until the write access violation interrupt WINTn is de-asserted by setting XCGnINTL1.WINTSTAT = 1.

(9) XCGnERRRTYPE - Read error type register

This register provides addition information about a read access violation detection.

Access: This register can be accessed in 32-bit units.

Address: <XCGn_base> + 74_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	ERRRUM	ERRRMST[7:0]							
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 14.53 XCGnERRRTYPE register contents

Bit position	Bit name	Function
31 to 9	Reserved	When read, the value after reset is returned.
8	ERRRUM	This bit indicates whether the read access violation has occurred during supervisor or user mode. 0: violation occurred in supervisor mode 1: violation occurred in user mode
7 to 0	ERRRMST[7:0]	Master ID of read access violation. Refer to Table 14.54, XC Guard access violation master IDs for the correspondence between ERRRMST[7:0], the XC master and XCGnCTLWi.MSTIDSEL[11:0] bit, that sets the access right to the master. ERRRMST[7:0] does not change when a read access violation overflow occurs. Thus it holds always the address of the first access violation, until the read access violation interrupt RINTn is de-asserted by setting XCGnINTL1.RINTSTAT = 1.

Table 14.54 XC Guard access violation master IDs

Master		Master identifier in XCGnERRRTYPE and XCGnERRWTYPE registers ERRRMST[7:0]/ERRWMST[7:0]	Master ID selection bit in XCGnCTLWi register MSTIDSEL[11:0]
Debug unit		$0000\ 0000_B$	MSTIDSEL0
CPU		$0000\ 0001_B$	MSTIDSEL1
DMA Controller		$0000\ 0010_B$	MSTIDSEL2
Reserved		$0000\ 0011_B$	MSTIDSEL3
2D Graphics Processing Unit (GPU2D)		$0001\ 0000_B$	MSTIDSEL4
JPEG Codec Unit A (JCUA)		$0010\ 0000_B$	MSTIDSEL5
Ethernet AVB MAC (ETNB)		$0011\ 0000_B$	MSTIDSEL6
Media Local Bus I/F (MLBB) NAND Flash Memory I/F A (NFMA)*1		$0100\ 0000_B$	MSTIDSEL7
Sprite Engine (SPEA)	RLE units	$0101\ 0000_B$	MSTIDSEL8
	Sprite Unit 0	$0101\ 0001_B$	MSTIDSEL9
	Sprite Unit 1	$0101\ 0010_B$	MSTIDSEL10
	Sprite Unit 2	$0101\ 0011_B$	MSTIDSEL11

Note 1. Only for D1M1A.

(10) XCGnERRWTYPE - Write error type register

This register provides addition information about a write access violation detection.

Access: This register can be accessed in 32-bit units.

Address: <XCGn_base> + 78_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	ERRWUM	ERRWMST[7:0]							
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 14.55 XCGnERRWTYPE register contents

Bit position	Bit name	Function
31 to 9	Reserved	When read, the value after reset is returned.
8	ERRWUM	This bit indicates whether the write access violation has occurred during supervisor or user mode. 0: violation occurred in supervisor mode 1: violation occurred in user mode
7 to 0	ERRWMST[7:0]	Master ID of write access violation. Refer to Table 14.54, XC Guard access violation master IDs for the correspondence between ERRWMST[7:0], the XC master and XCGnCTLWi.MSTIDSEL[11:0] bit, that sets the access right to the master. ERRWMST[7:0] does not change when a write access violation overflow occurs. Thus it holds always the address of the first access violation, until the write access violation interrupt WINTn is de-asserted by setting XCGnINTL1.WINTSTAT = 1.

14.6.5.4 XC Guard Operation

It is recommended to setup all XC Guards to deny slave access from any master by default in order to prevent unexpected faults.

- Setup all Guards including those of unavailable slaves (e.g. SDRAM on D1M1).
- Setup of a single window for the slaves full address window is sufficient for basic setup. Several windows may be configured to comply with specific safety and security requirements.
- Deny access by any master.
- Allow those masters expected to access the specific slave.

This basic XC Guard setup is an effective measure to prevent unintended reading or manipulation of data.

14.7 Performance Monitor

This function is only available in D1M1A and D1M1-V2, or when using IE-POD (RTE7701460EPA00000R).

The Performance Monitor has the following number of units of the Performance-Monitor PM_xx for measuring the XC slave performance.

Table 14.56 Performance Monitor units

Unit	<PM_xx_base> address	Performance Monitor for
PM_R	FFFC C000$_H$	Retention RAM (RRAM)
PM_SF0	FFFC C100$_H$	Serial Flash Memory I/F 0 (SFMA0)
PM_SF1	FFFC C200$_H$	Serial Flash Memory I/F 1 (SFMA1)
PM_V0	FFFC C300$_H$	Video RAM 0 (VRAM0)
PM_V1	FFFC C400$_H$	Video RAM 1 (VRAM1)
PM_SD	FFFC C600$_H$	SDR-SDRAM Memory Controller (SDRA0)
PM_HB	FFFC CA00$_H$	HyperBus/OctaBus Controller (HYPB0/OCTA0)

The Performance Monitor can measure the following items. Also, this monitor can measure for some masters at the same time.

- request/data cycle measurement
  - read request count for a period as specified below
  - write request count for a period as specified below
  - read data count for a period as specified below
  - write data count for a period as specified below
  - clock cycle count (time elapsed) for a period as specified below
- configurable measurement periods
  - period until read request count reaches the user defined threshold
  - period until write request count reaches the user defined threshold
  - period until read data count reaches the user defined threshold
  - period until write data count reaches the user defined threshold
  - period until clock cycle count reaches the user defined threshold

14.7.1 Performance Monitor registers

The Performance Monitors are controlled and operated by the following registers:

Table 14.57 Performance Monitor registers overview (1/2)

Register name	Shortcut	Address
Measurement enable register	PMCNTEN	<PM_xx_base> + 00$_H$
Base counter select register	PMBSCNTSEL	<PM_xx_base> + 04$_H$
Stop condition threshold register	PMDCNTSET	<PM_xx_base> + 08$_H$
Read ID register	PMRIDSET	<PM_xx_base> + 0C$_H$
Write ID register	PMWIDSET	<PM_xx_base> + 10$_H$
Read request count register	PMRQRDCNT	<PM_xx_base> + 14$_H$
Write request count register	PMRQWTCNT	<PM_xx_base> + 18$_H$

Table 14.57 Performance Monitor registers overview (2/2)

Register name	Shortcut	Address
Read transferred data count register	PMDTRDCNT	<PM_xx_base> + $1C_H$
Write transferred data count register	PMDTWTCNT	<PM_xx_base> + 20_H
Clock count register	PMCKCNT	<PM_xx_base> + 24_H

14.7.1.1 PMCNTEN – Measurement enable register

Access: This register can be read/written in 32-bit units.

Address: <PM_xx_base> + 00_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	CNTEN
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 14.58 PMCNTEN register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, these bits are always read as 0. When writing, always write 0.
0	CNTEN	Performance Monitor control 0: Stop measurement (stopped) 1: Start measurement (measuring) When the measurement is finished, CNTEN is set to 0. When CNTEN is set from 0 to 1 by write access, the measurement is started. When CNTEN is set from 1 to 0 by write access, the measurement is stopped. Reading CNTEN gives current status.

14.7.1.2 PMBSCNTSEL – Base counter select register

Access: This register can be read/written in 32-bit units.

Address: <PM_xx_base> + 04_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	–	–	–	–	–	–	–	–	–	–	–	–	–	BSCNTSEL[2:0]		
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 14.59 PMBSCNTSEL register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, these bits are always read as 0. When writing, always write 0.
2 to 0	BSCNTSEL[2:0]	Base count condition for measurement stop 000_B: read request count 001_B: write request count 010_B: read data count 011_B: write data count All others: clock count

14.7.1.3 PMDCNTSET – Stop condition threshold register

Access: This register can be read/written in 32-bit units.

Address: <PM_xx_base> + 08_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DCNTSET[31:16]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DCNTSET[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 14.60 PMDCNTSET register contents

Bit Position	Bit Name	Function
31 to 0	DCNTSET[31:0]	The threshold of stop condition

CAUTIONS

1. **Don't set DCNTSET[31:0] under 20_H.**
2. **Don't set PMCNTEN.CNTEN to 1 with DCNTSET[31:0] = 0.**

14.7.1.4 PMRIDSET – Read ID register

Access: This register can be read/written in 32-bit units.

Address: <PM_xx_base> + $0C_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RIDVAL	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	RIDSET[3:0]			
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 14.61 PMRIDSET register contents

Bit Position	Bit Name	Function
31	RIDVAL	The valid of Read ID comparison 0: ID comparison disable 1: ID comparison enable When this bit is 0, all master are measured.
30 to 4	Reserved	When read, these bits are always read as 0. When writing, always write 0.
3 to 0	RIDSET[3:0]	Comparison target for Read ID When RIDVAL = 1, Performance Monitor only counts events with a Read ID matching the value of RIDSET[3:0]. [When using IE-POD] 0: CPU Subsystem (DMA, OCD) 1: CPU Subsystem (CPU) 2: JCUA 3: ETNB 4: MLBB 5: RLE/Sprite Units 0 and 1 6: RLE/Sprite Units 2 and 3 7: GPU2D (D1M2(H) emulation) 8: GPU2D (other emulation) 9: NFMA [D1M1A] 0: CPU Subsystem (DMA, OCD) 1: CPU Subsystem (CPU) 2: RLE/Sprite Unit 0 and 1 3: RLE/Sprite Unit 2 and 3 4: JCUA 5: GPU2D 6: NFMA 7: ETNB [D1M1-V2] 0: CPU Subsystem (DMA, OCD) 1: CPU Subsystem (CPU) 2: RLE/Sprite Unit 0 and 1 3: RLE/Sprite Unit 2 and 3 4: JCUA 5: GPU2D 6: ETNB

14.7.1.5 PMWIDSET – Write ID register

Access: This register can be read/written in 32-bit units.

Address: <PM_xx_base> + 10_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WIDVAL	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

Table 14.67 PMCKCNT register contents

Bit Position	Bit Name	Function
31 to 0	CKCNT[31:0]	Clock count register This register is counted up with the cross-connect clock C_ISO_XCCLK. • Stop condition – Selected base count reaches the stop condition threshold – PMCNTEN.CNTEN is set from 1 to 0 – Overflow of this register (counter value is stopped at all 1) • Clear condition – PMCNTEN.CNTEN is set from 0 to 1

14.7.2 Measurement operation

14.7.2.1 Register setting

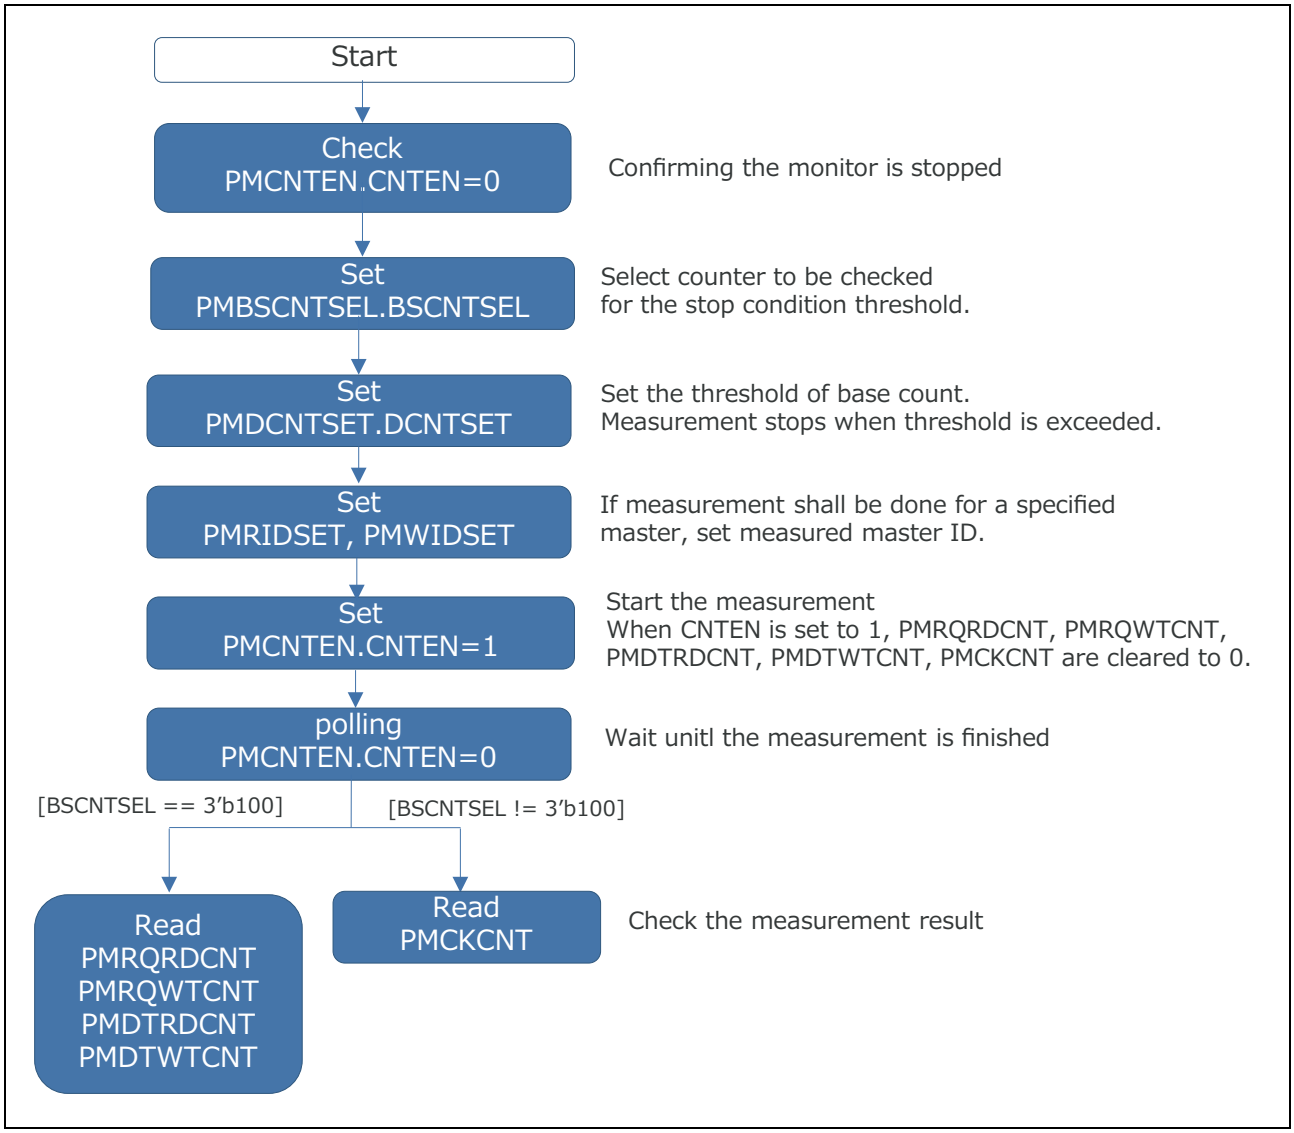

Figure 14.29 Performance Monitor register setting

14.7.2.2 Calculating the bandwidth

In order to obtain the bandwidth from the measurement result, calculation is needed from register value. The following shows an example of a bandwidth calculation.

Example

- Measurement condition
  - XC bus clock C_ISO_XCCLK: 120 MHz [= 8.33 ns]
  - Measurement type: period (PMBSCNTSEL.BSCNTSEL[2:0] = 100_B)
  - BSCNTSEL[2:0] == 100_B
    To define a measurement period of 1s:
    PMDCNTSET = C_ISO_XCCLK / t_measurement = 120MHz / 1s = 727 $0E00_H$
  - BSCNTSEL[2:0] != 100_B
    To calculate the measurement period form the clock count register:
    t_measurement = C_ISO_XCCLK / PMCKCNT
- Measurement result
  - PMDTRDCNT : 2AE $A540_H$
  - PMDTWTCNT : E4 $E1C0_H$
- Bandwidth calculation
  - Read Bandwidth: 360 MB/s ((2AE $A540_H$ x 8 byte) / 1 s))
  - Write Bandwidth: 120 MB/s ((E4 $E1C0_H$ x 8 byte / 1 s))

PMDTRDSET, PMDTWTCNT count valid data cycles on the cross-connect bus. Therefore, for calculating the amount of data, it is required to multiple by 8 byte (due to 64-bit XC bus width). This bandwidth is the view from the slave side.

NOTE

The CPU can access XC slaves with byte, half-word, word, double-word size.
In order to check the bandwidth from the view of CPU side, bandwidth calculation must be changed to respect the access size of the currently executed instructions.

14.8 Preload Buffer (PRLBn) (D1M1-V2, D1M1A only)

The Preload Buffer pre-fetches read data for XC2 masters.

14.8.1 Features

One Preload Buffer comprises 3 separate 3-entry sub-buffers, which can be assigned to different XC2 masters.

- Preloading
  - PRLB starts to issue 3 read requests (1 currently requested + 2 preload request) by the first read request from the XC2 master.
  - PRLB returns the currently requested data to the requesting XC2 master and issues 2 speculative requests in addition.
  - PRLB keeps issuing 3 request.
- Preload Conditions
  - Preloading enable by register setting
    When it is disabled, transactions go through without delay. (default setting)
  - Master assignment by register setting
    Requests of un-assigned master are not preloaded.
  - Preload is executed by 128 byte data request
    Requests shorter than 128 byte are not preloaded, even if the master is assigned.
    Because such preloading is not effective to performance.
- Preloading Cancel Condition
  When the following conditions occur, preloading is canceled.
  - Non-consecutive address
    When addresses from the master side are not consecutive, preloading is canceled.
  - Shorter data request
    When requested data from master side is shorter than 128 byte, preloading is canceled.
  - Timeout
    When the master side doesn't request the preloaded data before the timeout expires, preloading is canceled.

14.8.2 Preload Buffers registers

The Preload Buffers are controlled and operated by the following registers:

Table 14.68 Preload Buffers registers overview

Register name	Shortcut	Address
Preload buffer 0 register	PRL0REG	F200 A000$_H$
Preload buffer 1 register	PRL1REG	F200 A004$_H$
Preload buffer 2 register	PRL2REG	F200 A008$_H$
Preload buffer 3 register	PRL3REG	F200 A00C$_H$

14.8.2.1 PRLnREG – Preload buffer n register (n = 0 to 3)

Access: This register can be read/written in 32-bit units.

Address: PRL0REG: F200 A000$_H$
PRL1REG: F200 A004$_H$
PRL2REG: F200 A008$_H$
PRL3REG: F200 A00C$_H$

Initial value: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	PRLTO[3:0]				–	–	–	–	–	–	PRLISS[1:0]	
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PRLID2[3:0]				PRLID1[3:0]				PRLID0[3:0]				–	–	–	PRLEN
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 14.69 PRLnREG register contents

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, these bits are always read as 0. When writing, always write 0.
27 to 24	PRLTO[3:0]	Timeout cycles When the master side doesn't the request in spite of preloaded data reached to PRLB buffer,PRLB cancel preloading. 0: Timeout = 15 XC clock cycles Others: Setting prohibit
23 to 18	Reserved	When read, these bits are always read as 0. When writing, always write 0.
17 to 16	PRLISS[1:0]	Issuing request number 10_B: 3 requests Others: Setting prohibit
15 to 12	PRLID2[3:0]	Preload ID2 for assigning an XC2 master to sub-buffer 2 of Preload Buffer n About the ID assignment, refer to Section 14.8.2.2, PRLB setting.
11 to 8	PRLID1[3:0]	Preload ID1 for assigning an XC2 master to sub-buffer 1 of Preload Buffer n About the ID assignment, refer to Section 14.8.2.2, PRLB setting.
7 to 4	PRLID0[3:0]	Preload ID0 for assigning an XC2 master to sub-buffer 0 of Preload Buffer n About the ID assignment, refer to Section 14.8.2.2, PRLB setting.
3 to 1	Reserved	When read, these bits are always read as 0. When writing, always write 0.
0	PRLEN	Preload function enable 0: disable (default) 1: enable In the case of PRLEN = 0, read request and data bypass preload bridge without latency.

14.8.2.2 PRLB setting

PRLnREG.PRLEN has to be set with following initialisation:

- Set PRLnREG.PRLTO[3:0] to 0xF
- Set PRLnREG.PRLISS[1:0] to 0x2
- Set PRLnREG.PRLIDm to
  - m if you want to use PRLB.
  - 15 if you don't want to use PRLB.
  - Example:
    To use PRLB for Image Synthesizer10, set PRLB0REG.PRLID1[3:0] to 0x1
    To use PRLB for Image Synthesizer03, set PRLB3REG.PRLID0[3:0] to 0x0
- Set PRLEN to 1

PRLB has to be set before Video output start.
Also, it is prohibit to change PRLB setting while video outputs are active.

Each of the PRLB Units covers up to three specific Video Output Units.
The table below explains the assignment of the different units.
The initialization as listed above can be done with a single write access to the registers PRLnREG.

Table 14.70 PRLB units assignments

	Unit PRLB0	Unit PRLB1	Unit PRLB2	Unit PRLB3	PRLID value
for D1M1A:					
Instance 0 [PRLID0[3:0]]	Image Synthesizer 00	Image Synthesizer 01	Image Synthesizer 02	Image Synthesizer 03	Set PRLID0[3:0] to 0 to enable this instance, set to F_H to disable this instance.
Instance 1 [PRLID1[3:0]]	Image Synthesizer 10	Image Synthesizer 13	Image Synthesizer 12	Image Synthesizer 11	Set PRLID1[3:0] to 1 to enable this instance, set to F_H to disable this instance.
Instance 2 [PRLID2[3:0]]	– *1	Output Image Generator	– *1	– *1	Set PRLID2[3:0] to 2 to enable this instance, set to F_H to disable this instance.
for D1M1V2:					
Instance 0 [PRLID0[3:0]]	Image Synthesizer 00	Image Synthesizer 01	Image Synthesizer 02	Image Synthesizer 03	Set PRLID0[3:0] to 0 to enable this instance, set to F_H to disable this instance.
Instance 1 [PRLID1[3:0]]	– *1	Output Image Generator	– *1	– *1	Set PRLID1[3:0] to 1 to enable this instance, set to F_H to disable this instance.
Instance 2 [PRLID2[3:0]]	– *1	– *1	– *1	– *1	Set PRLID2[3:0] to F_H to disable this instance.

Note 1. Aways set to disable: 0xF

NOTE

PRLID value must not be the same as other PRLID except 0xF in the same unit.

14.8.3 Preload Buffers use cases

PRLB can be used for improving the performance of the XC2 masters. However, in some use cases, the preloading may be ineffective.

GPU2D

When the GPU2D is used, number of outstanding requests of XC2 masters is increased to be on level with GPU2D.

However, if more than four masters, which are reading from the same memory slave, are using preloading, the performance is almost same with and without PRLB, because the request number on the XC cross-connect is already sufficient. Therefore, preloading is better to be used for a few layers with GPU2D.

Sprite Layer

If sprite layers are used, preloading may be ineffective. By using many sprites, addressing from the XC master is sometimes not consecutive in a layer.

Also, when the boundary of sprite is not aligned to 128 byte, XC master data requests for a small amout of data are generated from sprite unit.

In both cases, preloading is canceled and already issued requests for preloading are redundant and may cause additional overhead.

Slow memory access (SFMA, HyperBus/OctaBus)

Preloading is not recommended to be used for memories with high read access latencies.
Due to the high initial overhead of a read access, preloading has only small influence.

However, many requests queued for a high latency memory may also affect access latency to other fast memories. This effect is caused by some requests waiting for completion of previously issued requests in situations of high bus load.

About other control methods for the bus traffic, refer Section 14.2.1.1, List of XC1 QoS Registers (D1M1(H), D1M1-V2, D1M1A only), Section 15.5, SDR-SDRAM Transaction Restrictor and Section 54.3, VRAM Transaction Restrictor.

14.8.4 Video frame buffer and PRLB usage

PRLB always issues 2 requests (256 byte read) as preloading with a current request to memory.

In addition, video frame buffer include additional 256 byte area at the end of frame buffer by VDCE restriction.

(Regarding VDCE restriction, refer to Section 38.6.1.2, Graphics Data Read Control **(6)**.)

Therefore, video frame buffer must include total 512 byte readable area at the end of frame buffer when PRLB is used.

Section 15 SDR-SDRAM Memory Controller (SDRA)

This section contains a generic description of the SDR-SDRAM Memory Controller.

The first section describes all properties specific to the RH850/D1L/D1M, such as units, register base addresses, input/output signal names, etc.
The subsequent sections describe the features that apply to all implementations.

15.1 Overview of RH850/D1L/D1M SDR-SDRAM Memory Controller

15.1.1 Units

This microcontroller has the following number of units of the SDR-SDRAM Memory Controller.

Table 15.1 Units

SDR-SDRAM Memory Controller	D1L1	D1L2(H)	D1M1 D1M1-V2	D1M1H D1M1A	D1M2(H)
Units	–	–	–	1	–
Names	–	–	–	SDRA0	–

Units index n

Throughout this section, the individual units of a SDR-SDRAM Memory Controller is identified by the index "n" (n = 0).

15.1.2 Register addresses

All SDR-SDRAM Memory Controller register addresses are given as address offsets from the individual base addresses <SDRAn_base>.
The <SDRAn_base> addresses of each SDRAn are listed in the following table:

Table 15.2 Register base addresses <SDRAn_base>

SDRAn unit	<SDRAn_base> address
SDRA0	F2FE 0000_H

15.1.3 Clock supply

All SDR-SDRAM Memory Controller provides two clock inputs.

Table 15.3 Clock supply

SDRAn unit	SDRAn clock	Connected to
SDRA0	Cross-connect clock	Clock Controller C_ISO_XCCLK
	MEMCLK	Clock Controller SDRBCLK

NOTE

The SDRACK memory clock signal output frequency equals to the Cross-connect clock (= C_ISO_XCCLK).

15.1.4 Interrupts

The SDR-SDRAM Memory Controller can generate the following interrupts:

Table 15.4 SDRAn interrupts

ADRAn signals	Function	Connected to
SDRA0:		
INTSDRA	Underflow flag of auto refresh cycle	Interrupt Controller INTSDRA

15.1.5 Reset sources

The SDR-SDRAM Memory Controller and their registers are initialized by the following reset signal:

Table 15.5 Reset sources

SDRAn unit	Reset signal
SDRAn	• Reset Controller SYSRES • Reset Controller SDRA0RES • reset upon wake-up from DEEPSTOP mode

CAUTION

By default the SDRA0RES reset is active.
Thus before accessing this module this reset must be released via the MRSTC register of the Reset Controller. Refer to Section 9, Reset Controller for details.

15.1.6 I/O signals

The following table shows the I/O signals of the SDR-SDRAM Memory Controller.

Table 15.6 SDRAn I/O signals

SDRAn signals	Function	Connected to
SDRA0		
SDRAA[12:11], SDRAA10, SDRAA[9:0]	Address output signals	Port SDRAA[12:11], SDRAA10, SDRAA[9:0]
SDRADQ[31:0]	Data input/output signals	Port SDRADQ[31:0]
SDRABA[1:0]	Bank address output signals	Port SDRABA[1:0]
SDRACK	Memory clock signal output	Port SDRACK
SDRACKE	Clock enable output signal	Port SDRACKE
SDRADM[3:0]	Data mask input/output signals	Port SDRADM[3:0]
SDRACSB	Chip select output signal	Port SDRACSB
SDRACASB	CAS strobe output signal	Port SDRACASB
SDRARASB	RAS strobe output signal	Port SDRARASB
SDRAWEB	Write enable output signal	Port SDRAWEB

Note 1. The suffix “B” in the signal names in the above table denotes low level active signals.

15.1.7 Partial Operation of I/O Signals

Table 15.7 D1M1H, D1M1A unused SDRAM interface handling

External SDRAM connection	Handling of unused data signals	Handling of unused address signals
32 bit	• DQ[31:0]: all used • DM[3:0]: all used	Leave open
16 bit	• DQ[31:16]: leave open • DM[3:2]: leave open	
None	Refer to Section 2.8, Recommend connection of unused pins.	

15.2 Overview

The SDR-SDRAM Memory Controller gives access to external single data rate type SDRAM memory devices.

Main features

- Data bus width and maximum bandwidth:
  - 32-bit
  - max. bandwidth
    - D1M1H: 400 MB/s
    - D1M1A: 480 MB/s
- up to 128 MB external SDR-SDRAM
- Multi bank operation
  - 4 banks
  - can be interleaved between RAS and CAS on several positions
- Burst length : fix to 4
- Timing and address size freely programmable
- Early precharge in case of page miss (different bank)
- Refresh
  - Auto refresh, with early refresh on idle cycles
  - Self refresh
  - average interval and the maximum post count selectable
- Power down mode

15.3 SDR-SDRAM Memory Controller Registers

This section contains a description of all registers of the SDR-SDRAM Memory Controller.

Table 15.8 SDR-SDRAM Memory Controller registers overview

Register name	Shortcut	Address
Error status register	DBSVCR	<SDRAn_base> + 004_H
SDRAM type selection register	DBKIND	<SDRAn_base> + 008_H
SDRAM enable register	DBEN	<SDRAn_base> + 010_H
SDRAM command control register	DBCMDCNT	<SDRAn_base> + 014_H
SDRAM configuration register	DBCONF	<SDRAn_base> + 020_H
SDRAM device control register	DBDMOV	<SDRAn_base> + 024_H
SDRAM timing register 0	DBTR0	<SDRAn_base> + 030_H
SDRAM timing register 1	DBTR1	<SDRAn_base> + 034_H
SDRAM timing register 2	DBTR2	<SDRAn_base> + 038_H
SDRAM refresh/power-down control register 0	DBRFPDN0	<SDRAn_base> + 040_H
SDRAM refresh/power-down control register 1	DBRFPDN1	<SDRAn_base> + 044_H
SDRAM refresh/power-down control register 2	DBRFPDN2	<SDRAn_base> + 048_H
SDRAM refresh status register	DBRFSTS	<SDRAn_base> + $04C_H$
SDRAM mode setting register	DBMRCNT	<SDRAn_base> + 060_H
PHY control register 0	DBPDCNT0	<SDRAn_base> + 108_H

<SDRAn_base>

The base addresses <SDRAn_base> of the SDRAn is defined in the first section of this chapter under the key word “Register addresses”.

15.3.1 SDR-SDRAM Memory Controller control registers details

15.3.1.1 DBSVCR – Error status register

This register holds various error indication flags.

Access: This register can be accessed in 32-bit units.

Address: <SDRAn_base> + 004_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	SRF PDN	INAC TIVE	0	0	BAD_ OPC	0	0	BAD_ ADDR	ERR_ SNT	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R/W	R	R	R/W	R/W	R

Table 15.9 DBSVCR register contents (1/2)

Bit position	Bit name	Function
31 to 10	Reserved	Reading returns the initial value. When written, write the initial value.
9	SRFPDN	Error cause: Data access to SDRAM during SDRAM self-refresh or power-down At read: 0: no error 1: SDRAM data was accessed while the SDRAM is in self-refresh or power-down mode, i.e. while DBRFPDN0.SRFEN = 1 or DBRFPDN0.PDN = 1. At write access: write 0: clear SRFPDN to 0 write 1: no function
8	INACTIVE	Error cause: Data access to SDRAM during SDRAM disable At read: 0: no error 1: SDRAM data was accessed while the SDRAM access is disabled, i.e. while DBEN.ACEN = 0. At write access: write 0: clear INACTIVE to 0 write 1: no function
7 to 6	Reserved	Reading returns the initial value. When written, write the initial value.
5	BAD_OPC	Error cause: Not supported transaction of the XC cross-connect At read: 0: no error 1: unsupported transaction of the XC cross-connect*1 At write access: write 0: clear BAD_OPC to 0 write 1: no function
4 to 3	Reserved	Reading returns the initial value. When written, write the initial value.
2	BAD_ADDR	Error cause: Access to undefined register of SDRA At read: 0: no error 1: access to undefined register of SDRA has occurred*2 At write access: write 0: clear BAD_ADDR to 0 write 1: no function

Table 15.9 DBSVCR register contents (2/2)

Bit position	Bit name	Function
1	ERR_SNT	Error flag: SDRA has issued an error to the cross-connect At read: 0: no error 1: SDRA error was returned to the cross-connect The error cause can be analyzed by the SRFPDN, INACTIVE and BAD_OPC error flags. At write access: write 0: clear ERR_SNT to 0 write 1: no function
0	Reserved	Reading returns the initial value. When written, write the initial value.

Note 1. The cause for unsupported transactions on XC cross-connect are unsupported data block width (bigger than 128 bit) or burst length errors (burst access to fixed address or unaligned bursts).
SDRA can detect those illegal transactions, even though they can not occur by normal cross-connect operation.

Note 2. Error cause of “undefined register access” means XC cross-connect access to register addresses of SDRA, where no SDRA register is present.

The error causes indicated by the DBSVCR register (SRFPDN, INACTIVE, BAD_OPC, BAD_ADDR and ERR_SNT) are signalled to the CPU directly by a SYSERR exception.

15.3.1.2 DBKIND – SDRAM type selection register

This register defines the SDRAM type.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBEN.ACEN = 0).
Thus write only to the DBKIND register during "Initial Sequence - 1st setting of SDRA" in Section 15.4.2, Initialization sequence.

Access: This register can be accessed in 32-bit units.

Address: <SDRAn_base> + 008_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 15.10 DBKIND register contents

Bit position	Bit name	Function
31 to 3	Reserved	Reading returns the initial value. When written, write the initial value.
2 to 0	DDCG[2:0]	SDRAM type selection 001_B: SDR-SDRAM others: setting prohibited

15.3.1.3 DBEN – SDRAM enable register

This register is used to enable or disable the SDRAM access.

Access: This register can be accessed in 32-bit units.

Address: <SDRAn_base> + 010_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 15.11 DBEN register contents

Bit position	Bit name	Function
31 to 1	Reserved	Reading returns the initial value. When written, write the initial value.
0	ACEN	SDRAM access enable/disable 0: SDRAM access disabled 1: SDRAM access enabled

NOTE

If the SDRAM is accessed while DBEN.ACEN = 0, the error INACTIVE flag in the error status register DBSVCR is set.

15.3.1.4 DBCMDCNT – SDRAM command control register

This register is used to send commands to the SDRAM devices.

CAUTION

Writing to this register is only permitted, when auto-refresh is not performed (DBRFPDN0.ARFEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRAn_base> + 014_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	0	CMD[2:0]		
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 15.12 DBCMDCNT register contents

Bit position	Bit name	Function
31 to 3	Reserved	Reading returns the initial value. When written, write the initial value.
2 to 0	CMD[2:0]	SDRAM command 000_B: Normal operation 010_B: Precharge all (PALL) command is issued. 011_B: SDRACKE signal goes to high level. 100_B: refresh command (REF) All others: Setting prohibited. These bits are always read as 0. Writing CMD[2:0] executes an initialization sequence and self-refresh shift/release of the SDRAM. Each write executes the respective command once. For instance, when the refresh command shall be executed twice, it is necessary to write CMD[2:0] = 100_B two times. The value set by the SDRAM timing registers is used at precharge period and minimum intervals etc. between refreshing and the next command.

15.3.1.5 DBCONF – SDRAM configuration register

This register is used to specify the SDRAM configuration.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBEN.ACEN = 0) and auto-refresh is not performed (DBRFPDN0.ARFEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRAn_base> + 020_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	SPLIT[8:0]

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 15.13 DBCONF register contents

Bit position	Bit name	Function
31 to 25	Reserved	Reading returns the initial value. When written, write the initial value.
24 to 16	SPLIT[8:0]	Memory configuration Refer to Section 15.4.1, Memory configuration by DBCONF.SPLIT[8:0].
15 to 14	BKADM[1:0]	Bank address definition selection*1 00_B: Consecutive addresses (BA0 and BA1 are specified by BKADP[5:0]) 01_B: Non-consecutive addresses (BA0 is specified by BKADP[5:0], BA1 is specified with BKADB[5:0]) Others: setting prohibited
13 to 8	BKADP[5:0]	Bank address position*1 00 0000_B: Top of the column address 00 1010_B: 1 KB (BA0 set to address 10) 00 1011_B: 2 KB (BA0 set to address 11) 00 1100_B: 4 KB (BA0 set to address 12) Others: setting prohibited
7 to 2	BKADB[5:0]	Upper bank address position*1 00 0000_B: setting prohibited 00 1101_B: BA1 set to address 13 00 1110_B: BA1 set to address 14 00 1111_B: BA1 set to address 15 01 0000_B: BA1 set to address 16 Others: setting prohibited BKADB[5:0] is only effective if BKADM[1:0] = 01_B.
1 to 0	BWIDTH[1:0]	External data bus width 01_B: 16 bit 10_B: 32 bit All others: Setting prohibited

Note 1. Refer to Section 15.6.2, Positioning of bank addresses for details.

15.3.1.6 DBDMOV – SDRAM device control register

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBEN.ACEN = 0) and auto-refresh is not performed (DBRFPDN0.ARFEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRAn_base> + 024_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	TRCDC[1:0]		0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R

Table 15.14 DBDMOV register contents

Bit position	Bit name	Function
31 to 4	Reserved	Reading returns the initial value. When written, write the initial value.
3 to 2	TRCDC[1:0]	TRCD bit modification for ACT-WRITE timing 00_B: less than 1 cycle from TRCD setting for ACT-WRITE timing Others: setting prohibited This register can modify the DBTR0.TRCD[2:0] setting for ACT-WRITE timing. ACT-READ timing is using DBTR0.TRCD[2:0] setting and does thus not depend on TRCDC[2:0].
1 to 0	Reserved	Reading returns the initial value. When written, write the initial value.

15.3.1.7 DBTR0 – SDRAM timing register 0

This register is used to define SDRAM timing parameters.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBEN.ACEN = 0) and auto-refresh is not performed (DBRFPDN0.ARFEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRAn_base> + 030_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	CL[2:0]			0	0	0	TRAS[4:0]				
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 15.15 DBTR0 register contents (1/2)

Bit position	Bit name	Function
31 to 27	Reserved	Reading returns the initial value. When written, write the initial value.
26 to 24	CL[2:0]	CAS latency 010_B: 2 cycles 011_B: 3 cycles Others: setting prohibited **Note:** The CL[2:0] value must be set to the same value as CAS latency, sent to the SDRAM's Mode Set Register (MSR) via the DBMRCNT register.
23 to 21	Reserved	Reading returns the initial value. When written, write the initial value.
20 to 16	TRAS[4:0]	ACT-PRE interval $0\ 0000_B$: 1 cycle $0\ 0001_B$: 2 cycles $0\ 0010_B$: 3 cycles ... $1\ 0001_B$: 18 cycles Others: setting prohibited
15	Reserved	Reading returns the initial value. When written, write the initial value.
14 to 8	TRFC[6:0]	REF-ACT/REF interval $000\ 0001_B$: 2 cycles $000\ 0010_B$: 3 cycles ... $110\ 1100_B$: 109 cycles Others: setting prohibited
7 to 3	Reserved	Reading returns the initial value. When written, write the initial value.

Table 15.15 DBTR0 register contents (2/2)

Bit position	Bit name	Function
2 to 0	TRCD[2:0]	ACT-READ interval setting bits 000_B: 1 cycle 001_B: 2 cycles 010_B: 3 cycles 011_B: 4 cycles 100_B: 5 cycles 101_B: 6 cycles Others: setting prohibited

15.3.1.8 DBTR1 – SDRAM timing register 1

This register is used to define SDRAM timing parameters.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBEN.ACEN = 0) and auto-refresh is not performed (DBRFPDN0.ARFEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRAn_base> + 034_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Table 15.16 DBTR1 register contents

Bit position	Bit name	Function
31 to 27	Reserved	Reading returns the initial value. When written, write the initial value.
26 to 24	CKEH[2:0]	CKEH period 000_B: 1 cycle 001_B: 2 cycles ... 111_B: 8 cycles
23 to 19	Reserved	Reading returns the initial value. When written, write the initial value.
18 to 16	TRP[2:0]	PRE period 000_B: 1 cycle 001_B: 2 cycles ... 101_B: 6 cycles Others: setting prohibited
15 to 11	Reserved	Reading returns the initial value. When written, write the initial value.
10 to 8	TRRD[2:0]	ACT(A)-ACT(B) period 000_B: 1 cycle 001_B: 2 cycles 010_B: 3 cycles 011_B: 4 cycles Others: setting prohibited
7 to 3	Reserved	Reading returns the initial value. When written, write the initial value.
2 to 0	TWR[2:0]	Write recovery period 001_B: 1 cycle 010_B: 2 cycles ... 101_B: 5 cycles Others: setting prohibited

15.3.1.9 DBTR2 – SDRAM timing register 2

This register is used to define SDRAM timing parameters.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBEN.ACEN = 0) and auto-refresh is not performed (DBRFPDN0.ARFEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRAn_base> + 038_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	TRTP[1:0]		0	0	0	TRC[4:0]

Table 15.17 DBTR2 register contents

Bit position	Bit name	Function
31 to 26	Reserved	Reading returns the initial value. When written, write the initial value.
25 to 24	TRTP[1:0]	READ-PRE period 01_B: 2 cycles 10_B: 3 cycles Others: setting prohibited
23 to 21	Reserved	Reading returns the initial value. When written, write the initial value.
20 to 16	TRC[4:0]	ACT-ACT/REF period $0\ 0000_B$: 1 cycle $0\ 0001_B$: 2 cycles ... $1\ 0110_B$: 23 cycles Others: setting prohibited
15 to 12	Reserved	Reading returns the initial value. When written, write the initial value.
11 to 8	RDWR[3:0]	READ-WRITE period 0011_B: 4 cycles 0100_B: 5 cycles ... 1000_B: 9 cycles Others: setting prohibited
7 to 4	Reserved	Reading returns the initial value. When written, write the initial value.
3 to 0	WRRD[3:0]	WRITE-READ period 0001_B: 2 cycles 0010_B: 3 cycles ... 1100_B: 13 cycles Others: setting prohibited

15.3.1.10 DBRFPDN0 – SDRAM refresh/power-down control register 0

This register is used to control refresh and power-down modes.

Access: This register can be accessed in 32-bit units.

Address: <SDRAn_base> + 040_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	ARFEN
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	0	PDN	0	SRFEN
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W

Table 15.18 DBRFPDN0 register contents

Bit position	Bit name	Function
31 to 17	Reserved	Reading returns the initial value. When written, write the initial value.
16	ARFEN	Auto-refresh control 0: auto-refresh disabled 1: auto-refresh enabled
15 to 3	Reserved	Reading returns the initial value. When written, write the initial value.
2	PDN	Power-down control 0: release power-down 1: enter power-down
1	Reserved	Reading returns the initial value. When written, write the initial value.
0	SRFEN	Self-refresh control 0: self-refresh disabled 1: self-refresh enabled

NOTE

If the SDRAM is accessed in self-refresh (SRFEN = 1) or power-down (PDN = 1) mode, the error SRFPDN flag in the error status register DBSVCR is set.

15.3.1.11 DBRFPDN1 – SDRAM refresh/power-down control register 1

This register is used to define the average refresh interval.

CAUTION

Writing to this register is only permitted, when auto-refresh is not performed (DBRFPDN0.ARFEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRAn_base> + 044_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 15.19 DBRFPDN1 register contents

Bit position	Bit name	Function
31 to 13	Reserved	Reading returns the initial value. When written, write the initial value.
12 to 0	TREFI[12:0]	Average refresh interval 0040_H: 65 cycles 0041_H: 66 cycles ... $1FFF_H$: 8192 cycles Others: setting prohibited

15.3.1.12 DBRFPDN2 – SDRAM refresh/power-down control register 2

This register is used to define the time for the refresh execution.

CAUTION

Writing to this register is only permitted, when auto-refresh is not performed (DBRFPDN0.ARFEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRAn_base> + 048_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	LV1TH[14:0]														
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	LV0TH[9:0]

R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 15.20 DBRFPDN2 register contents

Bit position	Bit name	Function
31	Reserved	Reading returns the initial value. When written, write the initial value.
30 to 16	LV1TH[14:0]	Level 1 threshold Number of SDRAM clock cycles during idle bus, before executing refresh.
15 to 10	Reserved	Reading returns the initial value. When written, write the initial value.
9 to 0	LV0TH[9:0]	Level 0 threshold Number of SDRAM clock cycles during busy bus, before pausing bus transactions and executing refresh.

NOTES

1. Set the LV1TH[14:0] value within the range of the ACT-PRE command interval described in SDRAM devices' data sheet.
2. LV1TH[14:0] should be set to $t_{REFI} \times 7$. Due to SDRAM timing constraints concerning the 9th REF command timing LV1TH[14:0] must fulfil $t_{REFI} < LV1TH[14:0] \leq t_{REFI} \times 9$.
3. LV0TH[9:0] register should be set to the WRITE-WRITE command timing $(t_{RP} + t_{RCD} + t_{WR} + 3) \times 5$ in order to prevent an underflow of refresh cycle counter.

15.3.1.13 DBRFSTS – SDRAM refresh status register

This register informs about an underflow of the refresh counter.

Access: This register can be accessed in 32-bit units.

Address: <SDRAn_base> + $04C_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	RFUDF
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 15.21 DBRFSTS register contents

Bit position	Bit name	Function
31 to 1	Reserved	Reading returns the initial value. When written, write the initial value.
0	RFUDF	Refresh counter underflow flag 0: refresh counter did not underflow 1: refresh counter underflow occurred The RFUDF flag can be cleared by writing 0.

RFUDF is set when the refresh counter changes from 1 to 0.

That means refresh could not be executed, because the LV0TH[9:0] value is smaller than the maximum number of command execution cycles. In that case, change the LV0TH[9:0] value.

Refresh counter underflow asserts also the refresh counter underflow interrupt INTSDRA.
For de-assertion of the INTSDRA interrupt the RFUDF flag must be cleared by writing RFUDF = 0.

Please refer to Section 15.4.4, Auto-refresh for the refreshing counter.

15.3.1.14 DBMRCNT – SDRAM mode setting register

This register is used to issue “Mode Register Set (MRS)” and “Extended Mode Register Set (EMRS)” commands towards the SDRAM devices.

A write to the DBMRCNT register initiates a MRS/EMRS command to the SDRAM, which transfers several parameters to the SDRAM during the initialization process.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBEN.ACEN = 0) and auto-refresh is not performed (DBRFPDN0.ARFEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRAn_base> + 060_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	BA[1:0]	
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	MA[12:0]

R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 15.22 DBMRCNT register contents

Bit position	Bit name	Function
31 to 18	Reserved	Reading returns the initial value. When written, write the initial value.
17 to 16	BA[1:0]	BA[1:0] defines the level of the bank address during the MRS/EMRS command (selection of MRS or EMRS SDRAM register) BA[1]: SDRABA[1] BA[0]: SDRABA[0] Reading these bits always returns 0.
15 to 13	Reserved	Reading returns the initial value. When written, write the initial value.
12 to 0	MA[12:0]	MA[12:0] defines the level of the address lines during the MRS/EMRS command output MA[12:11]: SDRAA[12:11] MA[10]: SDRAA10 MA[9:0]: SDRAA[9:0] Reading these bits always returns 0.

NOTE

The CAS latency, transferred to the SDRAM, must be set to the same value, as defined in DBTR0.CL[2:0].

15.3.1.15 DBPDCNT0 – PHY control register 0

This register is used to define the write recovery period.

Access: This register can be accessed in 32-bit units.

Address: <SDRAn_base> + 108_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OFFSET[2:0]			0	ENOFFSET[3:0]				0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	STBYN
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 15.23 DBPDCNT0 register contents

Bit position	Bit name	Function
31 to 29	OFFSET[2:0]	OFFSET[2:0] controls the read data capture timing of SDRAM. 001_B: for SDR-SDRAM other settings: prohibited
28 to 28	Reserved	Reading returns the initial value. When written, write the initial value.
27 to 24	ENOFFSET[3:0]	ENOFFSET[3:0] controls the I/O buffer input enable timing of SDRAM. 0011_B: for SDR-SDRAM other settings: prohibited
23 to 1	Reserved	Reading returns the initial value. When written, write the initial value.
0	STBYN	Clock standby control signal. 0: enter standby 1: exit standby

15.4 SDR-SDRAM Operation

15.4.1 Memory configuration by DBCONF.SPLIT[8:0]

Support memory devices

Following memory devices are supported:

- 16-bit data bus, that connects one 16-bit SDRAM
- 32-bit data bus, that connects one 32-bit SDRAM or two 16-bit SDRAMs in parallel

Memory configuration selection

The memory configuration is set up via the DBCONF.SPLIT[8:0] settings.

SPLIT[8:0] is a composition of different fields in form of xx_y_ppp_qqq. The meaning and the calculation formula of each numerical value are shown in the following.

- “x” specifies the width of the memory:
  - xx = 01_B: 16 bit memory width
  - xx= 10_B: 32 bit memory width
- “y” specifies the number of banks:
  - y = 0: 4 banks
- “p” specifies the width of the row address:
  - row address width = 1010_B + ppp_B
- “q" specifies the width of the column address:
  - column address width = 0111_B + $0qqq_B$

The following table shows settings for configuration with

- 16-bit (xx = 01_B) and 32-bit (xx = 10_B) SDRAM devices
- 4 banks (y = 0)
- different number of rows and columns

Table 15.24 Memory configuration settings

DBCONF.SPLIT[8:0] (xx_y_ppp_qqq)	Memory configuration	External bus width	Bank addresses	Row addresses	Column addresses
10_0_010_001	4M×32bit = 128Mbit	32-bit	2	12	8
10_0_010_010	8M×32bit = 256Mbit				9
10_0_010_011	16M×32bit = 512Mbit				10
10_0_011_001	8M×32bit = 256Mbit			13	8
10_0_011_010	16M×32bit = 512Mbit				9
10_0_011_011	32M×32bit = 1Gbit				10
01_0_010_001	4M×16bit = 64Mbit	16-bit	2	12	8
01_0_010_010	8M×16bit = 128Mbit				9
01_0_010_011	16M×16bit = 256Mbit				10
01_0_011_001	8M×16bit = 128Mbit			13	8
01_0_011_010	16M×16bit = 256Mbit				9
01_0_011_011	32M×16bit = 512Mbit				10

15.4.2 Initialization sequence

The following sequence enables SDRAM access after power-up.

NOTES

1. The sequences below are examples and may need to be changed according to the SDRAM device properties.
   Consult the SDRAM device vendor's data sheet for details.
2. Follow the values described in SDRAM device vendor's data sheet for correct waiting time between the steps in the sequence.

1. Wait until power supply for SDRA is stable.
2. Set DBPDCNT0.STBYN = 1 to release the clock supply of PHY.
3. Set DBCMDCNT.CMD[2:0] = 011_B to set CKE to high level.
4. Wait 200 µsec.
5. Set the following registers:
   – DBCONF
   – DBTR0
   – DBTR1
   – DBTR2
6. Set DBKIND.DDCG[2:0] = 001_B for SDR-SDRAM memory type
7. Set DBPDCNT0.OFFSET[2:0] = 001_B and DBPDCNT0.ENOFFSET[3:0] = 0011_B for SDR-SDRAM
8. Send the PALL (precharge all) command to the SDRAM by DBCMDCNT.CMD[2:0] = 010_B.
9. Send two times the REF (refresh) command to the SDRAM by writing two times DBCMDCNT.CMD[2:0] = 100_B.
10. Issue the MRS command towards the SDRAM by writing to the SDRAM mode setting register (DBMRCNT) in order to transfer various parameters to the SDRAM devices, in particular:
    – Set the burst length to 4.
    – The CAS latency must be set to the DBTR0.CL[2:0] value.
11. Enable SDRAM access by DBEN.ACEN = 1.
12. Set the refresh timing via the DBRFPDN1 and DBRFPDN2 registers.
13. Enable auto-refresh by DBRFPDN0.ARFEN = 1.

The SDRAM can be accessed.

15.4.3 Self-refresh

Changing to the self-refresh mode reduces power consumption, when the SDRAM is not accessed. The content of the SDRAM is retained.

NOTE

The sequences below are examples and may need to be changed according to the SDRAM device properties.
Consult the SDRAM device vendor's data sheet for details.

Self-refresh entry sequence

Follow the procedure below for entering the self-refresh mode.

(1) Stop all SDRAM accesses.

(2) Confirm that all SDRAM read transactions are completed by performing a dummy read from DBKIND register.

(3) Disable SDRAM access by DBEN.ACEN = 0.

(4) Disable auto-refresh by DBRFPDN0.ARFEN = 0.

(5) Send the PALL (precharge all) command to the SDRAM by DBCMDCNT.CMD[2:0] = 010_B.

(6) Send the REF (refresh) command to the SDRAM by DBCMDCNT.CMD[2:0] = 100_B.

(7) Enable self-refresh by DBRFPDN0.SRFEN = 1.

Now the clock can be stopped.

NOTE

If the SDRAM is accessed in self-refresh mode, the error SRFPDN flag in the error status register DBSVCR is set.

Self-refresh termination sequence

Follow the procedure below for terminating the self-refresh mode.

(1) Disable self-refresh by DBRFPDN0.SRFEN = 0.

(2) Enable SDRAM access by DBEN.ACEN = 1.

(3) Enable auto-refresh by DBRFPDN0.ARFEN = 1.

The SDRAM can be accessed.

NOTE

If the SDRAM is accessed in self-refresh mode, the error SRFPDN flag in the error status register DBSVCR is set.

15.4.4 Auto-refresh

Auto-refresh is enabled by DBRFPDN0.ARFEN = 1.
During auto-refresh the SDRAM can be accessed.

Refresh levels

In order to minimize the loss of data read/write bandwidth due to refresh cycles, the urgency for latching an auto-refresh cycles is set in different priority levels.

The auto-refresh level is determined by the current value of a 14-bit refresh counter, that counts down with the SDRAM clock. That means basically: the lower the refresh counter value, the higher the priority to perform a refresh.

The refresh levels are configurable by three register values:

- Level 0 threshold DBRFDPN2.LV0TH[9:0]
- Level 1 threshold DBRFDPN2.LV1TH[14:0]
- Average refresh interval time DBRFPDN1.TREFI[12:0]

Three refresh levels are defined:

- Level 0 - high priority refresh: 0 < refresh counter value ≤ LV0TH[9:0]
  Auto-refresh is performed during read/write transactions.
  Since the bus remains busy during continuous read/write transactions, the transactions must be paused for inserting an auto-refresh cycle. Consequently level 0 refreshing yields a loss of data transaction bandwidth.
- Level 1 - low priority refresh: LV0TH[9:0] < refresh counter value ≤ LV1TH[14:0]
  Auto-refresh is performed when the SDRAM bus is idle, i.e. no read/write transaction is ongoing.
- Level 2 - no refresh necessary: LV1TH[14:0] < refresh counter value ≤ t_{REFI} + LV1TH[14:0]
  Auto-refresh is not performed.

Refresh counter reload

After enabling auto-refresh (DBRFPDN0.ARFEN = 1), an auto-refresh cycle is immediately performed and the refresh counter is loaded with the average refresh interval DBRFPDN1.TREFI[12:0].

Each further refresh cycle adds TREFI[12:0] to the current refresh counter value, and shifts the next refresh towards lower priority.

Refresh counter underflow

If the counter underflows, i.e. no refresh has been performed until DBRFPDN1.TREFI[12:0] has count down to 0, the refresh counter underflow interrupt INTSDRA is asserted and the underflow flag DBRFSTS.RFUDF is set.

NOTE

The INTSDRA interrupt remains asserted until the underflow flag is cleared by DBRFSTS.RFUDF = 0.

After executing the precharge of all banks by using the PALL (precharge all) command, refreshing executes the auto refreshing command. Therefore, the data access to all banks enters the state of page miss after it refreshes it.

NOTE

When calculating the proper value for the refresh level 0 (DBRFDPN2.LV0TH[9:0]) take into account that launching refresh includes a 16 bytes transfer to the SDRAM and thus the actual refresh start is delayed by this.

The figure below illustrates the auto-refresh processing.

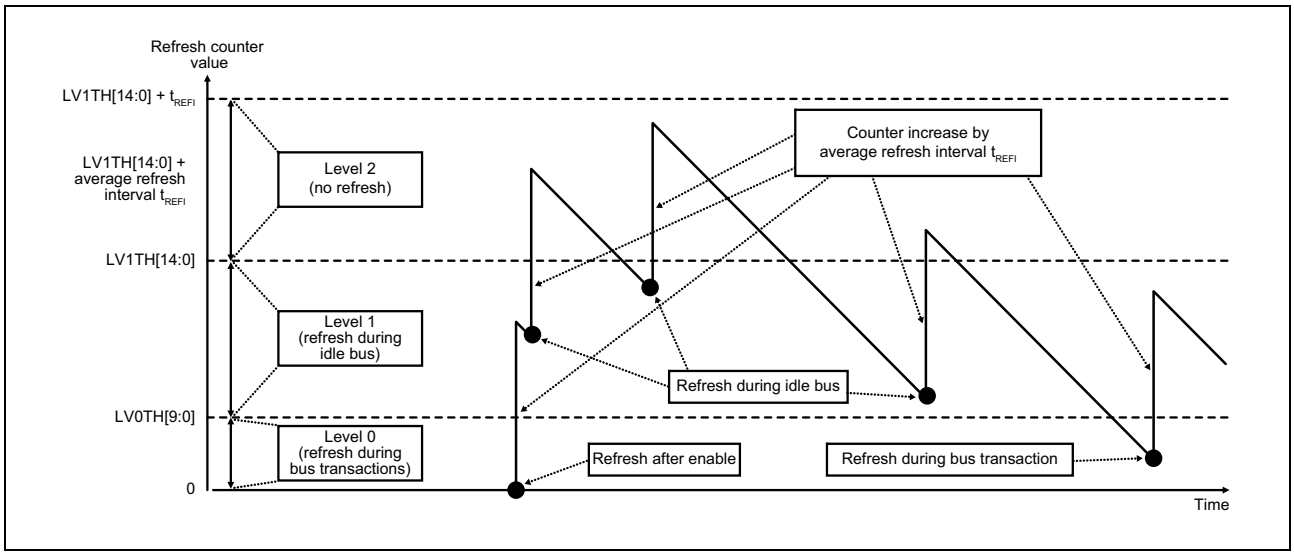

Figure 15.1 Auto-refresh processing

15.4.5 Power-down mode

Power consumption can be reduced when SDRAM access is not necessary by entering power-down mode.
In this mode the SDRAM internal clock is stopped and the SDRAM content is retained by the SDRA auto-refresh.
Power-down mode allows a fast return to normal operation, when the SDRAM must be accessed.

NOTES

1. The sequences below are examples and may need to be changed according to the SDRAM device properties.
   Consult the SDRAM device vendor's data sheet for details.
2. The here mentioned SDRAM power-down mode must not be mixed up with the microcontroller's DEEPSTOP mode.

Power-down entry sequence

Follow the procedure below for entering power-down mode.

(1) Stop all SDRAM accesses.

(2) Confirm that all SDRAM read transactions are completed by performing a dummy read from DBKIND register.

(3) Disable SDRAM access by DBEN.ACEN = 0.

(4) Send the PALL (precharge all) command to the SDRAM by DBCMDCNT.CMD[2:0] = 010_B.

(5) Enable power-down by DBRFPDN0.PDN = 1.

NOTE

If the SDRAM is accessed in power-down mode, the error SRFPDN flag in the error status register DBSVCR is set.

Power-up termination sequence

Follow the procedure below for terminating the power-down mode.

(1) Disable power-down by DBRFPDN0.PDN = 0.

(2) Enable SDRAM access by DBEN.ACEN = 1.

The SDRAM can be accessed.

In order to hold the SDRAM data in the SDRAM power-down mode, it is necessary to issue a regular refresh command as during normal operation.

Any attempt to access any SDRAM data during power-down mode results in an error and the DBSVCR.INACTIVE error flag is set.

15.5 SDR-SDRAM Transaction Restrictor

The SDR-SDRAM transaction restrictor can be used to serve cross-connect masters read request with higher priority than write request or vice versa.

It allows to contiguously process a programmable number of read (or write) transactions, while suspending any write (or read, respectively) request.

Transaction restrictor features overview

- The transaction restrictor can control the ratio between read and write transactions
- Three transaction restrictor modes:
  - write transaction restriction mode: gives priority to read requests
  - read transaction restriction mode: gives priority to write requests
  - normal mode: read and write requests are handled with same priority

This function is the same as VRAM transaction restrictor.

For the detail function, refer to Section 54.3, VRAM Transaction Restrictor.

15.5.1 SDR-SDRAM Transaction Restrictor Registers

The SDR-SDRAM transaction restrictor is controlled and operated by means of the following registers.

Table 15.25 SDR-SDRAM transaction restrictor registers overview

Address	Symbol	Register Name	R/W	Value after reset	Access Size
FFFD 3000_H	SDRATRCTL	SDRA transaction restrictor control register	R/W	0000 0000_H	32
FFFD 3004_H	SDRATRINTVL	SDRA transaction restrictor interval time register	R/W	0000 0000_H	32

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> is defined as “SDRAn” for the registers in the table above.

<Symbol> is defined in the above table.

15.5.1.1 SDRATRCTL — SDRA transaction restrictor control register (D1M1H, D1M1A only)

These registers control the transaction restrictor operation mode for SDRA.

CAUTION

This register must not be changed while SDR-SDRAM memory access is ongoing.

Access: This register can be read/written in 32-bit units.

Address: FFFD 3000_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 15.26 SDRATRCTL register contents

Bit Position	Bit Name	Function
31 to 24	IDLTIM[7:0]	IDLTIM[7:0] defines the idle time in number of C_ISO_XCCLK clock cycles. The idle time is the time to change from write suspend (WSUSP) or read suspend (RSUSP) state to initial state (INIT).
23 to 18	Reserved	When read, the value after reset is returned. When written, write the value after reset.
17 to 16	RCTL[1:0]	Transaction restrictor mode 00_B: normal mode (transaction restrictor disabled) 01_B: write transaction restrictor mode 10_B: read transaction restrictor mode 11_B: setting prohibited
15 to 9	RTOVFL[6:0]	Read overflow count RTOVFL[6:0] determines the number of written data in read suspend state (RSUSP) before changing to read interval state (RINTVL). The actual number of written data is RTOVFL[6:0] × 2. RTOVFL[6:0] is only valid in read transaction restrictor mode, i.e. RTCL[1:0] = 10_B.
8	Reserved	When read, the value after reset is returned. When written, write the value after reset.
7 to 1	WTOVFL[6:0]	Write overflow count WTOVFL[6:0] determines the number of read data in write suspend state (WSUSP) before changing to write interval state (WINTVL). The actual number of read data is WTOVFL[6:0] × 2. WTOVFL[6:0] is only valid in write transaction restrictor mode, i.e. RTCL[1:0] = 01_B.
0	Reserved	When read, the value after reset is returned. When written, write the value after reset.

15.5.1.2 SDRATRINTVL — SDRA transaction restrictor interval time register (D1M1H, D1M1A only)

These registers define the state change timing of from interval states to suspend states.

CAUTION

This register must not be changed while SDR-SDRAM memory access is ongoing.

Access: This register can be read/written in 32-bit units.

Address: FFFD 3004_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	ITVLTIM[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 15.27 SDRATRINTVL register contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When written, write the value after reset.
7 to 0	ITVLTIM[7:0]	ITVLTIM[7:0] defines the interval time in number of C_ISO_XCCLK clock cycles. The interval time is the time to change from write or read interval state (WINTVL or RINTVL) to write or read suspend state (WSUSP or RSUSP). ITVLTIM[7:0] is only valid in write or read transaction restrictor mode, i.e. RTCL[1:0] = 01_B or 10_B.

15.6 Appendix

In the description below

- SDRABA[1:0] is represented by BA[1:0]
- SDRAA[12:0] is represented by MA[12:0].

	COL	A13	A12	—	—	AP	A11	A10	A9	A8	A7	A6	A5	A4	A3	A2

Note 1. A31-A0 are logical address bits of byte unit, and A31 indicates the MSB side and A0 indicates the LSB side.
Note 2. AP indicates the auto pre-charge option.

15.6.2 Positioning of bank addresses

The position of the bank address in the logical address can be fixed without depending on the data bus width and the number of columns of SDRAM by setting the SDRAM configuration register DBCONF. Moreover, it is possible to set each bit of the bank address to non-continuous position.

Table 15.30 32-bit interface

DBCONF register settings			Logical address lines A[26:0]*1		
BKADM[1:0]	**BKADP[5:0]**	**BKADB[5:0]**	**BA[1:0]**	**Row address**	**Column address**
00_B	$00\ 0000_B$	xx $xxxx_B$	A[13:12]	A[26:14]	A[11:2]
	$00\ 1010_B$		A[11:10]	A[26:14]	A[13:12], A[9:2]
	$00\ 1011_B$		A[12:11]	A[26:14]	A[13], A[10:2]
01_B	$00\ 1010_B$	$00\ 1101_B$	A[13], A[10]	A[26:14]	A[12:11], A[9:2]
	$00\ 1011_B$	$00\ 1101_B$	A[13], A[11]	A[26:14]	A[12], A[10:2]
	$00\ 1010_B$	$00\ 1111_B$	A[15], A[10]	A[26:16], A[14:13]	A[12:11], A[9:2]

Note 1. A[1:0] is not used because of 32-bit alignment.

Table 15.31 16-bit interface

DBCONF register settings			Logical address lines A[26:0]*1		
BKADM[1:0]	**BKADP[5:0]**	**BKADB[5:0]**	**BA[1:0]**	**Row address**	**Column address**
00_B	$00\ 0000_B$	xx $xxxx_B$	A[12:11]	A[25:13]	A[10:1]
	$00\ 1010_B$		A[11:10]	A[25:13]	A[12], A[9:1]
	$00\ 1011_B$		A[12:11]	A[25:13]	A[10:1]
01_B	$00\ 1010_B$	$00\ 1101_B$	A[13], A[10]	A[25:14], A[12]	A[11], A[9:1]
	$00\ 1011_B$	$00\ 1101_B$	A[13], A[11]	A[25:14], A[12]	A[10:1]
	$00\ 1010_B$	$00\ 1111_B$	A[15], A[10]	A[25:16], A[14:12]	A[11], A[9:1]

Note 1. A[0] is not used because of 16-bit alignment.

15.6.2.1 Bank address as consecutive addresses (DBCONF.BKADM[1:0] = 00_B)

The position of the bank address in this case is specified with DBCONF.BKADP[5:0].

- BKADP[5:0] = 00 0000_B: Bank address is set to upper position of column address.
  i.e. column address[8:0] = A[9:1], bank address[1:0] = A[11:10]
- BKADP[5:0] ≠ 00 0000_B: Bank address can set the specified address position.
  i.e. BKADP[5:0] = 001100_B, column address[8:0] = A[9:1], bank address[1:0] = A[13:12]

If BKADP[5:0] ≠ 00 0000_B, BKADP[5:0] specifies the position of BA0.

The following tables show an example with one 32 M × 16-bit SDRAM and 16-bit external data bus width.

Table 15.32 BKADP[5:0] = 00 0000_B (consecutive BKADM[1:0] = 00_B)

	COL	A13	A12	—	—	AP	—	A9	A8	A7	A6	A5	A4	A3	A2	A1

15.6.2.2 Bank address as non-consecutive addresses (DBCONF.BKADM[1:0] = 01_B)

If DBCONF.BKADM[1:0] = 01_B, bank address position is controlled by DBCONF.BKADP[5:0] and DBCONF.BKADB[5:0].

BKADP[5:0] specifies the physical address position to BA0.
BKADB[5:0] specifies the physical address position to BA1.

Refer to Section 15.3.1.5, DBCONF – SDRAM configuration register for details about the register setting.

The following tables show an example with one 16 M × 16-bit SDRAM and 16-bit external data bus width.

Table 15.35 BKADP[5:0] = 00 1010_B and BKADB[5:0] = 00 1101_B (non-consecutive BKADM[1:0] = 01_B)

15.6.2.3 Bank address setting combinations

The following combinations can be set for the bank address position setting of the SDRAM composition setting register.
All other settings must not be used.

Table 15.37 Bank address setting combinations

Section 16 DDR2-SDRAM Memory Controller (SDRB)

This section contains a generic description of the DDR2-SDRAM Memory Controller.

The first section describes all properties specific to the RH850/D1L/D1M, such as units, register base addresses, input/output signal names, etc.
The subsequent sections describe the features that apply to all implementations.

16.1 Overview of RH850/D1L/D1M DDR2-SDRAM Memory Controller

16.1.1 Units

This microcontroller has the following number of units of the DDR2-SDRAM Memory Controller.

Table 16.1 Units

DDR2-SDRAM Memory Controller	D1L1	D1L2(H)	D1M1 D1M1-V2	D1M1H D1M1A	D1M2(H)
Units	–	–	–	–	1
Names	–	–	–	–	SDRB0

Units index n

Throughout this section, the individual units of a DDR2-SDRAM Memory Controller is identified by the index "n" (n = 0).

16.1.2 Register addresses

All DDR2-SDRAM Memory Controller register addresses are given as address offsets from the individual base addresses <SDRBn_base>.
The <SDRBn_base> addresses of each SDRBn are listed in the following table:

Table 16.2 Register base addresses <SDRBn_base>

SDRBn unit	<SDRBn_base> address
SDRB0	FFFA 0000_H

16.1.3 Clock supply

All DDR2-SDRAM Memory Controllers provide four clock inputs.

Table 16.3 Clock supply

SDRBn unit	SDRBn clock	Connected to
SDRB0	PBUS clock	Clock Controller C_ISO_PCLK
	MEMCLK	Clock Controller SDRBCLK / 2
	MEM2CLK	Clock Controller SDRBCLK
	Cross-connect clock	Clock Controller C_ISO_XCCLK

NOTE

The SDRBCK/$\overline{\text{SDRBCK}}$ memory clock signal output (non-inverted/inverted) frequency equals to MEMCLK (= SDRBCLK/2).

16.1.4 Interrupts

The DDR2-SDRAM Memory Controllers can generate the following interrupts:

Table 16.4 SDRBn interrupts

SDRBn signals	Function	Connected to
SDRB0:		
INTSDRB0	Refresh counter underflow interrupt	not connected

16.1.5 Reset sources

The DDR2-SDRAM Memory Controllers and their registers are initialized by the following reset signal:

Table 16.5 Reset sources

SDRBn unit	Reset signal
SDRBn	• Reset Controller SYSRES • Reset Controller SDRB0RES • reset upon wake-up from DEEPSTOP mode

CAUTION

By default the SDRB0RES reset is active.
Thus before accessing this module this reset must be released via the MRSTC register of the Reset Controller. Refer to Section 9, Reset Controller for details.

16.1.6 I/O signals

The following table shows the I/O signals of the DDR2-SDRAM Memory Controller.

Table 16.6 SDRBn I/O signals (1/2)

SDRBn signals	Function	Connected to
SDRB0		
SDRBA[13:11], SDRBA10, SDRBA[9:0]	Address output signals	Port SDRBA[13:11], SDRBA10, SDRBA[9:0]
SDRBDQ[31:0]	Data input/output signals	Port • D1M2: SDRBDQ[15:0] • D1M2H: SDRBDQ[31:0]
SDRBDQS[3:0]/ SDRBDQS[3:0]B	Data strobe input/output 3 to 0 (non-inverted/inverted)	Port • D1M2: SDRBDQS[1:0]/$\overline{\text{SDRBDQS[1:0]}}$ • D1M2H: SDRBDQS[3:0]/$\overline{\text{SDRBDQS[3:0]}}$
SDRBBA[2:0]	Bank address output signals	Port SDRBBA[2:0]
SDRBCK/SDRBCKB	Memory clock signal output (non-inverted/inverted)	Port SDRBCK/$\overline{\text{SDRBCK}}$
SDRBCKE	Clock enable output signal	Port SDRBCKE
SDRBDM[3:0]	Data mask input/output signals	Port • D1M2: SDRBDM[1:0] • D1M2H: SDRBDM[3:0]
SDRBODT	ODT output signal	Port SDRBODT

Table 16.6 SDRBn I/O signals (2/2)

SDRBn signals	Function	Connected to
SDRBCSB	Chip select output signal	Port $\overline{\text{SDRBCS}}$
SDRBCASB	CAS strobe output signal	Port $\overline{\text{SDRBCAS}}$
SDRBRASB	RAS strobe output signal	Port $\overline{\text{SDRBRAS}}$
SDRBWEB	Write enable output signal	Port $\overline{\text{SDRBWE}}$

Note 1. The suffix “B” in the signal names in the above table denotes low level active signals.

16.1.7 Partial Operation of I/O Signals

Table 16.7 D1M2H unused DDR2 interface handling

External SDRAM connection	Selection of DDR2 mode	Handling of unused data signals	Handling of unused address signals
32 bit	32 bit mode	• DQ[31:0]: all used • DQS[3:0]: all used	Leave open
16 bit	16 bit mode	• DQ[31:16]: leave open • DQS[3:2]: leave open	
None	32 bit mode	Refer to Section 2.8, Recommend connection of unused pins.	

Table 16.8 D1M2 unused DDR2 interface handling

External SDRAM connection	Selection of DDR2 mode	Handling of unused data signals	Handling of unused address signals
16 bit	16 bit mode	• DQ[15:0]: all used • DQS[1:0]: all used	Leave open
None	32 bit mode	Refer to Section 2.8, Recommend connection of unused pins.	

16.2 Overview

The DDR2-SDRAM Memory Controller gives access to external double data rate type 2 SDRAM memory devices.

Main features

- Supported memory devices: DDR2-SDRAM compliant with JEDEC JESD79-2F
- Data bus width and maximum bandwidth:
  - 16-bit data bus width: max. bandwidth 960 MB/s
  - 32-bit data bus width: max. bandwidth 1920 MB/s
- Support 32-bit data bus width only 2 x 16-bit DDR2-SDRAM devices
- Up to 512 MByte external DDR2-SDRAM
- Multi bank operation (4 or 8 banks selectable)
- Timing and address size freely programmable
- Burst length
  - 16-bit DDR2-SDRAM devices: 8
  - 32-bit DDR2-SDRAM devices: 4 or 8 selectable
- Early precharge in case of page miss (different bank)
- Refresh
  average interval and the maximum post count selectable
- Auto power-down
  automatic transition to power-down after selectable inactive period
- Four ports to cross-connect systems with Dynamic Priority Generator

NOTE

The DDR2-SDRAM Memory Controller (SDRB) in 32-bit mode can only be used in D1M2H devices.
The D1M2 devices supports 16-bit mode DDR2-SDRAM only, where D1M2H supports 32-bit and 16-bit mode.

For partial operation of DDR2-SDRAM Memory Controller (e.g. usage with 16-bit DDR2-SDRAM) please refer to the Section 16.1.7, Partial Operation of I/O Signals.

16.3 DDR2-SDRAM Memory Controller Registers

This section contains a description of all registers of Dynamic Priority Generator, Arbiter and the DDR2-SDRAM Memory Controller.

Table 16.9 DDR2-SDRAM Memory Controller registers overview (1/2)

Module Name	Register Name	Symbol	Address
DDR2-SDRAM I/F control registers			
SDRBn	Error status register	DBSVCR	<SDRBn_base> + 004_H
SDRBn	Status register 0	DBSTATE0	<SDRBn_base> + 008_H
SDRBn	SDRAM access enable register	DBACEN	<SDRBn_base> + 010_H
SDRBn	Auto-refresh enable register	DBRFEN	<SDRBn_base> + 014_H
SDRBn	Manual SDRAM command register	DBCMD	<SDRBn_base> + 018_H
SDRBn	Operating completion waiting register	DBWAIT	<SDRBn_base> + $01C_H$
SDRBn	SDRAM type setting register	DBKIND	<SDRBn_base> + 020_H
SDRBn	SDRAM configuration setting register 0	DBCONF0	<SDRBn_base> + 024_H
SDRBn	DDR2-PHY type setting register	DBPHYTYPE	<SDRBn_base> + 030_H
SDRBn	SDRAM timing register 0	DBTR0	<SDRBn_base> + 040_H
SDRBn	SDRAM timing register 1	DBTR1	<SDRBn_base> + 044_H
SDRBn	SDRAM timing register 2	DBTR2	<SDRBn_base> + 048_H
SDRBn	SDRAM timing register 3	DBTR3	<SDRBn_base> + 050_H
SDRBn	SDRAM timing register 4	DBTR4	<SDRBn_base> + 054_H
SDRBn	SDRAM timing register 5	DBTR5	<SDRBn_base> + 058_H

SDRBn	SDRAM timing register 11	DBTR11	<SDRBn_base> + 070_H
SDRBn	SDRAM timing register 12	DBTR12	<SDRBn_base> + 074_H
SDRBn	SDRAM timing register 13	DBTR13	<SDRBn_base> + 078_H
SDRBn	SDRAM timing register 14	DBTR14	<SDRBn_base> + $07C_H$
SDRBn	SDRAM timing register 15	DBTR15	<SDRBn_base> + 080_H
SDRBn	SDRAM timing register 16	DBTR16	<SDRBn_base> + 084_H
SDRBn	SDRAM timing register 17	DBTR17	<SDRBn_base> + 088_H
SDRBn	SDRAM timing register 18	DBTR18	<SDRBn_base> + $08C_H$
SDRBn	SDRAM burst length register	DBBL	<SDRBn_base> + $0B0_H$
SDRBn	SDRB operation adjustment register 0	DBADJ0	<SDRBn_base> + $0C0_H$
SDRBn	SDRB operation adjustment register 2	DBADJ2	<SDRBn_base> + $0C8_H$
SDRBn	Refresh configuration register 0	DBRFCNF0	<SDRBn_base> + $0E0_H$
SDRBn	Refresh configuration register 1	DBRFCNF1	<SDRBn_base> + $0E4_H$
SDRBn	Refresh configuration register 2	DBRFCNF2	<SDRBn_base> + $0E8_H$
SDRBn	ODT operation configuration register0	DBRNK0	<SDRBn_base> + 100_H
SDRBn	Power down configuration register	DBPDNCNF	<SDRBn_base> + 180_H
SDRBn	PHY control register 0	DBPDCNT0	<SDRBn_base> + 200_H
SDRBn	PHY control register 1	DBPDCNT1	<SDRBn_base> + 204_H
SDRBn	PHY control register 3	DBPDCNT3	<SDRBn_base> + $20C_H$

Table 16.9 DDR2-SDRAM Memory Controller registers overview (2/2)

Module Name	Register Name	Symbol	Address
SDRAM bus control registers			
SDRBn	Bus control unit 0 control register 1	DBBS0CNT1	<SDRBn_base> + 304_H
Dynamic priority control registers port index (i = 0 to 7)			
SDRBn	Dynamic Priority Generator control register	DBLGCNTi	<SDRBn_base> + i x 100_H + 1000_H
SDRBn	QoS counter initial value register	DBTMVAL0i	<SDRBn_base> + i x 100_H + 1004_H
SDRBn	QoS counter operation state transition condition register	DBRQCTRi	<SDRBn_base> + i x 100_H + 1014_H
SDRBn	Priority level threshold register 0	DBTHRES0i	<SDRBn_base> + i x 100_H + 1018_H
SDRBn	Priority level threshold register 1	DBTHRES1i	<SDRBn_base> + i x 100_H + $101C_H$
SDRBn	Priority level threshold register 2	DBTHRES2i	<SDRBn_base> + i x 100_H + 1020_H
SDRBn	Dynamic Priority Generator status register	DBLGSTSi	<SDRBn_base> + i x 100_H + 1024_H
SDRBn	Dynamic Priority Generator enable register	DBLGQONi	<SDRBn_base> + i x 100_H + 1028_H

<SDRBn_base>

The base addresses <SDRBn_base> of the SDRBn is defined in the first section of this chapter under the key word “Register addresses”.

NOTES

1. In the header files the names of the above registers are defined in the following format: <ModuleName> + <Symbol>.
   <ModuleName> and <Symbol> are defined in the above table.
2. Memory access right after register access has possibility to cause the racing between two accesses via different routes.
   Therefore, the last accessed register value must be confirmed at least before memory access. Refer to Section 3.4.1, Synchronization of Store Instruction Completion and Subsequent Instruction Generation for details.

16.3.1 DDR2-SDRAM Memory Controller control registers details

16.3.1.1 DBSVCR – Error status register

This register holds various error indication flags.

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 004_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	INACTIVE	0	0	BAD_OPC	0	0	BAD_ADDR	ERR_SNT	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R/W	R	R	R/W	R/W	R

Table 16.10 DBSVCR register contents (1/2)

Bit position	Bit name	Function
31 to 9	Reserved	Reading returns the initial value. When written, write the initial value.
8	INACTIVE	Error cause: Data access to SDRAM during SDRAM disable At read: 0: no error 1: SDRAM data was accessed while the SDRAM access is disabled, i.e. while DBACEN.ACCEN = 0. At write access: write 0: clear INACTIVE write 1: no function
7 to 6	Reserved	Reading returns the initial value. When written, write the initial value.
5	BAD_OPC	Error cause: Not supported transaction of the XC cross-connect At read: 0: no error 1: unsupported transaction of the XC cross-connect*1 At write access: write 0: clear BAD_OPC write 1: no function
4 to 3	Reserved	Reading returns the initial value. When written, write the initial value.
2	BAD_ADDR	Error cause: Access to undefined register of SDRB At read: 0: no error 1: access to undefined register of SDRB has occurred*2 At write access: write 0: clear BAD_ADDR write 1: no function
1	ERR_SNT	Error flag: Slave error issued to cross-connect At read: 0: no error 1: Slave error was returned to the cross-connect The error cause can be analyzed by the INACTIVE and BAD_OPC error flags. At write access: write 0: clear ERR_SNT write 1: no function

Table 16.10 DBSVCR register contents (2/2)

Bit position	Bit name	Function
0	Reserved	Reading returns the initial value. When written, write the initial value.

Note 1. The cause for unsupported transactions on XC cross-connect are unsupported data block width (bigger than 128 bit) or burst length errors (burst access to fixed address or unaligned bursts).
SDRB can detect those illegal transactions, even though they can not occur by normal cross-connect operation.

Note 2. Error cause of “undefined register access” means PBUS access to register addresses of SDRB, where no SDRB register is present.

The error causes indicated by the DBSVCR register (DBSVCR.INACTIVE, DBSVCR.BAD_OPC, DBSVCR.BAD_ADDR and DBSVCR.ERR_SNT) are signalled to the CPU either directly by a SYSERR exception or INTBUSERR internal bus error interrupt respectively.

The signalling mechanism used, depends on the accessing master causing the error.

- Errors caused by CPU (master) accessing the SDRB are signalled by SYSERR exception.
- Errors caused by other masters accessing the SDRB are signalled by INTBUSERR interrupt.

16.3.1.2 DBSTATE0 – Status register 0

This register indicates whether transactions are ongoing via each port.

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 008_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 16.11 DBSTATE0 register contents

Bit position	Bit name	Function
31 to 4	Reserved	Reading returns the initial value. When written, write the initial value.
3	AXBSY3	Port 3 busy indication 0: no transaction ongoing via the port 1: transaction ongoing via the port
2	AXBSY2	Port 2 busy indication 0: no transaction ongoing via the port 1: transaction ongoing via the port
1	AXBSY1	Port 1 busy indication 0: no transaction ongoing via the port 1: transaction ongoing via the port
0	AXBSY0	Port 0 busy indication 0: no transaction ongoing via the port 1: transaction ongoing via the port

16.3.1.3 DBACEN – SDRAM access enable register

This register is used to enable or disable the SDRAM access.

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 010_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	ACCEN
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 16.12 DBACEN register contents

Bit position	Bit name	Function
31 to 1	Reserved	Reading returns the initial value. When written, write the initial value.
0	ACCEN	SDRAM access enable/disable 0: SDRAM access disabled 1: SDRAM access enabled

NOTE

If the SDRAM is accessed while DBACEN.ACCEN = 0, the error INACTIVE flag in the error status register DBSVCR is set.

16.3.1.4 DBRFEN – Auto-refresh enable register

This register is used to enable or disable the SDRAM access.

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 014_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	ARFEN
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 16.13 DBRFEN register contents

Bit position	Bit name	Function
31 to 1	Reserved	Reading returns the initial value. When written, write the initial value.
0	ARFEN	Auto-refresh enable/disable 0: Auto-refresh stopped 1: Auto-refresh started Setting ARFEN = 1 resets the refresh counter and starts issuing auto-refresh commands in regular intervals. The refresh cycle time and other settings depend on the values held in the refresh configuration registers DBRFCNF0 to DBRFCNF2.

16.3.1.5 DBCMD – Manual SDRAM command-issuing register

This register is used to send commands to the SDRAM devices.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 018_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	OPC[5:0]						0	0	0	0	0	RANK[2:0]		
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ARG[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.14 DBCMD register contents

Bit position	Bit name	Function
31 to 30	Reserved	These bits are always read as 0. The write value should always be 0. If a value other than 0 is written, correct operation cannot be guaranteed.
29 to 24	OPC[5:0]	Operation Code Bits Specify the type of command to be issued. Refer to Table 16.15. If Wait is specified through these bits, valid SDRAM commands are not output and no processing is performed except reserving the time until the next operation. These bits are read as undefined values.
23 to 19	Reserved	These bits are always read as 0. The write value should always be 0. If a value other than 0 is written, correct operation cannot be guaranteed.
18 to 16	RANK[2:0]	RANK assignment 000_B: RANK0 100_B: all RANK All others: Setting prohibited The meaning depends on the operation code OPC, refer to Table 16.15.
15 to 0	ARG[15:0]	Parameter Bits The meaning can differ according to the operation code indicated by the OPC[5:0] bits. When OPC[5:0] indicates ModeRegisterSet (MRS0 to MRS3), the ARG[15:0] bits specify the value to be issued on the address pins (MA) of SDRAM. When OPC[5:0] is any other value, the ARG[15:0] bits specify the minimum interval to issuing of the next command in SDRAM cycles. When ARG[15:0] 0, however, the values default to those given in Interval cycle column of Table 16.15. These bits are read as undefined values.

The Manual SDRAM command-issuing register (DBCMD) is used to issue the required commands for the sequence of initializing the SDRAM and of transitions to and from the self-refresh mode. The command corresponding to the OPC[5:0] bits is issued once as a result of writing to this register. For instance, issuing the refresh command twice requires that "00 1100_B" be written to the OPC[5:0] bits

twice. Do not write to this register while access to the SDRAM is enabled (DBACEN.ACCEN = 1). The timing with which an operation is complete (i.e. the timing with which the specified SDRAM command is output to the PHY unit from SDRB) may be later than the response of SDRB to writing to this register. If you wish to wait until actual output of the specified SDRAM command to SDRAM; do this by reading the DBWAIT register (described later).

The length of these periods are given in the "interval cycle" column of Table 16.15. They can also be customized by using the ARG[15:0] bits (except in cases where the OPC[5:0] bits indicate MRS0 to MRS3).

Table 16.15 Manual command function

OPC[5:0]	Symbol	Operation	Interval cycle (MCK cycle)	RANK function	ARG function
$00\ 0000_B$	Wait	Device deselected (insert the wait cycle)	4	Don't care	Customization of intervals (If ARG[15:0] = 0 when use the left column value)
$00\ 1011_B$	PreA	Precharge All	TRPA[4:0]	Assign to target RANK	
$00\ 1100_B$	Ref	Refresh	TRFC[8:0]		
$01\ 0000_B$	PDEn	Power Down Entry	4		
$01\ 0001_B$	PDXt	Power Down Exit	4		
$01\ 1000_B$	SREn	Self-Refresh Entry	4		
$01\ 1001_B$	SRXt	Self-Refresh Exit	TRFC[8:0]		
$10\ 1000_B$	MRS0	ModeRegisterSet (MRS/MR0)(DDR2)	TMOD[5:0]		Value to be set in the mode register of SDRAM is set
$10\ 1001_B$	MRS1	ModeRegisterSet (MRS/MR1)(DDR2)	TMOD[5:0]		
$10\ 1010_B$	MRS2	ModeRegisterSet (MRS/MR2)(DDR2)	TMOD[5:0]		
$10\ 1011_B$	MRS3	ModeRegisterSet (MRS/MR3)(DDR2)	TMOD[5:0]		

When "Wait" (OPC[5:0] = 00 0000B) is specified, the valid SDRAM command is not output, and only the time interval between next operation will be secured.

When OPC[5:0] is ModeRegisterSet (MRS0 to MRS3), the value that is output to Address terminal (MA) of SDRAM is set.

When OPC[5:0] is not ModeRegisterSet (MRS0 to MRS3), the minimum interval until the issue of the next command is set in the SDRAM cycle count. However, when SRG = 0, the default value which is shown in the "Interval cycle" column of Table 16.15 will be used.

Note: The value which was set in the timing register, which will be mentioned later, is used for TRPA[4:0] and TMOD[5:0] of "Interval cycle" column of Table 16.15.

Note: Write in this register only when auto refresh function has been stopped (ARFEN = 0 of DBRFEN register). However, the sequence defined in 3rd chapter SDRB function explanation does not have this limitation. When OPC = Wait is written in this register during auto refresh function operation, this may interrupt the issuing of the refresh command by auto refresh function during the secured time interval.

16.3.1.6 DBWAIT – Operating completion waiting register

This register is used to wait until command issued by DBCMD register is completed.

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + $01C_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	WAIT
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 16.16 DBWAIT register contents

Bit position	Bit name	Function
31 to 1	Reserved	Reading returns the initial value. When written, write the initial value.
0	WAIT	Operation completion waiting bit.*1 This bit will always be read as 0.

Note 1. The completion of the read access to this register bit (DBWAIT.WAIT) will be delayed until the SDRB finished the current command execution. By this means the SDRB can ensure that the waiting times (e.g. after command output from the SDRB to the PHY unit) issued by DBCMD register are completed.

16.3.1.7 DBKIND – SDRAM type setting register

This register defines the SDRAM type.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 020_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	0	DDCG[2:0]		
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 16.17 DBKIND register contents

Bit position	Bit name	Function
31 to 3	Reserved	Reading returns the initial value. When written, write the initial value.
2 to 0	DDCG[2:0]	SDRAM type selection 101_B: DDR2-SDRAM All others: Setting prohibited

Only write to register DBKIND during “Initial Sequence - 1st setting of SDRB” in **Section 16.4.1, Initial sequence**.

16.3.1.8 DBCONF0 – SDRAM configuration setting register 0

This register is used to specify the SDRAM configuration.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 024_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.18 DBCONF0 register contents (1/2)

Bit position	Bit name	Function
31 to 29	Reserved	Reading returns the initial value. When written, write the initial value.
28 to 24	AWRW0[4:0]	Row bit width $0\ 1101_B$: 13 bit $0\ 1110_B$: 14 bit $0\ 1111_B$: 15 bit $1\ 0000_B$: 16 bit All others: Setting prohibited
23 to 21	Reserved	Reading returns the initial value. When written, write the initial value.
20	AWRK0	Number of Rank 0: 1 rank All others: Setting prohibited
19 to 18	Reserved	Reading returns the initial value. When written, write the initial value.
17 to 16	AWBK0[1:0]	Number of banks 10_B: 4 banks 11_B: 8 banks All others: Setting prohibited
15 to 12	Reserved	Reading returns the initial value. When written, write the initial value.
11 to 8	AWCL0[3:0]	Column bit width 1001_B: 9 bit 1010_B: 10 bit All others: Setting prohibited
7 to 2	Reserved	Reading returns the initial value. When written, write the initial value.
1 to 0	DW0[1:0]	External data bus width*1 01_B: 16 bit 10_B: 32 bit All others: Setting prohibited

Table 16.18 DBCONF0 register contents (2/2)

Bit position	Bit name	Function
Note 1.		If no DDR2-SDRAM device is connected to the SDRB, select DBCONF0.DW0[1:0] = 10_B: 32-bit external data bus width. Refer also to the Section 2.8, Recommend connection of unused pins for SDRB pin handling.

16.3.1.9 DBPHYTYPE – DDR2-PHY type register

This register is used to specify the type of the DDR2-PHY.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 030_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 16.19 DBPHYTYPE register contents

Bit position	Bit name	Function
31 to 2	Reserved	Reading returns the initial value. When written, write the initial value.
1 to 0	PHYTYPE[1:0]	DDR2-PHY type 00_B: MSPAD1 All others: Setting prohibited **CAUTION** The default value of this register must not be changed.

16.3.1.10 DBTR0 – SDRAM timing register 0

This register is used to define the CAS latency.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 040_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 16.21 DBTR1 register contents

Bit position	Bit name	Function
31 to 4	Reserved	Reading returns the initial value. When written, write the initial value.
3 to 0	CWL[3:0]	CAS write latency 0010_B: 2 cycles 0011_B: 3 cycles 0100_B: 4 cycles All others: Setting prohibited For DDR2-SDRAM types, set CAS write latency to 1 cycles less than CAS latency, i.e. CWL[3:0] = DBTR0.CL[3:0] - 1.

16.3.1.12 DBTR2 – SDRAM timing register 2

This register is used to define the additive latency.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 048_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 16.22 DBTR2 register contents

Bit position	Bit name	Function
31 to 4	Reserved	Reading returns the initial value. When written, write the initial value.
3 to 0	AL[3:0]	Additive latency 0000_B: 0 cycles All others: Setting prohibited

16.3.1.13 DBTR3 – SDRAM timing register 3

This register is used to set a timing parameter for the SDRAM.

CAUTIONS

1. **Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).**
2. **Writing to this register is only permitted, while automatic refresh function is stopped (DBRFEN.ARFEN).**

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 050_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 16.23 DBTR3 register contents

Bit position	Bit name	Function
31 to 5	Reserved	Reading returns the initial value. When written, write the initial value.
4 to 0	TRCD[4:0]	ACT-READ/WRITE interval setting bits 0 0011_B: 3 cycles 0 0100_B: 4 cycles ... 1 1111_B: 31 cycles All others: Setting prohibited TRCD[4:0] set the minimum interval from an ACT command to a READ/WRITE command.

16.3.1.14 DBTR4 – SDRAM timing register 4

This register is used to define the precharge interval.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 054_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	TRPA[4:0]				
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	TRP[4:0]				
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 16.24 DBTR4 register contents

Bit position	Bit name	Function
31 to 21	Reserved	Reading returns the initial value. When written, write the initial value.
20 to 16	TRPA[4:0]	PREA interval $0\ 0011_B$: 3 cycles $0\ 0100_B$: 4 cycles ... $1\ 1111_B$: 31 cycles All others: Setting prohibited TRPA[4:0] sets the minimum interval from a PREA (precharge all banks) command to an ACT/REF command. TRPA[4:0] must be greater than or equal to TRP[4:0].
15 to 5	Reserved	Reading returns the initial value. When written, write the initial value.
4 to 0	TRP[4:0]	PRE interval $0\ 0011_B$: 3 cycles $0\ 0100_B$: 4 cycles ... $1\ 1111_B$: 31 cycles All others: Setting prohibited TRP[4:0] sets the minimum interval from a PRE (precharge) command to an ACT/REF command.

16.3.1.15 DBTR5 – SDRAM timing register 5

This register is used to define the ACT-ACT/REF interval.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 058_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.25 DBTR5 register contents

Bit position	Bit name	Function
31 to 6	Reserved	Reading returns the initial value. When written, write the initial value.
5 to 0	TRC[5:0]	ACT-ACT/REF interval 00 1000_B: 8 cycles 00 1001_B: 9 cycles ... 11 1111_B: 63 cycles All others: Setting prohibited TRC[5:0] sets the minimum interval from one ACT command to another ACT command (for the same bank) or to a REF command.

16.3.1.16 DBTR6 – SDRAM timing register 6

This register is used to define the ACT-PRE interval.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + $05C_H$

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.26 DBTR6 register contents

Bit position	Bit name	Function
31 to 6	Reserved	Reading returns the initial value. When written, write the initial value.
5 to 0	TRAS[5:0]	ACT-PRE interval 00 0101_B: 5 cycles 00 0110_B: 6 cycles ... 11 1111_B: 63 cycles All others: Setting prohibited TRAS[5:0] sets the minimum interval from an ACT command to a PRE command.

16.3.1.17 DBTR7 – SDRAM timing register 7

This register is used to define the ACT(A)-ACT(B) interval.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 060_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	TRRD[3:0]			
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 16.27 DBTR7 register contents

Bit position	Bit name	Function
31 to 4	Reserved	Reading returns the initial value. When written, write the initial value.
3 to 0	TRRD[3:0]	ACT(A)-ACT(B) interval 0010_B: 2 cycles 0011_B: 3 cycles ... 1111_B: 15 cycles All others: Setting prohibited TRRD[3:0] sets the minimum interval between ACT commands issued for different banks.

16.3.1.18 DBTR8 – SDRAM timing register 8

This register is used to define the Four Activate window length.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 064_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	TFAW[7:0]							
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.28 DBTR8 register contents

Bit position	Bit name	Function
31 to 8	Reserved	Reading returns the initial value. When written, write the initial value.
7 to 0	TFAW[7:0]	Four Activate window length 0000 1000_B: 8 cycles 0000 1001_B: 9 cycles ... 0011 1111_B: 63 cycles All others: Setting prohibited TFAW[7:0] sets the length of the four activate window. TFAW[7:0] must be at least four times as large as the minimum interval between ACT commands issued for different banks, i.e. TFAW[7:0] ≥ 4 × DBTR7.TRRD[3:0].

16.3.1.19 DBTR9 – SDRAM timing register 9

This register is used to define the READ-PRE interval.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 068_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	TRDPR[3:0]			
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 16.29 DBTR9 register contents

Bit position	Bit name	Function
31 to 4	Reserved	Reading returns the initial value. When written, write the initial value.
3 to 0	TRDPR[3:0]	READ-PRE interval*1 0010_B: 2 cycles 0011_B: 3 cycles ... 1111_B: 15 cycles All others: Setting prohibited TRDPR[3:0] sets the minimum interval from a READ command to a PRE command.

Note 1. For JEDEC compliant DDR2-SDRAM the READ-PRE interval can be calculated with the following formula.
TRDPR[3:0] = BL[1:0]/2 + t_{RTP_cyc} - 2
Where the t_{RTP_cyc} need to be calculated to be
t_{RTP_cyc} = max (2, t_{RTP}/t_{CK})

16.3.1.20 DBTR10 – SDRAM timing register 10

This register is used to define the write recovery period.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + $06C_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	TWR[3:0]			
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 16.30 DBTR10 register contents

Bit position	Bit name	Function
31 to 4	Reserved	Reading returns the initial value. When written, write the initial value.
3 to 0	TWR[3:0]	Write recovery period 0010_B: 2 cycles 0011_B: 3 cycles ... 1111_B: 15 cycles All others: Setting prohibited

16.3.1.21 DBTR11 – SDRAM timing register 11

This register is used to define the READ-WRITE interval.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 070_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	TRDWR[5:0]					
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.31 DBTR11 register contents

Bit position	Bit name	Function
31 to 6	Reserved	Reading returns the initial value. When written, write the initial value.
5 to 0	TRDWR[5:0]	READ-WRITE interval*1 00 0100_B: 4 cycles 00 0101_B: 5 cycles ... 00 1111_B: 15 cycles All others: Setting prohibited TRDWR[5:0] sets the minimum interval from a READ command to a WRITE command.

Note 1. The READ-WRITE interval for JEDEC standard compliant DDR2-SDRAM can be calculated with the formula:
$TRDWR[5:0] \geq BL[1:0]/2 + 3 + db\_enoffset/2$

16.3.1.22 DBTR12 – SDRAM timing register 12

This register is used to define the WRITE-READ interval.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 074_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	TWRRD[5:0]					
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.32 DBTR12 register contents

Bit position	Bit name	Function
31 to 6	Reserved	Reading returns the initial value. When written, write the initial value.
5 to 0	TWRRD[5:0]	WRITE-READ interval*1 00 0110_B: 6 cycles 00 0111_B: 7 cycles ... 01 1111_B: 31 cycles All others: Setting prohibited TWRRD[5:0] sets the minimum interval from a WRITE command to a READ command.

Note 1. The WRITE-READ interval for JEDEC standard compliant DDR2-SDRAM can be calculated with the formula:
TWRRD$[5:0]$ >= CWL$[3:0]$ + BL$[1:0]$/2 + t_{WTR}

16.3.1.23 DBTR13 – SDRAM timing register 13

This register is used to define the REF-ACT/REF interval.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 078_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.33 DBTR13 register contents

Bit position	Bit name	Function
31 to 9	Reserved	Reading returns the initial value. When written, write the initial value.
8 to 0	TRFC[8:0]	REF-ACT/REF interval 008_H: 8 cycles 009_H: 9 cycles ... $1FF_H$: 511 cycles All others: Setting prohibited TRFC[8:0] sets the minimum interval from a REF (refresh) command to an ACT/REF command.

16.3.1.24 DBTR14 – SDRAM timing register 14

This register is used to define the CKEH(DLL-LOCK) and CKEH period.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + $07C_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	TCKEHDLL[7:0]							
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	TCKEH[7:0]							
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.34 DBTR14 register contents

Bit position	Bit name	Function
31 to 24	Reserved	Reading returns the initial value. When written, write the initial value.
23 to 16	TCKEHDLL[7:0]	CKEH(DLL-LOCK) period 02_H: 2 cycles 03_H: 3 cycles ... $1F_H$: 31 cycles All others: Setting prohibited TCKEHDLL[7:0]] sets the minimum interval from the time the CKE signal goes high until the issuing of a further valid command that requires the DLL to be locked.
15 to 8	Reserved	Reading returns the initial value. When written, write the initial value.
7 to 0	TCKEH[7:0]	CKEH period*1 02_H: 2 cycles 03_H: 3 cycles ... $0F_H$: 15 cycles All others: Setting prohibited TCKEH[7:0] sets the minimum interval from the time the CKE signal goes high until the issuing of a further valid command.

Note 1. Please ensure that the register setup meets the condition
DBTR14.TCKEH[7:0] ≤ DBTR14.TCKEHDLL[7:0]

16.3.1.25 DBTR15 – SDRAM timing register 15

This register is used to define the CKEL period.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 080_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	0	0	0	0	0	0	0	0	0	0	0	0	TCKEL[3:0]			
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 16.35 DBTR15 register contents

Bit position	Bit name	Function
31 to 4	Reserved	Reading returns the initial value. When written, write the initial value.
3 to 0	TCKEL[3:0]	CKEL period 0010_B: 2 cycles 0011_B: 3 cycles ... 1111_B: 15 cycles All others: Setting prohibited TCKEL[3:0] sets the minimum time from the time the CKE signal goes low until it goes high.

16.3.1.26 DBTR16 – SDRAM timing register 16

This register is used to define the latency timing for the DDR2 PHY.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 084_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.36 DBTR16 register contents (1/2)

Bit position	Bit name	Function
31 to 28	DQIENLTNCY[3:0]	DQIENLTNCY setting 0001_B: 1 cycle Others: setting prohibited DQIENLTNCY[3:0] sets the latency from issuing of a read command to the PHY unit the dqi_en signal is output.
27 to 26	Reserved	Reading returns the initial value. When written, write the initial value.
25 to 24	DQLOFFSET[1:0]	DQLTNCY offset 10_B: 2 cycles All others: Setting prohibited DQLOFFSET[1:0] sets the additional latency necessary for SDRB internal operation when a read command is issued to the PHY unit.
23 to 22	Reserved	Reading returns the initial value. When written, write the initial value.
21 to 16	DQL[5:0]	DQLTNCY setting 0 0110_B: 6 cycles 0 0111_B: 7 cycles 0 1000_B: 8 cycles 0 1001_B: 9 cycles 0 1010_B: 10 cycles All others: Setting prohibited DQL[5:0] sets the latency from issuing of a read command to the PHY unit until the read data is returned from the PHY unit. Set the following value for DQL[5:0]: DQL[5:0] = CL[3:0] + 3 + db_offset
15 to 12	DQENLTNCY[3:0]	DQENLTNCY setting 0001_B: 1 cycle All others: Setting prohibited DQENLTNCY[3:0] sets the latency from issuing of a write command to the PHY unit until the dqi_en signal is output.
11 to 4	Reserved	Reading returns the initial value. When written, write the initial value.

Table 16.36 DBTR16 register contents (2/2)

Bit position	Bit name	Function
3 to 0	WDQL[3:0]	WDQLTNCY setting 0001_B: 1 cycle All others: Setting prohibited WDQL[3:0] sets the latency from issuing of a write command until the write data is output.

16.3.1.27 DBTR17 – SDRAM timing register 17

This register is used to define the MRS/MRW interval.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 088_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	TMOD[5:0]					
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.37 DBTR17 register contents

Bit position	Bit name	Function
31 to 22	Reserved	Reading returns the initial value. When written, write the initial value.
21 to 16	TMOD[5:0]	MRS/MRW interval 00 0010_B: 2 cycles 00 0011_B: 3 cycles ... 00 1111_B: 15 cycles All others: Setting prohibited TMOD[5:0] indicates the minimum interval from an MRS (mode register set) / MRW (mode register write) command to a subsequent command.
15 to 0	Reserved	Reading returns the initial value. When written, write the initial value.

16.3.1.28 DBTR18 – SDRAM timing register 18

This register is used to define the ODT (On-Die-Termination) terminal control timing settings.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + $08C_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.38 DBTR18 register contents (1/2)

Bit position	Bit name	Function
31 to 27	Reserved	Reading returns the initial value. When written, write the initial value.
26 to 24	RODTL[2:0]	ODT assert period for read 000_B: BL[1:0]/2 cycles 001_B: BL[1:0]/2 + 1 cycles ... 111_B: BL[1:0]/2 + 7 cycles RODTL[2:0] sets the assert period of the ODT signal that is output when a read command is output.
23 to 19	Reserved	Reading returns the initial value. When written, write the initial value.
18 to 16	RODTA[2:0]	ODT assert start timing for read 000_B: Simultaneous with read command 001_B: after 1 cycle of read command 010_B: after 2 cycles of read command 011_B: after 3 cycles of read command 111_B: before 1 cycle of read command All others: Setting prohibited RODTA[2:0] sets the assert start timing for the ODT signal that is output when a read command is output.
15 to 11	Reserved	Reading returns the initial value. When written, write the initial value.
10 to 8	WODTL[2:0]	ODT assert period for write 000_B: BL[1:0]/2 cycles 001_B: BL[1:0]/2 + 1 cycles ... 111_B: BL[1:0]/2 + 7 cycles WODTL[2:0] sets the assert period of the ODT signal that is output when a write command is output.
7 to 3	Reserved	Reading returns the initial value. When written, write the initial value.

Table 16.38 DBTR18 register contents (2/2)

Bit position	Bit name	Function
2 to 0	WODTA[2:0]	ODT assert start timing for write 000_B: Simultaneous with write command 001_B: after 1 cycle of write command 010_B: after 2 cycles of write command 011_B: after 3 cycles of write command 111_B: before 1 cycle of write command All others: Setting prohibited WODTA[2:0] sets the assert start timing for the ODT signal that is output when a write command is output.

16.3.1.29 DBBL – SDRAM burst length register

This register is used to define the burst length.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + $0B0_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	0	0	0	0	0	0	0	0	0	0	0	0	0	0	BL[1:0]	
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 16.39 DBBL register contents

Bit position	Bit name	Function
31 to 2	Reserved	Reading returns the initial value. When written, write the initial value.
1 to 0	BL[1:0]	Burst length selection 00_B: 8 10_B: 4 All others: Setting prohibited BL[1:0] specifies the burst length of SDRAM. If DDR2-SDRAM bus width is 16 bit, then BL[1:0] should be set to 10_B.

16.3.1.30 DBADJ0 – SDRB operation adjustment register 0

This register is used to control of SDRB operation.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + $0C0_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	FREQRATIO[1:0]	
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	CAMODE
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 16.40 DBADJ0 register contents

Bit position	Bit name	Function
31 to 18	Reserved	Reading returns the initial value. When written, write the initial value.
17 to 16	FREQ RATIO[1:0]	Frequency ratio 01_B: 1:2 SDRB: memory frequency ratio All others: Setting prohibited FREQRATIO[1:0] specifies the clock frequency ratio of PHY and SDRB.
15 to 1	Reserved	Reading returns the initial value. When written, write the initial value.
0	CAMODE	Command/Address output mode 0: 1 command issued per 1 clock 1: 1 command issued per 2 clocks CAMODE specifies the SDRAM command/address output mode. • CAMODE = 0: the SDRB outputs a single command per clock cycle. • CAMODE = 1: the SDRB outputs a single command per two clock cycles. In this case, command signals and address signals, except for the MCS[1:0] signals of SDRAM, are kept constant for two clock cycles. During this period, the CS signal becomes low only in the latter one clock cycle

16.3.1.31 DBADJ2 – SDRB operation adjustment register 2

This register is used to control of SDRB operation.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + $0C8_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ACAPC0[7:0]								0	0	0	0	ACAP0[3:0]			
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 16.41 DBADJ2 register contents

Bit position	Bit name	Function
31 to 16	Reserved	Reading returns the initial value. When written, write the initial value.
15 to 8	ACAPC0[7:0]	Acceptable data cell count bits by device control unit 01_H: 1 cell 02_H: 2 cells ... 20_H: 32 cells All others: Setting prohibited ACAPC0[7:0] sets the number of requests acceptable by the device control unit in the SDRB in data cell units.
7 to 4	Reserved	Reading returns the initial value. When written, write the initial value.
3 to 0	ACAP0[3:0]	Acceptable transaction count bits by device control unit 1_H: 1 transaction 2_H: 2 transactions ... 8_H: 8 transactions All others: Setting prohibited ACAP0[3:0] sets the number of requests acceptable by the device control unit in the SDRB in transaction units.

16.3.1.32 DBRFCNF0 – Refresh configuration register 0

DBRFCNF0 is used to set the timing for refreshing of the SDRAM.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + $0E0_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	REFTHF[11:0]											
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.42 DBRFCNF0 register contents

Bit position	Bit name	Function
31 to 12	Reserved	Reading returns the initial value. When written, write the initial value.
11 to 0	REFTHF[11:0]	Forcible Auto-Refresh threshold setting bits 080_H: 128 SDRAM operation clock cycles ... $1FF_H$: 511 SDRAM operation clock cycles All others: Setting prohibited

If you change the value of this register while auto-refresh is active (i.e. the ARFEN bit in the DBRFEN register is 1), the auto-refresh facility must be re-activated to reflect the new value in refreshing. To re-activate the auto-refresh facility, write 1 to the ARFEN bit in the DBRFEN register.

These bits set the timing for forcible refreshing regardless of bus requests.

The value represented by these bits affects the amount of jitter in the refresh interval and performance in access to memory. A smaller value means less jitter in the refresh interval but may reduce performance in access. For details on the amount of jitter in the refresh interval, see Section 16.3.1.33, DBRFCNF1 – Refresh configuration register 1.

The setting value should meet the following criteria:

REFTHF[11:0] ≥ (TCKEL[3:0] + TCKEH[7:0]) + REFTH0

(REFTH0 = max (TRDPR[3:0], CWL[3:0] + BL[1:0]/2 + TWR[3:0], TRAS[5:0], TRC[5:0] - TRP[4:0]) + RKRP * (installation rank number - 1) + TRPA[4:0] + 100)

16.3.1.33 DBRFCNF1 – Refresh configuration register 1

DBRFCNF1 is used to set the timing for refreshing of the SDRAM.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + $0E4_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	REFPMAX[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	REFINT[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.43 DBRFCNF1 register contents

Bit position	Bit name	Function
31 to 16	REFPMAX[15:0]	Maximum post number of refresh commands setting bits 0002_H: 2 0003_H: 3 ... 0008_H: 8 All others: Setting prohibited
15 to 0	REFINT[15:0]	Average refresh interval setting bits 0080_H: 128 SDRAM operation clock cycles 0081_H: 129 SDRAM operation clock cycles ... $3FFF_H$: 16383 SDRAM operation clock cycles All others: Setting prohibited

If you change the value of this register while auto-refresh is active (i.e. the ARFEN bit in the DBRFEN register is 1), the auto-refresh facility must be re-activated to reflect the new value in refreshing. To re-activate the auto-refresh facility, write 1 to the ARFEN bit in the DBRFEN register.

REFPMAX[15:0] (Maximum post number of refresh commands setting)

These bits set the maximum number of refresh commands (post number) accumulated by auto-refresh. As long as the number of refresh commands that has been accumulated is smaller than REFPMAX, refresh commands are issued while there are no bus requests.

REFINT[15:0] (Average refresh interval setting)

These bits set the average interval for issuing of refresh commands. When the REFINTS bit of the DBRFCNF2 register is 0, the average interval (in cycles) is REFINT[15:0]. When the REFINTS bit of the DBRFCNF2 register is 1, on the other hand, the average interval (in cycles) is floor (REFINT[15:0]/2). This average interval is hereafter referred to as REFINT_E. Thus, REFINT_E = REFINT >> REFINTS (>>: logical right-shift operator).

Register set value and refresh issue timing

Setting example of refresh set register 1~2 and refresh issue timing at that time is explained.

a ± b indicates the range of above a-|b and below a+b.

For REFINT[15:0] set the discarded value in integer that shows an average refresh interval (t_{REFI} in Normal Operating Temperature Range) mentioned in data sheet of memory vendor by number of cycles. REFINTS sets 0 or 1 according to temperature.

In this case, considering n as right integer, time from refresh issue till refresh issue after that n refresh will be below n x REFINT_E + REFPMAX x REFINT_E cycle. However, it is assumed that there will be no writing to DBRFEN register within this period.

The setting value should meet the following criteria:

REFINT ≥ (TCALRZ + TCALZR + REFTHFx2) << REFINTS

16.3.1.34 DBRFCNF2 – Refresh configuration register 2

DBRFCNF2 is used to set the timing for refreshing of the SDRAM.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + $0E8_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	REFPMIN[3:0			
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	REFINTS
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 16.44 DBRFCNF2 register contents

Bit position	Bit name	Function
31 to 20	Reserved	Reading returns the initial value. When written, write the initial value.
19 to 16	REFPMIN[3:0]	Minimum post number of refresh commands setting 1_H: 1 All others: Setting prohibited
15 to 1	Reserved	Reading returns the initial value. When written, write the initial value.
0	REFINTS	Average refresh interval adjustment bits 0: Average refresh interval is REFINT[15:0] 1: Average refresh interval is 1/2 of REFINT[15:0]

If you change the value of this register while auto-refresh is active (i.e. the ARFEN bit in the DBRFEN register is 1), the auto-refresh facility must be re-activated to reflect the new value in refreshing. To re-activate the auto-refresh facility, write 1 to the ARFEN bit in the DBRFEN register.

REFPMIN[3:0] (minimum post number of refresh commands setting)

These bits are always read as 0. The write value should always be 0. If a value other than 0 is written, correct operation cannot be guaranteed.

REFINTS (Average refresh interval adjustment)

When this bit is 0, the average interval (in cycles) is the value set in the REFINT[15:0] bits. When this bit is 1, on the other hand, the average interval (in cycles) is floor (REFINT[15:0]/2).

16.3.1.35 DBRNK0 – ODT operation configuration register 0

This register is used to control ODT enable/disable.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 100_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	RODT OUT0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 16.45 DBRNK0 register contents

Bit position	Bit name	Function
31 to 17	Reserved	Reading returns the initial value. When written, write the initial value.
16	RODTOUT0	The value of this bit determines the level of the SDRBODT output signal during read: 0: SDRBODT signal at low level during read 1: SDRBODT signal at high level during read
15 to 1	Reserved	Reading returns the initial value. When written, write the initial value.
0	WODTOUT0	The value of this bit determines the level of the SDRBODT output signal during write: 0: SDRBODT signal at low level during write 1: SDRBODT signal at high level during write

16.3.1.36 DBPDNCNF – Power down configuration register

This register is used to control the SDRAM power-down mode.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 180_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 16.46 DBPDNCNF register contents

Bit position	Bit name	Function
31 to 16	Reserved	Reading returns the initial value. When written, write the initial value.
15 to 8	PDWAIT[7:0]	SDRAM power down wait 10_H: 16 cycles 11_H: 17 cycles ... FF_H: 255 cycles All others: Setting prohibited PDWAIT[7:0] sets the number of cycles it takes to enter power-down mode after memory accesses no longer occur.
7 to 5	Reserved	Reading returns the initial value. When written, write the initial value.
4	PDDLL	SDRAM power down DLL control 0: DLL is turned off at a precharged power-down. DLL is turned on at an active power-down 1: DDR2: DLL is turned off at a power-down. PDDLL turns on or off the DLL of SDRAM when entering power-down mode.
3 to 2	Reserved	Reading returns the initial value. When written, write the initial value.
1 to 0	PDMODE[1:0]	SDRAM power down mode 00_B: Auto power-down mode is off 01_B: Auto power-down mode is on All others: Setting prohibited if PDMODE[1:0] = 01_B and there has been no memory access for a certain period, the CKE pin is set to the low level causing SDRAM to enter a power-down mode.

16.3.1.37 DBPDCNT0 – PHY control register 0

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 200_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.49 DBPDCNT3 register contents

Bit position	Bit name	Function
31 to 29	Reserved	Reading returns the initial value. When written, write the initial value.
28	DB_STBY	Control of PHY standby release 0: enter standby state 1: release standby state
27 to 0	Reserved	Reading returns the initial value. When written, write the initial value.

16.3.2 SDRAM bus control registers

16.3.2.1 DBBS0CNT1 – Bus control unit 0 control register 1

This register is used for bank address position.

CAUTION

Writing to this register is only permitted, when SDRAM access is disabled (DBACEN.ACCEN = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + 304_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 16.50 DBBS0CNT1 register contents

Bit position	Bit name	Function
31 to 8	Reserved	Reading returns the initial value. When written, write the initial value.
7 to 2	BKADP0[5:0]	Address position for bank of RANK0 Refer to Section 16.6.2, Relation between external SDRAM and logical addresses for details.
1 to 0	Reserved	Reading returns the initial value. When written, write the initial value.

16.3.3 Dynamic priority control registers

16.3.3.1 DBLGCNTi – Dynamic Priority Generator control register

This register allows to select the different operation modes of the Dynamic Priority Generator i.

CAUTION

This register must only be changed while the Dynamic Priority Generator is disabled (DBLGQONi = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + n x 100_H + 1000_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	UDF CLR	0	0	0	0	0	0	0	RGLMD
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	0	0	0	0	0	0	0	LDMD	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

Table 16.51 DBLGCNTi register contents

Bit position	Bit name	Function
31 to 25	Reserved	When read, the value after reset is returned. When written to these bits, write the value after reset.
24	UDFCLR	QoS counter underflow bit clear 0: no function 1: clear bit of DBLGSTSi.UDF bit
23 to 17	Reserved	When read, the value after reset is returned. When written to these bits, write the value after reset.
16	RGLMD	Selection of condition for QoS counter operation state transition (Active state → Idle state) 0: State transition with number of requests 1: State transition with number of transferred bytes
15 to 9	Reserved	When read, the value after reset is returned. When written to these bits, write the value after reset.
8	LDMD	QoS counter reload mode selection 0: QoS counter reload without carry-over function 1: QoS counter reload with carry-over function
7 to 2	Reserved	When read, the value after reset is returned. When written to these bits, write the value after reset.
1	Bit 1	The default value “0” of this bit must not be changed.
0	Bit 0	The default value “0” of this bit must not be changed.

16.3.3.2 DBTMVAL0i – QoS counter initial value register

This register sets the initial value of the QoS counter of the Dynamic Priority Generator i.

CAUTION

This register must only be changed while the Dynamic Priority Generator is disabled (DBLGQONi = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + n x 100_H + 1004_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	0	0	CTSET[13:0]													
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.52 DBTMVAL0i register contents

Bit position	Bit name	Function
31 to 14	Reserved	When read, the value after reset is returned. When written to these bits, write the value after reset.
13 to 0	CTSET[13:0]	QoS counter initial value Allowed setting range: • CTSET[13:0] = 2001_H to $3FFF_H$ corresponds to QoS counter value 1 to 8191 • all other settings are prohibited

16.3.3.3 DBRQCTRi – QoS counter operation state transition condition register

This register defines the number of request or bytes, respectively, to change the QoS counter operation state from count to idle of the Dynamic Priority Generator i.

CAUTION

This register must only be changed while the Dynamic Priority Generator is disabled (DBLGQONi = 0).

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + n x 100_H + 1014_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	RQCTR[13:0]													
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.53 DBRQCTRi register contents

Bit position	Bit name	Function
31 to 14	Reserved	When read, the value after reset is returned. When written to these bits, write the value after reset.
13 to 0	RQCTR[13:0]	QoS counter operation state transition condition RQCTR[13:0] defines the number of • requests, if DBLGCNTi.RGLMD = 0 • bytes, if DBLGCNTi.RGLMD = 1 to change the QoS operation state from active to idle.

16.3.3.4 DBTHRES0i, DBTHRES1i, DBTHRES2i – Priority level threshold registers

This register defines the thresholds for changing the priority level of the Dynamic Priority Generator i.

CAUTION

This register must only be changed while the Dynamic Priority Generator is disabled (DBLGQONi = 0).

Access: This register can be accessed in 32-bit units.

Address: DBTHRES0i: <SDRBn_base> + n x 100_H + 1018_H
DBTHRES1i: <SDRBn_base> + n x 100_H + $101C_H$
DBTHRES2i: <SDRBn_base> + n x 100_H + 1020_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	CTTHRES[13:0]													
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.54 DBTHRES0i, DBTHRES1i, DBTHRES2i register contents

Bit position	Bit name	Function
31 to 14	Reserved	When read, the value after reset is returned. When written to these bits, write the value after reset.
13 to 0	CTTHRES[13:0]	Priority level generation threshold CTTHRES[13:0] = 0000_H to $3FFF_H$ corresponds to threshold value -8192 to 8191

16.3.3.5 DBLGSTSi – Dynamic Priority Generator status register

This register holds various status information about the Dynamic Priority Generator i.

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + n x 100_H + 1024_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	UDF	0	0	0	0	0	0	0	REQ
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	CCT[13:0]													
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.55 DBLGSTSi register contents

Bit position	Bit name	Function
31 to 25	Reserved	When read, the value after reset is returned. When written to these bits, write the value after reset.
24	UDF	QoS counter underflow bit 0: no underflow 1: underflow UDF is set to 1 if the QoS counter reaches -8192 (that corresponds to CCT[13:0] = 0000_H). This bit can be cleared by setting DBLGCNTi.UDFCLR = 1.
23 to 17	Reserved	When read, the value after reset is returned. When written to these bits, write the value after reset.
16	REQ	Request detection bit 0: no request active on port i 1: request active on port i
15 to 14	Reserved	When read, the value after reset is returned. When written to these bits, write the value after reset.
13 to 0	CCT[13:0]	Present QoS counter value

16.3.3.6 DBLGQONi – Dynamic Priority Generator enable register

This register is used to enable or disable the Dynamic Priority Generator i.

Access: This register can be accessed in 32-bit units.

Address: <SDRBn_base> + n x 100_H + 1028_H

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	QON
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 16.56 DBLGQONi register contents

Bit position	Bit name	Function
31 to 1	Reserved	When read, the value after reset is returned. When written to these bits, write the value after reset.
0	QON	Dynamic Priority Generator enable/disable 0: Dynamic Priority Generator disabled 1: Dynamic Priority Generator enabled

16.4 DDR2-SDRAM Operation

16.4.1 Initial sequence

The following sequence enables SDRAM access after power-up.

NOTE

The sequence may vary with the specification of used memory.

1st setting of SDRB

(1) The type of memory is set through SDRAM type setting register DBKIND.

(2) Setting of the
- SDRAM configuration register DBCONF0
- SDRAM timing registers DBTR0, DBTR1 and DBTR3 to DBTR18
- SDRAM burst length register DBBL
- ODT operation configuration register 0 DBRNK0
- SDRB operation adjustment register 0 DBADJ0
- SDRB operation adjustment register 2 DBADJ2
- Dynamic Priority Generators related registers

is performed.

(3) Setting of the
- PHY control registers DBPDCNT0, DBPDCNT1, DBPDCNT3

(4) Release the PHY macro reset by MRSTC.SDRB0RES

DDR2-SDRAM setting

(1) The CKE terminal of all the ranks of the SDRAM is set to low by the manual SDRAM command register DBCMD with:
- OPC[5:0] = PDEn
- ARG[15:0] = 100 µs.

(2) Insert the wait time using the manual SDRAM command register DBCMD with:
- OPC[5:0] = Wait
- ARG[15:0] = 100 µs.

(3) The CKE terminal of the total rank of SDRAM is set to high by the manual SDRAM command register DBCMD with:
- OPC[5:0] = PDXt
- ARG[15:0] = 400 ns.

(4) PREA (pre-charge All) command is issued to RANK0 by manual SDRAM command register DBCMD with:

– OPC[5:0] = PreA
– ARG[15:0] = 0.

(5) The EMRS (MR2) command is issued to RANK0 by the manual SDRAM command register DBCMD.

(6) The EMRS (MR3) command is issued to RANK0 by the manual SDRAM command register DBCMD.

(7) The EMRS (MR1) command is issued to RANK0 by the manual SDRAM command register DBCMD. Additive Latency is set to 0, and DLL Enable is set to enable.

(8) The MRS (MR0) command is issued to RANK0 by the manual SDRAM command register DBCMD. In this case, the operation mode is set to Normal, DLL reset to reset, and burst type to sequential.
Perform following settings:
– burst length DBBL.BL[1:0]
– write recovery period DBTR10.TWR[3:0]
– power-down DLL control DBPDNCNF.PDDLL

(9) PREA (pre-charge All) command is issued to RANK0 by the manual SDRAM command register DBCMD with:
– OPC[5:0] = PreA
– ARG[15:0] = 0.

(10) REF (refresh) command is issued to RANK0 by the manual SDRAM command register DBCMD with:
– OPC[5:0] = Ref
– ARG[15:0] = 0.

(11) REF (refresh) command is issued to RANK0 by the manual SDRAM command register DBCMD with:
– OPC[5:0] = Ref
– ARG[15:0] = 0.

(12) The MRS (MR0) command is issued to RANK0 by the manual SDRAM command register DBCMD. In this case, perform the settings without the DLL reset.

(13) Insert the wait time using the manual SDRAM command register DBCMD with:
– OPC[5:0] = Wait
– ARG[15:0] = 200 cycles.

(14) The EMRS (MR1) command is issued to RANK0 by the manual SDRAM command register DBCMD. At this time, in addition, for the OCD calibration Program, set the value same as **(7)** to the OCD Calibration default.

(15) The EMRS (MR1) command is issued to RANK0 by the manual SDRAM command register DBCMD. At this time, in addition, for the OCD calibration Program, set a value same as **(7)** to the OCD Calibration mode exit.

2nd setting of SDRB

(1) If necessary, perform setting of bus control register 1 (DBBS0CNT1) and power-down configuration register (DBPDNCNF).

(2) Perform the setting of the refresh configuration registers DBRFCNF0 and DBRFCNF2).

(3) Enable SDRAM access by DBACEN.ACCEN = 1.

(4) Read the operation completion waiting register DBWAIT, and wait until a response is returned.

16.4.2 Power-down and -up sequence

If there is no need to access the SDRAM, it is possible to deactivate the internal clock of the SDRAM device and thereby reduce the power consumption of the device by changing to SDRAM power-down mode. Moreover, even in SDRAM power-down mode, the memory clock (SDRBCK/SDRBCKB) from the SDRB and the power to the SDRB and the SDRAM device must be supplied.

NOTE

The here mentioned SDRAM power-down mode must not be mixed up with the microcontroller's DEEPSTOP mode.

Power-down sequence

(1) Disable SDRAM access by DBACEN.ACCEN = 0.

(2) The Power Down Entry command is issued by the SDRAM manual command register DBCMD with:
- OPC[5:0] = PDEn
- ARG[15:0] = 0.

Power-up sequence

(1) The Power Down Exit command is issued by the SDRAM manual command register DBCMD with:
- OPC[5:0] = PDXt
- ARG[15:0] = 0.

(2) Enable SDRAM access by DBACEN.ACCEN = 1.

In order to hold the SDRAM data in the SDRAM power-down mode, it is necessary to issue a regular refresh command as during normal operation.

Any attempt to access any SDRAM data during power-down mode results in an error and the DBSVCR.INACTIVE error flag is set.

16.5 Dynamic Priority Generator and Arbitration

The Priority Generators and the Arbiter rule the access of the cross-connect masters to the DDR2-SDRAM Memory Controller.

The Arbiter finally grants access to the DDR2-SDRAM, based on various criteria, refer to Section 16.5.7, Arbiter operation for details.

The main criterion for the Arbiter is the priority level.
The Dynamic Priority Generators generate this priority level. It provides facilities to change the priority level dynamically in order to assign sufficient SDRAM bandwidth for the various master.

Each of the four ports has two Priority Generators, one handles the read, the other the write requests. Throughout this section the individual Priority Generators are identified by the index i (i = 0 to 7) with following assignment:

- i = 0: port 0 read (Port 0R Priority Generator)
- i = 1: port 1 read (Port 1R Priority Generator)
- i = 2: port 2 read (Port 2R Priority Generator)
- i = 3: port 3 read (Port 3R Priority Generator)
- i = 4: port 0 write (Port 0W Priority Generator)
- i = 5: port 1 write (Port 1W Priority Generator)
- i = 6: port 2 write (Port 2W Priority Generator)
- i = 7: port 3 write (Port 3W Priority Generator)

The following diagram shows the connections between the cross-connects, Priority Generators, Arbiter and DDR2-SDRAM Memory Controller.

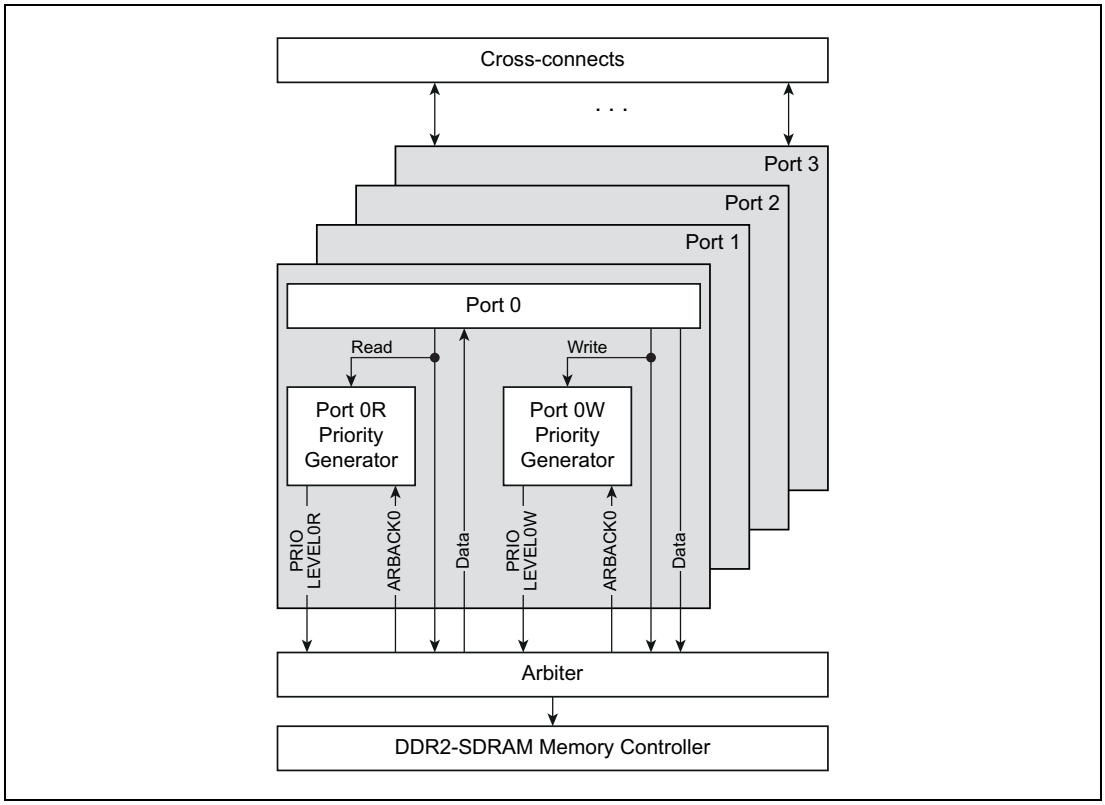

Figure 16.1 Priority Generators connection

The following diagram shows the main functional blocks of the Dynamic Priority Generators.

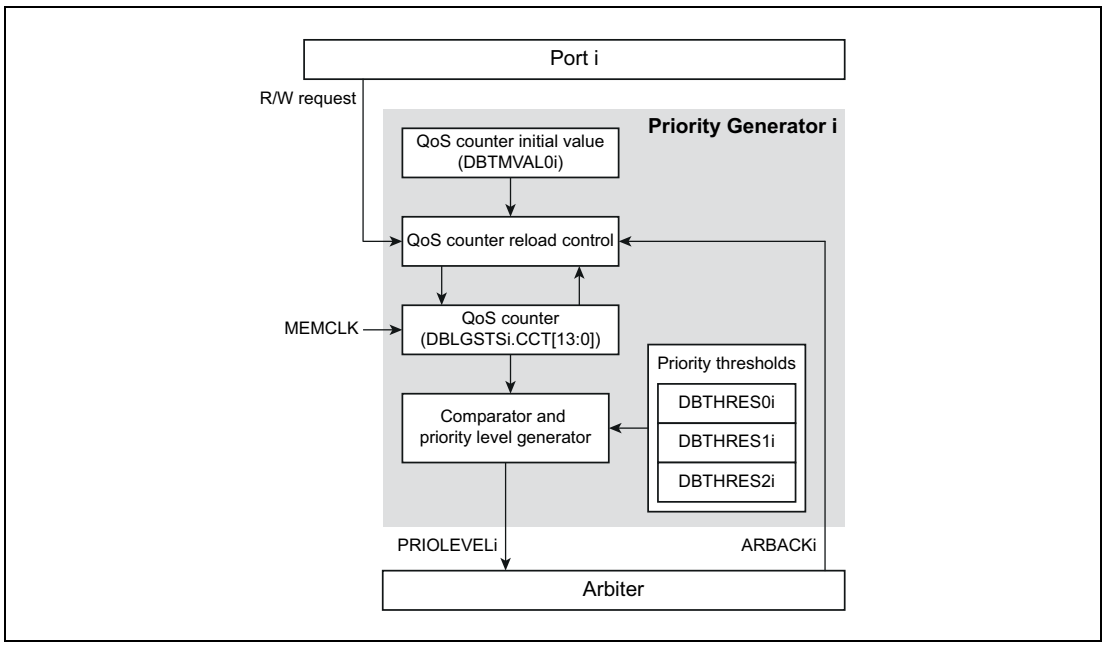

Figure 16.2 Dynamic Priority Generator block diagram

16.5.1 Dynamic priority control principle

The priority level of a port is dynamically changed over the time. The QoS counter DBLGSTi.CCT[13:0] is used as the time base. It starts counting down from a port specific start value with a data transfer request applied to its port.
At each point in time the counter value DBLGSTSi.CCT[13:0] is compared with three threshold values DBTHRES[2:0]i.CTTHRES[13:0]. The compare result defines the priority level PRIOLEVELi:

- DBLGSTSi.CCT[13:0] ≥ DBTHRES0i.CTTHRES[13:0]: PRIOLEVELi = 0
- DBTHRES0i.CTTHRES[13:0] > DBLGSTSi.CCT[13:0] ≥ DBTHRES1i.CTTHRES[13:0]: PRIOLEVELi = 1
- DBTHRES1i.CTTHRES[13:0] > DBLGSTSi.CCT[13:0] ≥ DBTHRES2i.CTTHRES[13:0]: PRIOLEVELi = 2
- DBTHRES2i.CTTHRES[13:0] > DBLGSTSi.CCT[13:0]: PRIOLEVELi = 3

The following diagram illustrates this process by using port 0 and 1 as examples.

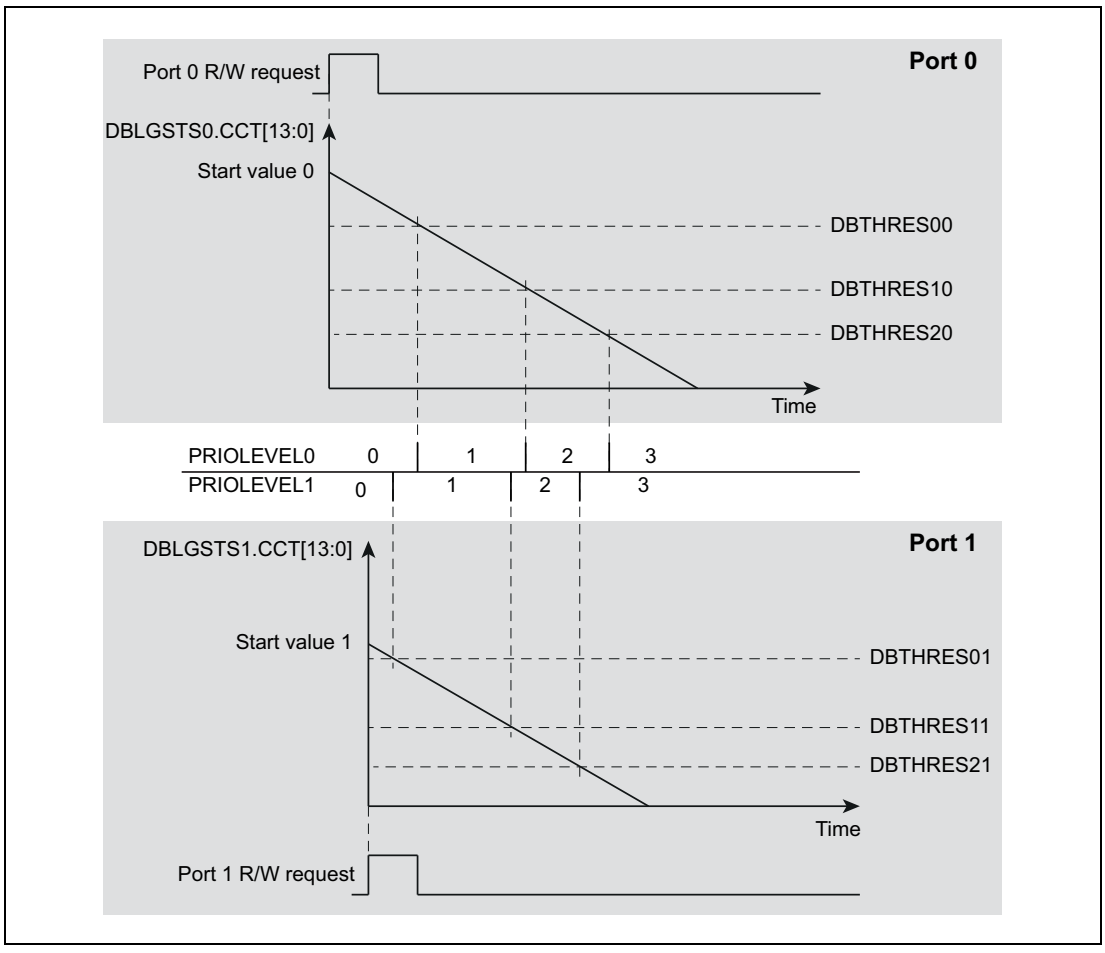

Figure 16.3 Dynamic priority control principle

The priority level of each port's R/W request at each point in time is determined by the

- start value of the QoS counter DBTMVAL0i.CTSET[13:0]
- priority threshold values DBTHRES[2:0]i.CTTHRES[13:0]

Thus adapting the start value and the thresholds means adjusting the priority as a function in time, and thus the waiting time for R/W request to be served.

Basically,

- higher thresholds mean higher priority, and thus lower waiting time for service
- higher start value means lower priority, and thus higher waiting time for service

16.5.2 Priority control by threshold adaptation

The threshold registers DBTHRES[2:0]i.CTTHRES[13:0] must only be changed by the application software, when the Priority Generator is disabled ((DBLGQONi.QON = 0).

The values of the thresholds CTTHRES[13:0] ranges
from -8192 (CTTHRES[13:0] = 0000_H) to +8191 (CTTHRES[13:0] = $3FFF_H$).

16.5.3 Enabling the Priority Generator

By default the Priority Generator is disabled (DBLGQONi.QON = 0) issues priority level PRIOLEVELi = 0.
The Priority Generator i is enabled by DBLGQONi.QON = 1.

CAUTION

The control bits RGLMD and LDMD in the dynamic priority level generation register DBLGCNTi must not be changed while the Priority Generator is enabled (DBLGQONi.QON = 1).

16.5.4 QoS counter states

The QoS counter has two operation states (provided it is enabled by DBLGQONi.QON = 1):

- Active state: In active state the QoS counter counts down.
- Idle state: In idle state the QoS counter holds the value 0 and does not count down.

The transition from idle state to active state is initiated upon a R/W request from the port.

The transition from active to idle state is performed when a certain number of requests have been served or a certain number of bytes have been transferred consecutively via one port.

The number of R/W requests or transferred bytes can be set for each Priority Generator i:

- DBLGCNTi.RGLMD = 0: QoS active-to-idle transition after DBRQCTRi.RQCTR[15:0] number of served requests
- DBLGCNTi.RGLMD = 1: QoS active-to-idle transition after DBRQCTRi.RQCTR[15:0] number of transferred bytes

16.5.5 Dynamic Priority Generator status information

The DBLGSTSi register holds various status information:

DBLGSTSi.UDF: QoS counter underflow

The count values of the QoS counter DBLGSTi.CCT[13:0] ranges
from -8192 (CCT[13:0] = 0000_H)
via 0 (CCT[13:0] = 2000_H)
to +8191 (CCT[13:0] = $3FFF_H$).

If a R/W request is received from the port, while the counter underflows (counter value ≤ 0, i.e. CCT[13:0] ≤ 2000_H), the QoS counter underflow bit DBLGSTSi.UDF is set.

Once set, this bit is not automatically cleared, but can be cleared by the application program by setting DBLGCNTi.UDFCLR = 1.

DBLGSTSi.REQ: R/W request status

REQ = 1 indicates, that a R/W request has been received from the port and pending or under process.

DBLGSTSi.CCT[13:0]: QoS counter value

CCT[13:0] holds the current value of the QoS counter.

16.5.6 Priority control by QoS counter start value adaptation

16.5.6.1 QoS counter reload modes

The reload of the start value of the QoS counter DBLGSTi.CCT[13:0] can operate in two different modes:

- DBLGCNTi.LDMD = 0: reload without carry-over function
- DBLGCNTi.LDMD =1: reload with carry-over function

QoS counter initial value

In both modes the QoS counter is set to an initial value at the first R/W request after enabling the Dynamic Priority Generator.

The initial value is defined by the CTSET[13:0] bits in the DBTMVAL0i register.
The initial value must not define a negative counter value, thus the allowed range is
from 1 (CTSET[13:0] = 2001_H)
to +8191 (CTSET[13:0] = $3FFF_H$).

16.5.6.2 QoS counter reload without carry-over function (DBLGCNTi.LDMD = 0)

In this mode the QoS counter is always reloaded with its
initial value DBTMVALi.CTSET[13:0]
upon R/W request.

In normal case, all data transfers via the DDR2-SDRAM Memory Controller, related to the R/W request, are completed within the QoS count time from it's initial value DBTMVALi.CTSET[13:0] down to 0. If these data transfers could not be completed within this time, the QoS counter underflow bit DBLGSTSi.UDF is set.

The following diagram explains the QoS counter behaviour under different circumstances.

The example in the diagram assumes, that each R/W request generates two data transfers (1, 2) via the DDR2-SDRAM Memory Controller and thus the Memory Controller arbiter replies two acknowledges (ARBACK) upon completion of each transfer.

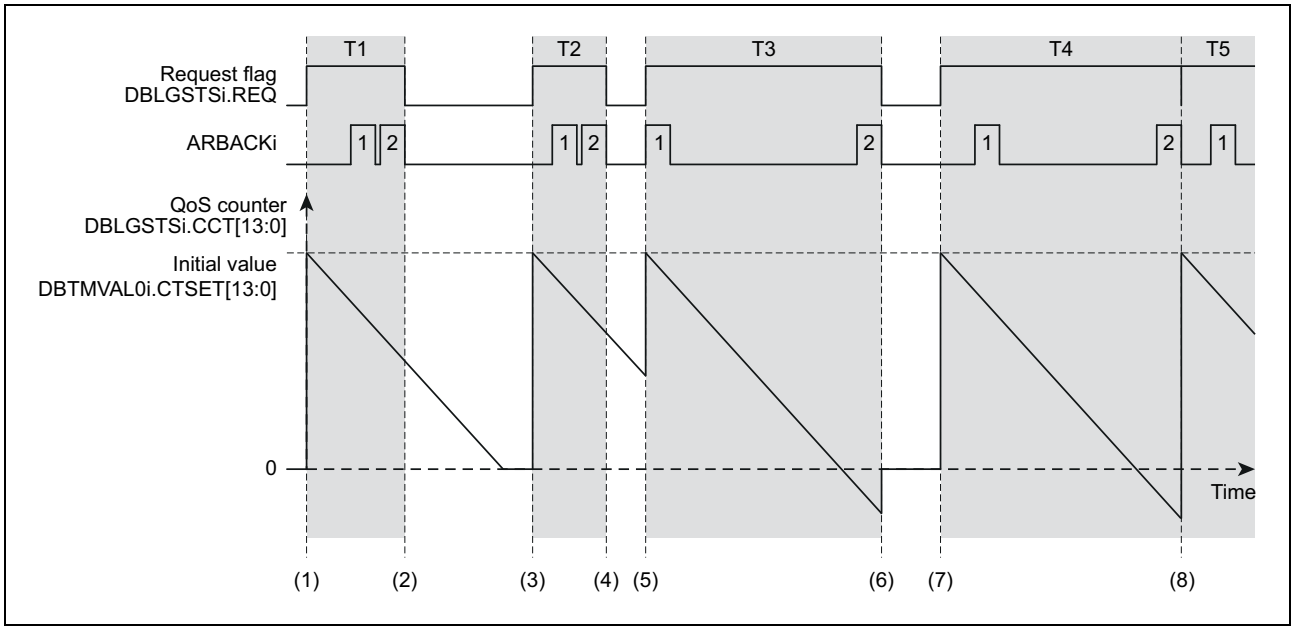

Figure 16.4 QoS counter reload without carry-over function examples

(1) The first R/W request starts the T1 transfer.
The QoS counter DBLGSTi.CCT[13:0] is loaded with the initial value DBTMVALi.CTSET[13:0] and starts counting down.

(2) After the arbiter has acknowledged both transfers (1, 2) T1 is completed.
The QoS counter counts down to 0 and remains there until the next R/W request, i.e. stays in idle state.

(3) The next R/W request initiates the T2 transfer.
The QoS counter DBLGSTi.CCT[13:0] is loaded with the initial value DBTMVALi.CTSET[13:0] and starts counting down.

(4) T2 is completed.

(5) Before the QoS counter reaches 0 a new T3 transfer is initiated.
The QoS counter is reloaded with the initial value and counts down.

(6) T3 is completed while the QoS counter underflows, i.e. the count value is < 0.

(7) The next R/W request initiates the T4 transfer.
The QoS counter DBLGSTi.CCT[13:0] is loaded with the initial value DBTMVALi.CTSET[13:0] and starts counting down.

(8) T4 is completed during QoS counter underflow and the next transfer T5 is started immediately.
The QoS counter is reloaded with the initial value and starts count-down.

16.5.6.3 QoS counter reload with carry-over function (DBLGCNTi.LDMD = 1)

In this mode the QoS counter is reloaded with the
DBTMVALi.CTSET[13:0] plus the current QoS counter value
upon R/W request.

Thus a R/W request, that occurs

- while the QoS counter has not reached 0 after the previous transfer, results in a higher QoS counter start value, i.e. lower priority and longer service waiting time, see change from T2 to T3 transfer in **Figure 16.5**
- during an underflow of the QoS counter results in a lower QoS counter start value, i.e. higher priority and shorter service waiting time, see change from T4 to T5 transfer in **Figure 16.5**

The following diagram explains the QoS counter behaviour under different circumstances.

The example in the diagram assumes, that each R/W request generates two data transfers (1, 2) via the DDR2-SDRAM Memory Controller and thus the Memory Controller arbiter replies two acknowledges (ARBACK) upon completion of each transfer.

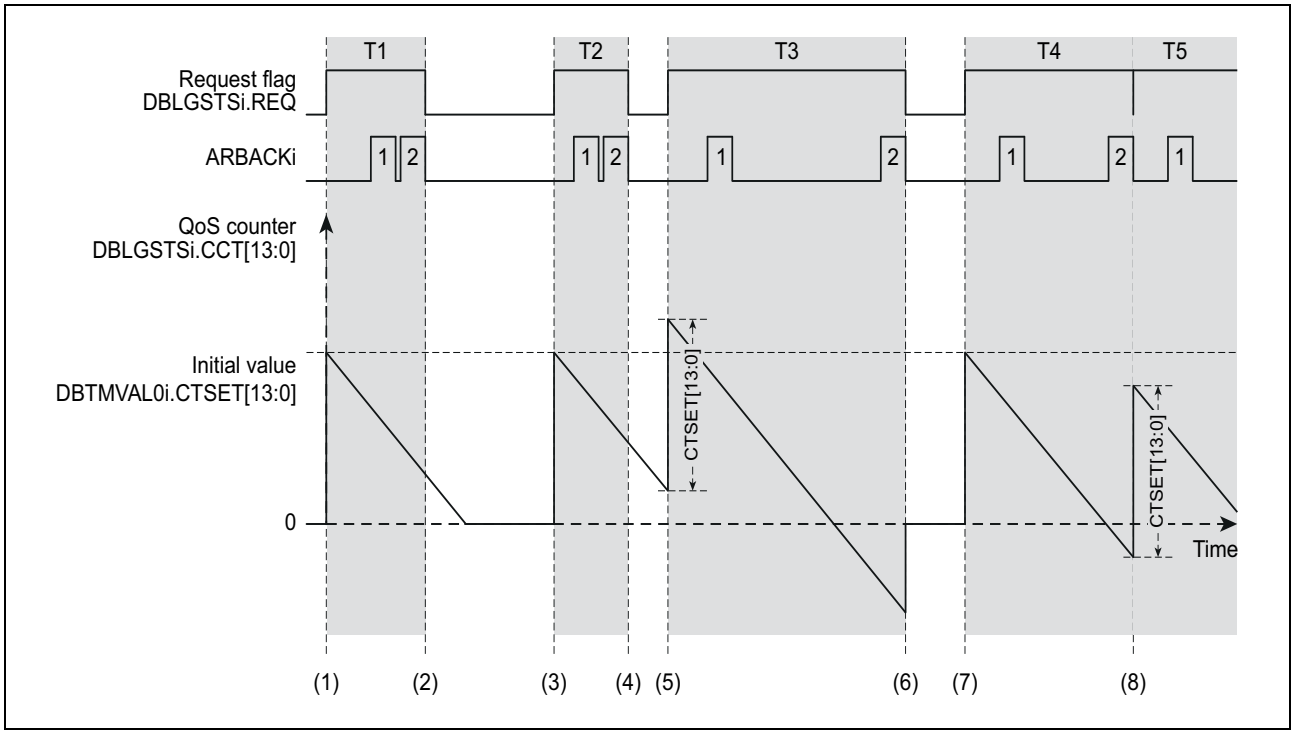

Figure 16.5 QoS counter reload with carry-over function examples

(1) The first R/W request starts the T1 transfer.
The QoS counter DBLGSTi.CCT[13:0] is loaded with the initial value DBTMVALi.CTSET[13:0] and starts counting down.

(2) After the arbiter has acknowledged both transfers (1, 2) T1 is completed.
The QoS counter continues to count down.

(3) The next R/W request initiates the T2 transfer.
The QoS counter is reloaded with the remaining counter value (here 0) plus the DBTMVALi.CTSET[13:0] value and starts count-down.

(4) T2 is completed.

(5) Before the QoS counter reaches 0 a new T3 transfer is initiated.
The QoS counter is reloaded with the remaining counter value plus the DBTMVALi.CTSET[13:0] value and starts count-down.

(6) T3 is completed while the QoS counter underflows, i.e. the count value is < 0.
The counter value is set to 0.

(7) The next R/W request initiates the T4 transfer.
The QoS counter is reloaded with the remaining counter value (here 0) plus the DBTMVALi.CTSET[13:0] value and starts count-down.

(8) T4 is completed during QoS counter underflow and the next transfer T5 is started immediately.
The QoS counter is reloaded with the remaining counter value (here a negative value) plus the DBTMVALi.CTSET[13:0] value and starts count-down.

16.5.7 Arbiter operation

The arbiter selects the port of the next transaction along the follow list of criteria:

(1) Serve the request with the largest priority level PRIOLEVELi.

(2) If multiple requests fulfil above criterion, serve the request with the same R/W direction as the previously served request.

(3) If multiple requests fulfil all above criteria, serve the request with access to the same SDRAM bank as the previously served request.

(4) If multiple requests fulfil all above criteria, serve the request with different access size than with the previous access. I.e. the request, that has changed its access size, gets higher priority and will be served.

(5) If multiple requests fulfil all above criteria, serve the request with the smaller port number i.

Section 17 Serial Flash Memory Interface A (SFMA)

This section contains a generic description of the Serial Flash Memory Interface A.

The first section describes all properties specific to the RH850/D1L/D1M, such as units, register base addresses, input/output signal names, etc.
The subsequent sections describe the features that apply to all implementations.

17.1 Overview of RH850/D1L/D1M Serial Flash Memory Interface A

17.1.1 Units

This microcontroller has the following number of units of the Serial Flash Memory Interface A.

Table 17.1 Units

Serial Flash Memory Interface A (SFMA)	D1L1 D1L2(H)	D1M1(H)	D1M1-V2	D1M1A	D1M2(H)
Units	1	1	2	3	1
Names	SFMA0	SFMA0	SFMA0, SFMA1	SFMA0, SFMA1, SFMA2	SFMA0

Units index n

Throughout this section, the individual units of a Serial Flash Memory Interface A is identified by the index "n" (n = 0), for example SFMAnCMNCR for the SFMAn common control register.

17.1.2 Register addresses

All Serial Flash Memory Interfaces A register addresses are given as address offsets from the individual base addresses <SFMAn_base>.
The <SFMAn_base> addresses of each SFMAn are listed in the following table:

Table 17.2 Register base addresses <SFMAn_base>

SFMAn unit	<SFMAn_base> address
SFMA0	F2FF 0000_H
SFMA1*1	F2FF 1000_H
SFMA2*1	

Note 1. SFMA1 and SFMA2 cannot be used concurrently. One of them must be selected by XCRAMCFG0.SFMASEL. Refer to Section 14.4, Bus Switch for external memory interfaces (D1M1-V2, D1M1A only) for details.

17.1.3 Clock supply

All Serial Flash Memory Interfaces A provide two clock inputs.

Table 17.3 Clock supply

SFMAn unit	SFMAn clock	Connected to
SFMA0 SFMA2	BΦ	Clock Controller CKSC_ISFMAD_CTL clock divider output
	PHCLK	Clock Controller CKSC_ISFMAS_CTL clock selector output
SFMA1	BΦ	Clock Controller CKSC_ISFMAD_CTL clock divider output divided by 2
	PHCLK	Clock Controller CKSC_ISFMAS_CTL clock selector output divided by 2

17.1.4 Reset sources

The Serial Flash Memory Interfaces A and their registers are initialized by the following reset signal:

Table 17.4 Reset sources

SFMAn unit	Reset signal
SFMAn	• Reset Controller SYSRES • reset upon wake-up from DEEPSTOP mode

17.1.5 I/O signals

The following table shows the I/O signals of the Serial Flash Memory Interfaces A.

Table 17.5 SFMAn I/O signals (1/2)

SFMAn signals	Function	Connected to
SFMA0		
SPBCLK	Clock output	Port SFMA0CLK
SPBSSL	Slave select signal output	Port SFMA0SSL
SPBMO0/ SPBIO00	Port 0 master transmit data/data 0	Port SFMA0I00
SPBMI0/ SPBIO10	Port 0 master input data/data 1	Port SFMA0I10
SPBIO20	Port 0 data 2	Port SFMA0I20
SPBIO30	Port 0 data 3	Port SFMA0I30
SPBMO1/ SPBIO01	Port 1 master transmit data/data 0	Port SFMA0I01
SPBMI1/ SPBIO11	Port 1 master input data/data 1	Port SFMA0I11
SPBIO21	Port 1 data 2	Port SFMA0I21
SPBIO31	Port 1 data 3	Port SFMA0I31
SFMA1		
SPBCLK	Clock output	Port SFMA1CLK
SPBSSL	Slave select signal output	Port SFMA1SSL
SPBMO0/ SPBIO00	Port 0 master transmit data/data 0	Port SFMA1I00
SPBMI0/ SPBIO10	Port 0 master input data/data 1	Port SFMA1I10
SPBIO20	Port 0 data 2	Port SFMA1I20
SPBIO30	Port 0 data 3	Port SFMA1I30
SPBMO1/ SPBIO01	Port 1 master transmit data/data 0	Port SFMA1I01
SPBMI1/ SPBIO11	Port 1 master input data/data 1	Port SFMA1I11
SPBIO21	Port 1 data 2	Port SFMA1I21
SPBIO31	Port 1 data 3	Port SFMA1I31
SFMA2		
SPBCLK	Clock output	Port SFMA2CLK
SPBSSL	Slave select signal output	Port SFMA2SSL
SPBMO0/ SPBIO00	Port 0 master transmit data/data 0	Port SFMA2I00

Table 17.5 SFMAn I/O signals (2/2)

SFMAn signals	Function	Connected to
SPBMI0/ SPBIO10	Port 0 master input data/data 1	Port SFMA2I10
SPBIO20	Port 0 data 2	Port SFMA2I20
SPBIO30	Port 0 data 3	Port SFMA2I30

17.2 Features

The Serial Flash Memory Interface outputs control signals to the serial flash memory connected to the SPI multi I/O bus space, thus enabling direct connection of the serial flash memory.

This module allows the connected serial flash memory to be accessed by directly reading the SPI multi I/O bus space, or using SPI operating mode to transmit and receive data.

- Serial Flash Memory Interface
  One serial flash memory device can be connected to each port
  A data bus size of 1 bit, 2 bits, or 4 bits can be selected for one serial flash memory device.
  Serial flash memory for DDR transfer can be directly connected.
- External Address Space Read Mode
  A maximum of 8-Gbyte address space is supported (when two serial flash memories are connected)
  The SPBSSL pin can be automatically controlled through access address monitoring
  Efficient data reception due to built-in read cache (64-bit line × 16 entries)
- SPI Operating Mode
  Desired read/write access to serial flash memory possible
- Bit rate
  SPBCLK is generated by frequency division of Bϕ by internal baud rate generator
  SPBCLK frequency division ratio can be set from 2 to 4080
- SPBSSL Pin Control
  Delay from SPBSSL signal assertion to SPBCLK operation (clock delay) can be set
  Range: 1 to 8 SPBCLK cycles (set in SPBCLK-cycle units)
  Delay from SPBCLK stop to SPBSSL output negation (SPBSSL negation delay) can be set
  Range: 1.5 to 8.5 SPBCLK cycles (set in SPBCLK-cycle units)
  SPBSSL output assertion wait before next access (next access delay) can be set
  Range: 1 to 8 SPBCLK cycles (set in SPBCLK-cycle units)
  SPBSSL polarity can be changed

17.3 Block Diagram

The following figure shows a block diagram of this module for one channel.

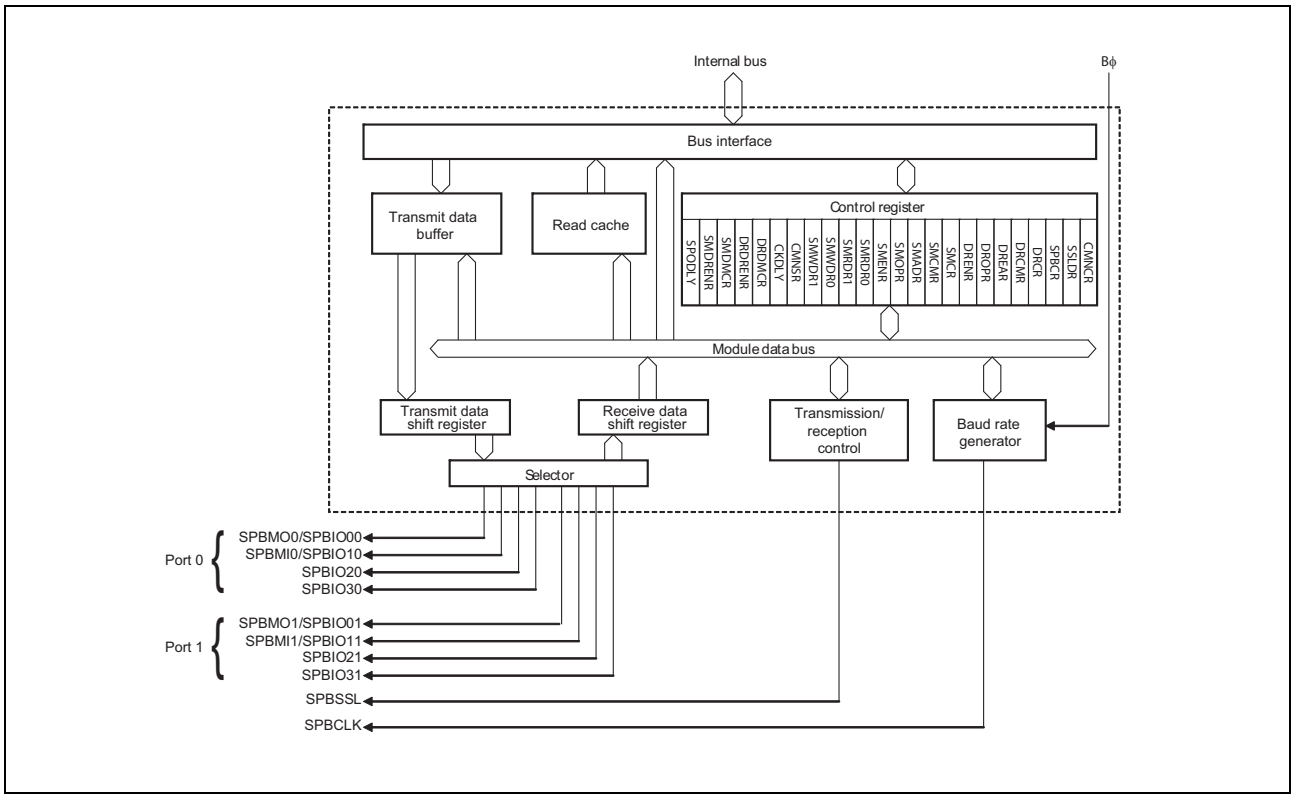

Figure 17.1 Block Diagram

17.4 Register Descriptions

The following table shows the register configuration.

Table 17.6 Register Configuration

Module Name	Register Name	Symbol	Initial Value	R/W	Address	Access Size
SFMAn	Common control register	CMNCR	H'01AA4000	R/W	<SFMAn_base> + 00_H	32
SFMAn	SSL delay register	SSLDR	H'00070707	R/W	<SFMAn_base> + 04_H	32

<SFMAn_base>

The base addresses <SFMAn_base> of the SFMAn is defined in the first subsection of this section under the key word “Register addresses”.

NOTE

In the header files the names of the above registers are defined in the following format:

<ModuleName> + <Symbol>.

<ModuleName> and <Symbol> are defined in the above table.

17.4.1 Common Control Register (CMNCR)

CMNCR is a 32-bit register that controls the SPI multi I/O bus controller. The settings of this register are reflected both in external address space read mode and SPI operating mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
31	MD	0	R/W	Operating Mode Switch Switches the operating modes. 0: External address space read mode 1: SPI operating mode
30 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	SFDE	1	R/W	Data Swap Setting for Serial Flash Memory Specifies whether or not swapping of data in serial flash memory is performed. 0: Swapping is not performed. 1: Swapping is performed in 8-bit units. For details, see Section 17.5.4, Data Alignment.
23, 22	MOIIO3[1:0]	10	R/W	SPBSSL Output Idle Value Fix SPBIO30, SPBIO31 Fixes output values of SPBIO30 and SPBIO31 in SPBSSL negation period. 00: Output value 0 01: Output value 1 10: Output value is the value of the immediately previous bit (or the pin is Hi-Z, if Hi-Z was the state in the immediately previous bit period). 11: Output value Hi-Z
21, 20	MOIIO2[1:0]	10	R/W	SPBSSL Output Idle Value Fix SPBIO20, SPBIO21 Fixes output values of SPBIO20 and SPBIO21 in SPBSSL negation period. 00: Output value 0 01: Output value 1 10: Output value is the value of the immediately previous bit (or the pin is Hi-Z, if Hi-Z was the state in the immediately previous bit period). 11: Output value Hi-Z
19, 18	MOIIO1[1:0]	10	R/W	SPBSSL Output Idle Value Fix SPBIO10, SPBIO11 Fixes output values of SPBIO10 and SPBIO11 in SPBSSL negation period. 00: Output value 0 01: Output value 1 10: Output value is the value of the immediately previous bit (or the pin is Hi-Z, if Hi-Z was the state in the immediately previous bit period). 11: Output value Hi-Z

Bit	Bit Name	Initial Value	R/W	Description
17, 16	MOIIO0[1:0]	10	R/W	SPBSSL Output Idle Value Fix SPBIO00, SPBIO01 Fixes output values of SPBIO00 and SPBIO01 in SPBSSL negation period. 00: Output value 0 01: Output value 1 10: Output value is the value of the immediately previous bit (or the pin is Hi-Z, if Hi-Z was the state in the immediately previous bit period). 11: Output value Hi-Z
15, 14	IO3FV[1:0]	01	R/W	SPBIO30, SPBIO31 Fixed Value for 1-bit/2-bit Size Fixes the output value of SPBIO30 and SPBIO31 pins for 1-bit/2-bit size. 00: Output value 0 01: Output value 1 10: Output value is the value of the immediately previous bit (or the pin is Hi-Z, if Hi-Z was the state in the immediately previous bit period). 11: Output value Hi-Z
13, 12	IO2FV[1:0]	00	R/W	SPBIO20, SPBIO21 Fixed Value for 1-bit/2-bit Size Fixes the output value of SPBIO20 and SPBIO21 pins for 1-bit/2-bit size. 00: Output value 0 01: Output value 1 10: Output value is the value of the immediately previous bit (or the pin is Hi-Z, if Hi-Z was the state in the immediately previous bit period). 11: Output value Hi-Z
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	IO0FV[1:0]	00	R/W	SPBIO00, SPBIO01 Fixed Value for 1-bit Size Input Fixes the output value of SPBIO00 and SPBIO01 pins for 1-bit size input. 00: Output value 0 01: Output value 1 10: Output value is the value of the immediately previous bit (or the pin is Hi-Z, if Hi-Z was the state in the immediately previous bit period). 11: Output value Hi-Z
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	CPHAT	0	R/W	Output Shift Sets the SPBCLK edge of the output data. CPHAT and CPHAR should be set according to the table in the description of CPHAR. 0: Data transmission at even edge during SDR transfer Data transmission starts at even edge during DDR transfer. 1: Data transmission at odd edge during SDR transfer Data transmission starts at odd edge during DDR transfer.
5	CPHAR	0	R/W	Input Latch Sets the SPBCLK edge of the reception data. CPHAT and CPHAR should be set according to the following table. 0: Data reception at odd edge during SDR transfer Data reception starts at odd edge during DDR transfer. 1: Data reception at even edge during SDR transfer Data reception starts at even edge during DDR transfer

CPHAT	CPHAR	
0	0	Setting enabled
0	1	Setting enabled during SDR transfer
1	0	Setting prohibited
1	1	Setting enabled

Note: To set DDR transfer, set both the CPHAT and CPHAR bits to 0 or 1.

Bit	Bit Name	Initial Value	R/W	Description
4	SSLP	0	R/W	SPBSSL Signal Polarity Sets the polarity of SPBSSL signal. 0: Active low SPBSSL signal 1: Active high SPBSSL signal
3	CPOL	0	R/W	SPBSSL Negation Period SPBCLK Output Direction Sets the SPBCLK output direction during SPBSSL negation period. 0: SPBCLK output is 0 during SPBSSL negation period. 1: SPBCLK output is 1 during SPBSSL negation period.
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	BSZ[1:0]	00	R/W	Data Bus Size Specifies the number of serial flash memories to be connected. 00: 1 memory 01: 2 memories 1X: Setting prohibited Note: After changing (the value of) this bit, all the entries in the read cache must be cleared by setting the RCF bit in DRCR to 1.

17.4.2 SSL Delay Register (SSLDR)

SSLDR is a 32-bit register that adjusts the timing between the SPBSSL signal and the SPBCLK signal.

The settings of this register are reflected both in external address space read mode and SPI operating mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial value:	0	0	0	0	0	1	1	1	0	0	0	0	0	1	1	1
R/W:	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 19	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
18 to 16	SPNDL[2:0]	111	R/W	Next Access Delay Sets the period from transfer end to next transfer start (next access). 000: 1 SPBCLK cycle 001: 2 SPBCLK cycles 010: 3 SPBCLK cycles 011: 4 SPBCLK cycles 100: 5 SPBCLK cycles 101: 6 SPBCLK cycles 110: 7 SPBCLK cycles 111: 8 SPBCLK cycles
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 8	SLNDL[2:0]	111	R/W	SPBSSL Negation Delay Sets the period from the time the last SPBCLK edge is sent of a transfer to SPBSSL pin negation (SPBSSL negation delay). 000: 1.5 SPBCLK cycles 001: 2.5 SPBCLK cycles 010: 3.5 SPBCLK cycles 011: 4.5 SPBCLK cycles 100: 5.5 SPBCLK cycles 101: 6.5 SPBCLK cycles 110: 7.5 SPBCLK cycles 111: 8.5 SPBCLK cycles
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	SCKDL[2:0]	111	R/W	Clock Delay Sets the period from SPBSSL pin assertion to SPBCLK oscillation (clock delay). 000: 1 SPBCLK cycle 001: 2 SPBCLK cycles 010: 3 SPBCLK cycles 011: 4 SPBCLK cycles 100: 5 SPBCLK cycles 101: 6 SPBCLK cycles 110: 7 SPBCLK cycles 111: 8 SPBCLK cycles

17.4.3 Bit Rate Register (SPBCR)

SPBCR is a 32-bit register that sets the bit rate.

The settings of this register are reflected both in external address space read mode and SPI operating mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPBR[7:0]								-	-	-	-	-	-	BRDV[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 8	SPBR[7:0]	All 0	R/W	Bit Rate Sets the bit rate. The bit rate is determined by a combination of these bits with the BRDV[1:0] bits. For details, see Section 17.4.3.1, Bit Rate .
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	BRDV[1:0]	11	R/W	Bit Rate Frequency Division Sets the bit rate. The bit rate is determined by a combination of these bits with the SPBR[7:0] bits. The SPBR[7:0] value is used to set the base bit rate. The BRDV[1:0] value is used to select a division ratio of the base bit rate from among no division, 2, 4, and 8. 00: Base bit rate 01: Base bit rate divided by 2 10: Base bit rate divided by 4 11: Base bit rate divided by 8

17.4.3.1 Bit Rate

SPBR[7:0] and BRDV[1:0] are used for setting the bit rate.

The following formula is used to calculate the bit rate when SPBR[7:0] ≠ 0.

$$\text{Bit rate} = B\phi / (2 \times n \times 2^N)$$

n: SPBR[7:0] setting (1, …, 255)
N: BRDV[1:0] setting (0 to 3)

17.4.4 Data Read Control Register (DRCR)

DRCR is a 32-bit register that sets the operation in external address space read mode.

The bits except the SSLN bit should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BFM[2:0]			-	-	-	-	SSLN	-	-	-	-	RBURST[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R	R	R	W	R	R	R	R	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	RCF	RBE	-	-	-	-	-	-	-	SSLE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	W	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	BFM [2:0]	000	R/W	Enable SFMA cache 000: Burst length depends on the access size. Further the cache is flushed at each cycle. 111: Burst length of Serial Flash depends on values of RBE and RBURST[3:0]. The read cache is enabled when the RBE is set to 1. All others: Setting prohibited **Note:** If the SFMA is accessed by the CPU via XC Cache, make sure to also enable the SFMA cache as described in Section 17.6.3, Notes on using the SFMA Cache.
28 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	SSLN	0	W	SPBSSL Negation Asserted SPBSSL can be negated by writing 1 to this bit when both the RBE and SSLE bits are 1. This bit is always read as 0. Note: To start next access after SPBSSL negation using this bit, read SSLF in CMNSR = 0 to confirm that the SPBSSL has been negated.
23 to 20	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
19 to 16	RBURST [3:0]	0000	R/W	Read Data Burst Length Sets the burst length (data unit count) when reading. This bit is enabled when the RBE bit is set to 1. 0000: 1 data unit 0001: 2 continuous data units : 1110: 15 continuous data units 1111: 16 continuous data units One data unit is 64 bits long.
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	RCF	0	W	Read cache Flush When 1 is written to this bit, all the entries in the read cache are cleared. This bit is always read as 0. Note: After flushing the read cache by writing 1 to the RCF bit, read the DRCR before proceeding to read from the external address space.

Bit	Bit Name	Initial Value	R/W	Description
8	RBE	0	R/W	Read Burst Turns burst ON or OFF when reading. 0: Data is read according to the access size. 1: read cache is enabled, and as many data units as the burst count specified in RBURST[3:0] bits is read. Please set "111" to BFM[2:0] bit when this bit is set to 0.
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SSLE	0	R/W	SPBSSL Negation Sets the conditions for SPBSSL negation during read burst. SPBSSL is negated for each access during normal read. 0: SPBSSL is negated after transfer of data set in burst length. 1: SPBSSL is negated when the accessed address is not continuous with the previously transferred address.

17.4.5 Data Read Command Setting Register (DRCMR)

DRCMR is a 32-bit register that sets the commands issued in external address space read mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	CMD[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	OCMD[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	CMD[7:0]	H'03	R/W	Command Sets the command.
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	OCMD[7:0]	H'00	R/W	Optional Command Sets the optional command.

17.4.6 Data Read Extended Address Setting Register (DREAR)

DREAR is a 32-bit register that sets the address when the serial flash address is output in 32-bit mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	EAV[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	EAC[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	EAV[7:0]	H'00	R/W	32-Bit Extended Upper Address Fixed Value Sets the upper address bit values of the external address specified by the EAC[2:0] bits when the serial flash address is output in 32-bit mode. Bit 0 corresponds to the serial flash address bit [25], and bit 7 corresponds to the bit [32]. This setting is valid when the ADE[3] bit in DRENR is 1. When EAC[2:0] are 000, serial flash address [32:25] fixed values should be set to EAV[7:0]. When EAC[2:0] are 001, serial flash address [32:26] fixed values should set to EAV[7:1]. (1) When BSZ[1:0] in CMNCR = 00 (one serial flash memory connected) Serial flash addresses [31:0] are used for accessing. (2) When BSZ[1:0] in CMNCR = 01 (two serial flash memories connected) Serial flash addresses [32:1] are used for accessing.
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	EAC[2:0]	000	R/W	32-Bit Extended External Address Valid Range Sets the range of the external address to be used as serial flash address when the serial flash address is output in 32-bit mode. This setting is valid when the ADE[3] bit in DRENR is 1. 000: External address bits [24:0] enabled 001: External address bits [25:0] enabled 010: External address bits [26:0] enabled 011: External address bits [27:0] enabled 100: External address bits [28:0] enabled Other than above: Setting prohibited

17.4.7 Data Read Option Setting Register (DROPR)

DROPR is a 32-bit register that sets the option data in external address space read mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	OPD3[7:0]	H'00	R/W	Option Data 3 Sets the option data 3.
23 to 16	OPD2[7:0]	H'00	R/W	Option Data 2 Sets the option data 2.
15 to 8	OPD1[7:0]	H'00	R/W	Option Data 1 Sets the option data 1.
7 to 0	OPD0[7:0]	H'00	R/W	Option Data 0 Sets the option data 0.

Note: OPD3, OPD2, OPD1, and OPD0 are output in this order.

17.4.8 Data Read Enable Setting Register (DRENR)

DRENR is a 32-bit register that sets the bit size of the command, optional command, address, option data, and read data in external address space read mode and enables outputting them other than read data.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	CDB[1:0]	00	R/W	Command Bit Size Sets the command size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
29, 28	OCDB[1:0]	00	R/W	Optional Command Bit Size Sets the optional command size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
27, 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25, 24	ADB[1:0]	00	R/W	Address Bit Size Sets the address size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21, 20	OPDB[1:0]	00	R/W	Option Data Bit Size Sets the option data size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
19, 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17, 16	DRDB[1:0]	00	R/W	Data Read Bit Size Sets the data read size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
15	DME	0	R/W	Dummy Cycle Enable Enables insertion of the dummy cycle before the read data. Note: A setting is prohibited for a transfer starting with a dummy cycle. 0: Dummy cycle insertion disabled 1: Dummy cycle insertion enabled
14	CDE	1	R/W	Command Enable Sets the command to be output. 0: Command output disabled 1: Command output enabled
13	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
12	OCDE	0	R/W	Optional Command Enable Sets the optional command to be output. 0: Optional command output disabled 1: Optional command output enabled
11 to 8	ADE[3:0]	0111	R/W	Address Enable Sets the address to be output. Be sure to use the following setting; otherwise, the operation is not guaranteed. (1) BSZ[1:0] in CMNCR = 00 (one serial flash memory connected) 0000: Output disabled 0111: Address[23:0] 1111: Address[31:0] Other than above: Setting prohibited (2) BSZ[1:0] in CMNCR = 01 (two serial flash memories connected) 0000: Output disabled 0111: Address[24:1] 1111: Address[32:1] Other than above: Setting prohibited
7 to 4	OPDE[3:0]	0000	R/W	Option Data Enable Sets the option data to be output. Use only the settings given below. Otherwise, the operation cannot be guaranteed. 0000: Output disabled 1000: OPD3 1100: OPD3, OPD2 1110: OPD3, OPD2, OPD1 1111: OPD3, OPD2, OPD1, OPD0 Other than above: Setting prohibited
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

17.4.9 SPI Mode Control Register (SMCR)

SMCR is a 32-bit register that sets the operation in SPI operating mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	SSLKP	-	-	-	-	-	SPIRE	SPIWE	SPIE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R/W	R/W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	SSLKP	0	R/W	SPBSSL Signal Level Determines the SPBSSL status after the end of transfer. 0: SPBSSL signal is negated at the end of transfer. 1: SPBSSL signal level is maintained from the end of transfer to the start of next access.
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	SPIRE	0	R/W	Data Read Enable Enables reading in SPI operating mode. 0: Data reading disabled 1: Data reading enabled Note: When the transfer data bit size is set to 2 bits or 4 bits with the SPIDB[1:0] bits, the SPIRE and SPIWE bits should not be set to 1 at the same time.
1	SPIWE	0	R/W	Data Write Enable Enables writing in SPI operating mode. 0: Data writing disabled 1: Data writing enabled Note: When the transfer data bit size is set to 2 bits or 4 bits with the SPIDB[1:0] bits, the SPIRE and SPIWE bits should not be set to 1 at the same time.
0	SPIE	0	W	SPI Data Transfer Enable Data is transferred by setting this bit to 1. This bit is enabled only when the TEND bit in CMNSR is set to 1. The operation cannot be guaranteed when this bit is set to 1 with the TEND bit set to 0. This bit is always read as 0. Note: When the SPBSSL pin is de-asserted, the command, optional command, address, and option data that are output enabled are output even if the SPIRE and SPIWE bits are set to 0. When the SPBSSL pin is asserted, follow the notes described in Section 17.6.2, Notes on Starting Transfer from the SPBSSL Retained State in SPI Operating Mode.

17.4.10 SPI Mode Command Setting Register (SMCMR)

SMCMR is a 32-bit register that sets the commands issued in SPI operating mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	CMD[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	OCMD[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	CMD[7:0]	H'00	R/W	Command Sets the command.
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	OCMD[7:0]	H'00	R/W	Optional Command Sets the optional command.

17.4.11 SPI Mode Address Setting Register (SMADR)

SMADR is a 32-bit register that sets the addresses in SPI operating mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADR[31:24]								ADR[23:16]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADR[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	ADR[31:24]	H'00	R/W	Address Sets the value of bits 31 to 24 when the serial flash address is output in 32-bit units. This setting is valid when ADE[3] in SMENR is 1.
23 to 0	ADR[23:0]	H'000000	R/W	Address Sets the address.

17.4.12 SPI Mode Option Setting Register (SMOPR)

SMOPR is a 32-bit register that sets the option data in SPI operating mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OPD3[7:0]								OPD2[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OPD1[7:0]								OPD0[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	OPD3[7:0]	H'00	R/W	Option Data 3 Sets the option data 3.
23 to 16	OPD2[7:0]	H'00	R/W	Option Data 2 Sets the option data 2.
15 to 8	OPD1[7:0]	H'00	R/W	Option Data 1 Sets the option data 1.
7 to 0	OPD0[7:0]	H'00	R/W	Option Data 0 Sets the option data 0.

Note: OPD3, OPD2, OPD1, and OPD0 are output in this order.

17.4.13 SPI Mode Enable Setting Register (SMENR)

SMENR is a 32-bit register that sets the bit size of the command, optional command, address, option data, and transfer data in SPI operating mode and enables their output. SMENR also enables dummy cycle insertion. Disabling all of the command, optional command, address, option data, dummy cycle, and transfer data is prohibited. At least one of them except dummy cycle must be enabled.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CDB[1:0]		OCDB[1:0]		-	-	ADB[1:0]		-	-	OPDB[1:0]		-	-	SPIDB[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R/W	R/W	R	R	R/W	R/W

Initial value:	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31, 30	CDB[1:0]	00	R/W	Command Bit Size Sets the command size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
29, 28	OCDB[1:0]	00	R/W	Optional Command Bit Size Sets the optional command size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
27, 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25, 24	ADB[1:0]	00	R/W	Address Bit Size Sets the address size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21, 20	OPDB[1:0]	00	R/W	Option Data Bit Size Sets the option data size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
19, 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17, 16	SPIDB[1:0]	00	R/W	Transfer Data Bit Size Sets the transfer data size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited

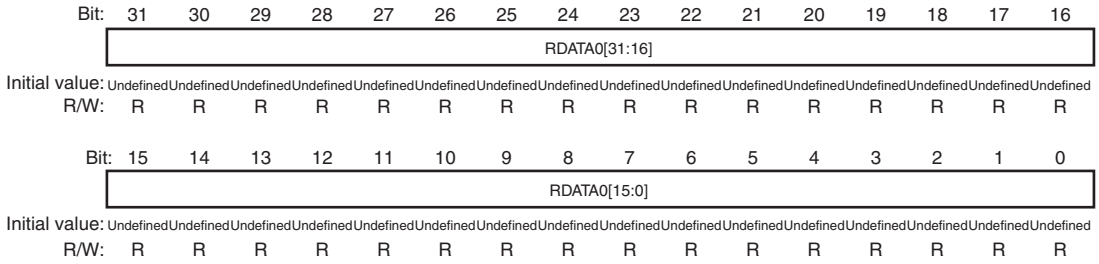
Bit	Bit Name	Initial Value	R/W	Description
15	DME	0	R/W	Dummy Cycle Enable Enables insertion of the dummy cycle before the read data. Note: Dummy cycle insertion is prohibited for write in SPI operating mode including the case in which a transfer ends with a dummy cycle. Note: A setting is prohibited for a transfer starting with a dummy cycle. 0: Dummy cycle insertion disabled 1: Dummy cycle insertion enabled
14	CDE	1	R/W	Command Enable Sets the command to be output. 0: Command output disabled 1: Command output enabled
13	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
12	OCDE	0	R/W	Optional Command Enable Sets the optional command to be output. 0: Optional command output disabled 1: Optional command output enabled
11 to 8	ADE[3:0]	0000	R/W	Address Enable Sets the address to be output. Use only the settings given below. Otherwise, the operation cannot be guaranteed. 0000: Output disabled 0100: ADR[23:16] 0110: ADR[23:8] 0111: ADR[23:0] 1111: ADR[31:0] Other than above: Setting prohibited
7 to 4	OPDE[3:0]	0000	R/W	Option Data Enable Sets the option data to be output. Use only the settings given below. Otherwise, the operation cannot be guaranteed. 0000: Output disabled 1000: OPD3 1100: OPD3, OPD2 1110: OPD3, OPD2, OPD1 1111: OPD3, OPD2, OPD1, OPD0 Other than above: Setting prohibited
3 to 0	SPIDE[3:0]	0000	R/W	Transfer Data Enable Sets valid transfer data. Valid data differs depending on the BSZ[1:0] bit setting in CMNCR. The following settings must be used. Otherwise, the operation is not guaranteed. (1) BSZ[1:0] bits in CMNCR = 00 (one serial flash memory connected) 0000: Not transferred 1000: 8 bits transferred (enables data at address 0 of the SPI mode read/write data registers 0) 1100: 16 bits transferred (enables data at addresses 0 and 1 of the SPI mode read/write data registers 0) 1111: 32 bits transferred (enables data at addresses 0 to 3 of the SPI mode read/write data registers 0) Other than above: Setting prohibited (2) BSZ[1:0] bits in CMNCR = 01 (two serial flash memories connected) 0000: Not transferred 1000: 16 bits transferred (enables data at addresses 0 and 1 of the SPI mode read/write data registers 0) 1100: 32 bits transferred (enables data at addresses 0 to 3 of the SPI mode read/write data registers 0) 1111: 64 bits transferred (enables data at addresses 0 to 3 of the SPI mode read/write data registers 0 and data at addresses 0 to 3 of the SPI mode read/write data registers 1) Other than above: Setting prohibited

17.4.14 SPI Mode Read Data Register 0 (SMRDR0)

SMRDR0 is a 32-bit register that stores the read data in SPI operating mode.

Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the SPI mode enable setting register (SMENR). Be sure to access from address 0.

The settings of this register should be read when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RDATA0 [31:0]	Undefined	R	Read Data Holds the data read in SPI operating mode. Data bits differ depending on the settings of SFDE and BSZ[1:0] bits in CMNCR and SPIDE[3:0] bits in SMENR. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 1: Read data[63:32]. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 0: Read data[31:0]. Other than the above: Read data[31:0].

Note: The contents of this register and SMRDR1 are modified upon completion of reception in SPI operating mode. Be sure to read data when reception in SPI operating mode is completed.

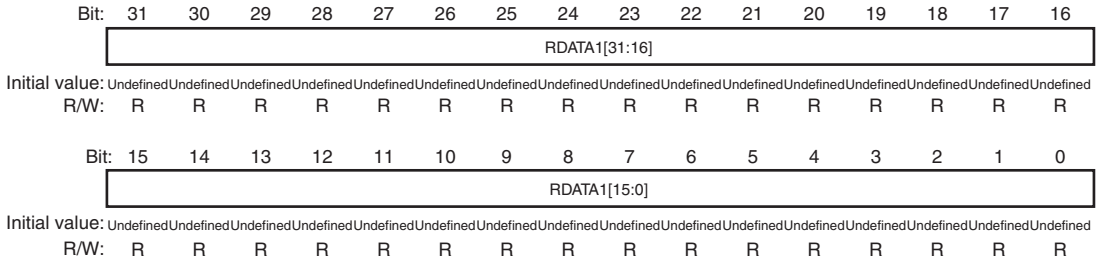
17.4.15 SPI Mode Read Data Register 1 (SMRDR1)

SMRDR1 is a 32-bit register that stores the read data in SPI operating mode.

This register is enabled when the BSZ[1:0] bits in CMNCR are set to 01 (two serial flash memories connected) and disabled when the BSZ[1:0] bits in CMNCR are set to 00 (one serial flash memory connected).

Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the SPI mode enable setting register (SMENR). Be sure to access from address 0.

The settings of this register should be read when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RDATA1 [31:0]	Undefined	R	Read Data Holds the data read in SPI operating mode. Data bits differ depending on the settings of SFDE and BSZ[1:0] bits in CMNCR and SPIDE[3:0] bits in SMENR. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 1: Read data[31:0]. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 0: Read data[63:32]. Other than the above: Bits in this register are disabled.

17.4.16 SPI Mode Write Data Register 0 (SMWDR0)

SMWDR0 is a 32-bit register that sets the write data in SPI operating mode.

Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the SPI mode enable setting register (SMENR). Be sure to access from address 0.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	WDATA0 [31:0]	All 0	R/W	Write Data Holds the data to be written in SPI operating mode. Data bits differ depending on the settings of SFDE and BSZ[1:0] bits in CMNCR and SPIDE[3:0] bits in SMENR. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 1: Write data[63:32]. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 0: Write data[31:0]. Other than the above: Write data[31:0].

17.4.17 SPI Mode Write Data Register 1 (SMWDR1)

SMWDR1 is a 32-bit register that sets the write data in SPI operating mode.

This register is enabled when the BSZ[1:0] bits in CMNCR are set to 01 (two serial flash memories connected) and disabled when the BSZ[1:0] bits in CMNCR are set to 00 (one serial flash memory connected).

Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the SPI mode enable setting register (SMENR). Be sure to access from address 0.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	WDATA1 [31:0]	All 0	R/W	Write Data Holds the data to be written in SPI operating mode. Data bits differ depending on the settings of SFDE and BSZ[1:0] bits in CMNCR and SPIDE[3:0] bits in SMENR. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 1: Write data[31:0]. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 0: Write data[63:32]. Other than the above: Bits in this register are disabled.

17.4.18 Common Status Register (CMNSR)

CMNSR is a 32-bit register that holds flags indicating the operating state.

The settings of this register are reflected both in external address space read mode and SPI operating mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	SSLF	TEND
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	SSLF	0	R	SPBSSL Pin Monitor 0: SPBSSL pin is negated 1: SPBSSL pin is asserted
0	TEND	1	R	Transfer End Flag Indicates whether the data transfer has ended. 0: Indicates that data transfer is in progress 1: Indicates that data transfer has ended

17.4.19 Clock phase adjust register (CKDLY)

This register defines phase shifts between the SPBCLK clock, sampling point and input/output data.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

For detailed information about how to set the register values, refer to Section 17.5.14, Adjustment between input/output data and sampling clocks.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PROT_CKDLY[7:0]								-	-	CKDLY_TS[1:0]*1		-	CKDLYOC[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	R	R	R/W	R/W	R	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	CKDLYRX[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Note 1. These bits are only available in SFMA1 of D1M1A and D1M1-V2.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	PROT_ CKDLY[7:0]	All 0	W	CKDLY write protection While changing the settings of this register, set PROT_CKDLY[7:0] = $A5_H$. If this register is written with a different PROT_CKDLY[7:0] value, writing is ignored.
23 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21, 20	CKDLY_TS[1:0]	All 0	R/W	Output timing adjustment 00_B: No shift 01_B: 0.5 f_{PHCLK} cycle delay from SPBCLK 10_B: 1.0 f_{PHCLK} cycle delay from SPBCLK 11_B: 1.5 f_{PHCLK} cycle delay from SPBCLK *1 Note 1. This selection is only available when CKSC_ISFMAD_CTL = 011_B or 100_B.
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
18 to 16	CKDLYOC[2:0]	0	R/W	SPBCLK clock phase shift CKDLYOC[2:0] defines a phase shift between the SPBCLK clock and data output towards the external flash memory devices. The phase shift value delays the data outputs with respect to the SPBCLK clock by the defined value. The phase shift is set in units of $1/(2xf_{PHCLK})$, i.e. in half of the phase shift clock PHCLK cycle time. 000_B: no phase shift 010_B: phase shift = 2 x $[1/(2xf_{PHCLK})]$ - $1/f_{B\Phi}$ 011_B: phase shift = 3 x $[1/(2xf_{PHCLK})]$ - $1/f_{B\Phi}$ 100_B: phase shift = 4 x $[1/(2xf_{PHCLK})]$ - $1/f_{B\Phi}$ 101_B: phase shift = 5 x $[1/(2xf_{PHCLK})]$ - $1/f_{B\Phi}$ 110_B: phase shift = 6 x $[1/(2xf_{PHCLK})]$ - $1/f_{B\Phi}$ 111_B: phase shift = 7 x $[1/(2xf_{PHCLK})]$ - $1/f_{B\Phi}$ others: setting prohibited CAUTION The phase shift must not exceed the cycle time of the BΦ clock.
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	CKDLYRX[2:0]	0	R/W	Sampling point phase shift CKDLYRX[2:0] defines a phase shift between the input data from the external flash memory devices and the sampling point. The sampling point shift is set in units of $1/2xf_{PHCLK}$, i.e. in half of the phase shift clock PHCLK cycle time. 000_B: no sampling point shift 001_B: sampling point shift = 1 x $[1/(2xf_{PHCLK})]$ 010_B: sampling point shift = 2 x $[1/(2xf_{PHCLK})]$ 011_B: sampling point shift = 3 x $[1/(2xf_{PHCLK})]$ 100_B: sampling point shift = 4 x $[1/(2xf_{PHCLK})]$ 101_B: sampling point shift = 5 x $[1/(2xf_{PHCLK})]$ others: setting prohibited*1 Note 1. For calibration usage only, – 110_B (sampling point shift = 6 x $[1/(2xf_{PHCLK})]$) and – 111_B (sampling point shift = 7 x $[1/(2xf_{PHCLK})]$) can be also used.

17.4.20 Data Read Dummy Cycle Setting Register (DRDMCR)

DRDMCR is a 32-bit register that sets the size and number of dummy cycles to be inserted in external address space read mode.

The settings of this register are enabled when the DME bit in the data read enable setting register (DRENR) is 1.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	DMDB[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	DMCYC[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17, 16	DMDB [1:0]	00	R/W	Dummy Cycle Bit Size Sets the dummy cycle size in bit units. The setting of these bits is combined with the setting of the IO0FV[1:0], IO2FV[1:0], and IO3FV[1:0] bits in the common control register (CMNCR) to determine the state of the unused pins during the dummy cycles. The state of the used pins is Hi-Z. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	DMCYC [2:0]	000	R/W	Number of Dummy Cycles Sets the number of dummy cycles to be inserted when the DME bit in the data read enable setting register (DRENR) is 1. 000: 1 cycle 001: 2 cycles 010: 3 cycles 011: 4 cycles 100: 5 cycles 101: 6 cycles 110: 7 cycles 111: 8 cycles

17.4.21 Data Read DDR Enable Register (DRDRENR)

DRDRENR is a 32-bit register that sets SDR or DDR transfer of the address, option data, and read data in external address space read mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	ADDRE	0	R/W	Address DDR Enable Sets SDR or DDR transfer of the address. 0: SDR transfer 1: DDR transfer
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	OPDRE	0	R/W	Option Data DDR Enable Sets SDR or DDR transfer of the option data. 0: SDR transfer 1: DDR transfer
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DRDRE	0	R/W	Data Read DDR Enable Sets SDR or DDR transfer of the read data. 0: SDR transfer 1: DDR transfer

17.4.22 SPI Mode Dummy Cycle Setting Register (SMDMCR)

SMDMCR is a 32-bit register that sets the size and number of dummy cycles to be inserted in SPI operating mode.

The settings of this register are enabled when the DME bit in the SPI mode enable setting register (SMENR) is 1.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	DMDB[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	-	-	-	-	-	-	-	-	-	-	-	-	-	DMCYC[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17, 16	DMDB [1:0]	00	R/W	Dummy Cycle Bit Size Sets the dummy cycle size in bit units. The setting of these bits is combined with the setting of the IO0FV[1:0], IO2FV[1:0], and IO3FV[1:0] bits in the common control register (CMNCR) to determine the state of the unused pins during the dummy cycles. The state of the used pins is Hi-Z. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	DMCYC[2:0]	000	R/W	Number of Dummy Cycles Sets the number of dummy cycles to be inserted when the DME bit in the SPI mode enable setting register (SMENR) is 1. 000: 1 cycle 001: 2 cycles 010: 3 cycles 011: 4 cycles 100: 5 cycles 101: 6 cycles 110: 7 cycles 111: 8 cycles

17.4.23 SPI Mode DDR Enable Register (SMDRENR)

SMDRENR is a 32-bit register that sets SDR or DDR transfer of the address, option data, and transfer data in SPI operating mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	-	-	-	-	-	-	-	ADDRE	-	-	-	OPDRE	-	-	-	SPIDRE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	ADDRE	0	R/W	Address DDR Enable Sets SDR or DDR transfer of the address. 0: SDR transfer 1: DDR transfer
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	OPDRE	0	R/W	Option Data DDR Enable Sets SDR or DDR transfer of the option data. 0: SDR transfer 1: DDR transfer
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SPIDRE	0	R/W	Transfer Data DDR Enable Sets SDR or DDR transfer of the transfer data. 0: SDR transfer 1: DDR transfer

17.4.24 Output data delay register (SPODLY)

This register defines a fixed delay between the SPBCLK clock and the data output signals SPIO[3:0]i (i = 0, 1).

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

For detailed information about how to set the register values, refer to Section 17.5.14, Adjustment between input/output data and sampling clocks.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PROT_SPODLY[7:0]								-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	1	0	0	0	1	0	0	0	1	0	0	0	1
R/W:	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	PROT_ SPODLY[7:0]	All 0	W	SPODLY write protection While changing the settings of this register, set PROT_SPODLY[7:0] = $A5_H$. If this register is written with a different PROT_SPODLY[7:0] value, writing is ignored.
23 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 8	DLYOE1 DLYO1	1 1	R/W	Enable port 1 output delay 1: Output delay minimum 2 ns*1 0: No output delay **CAUTION** Both bits DLYOE1 and DLYO1 must be changed together to the same value.
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4 0	DLYOE0 DLYO0	1 1	R/W	Enable port 0 output delay 1: Output delay minimum 2 ns*1 0: No output delay **CAUTION** Both bits DLYOE0 and DLYO0 must be changed together to the same value.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note 1. Refer to the Data Sheet for the range of the output delay.

17.5 Operation

17.5.1 System Configuration

With this module, one or two serial flash memories can be directly connected per channel (data size of 1, 2, and 4 bits). The number of connected memories can be selected using the BSZ[1:0] bits in CMNCR.

Examples of system configuration with one serial flash memory connected and two serial flash memories connected are shown in **Figure 17.2** and **Figure 17.3**, respectively.

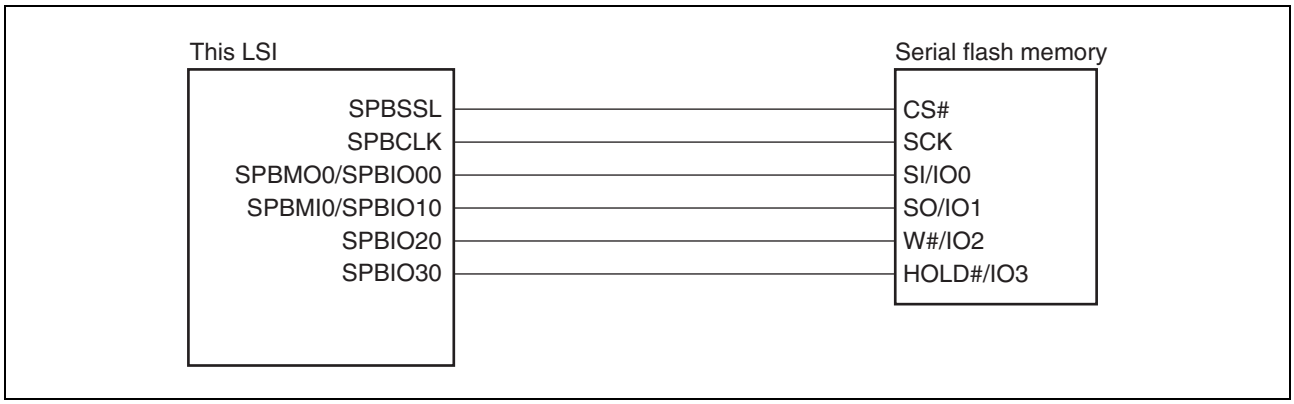

Figure 17.2 System Configuration Example with 4-Bit Data Size and One Serial Flash Memory Connected (BSZ[1:0] Bits in CMNCR = 00)

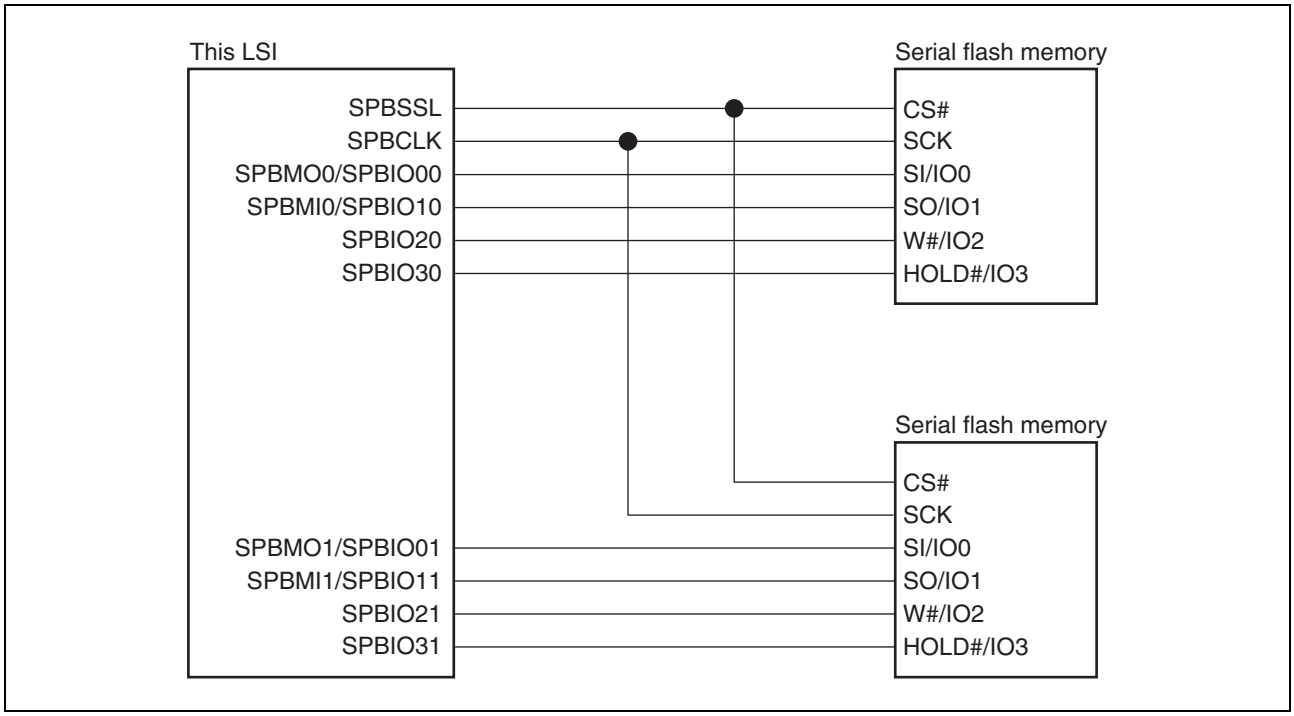

Figure 17.3 System Configuration Example with 4-Bit Data Size and Two Serial Flash Memories Connected (BSZ[1:0] Bits in CMNCR = 01)

17.5.2 Address Map

In external address space read mode, the serial flash connected is assigned in the SPI multi I/O bus space. A maximum accessible address space differs depending on the number of serial flash memories connected. In combination with DREAR, a maximum of 4 Gbytes can be accessed when one serial flash memory is connected, and a maximum of 8 Gbytes can be accessed when two memories are connected.

Table 17.7 Address Map

Number of Serial Flash Memories Connected	Internal Address	Max. Access Area
1	H'1000 0000 to H'2FFF FFFF	4 Gbytes
2		8 Gbytes

17.5.3 32-bit Serial Flash Addresses

Since the SPI multi I/O bus space is 512 Mbytes, only a part of the 32-bit serial flash address area can be directly accessed. Here, the fixed value set in the pertinent register is used as the upper bit value of a 32-bit address.

To output serial flash addresses in 32 bits, set the ADE[3] bit in DRENR to 1, set the range of the external addresses used as the serial flash addresses to the EAC[2:0] bits in DREAR, and set the upper bit value of the 32-bit address as the fixed value to the EAV[7:0] bits in DREAR.

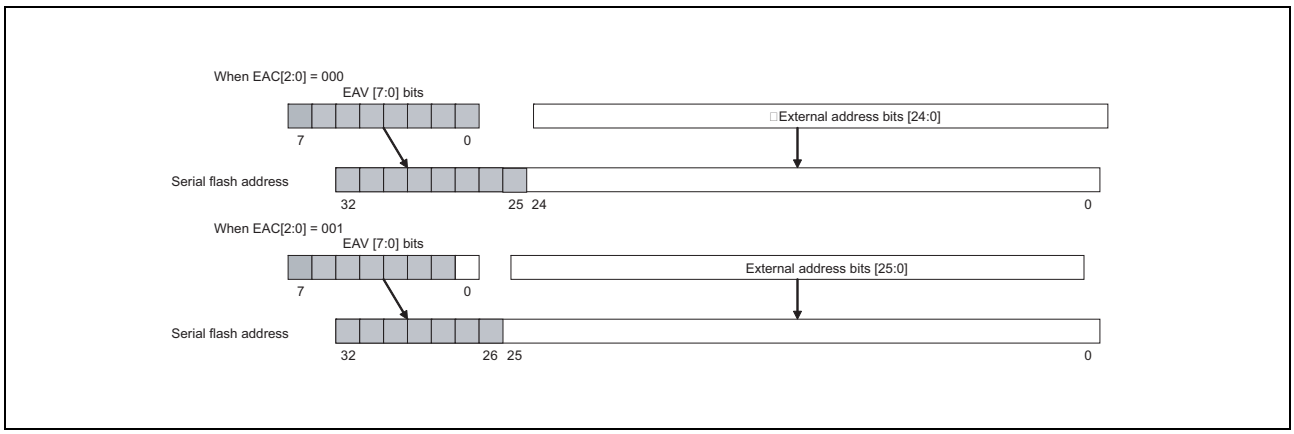

Figure 17.4 32-Bit Address Setting (example for EAC[2:0] = 000 and 001)

Setting the ADE[3] bit in DRENR to 1 allows the serial flash address to be output using [31:0] bits.
When EAC[2:0] = 000, external address bits [24:0] are valid; set the value for [32:25] bits to EAV[7:0].
When EAC[2:0] = 001, external address bits [25:0] are valid; set the value for [32:26] bits to EAV[7:1].
When EAC[2:0] = 010, external address bits [26:0] are valid; set the value for [32:27] bits to EAV[7:2].
When EAC[2:0] = 011, external address bits [27:0] are valid; set the value for [32:28] bits to EAV[7:3].
When EAC[2:0] = 100, external address bits [28:0] are valid; set the value for [32:29] bits to EAV[7:4].

The address bits actually used for access depend on the number of serial flash memories connected. When one serial flash memory is connected, address bits [31:0] are used and when two memories are connected, address bits [32:1] are used.

NOTE

When the capacity of the serial flash memory used is smaller than 4 Gbytes, keep the following point in mind.
If an access spreads over the last address of the serial flash in burst mode (RBE bit in DRCR = 1), the access address does not agree with the internal address of the serial flash. To prevent this, software should appropriately manage the accessible address areas for the serial flash memory used according to the memory capacity.

17.5.4 Data Alignment

Data alignment can be set by using the SFDE bit in the common control register (CMNCR). Data alignment in data read mode and in SPI mode are shown in **Figure 17.5** and **Figure 17.6**, respectively.

When two serial flash memories are connected, the serial flash memory connected to the pin SPBIO30-SPBIO00 has the address 2n and the serial flash memory connected to the pin SPBIO31-SPBIO01 has the address 2n + 1. The data must be accessed in word or larger units. It cannot be accessed in byte units.

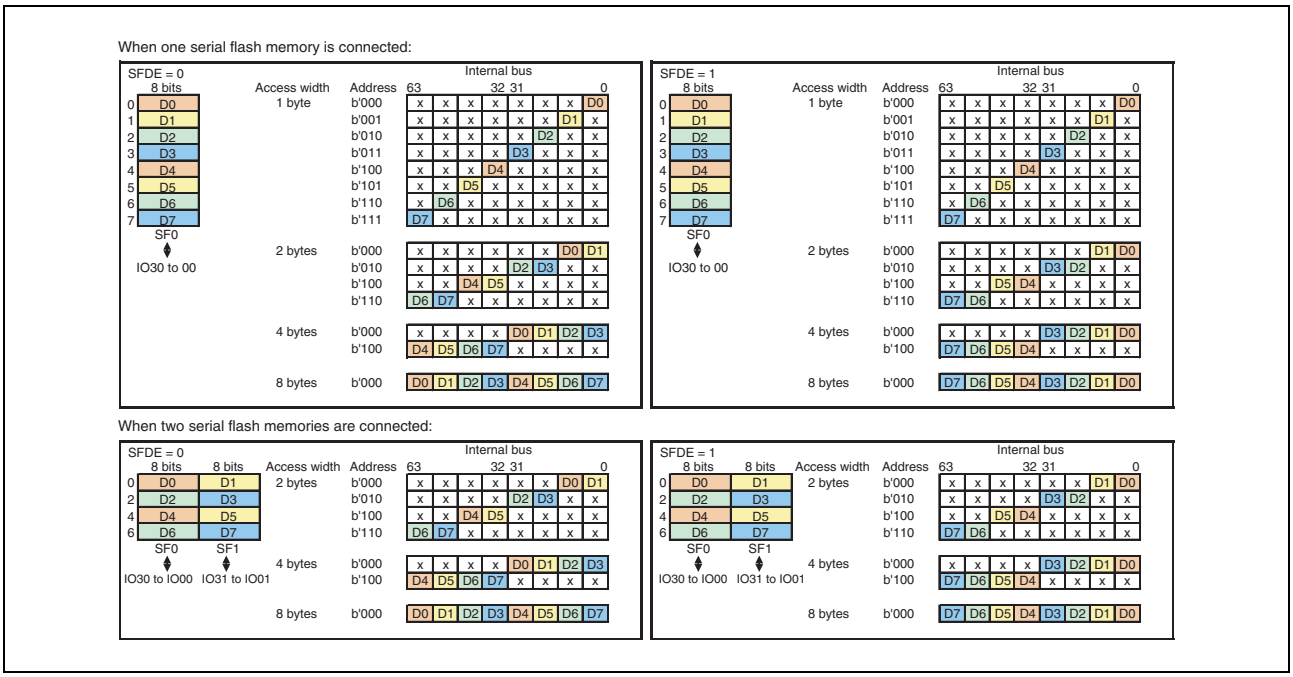

Figure 17.5 Data Alignment in Data Read Mode

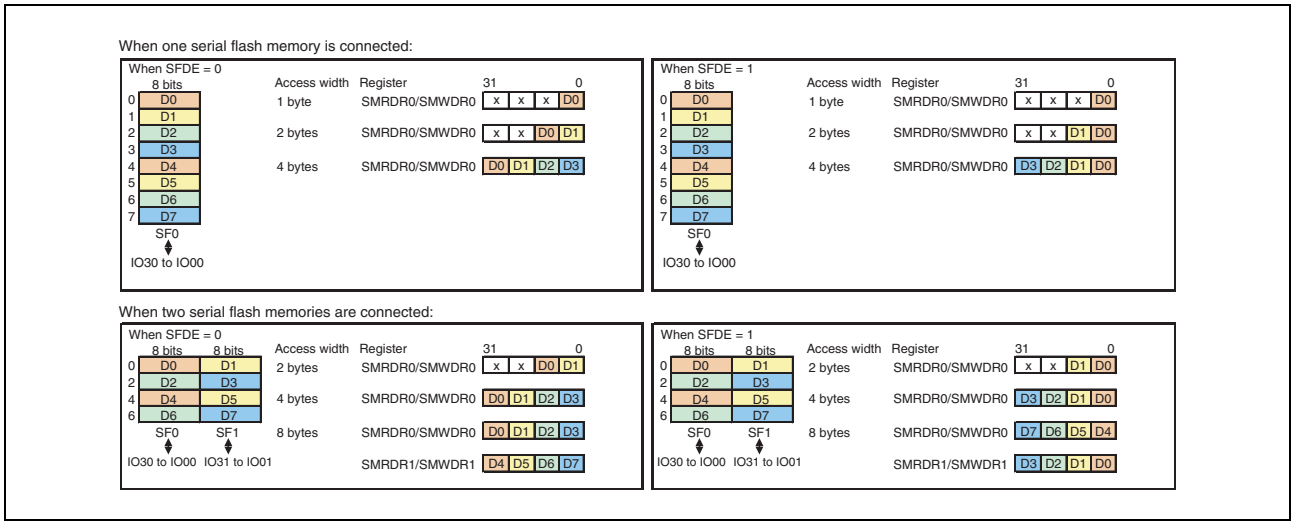

Figure 17.6 Data Alignment in SPI Mode

17.5.5 Operating Modes

This module has two operating modes: external address space read mode and SPI operating mode.

In external address space read mode, a read access to the SPI multi I/O bus space is converted into SPI communication and data is received. After data acquisition, data is returned to the bus master that is the issuing source. For details, see Section 17.5.6, External Address Space Read Mode.

In SPI operating mode, arbitrary SPI communication is carried out using register settings. For details, see Section 17.5.8, SPI Operating Mode.

17.5.6 External Address Space Read Mode

A read access to the SPI multi I/O bus space can be converted into SPI communication in external address space read mode. Further, the commands, optional commands, option data, and dummy cycle issued for reading can be modified using registers. For the address, option data, and read data, either SDR or DDR transfer can be selected using the appropriate register when the SPBCLK frequency division ratio is two or larger.

In external address space read mode, either normal read operation or burst read operation can be selected. The transfer format is determined based on the common control register (CMNCR), SSL delay register (SSLDR), bit rate setting register (SPBCR), data read control register (DRCR), data read command setting register (DRCMR), data read extended address setting register (DREAR), data read option setting register (DROPR), data read enable setting register (DRENR), data read dummy cycle setting register (DRDMCR), and data read DDR enable register (DRDRENR).

17.5.6.1 Normal Read Operation

When the RBE bit in DRCR is set to 0, normal read operation is performed.

In the normal read operation, the data of 8 bits, 16 bits, 32 bits, and 64 bits are read for respectively a byte, a word, and a longword read access. Here, a byte access is enabled only when one serial flash memory is connected. After reading, the SPBSSL pin is negated.

The normal read operation timing is shown in **Figure 17.7**.

t1 is the time period from SPBSSL pin assertion to SPBCLK oscillation (clock delay), t2 is the time period from transmission of the last SPBCLK edge of a transfer to SPBSSL pin negation (SPBSSL

negation delay), and t3 is the time period from one transfer end to the next transfer start (next access). For details of t1, t2, and t3, see Section 17.5.9, Transfer Format.

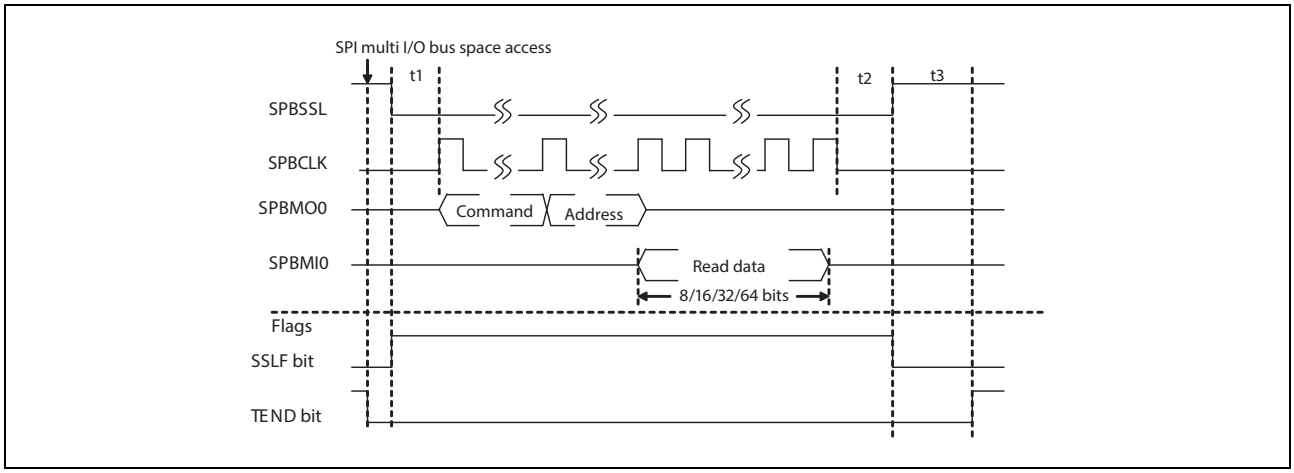

Figure 17.7 Normal Read Operation Timing

17.5.6.2 Burst Read Operation

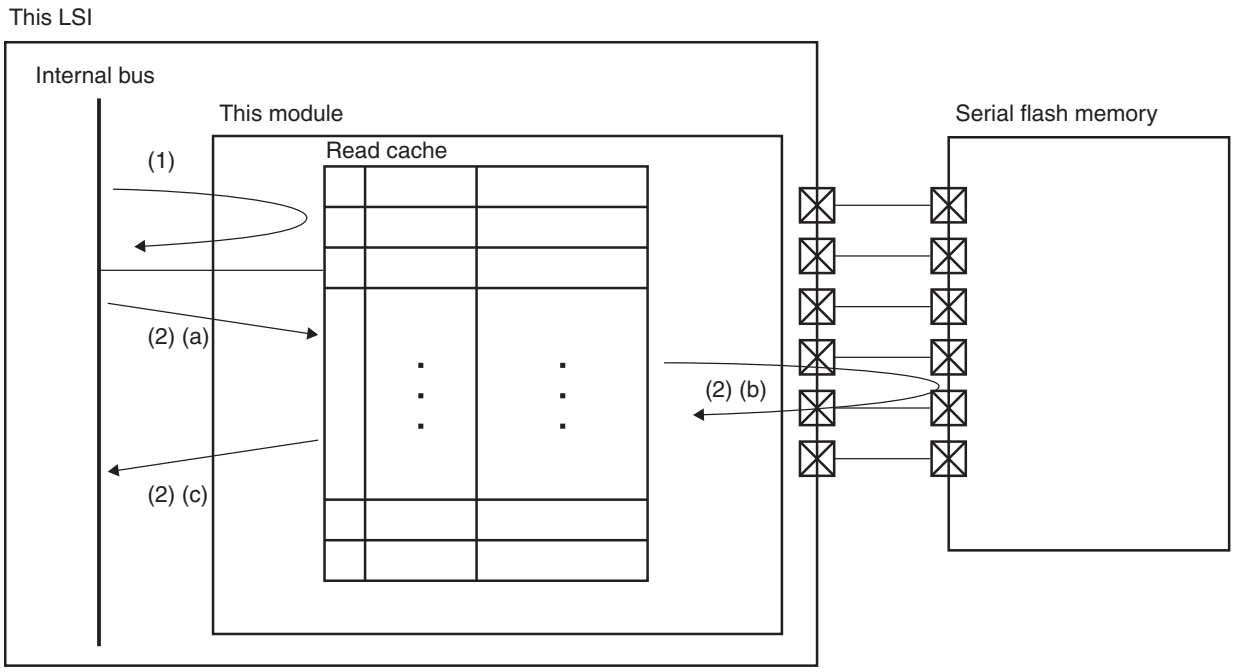
When the RBE bit in DRCR is set to 1, burst read operation is performed.

read cache is enabled in the burst read operation. For read cache operation, see Section 17.5.7, Read Cache.

For reading bytes, words, or longwords, the read cache is first referred to for the data. When the read cache contains the data, the data is read from the read cache without accessing the serial flash memory. When the read cache does not contain the data, burst read operation is performed in the serial flash memory and the read data is stored in the read cache. The data transfer length at that time is 64 bits × (RBURST[3:0] + 1) bits and the data is always read from the 64-bit boundary.

The SPBSSL pin status after data transfer can be selected by using the SSLE bit in DRCR. When the SSLE bit is set to 0, the SPBSSL pin is negated after data transfer. For an operation performed when the SSLE bit is set to 1, see Section 17.5.6.3, Burst Read Operation with Automatic SPBSSL Negation, just below.

A pattern diagram of this operation and a burst read operation timing diagram when SSLE bit is set to 0 are shown in **Figure 17.8** and **Figure 17.9**.



(1) When the read cache contains the data
The data is read from the read cache without performing SPI communication.

(2) When the read cache does not contain the data
(a) The read cache is accessed to confirm that the data is not in the read cache.
(b) The data is read from the serial flash memory and the read data is stored in the read cache.
(c) The data is read from the read cache.

Figure 17.8 Burst Read Operation

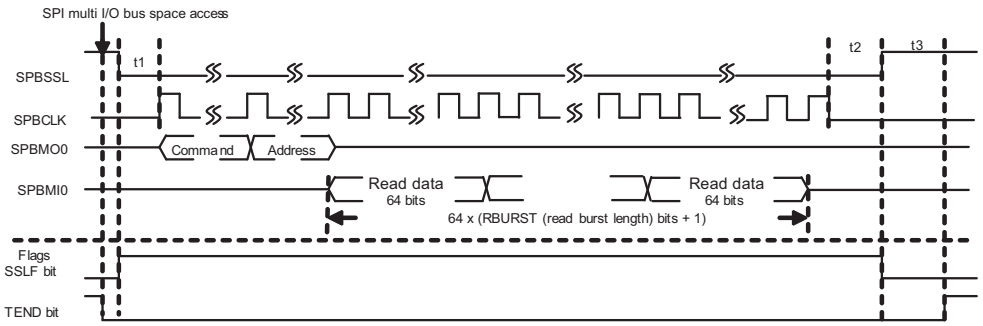


Figure 17.9 Burst Read Operation Timing (SSLE Bit = 0)

17.5.6.3 Burst Read Operation with Automatic SPBSSL Negation

When SSLE bit in DRCR is set to 1, this module does not negate the SPBSSL pin after the burst read transfer. When accessing the next time, if the address is continuous with the previous read address, the burst read operation is performed without issuing the command, optional command, address, option data, or dummy cycle. If the address is not continuous with the previous read address, the SPBSSL pin is once negated and the burst read operation is performed after issuing the command, optional command, address, option data, or dummy cycle.

Burst read timing diagrams for continuous address and non-continuous address are shown in **Figure 17.10** and **Figure 17.11**.

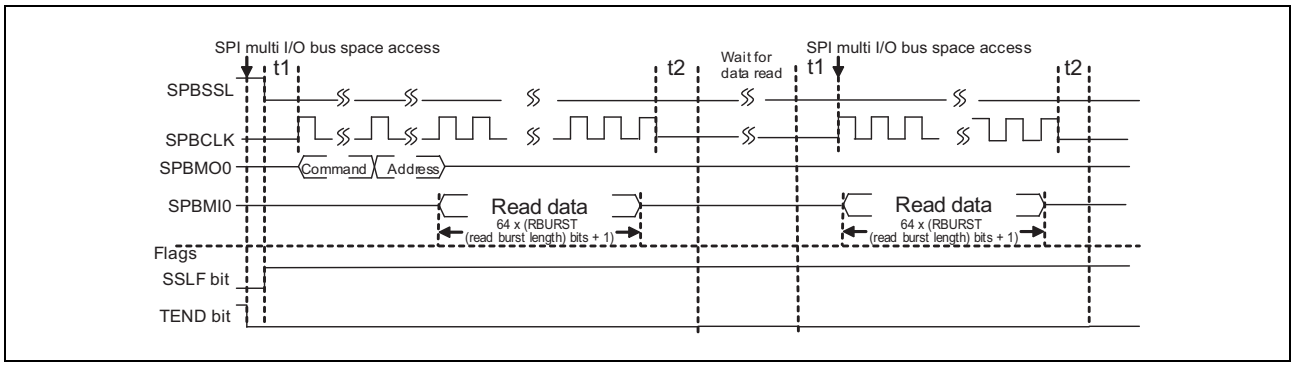

Figure 17.10 Burst Read Timing for Continuous Address (SSLE Bit = 1)

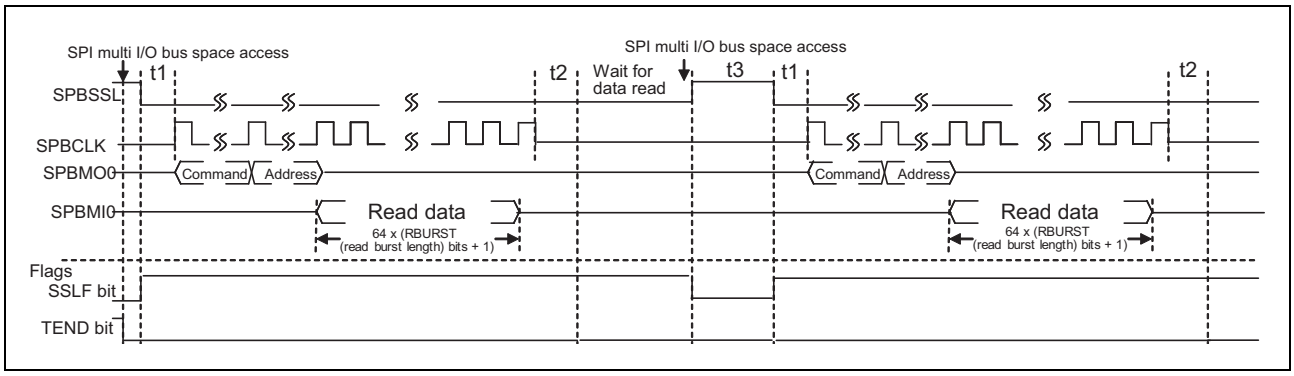

Figure 17.11 Burst Read Timing for Non-Continuous Address (SSLE Bit = 1)

For the next access after negation of the SPBSSL with the SSLN bit in DRCR with this operation, read SSLF = 0 in CMNSR to confirm that the SPBSSL has been negated.

17.5.6.4 Initial Setting Flow

An example of an initial setting flow in external address space read mode is shown in **Figure 17.12**.

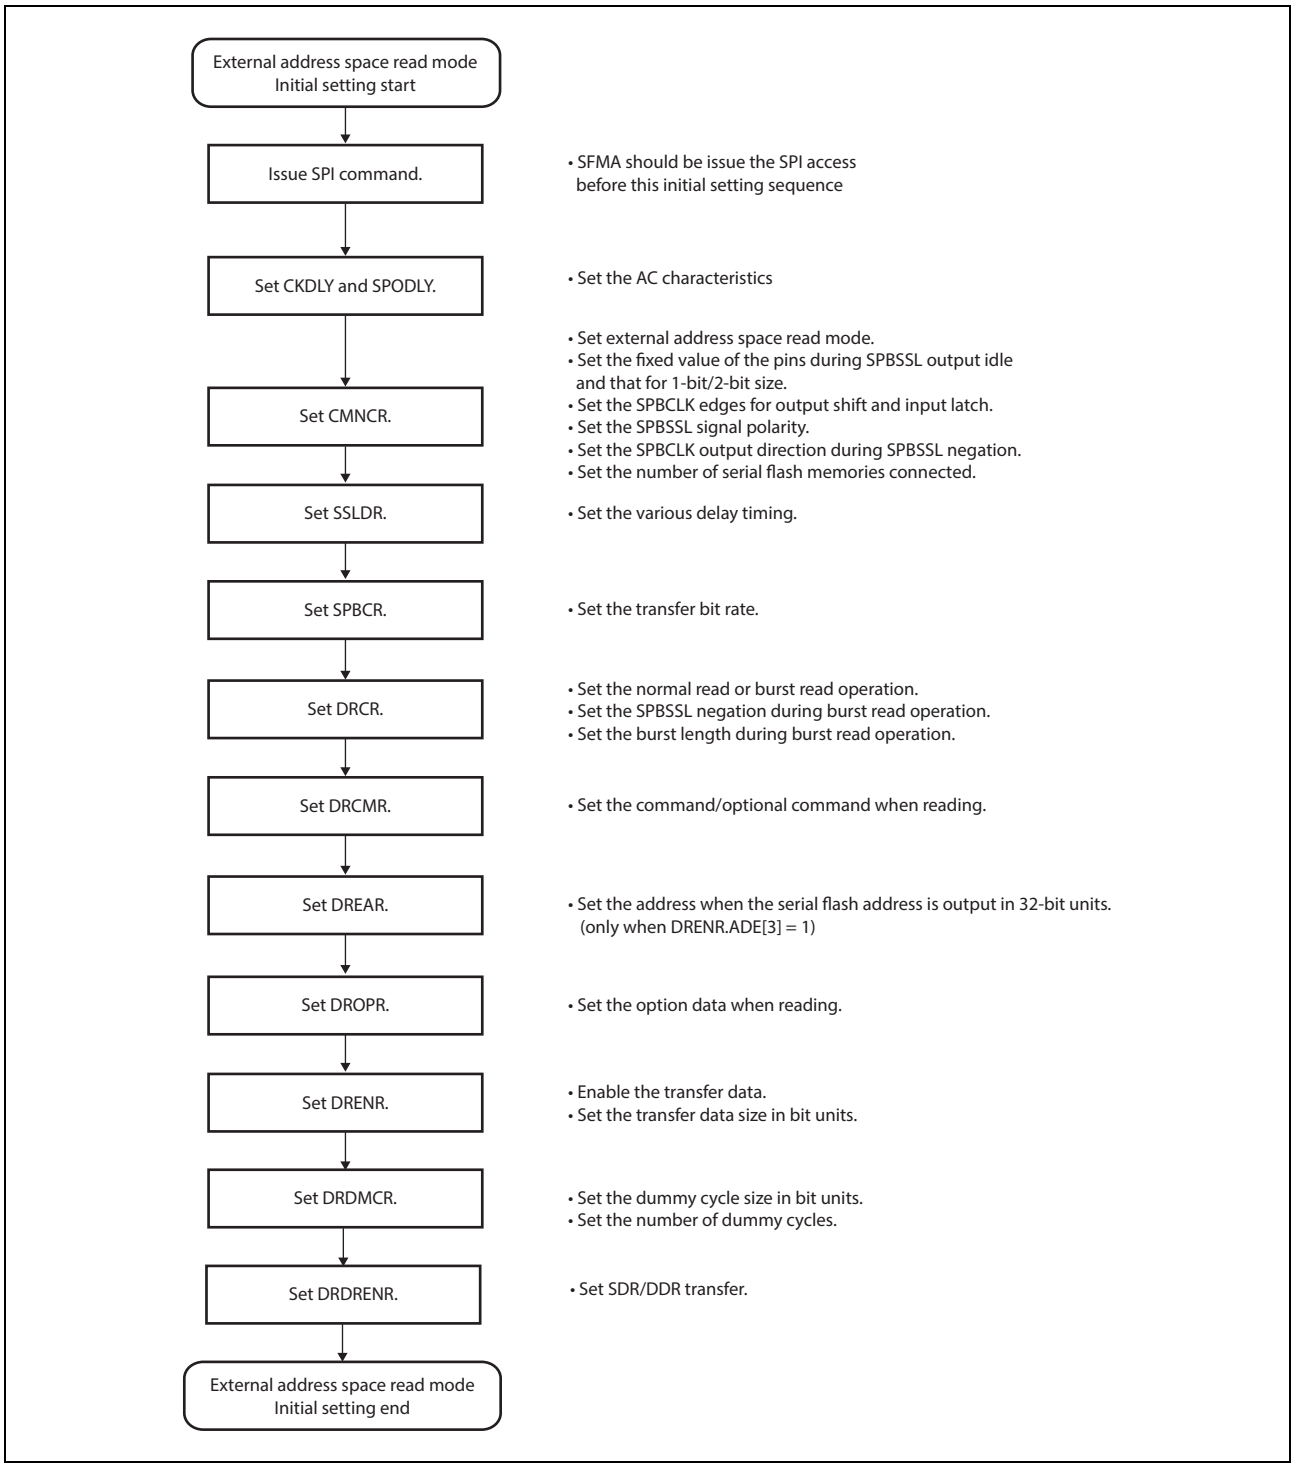

Figure 17.12 Example of Initial Setting Flow in External Address Space Read Mode

17.5.7 Read Cache

This module has a simple built-in read cache. The read cache can be used during external address space read mode and burst read operation. The read cache is configured with a line size of 64 bits and 16 entries.

Read cache configuration is shown in **Figure 17.13**.

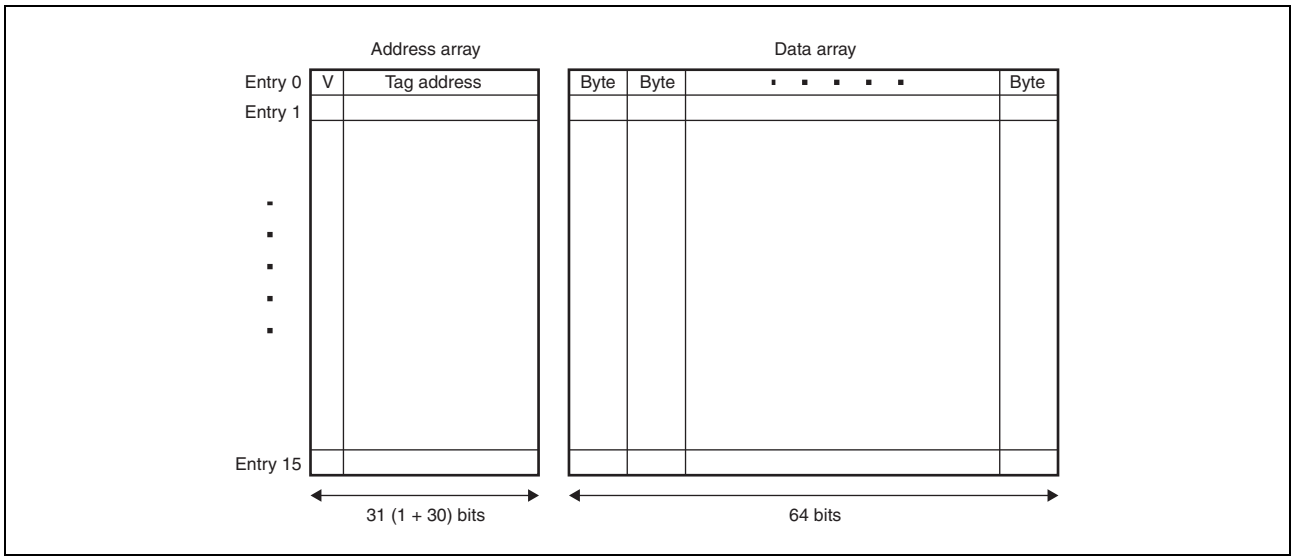

Figure 17.13 Read Cache Configuration

NOTE

If the SFMA is accessed by the CPU via XC Cache, make sure to also enable the SFMA cache as described in Section 17.6.3, Notes on using the SFMA Cache.

17.5.7.1 Address Array

The V bit indicates whether the entry data is valid. When the V bit is 1, the data is valid and when V bit is 0, the data is invalid.

The tag address bits hold the address used for the serial flash memory. Address bits 32 to 3 are used for the tag address.

Address bits 23 to 3 are enabled when address output is 24 bits and one serial flash memory is connected; and address bits 24 to 3 are enabled when two serial flash memories are connected.

Address bits 31 to 3 are enabled when address output is 32 bits and one serial flash memory is connected; and address bits 32 to 3 are enabled when two serial flash memories are connected.

17.5.7.2 Data Array

It retains the 64-bit read data. Registration in the read cache is performed in line units.

17.5.7.3 Read Operation

In case of read-hit, data is read from the read cache. In case of read-miss, after the 64 × (RBURST[3:0] (read burst length) + 1) data is read from the serial flash memory and the read cache is updated, the data is returned to the bus master.

17.5.7.4 Data Replacement

The write pointer is used to update data. In case of read-miss, the RBURST[3:0] (read burst length) portion data is replaced starting at the entry specified by the write pointer. In other words, the data is replaced in the storage order of the data. Whether data is referred to or not will not affect the replacement order of data.

17.5.8 SPI Operating Mode

This module can carry out an arbitrary SPI operation by using the register settings.

The transfer format is determined based on the common control register (CMNCR), SSL delay register (SSLDR), bit rate setting register (SPBCR), SPI mode control register (SMCR), SPI mode command setting register (SMCMR), SPI mode address setting register (SMADR), SPI mode option setting register (SMOPR), and SPI mode enable setting register (SMENR), SPI mode read data register (SMRDR), SPI mode write data register (SMWDR), SPI mode dummy cycle setting register (SMDMCR), and SPI mode DDR enable register (SMDRENR). For the address, option data, and transfer data, either SDR or DDR transfer can be selected using the appropriate register when the SPBCLK frequency division ratio is two or larger.

SPI operating mode can be used for reading the status of the serial flash memory and writing to the serial flash memory.

In this mode, one transfer refers to the operation from when the SPIE bit in SMCR is set to 1 when the TEND bit in CMNSR is set to 1.

17.5.8.1 Transfer Start

The transfer of data is started in the set transfer format by setting the SPIE bit in SMCR to 1. When write operation is enabled, the SPI mode write data register is transmitted to the serial flash memory. When read operation is enabled, data read from the serial flash memory is stored into the SPI mode read data register.

The SPI operation timing is shown in **Figure 17.14**.

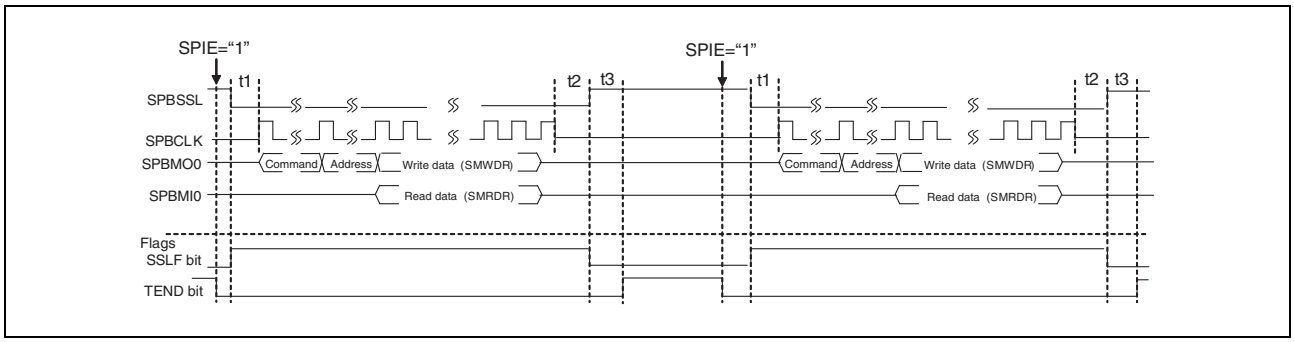

Figure 17.14 SPI Operation Timing

17.5.8.2 Read/Write Enable

- Read operation: Data can be read by setting the SPIRE bit in SMCR to 1. The read data is stored into SMRDR.
- Write operation: Data can be written by setting the SPIWE bit in SMCR to 1. The data stored in SMWDR is output.

When the data size is set to 1 bit using the SPIDB[1:0] bits in SMENR, data can be transmitted and received by setting the SPIRE and SPIWE bits to 1. However, when the data size is set to 2 or 4 bits by using the SPIDB[1:0] bits, only one of the SPIRE and SPIWE bits should be enabled. The operation is not guaranteed if both the bits are enabled.

17.5.8.3 Retention of SPBSSL Pin Assertion

By setting the SSLKP bit in SMCR to 1, assertion of the SPBSSL pin can be continued till the next transfer. With this function, the transfer can be carried out continuously with the SPBSSL kept in the asserted state.

The data transfer timing using the SSLKP bit is shown in **Figure 17.15**.

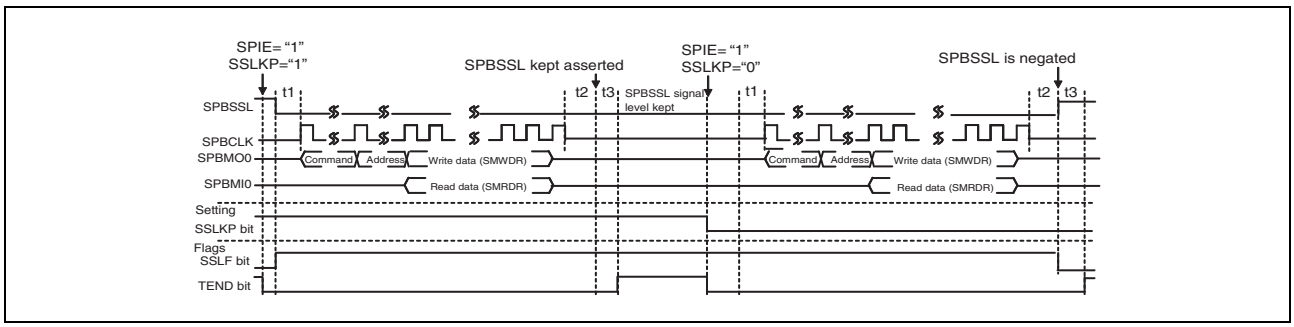

Figure 17.15 Data Transfer Timing using the SSLKP Bit

17.5.8.4 Initial Setting Flow

An example of an initial setting flow in SPI operating mode is shown in **Figure 17.16**.

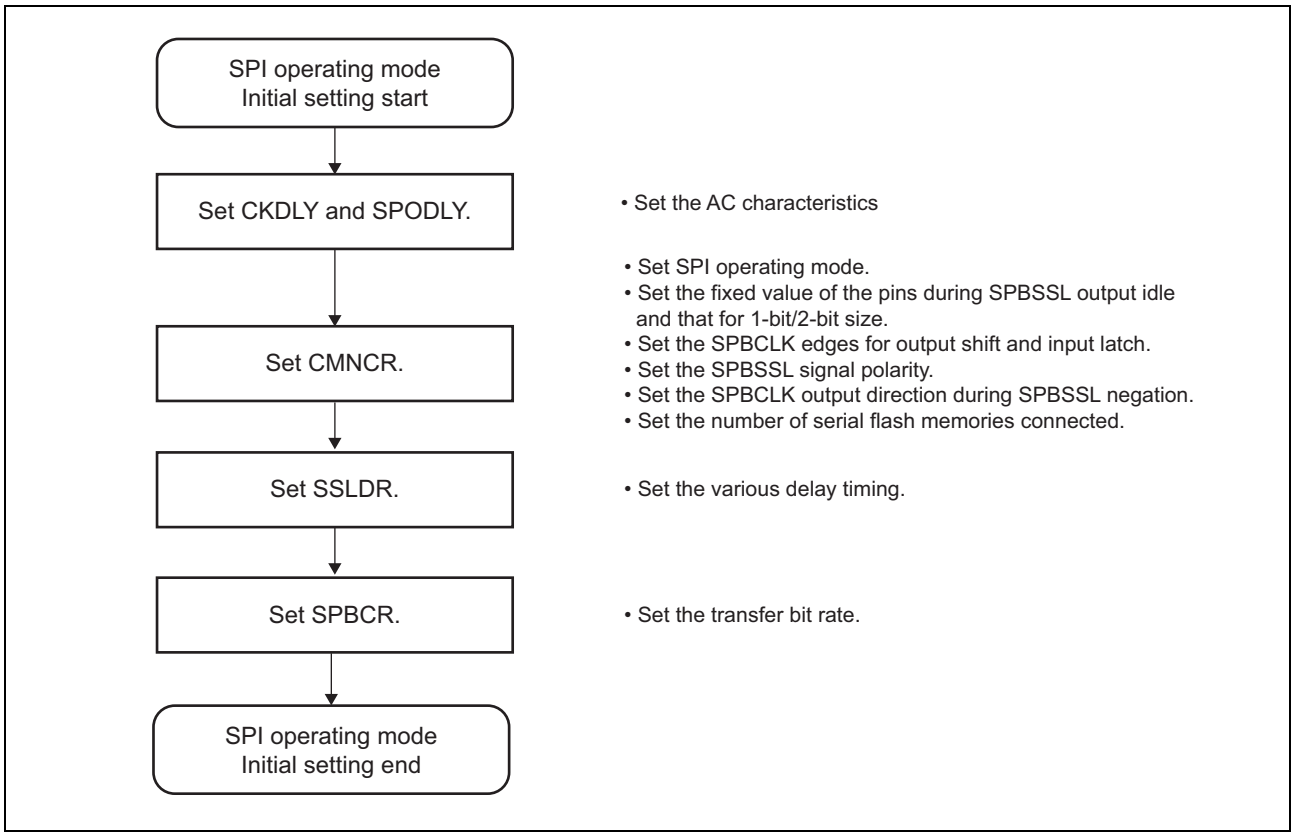

Figure 17.16 Example of Initial Setting Flow in SPI Operating Mode

17.5.8.5 Data Transfer Setting Flow

An example of a data transfer setting flow in SPI operating mode is shown in **Figure 17.17**.

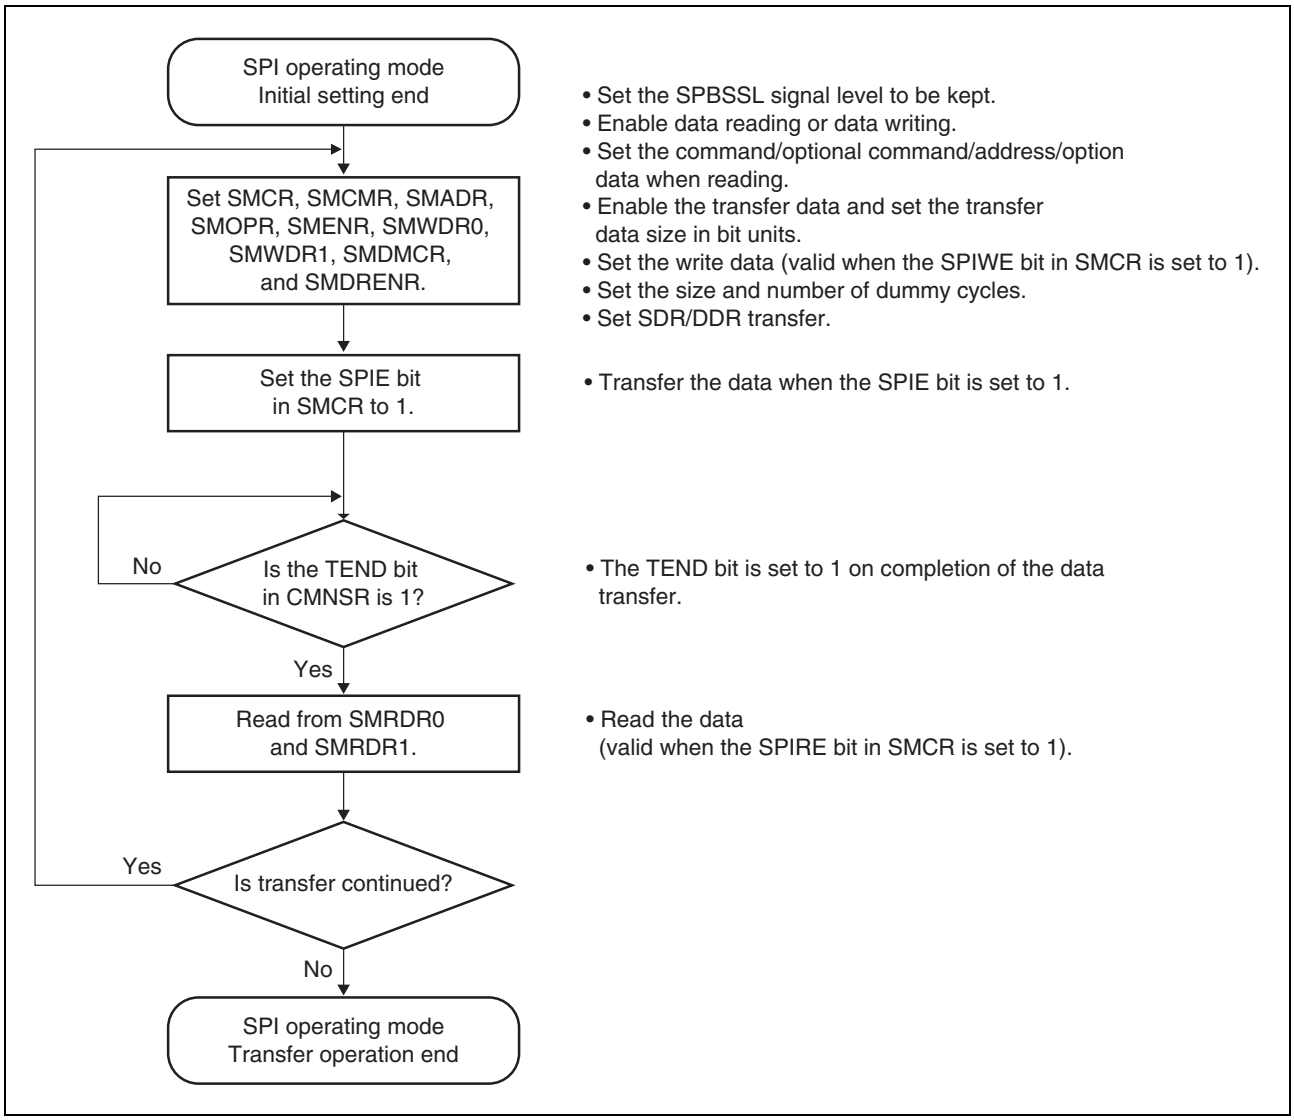

Figure 17.17 Example of a Data Transfer Setting Flow in SPI Operating Mode

17.5.9 Transfer Format

17.5.9.1 SPBSSL Pin Enable Polarity Control

The enable polarity of the SPBSSL pin can be changed with the SSLP bit in CMNCR.

17.5.9.2 SPBCLK Output

The SPBCLK output direction during SPBSSL negation can be set with the CPOL bit in CMNCR.

17.5.9.3 Data Transmission and Reception Timing

Data transmission and reception timing is different between SDR transfer and DDR transfer.

During SDR transfer, data is transmitted and received at either the odd or even edges. The data transmission timing can be set to the odd or even edge with the CPHAT bit in CMNCR. Similarly, the data reception timing can be set to the odd or even edge with the CPHAR bit in CMNCR.

During DDR transfer, data is transmitted and received at both the odd and even edges. The first data transmission timing can be set to the odd or even edge with the CPHAT bit in CMNCR. Similarly, the first data reception timing can be set to the odd or even edge with the CPHAR bit in CMNCR.

17.5.9.4 Delay Settings

t1 is the time period from SPBSSL pin assertion to SPBCLK oscillation (clock delay). It can be set with the SCKDL[2:0] bits in SSLDR. t2 is the time period till the SPBSSL signal negation after the SPBCLK oscillation is stopped (SPBSSL negation delay). It can be set with the SLNDL[2:0] bits in SSLDR. t3 is the time period required to prevent SPBSSL signal assertion for the next transfer after the end of the previous transfer (next access delay). It can be set with the SPNDL[2:0] bits in SSLDR.

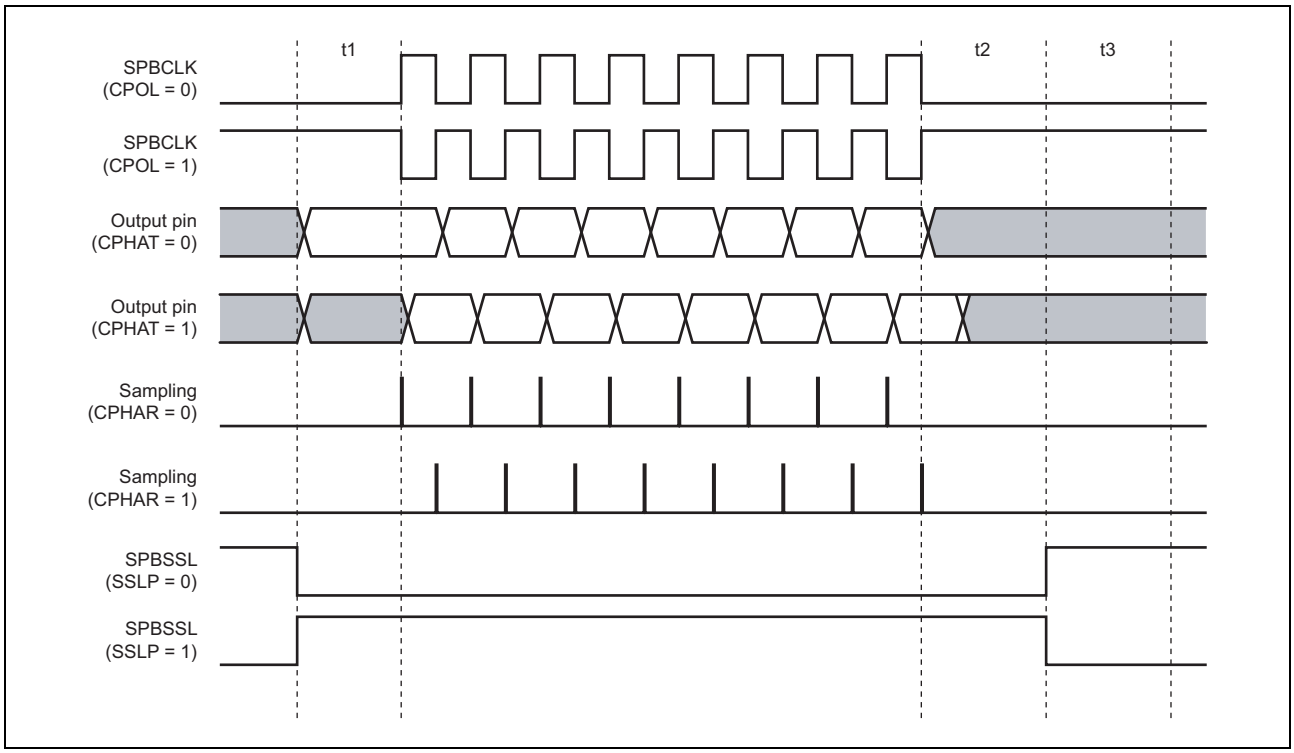

Figure 17.18 SDR Transfer Format

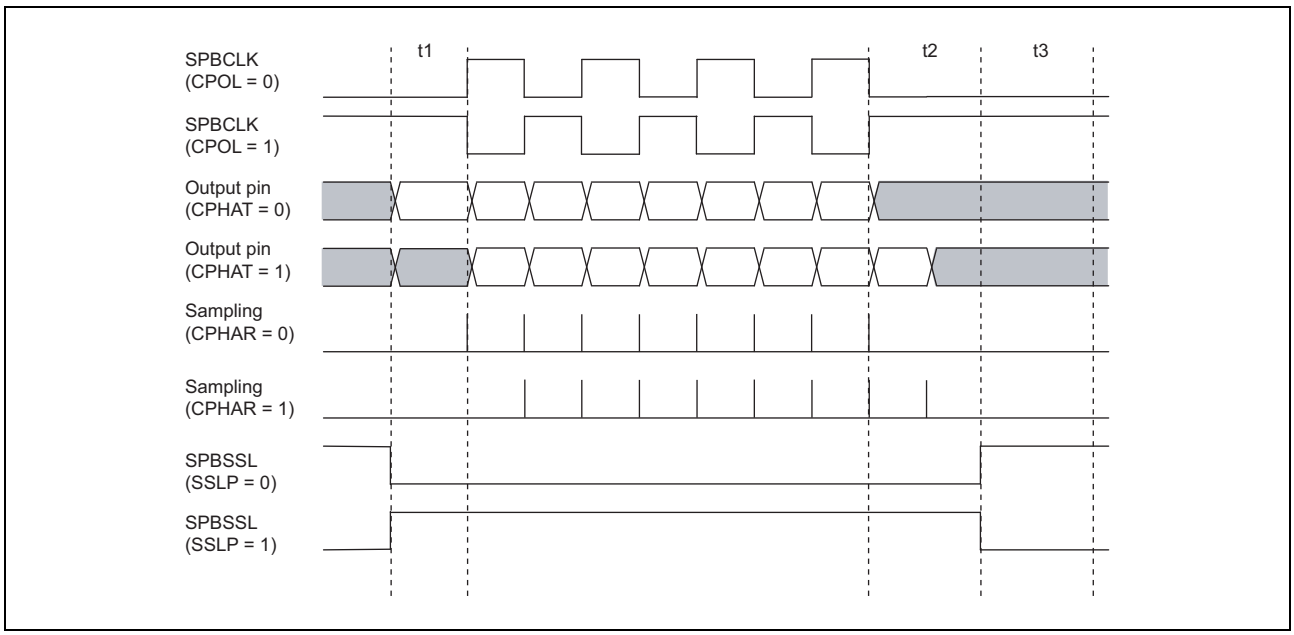

Figure 17.19 DDR Transfer Format

NOTE

In DDR reception when CPHAR = 1, the sampling timing of the last bit is based on the frequency-divided clock in this module.
When CPHAT = 1 in DDR transfer, the serial flash memory cannot provide the sampling timing of the last bit; therefore, a transfer ending with a DDR transfer is not performed correctly when CPHAT = 1.

17.5.10 Data Format

This module can input and output data in the order of command, optional command, address, option data, dummy cycle and data.

17.5.10.1 Data Registers

Table 17.8 shows the input and output data.

Table 17.8 Data Registers

Data		External Address Space Read Operation	SPI Operation
Command (8 bits)		CMD[7:0] bits in DRCMR	CMD[7:0] bits in SMCMR
Optional command (8 bits)		OCMD[7:0] bits in DRCMR	OCMD[7:0] bits in SMCMR
Address (32/24 bits)	BSZ[1:0] = 00 (one flash memory connected)	32 bits: DREAR.EAV[6:1 to 0] bits + lower [25 to 24:0] bits of the read address. 24 bits: Lower [23:0] bits of the read address	32 bits: ADR[31:0] bits in SMADR 24 bits: ADR[23:0] bits in SMADR
	BSZ[1:0] = 01 (two flash memories connected)	32 bits: DREAR.EAV[7:1 to 0] bits + lower [25 to 24:1] bits of the read address. 24 bits: Lower [24:1] bits of the read address	
Option data (8 bits × 4)		DROPR	SMOPR
Dummy cycle (1 to 8 cycles)		DRDMCR	SMDMCR (only when read)
Transfer data		Normal read: 8, 16, and 32 bits Burst read: 64 × (RBURST[3:0] bits + 1)	Read: SMRDR0, SMRDR1 Write: SMWDR0, SMWDR1

17.5.10.2 Data Enable

In external address space read mode, transfer enable or disable of the command, optional command, address, option data, and dummy cycle can be controlled with the CDE, OCDE, ADE[3:0], OPDE[3:0], and DME bits in DRENR, respectively. The size and number of dummy cycles can be controlled with the data read dummy cycle setting register (DRDMCR). When the SPBCLK frequency division ratio is two or larger, either SDR or DDR transfer can be selected for the address, option data, and read data, using the ADDRE, OPDRE, and DRDRE bits in the data read DDR enable register (DRDRENR).

Similarly, in SPI operating mode, enable or disable of the command, optional command, address, option data, dummy cycle, and transfer data can be controlled with the CDE, OCDE, ADE[3:0], OPDE[3:0], DME, and SPIDE[3:0] bits in SMENR, respectively. However, disabling all the above parameters is prohibited in SPI operating mode. At least one of them except dummy cycle must be enabled. The size and number of dummy cycles can be controlled with the SPI mode dummy cycle setting register (SMDMCR). When the SPBCLK frequency division ratio is two or larger, either SDR or DDR transfer can be selected for the address, option data, and transfer data, using the ADDRE, OPDRE, and SPIDRE bits in the SPI mode DDR enable register (SMDRENR).

For the address and option data in external address space read mode; and the address, option data, and transfer data in SPI operating mode, the enable bit setting allowed is determined according to the transfer data size. For the allowed setting combinations of the enable bits and transfer data size, refer to the description of the pertinent registers.

If data is disabled, that data is skipped, and input and output of the next data is carried out. The command, optional command, address, and option data are always output. During dummy cycles, the state of the used pins is Hi-Z. In external address space read mode, data is always input; and in SPI operating mode, input and output of data is determined based on the settings of the SPIRE and SPIWE bits in SMCR.

There are some restrictions on dummy cycle insertion; refer to the description of the DME bits in DRENR and SMENR for details.

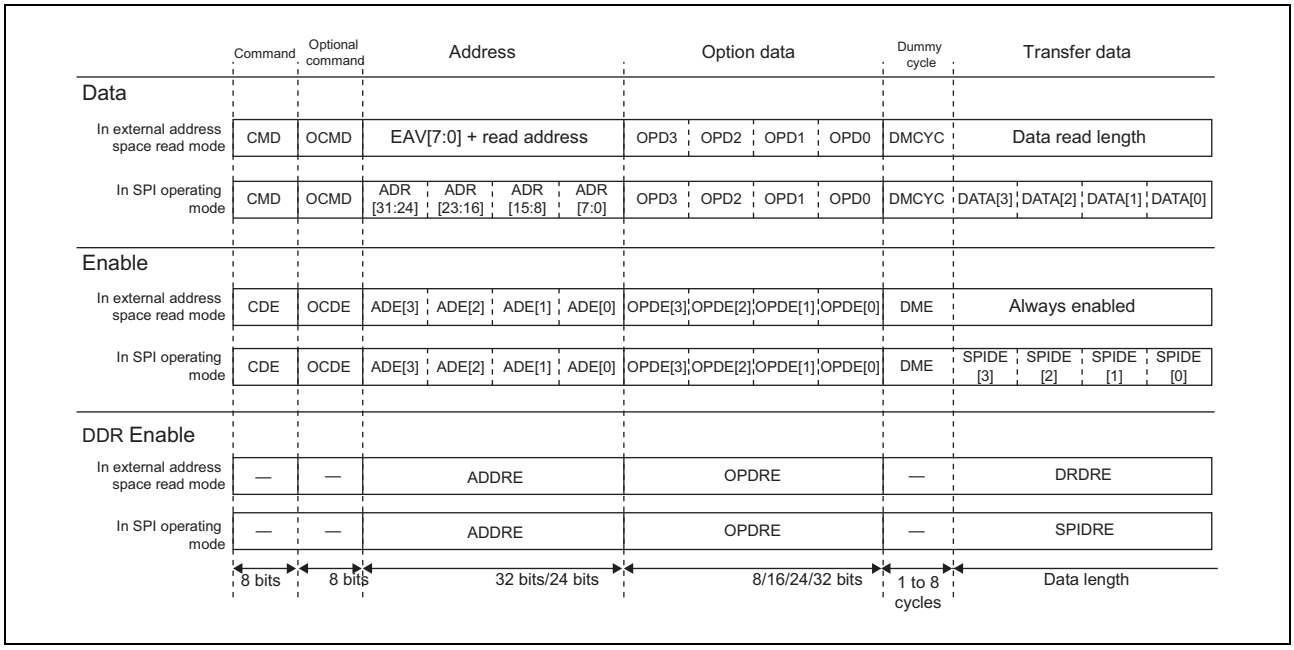

Figure 17.20 Data and Enable

17.5.10.3 Bit Size

In external address space read mode, the size of the command, optional command, address, option data, and the read data in bit units is respectively controlled with the CDB[1:0], OCDB[1:0], ADB[1:0], OPDB[1:0], and DRDB[1:0] bits in DRENR. The size of the dummy cycle in bit units is also controlled with the DMDB[1:0] bits in DRDMCR.
Similarly, in SPI operating mode, the size of the command, optional command, address, option data, and read write data in bit units is controlled with the CDB[1:0], OCDB[1:0], ADB[1:0], OPDB[1:0], and SPIDB[1:0] bits in SMENR. The size of the dummy cycle in bit units is also controlled with the DMDB[1:0] bits in SMDMCR.

(1) 1-bit Size

When the size is set to 1 bit, SPBMI0 and SPBMI1 pins will be the input pins and SPBMO0 and SPBMO1 pins will be the output pins. SPBIO20, SPBIO21, SPBIO30, and SPBIO31 pins are not used.

Figure 17.21 and **Figure 17.22** show the transfer format examples.

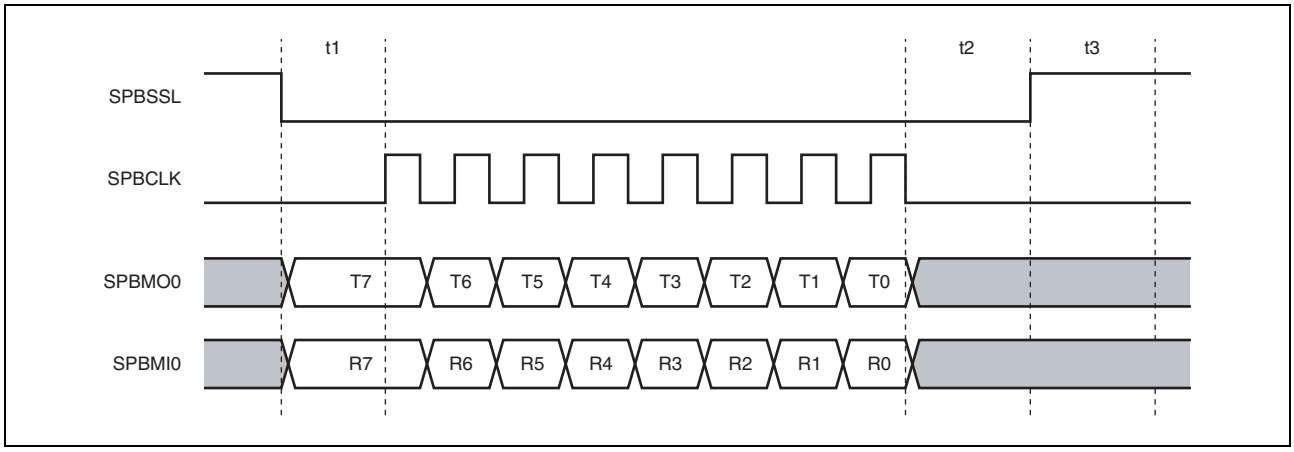

Figure 17.21 Transfer Format Example with 1-Bit Data Size and One Serial Flash Memory Connected

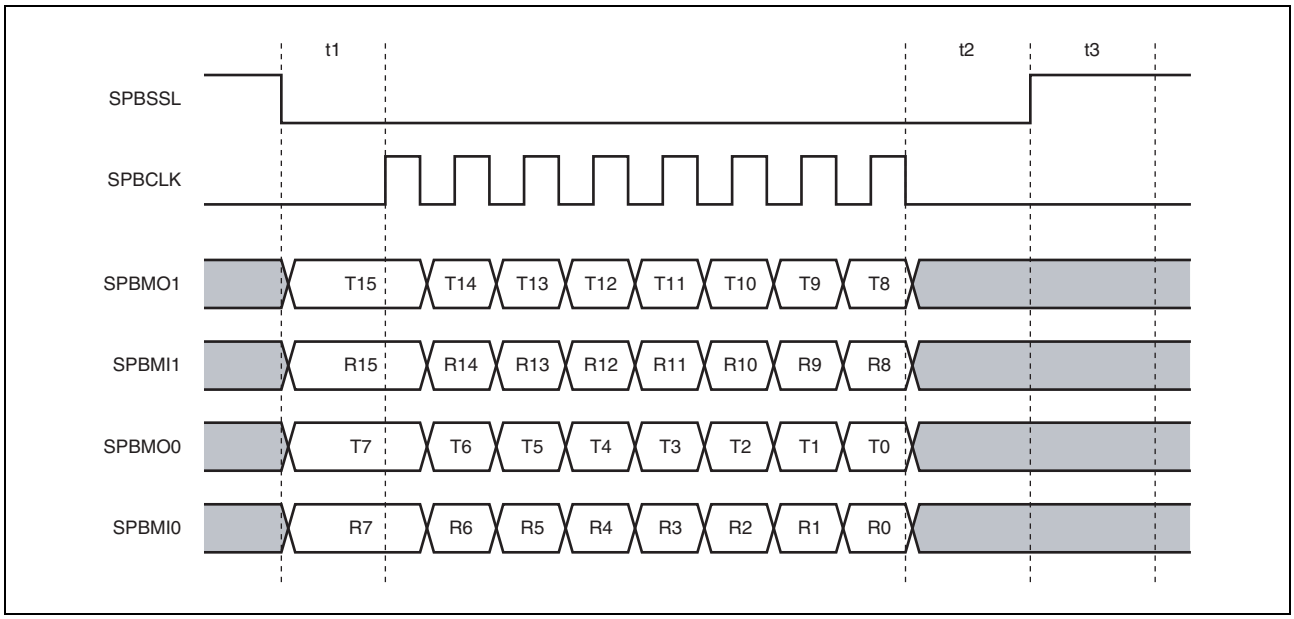

Figure 17.22 Transfer Format Example with 1-Bit Data Size and Two Serial Flash Memories Connected

(2) 2-bit Size

When the size is set to 2 bits, SPBIO00, SPBIO01, SPBIO10, and SPBIO11 pins will be either the input pins or the output pins. SPBIO20, SPBIO21, SPBIO30, and SPBIO31 pins are not used.

Figure 17.23 and **Figure 17.24** show the transfer format examples.

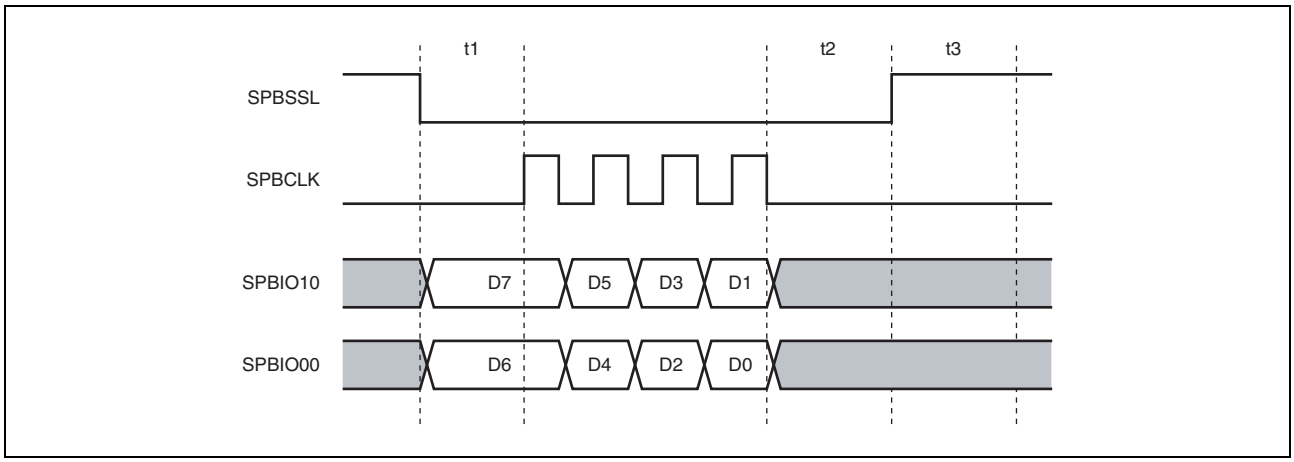

Figure 17.23 Transfer Format Example with 2-Bit Data Size and One Serial Flash Memory Connected

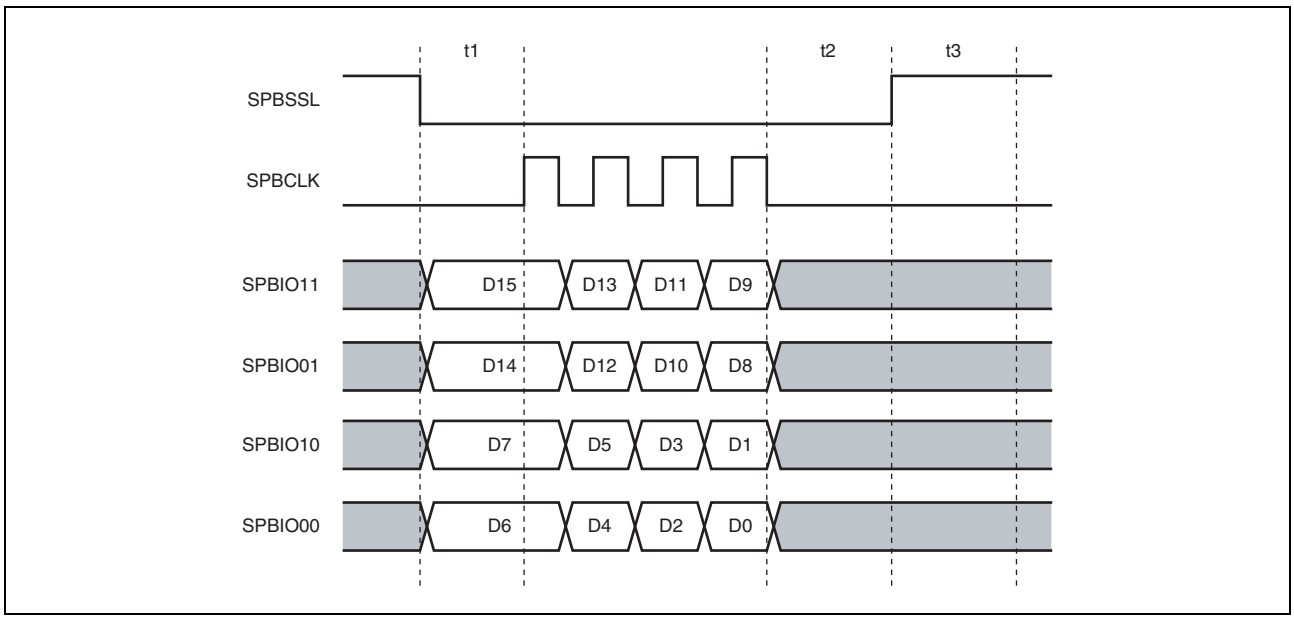

Figure 17.24 Transfer Format Example with 2-Bit Data Size and Two Serial Flash Memories Connected

(3) 4-bit Size

When the size is set to 4 bits, SPBIO00, SPBIO01, SPBIO10, SPBIO11, SPBIO20, SPBIO21, SPBIO30, and SPBIO31 pins will be either the input pins or the output pins.

Figure 17.25 and **Figure 17.26** show the transfer format examples.

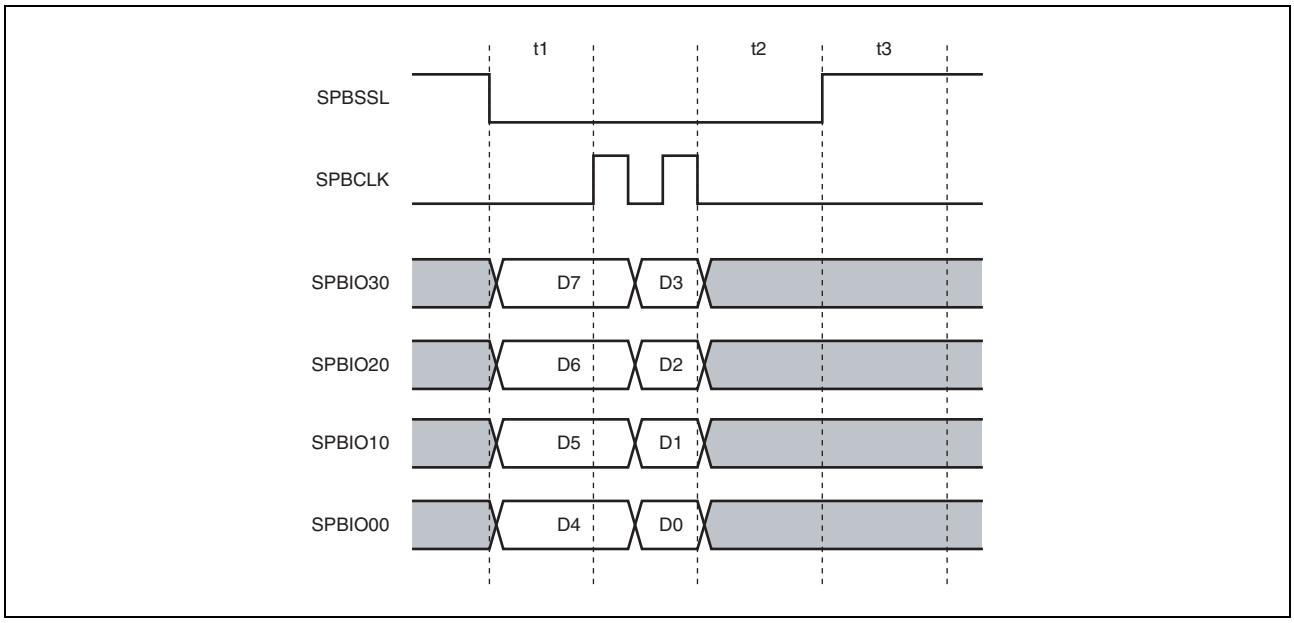

Figure 17.25 Transfer Format Example with 4-Bit Data Size and One Serial Flash Memory Connected

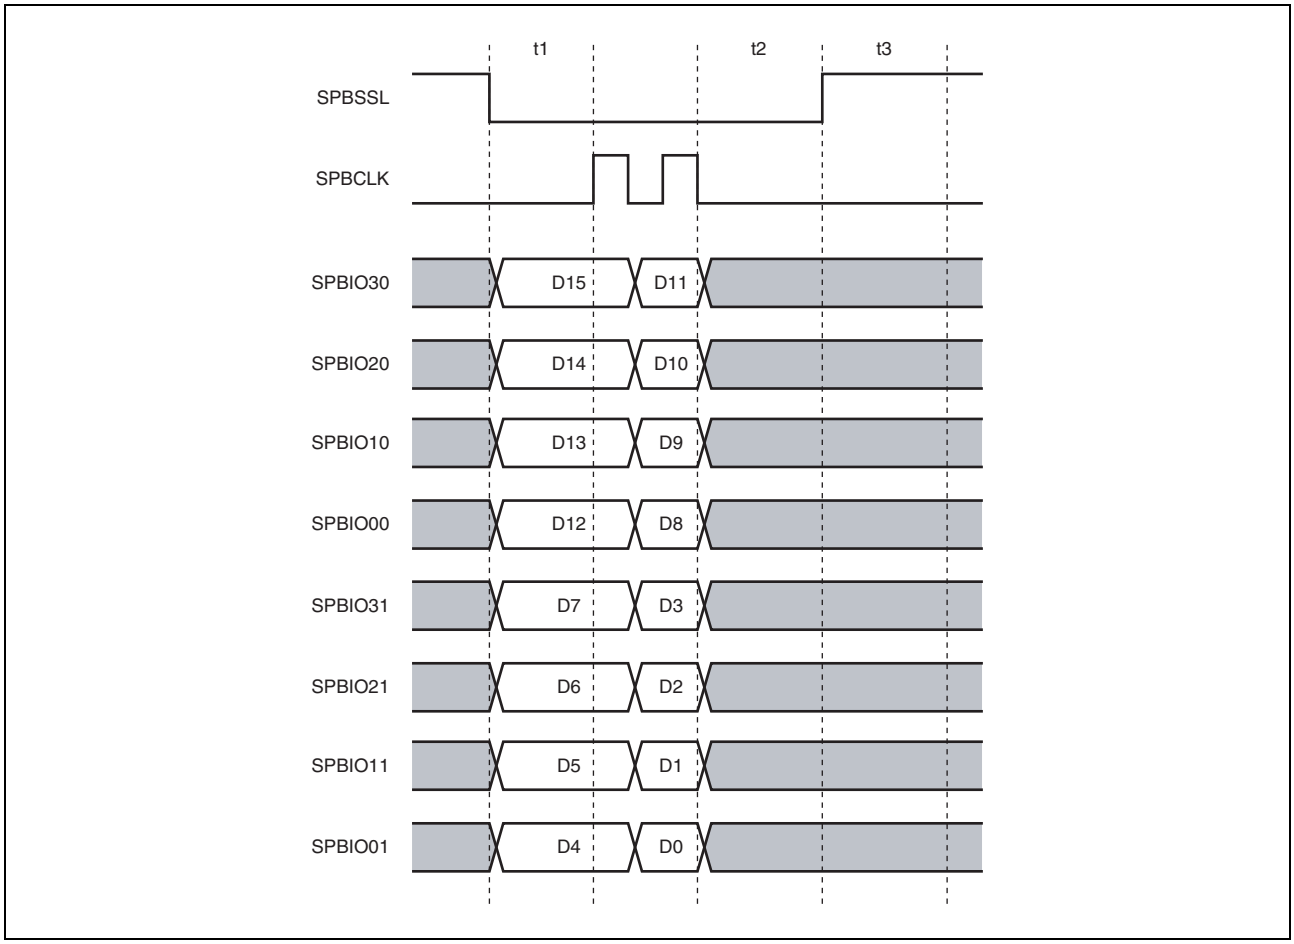

Figure 17.26 Transfer Format Example with 4-Bit Data Size and Two Serial Flash Memories Connected

17.5.11 Data Pin Control

With this module, the status of pins can be automatically changed based on the data size to be used and the read/write settings. The pin status during the SPBSSL negation can be set with the MOIIO3[1:0], MOIIO2[1:0], MOIIO1[1:0], and MOIIO0[1:0] bits in CMNCR. The SPBSSL and SPBCLK pins are always output pins. The status of respective pins is specified in **Table 17.9** to **Table 17.12**.

Table 17.9 Pin Status (1)

		SPBSSL Assertion		
		Command, Optional Command, Address, Option Data		
Pin	**SPBSSL Negation**	**1-bit Size**	**2-bit Size**	**4-bit Size**
SPBMO0/ SPBIO00, SPBMO1/ SPBIO01	MOIIO0[1:0] bit value	Output	Output	Output
SPBMI0/ SPBIO10, SPBMI1/ SPBIO11	MOIIO1[1:0] bit value	Hi-Z	Output	Output
SPBIO20, SPBIO21	MOIIO2[1:0] bit value	IO2FV[1:0] bit value	IO2FV[1:0] bit value	Output
SPBIO30, SPBIO31	MOIIO3[1:0] bit value	IO3FV[1:0] bit value	IO3FV[1:0] bit value	Output

Table 17.10 Pin Status (2)

	Transfer Data					
	External Address Space Read Operation			SPI Operation		
				SPIRE Bit = 1, SPIWE Bit = 0		
Pin	1-bit Size	2-bit Size	4-bit Size	1-bit Size	2-bit Size	4-bit Size
SPBMO0/ SPBIO00, SPBMO1/ SPBIO01	IO0FV[1:0] bit value	Input	Input	IO0FV[1:0] bit value	Input	Input
SPBMI0/ SPBIO10, SPBMI1/ SPBIO11	Input	Input	Input	Input	Input	Input
SPBIO20, SPBIO21	IO2FV[1:0] bit value	IO2FV[1:0] bit value	Input	IO2FV[1:0] bit value	IO2FV[1:0] bit value	Input
SPBIO30, SPBIO31	IO3FV[1:0] bit value	IO3FV[1:0] bit value	Input	IO3FV[1:0] bit value	IO3FV[1:0] bit value	Input

Table 17.11 Pin Status (3)

Table 17.12 Pin Status (4)

	Dummy Cycle		
Pin	1-bit Size	2-bit Size	4-bit Size
SPBMO0/ SPBIO00, SPBMO1/ SPBIO01	IO0FV[1:0] bit value	Hi-Z	Hi-Z
SPBMI0/ SPBIO10, SPBMI1/ SPBIO11	Hi-Z	Hi-Z	Hi-Z
SPBIO20, SPBIO21	IO2FV[1:0] bit value	IO2FV[1:0] bit value	Hi-Z
SPBIO30, SPBIO31	IO3FV[1:0] bit value	IO3FV[1:0] bit value	Hi-Z

17.5.12 SPBSSL Pin Control

Negation conditions of the SPBSSL pin are as follows.

17.5.12.1 External Address Space Read Mode

(1) Normal read operation (RBE bit in DRCR = 0)

SPBSSL negated after completing the data transfer and t2 cycle.

(2) Burst read without automatic SPBSSL negation (RBE bit in DRCR = 1, SSLE bit in DRCR = 0)

SPBSSL negated after completing the data transfer and t2 cycle.

(3) Burst read with automatic SPBSSL negation (RBE bit in DRCR = 1, SSLE bit in DRCR = 1)

- SPBSSL negated after t2 cycle when the read address is not continuous with the previously read address
- SPBSSL negated after the SSLN bit in DRCR is set to 1

17.5.12.2 SPI Operating Mode

(1) SPBSSL pin assertion not retained (SSLKP bit in SMCR = 0)

SPBSSL negated after completing the data transfer and t2 cycle.

(2) SPBSSL pin assertion retained (SSLKP bit in SMCR = 1)

SPBSSL not negated.

When to be negated, data should be transferred after setting the SSLKP bit to 0.

17.5.13 Flags

This module has two flag bits SSLF and TEND in CMNSR. These bits are read-only bits.

17.5.13.1 SSLF Bit

This bit indicates the SPBSSL pin status. The status is 1 when the SPBSSL is asserted, and the status is 0 when the SPBSSL is negated.

17.5.13.2 TEND Bit

This bit indicates whether transfer of data is in progress or the transfer of data has ended.

During t1 time period, data transfer, t2 time period, t3 time period, and waiting for read access by burst read and SPBSSL automatic negation, the TEND bit is read as 0 to indicate that the transfer of data is in progress.

When other than the above, the TEND bit is read as 1 to indicate that transfer of data has ended.

17.5.13.3 Register Re-writing Timing

The status of the TEND bit determines the rewritable registers.

The registers which can be written to, except the SSLN bit in DRCR, should be modified when TEND = 1. Read SMRDR0 and SMRDR1 when TEND = 1. CMNSR can always be read.

17.5.14 Adjustment between input/output data and sampling clocks

If the frequency of the SPBCLK output clock exceeds a certain limit, the phase relation between output and input data and the respective clock signals need to be adjusted:

- SPBCLK frequency < 60 MHz:
  - delay between SPBCLK and the output data is set to a fixed value
  - sampling point of input data is not shifted

  Refer to Section 17.5.14.1, Adjustments for SPBCLK frequency < 60 MHz.
- SPBCLK frequency ≥ 60 MHz:
  - delay between SPBCLK and the output data depends on the $f_{PHCLK}/f_{B\Phi}$ relation
  - sampling point of input data depends on the $f_{PHCLK}/f_{B\Phi}$ relation

  Refer to Section 17.5.14.2, Adjustments for SPBCLK frequency ≥ 60 MHz.

NOTE

The phase shift effects described in this section are independent from any other shift or signal polarity settings, like e.g. via the CPHAT, CPHAR, CPOL, SSLP bit settings of the common control register CMNCR.

17.5.14.1 Adjustments for SPBCLK frequency < 60 MHz

(1) Output clock adjustment

In this case the phase relation between SPBCLK and the output data is set fixed delay of minimum 2 ns by the output data delay register:

- SPODLY.DLYOE0 = SPODLY.DLYO0 = 1: 2 ns delay for port 0
- SPODLY.DLYOE1 = SPODLY.DLYO1 = 1: 2 ns delay for port 1

Refer to the Data Sheet for the delay value range.

Further the SPBCLK clock phase shift value in the clock phase shift adjust register CKDLY needs to be disabled:

- CKDLY.CKDLYOC[2:0] = 000_B: no phase shift

(2) Input sampling point calibration

The sampling point of the input data does not need to be calibrated, thus set

- CKDLY.CKDLYRX[2:0] = 000_B: no sampling point shift

17.5.14.2 Adjustments for SPBCLK frequency ≥ 60 MHz

(1) Output clock adjustment

In this case the delay between SPBCLK and the output data depends on the $f_{PHCLK}/f_{B\Phi}$ relation and needs to be adjusted:

- $f_{PHCLK}/f_{B\Phi} = 2$: set CKDLY.CKDLYOC[2:0] = 010_B
- $f_{PHCLK}/f_{B\Phi} = 3$: set CKDLY.CKDLYOC[2:0] = 011_B
- $f_{PHCLK}/f_{B\Phi} = 4$: set CKDLY.CKDLYOC[2:0] = 101_B

NOTE

The $f_{PHCLK}/f_{B\Phi}$ relation is selected via the clock divider register CKSC_ISFMAD_CTL, which allows to select ratios of 2, 3, 4, 6. If f_{PHCLK} is at its maximum of 480 MHz and $f_{PHCLK}/f_{B\Phi} = 6$ is selected, the serial clock SPBCLK is maximum 40 MHz by SPBR[7:0] = 1. Thus the settings described in Section 17.5.14.1, Adjustments for SPBCLK frequency < 60 MHz are to be used.

The fixed delay needs to be disabled:

- SPODLY.DLYOE0 = SPODLY.DLYO0 = 0: no fixed delay for port 0
- SPODLY.DLYOE1 = SPODLY.DLYO1 = 0: no fixed delay for port 1

(2) Input sampling point calibration

The sampling point calibration process optimizes the time of the sampling point of the input data, read from the external flash memory device.

This is achieved by shifting the sampling edge of the SPBCLK clock signal versus the data signals SPBIO. The shift values are defined as parts of the BΦ cycle period.

The sampling point value CKDLY.CKDLYRX[2:0] is used for the calibration. If AC timing between target flash memory device meets with CKDLY.CKDLYRX[2:0] = 000_B setting, fixed setting of CKDLY.CKDLYRX[2:0] = 000_B can be used and the calibration is not needed.

The StepSize of the sampling point shift value is calculated as follows:

$$StepSize = \frac{180°}{f_{PHCLK}/f_{B\Phi}}$$

The maximum number of shift steps MaxSteps, selectable by CKDLY.CKDLYRX[2:0], is

$$MaxSteps = \frac{360°}{StepSize} - 2$$

and thus the maximum sample point shift MaxShift

$$MaxShift = \left(\frac{360°}{StepSize} - 2\right) \bullet StepSize$$

The following table summarizes the clock frequencies and necessary register settings for some examples.

Table 17.13 Clock adjustment settings examples (for f_{PHCLK} = 480 MHz)

$f_{PHCLK}/f_{B\Phi}$	CKDLYOC[2:0]	$f_{B\Phi}$	max. f_{SPBCLK}	StepSize	MaxSteps	CKDLYRX[2:0]	Sampling point
2*1	010_B	240 MHz	120 MHz	90°	2 steps	000_B:	no shift
						001_B:	90° shift
						010_B: MaxShift =	180° shift
3	011_B	160 MHz	80 MHz	60°	4 steps	000_B:	no shift
						001_B:	60° shift
						010_B:	120° shift
						011_B:	180° shift
						100_B: MaxShift =	240° shift
4	101_B	120 MHz	60 MHz	45°	6 steps	000_B:	no shift
						001_B:	45° shift
						010_B:	90° shift
						011_B:	135° shift
						100_B:	180° shift
						101_B:	225° shift
						110_B: MaxShift =	270° shift

Note 1. The $f_{PHCLK}/f_{B\Phi}$ ratio of 2 can only be used for SDR mode operation.

Sampling point calibration procedure

Perform the calibration procedure below before using the external flash memory.

1. Configure the SFMA and the external flash memory devices for data read from the external address space.
2. First select the maximum sample point shift value for the selected clocks via CKDLY.CKDLYRX[2:0].
3. Read predefined data from flash.
   - If the read data is incorrect, decrement CKDLYRX[2:0] to next lower value and read data again.
   - If the read data is correct, decrement current CKDLYRX[2:0] value by 1 finally. Calibration is completed.

   If the read data is already correct with the maximum sampling point shift, increment current CKDLYRX[2:0] value by 1.
   If the CKDLYRX[2:0] value reaches 000_B and read data is correct at this point, set CKDLYRX[2:0] = 000_B as the phase shift value.
   - If Read data correct, previous value(maximum value) is to be used and Calibration is completed.
   - If Read data not correct, CKDLYRX[2:0] value decrement by 1 from maximum sampling point value.

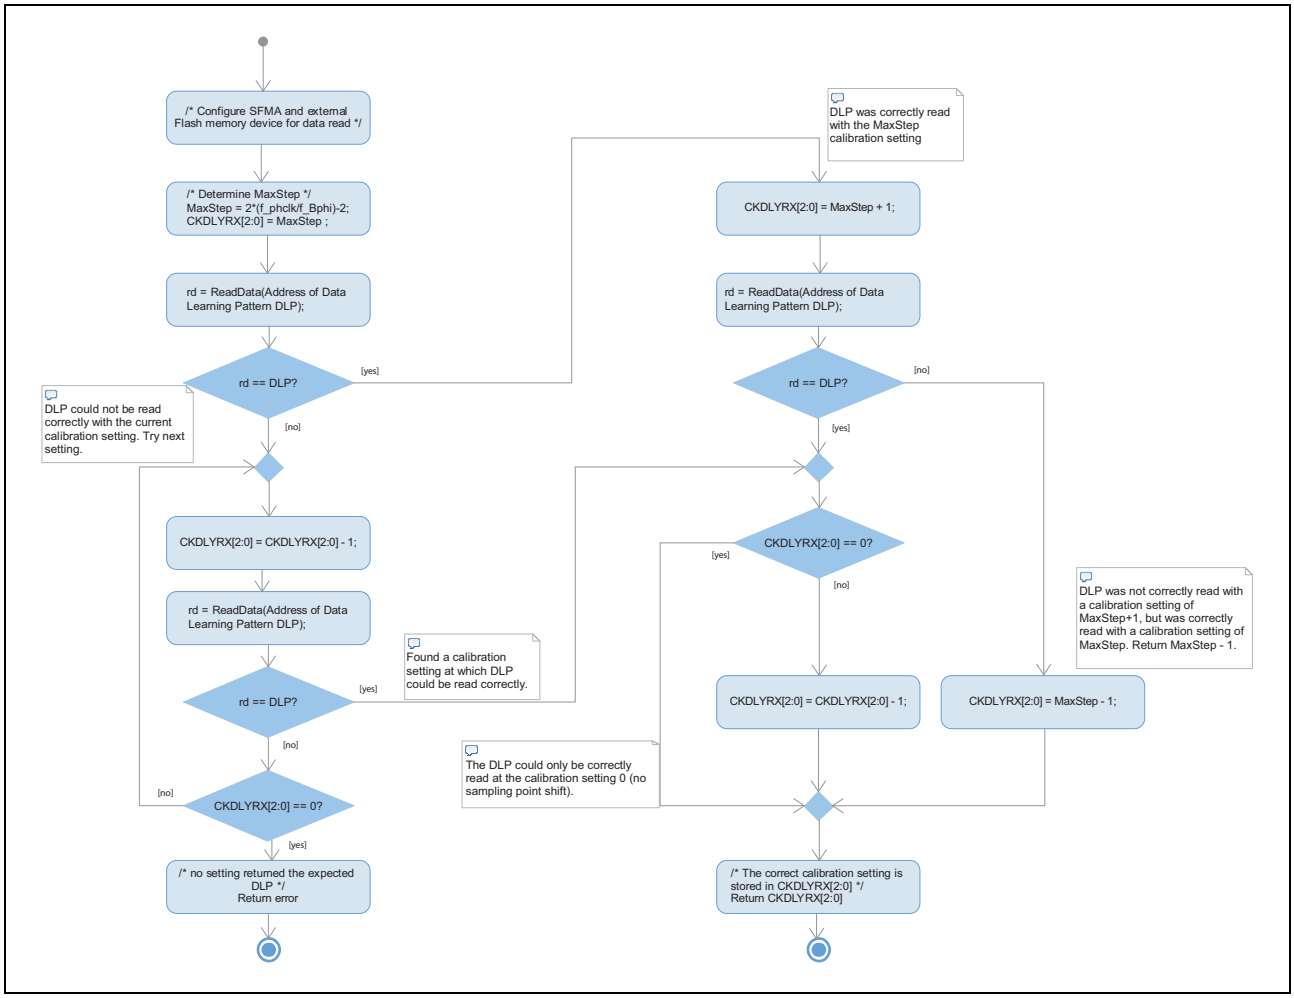

Figure 17.27 Sampling point calibration procedure flow

NOTE

For the calibration the usage of the below data pattern is preferred.

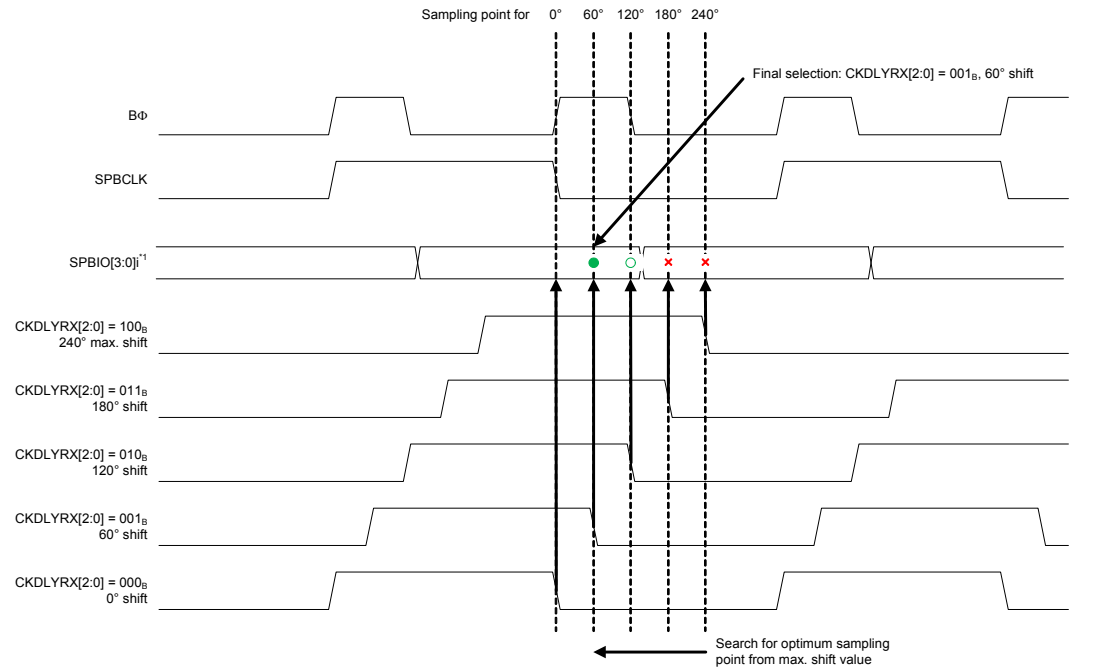
1. 1-bit DDR: 3434_H
2. 1-bit DDR with other Data-Learn Pattern: 6969_H
3. 2-bit DDR with other Data-Learn Pattern: $3CC33CC3_H$
4. 4-bit DDR with other Data-Learn Pattern: $0FF0F00F0FF0F00F_H$
5. 4-bit DDR x 2 device with other Data-Learn Pattern: $0F0FF0F0F0F00F0F0F0FF0F0F0F00F0F_H$

However also the Data-Learn Pattern (DLP) or any other data can be used.

Example: Calibration for f_{PHCLK} = 480 MHz, BΦ = 160 MHz

- start with MaxShift = 240°, i.e. CKDLYRX[2:0] = 100_B
- read data is not correct → CKDLYRX[2:0] decrement to 011_B, i.e. shift by 180°
- read data is not correct → CKDLYRX[2:0] decrement to 010_B, i.e. shift by 120°
- read data is correct → CKDLYRX[2:0] decrement to 001_B, i.e. shift by 60°
- read data is correct. Use CKDLYRX[2:0] value 001_B (i.e. shift by 60°) finally.

The following diagram visualizes this calibration process.



Note 1. i = 0, 1

Figure 17.28 Sampling point calibration

17.6 Usage Notes

17.6.1 Notes on Transfer to Read Data in SPI Operating Mode

If the setting for the bit mode is for division by two or more in SPI operating mode, take note of the following points for caution when setting the SPI mode enable setting register (SMENR) to enable transfer only for reading data.

"Transfer only for reading data" indicates transfer to read data while the CDE, OCDE, ADE[3:0], and OPDE[3:0] bits in SMENR are all 0.

17.6.1.1 Transfer to read data while the signal on the SPBSSL pin is de-asserted

Set the SMENR.SPIDE[3:0] bits to 1100 or 1111 when transfer only for reading data is to proceed.

Transfer will not proceed normally if the setting of the SMENR.SPIDE[3:0] bits is 1000.

17.6.1.2 Transfer to read data while the signal on the SPBSSL pin is asserted

When transfer only for reading data is to proceed, set the SMENR.SPIDE[3:0] bits to 1100 or 1111, or end the immediately preceding transfer with reading data.

When the immediately preceding transfer is of a command, optional command, address, or option data, or is transfer for writing data, the subsequent transfer only for reading data will not proceed normally if the setting of the SMENR.SPIDE[3:0] bits is 1000.

17.6.2 Notes on Starting Transfer from the SPBSSL Retained State in SPI Operating Mode

Be sure to set the SPIWE bit in the SMCR register to 1 when the transfer of a command, optional command, address, or option data is started while the SPBSSL pin is being asserted in SPI operating mode.

17.6.3 Notes on using the SFMA Cache

If the SFMA or its mirror addresses are accessed by CPU in External Address Space Read Mode, special care has to be taken for the XC Cache and the SFMA Cache settings.

Condition:

An XC Cache window has been defined for any address range used by SFMA and CPU accesses SFMA inside of this address window.

Action:

The SFMA Cache has to be activated by setting DRCR.BFM[2:0] = 111_B and DRCR.RBE = 1_B.

For activated SFMA cache, burst length is recommended to be set to DRCR.RBURST[3:0] = 1111_B.

Section 18 Clocked Serial Interface G (CSIG)

This section contains a generic description of the Clocked Serial Interface G (CSIG).

The first part in this section describes all RH850/D1L/D1M specific properties, such as the number of units, register base addresses, etc. The remainder of the section describes the functions and registers of the CSIG.

18.1 Features of RH850/D1L/D1M CSIG

18.1.1 Number of Units

This microcontroller has the following number of units of the CSIG.

Each CSIG unit has one channel interface. “Number of channels” is used with the same meaning as “number of units” in this section.

Table 18.1 Number of Units

Product Name	All products
Number of Units	4
Name	CSIGn (n = 0 to 3)

Table 18.2 Index

Index	Meaning
n	Throughout this section, the individual CSIG units are identified by the index “n” (n = 0 to 3): for example, CSIGnCTL0 is the CSIGn control register 0.

18.1.2 Register Base Address

CSIG base addresses are listed in the following table.

CSIG register addresses are given as offsets from the base addresses in general.

Table 18.3 Register Base Address

Base Address Name	Base Address
<CSIG0_base>	FFDA 0000_H
<CSIG1_base>	FFDA 2000_H
<CSIG2_base>	FFDA 4000_H
<CSIG3_base>	FFDA 6000_H

18.1.3 Clock Supply

The CSIG clock supply is shown in the following table.

Table 18.4 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
CSIGn	PCLK	Clock Controller CLKJIT

18.1.4 Interrupt Request

CSIG interrupt requests are listed in the following table.

Table 18.5 Interrupt Requests

CSIGn signals	Function	Connected to
CSIG0:		
INTCSIGTIC	Communication status interrupt	Interrupt Controller INTCSIG0IC DMA Controller trigger ID 95
INTCSIGTIR	Receive status interrupt	Interrupt Controller INTCSIG0IR DMA Controller trigger ID 96
INTCSIGTIRE	Communication error interrupt	Interrupt Controller INTCSIG0IRE
CSIG1:		
INTCSIGTIC	Communication status interrupt	Interrupt Controller INTCSIG1IC DMA Controller trigger ID 97
INTCSIGTIR	Receive status interrupt	Interrupt Controller INTCSIG1IR DMA Controller trigger ID 98
INTCSIGTIRE	Communication error interrupt	Interrupt Controller INTCSIG1IRE
CSIG2:		
INTCSIGTIC	Communication status interrupt	Interrupt Controller INTCSIG2IC DMA Controller trigger ID 99
INTCSIGTIR	Receive status interrupt	Interrupt Controller INTCSIG2IR DMA Controller trigger ID 100
INTCSIGTIRE	Communication error interrupt	Interrupt Controller INTCSIG2IRE
CSIG3:		
INTCSIGTIC	Communication status interrupt	Interrupt Controller INTCSIG3IC DMA Controller trigger ID 101
INTCSIGTIR	Receive status interrupt	Interrupt Controller INTCSIG3IR DMA Controller trigger ID 102
INTCSIGTIRE	Communication error interrupt	Interrupt Controller INTCSIG3IRE

18.1.5 Reset Sources

CSIG reset sources are listed in the following table. CSIG is initialized by these reset sources.

Table 18.6 Reset Sources

Unit Name	Reset Source
CSIGn	• Reset Controller SYSRES • reset upon wake-up from DEEPSTOP mode

18.1.6 External Input/Output Signals

External input/output signals of CSIG are listed below.

Table 18.7 External Input/Output Signals

Unit Signal Name	Outline	Alternative Port Pin Signal
CSIG0		
CSIGTSCK	Serial clock signal	CSIG0SC*1
CSIGTSI	Serial data input signal	CSIG0SI*1
CSIGTSO	Serial data output signal	CSIG0SO
$\overline{\text{CSIGTSSI}}$	Slave select input signal	$\overline{\text{CSIG0SSI}}$*1
CSIGTRYI	Ready / busy input signal	CSIG0RYI*1*2
CSIGTRYO	Ready / busy output signal	CSIG0RYO*2
CSIG1		
CSIGTSCK	Serial clock signal	CSIG1SC*1
CSIGTSI	Serial data input signal	CSIG1SI*1
CSIGTSO	Serial data output signal	CSIG1SO
$\overline{\text{CSIGTSSI}}$	Slave select input signal	$\overline{\text{CSIG1SSI}}$*1
CSIGTRYI	Ready / busy input signal	CSIG1RYI*1*2
CSIGTRYO	Ready / busy output signal	CSIG1RYO*2
CSIG2		
CSIGTSCK	Serial clock signal	CSIG2SC*1
CSIGTSI	Serial data input signal	CSIG2SI*1
CSIGTSO	Serial data output signal	CSIG2SO
$\overline{\text{CSIGTSSI}}$	Slave select input signal	$\overline{\text{CSIG2SSI}}$*1
CSIGTRYI	Ready / busy input signal	CSIG2RYI*1*2
CSIGTRYO	Ready / busy output signal	CSIG2RYO*2
CSIG3		
CSIGTSCK	Serial clock signal	CSIG3SC*1
CSIGTSI	Serial data input signal	CSIG3SI*1
CSIGTSO	Serial data output signal	CSIG3SO
$\overline{\text{CSIGTSSI}}$	Slave select input signal	$\overline{\text{CSIG3SSI}}$*1
CSIGTRYI	Ready / busy input signal	CSIG3RYI*1*2
CSIGTRYO	Ready / busy output signal	CSIG3RYO*2

Note 1. These input signals are passed through a noise filter, refer to the section “Port Filters” in the section “Port Functions”.

Note 2. For availability of these signals, refer to the Section 2.3.2, List of Alternative Function Pins.

18.1.7 Data Consistency Check

The following table lists the port pins on which CSIGnSO pin functions are multiplexed and data consistency checking is possible. See Section 18.5.10, Error Detection for details on data consistency checking.

Table 18.8 CSIGn data consistency check ports

Unit Signal Name	Port Pin Name	Alternative Function
CSIG0		
CSIGTSO	P1_9	ALT_OUT1
	P45_3	ALT_OUT4
	P42_3	ALT_OUT4
CSIG1		
CSIGTSO	P1_3	ALT_OUT1
	P2_5	ALT_OUT1
	P45_12	ALT_OUT4
CSIG2		
CSIGTSO	P1_6	ALT_OUT1
	P44_2	ALT_OUT4
CSIG3		
CSIGTSO	P2_1	ALT_OUT1
	P44_7	ALT_OUT4
	P42_8	ALT_OUT4
	P42_12	ALT_OUT6

18.2 Overview

18.2.1 Functional Overview

- Three-wire serial synchronous data transfer
- Selection of master mode and slave mode
- Slave select input signal ($\overline{\text{CSIGTSSI}}$) is usable.
- Built-in baud rate generator
- Transfer clock frequency is adjustable in master mode, whereas it is determined by the input clock in slave mode.
- Maximum transfer clock frequency:
  - In master mode: equal to or lower than PCLK/4
  - In slave mode: equal to or lower than PCLK/6
- Selectable clock phase and data phase
- Data transfer selectable from MSB or LSB first
- Transfer data length selectable from 7 to 16 bits in 1-bit units
- Incorporates an EDL (extended data length) function for transferring more than 16 bits of data
- Three selectable transfer modes:
  - transmit-only mode
  - receive-only mode
  - transmit/receive mode
- Built-in handshake function
- Error detection (data consistency check, parity, overrun) included
- Three different interrupt request signals (INTCSIGTIC, INTCSIGTIR, INTCSIGTIRE)
- LBM (Loop Back Mode) function for self test included

18.2.2 Functional Overview Description

The CSIG uses three signals for communication:

- Transmission clock CSIGTSCK (output: in master mode, input: in slave mode)
- Serial data output signal CSIGTSO
- Serial data input signal CSIGTSI

The CSIGnCTL2 register is used to select whether the CSIG should be operated in master mode or slave mode.
In addition, the signals for the external control and monitoring are available.

- CSIGTSSI: Slave select input signal
- CSIGTRYO: Ready/busy output signal (handshake signal)
- CSIGTRYI: Ready/busy input signal (handshake signal)

Data transmission is bit-wise and serial and synchronous to the transmission clock.

The most important registers for setting up the CSIG are:

Table 18.9 Main Registers of CSIG

Register	Function
CSIGnCTL0	Provides and stops operating clock and enables/disables data transmission and data reception.
CSIGnCTL1	Controls options like interrupt timing, extended data length, data consistency check, loop-back mode, handshake, etc.
CSIGnCTL2	Selects master or slave mode, and the transfer clock frequency of the built-in baud rate generator (BRG) in master mode.
CSIGnCFG0	Configures the communication protocol.

18.2.3 Block Diagram

The block diagram shows the main components of the CSIG.

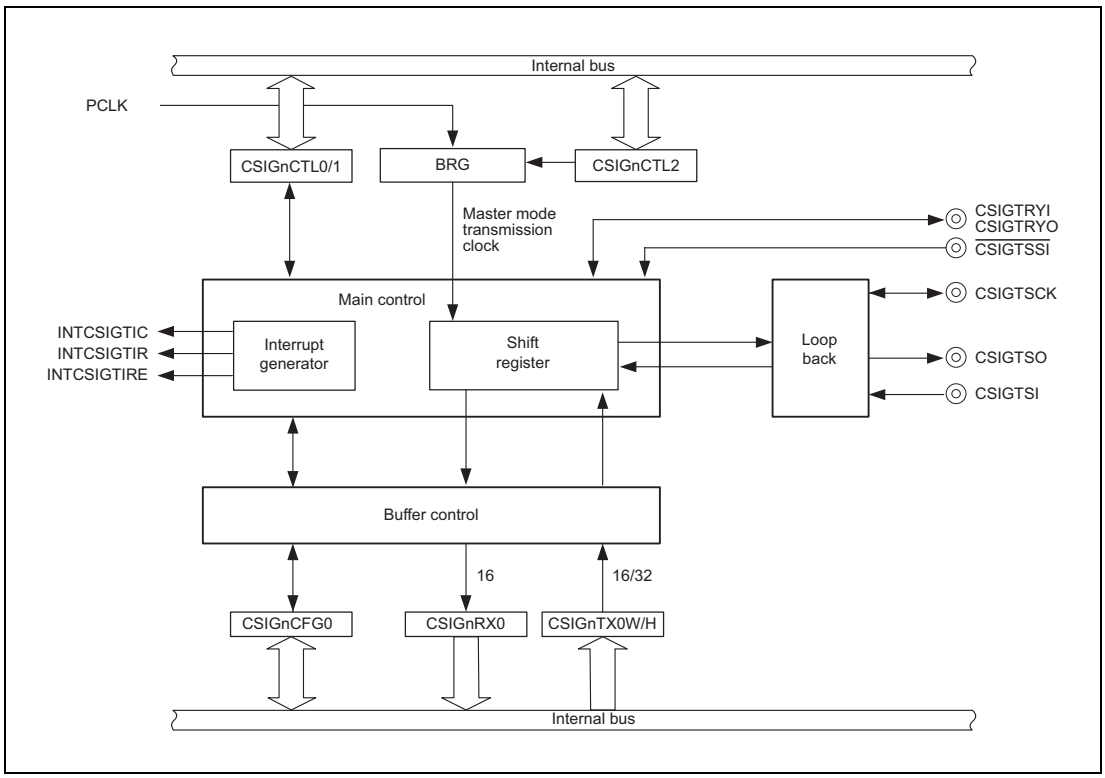


Figure 18.1 CSIG Block Diagram

In master mode, the transmission clock CSIGTSCK is generated by the built-in baud rate generator (BRG). In slave mode, the transmission clock is received from an external source.

18.3 Registers

18.3.1 List of Registers

CSIG registers are listed in the following table.

For details on <CSIGn_base>, see Section 18.1.2, Register Base Address.

Table 18.10 List of Registers

Module Name	Register Name	Symbol	Address
CSIGn	CSIGn control register 0	CSIGnCTL0	<CSIGn_base> + 0000_H
CSIGn	CSIGn control register 1	CSIGnCTL1	<CSIGn_base> + 0010_H
CSIGn	CSIGn control register 2	CSIGnCTL2	<CSIGn_base> + 0014_H
CSIGn	CSIGn status register 0	CSIGnSTR0	<CSIGn_base> + 0004_H
CSIGn	CSIGn status clear register 0	CSIGnSTCR0	<CSIGn_base> + 0008_H
CSIGn	CSIGn Rx-only mode control register 0	CSIGnBCTL0	<CSIGn_base> + 1000_H
CSIGn	CSIGn configuration register 0	CSIGnCFG0	<CSIGn_base> + 1010_H
CSIGn	CSIGn transmission data register 0 for word access	CSIGnTX0W	<CSIGn_base> + 1004_H
CSIGn	CSIGn transmission data register 0 for half word access	CSIGnTX0H	<CSIGn_base> + 1008_H
CSIGn	CSIGn reception data register 0	CSIGnRX0	<CSIGn_base> + $100C_H$
CSIGn	CSIGn emulation register	CSIGnEMU	<CSIGn_base> + 0018_H

NOTE

In the IO header files, availability of each register depends on whether they can be used by each product. The register has no corresponding function terminal has been removed from the IO header file by 1-bit. For availability of terminals, refer to the Section 2.3.2, List of Alternative Function Pins.

18.3.2 CSIGnCTL0 — CSIGn Control Register 0

This register controls the operation clock, and enables or disables transmission/reception.

Access: This register can be read/written in 1-bit and 8-bit units.

Address: <CSIGn_base> + 0000_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	CSIGnPWR	CSIGnTXE	CSIGnRXE	—	—	—	—	—*1
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R	R	R	R/W

Note 1. The default value “0” of this bit must be changed to “1” and must not be changed afterwards.

Table 18.11 CSIGnCTL0 Register Contents

Bit Position	Bit Name	Function
7	CSIGnPWR	Controls operation clock. 0: Stops operation clock. 1: Provides operation clock. Clearing CSIGnPWR to 0 resets the internal circuits, stops operation, and sets the CSIG to standby state. No clock is provided to internal circuits. If CSIGnPWR is cleared during communication, ongoing communication is aborted. A restart of the communication setting is then required.
6	CSIGnTXE	Enables/disables transmission. 0: Transmission disabled 1: Transmission enabled
5	CSIGnRXE	Enables/disables reception. 0: Receive disabled 1: Receive enabled
4 to 1	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	Bit 0	**CAUTION** The default value “0” of this bit must be changed to “1” and must not be changed afterwards.

CAUTION

When setting this register, see Table 18.24, List of Cautions when Setting Registers.

18.3.3 CSIGnCTL1 — CSIGn Control Register 1

This register specifies the interrupt timing and the interrupt delay mode. It enables/disables extended data length control, data consistency check, loop-back mode, handshake function, and slave select function.

Access: This register can be read/written in 32-bit units.

Address: <CSIGn_base> + 0010_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CSIGn CKR	CSIGn SLIT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CSIGn EDLE	—	CSIGn DCS	—	CSIGn LBM	CSIGn SIT	CSIGn HSE	CSIGn SSE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R	R/W	R	R/W	R/W	R/W	R/W

Table 18.12 CSIGnCTL1 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
17	CSIGnCKR	CSIGTSCK clock inversion function 0: Default level of CSIGTSCK is high. 1: Default level of CSIGTSCK is low. The CSIGnCKR bit is used in combination with the CSIGnCFG0.CSIGnDAP bit. For details, see Section 18.3.8, CSIGnCFG0 — CSIGn Configuration Register 0.
16	CSIGnSLIT	Selects the timing of interrupt INTCSIGTIC. 0: Normal interrupt timing (interrupt is generated after the transfer) 1: Interrupt generation when CSIGnTX0W/H is free for next data. For details, see 18.4.2, INTCSIGTIC (Communication Status Interrupt)
15 to 8	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
7	CSIGnEDLE	Enables/disables extended data length (EDL) mode. 0: Extended data length mode disabled 1: Extended data length mode enabled For details, see 18.5.5.2, Data Length Selection with Extended Data Length.
6	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
5	CSIGnDCS	Enables/disables data consistency check. 0: Data consistency check disabled 1: Data consistency check enabled For details, see 18.5.10.1, Data Consistency Check.
4	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
3	CSIGnLBM	Controls loop-back mode (LBM). 0: Loop-back mode deactivated 1: Loop-back mode activated Loop-back mode can be set only in master mode. Set this bit to 0 in slave mode. For details, see Section 18.5.9, Loop-Back Mode.

Table 18.12 CSIGnCTL1 Register Contents (2/2)

Bit Position	Bit Name	Function
2	CSIGnSIT	Selects interrupt delay mode. 0: No delay 1: Half clock delay for all interrupts This bit is only valid in master mode. In slave mode, no delay is generated. For details, see Section 18.4.1, Interrupt Delay.
1	CSIGnHSE	Enables/disables handshake mode. 0: Handshake function disabled 1: Handshake function enabled For details, see Section 18.5.8, Handshake Function.
0	CSIGnSSE	Enables/disables slave select function. 0: Input signal $\overline{\text{CSIGTSSI}}$ is ignored. 1: Input signal $\overline{\text{CSIGTSSI}}$ is enabled. If the slave select function is not used, this bit must be set to 0 (see also Section 18.5.2, Master/Slave Connections).

Details about CSIGnCTL1.CSIGnSSE:

Table 18.13 Operation of the Slave Select Function during Reception

CSIGnCTL0. CSIGnRXE	CSIGnCTL1. CSIGnSSE	$\overline{\text{CSIGTSSI}}$	Receive Operation
0	—	—	Reception disabled
1	0	—	Possible
1	1	0	Possible
1	1	1	Disabled

Table 18.14 Operation of the Slave Select Function during Transmission

CSIGnCTL0. CSIGnTXE	CSIGnCTL1. CSIGnSSE	$\overline{\text{CSIGTSSI}}$	Transmit Operation
0	—	—	Transmission disabled
1	0	—	Possible
1	1	0	Possible
1	1	1	Disabled

CAUTION

When setting this register, see Table 18.24, List of Cautions when Setting Registers.

18.3.4 CSIGnCTL2 — CSIGn Control Register 2

This register selects the communication clock.

Access: This register can be read/written in 16-bit units.

Address: <CSIGn_base> + 0014_H

Value after reset: $E000_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CSIGnPRS[2:0]			—	CSIGnBRS[11:0]											
Value after reset	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 18.15 CSIGnCTL2 Register Contents

Bit Position	Bit Name	Function
15 to 13	CSIGnPRS [2:0]	Selects the value of the prescaler.
12	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
11 to 0	CSIGnBRS [11:0]	Selects the transfer clock frequency. Settings of the CSIGnBRS[11:0] bits are valid only in master mode. They are ignored in slave mode.

CSIGn PRS2	CSIGn PRS1	CSIGn PRS0	Prescaler Output (PRSOUT)
0	0	0	PCLK (master mode)
0	0	1	PCLK / 2 (master mode)
0	1	0	PCLK / 4 (master mode)
0	1	1	PCLK / 8 (master mode)
1	0	0	PCLK / 16 (master mode)
1	0	1	PCLK / 32 (master mode)
1	1	0	PCLK / 64 (master mode)
1	1	1	External clock via CSIGTSCK (slave mode)

CSIGnBRS [11:0]	Transfer Clock Frequency of CSIGTSCK
0	BRG is stopped
1	PCLK / (2^{α} × 1 × 2)
2	PCLK / (2^{α} × 2 × 2)
3	PCLK / (2^{α} × 3 × 2)
4	PCLK / (2^{α} × 4 × 2)
...	...
4095	PCLK / (2^{α} × 4095 × 2)

Note: α = 0 to 6 (value set by CSIGnPRS[2:0])

CAUTION

When setting this register, see Table 18.24, List of Cautions when Setting Registers.

18.3.5 CSIGnSTR0 — CSIGn Status Register 0

This register indicates the status of the CSIG.

Access: This register can only be read in 32-bit units.

Address: <CSIGn_base> + 0004_H

Value after reset: $0000\ 0010_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CSIGn TSF	—	—	—	CSIGn DCE	—	CSIGn PE	CSIGn OVE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.16 CSIGnSTR0 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned.
7	CSIGnTSF	Transfer Status Flag 0: Idle state 1: Transmission is in progress or being prepared Setting and clearing of this bit is as follows:
6 to 4	Reserved	When read, the value after reset is returned.
3	CSIGnDCE	Data Consistency Check Error Flag 0: No data consistency check error detected 1: Data consistency check error detected This bit is cleared by writing 1 to CSIGnSTCR0.CSIGnDCEC. When setting to 1 due to data consistency error detection and clearing to 0 by CSIGnSTCR0.CSIGnDCEC occur simultaneously, setting to 1 due to data consistency error detection takes precedence. This bit is initialized when CSIGnCTL0.CSIGnPWR changes from 1 to 0 or from 0 to 1.
2	Reserved	When read, the value after reset is returned.

Master Mode	Set by	Cleared by
Tx-only mode	Writing to transmit register	Within a half clock cycle from the last serial clock edge
Tx/Rx mode		
Rx-only mode	Reading from receive register	

Slave Mode	Set by	Cleared by
Tx-only mode	Writing to transmit register	Within a half clock cycle from the last serial clock edge
Tx/Rx mode		
Rx-only mode	CSIGTSCK input	

Table 18.16 CSIGnSTR0 Register Contents (2/2)

Bit Position	Bit Name	Function
1	CSIGnPE	Parity Error Flag 0: No parity error detected 1: Parity error detected This bit is cleared by writing 1 to CSIGnSTCR0.CSIGnPEC. When setting to 1 due to parity error detection and clearing to 0 by writing to CSIGnSTCR0.CSIGnPEC occur simultaneously, setting to 1 due to parity error detection takes precedence. This bit is initialized by the value of CSIGnCTL0.CSIGnPWR changes from 0 to 1, or from 1 to 0.
0	CSIGnOVE	Overrun Error Flag 0: No overrun error detected 1: Overrun error detected This bit is cleared by writing 1 to CSIGnSTCR0.CSIGnOVEC. When setting to 1 due to overrun error detection and clearing to 0 by writing to CSIGnSTCR0.CSIGnOVEC occur simultaneously, setting to 1 due to overrun error detection takes precedence. This bit is initialized by the value of CSIGnCTL0.CSIGnPWR changes from 0 to 1, or from 1 to 0.

CAUTION

When setting this register, see Table 18.24, List of Cautions when Setting Registers.

18.3.6 CSIGnSTCR0 — CSIGn Status Clear Register 0

This register clears the status flags of the CSIGnSTR0 status register.

Access: This register can be read/written in 16-bit units.
When read, the value 0000_H is always returned.

Address: <CSIGn_base> + 0008_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	CSIGn DCEC	—	CSIGn PEC	CSIGn OVEC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W

Table 18.17 CSIGnSTCR0 Register Contents

Bit Position	Bit Name	Function
15 to 4	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	CSIGnDCEC	Controls the data consistency error flag clear command. 0: No operation. Read value is always 0. 1: Clear data consistency check error flag (CSIGnSTR0.CSIGnDCE).
2	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
1	CSIGnPEC	Controls the parity error flag clear command. 0: No operation. Read value is always 0. 1: Clear parity error flag (CSIGnSTR0.CSIGnPE).
0	CSIGnOVEC	Controls the overrun error flag clear command. 0: No operation. Read value is always 0. 1: Clear overrun error flag (CSIGnSTR0.CSIGnOVE).

18.3.7 CSIGnBCTL0 — CSIGn Rx-Only Mode Control Register 0

This register enables/disables the data transfer in Rx-only mode.

Access: This register can be read/written in 1-bit and 8-bit units.

Address: <CSIGn_base> + 1000_H

Value after reset: 01_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CSIGnSCE
Value after reset	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R/W

Table 18.18 CSIGnBCTL0 Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	CSIGnSCE	Disables/enables next data reception start by reading CSIGnRX0. 0: Next reception disabled 1: Next reception enabled For details, see Section 18.5.4.2, Receive-Only Mode.

CAUTION

When setting this register, see Table 18.24, List of Cautions when Setting Registers.

18.3.8 CSIGnCFG0 — CSIGn Configuration Register 0

This register configures the communication protocol – data length, parity, transfer direction, clock phase, and data phase.

Access: This register can be read/written in 32-bit units.

Address: <CSIGn_base> + 1010_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	0	0	1	1	0	1	1	
CAUTION

When setting this register, see Table 18.24, List of Cautions when Setting Registers.

18.3.9 CSIGnTX0W — CSIGn Transmission Register 0 for Word Access

This register stores the transmission data and specifies the extended data length.

Access: This register can be read/written in 32-bit units.

Address: <CSIGn_base> + 1004_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.20 CSIGnTX0W Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
29	CSIGnEDL	Specifies the extended data length. 0: Normal operation 1: Extended data length enabled The associated data is transmitted as 16-bit data. This bit can only be set if CSIGnCTL1.CSIGnEDLE = 1.
28 to 16	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
15 to 0	CSIGnTX[15:0]	Data to be transmitted

CAUTION

When setting this register, see Table 18.24, List of Cautions when Setting Registers.

18.3.10 CSIGnTX0H — CSIGn Transmission Register 0 for Half Word Access

This register stores the transmission data. This register is the same as bits 15 to 0 of register CSIGnTX0W.
The 16 high-order bits of CSIGnTX0W are applied for transfer.

Access: This register can be read/written in 16-bit units.

Address: <CSIGn_base> + 1008_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 18.21 CSIGnTX0H Register Contents

Bit Position	Bit Name	Function
15 to 0	CSIGnTX[15:0]	Data to be transmitted

CAUTION

When setting this register, see Table 18.24, List of Cautions when Setting Registers.

18.3.11 CSIGnRX0 — CSIGn Reception Register 0

This register stores the received data.

Access: This register can only be read in 16-bit units.

Address: <CSIGn_base> + $100C_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CSIGnRX[15:0]

Table 18.22 CSIGnRX0 Register Contents

Bit Position	Bit Name	Function
15 to 0	CSIGnRX [15:0]	Received Data These bits are initialized when CSIGnCTL0.CSIGnPWR changes from 0 to 1 or from 1 to 0. When reading, the values of these bits must be read at least 1 clock before the generation of CSIGTIR interrupt.

CAUTION

When setting this register, see Table 18.24, List of Cautions when Setting Registers.

18.3.12 CSIGnEMU — CSIGn Emulation Register

This register controls operation by SVSTOP.

Access: This register can be read/written in 1-bit and 8-bit units.
Write to this register when EPC.SVSTOP = 0.

Address: <CSIGn_base> + 0018_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	CSIGnSVSDIS	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R

Table 18.23 CSIGnEMU Register Contents

Bit Position	Bit Name	Function
7	CSIGnSVSDIS	Selects to continue or stop transmit/receive operation during debugging. • When the EPC.SVSTOP bit is set to 0: Continues transmit/receive operation regardless of the setting of this bit. • When the EPC.SVSTOP bit is set to 1: 0: Stops transmit/receive operation. 1: Continues transmit/receive operation.
6 to 0	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.

CAUTION

When setting this register, see Table 18.24, List of Cautions when Setting Registers.

18.3.13 List of Cautions

Table 18.24 List of Cautions when Setting Registers

Register Name	Bit Name	Contents
CSIGnCTL0	CSIGnPWR	If this bit is cleared during communication, ongoing communication is suspended. After the communication is suspended, it is necessary to restart the communication.
CSIGnCTL0	CSIGnTXE CSIGnRXE	Do not modify any of these bits while CSIGnCTL0.CSIGnPWR = 0. (These bits can be modified at the same time with the CSIGnCTL0.CSIGnPWR bit.) Do not modify these bits while CSIGnSTR0.CSIGnTSF = 1, because the specified operation is not guaranteed if ongoing communication is suspended.
CSIGnCTL0	Bit 0	When writing, always write 1. (The value after reset is "0".) This bit must be modified at the same time with CSIGnCTL0.CSIGnPWR bit.
CSIGnCTL1	CSIGnCKR	Modification of this bit is only permitted while CSIGnCTL0.CSIGnPWR = 0.
CSIGnCTL1	CSIGnSLIT CSIGnEDLE CSIGnDCS CSIGnHSE	Modification of these bits is only permitted while CSIGnCTL0.CSIGnPWR = 0.
CSIGnCTL1	CSIGnLBM	Modification of this bit is only permitted while CSIGnCTL0.CSIGnPWR = 0. Setting of this bit is prohibited in slave mode.
CSIGnCTL1	CSIGnSSE	Modification of this bit is only permitted while CSIGnCTL0.CSIGnPWR = 0. Setting this bit to 1 is prohibited in master mode.
CSIGnCTL1	CSIGnSIT	Modification of this bit is only permitted while CSIGnCTL0.CSIGnPWR = 0. This bit is only valid in master mode. In slave mode, no delay is generated.
CSIGnCTL2	CSIGnPRS[2:0] CSIGnBRS[11:0]	Modification of this bit is only permitted while CSIGnCTL0.CSIGnPWR = 0. Setting of the max transfer clock frequency is as follows. • Master mode: up to PCLK/4 • Slave mode: up to PCLK/6
CSIGnSTR0	CSIGnTSF	Writing to this bit is prohibited, and only reading is permitted.
CSIGnSTR0	CSIGnDCE CSIGnPE CSIGnOVE	Writing to these bits is prohibited, and only reading is permitted. These bits are initialized when CSIGnCTL0.CSIGnPWR = 0 → 1 or CSIGnCTL0.CSIGnPWR = 1 → 0.
CSIGnBCTL0	CSIGnSCE	Write to this bit before CSIGnRX0 is read. Fix the CSIGnSCE bit to 0 when the transfer mode is transmit mode or transmit/receive mode.
CSIGnCFG0	CSIGnPS[1:0] CSIGnDLS[3:0] CSIGnDIR CSIGnDAP	Modification of these bits is only permitted while CSIGnCTL0.CSIGnPWR = 0.
CSIGnTX0W	CSIGnEDL	This bit is valid only when CSIGnCTL1.CSIGnEDLE = 1.
CSIGnTX0W CSIGnTX0H		Write access to these bits are prohibited when CSIGnCTL0.CSIGnTXE = CSIGnCTL0.CSIGnRXE = 0.
CSIGnRX0		This bit is initialized when CSIGnRX0 CSIGnCTL0.CSIGnPWR = 0 → 1 or CSIGnCTL0.CSIGnPWR = 1→ 0. Read access to this bit is prohibited when CSIGnCTL0.CSIGnTXE = CSIGnCTL0.CSIGnRXE = 0.
CSIGnEMU	CSIGnSVSDIS	Modification of this bit is prohibited while SVSTOP = 1.

18.4 Interrupt Sources

CSIG can generate the following interrupts:

- INTCSIGTIC (communication status interrupt)
- INTCSIGTIR (reception status interrupt)
- INTCSIGTIRE (communication error interrupt)

18.4.1 Interrupt Delay

In master mode, all interrupts generated by the master can be delayed by one half period of the transmission clock CSIGTSCK. This is not possible in slave mode.

The delay is specified by setting bit CSIGnCTL1.CSIGnSIT = 1. (The setting of the CSIGnSIT bit is invalid in slave mode.)

The following example illustrates the interrupt delay function, assuming a setting of CSIGnCTL1.CSIGnSIT = 1 (interrupt delay enabled), CSIGnCTL1.CSIGnCKR = 0, CSIGnCFG0.CSIGnDAP = 0 (normal clock and data phase), and CSIGnCFG0.CSIGnDLS[3:0] = 1000_B (data length 8 bits).

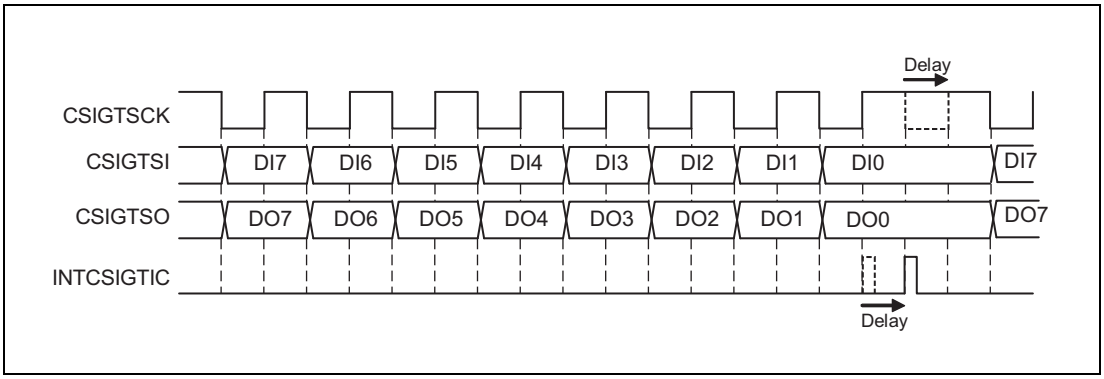

Figure 18.2 Interrupt Delay Function (CSIGnCTL1.CSIGnSIT = 1)

18.4.2 INTCSIGTIC (Communication Status Interrupt)

This interrupt is normally generated after every data transfer. It can be used to trigger a DMA for writing new transmission data to register CSIGnTX0W or CSIGnTX0H.

The following example assumes master mode and a setting of CSIGnCTL1.CSIGnSIT = 0 (no interrupt delay), CSIGnCTL1.CSIGnCKR = 0, CSIGnCFG0.CSIGnDAP = 0 (normal clock and data phase), CSIGnCFG0.CSIGnDLS[3:0] = 1000_B (data length 8 bits), and CSIGnCTL1.CSIGnSLIT = 0 (normal interrupt timing).

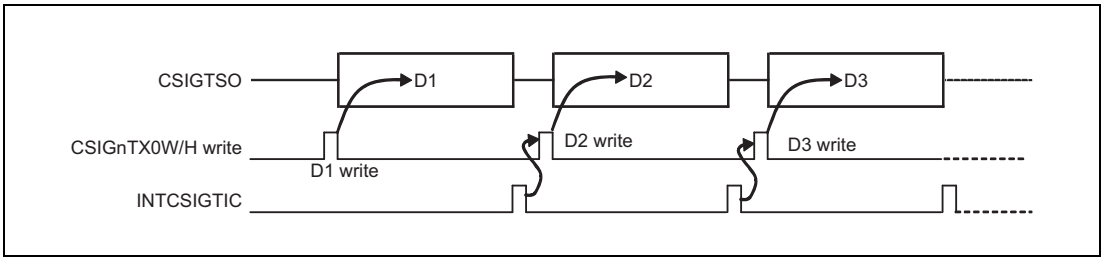

Figure 18.3 Generation of INTCSIGTIC after Communication (CSIGnCTL1.CSIGnSLIT = 0)

However, INTCSIGTIC can also be set up to occur when the CSIGnTX0W/H register is free for the next data. This is specified by setting CSIGnCTL1.CSIGnSLIT = 1.

This mode allows more efficient data transfers.

The effect is illustrated in the figure below.

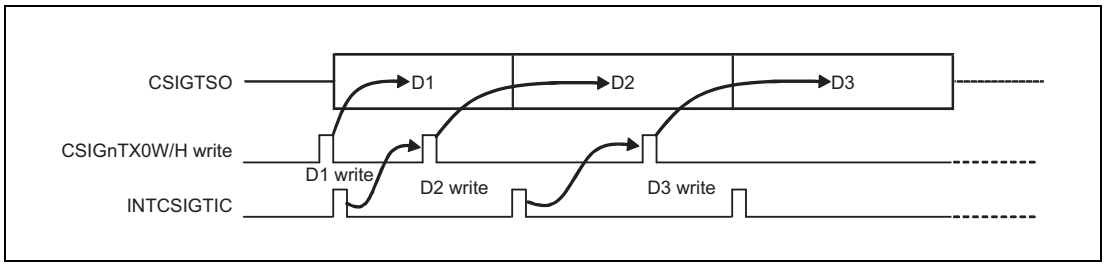

Figure 18.4 Generation of INTCSIGTIC at the Beginning of Communication

18.4.3 INTCSIGTIR (Reception Status Interrupt)

This interrupt is generated in receive-only and transmit/receive mode after data has been received and is available in the reception register. It can be used to trigger a DMA for reading the received data from register CSIGnRX0.

The following example assumes master mode and a setting of CSIGnCTL1.CSIGnSIT = 0 (no interrupt delay), CSIGnCTL1.CSIGnCKR = 0, CSIGnCFG0.CSIGnDAP = 0 (normal clock and data phase), and CSIGnCFG0.CSIGnDLS[3:0] = 1000_B (data length 8 bits).

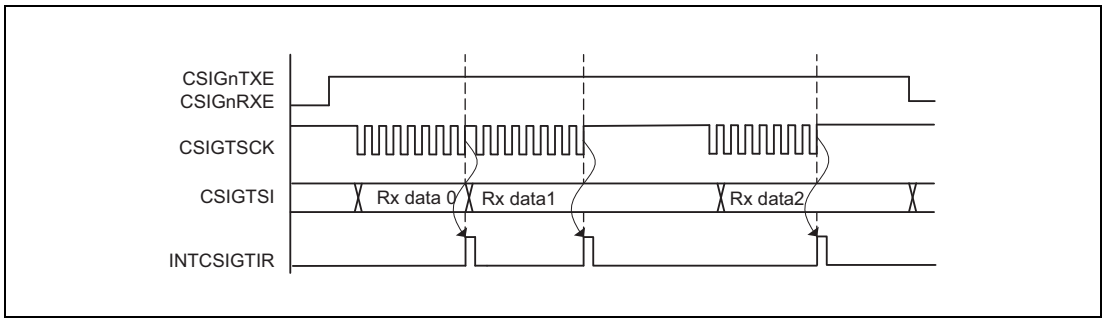

Figure 18.5 Generation of INTCSIGTIR

18.4.4 INTCSIGTIRE (Communication Error Interrupt)

This interrupt is generated whenever an error is detected.

Table 18.25 Data Error Types

Error Type	Communication Status After Error Interrupt
Parity error	Interrupt is generated and communication continues.
Data consistency error	Interrupt is generated and communication continues.
Overrun error	When CSIGnCTL1.CSIGnHSE = 0 (handshake function disabled) in slave mode, interrupt is generated and communication continues.
	When CSIGnCTL1.CSIGnHSE = 1 (handshake function enabled) in slave mode, communication stops due to the handshake. Interrupt is not generated and overrun errors do not occur.

Note 1. In master mode, overrun errors do not occur.
In slave mode, communication cannot be stopped.

The type of error that caused the generation of INTCSIGTIRE is indicated in register CSIGnSTR0.

For details about the various error types, see Section 18.5.10, Error Detection.

18.5 Operation

18.5.1 Master/Slave Mode

CSIG operation in master mode or in slave mode depends on the setting of bits CSIGnCTL2.CSIGnPRS[2:0]. If master mode is selected, the source of the transmission clock must be selected too.

18.5.1.1 Master Mode

In master mode, the serial communication clock is generated by the internal baud rate generator (BRG) and provided by signal CSIGTSCK.

Master mode is enabled by setting bits CSIGnCTL2.CSIGnPRS[2:0] to anything but 111_B. In master mode, the frequency setting of the BRG becomes effective by setting bits CSIGnCTL2. CSIGnPRS[2:0] and bits CSIGnCTL2.CSIGnBRS[11:0].

The default level of CSIGTSCK depends on the clock phase selection bit: it is high when CSIGnCTL1.CSIGnCKR = 0, and is low when CSIGnCTL1.CSIGnCKR = 1.

The example below shows the communication in master mode for 8 data bits, CSIGnCFG0.CSIGnCKR = 0, CSIGnCFG0.CSIGnDAP = 0, and MSB first:

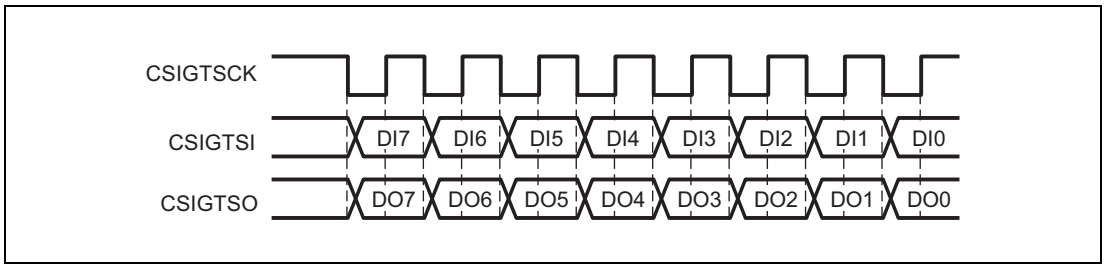

Figure 18.6 Transmission/Reception in Master Mode

18.5.1.2 Slave Mode

In slave mode, another device is the communication master. The external clock is received by signal CSIGTSCK. Send/receive operation starts as soon as a clock signal is detected.

Slave mode is selected by setting CSIGnCTL2.CSIGnPRS[2:0] to 111_B.

NOTE

When using slave mode, disable the baud rate generator (BRG) by setting bits CSIGnCTL2.CSIGnBRS[11:0] to 000_H.

The example below shows the communication in slave mode for 8 data bits, CSIGnCTL1.CSIGnCKR = 0, CSIGnCFG0.CSIGnDAP = 0, and MSB first:

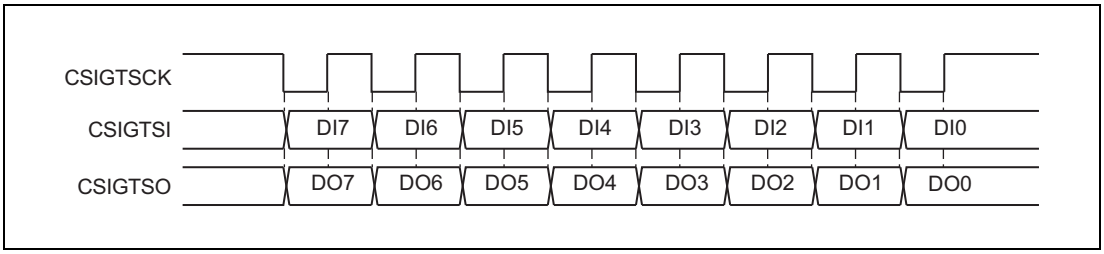

Figure 18.7 Transmission/Reception in Slave Mode

18.5.2 Master/Slave Connections

18.5.2.1 One Master and One Slave

The following figure illustrates the connections between one master and one slave.

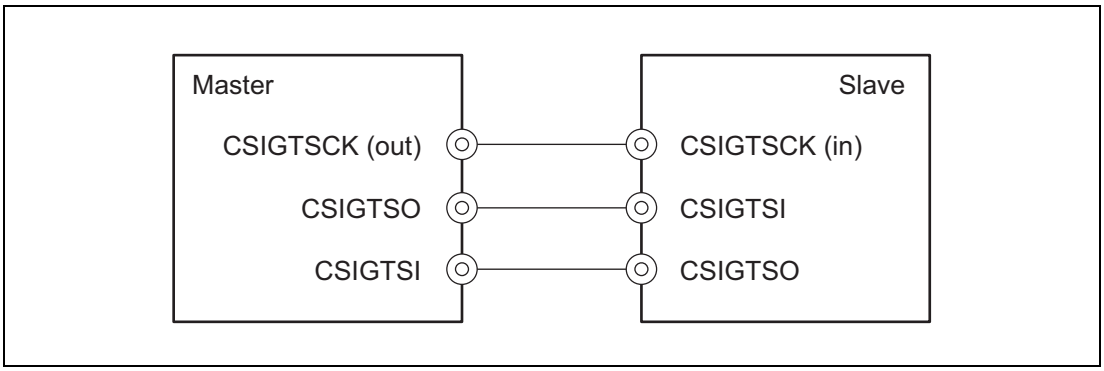

Figure 18.8 Direct Master/Slave Connection

18.5.2.2 One Master and Multiple Slaves

The following figure illustrates the connections between one master and multiple slaves. In this case, the master must provide one slave select (SS) signal to each of the slaves. This signal is connected to the slave select input $\overline{\text{CSIGTSSI}}$ of the slave.

The $\overline{\text{CSIGTSSI}}$ signal can be enabled/disabled by bit CSIGnCTL1.CSIGnSSE.

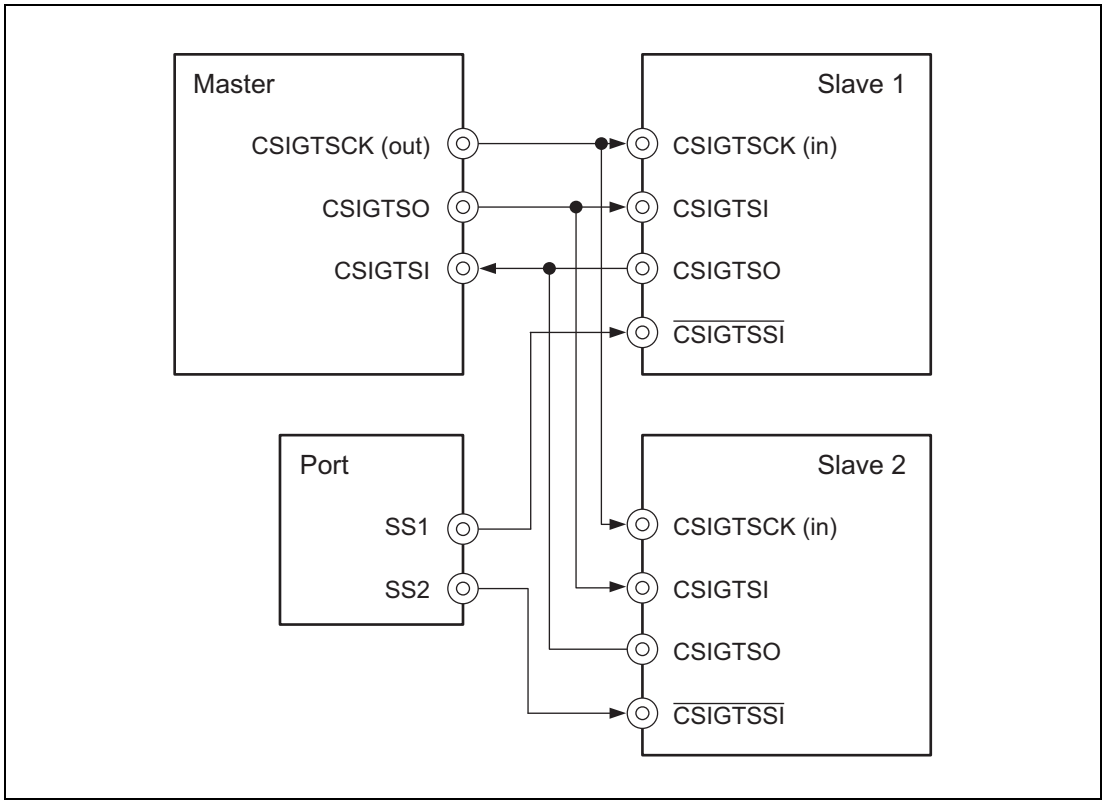

Figure 18.9 Master to Multiple Slaves Connection

A slave is selected (enabled) when its $\overline{\text{CSIGTSSI}}$ signal is low.

If it is not selected, the slave will neither receive nor transmit data. In addition, the CSIGTSO output buffer is disabled and set to input mode in order to avoid interference with the output of another slave which was selected, in transmit-only mode or transmit/receive mode (CSIGnCTL0.CSIGnTXE = 1).

18.5.3 Transmission Clock Selection

In master mode, the transfer clock frequency is selectable using the CSIGnPRS[2:0] and CSIGnBRS[11:0] bits in the CSIGnCTL2 register.

The following figure shows a block diagram of the BRG.

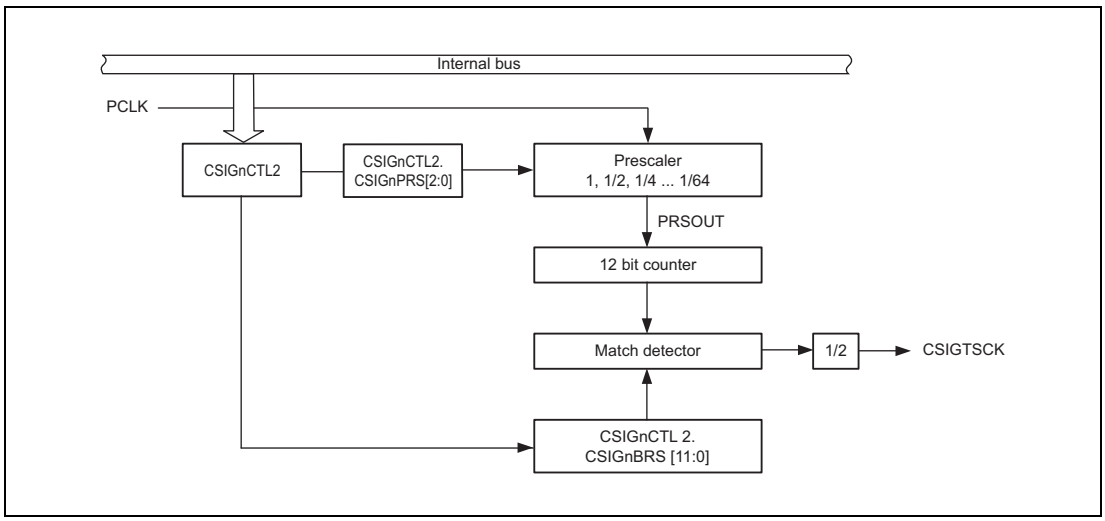

Figure 18.10 BRG Block Diagram

Setting CSIGnCTL2.CSIGnBRS[11:0] to 000_H disables the BRG.

Transfer clock frequency calculation

The transfer clock frequency in master mode is calculated as:

Transfer clock frequency (CSIGTSCK) = PCLK / (division ratio of PCLK) = PCLK / ($2^{\alpha} \times k \times 2$), where

α = CSIGnCTL2.CSIGnPRS[2:0] = 0 to 6

k = CSIGnCTL2.CSIGnBRS[11:0] = 1 to 4095

Transfer clock frequency upper and lower limits

When setting the transfer clock frequency, please note the followings.

- For the maximum transfer clock frequency of this product in master mode or slave mode, see the CSIG timing shown in the electrical characteristics. In addition, in either mode, set it within the specified range.
- The minimum transfer clock frequency in master mode and slave mode is PCLK/524160.
- The maximum transfer clock frequency is as follows:
  - In master mode: equal to or lower than PCLK/4
  - In slave mode: equal to or lower than PCLK/6

18.5.4 Data Transfer Modes

18.5.4.1 Transmit-Only Mode

Setting CSIGnCTL0.CSIGnTXE = 1 and CSIGnCTL0.CSIGnRXE = 0 puts the CSIG in transmit-only mode. Transmission starts when transmit data is written in the CSIGnTX0W or CSIGnTX0H register.

CAUTION

In case transmit-only mode has been entered after any reception mode, the data in the CSIGnRX0 buffer becomes undefined after completion of the first transmission. Consequently the reception register CSIGnRX0 has to be read before changing to transmit-only mode.

18.5.4.2 Receive-Only Mode

Setting CSIGnCTL0.CSIGnTXE = 0 and CSIGnCTL0.CSIGnRXE = 1 puts the CSIG in receive-only mode.

In master mode, reception starts when dummy data is read from the CSIGnRX0 register.
All following receptions are triggered by a read from the receive data register CSIGnRX0, as long as CSIGnBCTL0.CSIGnSCE = 1.

Moreover the communication start bit CSIGnBCTL0.CSIGnSCE has to be set to 1 and has to set back to 0 before reading the last received data from CSIGnRX0.

The recommended procedure is:

1. Set CSIGnBCTL0.CSIGnSCE = 1.
2. Read CSIGnRX0 (dummy data).
3. Wait for the reception interrupt INTCSIGTIR.
4. Read CSIGnRX0 (received data).
   In case of further data receptions continue at step 3, continue to read it until all data has been received.
   Before reading the last received data from CSIGnRX0, set CSIGnBCTL0.CSIGnSCE = 0.

In slave mode, reception starts when the communication clock CSIGTSCK from the master is received. In this case, it is not necessary to read data from the CSIGnRX0 register of the slave.

NOTE

In slave mode, any previously received data must be read from the reception register CSIGnRX0 in order to avoid any overwrite situation.

18.5.4.3 Transmit/Receive Mode

Setting CSIGnCTL0.CSIGnTXE = 1 and CSIGnCTL0.CSIGnRXE = 1 puts the CSIG in transmit/receive mode.

Data transfer (transmission and reception) starts when transmit data is written to the CSIGnTX0W or CSIGnTX0H register.

18.5.5 Data Length Selection

18.5.5.1 Data Length Selection without Extended Length

Transmission data length is selectable from 7 to 16 bits using the CSIGnDLS[3:0] bits in the CSIGnCFG0 register. The examples below show the communication with MSB first (CSIGnCFG0.CSIGnDIR = 0):

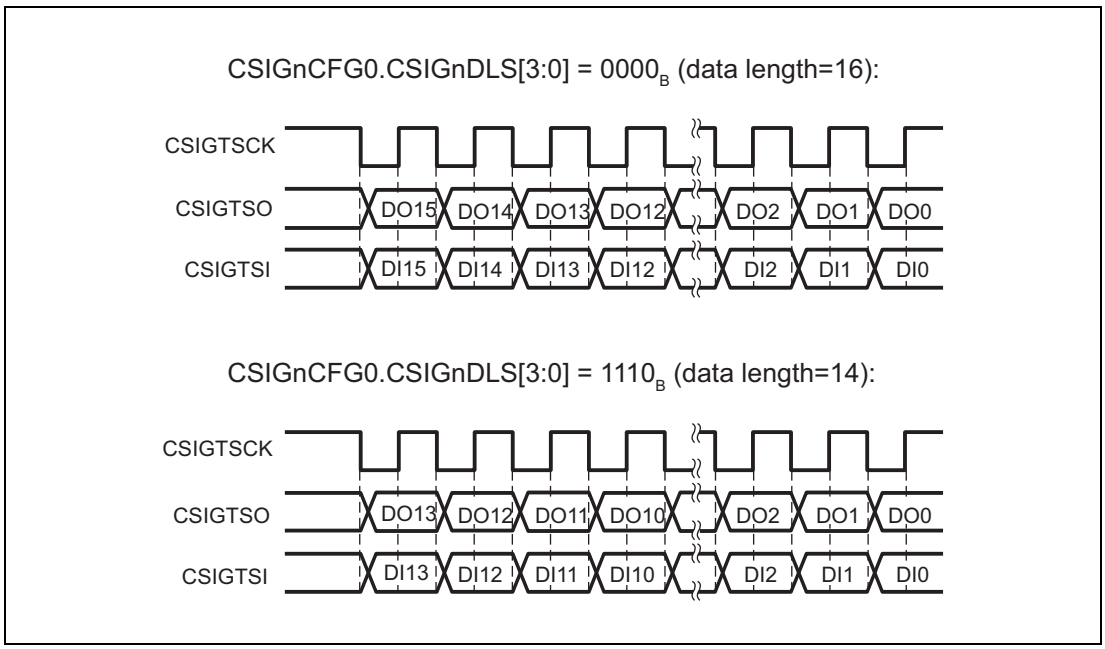

Figure 18.11 Data Length Select Function

18.5.5.2 Data Length Selection with Extended Data Length

If the data to be sent/received exceeds 16 bits, the extended data length (EDL) feature can be used.

The EDL function is enabled by setting bit CSIGnCTL1.CSIGnEDLE to 1.

The following describes how the EDL function works and how to specify the setting.

- The data has to be broken into 16-bit blocks plus remainder. For example, data of 42 bits would be broken into two 16-bit blocks plus 10 bits.
- The bit length of the remainder is set as “data length” in CSIGnCFG0.CSIGnDLS[3:0] bits.
- Set the CSIGnTX0W.CSIGnEDL bit to 1 to transmit 16-bit blocks. In this case, the data written to the CSIGnTX0W register is sent as 16-bit data regardless of the setting of the CSIGnCFG0.CSIGnDLS[3:0] bits.
- The transfer is complete after the data with the specified data length (the remainder with CSIGnTX0W.CSIGnEDL = 0) has been sent.

Example

Example for sending 40-bit data, for example the data $123456789A_H$:

40 bits are split into 2 × 16 bits plus 8 bits.

- Initialize CSIGnCFG0.CSIGnDLS[3:0] = 8_D.

- To send the data $123456789A_H$ with MSB first, write the following sequence to CSIGnTX0W:
  - $2000\ 1234_H$ (CSIGnTX0W.CSIGnEDL = 1)
  - $2000\ 5678_H$ (CSIGnTX0W.CSIGnEDL = 1)
  - $0000\ 009A_H$ (CSIGnTX0W.CSIGnEDL = 0)

The following figure illustrates the timing.

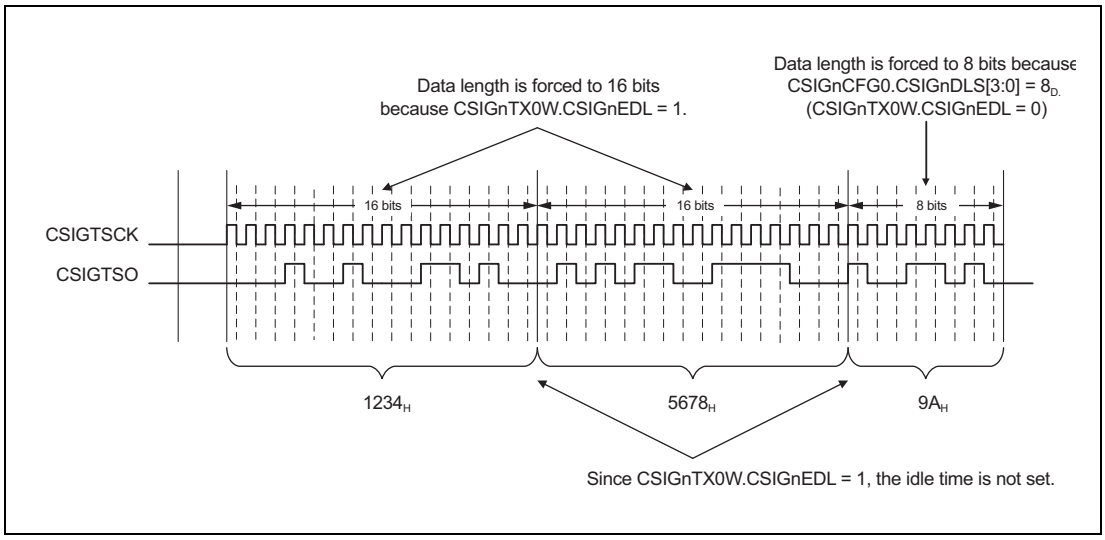

Figure 18.12 EDL Timing Diagram

NOTES

1. Data length with less than 7 bits can be set only when EDL mode is used.
2. It is not possible to send two consecutive data with a data length of less than 7 bits.
3. If parity is enabled, the parity bit is added after the last bit.
4. Explanation of data direction is provided in the following example.
   - Data to be transmitted: 123456_H
   - MSB first:
     Set CSIGnCFG0.CSIGnDIR to 0.
     Write $2000\ 1234_H$ to CSIGnTX0W (EDL bit = 1).
     Write $0000\ 0056_H$ to CSIGnTX0W (EDL bit = 0).
   - LSB first:
     Set CSIGnCFG0.CSIGnDIR to 1.
     Write $2000\ 3456_H$ to CSIGnTX0W (EDL bit = 1).
     Write $0000\ 0012_H$ to CSIGnTX0W (EDL bit = 0).
5. EDL mode cannot be used in the slave mode exclusive for receive.
   (CSIGnCTL2.CSIGnPRS[2:0] = 111B, CSIGnCTL0.CSIGnTXE = 0,
   CSIGnCTL0.CSIGnRXE = 1)

18.5.6 Serial Data Direction Select Function

The serial data direction is selectable using the CSIGnDIR bit in the CSIGnCFG0 register. The examples below show the communication for 8-bit data (CSIGnCFG0.CSIGnDLS[3:0] = 1000_B):

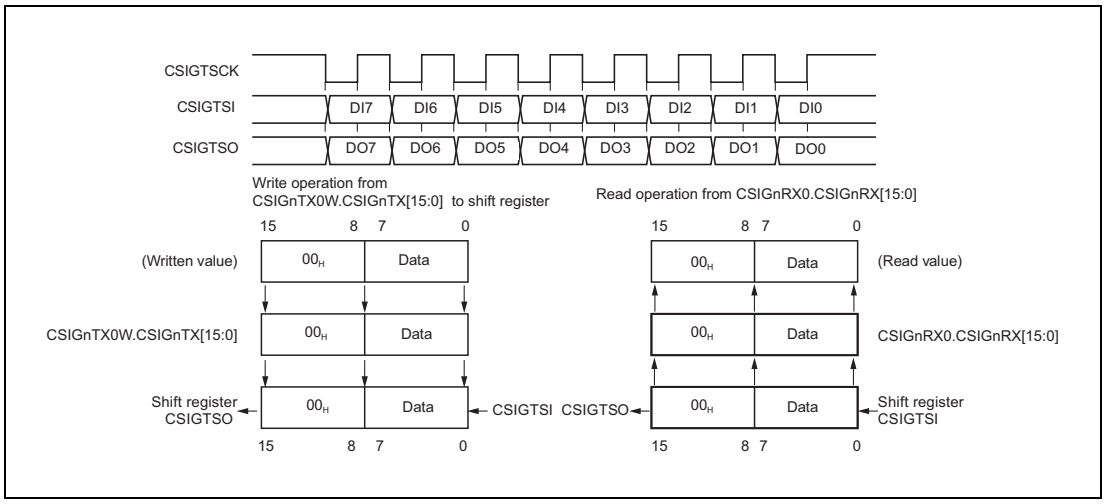

Figure 18.13 Serial Data Direction Select Function — MSB First (CSIGnDIR = 0)

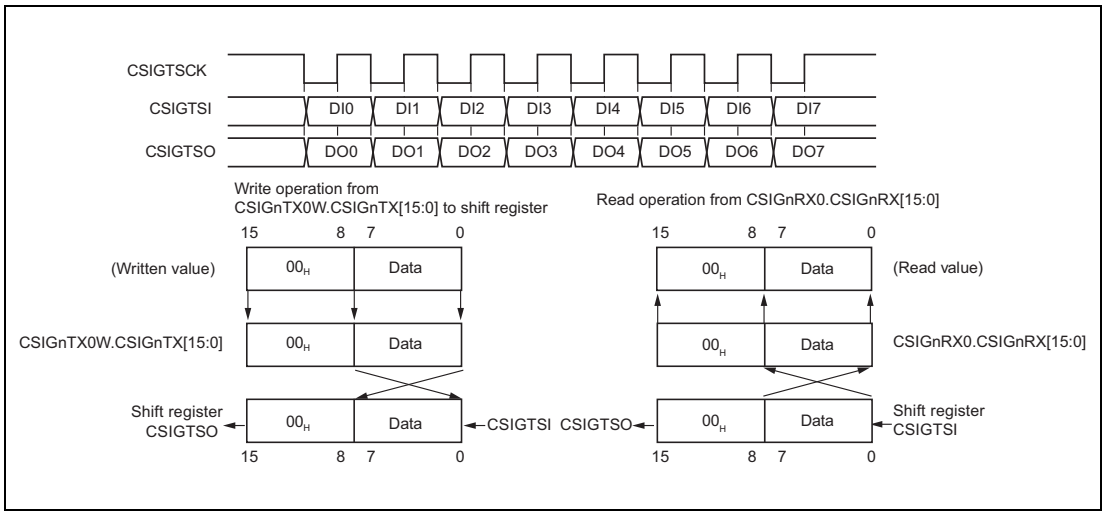

Figure 18.14 Serial Data Direction Select Function — LSB First (CSIGnDIR = 1)

18.5.7 Communication in Slave Mode

The following figure illustrates the communication signals and timings in slave mode.

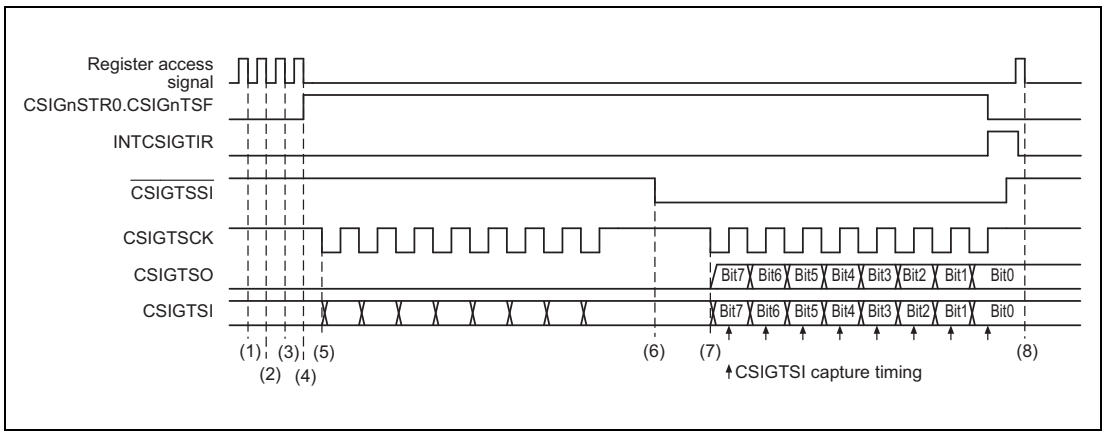

Figure 18.15 Rx/Tx Communication Timing in Slave Mode

1. CSIG is put into slave mode by setting CSIGnCTL2.CSIGnPRS[2:0] = 111_B. The $\overline{\text{CSIGTSSI}}$ signal is enabled (CSIGnCTL1.CSIGnSSE = 1) and the clock phase is at the high level (CSIGnCTL1.CSIGnCKR = 0).
2. Data length is 8 bits (CSIGnCFG0.CSIGnDLS[3:0] = 1000_B).
   Data direction is MSB first (CSIGnCFG0.CSIGnDIR = 0).
3. CSIG is set to transmit/receive mode (CSIGnCTL0.CSIGnPWR = 1, CSIGnCTL0.CSIGnTXE = 1, CSIGnCTL0.CSIGnRXE = 1).
4. When transfer data is written to the transmission register CSIGnTX0H, the “transmission in progress” flag CSIGnSTR0.CSIGnTSF is automatically set and the CSIG waits until signal $\overline{\text{CSIGTSSI}}$ goes low.
5. As long as signal $\overline{\text{CSIGTSSI}}$ is high, transmission/reception is not started even if the serial clock in input. CSIGTSO retains the values and input at CSIGTSI is ignored.
6. As soon as $\overline{\text{CSIGTSSI}}$ falls to low level, the chip serial data output is enabled and ready for transmission.
7. If the serial clock is input to the CSIG while $\overline{\text{CSIGTSSI}}$ is low, data is sent to CSIGTSO in synchronization with the serial clock, and at the same time, data is received from CSIGTSI.
8. The register CSIGnRX0 is read.

18.5.8 Handshake Function

CSIG features a handshake function to synchronize the master and the slave devices. This function can be enabled/disabled by bit CSIGnCTL1.CSIGnHSE. For handshake, the signals CSIGTRYI and CSIGTRYO are used.

The timing depends on the data phase selection bit CSIGnCFG0.CSIGnDAP.

18.5.8.1 Slave Mode

If CSIGnCTL1.CSIGnHSE = 1, a low-level CSIGTRYO signal is output when the slave becomes busy. This happens when previous receive data is still in the CSIGnRX0 register, and new data cannot be copied from the shift register to CSIGnRX0 (CSIGnRX0 full condition).

The following examples assume a data length of 8 bits.

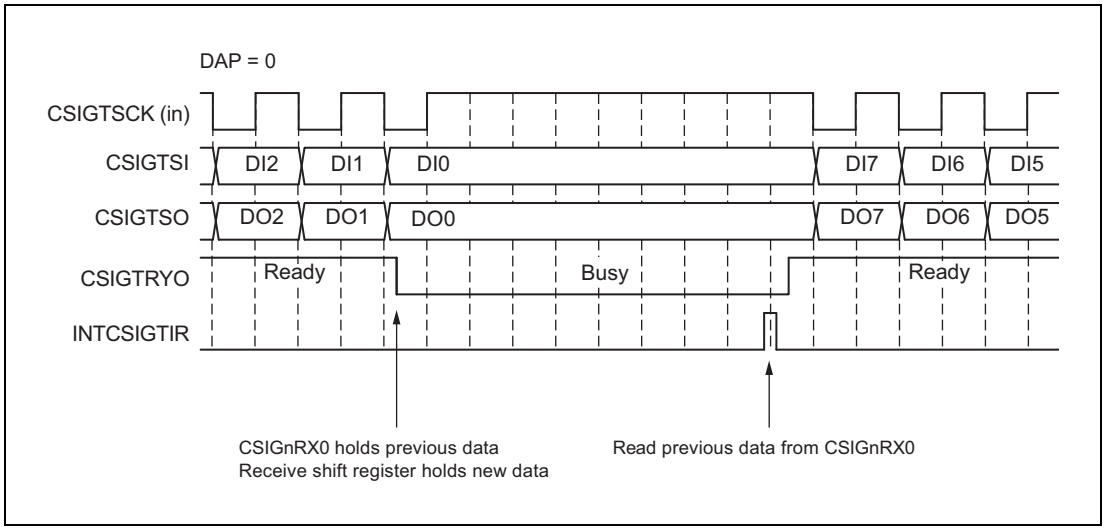

Figure 18.16 Ready/Busy Signal from Slave (CSIGnCFG0.CSIGnDAP = 0)

As long as the slave is busy, the master has to wait (i.e. suspend the transmission clock). The slave sets CSIGTRYO to high (“ready”) as soon as the reception register CSIGnRX0 has been read.

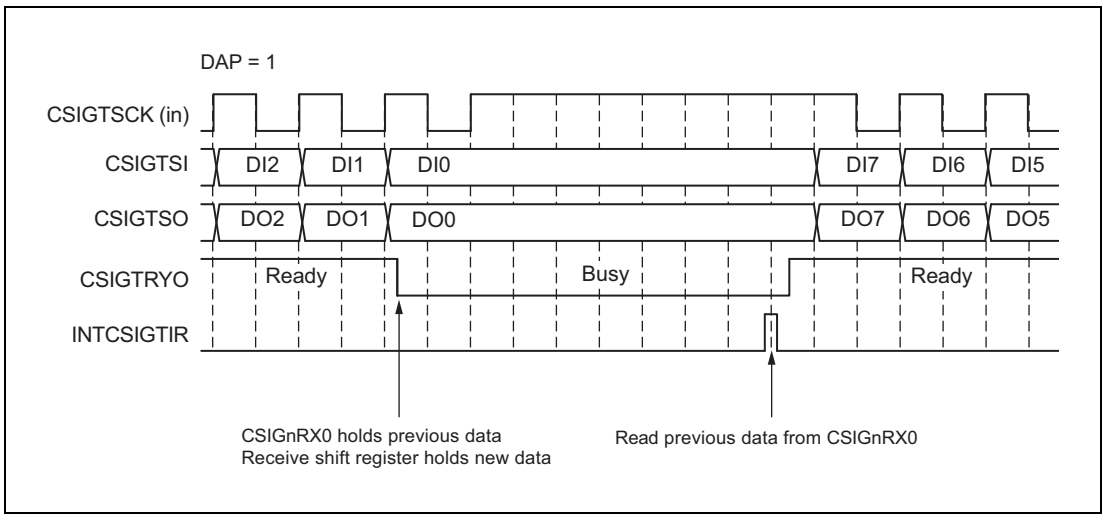

Figure 18.17 Ready/Busy Signal from Slave (CSIGnCFG0.CSIGnDAP = 1)

18.5.8.2 Master Mode

When the master detects low level of the CSIGTRYI, the following transfer is put on hold, and the master goes into wait status. It suspends the CSIGTSCK clock.

The CSIGTRYI level is checked at each half clock cycle of CSIGTSCK.

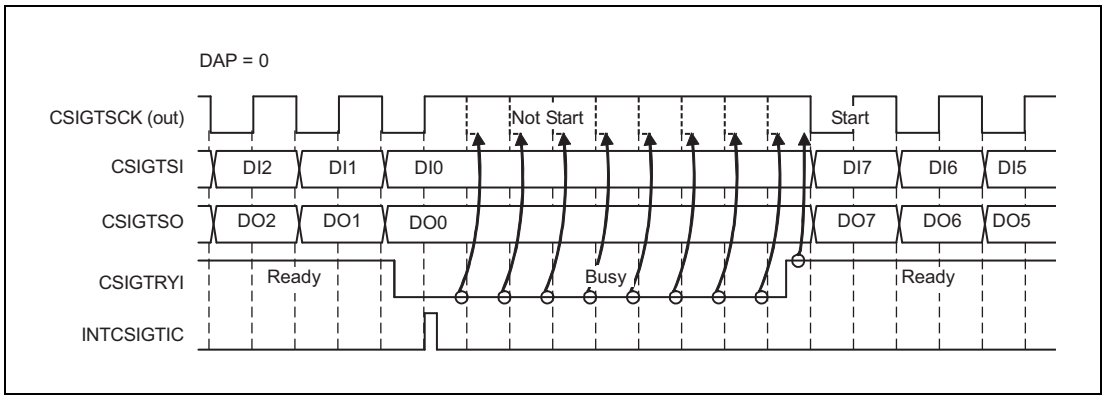

Figure 18.18 Master's Reaction to CSIGTRYI (CSIGnCFG0.CSIGnDAP = 0)

If the CSIGTRYI low signal comes from the slave while data transfer is in progress, the serial clock is suspended after the transfer is complete.

The master resumes the communication as soon as CSIGTRYI becomes high (slave is "ready").

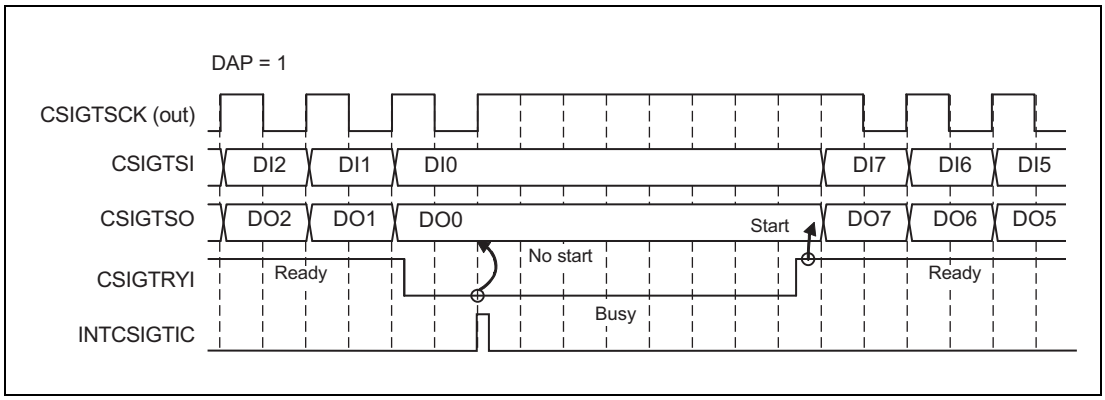

Figure 18.19 Master's Reaction to CSIGTRYI (CSIGnCFG0.CSIGnDAP = 1)

CAUTION

If multiple slaves are connected, the master must only detect the CSIGTRYI signal of the slave it has selected for communication.

CSIGTRYI must be pulled down by the slave before the next transfer starts. Even if the signal is pulled down by the slave during the transfer, the transfer will continue until it is finished.

18.5.9 Loop-Back Mode

Loop-back mode is a special mode for self-test. This feature is only available in master mode.

When this mode is active (CSIG0CTL1.CSIG0LBM = 1), the transmit and receive signals are internally connected, as shown in the figures below. The signals CSIGTSCK, CSIGTSO, and CSIGTSI are disconnected from the ports. In addition, the CSIGTSO output level is fixed to low, and CSIGTSCK is set to reset level (High). The rest of CSIG works as in normal operation.

In order to test the CSIG, set in loop-back mode and carry out normal transfer operations. Then check that the received data is the same as the transmitted data.

Table 18.26 Output Level of Pins

Pin	Output Level
CSIGTSCK(out)	High level
CSIGTSO	Low level (not dependent on the previous value)
Interrupt	Normal function
CSIGTRYO	Normal function (Low level)

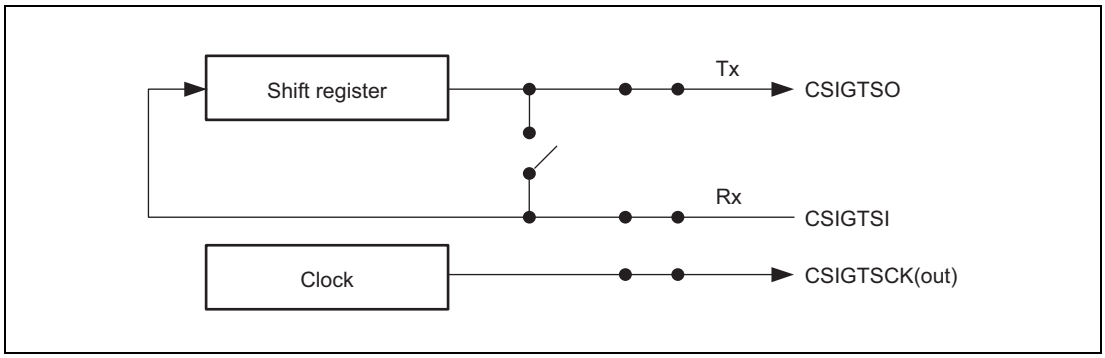

Figure 18.20 Normal Operation

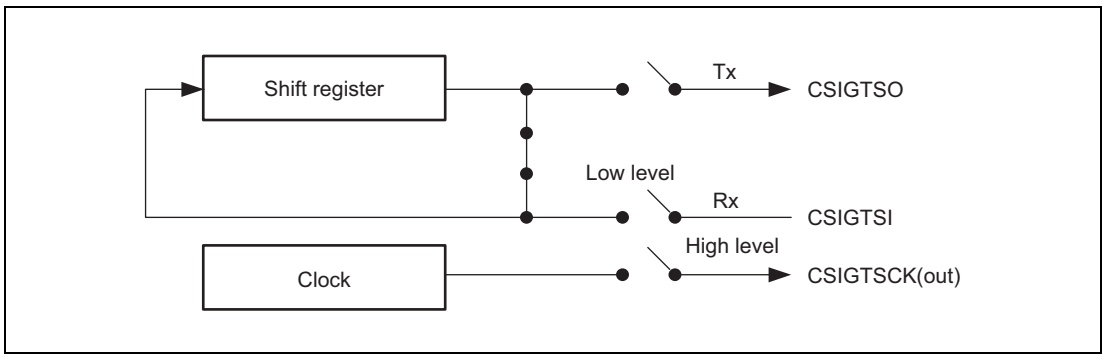

Figure 18.21 Operation in Loop-Back Mode

18.5.10 Error Detection

CSIG can detect three error types:

- Data consistency error (transmission data)
- Parity error (received data)
- Overrun error (received data)

Data consistency error and parity error check functions are independently enabled or disabled.

If one of these errors is detected, the interrupt INTCSIGTIRE is generated.

18.5.10.1 Data Consistency Check

The purpose of the data consistency check is to ensure that the data physically sent as an output signal is identical to the original data that was copied to the shift register.

The data consistency check can be enabled/disabled by bit CSIGnCTL1.CSIGnDCS (When checking data consistency, make sure that PIPCn.PIPCn_m = 1.). It is not active if data transmission is disabled (CSIGnCTL0.CSIGnTXE = 0).

When the data consistency check is active, the data transferred from CSIGnTX0W or CSIGnTX0H to the shift register is copied to a separate register. In addition, the physical levels at CSIGTSO are capture and the logical interpretation is written to an own shift register.

After completion of the transmission, the data sent is compared with the original transmission data.

Mismatch is considered as a data consistency error:

- Interrupt INTCSIGTIRE is generated.
- Bit CSIGnSTR0.CSIGnDCE is set.

The function is illustrated in the following block diagram.

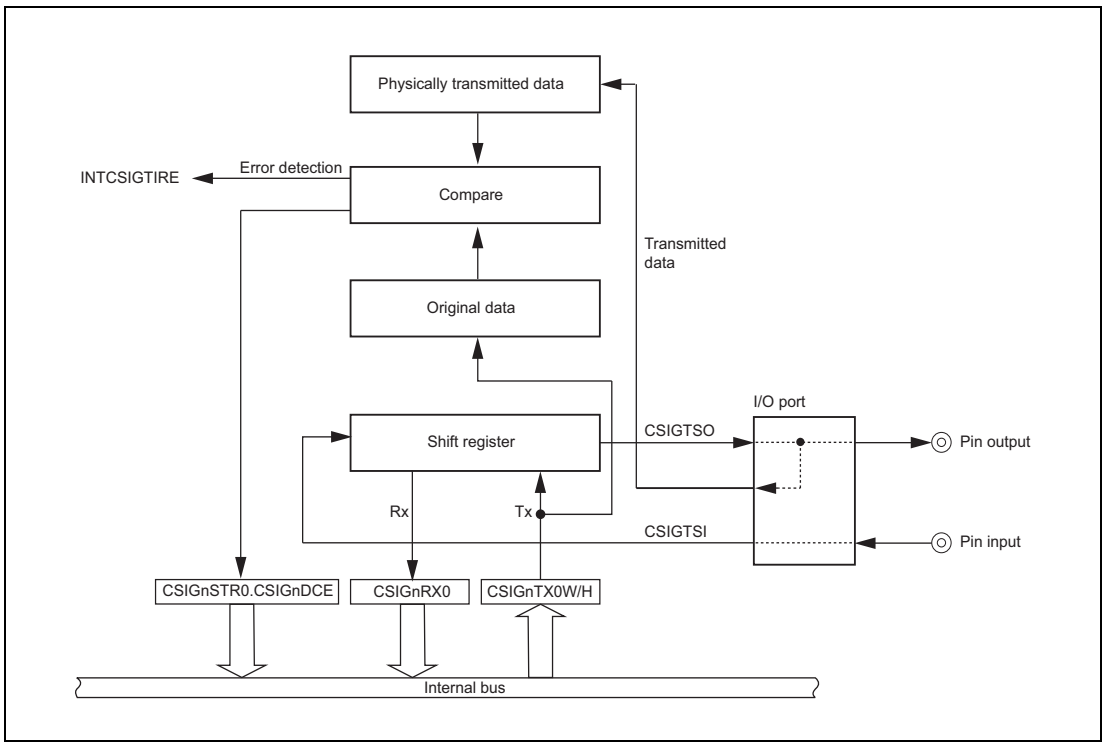

Figure 18.22 Functional Block Diagram of the Data Consistency Check

18.5.10.2 Parity Check

Parity is a common mean to detect a single bit failure during data transmission. CSIG can append a parity bit to the last data bit (even if extended data length is used).

The use and type of parity is specified in CSIGnCFG0.CSIGnPS[1:0].

Parity check is enabled if CSIGnCFG0.CSIGnPS[1] = 1.

The parity bit is checked after reception is complete. If a parity error occurs:

- Interrupt INTCSIGTIRE is generated.
- Bit CSIGnSTR0.CSIGnPE is set.

The following figure shows an example.

Data length is 8 bits. The data transmitted is 05_H and 35_H. Parity type is odd.

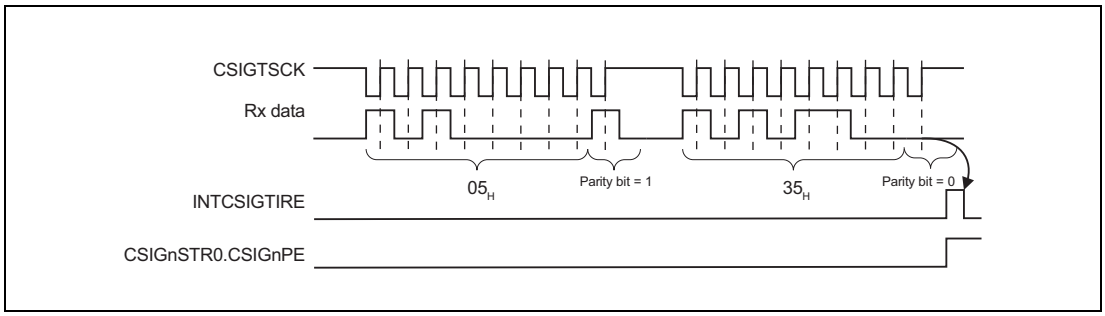

Figure 18.23 Parity Check Example

For the first 8 bits, the parity bit is 1. There is no parity error, because the total number of ones (including the parity bit) is odd.

For the second 8 bits, the parity bit is 0. This is detected as a parity error, because the total number of ones (including the parity bit) is even.

If the EDL (extended data length) function is used, the parity bit is added after the last bit of the data.

18.5.10.3 Overrun Error

This error occurs when previously received data still resides in the reception register CSIGnRX0, because it wasn't read, and new data is received.

The overrun error is not generated if data reception is disabled (CSIGnCTL0.CSIGnRXE = 0).

If overrun occurs:

- Interrupt INTCSIGTIRE is generated
- Bit CSIGnSTR0.CSIGnOVE is set
- Received data is overwritten and communication continues.

The following figure illustrates the function.

CSIG cannot store reception data because Rx register contains previous data.

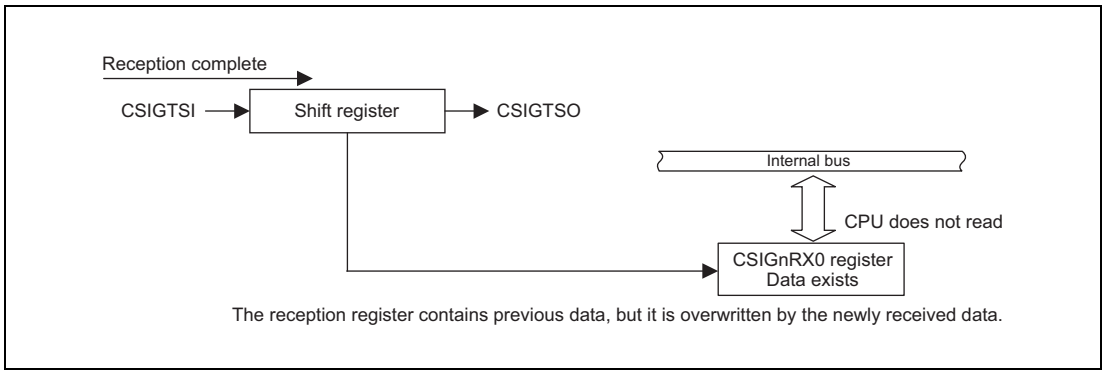

Figure 18.24 Overrun Error Detection

The following figure illustrates an example where:

- Rx data 3 was not read
- Rx data 4 was received, and data is overwritten.

Thus an overrun error occurs.

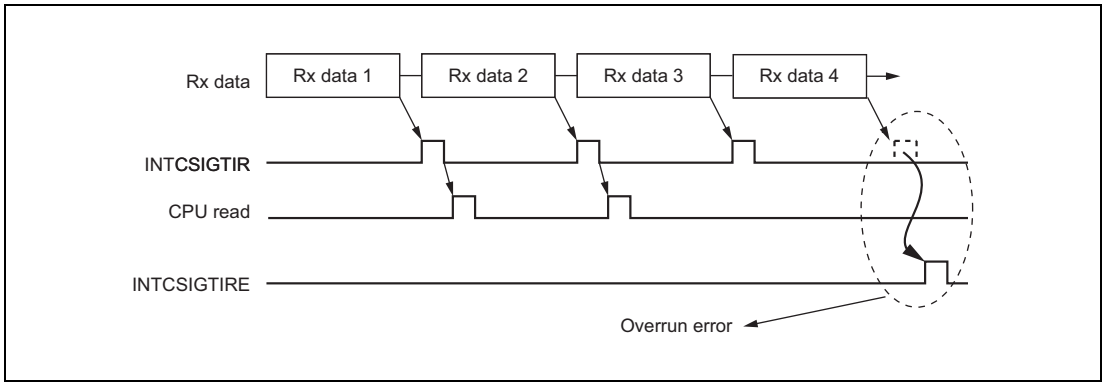

Figure 18.25 Overrun Error Detection - Example

NOTE

An overrun error can be avoided by using the handshake.

When handshake is used in slave mode, the receiver (slave) signals to the transmitter (master) that it is busy. The transmitter then waits until the receiver has read its reception register and is ready again.

For details see Section 18.5.8, Handshake Function.

18.6 Operating Procedure

18.6.1 Master Mode Transmission/Reception by DMA

In the following a transmit/receive example in master mode in combination with a DMA is described.

The following instructions are based on the assumption that:

- Transmission data length is 8 bits (CSIGnCFG0.CSIGnDLS[3:0] = 1000_B)
- MSB is transmitted first (CSIGnCFG0.CSIGnDIR = 0)
- INTCSIGTIC interrupt at the end of the transfer (CSIGnCTL1.CSIGnSLIT = 0)
- Normal clock and data phase (CSIGnCTL1.CSIGnCKR = 0, CSIGnCFG0.CSIGnDAP = 0)
- The number of data is 10 (0 to 9)

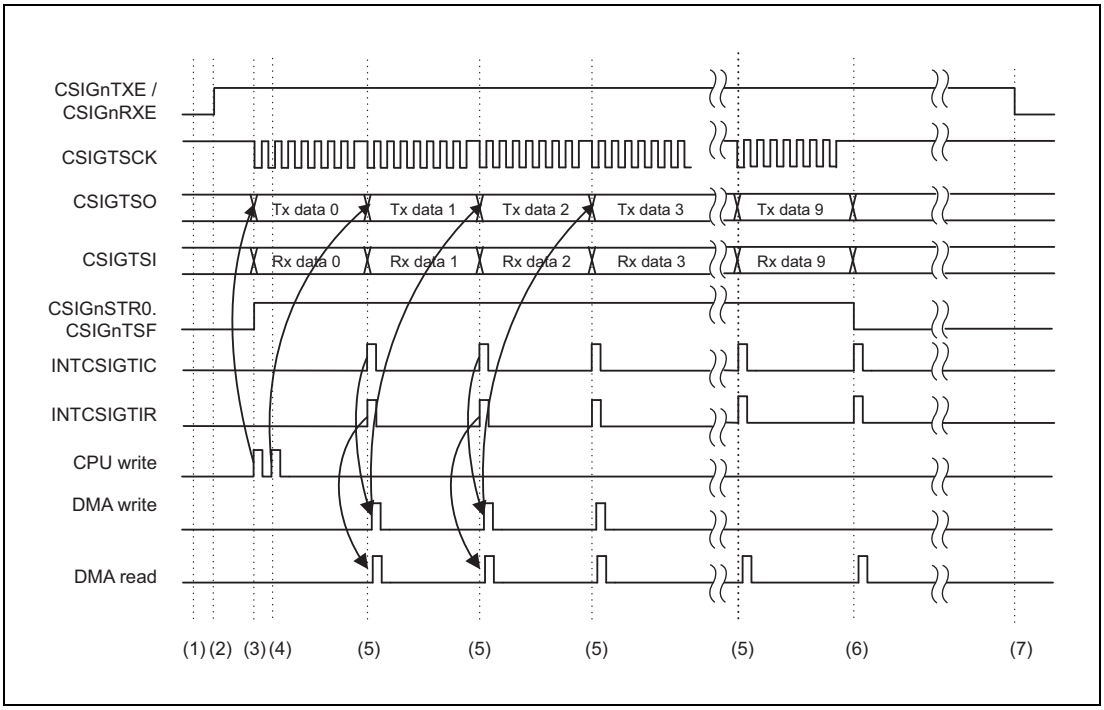

Figure 18.26 Communication in Master Mode

Procedure:

1. Configure the communication protocol in register CSIGnCFG0. Interrupt timing and operation mode are specified by setting the corresponding bits of the CSIGnCTL1 register and CSIGnCTL2 register.
2. In the CSIGnCTL0 register, set bits CSIGnPWR = 1 (enable the clock), CSIGnTXE = 1 (enable transmission), CSIGnRXE = 1 (enable reception).
3. Write the first data to be sent to the transmission register CSIGnTX0H. Transmission starts automatically when the first data is available.
4. Write the second data to CSIGnTX0H. Writing the second data immediately after the first one avoids unnecessary delays between the data.
5. After every data that has been transmitted or received, the interrupts INTCSIGTIC and INTCSIGTIR are generated. INTCSIGTIC indicates that the next data can be written to

CSIGnTX0H. INTCSIGTIR indicates that the reception register CSIGnRX0 must be read.
In this example, CPU write and DMA write are equivalent.

6. No more write action is required after transmit completion of data 8. Data 9 (the last data) has been written after the transmission of data 7.
However, the reception register CSIGnRX0 must be read after receive completion of data 8 and 9.

7. To finally disable the transmit/receive operation, clear CSIGnCTL0.CSIGnTXE and CSIGnCTL0.CSIGnRXE. When no communication is taking place, set CSIGnCTL0.CSIGnPWR to "0" to minimize the power consumption of the CSIGn.

Section 19 Clocked Serial Interface H (CSIH)

This section contains a generic description of the Clocked Serial Interface H (CSIH).

The first part in this section describes all RH850/D1L/D1M specific properties, such as the number of units, register base addresses, etc. The remainder of the section describes the functions and registers of CSIH.

19.1 Features of RH850/D1L/D1M CSIH

19.1.1 Number of Units

This microcontroller has the following number of CSIH units.

Each CSIH unit has one channel interface.

Table 19.1 Number of Units

Product Name	All products
Number of units	2
Name	CSIHn (n = 0, 1)

Table 19.2 Index

Index	Meaning
n	Throughout this section, the individual CSIH units are identified by the index “n” (n = 0, 1): for example, CSIHnCTL0 is the CSIHn control register 0.
x	CSIHn has up to 8 chip select signals. Throughout this section, the individual chip select signals are identified by the index “x”: that is, CSx denotes a non-specified chip select signal.
y	A variable used for explanation is identified by the index “y”: for example, CSIHnBRSy is a non-specified baud rate setting register of CSIHn.

The following table shows values indicated by the indexes of each product.

Table 19.3 Indexes of Products

Indexes of Each Product
For the value of x, see Table 19.4, Number of Chip Select Signals.
y = 0 to 3

The numbers of chip select signals for each of the CSIH units are listed in the following table.

Table 19.4 Number of Chip Select Signals

Unit Name	Chip Select Index
CSIHn	CSx (x = 0)

19.1.2 Register Base Address

CSIH base addresses are listed in the following table.

CSIH register addresses are given as offsets from the base addresses in general.

Table 19.5 Register Base Address

Base Address Name	Base Address
<CSIH0_base>	FFDA 8000_H
<CSIH1_base>	FFDA $A000_H$

19.1.3 Clock Supply

The CSIH clock supply is shown in the following table.

Table 19.6 Clock Supply

Unit Name	Unit Clock Name	Internal Clock Signal
CSIHn	PCLK	Clock Controller CLKJIT

19.1.4 Interrupt Requests

CSIH interrupt requests are listed in the following table.

Table 19.7 Interrupt Requests

CSIHn signals	Function	Connected to
CSIH0:		
INTCSIHTIC	Communication status interrupt	Interrupt Controller INTCSIH0IC DMA Controller trigger ID 103
INTCSIHTIR	Receive status interrupt	Interrupt Controller INTCSIH0IR DMA Controller trigger ID 104
INTCSIHTIRE	Communication error interrupt	Interrupt Controller INTCSIH0IRE
INTCSIHTIJC	Job completion interrupt	Interrupt Controller INTCSIH0IJC DMA Controller trigger ID 105
CSIH1:		
INTCSIHTIC	Communication status interrupt	Interrupt Controller INTCSIH1IC DMA Controller trigger ID 106
INTCSIHTIR	Receive status interrupt	Interrupt Controller INTCSIH1IR DMA Controller trigger ID 107
INTCSIHTIRE	Communication error interrupt	Interrupt Controller INTCSIH1IRE
INTCSIHTIJC	Job completion interrupt	Interrupt Controller INTCSIH1IJC DMA Controller trigger ID 108

19.1.5 Reset Sources

CSIH reset sources are listed in the following table. CSIH is initialized by these reset sources.

Table 19.8 Reset Sources

Unit Name	Reset Source
CSIHn	• Reset Controller SYSRES • reset upon wake-up from DEEPSTOP mode

19.1.6 External Input/Output Signals

External input/output signals of CSIH are listed below.

Table 19.9 External Input/Output Signals

Unit Signal Name	Outline	Alternative Port Pin Signal
CSIH0		
CSIHTSCK	Serial clock signal	CSIH0SC*1
CSIHTSI	Serial data input signal	CSIH0SI*1
$\overline{\text{CSIHTSSI}}$	Slave select input signal	$\overline{\text{CSIH0SSI}}$*1
CSIHTRYI	Ready/busy input signal	CSIH0RYI*1
CSIHTSO	Serial data output signal	CSIH0SO
CSIHTRYO	Ready/busy output signal	CSIH0RYO
CSIHTCSS0	Chip select signal	CSIH0CSS0
CSIHTCSS[7:1]		not connected
CSIH1		
CSIHTSCK	Serial clock signal	CSIH1SC*1
CSIHTSI	Serial data input signal	CSIH1SI*1
$\overline{\text{CSIHTSSI}}$	Slave select input signal	$\overline{\text{CSIH1SSI}}$*1
CSIHTRYI	Ready/busy input signal	CSIH1RYI*1
CSIHTSO	Serial data output signal	CSIH1SO
CSIHTRYO	Ready/busy output signal	CSIH1RYO
CSIHTCSS0	Chip select signal	CSIH1CSS0
CSIHTCSS[7:1]		not connected

Note 1. These input signals are passed through a noise filter, refer to the section “Port Filters” in the section “Port Functions”.

Note 2. For availability of these signals, refer to the Section 2.3.2, List of Alternative Function Pins.

19.1.7 Data Consistency Check

The following table lists the port pins on which CSIHnSO pin functions are multiplexed and data consistency checking. See Section 19.5.12, Error Detection for details on data consistency checking.

Table 19.10 Data Consistency Checking and Port Pins

Unit Signal Name	Port Pin Name	Alternative Function
CSIH0		
CSIHTSO	P0_1	ALT_OUT2
	P1_3	ALT_OUT2
CSIH1		
CSIHTSO	P1_0	ALT_OUT2

19.2 Overview

19.2.1 Functional Overview

- Three-wire serial synchronous data transfer
- Master mode and slave mode selectable
- Multiple slaves configuration plus RCB (Recessive Configuration for Broadcasting) due to eight configurable chip select output signals
- Slave select input signal ($\overline{\text{CSIHTSSI}}$) is usable
- Four built-in baud rate generators
- Transfer clock frequency is adjustable in master mode, whereas it is determined by the input clock in slave mode.
- Maximum transfer clock frequency:
  - Master mode: up to PCLK/4
  - Slave mode: up to PCLK/6
- Phase of clock and data selectable
- Data transfer with MSB or LSB first selectable
- Transfer data length selectable
  - CSIH0: from 2 to 16 bits in 1-bit units
  - CSIH1: from 7 to 16 bits in 1-bit units
- EDL (Extended Data Length) function for transferring data with more than 16 bits is included
- Three selectable transfer modes:
  - transmit-only mode
  - receive-only mode
  - transmit/receive mode
- Built-in handshake function
- Error detection (data consistency check, parity, time-out, overflow, and overrun) is included
- Support of job concept
- 16 words I/O buffer memory
- Selectable direct access mode and memory mode (FIFO, dual buffer, and transmit-only buffer)
- Four different interrupt request signals (INTCSIHTIC, INTCSIHTIR, INTCSIHTIRE, INTCSIHTIJC)
- LBM (Loop Back Mode) function for self test is included
- CPU-controlled high-priority communication function (CSIH0 only)
- Enforced chip select idle setting
- RCB (Recessive Configuration for Broadcasting) bit is included
- JOB enable control bit for AUTOSAR is included.

19.2.2 Functional Overview Description

The CSIH uses three signals for communication:

- Transmission clock CSIHTSCK (output in master mode, input in slave mode)
- Data output signal CSIHTSO
- Data input signal CSIHTSI

Additional signals are available for external control and monitoring.

- $\overline{\text{CSIHTSSI}}$: Slave select input signal
- CSIHTRYO: Ready/busy output signal (handshake signal)
- CSIHTRYI: Ready/busy input signal (handshake signal)
- CSIHTCSS[7:0]: Chip select signals

Data transmission is bit-wise and serial, and synchronous to the transmission clock.

The following table shows the most important registers for setting up the CSIH.

Table 19.11 Main Registers of CSIH

Register	Function
CSIHnCTL0	Enables/disables serial clock, and permits/ prohibits data transmission and data reception. Defines end-of-job behavior and enables/disables buffering (bypass of the buffer).
CSIHnCTL1	Controls options like interrupt timing, extended data length, job feature, data consistency check, loop-back mode, handshake, etc.
CSIHnCTL2	Selects master or slave mode, and the transfer clock frequency of the built-in baud rate generator (BRG) in master mode.
CSIHnMCTL0	Selects memory mode and specifies the time-out value
CSIHnMCTL1	Controls the memory in FIFO mode
CSIHnMCTL2	Controls the memory in dual buffer mode
CSIHnCFGx	Registers to configure the communication protocol for each chip select signal

19.2.3 Block Diagram

The block diagram shows the main components of the CSIH.

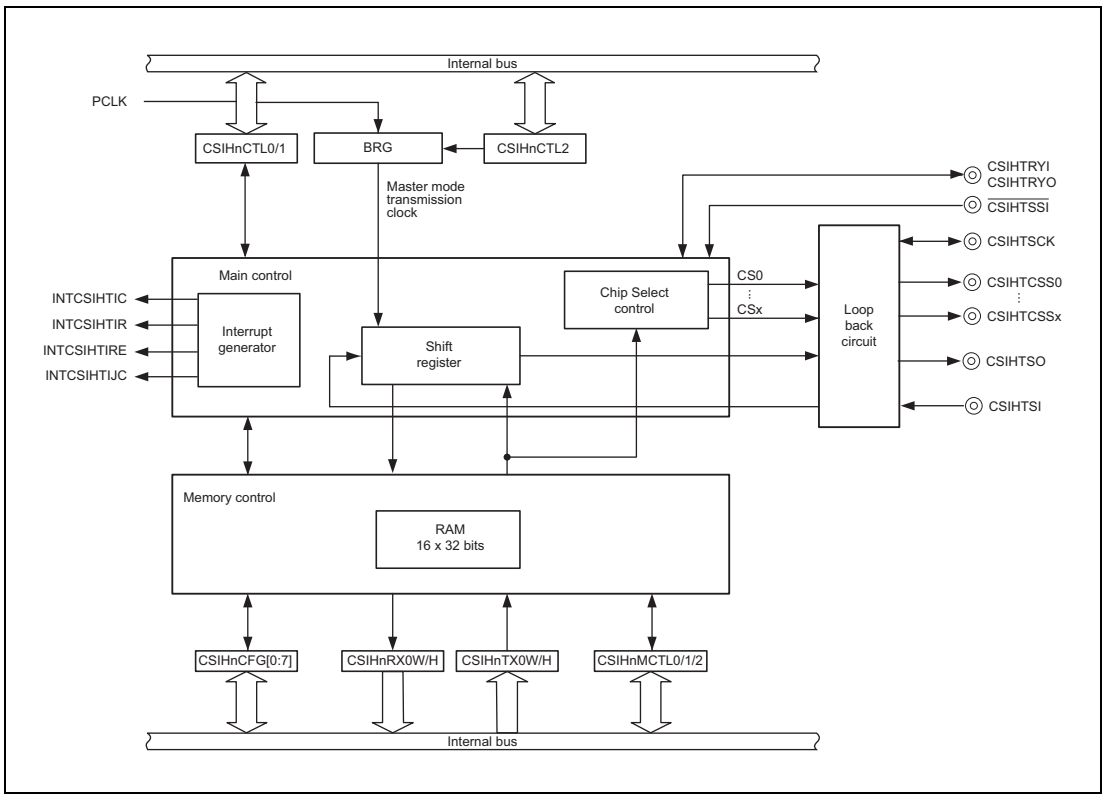

Figure 19.1 CSIH Block Diagram

NOTE

The following functional description of the CSIH module refers to a FIFO buffer size of 128 words. The description is also valid for the 16 words buffer size of the RH850/D1L/D1M devices.

In master mode, the transmission clock CSIHTSCK is generated by the built-in baud rate generator (BRG). In slave mode, the transmission clock is provided from an external source.

The built-in memory can be configured as FIFO, dual buffer (separate transmit and receive buffers), or transmit-only buffer. It can also be bypassed for data transmission and reception without buffering.

The loop back circuit disconnects the CSIH completely from the ports and supports internal self test.

NOTE

This section describes the following modes:

- The “operating mode” separates between master and slave mode. In this context, only a master can control and communicate with several slaves (for details see **Section 19.5.1, Operating Modes (Master/Slave)**).
- The “job mode” is related to the AUTOSAR job concept (for details see **Section 19.5.3.3, Job Concept**).
- The “memory mode” takes the various configurations of the associated buffer memory into account (for details see Section 19.5.6, CSIH Buffer Memory).
- The “data transfer mode” specifies the kind of the communication – transmit-only, receive-only, or transmit/receive (for details see Section 19.5.7, Data Transfer Modes).

19.3 Registers

19.3.1 List of Registers

CSIH registers are listed in the following table.

For details about CSIHn_base, see Section 19.1.2, Register Base Address.

Table 19.12 Registers

Module	Register	Symbol	Address
CSIHn	CSIHn control register 0	CSIHnCTL0	<CSIHn_base> + 0000_H
CSIHn	CSIHn control register 1	CSIHnCTL1	<CSIHn_base> + 0010_H
CSIHn	CSIHn control register 2	CSIHnCTL2	<CSIHn_base> + 0014_H
CSIHn	CSIHn status register 0	CSIHnSTR0	<CSIHn_base> + 0004_H
CSIHn	CSIHn status clear register 0	CSIHnSTCR0	<CSIHn_base> + 0008_H
CSIHn	CSIHn memory control register 0	CSIHnMCTL0	<CSIHn_base> + 1040_H
CSIHn	CSIHn memory control register 1	CSIHnMCTL1	<CSIHn_base> + 1000_H
CSIHn	CSIHn memory control register 2	CSIHnMCTL2	<CSIHn_base> + 1004_H
CSIHn	CSIHn memory read/write pointer register 0	CSIHnMRWP0	<CSIHn_base> + 1018_H
CSIHn	CSIHn configuration register 0	CSIHnCFG0	<CSIHn_base> + 1044_H
CSIHn	CSIHn configuration register 1	CSIHnCFG1	<CSIHn_base> + 1048_H
CSIHn	CSIHn configuration register 2	CSIHnCFG2	<CSIHn_base> + $104C_H$
CSIHn	CSIHn configuration register 3	CSIHnCFG3	<CSIHn_base> + 1050_H
CSIHn	CSIHn configuration register 4	CSIHnCFG4	<CSIHn_base> + 1054_H
CSIHn	CSIHn configuration register 5	CSIHnCFG5	<CSIHn_base> + 1058_H
CSIHn	CSIHn configuration register 6	CSIHnCFG6	<CSIHn_base> + $105C_H$
CSIHn	CSIHn configuration register 7	CSIHnCFG7	<CSIHn_base> + 1060_H
CSIHn	CSIHn transmit data register 0 for word access	CSIHnTX0W	<CSIHn_base> + 1008_H
CSIHn	CSIHn transmit data register 0 for half word access	CSIHnTX0H	<CSIHn_base> + $100C_H$
CSIHn	CSIHn receive data register 0 for word access	CSIHnRX0W	<CSIHn_base> + 1010_H
CSIHn	CSIHn receive data register 0 for half word access	CSIHnRX0H	<CSIHn_base> + 1014_H
CSIHn	CSIHn emulation register	CSIHnEMU	<CSIHn_base> + 0018_H
CSIHn	CSIHn baud rate setting register 0 (CSHI0 only)	CSIHnBRS0	<CSIHn_base> + 1068_H
CSIHn	CSIHn baud rate setting register 1 (CSHI0 only)	CSIHnBRS1	<CSIHn_base> + $106C_H$
CSIHn	CSIHn baud rate setting register 2 (CSHI0 only)	CSIHnBRS2	<CSIHn_base> + 1070_H
CSIHn	CSIHn baud rate setting register 3 (CSHI0 only)	CSIHnBRS3	<CSIHn_base> + 1074_H

NOTE

In the IO header files, availability of each register depends on whether they can be used by each product. The register has no corresponding function terminal has been removed from the IO header file by 1-bit. For availability of terminals, refer to the Section 2.3.2, List of Alternative Function Pins.

19.3.2 CSIHnCTL0 — CSIHn Control Register 0

This register controls the operation clock and enables/disables transmission/reception and the memory part for transmission and/or reception. It forces the stop of communication at the end of the current job.

Access: This register can be read/written in 8-bit or 1-bit units.

Address: <CSIHn_base> + 0000_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	CSIHnPWR	CSIHnTXE	CSIHnRXE	—	—	—	CSIHnJOBE	CSIHnMBS
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R	R	R/W	R/W

Table 19.13 CSIHnCTL0 Register Contents

Bit Position	Bit Name	Function
7	CSIHnPWR	Controls the operation clock. 0: Stops operation clock. 1: Provides operation clock. Clearing CSIHnPWR to 0 resets the internal circuits, stops operation, and sets CSIH to standby state. No clock is provided to internal circuits. If CSIHnPWR is cleared (to 0) during communication, ongoing communication is immediately aborted. In this case, communication setting must be started over.
6	CSIHnTXE	Permits or prohibits transmission. 0: Prohibits transmission. 1: Permits transmission.
5	CSIHnRXE	Permits or prohibits reception. 0: Prohibits reception. 1: Permits reception.
4 to 2	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
1	CSIHnJOBE	Stops communication at the end of the current job (Communication ends if data is written to the transmission buffer when CSIHnTX0W.CSIHnEOJ = 1 (job completion)). 0: Communication stop is not requested. 1: Stops communication. This bit can be used to abort an ongoing job. This bit is cleared to 0 automatically. If this bit is set to 1, the read value is always 0. In FIFO mode, the pointer must be cleared by setting CSIHnSTCR0.CSIHnPCT = 1 before the next communication is started
0	CSIHnMBS	Bypasses the memory for transmission and/or reception data. 0: Memory mode CSIH memory is used for transmission and/or reception data. 1: Direct access mode CSIH memory is bypassed.

CAUTION

For the setting of this register, see Table 19.32, Notes on Setting Registers.

19.3.3 CSIHnCTL1 — CSIHn Control Register 1

This register specifies the interrupt timing and the interrupt delay mode. It enables/disables extended data length control, data consistency check, loop-back mode, handshake functionality, and job mode. It selects the active output level of each chip select signal and the behavior of the chip select signals after the transfer of the final data.

Access: This register can be read/written in 32-bit units.

Address: <CSIHn_base> + 0010_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	CSIH0 SLRS*1	—	—	—	—	—	CSIH0 PHE*1	CSIHn CKR	CSIHn SLIT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CSIHn CSL7	CSIHn CSL6	CSIHn CSL5	CSIHn CSL4	CSIHn CSL3	CSIHn CSL2	CSIHn CSL1	CSIHn CSL0	CSIHn EDLE	CSIHn JE	CSIHn DCS	CSIHn CSRI	CSIHn LBM	CSIHn SIT	CSIHn HSE	CSIHn SSE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. This bit is only available for CSIH0.

Table 19.14 CSIHnCTL1 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
24 of CSIH0	CSIH0SLRS	Sets the internal synchronization timing for receive data input. 0: Rising edge of PCLK 1: Falling edge of PCLK For differences by the setting, see Data Sheet.
24 of CSIH1	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
23 to 19	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
18 of CSIH0	CSIH0PHE	Sets the CPU-controlled priority-based communication function. 0: The CPU-controlled high-priority communication function is disabled. 1: The CPU-controlled high-priority communication function is enabled. To enable the CPU-controlled high-priority communication function, set this bit to 1 and set CSIHnJE = 1. This bit can only be set in transmit-only buffer mode.
18 of CSIH1	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
17	CSIHnCKR	CSIHTSCK Clock Inversion Function 0: The default level of CSIHTSCK is high 1: The default level of CSIHTSCK is low For details, see Section 19.3.11, CSIHnCFGx — CSIHn Configuration Register x.
16	CSIHnSLIT	Selects the timing of interrupt INTCSIHTIC. 0: Normal interrupt timing (interrupt is generated after the transfer) 1: As soon as the contents of the CSIHnTX0W/H register are transferred to the shift register, an interrupt is generated (this function is activated only in direct access memory mode/transmit-only buffer mode). For details, see Section 19.4.3, INTCSIHTIC (Communication Status Interrupt).

Table 19.14 CSIHnCTL1 Register Contents (2/2)

Bit Position	Bit Name	Function
15 to 8	CSIHnCSLx	Selects the active output level of chip select signal x (CSIHTCSSx). 0: Chip select is active low. 1: Chip select is active high. For details, see Section 19.5.3, Chip Selection (CS) Features.
7	CSIHnEDLE	Enables/disables extended data length (EDL) mode. 0: Disables extended data length mode. 1: Enables extended data length mode. For details, see Section 19.5.8.2, Data Length Greater than 16 Bits.
6	CSIHnJE	Enables/disables job mode. 0: Disables job mode. 1: Enables job mode. For details, see Section 19.5.3.3, Job Concept. The CSIHnCTL0.CSIHnJOBE, CSIHnTX0W.CSIHnEOJ, and CSIHnTX0W.CSIHnCIRE bits are enabled only when CSIHnJE = 1. Setting this bit in slave mode is prohibited. **For CSIH0 only:** In addition, to enable the CPU-controlled high-priority communication function, set CSIHnPHE = 1 and this bit to 1.
5	CSIHnDCS	Enables/disables data consistency check. 0: Disables data consistency check. 1: Enables data consistency check. For details, see Section 19.5.12.1, Data Consistency Check.
4	CSIHnCSRI	Defines chip select signal behavior after last data transfer. 0: Chip select signal holds the active level. 1: Chip select signal returns to the inactive level. The last data is determined at the interrupt timing in direct access mode or FIFO mode. When CSIHnCTL1.CSIHnSLIT = 0, the last data is determined in direct access mode.
3	CSIHnLBM	Controls loop-back mode (LBM). 0: Deactivates loop-back mode. 1: Activates loop-back mode. For details, see Section 19.5.13, Loop-Back Mode.
2	CSIHnSIT	Selects interrupt delay mode. 0: No delay is generated. 1: Half clock delay is generated for all interrupts. This bit is only valid in master mode. In slave mode, no delay is generated. For details, see Section 19.4.2, Interrupt Delay.
1	CSIHnHSE	Enables/disables handshake function. 0: Disables the handshake function. 1: Enables the handshake function. For details see Section 19.5.11, Handshake Function.
0	CSIHnSSE	Enables/disables the slave select function. 0: Input signal $\overline{\text{CSIHTSSI}}$ is disabled. 1: Input signal $\overline{\text{CSIHTSSI}}$ is recognized. If the slave select function is not used, this bit must be set to 0 (see also Section 19.5.2, Master/Slave Connections).

Details about CSIHnCTL1.CSIHnSSE are shown in the following tables.

Table 19.15 Operation of the Slave Select Function during Reception

CSIHnCTL0. CSIHnRXE	CSIHnCTL1. CSIHnSSE	$\overline{\text{CSIHTSSI}}$	Receive Operation
0	—	—	Reception is prohibited
1	0	—	Possible
1	1	0	Possible
1	1	1	Disabled

Table 19.16 Operation of the Slave Select Function during Transmission

CSIHnCTL0. CSIHnTXE	CSIHnCTL1. CSIHnSSE	$\overline{\text{CSIHTSSI}}$	Transmit Operation
0	—	—	Transmission is prohibited
1	0	—	Possible
1	1	0	Possible
1	1	1	Disabled

CAUTION

For the setting of this register, see Table 19.32, Notes on Setting Registers.

19.3.4 CSIHnCTL2 — CSIHn Control Register 2

This register selects operating mode and the basic clock value, and specifies the transfer clock frequency.

For details see Section 19.5.5, Transmission Clock Selection.

Access: This register can be read/written in 16-bit units.

Address: <CSIHn_base> + 0014_H

Value after reset: $E000_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CSIHnPRS[2:0]			–	CSIH1BRS[11:0]*1											
Value after reset	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. These bits are only available for CSIH1.

Table 19.17 CSIHnCTL2 Register Contents

Bit Position	Bit Name	Function
15 to 13	CSIHnPRS[2:0]	These bits select the operation mode and the reference clock value.
12	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
11 to 0 of CSIH0	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
11 to 0 of CSIH1	CSIH1BRS[11:0]	Selects the baud rate:

CSIHnPRS2	CSIHnPRS1	CSIHnPRS0	Selection of Reference Clock (PRSOUT)
0	0	0	PCLK (Master mode)
0	0	1	PCLK/2 (Master mode)
0	1	0	PCLK/4 (Master mode)
0	1	1	PCLK/8 (Master mode)
1	0	0	PCLK/16 (Master mode)
1	0	1	PCLK/32 (Master mode)
1	1	0	PCLK/64 (Master mode)
1	1	1	External clock via CSIHTSCK(in) (Slave mode)

CSIHnBRS[11:0]	Baud rate at CSIHTSCK
0	BRG stopped
1	PCLK / (2^{α} × 1 × 2)
2	PCLK / (2^{α} × 2 × 2)
3	PCLK / (2^{α} × 3 × 2)
4	PCLK / (2^{α} × 4 × 2)
…	…
4095	PCLK / (2^{α} × 4095× 2)

19.3.4.1 CSIH0 transfer clock frequency setting

In master mode, the following bits are used to set the transfer clock frequency:

CSIH0CTL2.CSIH0PRS[2:0], CSIH0CFGx.CSIH0BRSS[1:0], CSIH0BRSy.CSIH0BRS[11:0]

In addition, any of the four different transfer clock frequency settings that are specified by the CSIH0BRSy.CSIH0BRS[11:0] bits is selected according to the chip select signal. To select the transfer clock frequency setting for each chip select signal, use the CSIH0CFGx.CSIH0BRSS[1:0] bits.

The following table shows the relationship between CSIH0CFGx.CSIH0BRSS[1:0] and CSIH0BRSy.CSIH0BRS[11:0].

CSIH0CFGx (x = 0) CSIH0BRSS1 to 0	Transfer Clock Frequency Setting Bit to be Selected
00	CSIH0BRS0.CSIH0BRS[11:0]
01	CSIH0BRS1.CSIH0BRS[11:0]
10	CSIH0BRS2.CSIH0BRS[11:0]
11	CSIH0BRS3.CSIH0BRS[11:0]

The following table shows the relationship between the transfer clock frequency and the transfer clock frequency setting (CSIH0BRSy[11:0]) selected by the CSIH0BRSS[1:0] bits when the bit value of the CSIH0PRS[2:0] bits is α.

CSIH0BRSy[11:0]	Transfer clock frequency
0	BRG stopped
1	PCLK / (2^{α} × 1 × 2)
2	PCLK / (2^{α} × 2 × 2)
3	PCLK / (2^{α} × 3 × 2)
4	PCLK / (2^{α} × 4 × 2)
...	…
4095	PCLK / (2^{α} × 4095× 2)

When a time-out error is used in slave mode, the clock selected by this setting is used. In slave mode, the CSIHnPRS[2:0] bits are set to 111_B. In this case, the prescaler has the same setting as when the CSIHnPRS[2:0] bits are set to 000_B. If you are using a time-out error of CSIH0, set the CSIH0BRSy.CSIH0BRS[11:0] bits to a value other than 000_H. If you are using a time-out error of CSIH1, set the CSIH1CTL2.CSIH1BRS[11:0] bits to a value other than 000_H.

CAUTION

For the setting of this register, see Table 19.32, Notes on Setting Registers.

19.3.5 CSIHnSTR0 — CSIHn Status Register 0

This register indicates the status of CSIH.

Access: This register can only be read in 32-bit units.

Address: <CSIHn_base> + 0004_H

Value after reset: $0000\ 0010_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CSIHnSRP[7:0]								CSIHnSPF[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CSIHn TMOE	CSIHn OFE	—	—	—	—	—	CSIH0 HPST*1	CSIHn TSF	—	CSIHn FLF	CSIHn EMF	CSIHn DCE	—	CSIHn PE	CSIHn OVE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. This bit is only available for CSIH0.

Table 19.18 CSIHnSTR0 Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 24	CSIHnSRP[7:0]	Indicates the number of received data packets in FIFO mode. **CSIHnSRP[7:0]** / **Description** 00_H / Number of received data (0 to 128) … 80_H Other than the above / Undefined These bits are cleared by CSIHnSTCR0.CSIHnPCT. In direct access mode, dual buffer memory mode, or transmit-only buffer memory mode, this value is fixed to 00_H. In direct access mode, this bit is fixed to 0 because there is no pointer. In buffer mode, this bit is fixed to 0 because the number of data packets is managed by CSIHnMCTL2.CSIHnND[7:0].
23 to 16	CSIHnSPF[7:0]	Indicates the number of unsent data in FIFO mode. (The number of data written by the CPU is the number of sent data.) **CSIHnSPF[7:0]** / **Description** 00_H / Number of unsent data packets (0 to 128) … 80_H Other than the above / Undefined These bits are cleared by CSIHnSTCR0.CSIHnPCT. In direct access mode, dual buffer memory mode, or transmit-only buffer memory mode, this value is fixed to 00_H. In direct access mode, this bit is fixed to 0 because there is no pointer. In buffer mode, this bit is fixed to 0 because the number of data packets is managed by CSIHnMCTL2.CSIHnND[7:0].

Table 19.18 CSIHnSTR0 Register Contents (2/3)

<table>
<tr><th>Bit Position</th><th>Bit Name</th><th>Function</th></tr>
<tr><td>15</td><td>CSIHnTMOE</td><td>Time-out Error Flag in FIFO Mode
Indicates whether a time-out error was detected in FIFO mode.
0: No time out error is detected.
1: A time out error is detected.
For details, see Section 19.5.12.3, Time-Out Error.
This bit is cleared by CSIHnSTCR0.CSIHnTMOEC.
When setting to 1 by time-out error detection and clearing to 0 by CSIHnSTCR0.CSIHnTMOEC occur simultaneously, setting to 1 takes precedence over clearing to 0.
This bit is also initialized when CSIHnCTL0.CSIHnPWR is changed to 0 to 1 or 1 to 0.</td></tr>
<tr><td>14</td><td>CSIHnOFE</td><td>Overflow Error Flag in FIFO mode
Indicates whether an overflow error was detected in FIFO mode.
0: No overflow error is detected.
1: An overflow error is detected.
For details, see Section 19.5.12.4, Overflow Error.
This bit is cleared by CSIHnSTCR0.CSIHnOFEC.
When setting to 1 by overflow error detection and clearing to 0 by CSIHnSTCR0.CSIHnOFEC occur simultaneously, setting to 1 by CSIHnSTCR0.CSIHnOFEC takes precedence over clearing to 0.
This bit is also initialized when CSIHnCTL0.CSIHnPWR is changed to 0 to 1 or 1 to 0.</td></tr>
<tr><td>13 to 9</td><td>Reserved</td><td>When read, the value after reset is returned.</td></tr>

<tr><td>8 of CSIH1</td><td>Reserved</td><td>When read, the value after reset is returned.</td></tr>
<tr><td>7</td><td>CSIHnTSF</td><td>Transfer Status Flag
0: Idle state
1: Communication is in progress or being prepared.
The timing to set or clear this bit is as in the following tables.
<table>
<tr><th rowspan="2">Master Mode</th><th colspan="2">Timing to set</th><th rowspan="2">Timing to clear</th></tr>
<tr><th>Direct Access Mode, FIFO Mode</th><th>Double Buffer Mode, Transmit-Only Mode</th></tr>
<tr><td>Transmit-only mode</td><td rowspan="3">Data is written to a transmit register (CSIHnTX0W/ CSIHnTX0H)</td><td rowspan="3">Bit CSIHnMCTL2.CSIHnBTST is set</td><td rowspan="3">Within a half clock of the last serial clock edge</td></tr>
<tr><td>Transmit/receive mode</td></tr>
<tr><td>Receive-only mode</td></tr>
</table>
<table>
<tr><th rowspan="2">Slave Mode</th><th colspan="2">Timing to set</th><th rowspan="2">Timing to clear</th></tr>
<tr><th>Direct Access Mode, FIFO Mode</th><th>Double Buffer Mode, Transmit-Only Mode</th></tr>
<tr><td>Transmit-only mode</td><td rowspan="2">Data is written to a transmit register (CSIHnTX0W/CSIHnTX0H)</td><td rowspan="2">Bit CSIHnMCTL2.CSIHnBTST is set</td><td rowspan="2">Within a half clock of the last serial clock edge</td></tr>
<tr><td>Transmit/receive mode</td></tr>
<tr><td>Receive-only mode</td><td>Input timing of CSIHTSCK</td><td></td><td></td></tr>
</table></td></tr>
<tr><td>6</td><td>Reserved</td><td>When read, the value after reset is returned.</td></tr>
<tr><td>5</td><td>CSIHnFLF</td><td>A flag indicating that the buffer is full in FIFO mode.
0: FIFO buffer is not full.
1: FIFO buffer is full.
This bit is cleared by CSIHnSTCR0.CSIHnPCT.
The FIFO buffer might be filled with unsent data or received data.</td></tr>
</table>

Table 19.18 CSIHnSTR0 Register Contents (3/3)

Bit Position	Bit Name	Function
4	CSIHnEMF	A flag indicating that the buffer is empty in FIFO mode. 0: FIFO buffer is not empty. 1: FIFO buffer is empty. This bit is set to 1 by CSIHnSTCR0.CSIHnPCT. This bit is set to 1 when CSIHnSTR0.CSIHnSRP[7:0] + CSIHnSTR0.CSIHnSPF[7:0] = 00_H. The FIFO buffer might be filled with unsent data or received data.
3	CSIHnDCE	Data Consistency Check Error Flag 0: No data consistency error is detected. 1: Data consistency error is detected. This bit is cleared by writing 1 to CSIHnSTCR0.CSIHnDCEC. When setting to 1 by data consistency error detection and clearing to 0 by CSIHnSTCR0.CSIHnDCEC occur simultaneously, setting to 1 due to data consistency error detection takes precedence over clearing to 0. This bit is initialized when CSIHnCTL0.CSIHnPWR is changed from 0 to 1 or 1 to 0.
2	Reserved	When read, the value after reset is returned.
1	CSIHnPE	Parity Error Flag 0: No parity error is detected. 1: Parity error is detected. This bit is cleared by writing 1 to CSIHnSTCR0.CSIHnPEC. When setting to 1 due to parity error detection and clearing to 0 by CSIHnSTCR0.CSIHnPEC occur simultaneously, setting to 1 by parity error detection takes precedence over clearing to 0. This bit is initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.
0	CSIHnOVE	Overrun Error Flag (Fixed to 0 in dual buffer mode) 0: No overrun error is detected. 1: Overrun error is detected. This bit is cleared by writing 1 to CSIHnSTCR0.CSIHnOVEC. When setting to 1 due to overrun error detection and clearing to 0 by writing to CSIHnSTCR0.CSIHnOVEC occur simultaneously, setting to 1 due to overrun error detection takes precedence over clearing to 0.This bit is Initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.

Table 19.19 Behavior in Memory ModeCSIH0CSIH0

Bit Name	Bit Position	Direct Access Mode	FIFO Mode	Transmit-Only Mode	Dual Buffer Mode
CSIHnSRP[7:0]	31 to 24	Fixed to 0	Number of received words	Fixed to 0	Fixed to 0
CSIHnSPF[7:0]	23 to 16	Fixed to 0	Number of unsent data	Fixed to 0	Fixed to 0
CSIHnTMOE	15	Fixed to 0	0: No error is detected. 1: An error is detected.	Fixed to 0	Fixed to 0
CSIHnOFE	14	Fixed to 0	0: No error is detected. 1: An error is detected.	Fixed to 0	Fixed to 0
CSIHnTSF	7	0: Idle state 1: Communication is in progress or being prepared			
CSIHnFLF	5	Fixed to 0	0: FIFO is not full 1: FIFO is full	Fixed to 0	Fixed to 0
CSIHnEMF	4	Fixed to 1	0: FIFO is not empty 1: FIFO is empty	Fixed to 1	Fixed to 1
CSIHnDCE	3	0: No error is detected. 1: An error is detected.			
CSIHnPE	1	0: No error is detected. 1: An error is detected.			
CSIHnOVE	0	0: No error is detected. 1: An error is detected.	0: No error is detected. 1: An error is detected.	0: No error is detected. 1: An error is detected.	Fixed to 0

CAUTION

For the setting of this register, see Table 19.32, Notes on Setting Registers.

19.3.6 CSIHnSTCR0 — CSIHn Status Clear Register 0

This register clears the status flags of the CSIHnSTR0 status register.

Access: This register can be read/written in 16-bit units.
When read, the value 0000_H is always returned.

Address: <CSIHn_base> + 0008_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CSIHn TMOEC	CSIHn OFEC	—	—	—	—	—	CSIHn PCT	—	—	—	—	CSIHn DCEC	—	CSIHn PEC	CSIHn OVEC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R/W	R	R	R	R	R/W	R	R/W	R/W

Table 19.20 CSIHnSTCR0 Register Contents

Bit Position	Bit Name	Function
15	CSIHnTMOEC	Controls the time-out error flag clear command. 0: No operation. The read value is always 0. 1: Clears the time out error flag (CSIHnSTR0.CSIHnTMOE).
14	CSIHnOFEC	Controls the overflow error flag clear command. 0: No operation. The read value is always 0. 1: Clears the overflow error flag (CSIHnSTR0.CSIHnOFE).
13 to 9	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
8	CSIHnPCT	Controls the FIFO pointer clear command. 0: No operation. The read value is always 0. 1: Clears the FIFO buffer pointers below (in FIFO mode, dual buffer mode, and transmit-only buffer mode) and the status bits. **FIFO Buffer Pointer** / **Status Bit** CSIHnMRWP0.CSIHnTRWA[6:0] / CSIHnSTR0.CSIHnSPF[7:0] CSIHnMRWP0.CSIHnRRA[6:0] / CSIHnSTR0.CSIHnSRP[7:0] CSIHnMCTL2.CSIHnSOP[6:0] / CSIHnSTR0.CSIHnFLF CSIHnSTR0.CSIHnTSF Additionally, the CSIHnSTR0.CSIHnEMF bit is set to 1 (FIFO empty) (in FIFO mode only).
7 to 4	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	CSIHnDCEC	Controls the data consistency error flag clear command. 0: No operation. The read value is always 0. 1: Clears the data consistency error flag (CSIHnSTR0.CSIHnDCE).
2	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
1	CSIHnPEC	Controls the parity error flag clear command. 0: No operation. The read value is always 0. 1: Clears the parity error flag (CSIHnSTR0.CSIHnPE).
0	CSIHnOVEC	Controls the overrun error flag clear command. 0: No operation. The read value is always 0. 1: Clears the overrun error flag (CSIHnSTR0.CSIHnOVE).

CAUTION

For the setting of this register, see Table 19.32, Notes on Setting Registers.

19.3.7 CSIHnMCTL0 — CSIHn Memory Control Register 0

This register selects the memory mode and the time-out setting.

Access: This register can be read/written in 16-bit units.

Address: <CSIHn_base> + 1040_H

Value after reset: $001F_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	CSIHn MMS[1:0]		—	—	—	CSIHnTO[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 19.21 CSIHnMCTL0 Register Contents

Bit Position	Bit Name	Function
15 to 10	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
9 to 8	CSIHnMMS [1:0]	Selects the memory mode. **CSIHn MMS1 / CSIHn MMS0 / Description** 0 / 0 / FIFO mode 0 / 1 / Dual buffer mode 1 / 0 / Transmit-only buffer mode 1 / 1 / Prohibited After a change of the memory mode, the respective buffer pointers must be cleared by setting the CSIHnSTCR0.CSIHnPCT bit to 1. In direct access mode, the setting of these bits is ignored.
7 to 5	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
4 to 0	CSIHnTO[4:0]	Selects the time-out setting in FIFO mode. **CSIHnTO[4:0] / Description** 00000_B / No time-out is detected 00001_B / Time-out is (1 × 8 × BRG output clocks) 00010_B / Time-out is (2 × 8 × BRG output clocks) ... 11111_B / Time-out is (31 × 8 × BRG output clocks) **CAUTION** Changing the time-out setting is only permitted when CSIHnCTL0.CSIHnPWR = 0. Set the CSIHnTO[4:0] bits to 00000_B in direct access mode, dual buffer mode, or transmit-only buffer mode (except FIFO mode). For details about time-out detection, see also Section 19.5.12.3, Time-Out Error.

CAUTION

For the setting of this register, see Table 19.32, Notes on Setting Registers.

19.3.8 CSIHnMCTL1 — CSIHn Memory Control Register 1

This register selects the conditions to generate the interrupt requests, INTCSIHTIC and INTCSIHTIR in FIFO mode.

Access: This register can be read/written in 32-bit units.

Address: <CSIHn_base> + 1000_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	CSIHnFES[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	CSIHnFFS[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 19.22 CSIHnMCTL1 Register Contents

Bit Position	Bit name	Function
31 to 23	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
22 to 16	CSIHnFES[6:0]	Selects the conditions to generate the INTCSIHTIC interrupt (transmit data empty) in FIFO mode. When the number of unsent data to be transmitted in FIFO (checked by the CSIHnSTR0.CSIHnSPF[7:0] bit) and CSIHnMCTL1.CSIHnFES[6:0] match, the FIFO empty flag (CSIHnSTR0.CSIHnEMF bit) is set to 1, and the INTCSIHTIC interrupt request is generated.
15 to 7	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
6 to 0	CSIHnFFS[6:0]	Selects the conditions to generate the INTCSIHTIR interrupt (receive data full) in FIFO mode. When the number of received data in FIFO (checked by the CSIHnSTR0.CSIHnSRP[7:0] bit) and (128 - CSIHnMCTL1.CSIHnFFS[6:0]) match and the INTCSIHTIR interrupt request is generated.

CAUTION

For the setting of this register, see Table 19.32, Notes on Setting Registers.

19.3.9 CSIHnMCTL2 — CSIHn Memory Control Register 2

This register controls the operation of the memory in dual buffer or transmit-only buffer mode and triggers to start communication in buffer mode.

Access: This register can be read/written in 32-bit units.

Address: <CSIHn_base> + 1004_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CSIHn BTST	—	—	—	—	—	—	—	CSIHnND[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	CSIHnSOP[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 19.23 CSIHnMCTL2 Register Contents (1/2)

Bit Position	Bit Name	Function
31	CSIHnBTST	Provides a start trigger for buffer transfer. 0: No operation. 1: Issues the start transfer command. The read value is always 0. **CAUTION** This bit can only be used in dual buffer mode and transmit-only buffer mode.
30 to 24	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
23 to 16	CSIHnND[7:0]	Specifies the number of data for each memory mode. The read value indicates the number of remaining communication data.

CSIHn ND[7:0]	Dual Buffer Mode	Transmit-Only Buffer Mode	FIFO Mode	Direct Access Mode
00_H	Send 0 data	Send 0 data	No influence	No influence
01_H	Send 1 data	Send 1 data	No influence	No influence
...	...	...	No influence	No influence
$3F_H$	Send 63 data	Send 63 data	No influence	No influence
40_H	Send 64 data	Send 64 data	No influence	No influence
...	Prohibited	...	No influence	No influence
$7F_H$	Prohibited	Send 127 data	No influence	No influence
80_H	Prohibited	Send 128 data	No influence	No influence
Other than the above	Setting is prohibited.			

The values are automatically decremented after data transfer (Not decremented in direct access mode).

15 to 7	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.

Table 19.23 CSIHnMCTL2 Register Contents (2/2)

Bit Position	Bit Name	Function
6 to 0	CSIHnSOP[6:0]	Selects the pointer of the data to be sent. If communication is forced to stop by setting CSIHnCTL0.CSIHnPWR to 0 or CSIHnSTCR0.CSIHnPCT to 1, these bits are cleared by hardware. In FIFO mode, these bits indicate the send address.

CSIHn SOP[6:0]	Dual Buffer Mode	Transmit-Only Buffer Mode	FIFO Mode	Direct Access Mode
00_H	0000_H	0000_H	0000_H	No influence
01_H	0004_H	0004_H	0004_H	No influence
...	...	...	...	No influence
$3F_H$	$00FC_H$	$00FC_H$	$00FC_H$	No influence
40_H	Prohibited	0100_H	0100_H	No influence
...	Prohibited	...	...	No influence
$7F_H$	Prohibited	$01FC_H$	$01FC_H$	No influence

CAUTION

In direct access mode, these bits are not incremented.

CAUTION

For the setting of this register, see Table 19.32, Notes on Setting Registers.

19.3.10 CSIHnMRWP0 — CSIHn Memory Read/Write Pointer Register 0

This register sets the pointers for reading from and writing to the dual buffer or transmit-only buffer.

Access: This register can be read/written in 32-bit units.

Address: <CSIHn_base> + 1018_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	CSIHnRRA[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	CSIHnTRWA[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 19.24 CSIHnMRWP0 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
22 to 16	CSIHnRRA[6:0]	Selects the read pointer of the receive buffer.

CSIHn RRA[6:0]	Dual Buffer Mode	Transmit-Only Buffer Mode	FIFO Mode	Direct Access Mode
00_H	0000_H	No influence	0000_H	No influence
01_H	0004_H	No influence	0004_H	No influence
...	...	No influence	...	No influence
$3F_H$	$00FC_H$	No influence	$00FC_H$	No influence
40_H	Prohibited	No influence	0100_H	No influence
...	Prohibited	No influence	...	No influence
$7F_H$	Prohibited	No influence	$01FC_H$	No influence

These bits are automatically incremented when received data is read.
If an overrun error is generated while reading the CSIHnRX0W or CSIHnRX0H register, the read pointer is not incremented.
These bits are cleared when CSIHnSTCR0.CSIHnPCT is set to 1.
In direct access mode and transmit-only buffer mode, these bits are not incremented.
To perform write access in transmit-only buffer mode, set 0000_H to these bits.
In FIFO mode, these bits indicate the read address of the received data.

15 to 7	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.

Table 19.24 CSIHnMRWP0 Register Contents (2/2)

Bit Position	Bit Name	Function
6 to 0	CSIHnTRWA [6:0]	Selects the read/write pointer of the transmit buffer.

CSIHn TRWA[6:0]	Dual Buffer Mode	Transmit-Only Buffer Mode	FIFO Mode	Direct Access Mode
00_H	0000_H	0000_H	0000_H	No influence
01_H	0004_H	0004_H	0004_H	No influence
...	...	...	...	No influence
$3F_H$	$00FC_H$	$00FC_H$	$00FC_H$	No influence
40_H	Prohibited	0100_H	0100_H	No influence
...	Prohibited	...	...	No influence
$7F_H$	Prohibited	$01FC_H$	$01FC_H$	No influence

These bits are automatically incremented when the transmission data is written or read.
These bits are cleared when CSIHnSTCR0.CSIHnPCT is set to 1.
In direct access mode, these bits are not incremented.
In FIFO mode, these bits indicate the read/write address of transmission data.

CAUTION

For the setting of this register, see Table 19.32, Notes on Setting Registers.

19.3.11 CSIHnCFGx — CSIHn Configuration Register x

These up to eight registers specify for each chip select signal CSIHTCSSx prescaler, parity, data length, recessive configuration for broadcasting, serial data direction, clock and data phase, idle enforcement configuration, idle time, hold time, inter-data time, and setup time.

Slave mode

In slave mode, the transmission protocol setting of the CSIHnCFG0 register is effective.

- CSIHnPSx[1:0]: parity usage
- CSIHnDLSx[3:0]: data length selection
- CSIHnDIRx: data direction
- CSIHnCKPx, CSIHnDAPx: clock and data phase

In slave mode, set 0 to all the bits other than above in the CSIHnCFG0 register, and the CSIHnCFG1 to CSIHnCFG7 registers.

Access: This register can be read/written in 32-bit units.

Address: CSIHnCFG0: <CSIHn_base> + 1044_H
CSIHnCFG1: <CSIHn_base> + 1048_H
CSIHnCFG2: <CSIHn_base> + $104C_H$
CSIHnCFG3: <CSIHn_base> + 1050_H
CSIHnCFG4: <CSIHn_base> + 1054_H
CSIHnCFG5: <CSIHn_base> + 1058_H
CSIHnCFG6: <CSIHn_base> + $105C_H$
CSIHnCFG7: <CSIHn_base> + 1060_H

Value after reset: $0000\ 0000_H$

CSIH0:

Table 19.25 CSIHnCFGx Register Contents (1/5)

Bit Position	Bit Name	Function
31, 30 of CSIH0	CSIH0BRSSx [1:0]	These bits select the baud rate setting register (CSIH0BRSy)..

CSIH0 BRSSx1	CSIH0 BRSSx0	Baud Rate Setting Register Selection
0	0	The transfer clock frequency is set according to the CSIH0BRS0 setting.
0	1	The transfer clock frequency is set according to the CSIH0BRS1 setting.
1	0	The transfer clock frequency is set according to the CSIH0BRS2 setting.
1	1	The transfer clock frequency is set according to the CSIH0BRS3 setting.

The maximum value for setting the transfer clock frequency, combining the CSIH0CTL2.CSIH0PRS[2:0] setting, must be as follows:
Master mode: PCLK/4
Slave mode: PCLK/6

Bit Position	Bit Name	Function
31, 30 of CSIH1	CSIH1PSCLx [1:0]	Selects the prescaler for chip select x

CSIH0 PSCLx1	CSIH0 PSCLx0	Prescaler output
0	0	CSIHBCLK
0	1	CSIHBCLK / 2
1	0	CSIHBCLK / 4
1	1	CSIHBCLK / 8

These bits are only available in master mode.

Bit Position	Bit Name	Function
29, 28	CSIHnPSx[1:0]	Selects the parity for sending or receiving chip select signal x.

CSIHn PSx1	CSIHn PSx0	Transmission	Reception
0	0	No parity is transmitted	No parity is waited for.
0	1	Adds parity bit fixed to 0	Parity bit is waited for but not judged.
1	0	Adds odd parity only	Odd parity bit is waited for.
1	1	Adds even parity	Even parity bit is waited for.

Table 19.25 CSIHnCFGx Register Contents (2/5)

1: Regardless of the CSIHnTX0W.CSIHnCSx setting of two consecutive transfers, an idle state is inserted between two transfers.
This bit is only available in master mode.
For details about the forced idle state, see Section 19.5.15, Enforced Chip Select Idle Setting.</td></tr>
</table>

Table 19.25 CSIHnCFGx Register Contents (4/5)

Bit Position	Bit Name	Function
14 to 12	CSIHnIDx[2:0]	Selects the idle time for chip select signal x. **CSIHn IDx[2:0]** / **Idle time** 000_B 0.5 transmission clock cycle 001_B 1.0 transmission clock cycle 010_B 1.5 transmission clock cycle 011_B 2.5 transmission clock cycle 100_B 3.5 transmission clock cycle 101_B 4.5 transmission clock cycle 110_B 6.5 transmission clock cycle 111_B 8.5 transmission clock cycle These bits are only available in master mode.
11 to 8	CSIHnHDx[3:0]	Specifies the hold time for chip select signal x in transmission clock cycles. **CSIHn HDx[3:0]** / **Hold time when CSIHnCTL1.CSIHnSIT is 0** / **Hold time when CSIHnCTL1.CSIHnSIT is 1** 0000_B 0.5 transmission clock cycle / 1.0 transmission clock cycle 0001_B 1.0 transmission clock cycle / 1.5 transmission clock cycle 0010_B 1.5 transmission clock cycle / 2.0 transmission clock cycle 0011_B 2.5 transmission clock cycle / 3.0 transmission clock cycle 0100_B 3.5 transmission clock cycle / 4.0 transmission clock cycle 0101_B 4.5 transmission clock cycle / 5.0 transmission clock cycle 0110_B 6.5 transmission clock cycle / 7.0 transmission clock cycle 0111_B 8.5 transmission clock cycle / 9.0 transmission clock cycle 1000_B 9.5 transmission clock cycle / 10.0 transmission clock cycle 1001_B 10.5 transmission clock cycle / 11.0 transmission clock cycle 1010_B 11.5 transmission clock cycle / 12.0 transmission clock cycle 1011_B 12.5 transmission clock cycle / 13.0 transmission clock cycle 1100_B 14.5 transmission clock cycle / 15.0 transmission clock cycle 1101_B 16.5 transmission clock cycle / 17.0 transmission clock cycle 1110_B 18.5 transmission clock cycle / 19.0 transmission clock cycle 1111_B 20.5 transmission clock cycle / 21.0 transmission clock cycle These bits are only available in master mode.

Table 19.25 CSIHnCFGx Register Contents (5/5)

Bit Position	Bit Name	Function
7 to 4	CSIHnINx[3:0]	Specifies the inter-data time for chip select signal x in transmission clock cycles.

CSIHn INx[3:0]	Inter-Data Delay when CSIHnCTL1.CSIHnSIT is 0	Inter-Data Delay when CSIHnCTL1.CSIHnSIT is 1
0000_B	0.0 transmission clock cycle	0.5 transmission clock cycle
0001_B	0.5 transmission clock cycle	1.0 transmission clock cycle
0010_B	1.0 transmission clock cycle	1.5 transmission clock cycle
0011_B	2.0 transmission clock cycle	2.5 transmission clock cycle
0100_B	3.0 transmission clock cycle	3.5 transmission clock cycle
0101_B	4.0 transmission clock cycle	4.5 transmission clock cycle
0110_B	6.0 transmission clock cycle	6.5 transmission clock cycle
0111_B	8.0 transmission clock cycle	8.5 transmission clock cycle
1000_B	9.0 transmission clock cycle	9.5 transmission clock cycle
1001_B	10.0 transmission clock cycle	10.5 transmission clock cycle
1010_B	11.0 transmission clock cycle	11.5 transmission clock cycle
1011_B	12.0 transmission clock cycle	12.5 transmission clock cycle
1100_B	14.0 transmission clock cycle	14.5 transmission clock cycle
1101_B	16.0 transmission clock cycle	16.5 transmission clock cycle
1110_B	18.0 transmission clock cycle	18.5 transmission clock cycle
1111_B	20.0 transmission clock cycle	20.5 transmission clock cycle

These bits are only available in master mode.

3 to 0	CSIHnSPx[3:0]	Specifies the setup time for chip select signal x in transmission clock cycles.

CSIHnSPx[3:0]	Setup Time
0000_B	0.5 transmission clock cycle
0001_B	1.0 transmission clock cycle
0010_B	1.5 transmission clock cycle
0011_B	2.5 transmission clock cycle
0100_B	3.5 transmission clock cycle
0101_B	4.5 transmission clock cycle
0110_B	6.5 transmission clock cycle
0111_B	8.5 transmission clock cycle
1000_B	9.5 transmission clock cycle
1001_B	10.5 transmission clock cycle
1010_B	11.5 transmission clock cycle
1011_B	12.5 transmission clock cycle
1100_B	14.5 transmission clock cycle
1101_B	16.5 transmission clock cycle
1110_B	18.5 transmission clock cycle
1111_B	20.5 transmission clock cycle

These bits are only available in master mode.

CAUTION

For the setting of this register, see Table 19.32, Notes on Setting Registers.

19.3.12 CSIHnTX0W — CSIHn Transmit Data Register 0 for Word Access

This register stores transmission data. In addition, it specifies the communication interrupt request, the end-of-job, the extended data length, and the chip select activation.

Access: This register can be read/written in 32-bit units.

Address: <CSIHn_base> + 1008_H

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CSIHnCIRE	CSIHnEOJ	CSIHnEDL	—	—	—	—	—	CSIHnCS7	CSIHnCS6	CSIHnCS5	CSIHnCS4	CSIHnCS3	CSIHnCS2	CSIHnCS1	CSIHnCS0

	CSIHnTX[15:0]															
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 19.26 CSIHnTX0W Register Contents (1/2)

Bit Position	Bit name	Function
31	CSIHnCIRE	Enables the communication interrupt request INTCSIHTIC in dual buffer or transmit-only buffer mode, or the job completion interrupt INTCSIHTJC request in FIFO mode. 0: No interrupt is requested. 1: An interrupt is requested. Generates interrupt INTCSIHTIC or INT_CSIHTIJC after transmission. For details, see **Section 19.4.3, INTCSIHTIC (Communication Status Interrupt)** and **Section 19.4.6, INTCSIHTIJC (Job Completion Interrupt)**. **CAUTION** This bit is only valid when job mode is enabled (CSIHnCTL1.CSIHnJE = 1).
30	CSIHnEOJ	Specifies the end of a job. 0: Indicates that the job does not end. The job continues. 1: Indicates end-of-job data. **CAUTION** This bit is only valid when job mode is enabled (CSIHnCTL1.CSIHnJE = 1). This bit must be set to 0 in slave mode.
29	CSIHnEDL	Specifies whether the associated data requires the extended data length (EDL) option. 0: Normal operation 1: Enables the extended data length. The associated data is transmitted as a 16-bit packet. No inter-data time or idle time will be inserted after the data is transmitted. If CSIHnCTL1.CSIHnEDLE = 1 and CSIHnTX0W.CSIHnEDL = 1, the subsequent data must have the same CS selection. If CS is modified for the subsequent data, the correct operation is not assured. **CAUTION** This bit is only available if CSIHnCTL1.CSIHnEDLE = 1.

Table 19.26 CSIHnTX0W Register Contents (2/2)

Bit Position	Bit name	Function
28 to 24	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
23 to 16	CSIHnCS[7:0]	Activates one or several chip select signals. 0: Activates chip select signals x for the associated transmission. 1: Deactivates chip select signals x for the associated transmission. Setting CSIHnTX0W.CSIHnCS[7:0] = FF_H is prohibited. **CAUTION** If several chip select signals are enabled for broadcasting, the configuration of one with CSIHnCFGx.CSIHnRCBx = 0 (dominant) is used. In this case, all dominant chip select signals must be set to precisely the same value. In slave mode, set the CSIHnCS[7:0] bit to FE_H.
15 to 0	CSIHnTX[15:0]	Stores the transmission data.

CAUTION

For the setting of this register, see Table 19.32, Notes on Setting Registers.

19.3.13 CSIHnTX0H — CSIHn Transmit Data Register 0 for Half Word Access

This register stores the transmission data. This register is the same as bits 15 to 0 of register CSIHnTX0W.

The upper 16 bits of CSIHnTX0W are applied for transfer. Set transmit data to CSIHnTX0W before using this register because the value of CSIHnTX0W is undefined after the reset.

Access: This register can be read/written in 16-bit units.

Address: <CSIHn_base> + $100C_H$

Value after reset: Undefined

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit Position	Bit name	Function
31 to 26	Reserved	When read, the value after reset is returned.
25	CSIHnRPE	Indicates whether a reception data parity error was detected. 0: No parity error was detected on the associated reception data. 1: A parity error was detected on the associated reception data.
24	CSIHnTDCE	Indicates whether a transmission data consistency error was detected. 0: No consistency error was detected on the associated transmission data. 1: A consistency error was detected on the associated transmission data.
23 to 16	CSIHnCSx (x = 7 to 0)	Indicates which chip select signal was activated. 0: Chip select x was activated for the associated reception. 1: Chip select x was deactivated for the associated reception.
15 to 0	CSIHnRX[15:0]	Stores the received data.

NOTE

To read this register, do so one serial clock cycle before an interrupt is generated.

CAUTION

For the setting of this register, see Table 19.32, Notes on Setting Registers.

19.3.15 CSIHnRX0H — CSIHn Receive Data Register 0 for Half Word Access

This register stores the received data. This register is the same as bits 15 to 0 of register CSIHnRX0W.

Access: This register can only be read in 16-bit units.

Address: <CSIHn_base> + 1014_H

Value after reset: Undefined

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CSIHnRX[15:0]															
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 19.29 CSIHnRX0H Register Contents

Bit Position	Bit name	Function
15 to 0	CSIHnRX[15:0]	Stores the received data.

CAUTION

For the setting of this register, see Table 19.32, Notes on Setting Registers.

19.3.16 CSIHnEMU — CSIHn Emulation Register

This register controls operation of SVSTOP.

Access: This register can be read/written in 8-bit or 1-bit units.
Perform write operation when (EPC.SVSTOP = 0).

Address: <CSIHn_base> + 0018_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	CSIHnSVSDIS	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R

Table 19.30 CSIHnEMU Register Contents

Bit Position	Bit name	Function
7	CSIHn SVSDIS	Selects to continue or stop transmit/receive operation during debugging. • When the EPC.SVSTOP bit is set to 0 Continues transmit/receive operation regardless of the setting of this bit. • When the EPC.SVSTOP bit is set to 1 0: Stops transmit/receive operation. 1: Continues transmit/receive operation.
6 to 0	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.

CAUTION

For the setting of this register, see Table 19.32, Notes on Setting Registers.

19.3.17 CSIH0BRSy — CSIH0 Baud Rate Setting Register y (y = 0 to 3) (CSIH0 only)

This register sets the transfer clock frequency for each chip select signal.

With CSIH0CFG0 to 7.CSIH0BRSSx[1:0] bits, one of the four types of transfer clock frequency settings can be selected for each chip select signal. For details of transfer clock frequency setting, see Section 19.5.5, Transmission Clock Selection.

Access: This register can be read/written in 16-bit units.

Address: CSIH0BRS0: <CSIH0_base> + 1068_H
CSIH0BRS1: <CSIH0_base> + $106C_H$
CSIH0BRS2: <CSIH0_base> + 1070_H
CSIH0BRS3: <CSIH0_base> + 1074_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	CSIH0BRS[11:0]											
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 19.31 CSIH0BRSy Register Contents

Bit Position	Bit Name	Function
15 to 12	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
11 to 0	CSIH0BRS [11:0]	0: BRG stopped 1: PCLK / (2^{α} × 1 × 2) 2: PCLK / (2^{α} × 2 × 2) 3: PCLK / (2^{α} × 3 × 2) 4: PCLK / (2^{α} × 4 × 2) . . . 4095: PCLK / (2^{α} × 4095 × 2) α is the value of CSIH0CTL2.CSIH0PRS[2:0].

CAUTION

For the setting of this register, see Table 19.32, Notes on Setting Registers.

19.3.18 List of Caution

Table 19.32 Notes on Setting Registers (1/3)

Register	Bit	Content
CSIHnCTL0	CSIHnPWR	If this bit is cleared during communication, ongoing communication is suspended. After cancelling the suspension, it is necessary to restart the communication.
CSIHnCTL0	CSIHnTXE CSIHnRXE	Do not modify any of these bits while CSIHnCTL0.CSIHnPWR = 0. (These bits can be modified at the same time with the CSIHnCTL0.CSIHnPWR bit.) Do not modify these bits while CSIHnSTR0.CSIHnTSF = 1, because the specified operation is not guaranteed if ongoing communication is suspended.
CSIHnCTL0	CSIHnJOBE	Do not modify this bit while CSIHnCTL0.CSIHnPWR = 0. This bit is only valid when CSIHnCTL1.CSIHnJE = 1. Setting this bit is prohibited in slave mode.
CSIHnCTL0	CSIHnMBS	Do not modify this bit while CSIHnCTL0.CSIHnPWR = 0. (This bit can modify at the same time with the CSIHnCTL0.CSIHnPWR bit.) Modification of this bit is only allowed while CSIHnSTR0.CSIHnTSF = 0. Do not change the mode between FIFO mode and direct access mode while CSIHnCTL0.CSIHnPWR = 1. When the CPU-controlled high-priority communication function is enabled, the operation is the same as that in direct access mode regardless of the CSIHnMBS bit setting.
CSIHnCTL1	CSIHnCKR	Modification of this bit is only allowed while CSIHnCTL0.CSIHnPWR = 0. When CS is not used, use this bit instead of CSIHnCFGx.CSIHnCKPx and set CSIHnCFGx.CSIHnCKPx to 0. This bit must be used in slave mode.
CSIHnCTL1	CSIHnSLIT CSIHnCSL[7:0] CSIHnEDLE CSIHnDCS CSIHnCSRI CSIHnHSE	Modification of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0.
CSIHnCTL1	CSIHnPHE CSIHnJE CSIHnLBM	Modification of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0. Setting of this bit is prohibited in slave mode.
CSIHnCTL1	CSIHnSSE	Modification of this bit is only permitted while CSIHnCTL0.CSIHnPWR = 0. Setting of this bit is prohibited in master mode.
CSIHnCTL1	CSIHnSIT	Modification of this bit is only permitted while CSIHnCTL0.CSIHnPWR = 0. This bit is only valid in master mode. In slave mode, no delay is generated.
CSIHnCTL2	CSIHnPRS[2:0]	Modification of this bit is only permitted while CSIHnCTL0.CSIHnPWR = 0. Setting of the max transfer clock frequency is as follows. • Master mode: up to PCLK/4 • Slave mode: up to PCLK/6
CSIHnSTR0	CSIHnSRP[7:0] CSIHnSPF[7:0] CSIHnFLF CSIHnEMF CSIHnTSF CSIHnHPST	Writing these bits is prohibited, and only reading is permitted.
CSIHnSTR0	CSIHnTMOE CSIHnOFE CSIHnDCE CSIHnPE CSIHnOVE	Writing these bits is prohibited, and only reading is permitted. These bits are initialized when CSIHnCTL0.CSIHnPWR = 0 → 1 or CSIHnCTL0.CSIHnPWR = 1 → 0.
CSIHnSTCR0	CSIHnPCT	If this bit is set to1 during communication, ongoing communication is suspended.
CSIHnMCTL0	CSIHnMMS[1:0]	Modification of these bits is only allowed while CSIHnCTL0.CSIHnPWR = 0 and CSIHnCTL0.CSIHnMBS = 0.

Table 19.32 Notes on Setting Registers (2/3)

Register	Bit	Content
CSIHnMCTL0	CSIHnTO[4:0]	Modification of these bits is only allowed while CSIHnCTL0.CSIHnPWR = 0. Set these bits to 0 in master mode. Set these bits to 0 in direct access, dual buffer, and transmit-only buffer mode.
CSIHnMCTL1	CSIHnFES[6:0] CSIHnFFS[6:0]	Write to these bits while communication is permitted.
CSIHnMCTL2	CSIHnBTST CSIHnND[7:0] CSIHnSOP[6:0]	Writing these bits is prohibited when CSIHnCTL0.CSIHnPWR = 0. Writing these bits is prohibited when CSIHnCTL0.CSIHnTXE = CSIHnCTL0.CSIHnRXE = 0. Writing these bits is prohibited when CSIHnSTR0.CSIHnTSF = 1. Writing these bits is prohibited in direct access or FIFO mode.
CSIHnMRWP0	CSIHnRRA[6:0]	Write to these bits while communication is permitted. Writing these bits is prohibited in direct access or FIFO mode. When writing is required, set "0000_H" to these bits in transmit only buffer mode.
CSIHnMRWP0	CSIHnTRWA[6:0]	Write to these bits while communication is permitted. Writing these bits is prohibited in direct access or FIFO mode.
CSIHnCFGx x = 0	CSIHnBRSSx[1:0] CSIHnRCBx CSIHnIDLx CSIHnIDx[2:0] CSIHnHDx[3:0] CSIHnINx[3:0] CSIHnSPx[3:0]	Modification of these bits is only allowed while CSIHnCTL0.CSIHnPWR = 0. These bits must be set to 0 in slave mode.
CSIHnCFGx x = 0	CSIHnPSx[1:0] CSIHnDLSx[3:0] CSIHnDIRx CSIHnDAPx	Modification of these bits is only allowed while CSIHnCTL0.CSIHnPWR = 0. In slave mode, the CSIHnCFG0 setting is used for the configuration. Therefore, all the bits in CSIHnCFG1 to CSIHnCFG7 must be set to 0.
CSIHnCFGx x = 0	CSIHnCKPx	Modification of this bit is only allowed while CSIHnCTL0.CSIHnPWR = 0. As CSIHnCTL1.CSIHnCKR must be used, set this bit to 0 in slave mode. If CS is not used, set the CSIHnCTL1.CSIHnCKR bit instead of this bit, and clear this bit to 0.
CSIHnTX0W	CSIHnEOJ CSIHnCIRE	This bit is only valid when CSIHnCTL1.CSIHnJE = 1. While CSIHnCTL1.CSIHnJE = 0, the value of this bit is ignored even if 1 is read. Set these bits to 0 in slave mode.
CSIHnTX0W	CSIHnEDL	This bit is only valid when CSIHnCTL1.CSIHnEDLE = 1. While CSIHnCTL1.CSIHnEDLE = 0, the value of this bit is ignored even if 1 is read.
CSIHnTX0W	CSIHnCS[7:0]	In master mode, setting this bit to "FF_H" is prohibited. In slave mode, set this bit to "FE_H".
CSIHnTX0W CSIHnTX0H		Reading to these bits while communication is prohibited in FIFO mode. While CSIHnCTL0.CSIHnPWR = 0 and FIFO mode is on, reading and writing these bits are prohibited. While CSIHnCTL0.CSIHnTXE = CSIHnCTL0.CSIHnRXE = 0, writing to these bits are prohibited in direct access mode.
CSIHnRX0W		These bits are initialized when CSIHnCTL0.CSIHnPWR = 0 → 1 or CSIHnCTL0.CSIHnPWR = 1 → 0. While CSIHnCTL0.CSIHnPWR = 0, reading and writing to these bits is prohibited in FIFO mode. While CSIHnCTL0.CSIHnPWR = 0, writing and reading to these bits is valid in direct access, dual buffer, and transmit-only buffer mode. While CSIHnCTL0.CSIHnPWR = 1, writing to these bits is invalid and reading to these bits is valid.

Table 19.32 Notes on Setting Registers (3/3)

Register	Bit	Content
CSIHnRX0H		These bits are initialized when CSIHnCTL0.CSIHnPWR = 0 → 1 or CSIHnCTL0.CSIHnPWR = 1 → 0. While CSIHnCTL0.CSIHnPWR = 0, reading and writing to these bits is prohibited in FIFO mode. While CSIHnCTL0.CSIHnPWR = 1, writing to these bits is invalid and reading to these bits is valid in FIFO mode. Regardless of CSIHnCTL0.CSIHnPWR value, writing to these bits invalid and reading to these bits is valid in direct access, dual buffer, and transmit-only buffer mode.
CSIHnEMU	CSIHnSVSDIS	Modification of this bit is only permitted while SVSTOP = 0.
CSIH0BRSy y = 0 to 3		Modification of this bit is only permitted while CSIH0CTL0.CSIH0PWR = 0.

19.4 Interrupt Sources

CSIH can generate the following interrupt requests:

- INTCSIHTIC (communication status interrupt)
- INTCSIHTIR (reception status interrupt)
- INTCSIHTIRE (communication error interrupt)
- INTCSIHTIJC (job completion interrupt)

19.4.1 Overview

The communication error interrupt INTCSIHTIRE is generated when an error is detected. The generation of the other interrupts depends on the memory mode, the job mode, and – in case of the job completion interrupt INTCSIHTIJC –also the operating mode.

The job completion interrupt INTCSIHTIJC is only generated when job mode is enabled (CSIHnCTL1.CSIHnJE = 1). It is not available in slave mode.

The following table gives an overview.

Table 19.33 Interrupt Generation (1/2)

		Cause of Interrupt	
Memory Mode	Interrupt	Job Mode Disabled CSIHnCTL1.CSIHnJE = 0	Job Mode Enabled CSIHnCTL1.CSIHnJE = 1
FIFO	INTCSIHTIC	Tx data empty*1 except job abort*4	Tx data empty*1 except job abort*4
	INTCSIHTIR	Rx data full*2 *and* CSIHnCTL0.CSIHnRXE = 1	Rx data full*2 *and* CSIHnCTL0.CSIHnRXE = 1
	INTCSIHTIRE	Error detected	Error detected
	INTCSIHTIJC*3	Not applicable	CSIHnTX0W.CSIHnCIRE = 1 (except Tx data empty), or job abort*4
Transmit-only buffer	INTCSIHTIC	End of communication	CSIHnTX0W.CSIHnCIRE = 1 and (CSIHnCTL0.CSIHnJOBE = 0 or CSIHnTX0W.CSIHnEOJ = 0)
	INTCSIHTIR	Data received *and* CSIHnCTL0.CSIHnRXE = 1	Data received *and* CSIHnCTL0.CSIHnRXE = 1
	INTCSIHTIRE	Error detected	Error detected
	INTCSIHTIJC*3	Not applicable	Job abort*4

Table 19.33 Interrupt Generation (2/2)

Memory Mode	Interrupt	Cause of Interrupt	
		Job Mode Disabled CSIHnCTL1.CSIHnJE = 0	Job Mode Enabled CSIHnCTL1.CSIHnJE = 1
Dual buffer	INTCSIHTIC	End of communication	CSIHnTX0W.CSIHnCIRE = 1 and (CSIHnCTL0.CSIHnJOBE = 0 or CSIHnTX0W.CSIHnEOJ = 0)
	INTCSIHTIR	End of communication *and* CSIHnCTL0.CSIHnRXE = 1	Data received *and* CSIHnCTL0.CSIHnRXE = 1
	INTCSIHTIRE	Error detected	Error detected
	INTCSIHTIJC*3	Not applicable	Job abort*4
Direct access	INTCSIHTIC	One single data transfer	One data transfer except the state of job abort*4
	INTCSIHTIR	Data received *and* CSIHnCTL0.CSIHnRXE = 1	Data received *and* CSIHnCTL0.CSIHnRXE = 1
	INTCSIHTIRE	Error detected	Error detected
	INTCSIHTIJC*3	Not applicable	Job abort*4

Note 1. "Tx data empty" refers to the FIFO fill level, defined by CSIHnMCTL1.CSIHnFES[6:0].
Note 2. "Rx data full" refers to the FIFO fill level, defined by CSIHnMCTL1.CSIHnFFS[6:0].
Note 3. INTCSIHTIJC is not available in slave mode.
Note 4. Job abort condition: CSIHnTX0W.CSIHnEOJ = 1 and CSIHnCTL0.CSIHnJOBE = 1.
CSIH0 only: During high priority communication in transmit-only buffer mode, the operation is the same as that in direct access mode.

19.4.2 Interrupt Delay

In master mode, all interrupts generated by the master can be delayed by one half period of the transmission clock, CSIHTSCK. This is not possible in slave mode.

The delay is specified by setting bit CSIHnCTL1.CSIHnSIT = 1. (The setting of the CSIHnSIT bit is invalid in slave mode.)

The following example illustrates the interrupt delay function, assuming a setting of CSIHnCTL1.CSIHnSIT = 1 (interrupt delay enabled), CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0 (clock and data phase), and CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B (data length 8 bits).

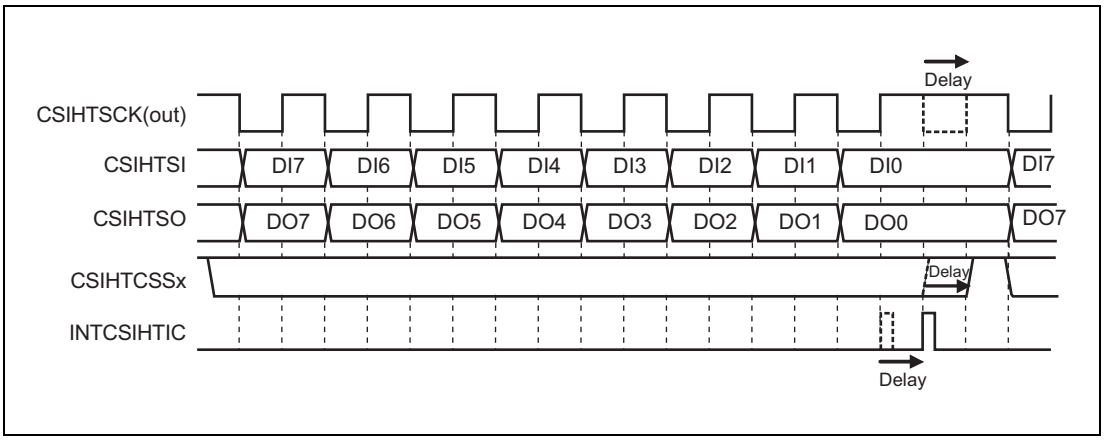

Figure 19.2 Interrupt Delay Function (CSIHnCTL1.CSIHnSIT = 1)

Setting CSIHnCTL1.CSIHnSIT = 1 adds half period delay to the transmission clock. This delays also the end of the present chip select signal (CSIHTCSSx).

19.4.3 INTCSIHTIC (Communication Status Interrupt)

Depending on the memory mode and the job mode, this interrupt is generated according to the conditions shown in the following table.

Table 19.34 INTCSIHTIC Interrupt Generation

	Cause of Interrupt	
Memory Mode	**Job Mode Disabled CSIHnCTL1.CSIHnJE = 0**	**Job Mode Enabled CSIHnCTL1.CSIHnJE = 1**
FIFO	This interrupt is generated just before transmission data is about to be missing in the FIFO, indicating to the application that new data should be added. INTCSIHTIC is generated, if the number of data to be sent remaining in the FIFO (CSIHnSTR0.CSIHnSPF[7:0]) equals CSIHnMTCL1.CSIHnFES[6:0].	Similar to “when JE is 0”, an interrupt is generated when the number of transmit data remained in the FIFO CSIHnSTR0.CSIHnSPF[7:0] is the same number as CSIHnMCTL1.CSIHnFES[6:0]. At the time of job abort, no interrupt is generated.
Transmit-only buffer, dual buffer	Generated at the End of communication. (Specified by the CSIHnMTLC2.CSIHnND[7:0] bit)	Generated when data with CSIHnTX0W.CSIHnCIRE = 1 is sent. Note that if data with CSIHnTX0W.CSIHnCIRE = 1 and job abort*1 are sent, the INTCSIHTIJC interrupt is generated instead of INTCSIHTIC.
Direct access	Generated after every data transfer.	Generated after every data transfer, except when the communication was aborted.

Note 1. Job abort condition: CSIHnTX0W.CSIHnEOJ = 1 and CSIHnCTL0.CSIHnJOBE = 1.
CSIH0 only: During high priority communication in transmit-only buffer mode, the operation is the same as that in direct access mode.

19.4.3.1 INTCSIHTIC in Direct Access Mode

The examples below show the INTCSIHTIC behavior in direct access mode.

The examples assume:

- Master mode
- Direct access mode
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Normal INTCSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

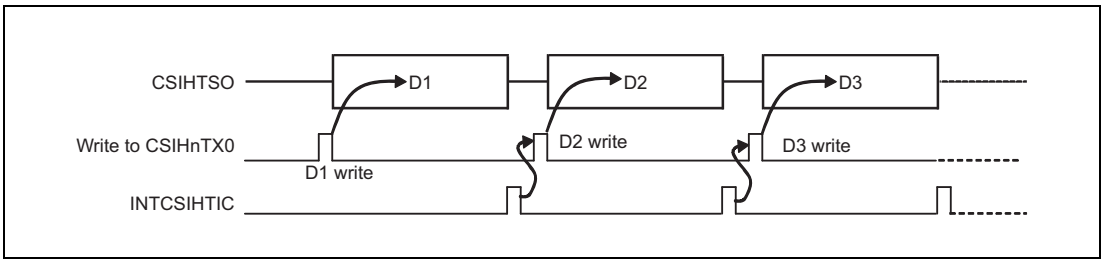

Figure 19.3 Generation of INTCSIHTIC after Transfer (CSIHnCTL1.CSIHnSLIT = 0)

If job mode is enabled (CSIHnCTL1.CSIHnJE = 1) and a job ends because data is sent with CSIHnTXOW.CSIHnEOJ = 1 and communication stop is requested (CSIHnCTL0.CSIHnJOBE = 1), then INTCSIHTIC is replaced by the job completion interrupt INTCSIHTIJC.

INTCSIHTIC can also be set up to occur as soon as the CSIHnTX0W/H register is free for the next data. This is specified by setting CSIHnCTL1.CSIHnSLIT = 1.

The effect is illustrated in the figure below.

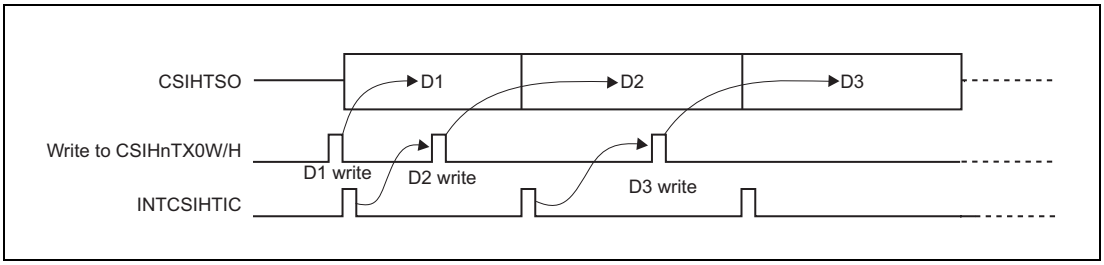

Figure 19.4 Immediate Generation of INTCSIHTIC (CSIHnCTL1.CSIHnSLIT = 1)

Thus, the new data can be written in advance.

NOTE

CSIH0 only: During high priority communication in transmit-only buffer mode, the operation is in the same way as direct access mode.

19.4.3.2 INTCSIHTIC in FIFO Mode

The example below shows the INTCSIHTIC behavior in FIFO mode.

The example assumes:

- Master mode
- FIFO mode
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)

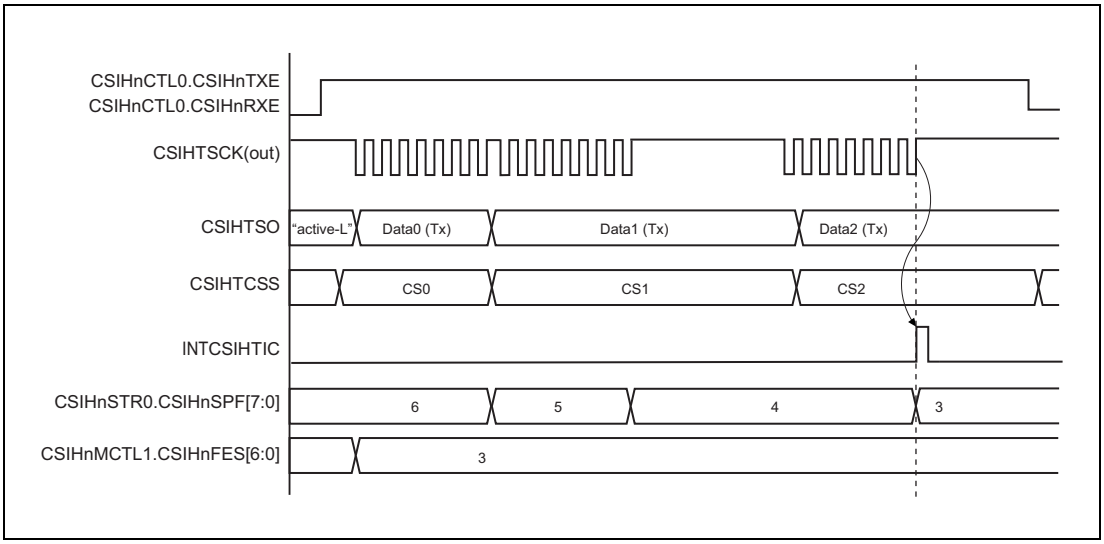

Figure 19.5 Generation of INTCSIHTIC in FIFO Memory Mode

The condition for “FIFO empty” is specified in CSIHnMCTL1.CSIHnFES[6:0]. In the example of the diagram above, the number of unsent data in FIFO is set to 3.

CSIHnSTR0.CSIHnSPF[7:0] indicates the number of unsent data. When both match, the interrupt INTCSIHTIC occurs.

19.4.3.3 INTCSIHTIC in Job Mode

The example below shows the INTCSIHTIC behavior in job mode.

The example assumes:

- Master mode
- Job mode enabled (CSIHnCTL1.CSIHnJE = 1)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Normal INTCSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

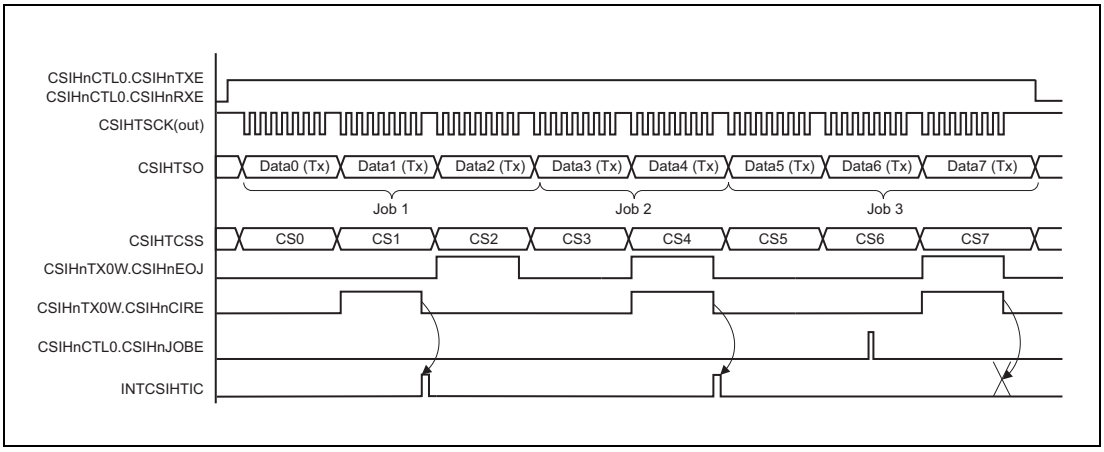

Figure 19.6 Generation of INTCSIHTIC in Job Mode

The rules for generating INTCSIHTIC in job mode are shown in the following table.

Table 19.35 Generation of INTCSIHTIC in Job Mode

CSIHnTX0W. CSIHnEOJ	CSIHnTX0W. CSIHnCIRE	INTCSIHTIC
0	0	Not generated
0	1	Generated
1	0	Not generated
1	1	CSIHnCTL0.CSIHnJOBE = 0: Generated
		CSIHnCTL0.CSIHnJOBE = 1: Not generated, replaced by interrupt INTCSIHTIJC

19.4.4 INTCSIHTIR (Reception Status Interrupt)

Depending on the memory mode and the job mode, this interrupt is generated according to the conditions below.

Table 19.36 INTCSIHTIR Interrupt Generation

Memory Mode	Cause of Interrupt	
	Job Mode Disabled CSIHnCTL1.CSIHnJE = 0	Job Mode Enabled CSIHnCTL1.CSIHnJE = 1
FIFO	This interrupt occurs when CSIHnCTL0.CSIHnRXE is 1 and the FIFO buffer is almost full with received data, indicating to the application that the FIFO must be emptied. INTCSIHTIR is generated, if the number of received data in the FIFO (CSIHnSTR0.CSIHnSRP[7:0]) equals (128 – CSIHnMCTL1.CSIHnFFS[6:0]).	
Dual buffer	Generated when the communication has finished (as specified by the CSIHnMCTL2.CSIHnND[7:0] bit) and CSIHnCTL0.CSIHnRXE = 1.	Generated after every data transfer.
Transmit-only buffer, Direct access	Generated after every data transfer.	

19.4.4.1 INTCSIHTIR in Direct Access Mode

The example below shows the INTCSIHTIR behavior in direct access mode.

The example below assumes:

- Master mode
- Direct access mode
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)

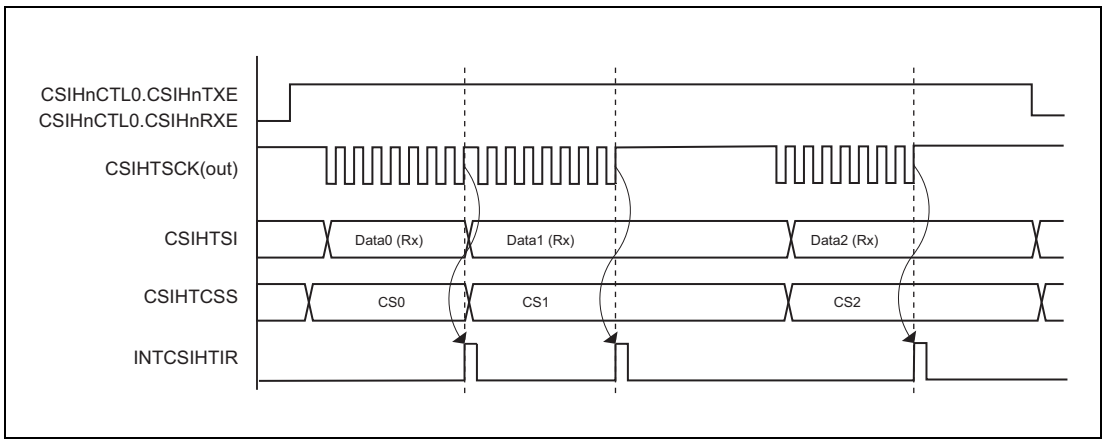

Figure 19.7 Generation of INTCSIHTIR in Direct Access Memory Mode

19.4.4.2 INTCSIHTIR in Dual Buffer Mode

The example below shows the INTCSIHTIR behavior in dual buffer mode.

The example assumes:

- Master mode
- Dual buffer mode
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Default clock and data phase
  (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)

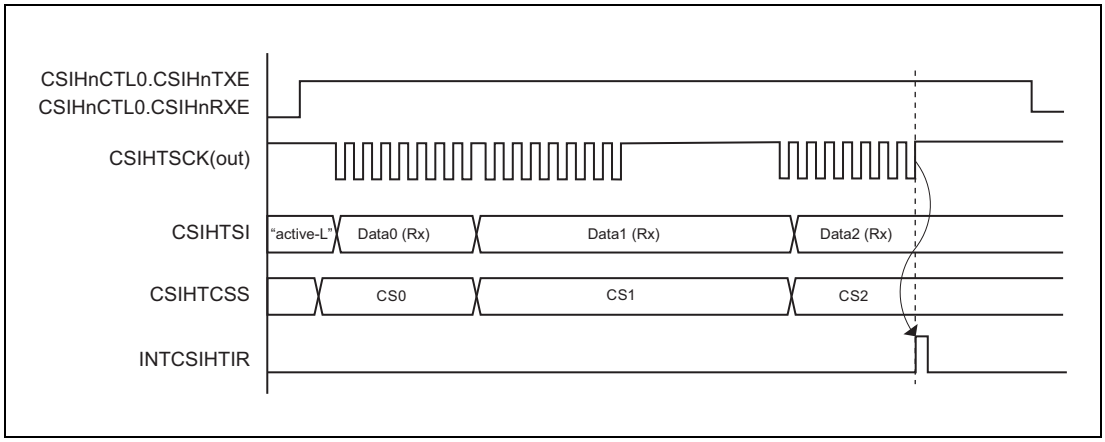

Figure 19.8 Generation of INTCSIHTIR in Dual Buffer Mode

19.4.5 INTCSIHTIRE (Communication Error Interrupt)

This interrupt is generated whenever an error is detected.

For details about generation interruption timing, see Section 19.5.12, Error Detection.

Table 19.37 Data Error Types

Error Type	Communication Status after Error Interrupt	Comment
FIFO overflow error	Interrupt is generated and communication continues.	The data are not written to the FIFO buffer and the overflow of data is lost, but communications started before the error is continued.
Parity error	Interrupt is generated and communication continues.	—
Data consistency error	Interrupt is generated and communication continues.	—
Time-out error	Interrupt is generated and communication continues.	—
Overrun error	**Condition for errors 1:** In FIFO mode, when the number of received data is 0 and CPU reads the CSIHnRX0W/H register, an interrupt is generated and communication continues.	—
	Condition for errors 2: In slave mode, when CSIHnCTL1.CSIHnHSE = 0 (handshake function disabled): (1) In direct access mode or transmit-only buffer mode, when reception is completed while the previous received data is remained in the CSIHnRX0W/H register, an interrupt is generated, and communication continues. (2) In FIFO mode, when reception by the FIFO buffer is completed and the buffer is in the full state, an interrupt is generated. Communication continues.	In slave mode, when CSIHnCTL1.CSIHnHSE = 1 (handshake function enabled), communication is suspended due to handshake, an overrun error is not generated.

The type of error that caused the generation of INTCSIHTIRE is flagged in register CSIHnSTR0.

Additionally a parity error flag and a data consistency error flag are attached to the received data in CSIHnRX0W.

For details about the various error types, see Section 19.5.12, Error Detection.

19.4.6 INTCSIHTIJC (Job Completion Interrupt)

This interrupt supports the handling of jobs, see Section 19.5.3.3, Job Concept. This interrupt is only available in master mode.

Job mode is enabled by setting CSIHnCTL1.CSIHnJE = 1. When CSIHnCTL1.CSIHnJE = 0, INTCSIHTIJC is not generated.

Depending on the memory mode, this interrupt is generated according to the condition shown in the following table.

Table 19.38 INTCSIHTIJC Interrupt Generation

Memory Mode	Job Mode Disabled CSIHnCTL1.CSIHnJE = 0	Job Mode Enabled CSIHnCTL1.CSIHnJE = 1
FIFO	Not applicable	Indicates that the communication has stopped at the end of a job after a job abort*1 was triggered If FIFO empty is not detected and when CSIHnCIRE is 1, INTCSIHTIJC is generated.
Transmit-only buffer		Indicates that the communication has stopped at the end of a job after a job abort*1 was triggered.
Dual buffer		
Direct access		

Note 1. Job abort condition: CSIHnTX0W.CSIHnEOJ = 1 and CSIHnCTL0.CSIHnJOBE = 1

19.5 Operation

19.5.1 Operating Modes (Master/Slave)

For a particular CSIH module, the master or slave mode determines the source of the serial clock.

19.5.1.1 Master Mode

In master mode, the serial transmission clock is generated by the internal baud rate generator (BRG) and provided to the slave(s) by signal CSIHTSCK.

Master mode is enabled by setting CSIHnCTL2.CSIHnPRS[2:0] to anything but 111_B.\

In master mode, the BRG frequency can be set by combining the CSIHnCTL2.CSIHnPRS[2:0] bit and the

- CSIH0BRSy.CSIH0BRS[11:0] bit for CSIH0
- CSIH1CTL2.CSIH1BRS[11:0] bit for CSIH1

(1) Chip select signals

In master mode, one or several chip select signals can be used. If several slaves are connected to the master, the chip select signals can be used to address one or several of the slaves. Only a selected slave is then enabled for communication.

The communication protocol as well as additional parameters are stored separately for each chip select signal. This makes it possible to adapt the data transfer individually to the requirements of each slave. For details, see Section 19.5.3, Chip Selection (CS) Features.

(2) Clock defaults

The default level of CSIHTSCK depends on the clock phase selection bit, and is high when CSIHnCTL1.CSIHnCKR = 0 and is low when CSIHnCTL1.CSIHnCKR = 1.

The example below shows the communication in master mode for 8-bit data, CSIHnCTL1.CSIHnCKR = 0, CSIHnCFGx.CSIHnDAPx = 0, and MSB first.

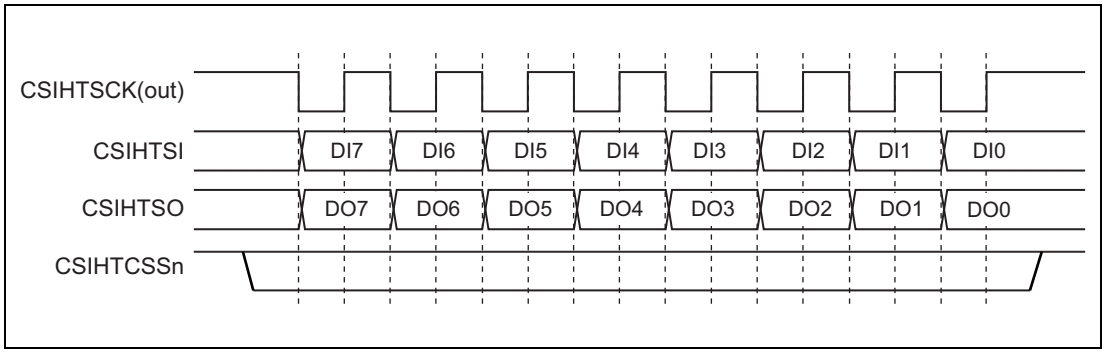

Figure 19.9 Transmit/Receive in Master Mode

19.5.1.2 Slave Mode

In slave mode, another device is the communication master and provides the transmission clock. Transmit/receive operation normally is started as soon as a clock signal is detected.

Slave mode is selected by setting the CSIHnCTL2.CSIHnPRS[2:0] bit to 111_B.

In slave mode, the transmission protocol setting of the CSIHnCFG0 register is enabled (setting of the CSIHnCFG1-CSIHnCFG7 register is disabled).

- CSIHnPSx[1:0]: parity usage
- CSIHnDLSx[3:0]: data length selection
- CSIHnDIRx: data direction
- CSIHnCKPx, CSIHnDAPx: clock phase and data phase

NOTE

When using slave mode, disable the baud rate generator (BRG) by setting the bits

- CSIH0BRSy.CSIH0BRS[11:0] to 000_H for CSIH0
- CSIH1CTL2.CSIH1BRS[11:0] to 000_H for CSIH1

However, if you are using a time-out error of CSIH0, set the CSIH0BRSy.CSIH0BRS[11:0] bits to a value other than 000_H. If you are using a time-out error of CSIH1, set the CSIH1CTL2.CSIH1BRS[11:0] bits to a value other than 000_H.

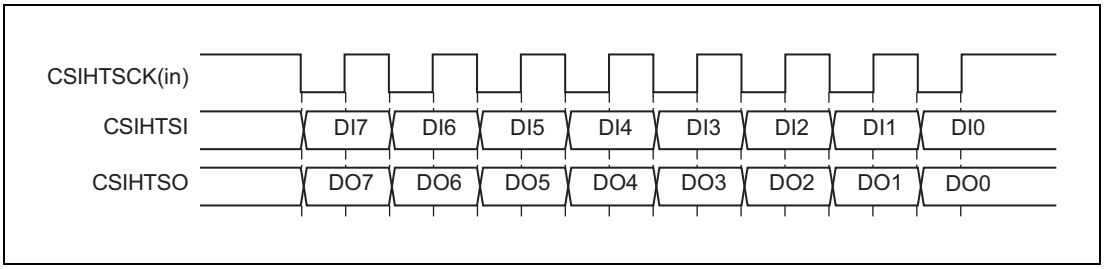

Figure 19.10 Transmit/Receive in Slave Mode

19.5.2 Master/Slave Connections

19.5.2.1 One Master and One Slave

The following figure illustrates the connections between one master and one slave.

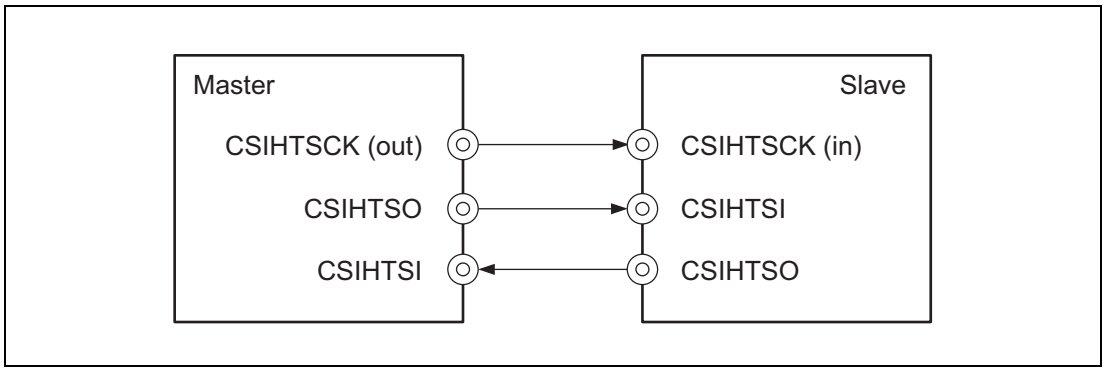

Figure 19.11 Direct Master/Slave Connection

19.5.2.2 One Master and Multiple Slaves

The following figure illustrates the connections between one master and multiple slaves. In this example, the master provides one chip select (CS) signal to each of the slaves. This signal is connected to the slave select input $\overline{\text{CSIHTSSI}}$ of the slave.

The $\overline{\text{CSIHTSSI}}$ signal can be enabled/disabled by using the CSIHnCTL1.CSIHnSSE bit.

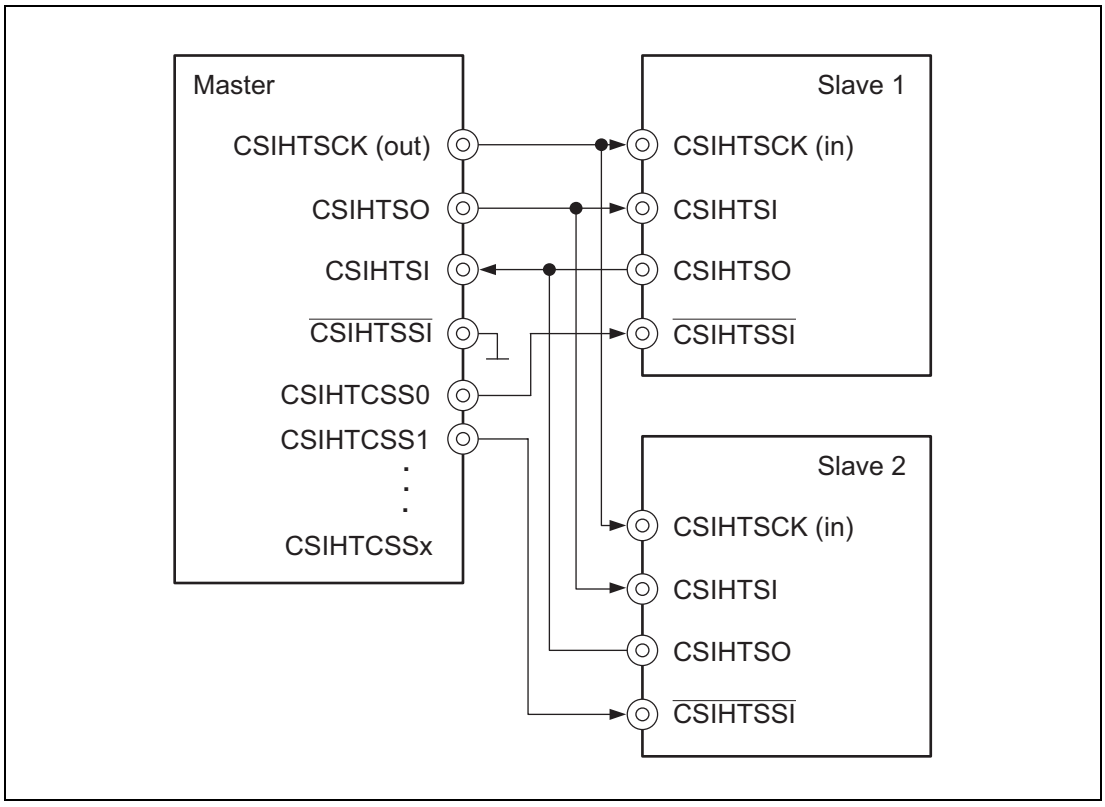

Figure 19.12 Connections between One Master and Multiple Slaves

By default, the chip select level is active low. That means, a slave is selected (enabled) as a CSIH slave when its $\overline{\text{CSIHTSSI}}$ signal has low level. However, to adapt the CS to other devices, the output level of each chip select signal can also be programmed to be active high.

If a slave is not selected, it will neither receive nor transmit data. In addition, its output CSIHTSO of a slave that is not selected is set to input mode in order to avoid interference with the output of another slave that was selected, in transmit-only mode or transmit/receive mode (CSIHnCTL0.CSIHnTXE = 1).

19.5.3 Chip Selection (CS) Features

The chip select signal, CSIHTCSSx can be used by the master to select one or several slaves for communication.

19.5.3.1 Configuration Registers

The parameters for each chip select signal CSIHTCSSx are defined in the corresponding configuration register CSIHnCFGx. The parameters include the communication protocol and additional CS parameters.

The communication protocol specifies:

- Data length: The number of bits to be sent or received. (CSIHnCFGx.CSIHnDLSx[3:0])
- Transfer direction: MSB or LSB first. (CSIHnCFGx.CSIHnDIRx)
- Parity usage: Odd, even, 0 parity or none. (CSIHnCFGx.CSIHnPSx[1:0])
- Clock phase and data phase. (CSIHnCFGx.CSIHnCKPx, CSIHnCFGx.CSIHnDAPx)

Additional parameters for each chip select signal that is only available in master mode are:

- Prescaler selection of the baud rate generator separately for each chip select signal (CSIH0CFGx.CSIH0BRSSx[1:0] for CSIH0, CSIH1CFGx.CSIH1PSCLx[1:0] for CSIH1)
- Chip select priority: Separates between “dominant” and “recessive” chip select signals. The priority applies if two or more chip selects signals with different configurations are simultaneously activated for message broadcasting. In this case, the configuration that is set as dominant is used. (CSIHnCFGx.CSIHnRCBx)

The principle is also called “Recessive Configuration for Broadcasting” (RCB).

CAUTION

It is forbidden to specify several chip select signals as dominant with different configurations unless all dominant chip selects have the same configuration.

- Chip select timing:

– Setup time T_{setup}: The time from setting the CS signal active to starting data output. (CSIHnCFGx.CSIHnSPx[3:0])
– Inter-data time T_{inter}: The time between one data and the next following data while the same CS signal is active. (CSIHnCFGx.CSIHnINx[3:0])
– Hold time T_{hold}: The time during which the CS signal remains active until CS is switched. (CSIHnCFGx.CSIHnHDx[3:0])
– Idle time T_{idle}: Inactive time after terminating a CS signal or after every data transfer to the same CSx. (CSIHnCFGx.CSIHnIDx[2:0])

The CS timings of the setup time, the inter-data time, the hold time, and the idle time are illustrated in the figure below. When CSIHnCFGx.CSIHnIDLx bit is set to 1, IDLE time is inserted for every transfer regardless of CS signal.

Figure 19.13 provides an example when the default CSIHTCSS1 and CSIHTCSS2 signals are active low (CSIHnCTL1.CSIHnCSL1 bit = 0, CSIHnCTL1.CSIHnCSL2 bit = 0). The active level can be specified individually for each CS.

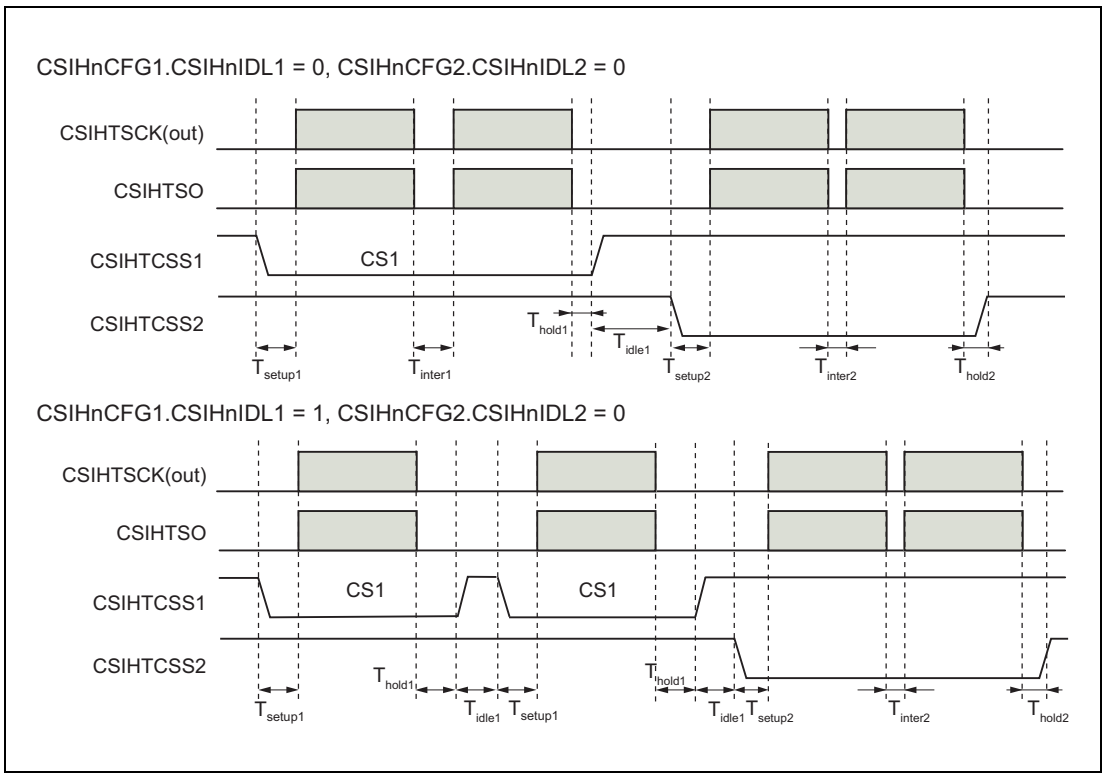

Figure 19.13 Chip Select Timings

Note that each CS signal can have a different value for setup, inter-data time, hold time, and idle time.

A particular chip select signal is activated by setting the appropriate bit in the transmission register CSIHnTX0W.CSIHnCSx.

CSIHnRX0W.CSIHnCSx in the reception register indicates the chip select signal associated with the received data.

CAUTION

For CSIH0 only:
When high priority communication function by CPU control is enabled

(CSIH0CTL1.CSIH0PHE = 1), IDLE state is inserted regardless of IDLn bit settings when priority communication mode is changed from low to high and from high to low.

19.5.3.2 CS Example

The following figure shows an example of two consecutive data transmissions.

The first communication uses CS0 to communicate with one single slave. The second enables CS0 and CS1 to broadcast a message to two slaves. The priority of CS0 is set to “recessive: low priority”, the priority of CS1 to “dominant: high priority”. Consequently, the second is conducted by using CS1 settings which are set in dominant.

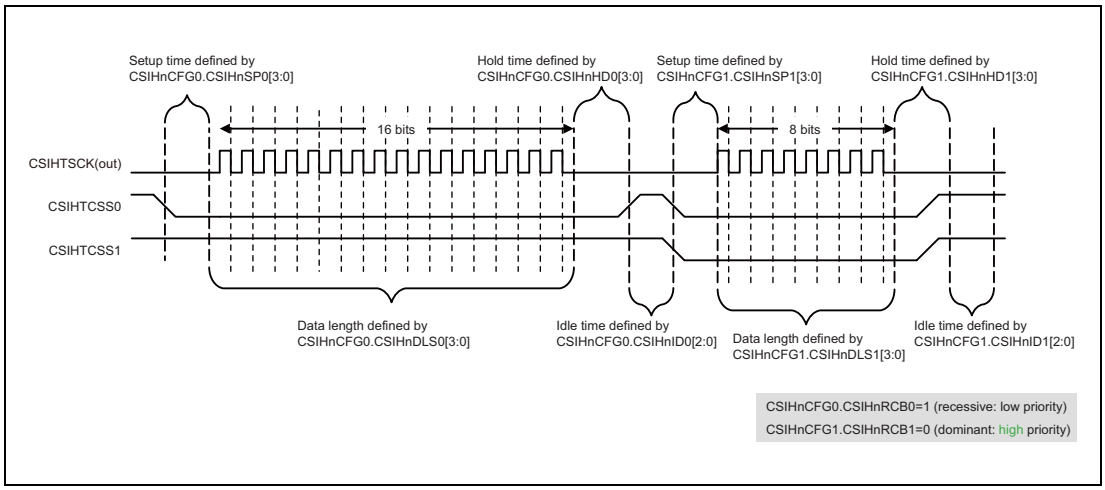

Figure 19.14 Chip Select and RCB Example

19.5.3.3 Job Concept

In terms of CSIH, a job consists of a number of data targeted for transfer.

Job mode enable

The job mode can only be enabled in master mode. The job mode is enabled and disabled by CSIHnCTL1.CSIHnJE, while the CSIH is disabled by CSIHnCTL0.CSIHnPWR = 0.

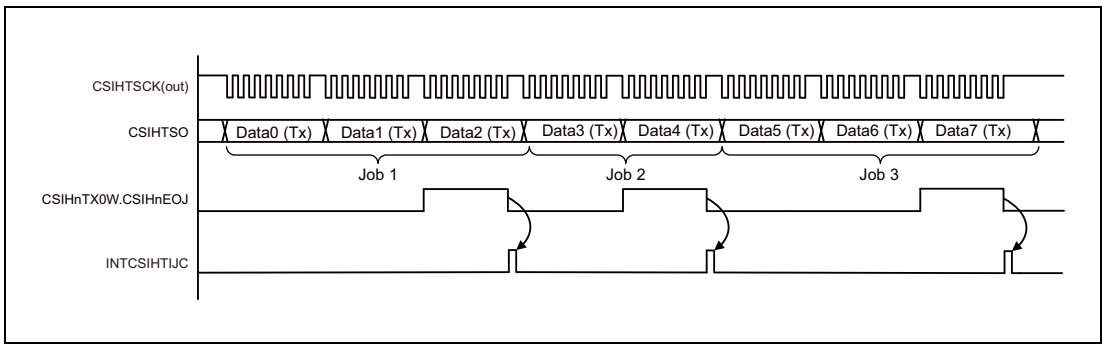

Figure 19.15 Job Examples

A job ends by transmitting data with CSIHnTX0W.CSIHnEOJ = 1.

A communication stop can be specified to occur after a job has finished. This is done by setting CSIHnCTL0.CSIHnJOBE. When CSIHnJOBE is set, the communication continues until data is sent, for which the CSIHnEOJ bit was set. After this data is sent, the communication is stopped and the interrupt INTCSIHTIJC is generated.

19.5.4 Details of Chip Select Timing

19.5.4.1 Changing the Clock Phase

The serial clock level specified by CSIHnCFGx.CSIHnCKPx can be changed while communication is stopped. The minimum value of an idle time is one period of transmission clock (CSIHTSCK(out)).

If the idle time is set to 0.5 transmission clock periods (in CSIHnCFGx.CSIHnIDx[2:0]) and two consecutive data is sent with different CSIHnCFGx.CSIHnCKPx configuration, the idle time is automatically extended to one period of CSIHTSCK(out).

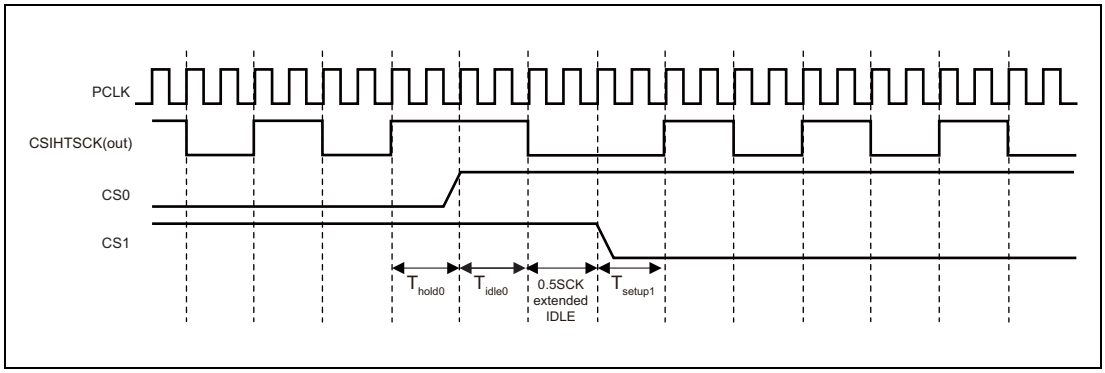

Figure 19.16 Clock Phase Timing with PCLK/4, $T_{hold}0 = T_{setup1}$ = 0.5CSIHTSCK, T_{idle0} = 0.5CSIHTSCK, CSIHnCFG0.CSIHnCKP0 = 0 (CSIHTCSS0) → CSIHnCFG1.CSIHnCKP1 = 1 (CSIHTCSS1)

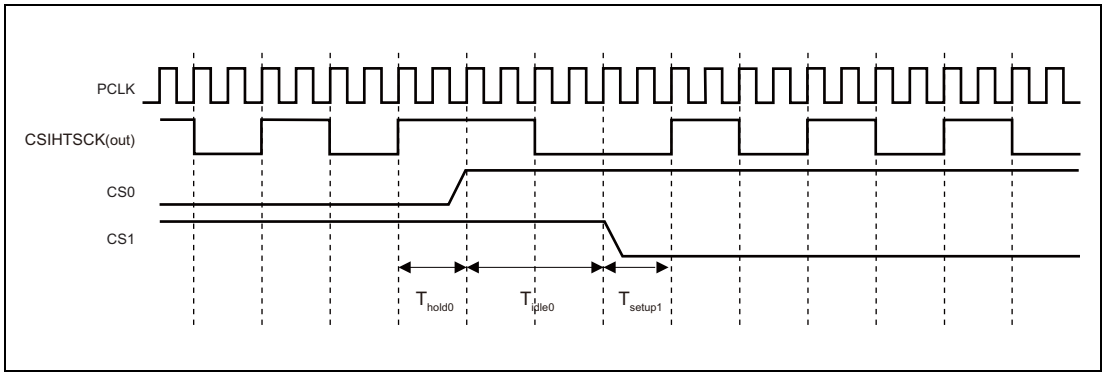

Figure 19.17 Clock Phase Timing with PCLK/4, $T_{hold}0 = T_{setup1}$ = 0.5CSIHTSCK, T_{idle0} = 1CSIHTSCK, CSIHnCFG0.CSIHnCKP0 = 0 (CSIHTCSS0) → CSIHnCFG1.CSIHnCKP1 = 1 (CSIHTCSS1)

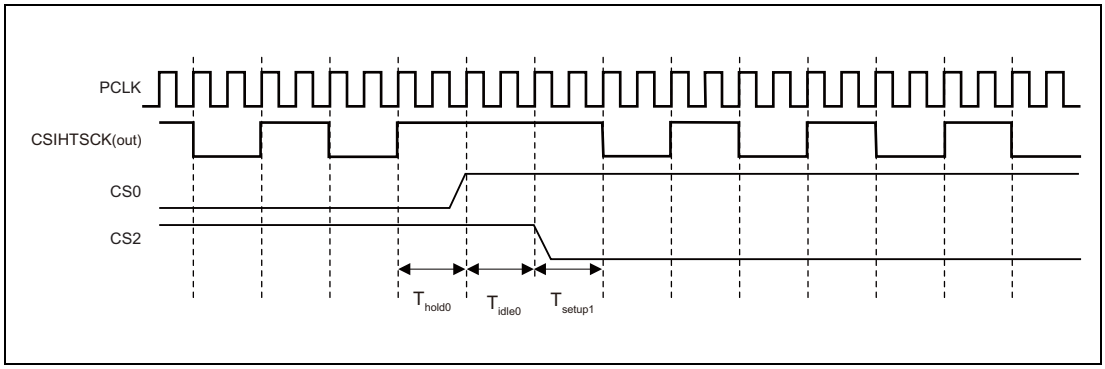

Figure 19.18 Clock Phase Timing with PCLK/4, $T_{hold}0 = T_{setup1}$ = 0.5CSIHTSCK, T_{idle0} = 0.5CSIHTSCK, CSIHnCFG0.CSIHnCKP0 = 0 (CSIHTCSS0) → CSIHnCFG2.CSIHnCKP2 = 0 (CSIHTCSS2)

19.5.4.2 Changing the Data Phase

The CSIHnCFGx.CSIHnDAPx bit defines the phase of the data bits relative to the clock.

The relation between the setting of the CSIHnCFGx.CSIHnDAPx bit and the hold and setup periods is described below.

Hold time is the period from the last edge of the serial clock (CSIHTSCK) until the signals on CSIHTCSS[7:0] change to the inactive level.

Setup time is the period from the signals on CSIHTCSS[7:0] changing to the active level until output (on CSIHTSO) of the data to be transmitted.

Accordingly, there is a gap of 0.5 cycles of CSIHTSCK until output of an edge of the serial clock signal (CSIHTSCK).

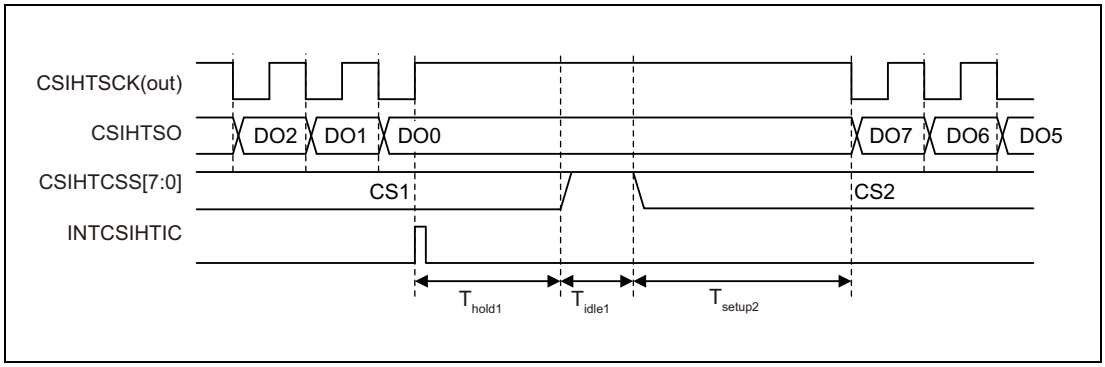

Figure 19.19 Data Phase Timing with CSIHnCFG1.CSIHnCKP1 = 0, CSIHnCFG1.CSIHnDAP1 = 0 and CSIHnCFG2.CSIHnCKP2 = 0, CSIHnCFG2.CSIHnDAP2 = 0

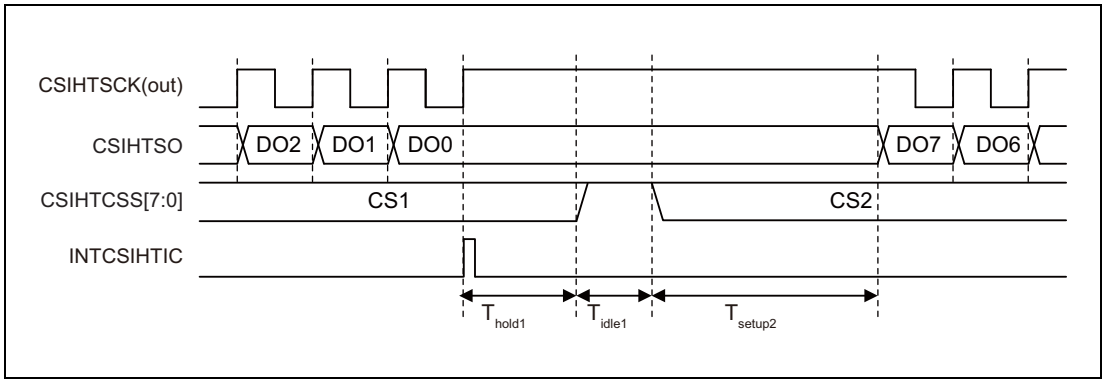

Figure 19.20 Data Phase Timing with CSIHnCFG1.CSIHnCKP1 = 1, CSIHnCFG1.CSIHnDAP1 = 0 and CSIHnCFG2.CSIHnCKP2 = 0, CSIHnCFG2.CSIHnDAP2 = 1

19.5.5 Transmission Clock Selection

19.5.5.1 CSIH0 Transmission Clock Selection

In master mode, the transfer clock frequency is selectable using the following bits:

- CSIH0CTL2.CSIH0PRS[2:0]
- CSIH0BRSy.CSIH0BRS[11:0](y = 0 to 3)
- CSIH0CFGx.CSIH0BRSSx[1:0] (x = 0)

The transfer clock frequency of transmission clock CSIHTSCK is determined by the setting of the CSIH0CTL2.CSIH0PRS[2:0] bits and the setting of the CSIH0BRSy.CSIH0BRS[11:0] bits, but any one of CSIH0BRS3 to CSIH0BRS0 can be selected for each chip select signal with the CSIH0CFGx.CSIH0BRSSx[1:0] bits.

The following figure shows a block diagram of the baud rate generator.

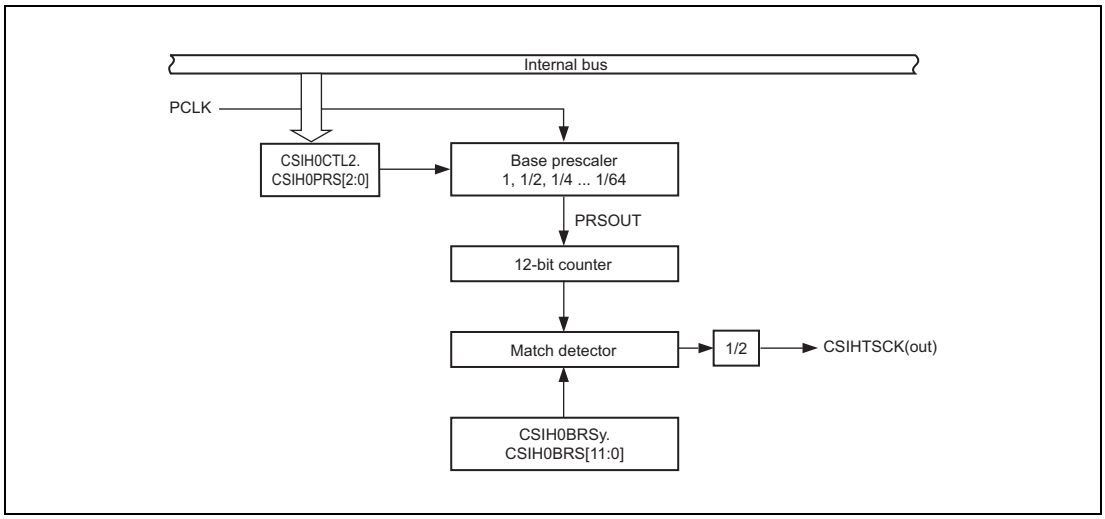

Figure 19.21 CSIH0 Baud Rate Generator Block Diagram

By setting CSIH0BRSy.CSIH0BRS[11:0] to 000_H, CSIH0BRSy.CSIH0BRS[11:0] disables the baud rate generator, and thus CSIHTSCK of the corresponding channel is stopped.

Transfer clock frequency calculation

The transfer clock frequency in master mode is calculated as:

Transfer clock frequency (CSIHTSCK) = PCLK / (division ratio of PCLK) = PCLK / (2α × k × 2),

where

α = CSIH0CTL2.CSIH0PRS[2:0] = 0 to 6

k = CSIH0BRS0.CSIH0BRS0[11:0] = 1 to 4095
(when CSIH0CFGx.CSIH0BRSSx[1:0] = 0)
CSIH0BRS1.CSIH0BRS1[11:0] = 1 to 4095
(when CSIH0CFGx.CSIH0BRSSx[1:0] = 1)
CSIH0BRS2.CSIH0BRS2[11:0] = 1 to 4095
(when CSIH0CFGx.CSIH0BRSSx[1:0] = 2)
CSIH0BRS3.CSIH0BRS3[11:0] = 1 to 4095
(when CSIH0CFGx.CSIH0BRSSx[1:0] = 3)

Transfer clock frequency upper and lower limits

When setting the transfer clock frequency, please note the followings.

- The minimum transfer clock frequency in master mode and slave mode is PCLK/524160.
- The maximum transfer clock frequency is as follows:
  - In master mode: up to PCLK/4
  - In slave mode: up to PCLK/6

19.5.5.2 CSIH1 Transmission Clock Selection

In master mode, the transfer clock frequency is selectable using the following bits:

- CSIH1CTL2.CSIH1PRS[2:0]
- CSIH1CTL2.CSIH1BRS[11:0]
- CSIH1CFGx.CSIH1PSCLx[1:0] (x = 0)

The clock frequency of base transmission clock CSIHBCLK is determined by the setting of the CSIH1CTL2.CSIH1PRS[2:0] bits and the setting of the CSIH1CTL2.CSIH1BRS[11:0] bits.

Additional prescalers CSIH1CFGx.CSIH1PSCLx[1:0], each dedicated to a chip select x, selects a divisor 1/1, 1/2, 1/4 or 1/8, that determines the transmission clock CSIHTSCKx for the chips select x.

The following figure shows a block diagram of the CSIH1 baud rate generator.

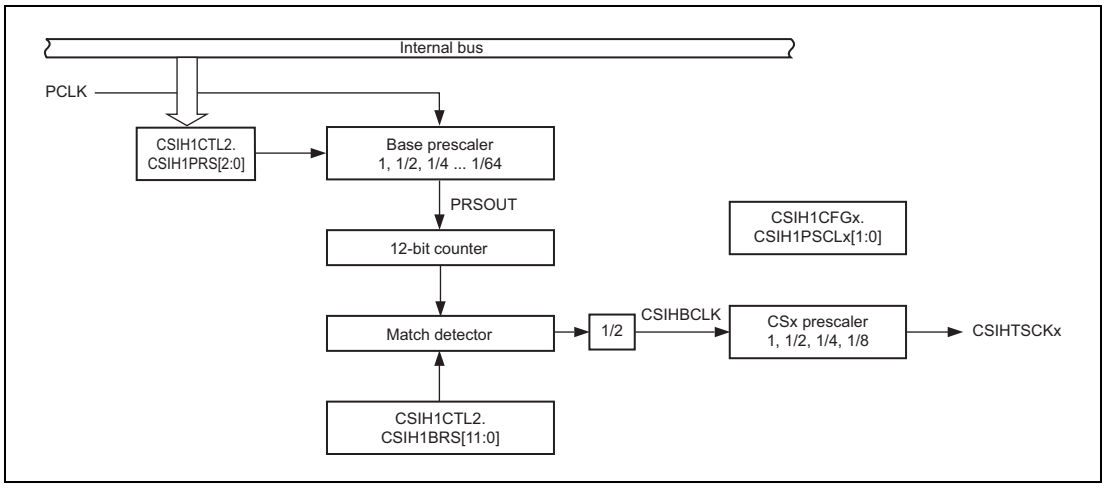

Figure 19.22 CSIH1 Baud Rate Generator Block Diagram

Setting CSIH1CTL2.CSIH1BRS[11:0] to 000_H disables the baud rate generator, and thus CSIHTSCK of the corresponding channel is stopped.

Transfer clock frequency calculation

The transmission clock frequency CSIHTSCKx in master mode is calculated as:

$$CSIHTSCKx = PCLK / (2^{\alpha} \times k \times 2 \times 2^{j})$$

where

α = CSIH1CTL2.CSIH1PRS[2:0] = 0 to 6

k = CSIH1CTL2.CSIH1BRS[11:0] = 1 to 4095

j = CSIH1CFGx.CSIH1PSCLx[1:0] = 0 to 3

Transfer clock frequency upper and lower limits

When setting the transfer clock frequency, please note the followings.

- The minimum transfer clock frequency in master mode and slave mode is PCLK/524160.
- The maximum transfer clock frequency is as follows:

– In master mode: up to PCLK/4
– In slave mode: up to PCLK/6

19.5.6 CSIH Buffer Memory

The CSIH has a configurable RAM that can be used for buffered I/O. One word is comprised of 32 bits data plus 7 bits ECC.

The following configurations are available:

Mode	CSIHnCTL0. CSIHnMBS	CSIHnMCTL0. CSIHnMMS[1:0]
FIFO mode	0	00_B
Dual buffer mode		01_B
Transmit-only buffer mode		10_B
Direct access mode	1	X

19.5.6.1 FIFO Mode

In FIFO mode, data can be written to the CSIHnTX0W register without waiting for completion of the transmission, and data can be received without reading the CSIHnRX0W register immediately, provided the FIFO is not full.

Data to be transmitted is stored to the FIFO memory. Transmission and reception occur simultaneously – one data is sent, one data is received. That means, received data overwrites the transmitted data in the FIFO.

The CSIH automatically updates the respective FIFO memory pointers when data is written to or read from the FIFO memory, or data is transmitted to or received from the FIFO memory:

Table 19.39 FIFO Mode

Pointer Description	Control Bit*1	Range
Number of unsent words	CCSIHnSTR0.CSIHnSPF[7:0]	0 to 128
Number of words received and stored in the FIFO	CSIHnSTR0.CSIHnSRP[7:0]	0 to 128
Address for write/read of transmit data	CSIHnMRWP0.CSIHnTRWA[6:0]	0000_H to $01FC_H$
Address for read of received data	CSIHnMRWP0.CSIHnRRA[6:0]	0000_H to $01FC_H$
Address to be sent	CSIHnMCTL2.CSIHnSOP[6:0]	0000_H to $01FC_H$

Note 1. The values are automatically updated after each read/write or data transmit/receive operation.

The CSIH status register contains also two FIFO status flags:

- CSIHnSTR0.CSIHnFLF: FIFO full
- CSIHnSTR0.CSIHnEMF: FIFO empty

When this mode is started, bit CSIHnSTCR0.CSIHnPCT must be set. By doing this, only CSIHnSTR0.CSIHnEMF is set, but not reset.

All FIFO pointers and FIFO flags excluding CSIHnSTR0.CSIHnEMF are reset and CSIHnSTR0.CSIHnEMF is set.

19.5.6.2 Dual Buffer Mode

In this mode, the memory is divided into two parts of equal size – this means 64 words for transmit data and 64 words for received data. In dual buffer mode, the respective buffer pointers indicate the values shown in the following table.

Table 19.40 Dual Buffer Mode

Pointer Description	Pointer*1	Range
Address of data written to and read from transmit buffer	CSIHnMRWP0.CSIHnTRWA[6:0]	0000_H to $00FC_H$
Address of data read from receive buffer	CSIHnMRWP0.CSIHnRRA[6:0]	0000_H to $00FC_H$
The number of transmit data remained in the transmit buffer	CSIHnMCTL2.CSIHnND[7:0]	0 to 64
Address to which data is sent to	CSIHnMCTL2.CSIHnSOP[6:0]	0000_H to $00FC_H$

Note 1. Both pointers are automatically incremented after each read/write.

19.5.6.3 Transmit-Only Buffer Mode

In this mode, the entire memory is used to save transmission data.

Received data must be read directly from CSIHnRX0W/H.

In transmit-only buffer mode, the respective buffer pointer indicates the values shown in the following table.

Table 19.41 Transmit-Only Buffer Mode

Pointer Description	Pointer*1	Range
Address of data written to and read from transmit buffer	CSIHnMRWP0.CSIHnTRWA[6:0]	0000_H to $01FC_H$
The number of transmit data remained in the transmit buffer	CSIHnMCTL2.CSIHnND[7:0]	0 to 128
Address to which data is sent to	CSIHnMCTL2.CSIHnSOP[6:0]	0000_H to $01FC_H$

Note 1. Pointers are automatically incremented after each read/write.

19.5.6.4 Direct Access Mode

In direct access mode, the CSIH memory is completely bypassed:

- Transmission data provided by the CPU to the transmission register CSIHnTX0W or CSIHnTX0H is directly copied to the shift register.
- Reception data is directly copied from the shift register to the reception register CSIHnRX0W or CSIHnRX0H.

19.5.7 Data Transfer Modes

19.5.7.1 Transmit-Only Mode

Setting CSIHnCTL0.CSIHnTXE = 1 and CSIHnCTL0.CSIHnRXE = 0 puts the CSIH in transmit-only mode. Start of transmission depends on the memory mode:

- In case of FIFO or direct access mode, transmission starts when transmit data is written to the CSIHnTX0W or CSIHnTX0H register.
- In case of dual buffer or transmit-only buffer mode, transmission starts when the CSIHnMCTL2.CSIHnBTST bit is set.

19.5.7.2 Receive-Only Mode

Setting CSIHnCTL0.CSIHnTXE = 0 and CSIHnCTL0.CSIHnRXE = 1 puts the CSIH in receive-only mode.

In master mode, start of reception depends on the memory mode:

- In case of FIFO or direct access mode, reception starts when dummy data is written in the CSIHnTX0W or CSIHnTX0H register.

In slave mode, reception starts as soon as the CSIHTSCK transmission clock from the master is received. It is not necessary to write data to the CSIHnTX0W or CSIHnTX0H register of the slave.

- In case of dual buffer mode or transmit-only buffer mode, reception starts when the CSIHnMCTL2.CSIHnBTST bit is set.

19.5.7.3 Transmit/Receive Mode

Setting CSIHnCTL0.CSIHnTXE = 1 and CSIHnCTL0.CSIHnRXE = 1 puts the CSIH in transmit/receive mode.

Start of communication (transmission and reception) depends on the memory mode:

- In case of FIFO or direct access mode, communication starts when transmit data is written to the CSIHnTX0W or CSIHnTX0H register.
- In case of dual buffer or transmit-only buffer mode, communication starts when the CSIHnMCTL2.CSIHnBTST bit is set..

19.5.7.4 Summary

The following table summarizes this section. It shows how data transfer is started in the various memory, operating, and transfer modes.

Table 19.42 Start of Data Transfer

Memory and Operating Mode		Transfer Mode	
		Transmit-Only Transmit/Receive	Receive-Only
FIFO, direct access	Master	Writing to the CSIHnTX0W register or the CSIHnTX0H register	Writing to the CSIHnTX0W register on the CSIHnTX0H register
	Slave	Incoming clock from master	Incoming clock from the master
Transmit-only buffer, dual buffer	Master	CSIHnMCTL2.CSIHnBTST = 1	CSIHnMCTL2.CSIHnBTST = 1
	Slave	Incoming clock from master	Incoming clock from master

19.5.8 Data Length Selection

19.5.8.1 Data Length from 2 to 16 Bits

The length of a data packet is selectable for each chip select signal from

- 2 to 16 bits for CSIH0
- 7 to 16 bits for CSIH1

using CSIHnCFGx.CSIHnDLSx[3:0]. The examples below show the communication with MSB first (CSIHnCFGx.CSIHnDIRx = 0).

Data length = 16 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 0000_B):

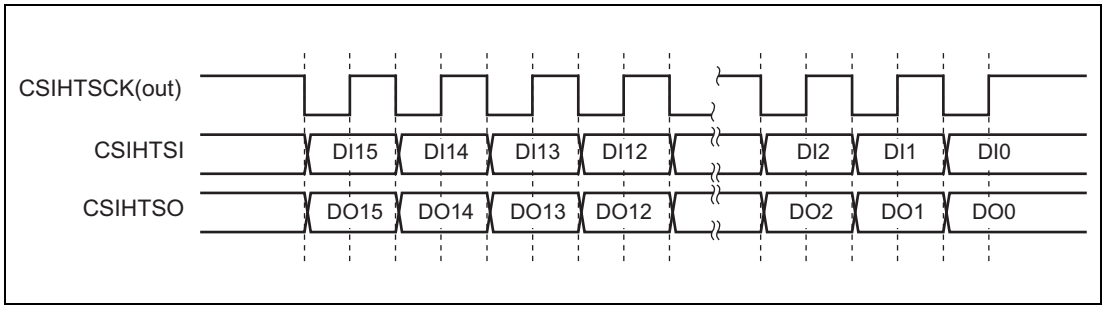

Figure 19.23 16 Bit Data Length, MSB First

Data length = 14 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1110_B):

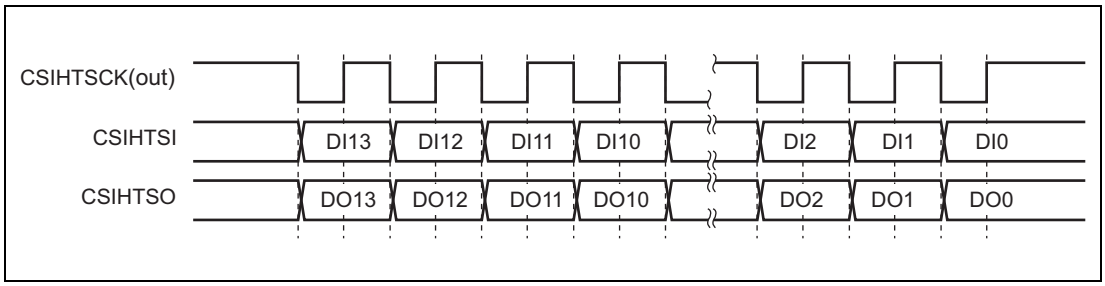

Figure 19.24 14 Bit Data Length, MSB First

19.5.8.2 Data Length Greater than 16 Bits

If the data to be sent/received exceeds 16 bits, the extended data length (EDL) feature can be used.

EDL function is enabled by setting the CSIHnCTL1.CSIHnEDLE bit to 1.

EDL function works as follows:

- The data has to be broken into 16-bit blocks plus remainder. For example, data of 42 bits would be broken into two 16-bit blocks plus 10 bits.
- The bit length of the remainder is set as “data length” in CSIHnCFGx.CSIHnDLSx[3:0].
- For transmitting the 16-bit blocks, CSIHnTX0W.CSIHnEDL must be set to 1. In this case, the data written to CSIHnTX0W is sent as a 16-bit data length regardless of the CSIHnCFGx.CSIHnDLSx[3:0] bit setting.
- The transfer is complete after a block with the specified data length (the remainder of data specified with CSIHnTX0W.CSIHnEDL = 0) has been sent.

Example

Example for sending 40-bit data ($123456789A_H$) to CS0:

40 bits are split into two blocks of 16 bits plus 8 bits.

- Initialize CSIHnCFG0.CSIHnDLS0[3:0] = 8.
- To send $123456789A_H$ with MSB first, write the following sequence to CSIHnTX0W:
  - $20FE\ 1234_H$ (CSIHnTX0W.CSIHnEDL = 1)
  - $20FE\ 5678_H$ (CSIHnTX0W.CSIHnEDL = 1)
  - $00FE\ 009A_H$ (CSIHnTX0W.CSIHnEDL = 0)

The following figure illustrates the timing.

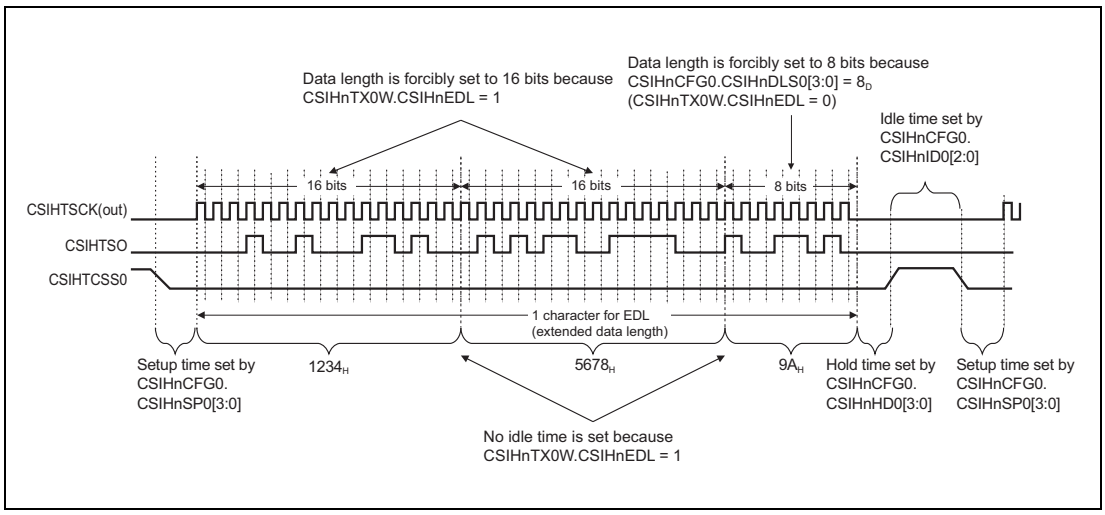

Figure 19.25 EDL Timing Diagram

NOTES

1. CSIH0:
   Data lengths settings of 1 bit is only permitted in combination with EDL mode.
   It is not possible to send two consecutive data with a data length of 1 bit.
2. CSIH1:
   Data lengths settings lower than 7 bits are only permitted in combination with EDL mode.
   It is not possible to send two consecutive data with a data length of less than 7 bits.
3. If parity is enabled, the parity bit is added after the last bit.
4. When data is sent using extended data length (EDL) function, use the same chip select signal.
5. To consider the data direction, pay attention to the following example:
   - Data to be sent:123456_H
   - MSB first:
     Set CSIHnCFGx.CSIHnDIRx = 0
     Write CSIHnTX0W = $20FE\ 1234_H$ (EDL bit = 1)
     Write CSIHnTX0W = $00FE\ 0056_H$ (EDL bit = 0)
   - LSB first:
     Set CSIHnCFGx.CSIHnDIRx = 1
     Write CSIHnTX0W = $20FE\ 3456_H$ (EDL bit = 1)

Write CSIHnTX0W = 00FE 0012$_H$ (EDL bit = 0)

6. Operation is not guaranteed if CSIHnTX0W.CSIHnEOJ and CSIHnTX0W.CSIHnEDL are simultaneously set to “1” while CSIHnCTL1.CSIHnJE = 1 and CSIHnCTL1.CSIHnEDLE = 1.
7. EDL mode cannot be used in receive-only mode of slave mode. (CSIHnCTL2.CSIHnPRS[2:0] = 111$_B$, CSIHnCTL0.CSIHnTXE = 0, CSIHnCTL0.CSIHnRXE = 1)

19.5.9 Serial Data Direction Selection

The serial data direction is selectable for each chip select signal using the CSIHnDIRx bit in the CSIHnCFGx register.

The examples below show communication for a data length of 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000$_B$).

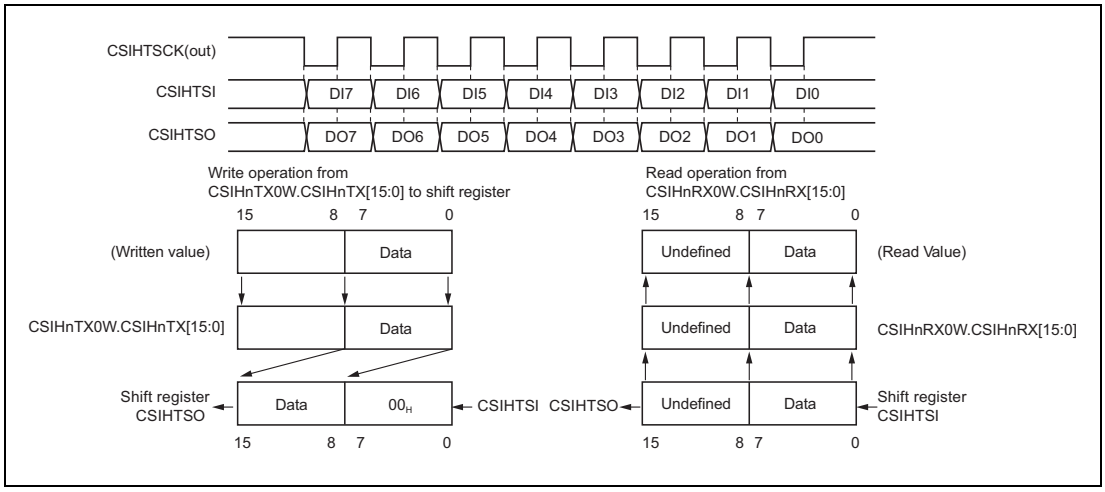

Figure 19.26 Serial Data Direction Select Function - MSB First (CSIHnDIRx = 0)

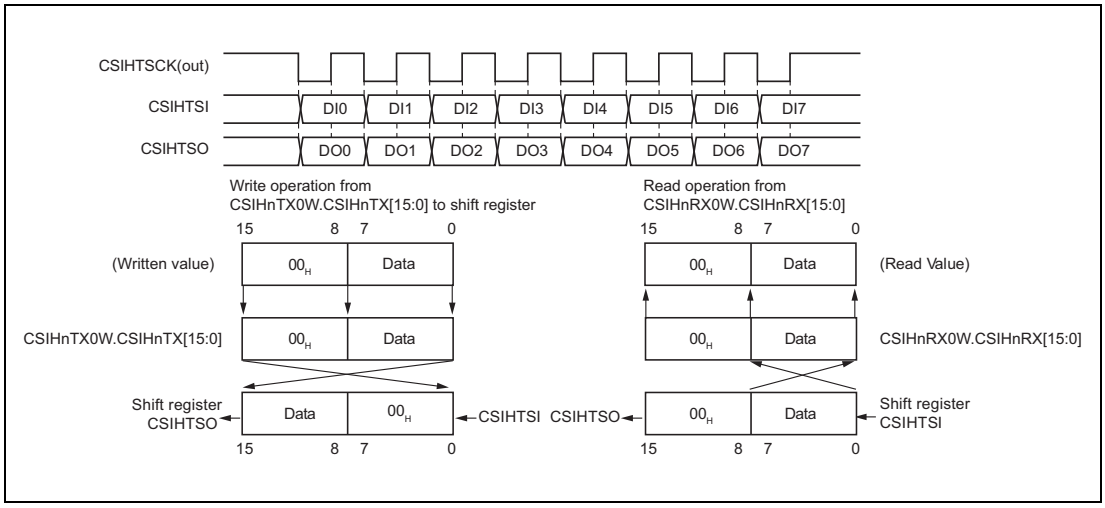

Figure 19.27 Serial Data Direction Select Function - LSB First (CSIHnDIRx = 1)

19.5.10 Slave Select (SS) Function

The Slave Select (SS) function realizes communication between one master and multiple slaves.

In master mode, the master device outputs the salve select signal (CSIHTCSSx) to select a single slave. Communication by a device in slave mode is enabled when the slave input select signal (CSIHTSSI) is at the low level.

See the Section 19.5.2, Master/Slave Connections, for an example of a connection using the SS function.

19.5.10.1 Communication Timing Using SS Function

The following figure illustrates the communication signal using the SS function and timings.

In slave mode, the data transfer configuration is determined by the CSIHnCFG0 register.

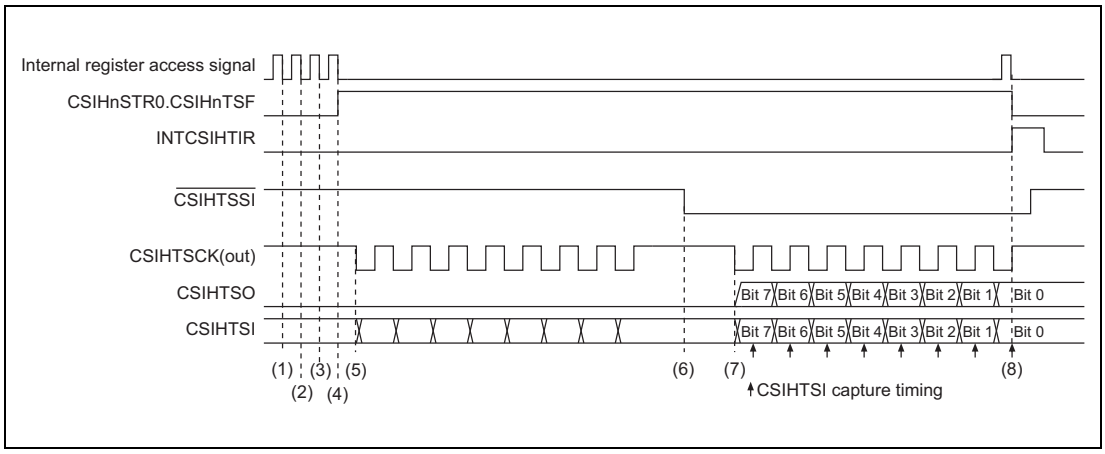

Figure 19.28 Tx/Rx Timing of Communication Using SS Function

(1) CSIH is put into slave mode by setting CSIHnCTL2.CSIHnPRS[2:0] = 111_B. CSIHnCFG0.CSIHnCKP0 and CSIHnCFG0.CSIHnDAP0 are 0.

(2) The data length is 8 bits (CSIHnCFG0.CSIHnDLS0[3:0] = 1000_B). The data direction is MSB first (CSIHnCFG0.CSIHnDIR0 = 0).

(3) The transmit/receive mode is set (CSIHnCTL0.CSIHnTXE = 1, CSIHnCTL0.CSIHnRXE = 1, and CSIHnCTL0.CSIHnPWR = 1). Communication start is permitted.

(4) The transfer status flag CSIHnSTR0.CSIHnTSF is automatically set when transfer data is written to the CSIHnTX0W or CSIHnTX0H transmission register during direct access mode or FIFO mode.

(5) As long as signal $\overline{\text{CSIHTSSI}}$ is at the high level, transmission/reception is not started, even if an external transmission clock CSIHTSCK is applied. Input at CSIHTSI is ignored.

(6) As soon as $\overline{\text{CSIHTSSI}}$ falls to low level, indicating that CSIHTSO is enabled and ready for transmission.

(7) Now, as soon as the external clock signal CSIHTSCK is detected, the slave transmits data to CSIHTSO and simultaneously captures data from CSIHTSI.

(8) Interrupt INTCSIHTIR indicates when the reception is complete. The CSIHnRX0W/H register can be read.

19.5.10.2 CSIHTSSO Operation

CSIHnPWR	CSIHnTXE	CSIHnRXE	CSIHnSSE	CHISTSSO
0	—	—	—	H
1	—	—	0	H
	0		1	H
	1		1	Reversed value of $\overline{\text{CSIHTSSI}}$ level

The CSIHTSSO pin is a signal to control the I/O function of the chip's SO pin in case of using the SS function.

The CSIHTSO pin is enabled when the CSIHTSSO pin is "High" (the chip's SO pin is being driven).

The CSIHTSO pin is disabled when the CSIHTSSO pin is "Low" (the chip's SO pin is not being driven).

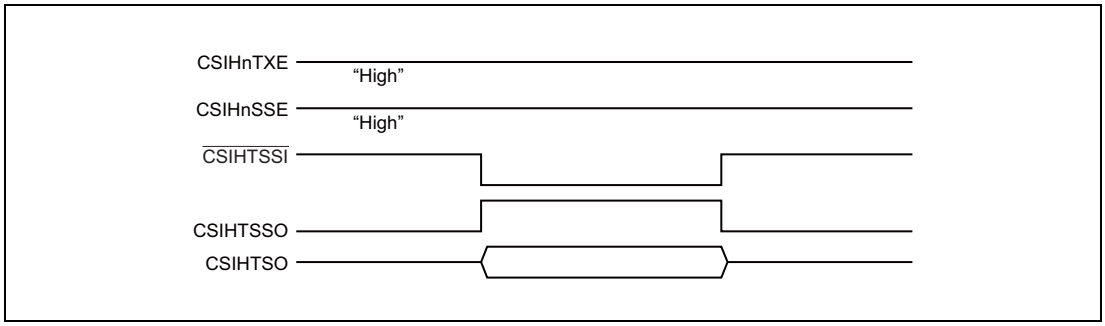

Figure 19.29 Operation of CSIHTSSO

CAUTION

If $\overline{\text{CSIHTSSI}}$ pin is changed during communication (CSIHnSTR0.CSIHnTSF = 1), current communication is not assured.

19.5.11 Handshake Function

CSIH features a handshake function to synchronize the master and the slave devices. This function can be enabled/disabled by the CSIHnCTL1.CSIHnHSE bit. For handshake, the signals CSIHTRYI and CSIHTRYO are used.

The busy timing depends on the data phase selection bit CSIHnCFGx.CSIHnDAPx.

19.5.11.1 Slave Mode

When CSIHnCTL1.CSIHnHSE = 1 and the slave is busy, the CSIHTRYO signal outputs low level (0). This can happen in two cases:

1. When the next data to be sent is not ready:
   When the slave is in transmit-only mode or transmit/receive mode (CSIHnCTL0.CSIHnTXE = 1) and is in the states listed below, the CSIHTRYO output indicates the busy state (is at the low level).

Table 19.43 Memory Mode and Slave Transfer State

Memory Mode	Slave Transfer State
Direct access mode	When there is no more data to be sent
FIFO mode	When there is no more data to be sent (CSIHnSTR0.CSIHnEMF = 1)
Dual buffer mode	When CSIHnMCTL2.CSIHnBTST is not set to 1
Transmit-only buffer mode	

The example below is on the assumption of an eight-bit data length.

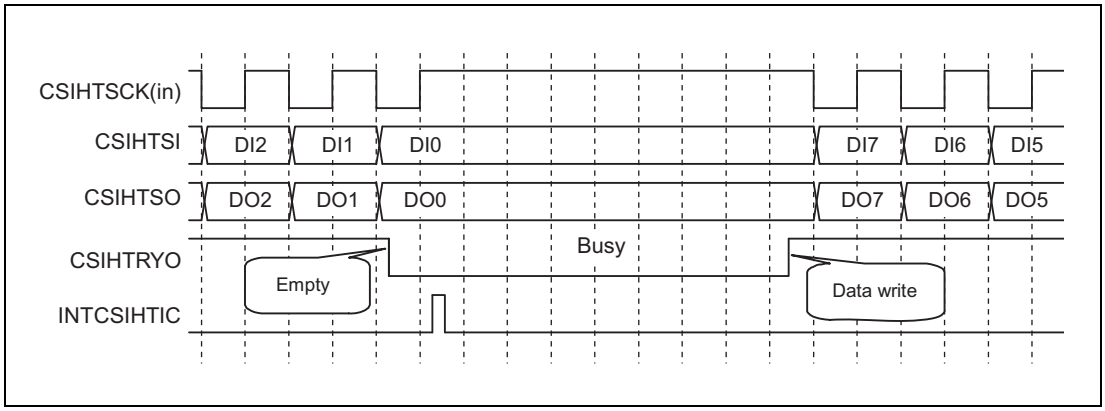

Figure 19.30 Busy Signal from the Slave (FIFO Mode; CSIHnCFGx.CSIHnDAPx = 0)

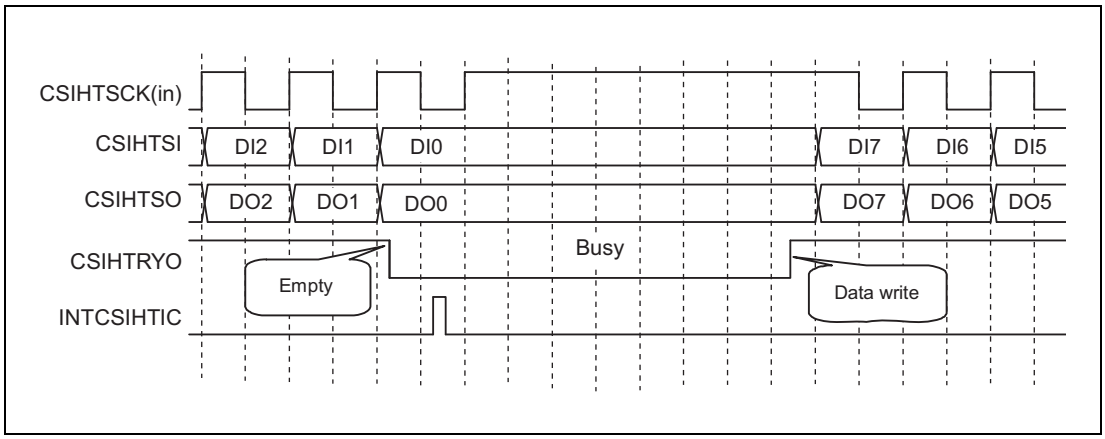

Figure 19.31 Busy Signal from the Slave (FIFO Mode; CSIHnCFGx.CSIHnDAPx = 1)

2. When receive register is full:
   When slave is set in receive-only mode or transmit/receive mode (CSIHnCTL0.CSIHnRXE = 1), and new data cannot be copied from a shift register to CSIHnRX0W/H (CSIHnRX0W/H is full) because the previously received data is still in the CSIHnRX0W/H register.
   When CSIHnCTL0.CSIHnRXE is 1 and is in the following states, CSIHTRYO outputs busy state (low level).

Table 19.44 Memory Mode and Slave Reception State

Memory Mode	Slave Reception State
Direct access mode	When CSIHnRX0W or CSIHnRX0H is full
FIFO mode	When receive data is remained in buffer (CSIHnSTR0.CSIHnFLF = 1)
Dual buffer mode	No applicable case
Transmit-only buffer mode	When CSIHnRX0W or CSIHnRX0H is full

The example below is on the assumption of an eight-bit data length.

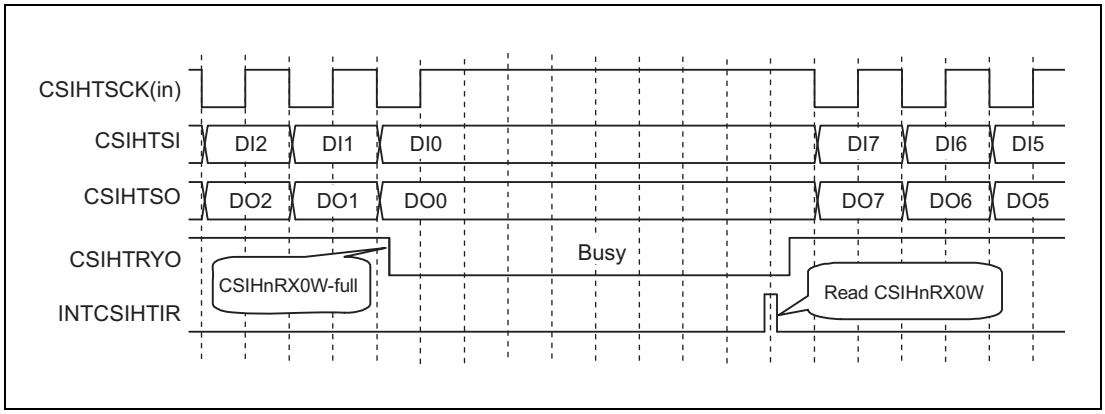

Figure 19.32 Busy Signal from the Slave (Direct Access Mode; CSIHnCFGx.CSIHnDAPx = 0)

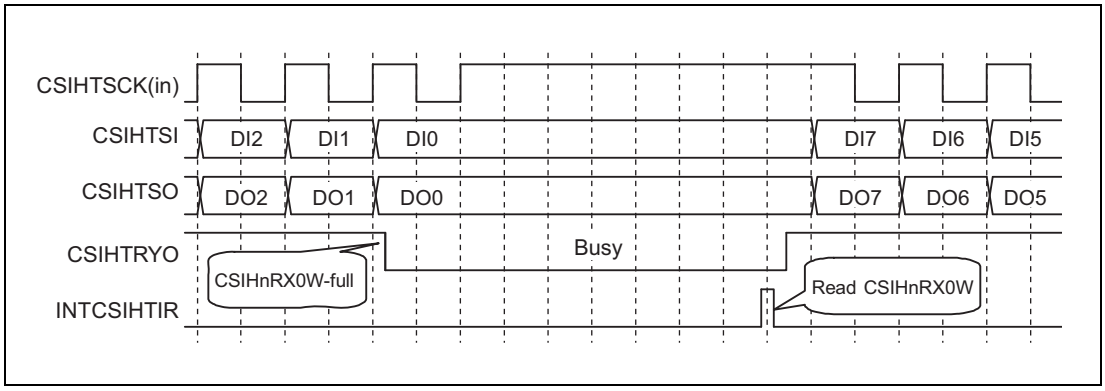

Figure 19.33 Busy Signal from the Slave (Direct Access Mode; CSIHnCFGx.CSIHnDAPx = 1)

19.5.11.2 Master Mode

When the master detects CSIHTRYI = 0 while CSIHnCTL1.CSIHnHSE = 1, the following transfer is put on hold, and the master goes into wait status. It suspends the CSIHTSCK clock.

The CSIHTRYI level is checked at each half clock cycle of CSIHTSCK.

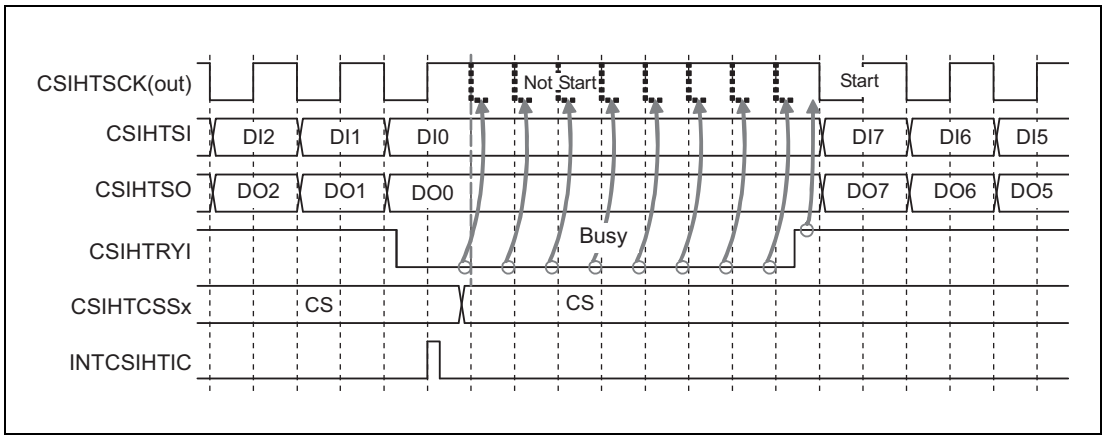

Figure 19.34 Master's Reaction on CSIHTRYI (CSIHnCFGx.CSIHnDAPx = 0)

The CSIHTRYI signal must be pulled down by the slave before the next transfer starts. If this is done while data transfer is in progress, the serial clock from the master is suspended after the transfer is complete.

The master resumes the communication as soon as CSIHTRYI becomes high (the slave is "ready").

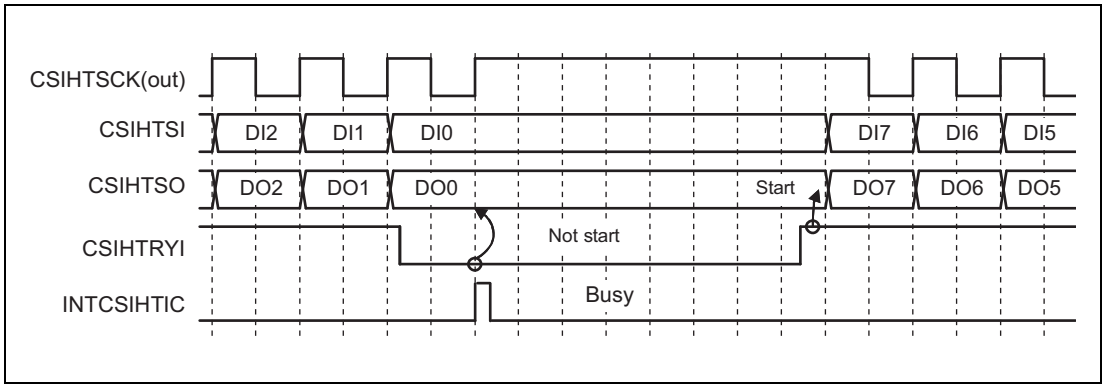

Figure 19.35 Master's Reaction on CSIHTRYI (CSIHnCFGx.CSIHnDAPx = 1)

CAUTIONS

1. **If multiple slaves are connected, the master must only detect the CSIHTRYI signal of the slave it has selected for communication.**
2. **Even when the CSIHTRYI pin of the master detects a CSIHTRYO signal from the slave during data transfer, the communication is not made to wait but continues until the data transfer is completed.**

19.5.12 Error Detection

CSIH can detect five error types:

- Data consistency error (transmission data)
- Parity error (received data)
- Overrun error (received data)
- Time-out error (in FIFO mode)
- Overflow error (in FIFO mode)

Check for parity, data consistency and time-out errors can be enabled/disabled individually.

If one of these errors is detected, the interrupt request, INTCSIHTIRE is generated and the corresponding flags are set.

19.5.12.1 Data Consistency Check

The purpose of the data consistency check is to ensure that the data physically sent as output signal is identical to the original data that was copied to the shift register.

The data consistency check can be enabled/disabled by the CSIHnCTL1.CSIHnDCS bit (when checking data consistency, make sure that PIPCn.PIPCn_m = 1). It is not active if data transmission is disabled (CSIHnCTL0.CSIHnTXE = 0).

When the data consistency check is active, the data transferred from CSIHnTX0W or CSIHnTX0H to the shift register is copied to a separate register. In addition, the physical levels at CSIHTSO are read back via the CSIHTDCS signal into an own shift register.

After completion of the transmission, the sent data is compared with the original transmission data.

Mismatch is considered as a data consistency error:

- Interrupt INTCSIHTIRE is generated.
- The CSIHnSTR0.CSIHnDCE bit is set.

Additionally, CSIHnRX0W.CSIHnTDCE of data that contains the error is set.

The data consistency check function is illustrated in the following block diagram.

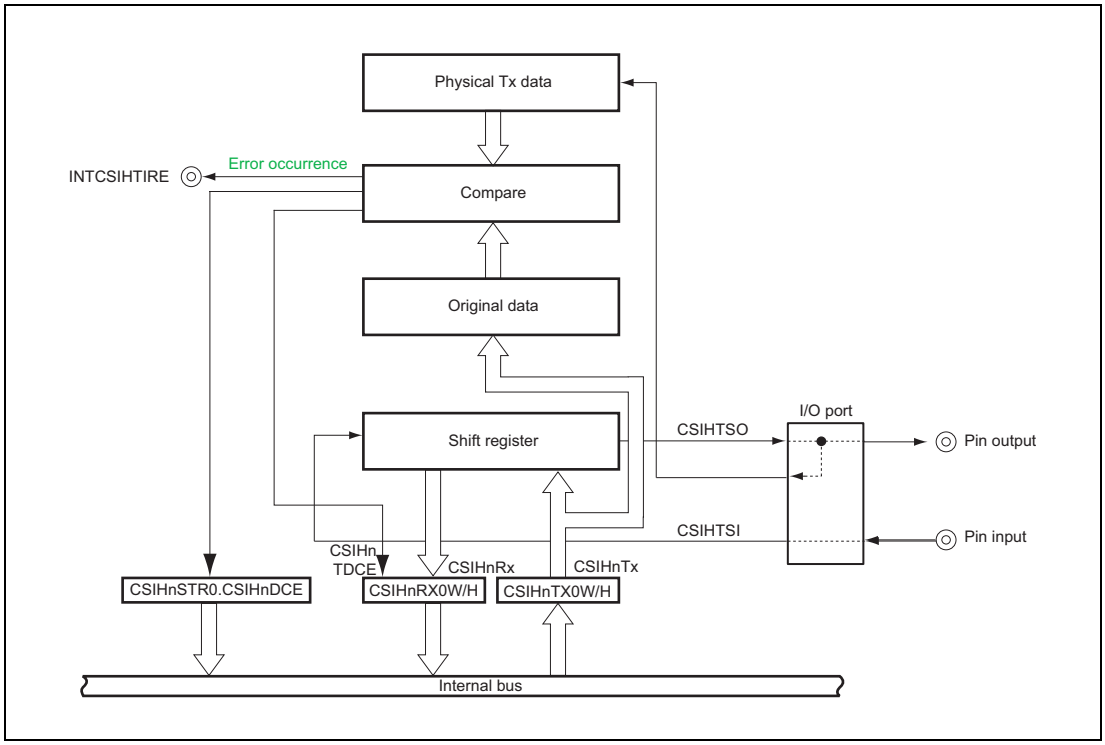

Figure 19.36 Data Consistency Check Functional Block Diagram

19.5.12.2 Parity Check

CSIH can append a parity bit to the last data bit (even if extended data length is used).

The use and type of parity is specified in CSIHnCFGx.CSIHnPSx[1:0].

Parity check is enabled if CSIHnCFGx.CSIHnPSx[1] = 1.

The parity bit is checked after a reception is complete. In case of parity error:

- Interrupt INTCSIHTIRE is generated.
- The CSIHnSTR0.CSIHnPE bit is set.

Additionally, CSIHnRX0W.CSIHnRPE of data that contains the error is set.

The figure below shows an example.

- Data length is 8 bits.
- The data to be transmitted is 05_H and 35_H.
- Data direction is LSB first.
- Parity type is odd.

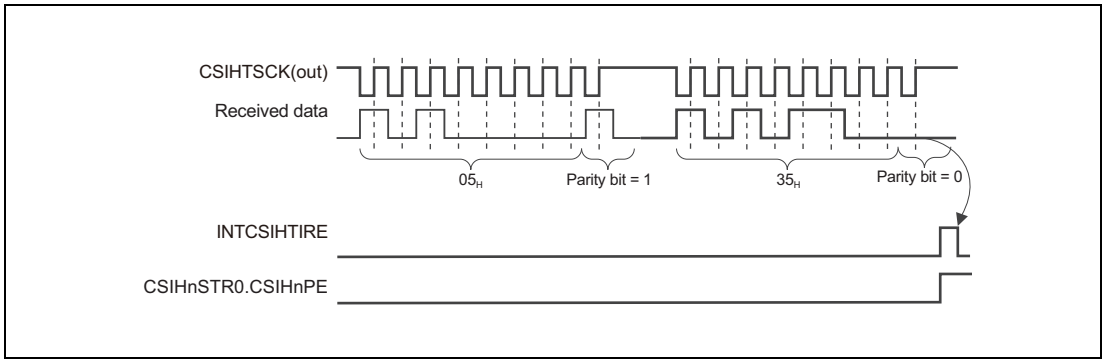

Figure 19.37 Parity Check Example

The parity bit of the first data is 1. There is no parity error, because the total number of ones (including the parity bit) is odd.

The parity bit of the second data is 0. This is detected as a parity error, because the total number of ones (including the parity bit) is even.

If the EDL (extended data length) function is used, the parity bit is added after the last bit of the data.

19.5.12.3 Time-Out Error

Time-out errors can be checked only in slave FIFO mode.

This error occurs if neither of the following occurred within a certain period of time:

- Received data in FIFO is read
- FIFO receives data from CSIHTSI

The time is defined in CSIHnMCTL0.CSIHnTO[4:0] in multiples of 8 times the transmission clock, CSIHTSCK. A time-out error occurs when the specified time is exceeded (The time-out time is not detected when CSIHnMCTL0.CSIHnTO[4:0] = 00000_B).

A dedicated time-out counter measures the time between the last and the next read operation.

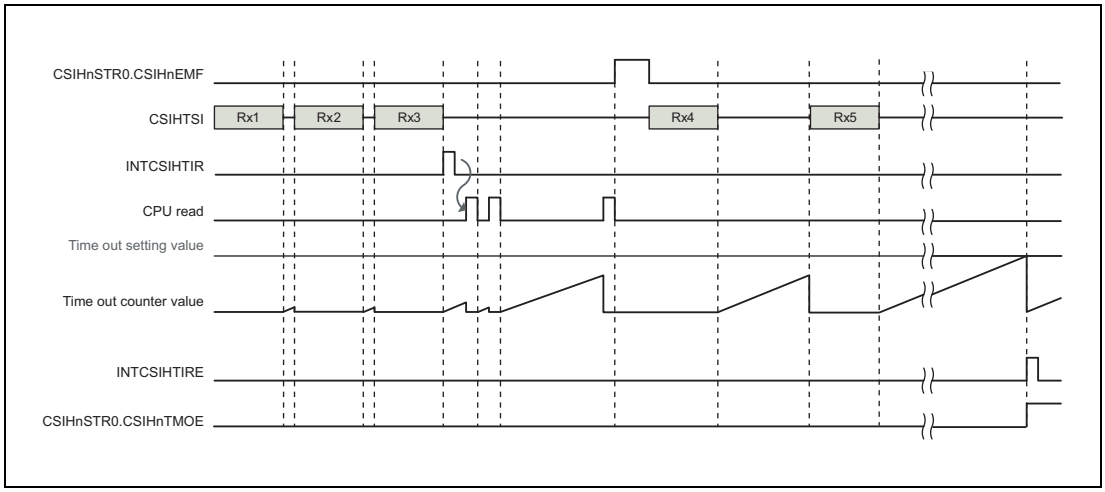

Figure 19.38 Time-Out Check Functional Timing Diagram

The start timing of the time-out counter is as follows:

- When reception is completed,

- When data read from the CPU completes,
  (The counter does not start if the buffer is empty.)
- When a time-out error is detected,

After a time-out error is detected, if data is still available in FIFO, the time-out counter restarts.

If the value set by bit CSIHnMCTL0.CSIHnTO[4:0] is reached again, the INTCSIHTIRE interrupt is output again.

The timeout counter continues to count until received data is read. To stop the counter, read all received data or set CSIHnSTCR0.CSIHnPCT to 1. Note that the pointer is cleared if you perform the latter.

The counter is reset at the following timing:

- Data is read once.
- A new data item is received.
- A timeout error is detected.
- The CSIHnSTR0.CSIHnPCT bit is set.

If a timeout error occurs, the following occurs:

- Interrupt INTCSIHTIRE is generated.
- The CSIHnSTR0.CSIHnTMOE bit is set.

The dedicated time-out counter of CSIH0 is set by the CSIHnCTL2.CSIHnPRS[2:0] and CSIH0BRSy.CSIH0BRS[11:0] bits. If the value of the CSIH0BRSy.CSIH0BRS[11:0] bits is left as 000_H, the dedicated time-out counter of CSIH0 does not operate.

The dedicated time-out of CSIH1 counter is set by the CSIHnCTL2.CSIHnPRS[2:0] and CSIH1CTL2.CSIH1BRS[11:0] bits. If the value of the CSIH1CTL2.CSIH1BRS[11:0] bits is left as 000_H, the dedicated time-out counter of CSIH1 does not operate.

19.5.12.4 Overflow Error

An overflow error can happen in FIFO mode. It occurs when transmission data is written to the CSIHnTX0W register while the FIFO buffer is filled with received data.

Example

100 data have been transmitted. That means, the FIFO contains 100 received data. The application starts to read the received data.

While the read operation is in progress, the application begins to write another set of 50 transmission data to the FIFO. However, only 10 received data have been read up to now, 90 are still in the FIFO.

In this case, only 38 cells are available for new transmission data packets. When the CPU tries to write the 39th data, an overflow error happens.

This is illustrated in the following figure.

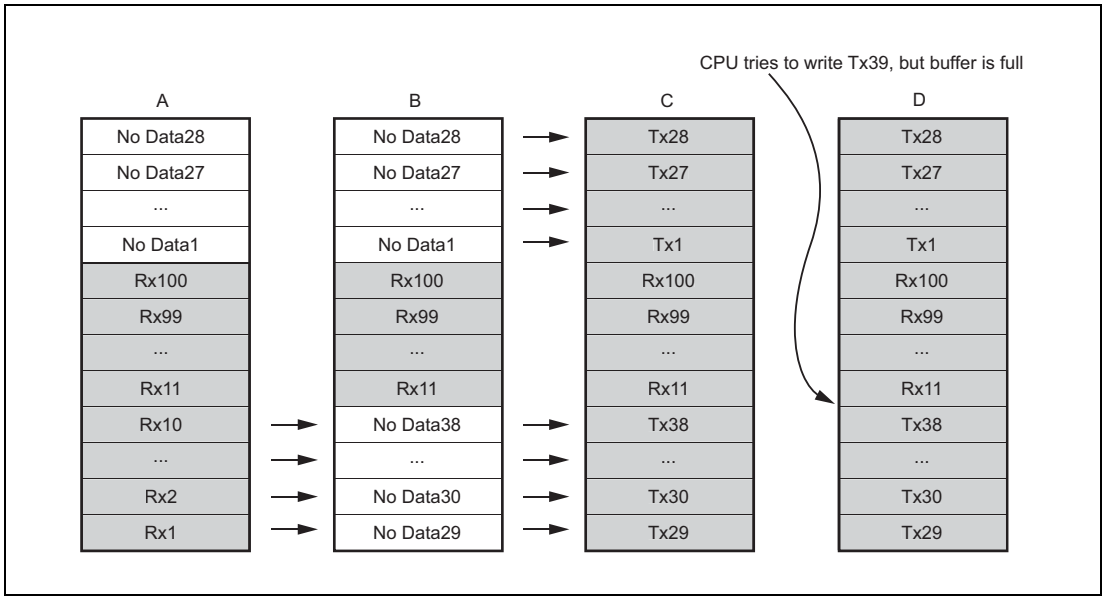

Figure 19.39 FIFO Overview

The 39th and subsequent data are discarded. The figure below shows the overflow timing.

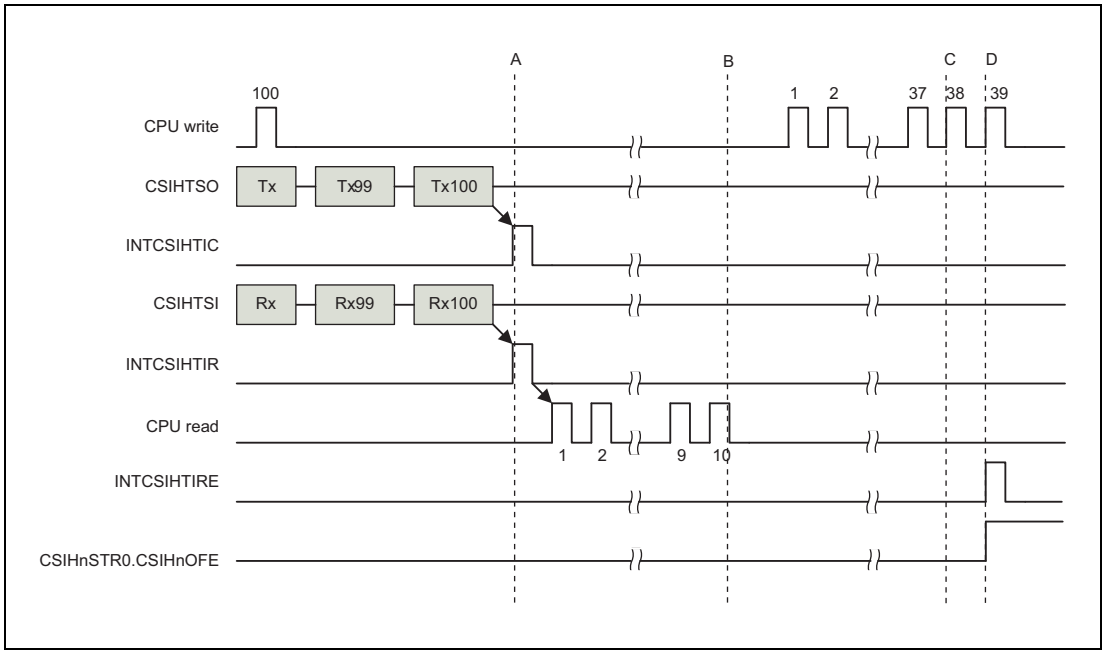

Figure 19.40 FIFO Overflow Timing

In case of overflow error:

- Interrupt INTCSIHTIRE is generated.
- The CSIHnSTR0.CSIHnOFE bit is set.

19.5.12.5 Overrun Error

An overrun error can happen in direct access, transmit-only buffer, and FIFO modes. It cannot happen in dual buffer mode. The overrun error is not generated if data reception is disabled (CSIHnCTL0.CSIHnRXE = 0).

There are two conditions for overrun errors.

Condition for errors 1

- In FIFO mode, while the number of received data is 0 and CPU reads the CSIHnRX0W/H register

Condition for errors 2

- In slave mode, when CSIHnCTL1.CSIHnHSE = 0 (handshake function disabled):
  - In direct access mode or transmit-only buffer mode, when reception is completed while the previous received data is remained in the CSIHnRX0W/H register.
  - In FIFO mode, when FIFO buffer completes receiving data in the full state, an interrupt is generated, and communication continues.

(1) Direct access/transmit-only buffer

In direct access and transmit-only buffer mode, this error occurs when newly received data cannot be transferred from the shift register to the reception register CSIHnRX0W/H. This happens when CSIHnRX0W/H was not read and therefore contains previous reception data.

The following figure illustrates the function.

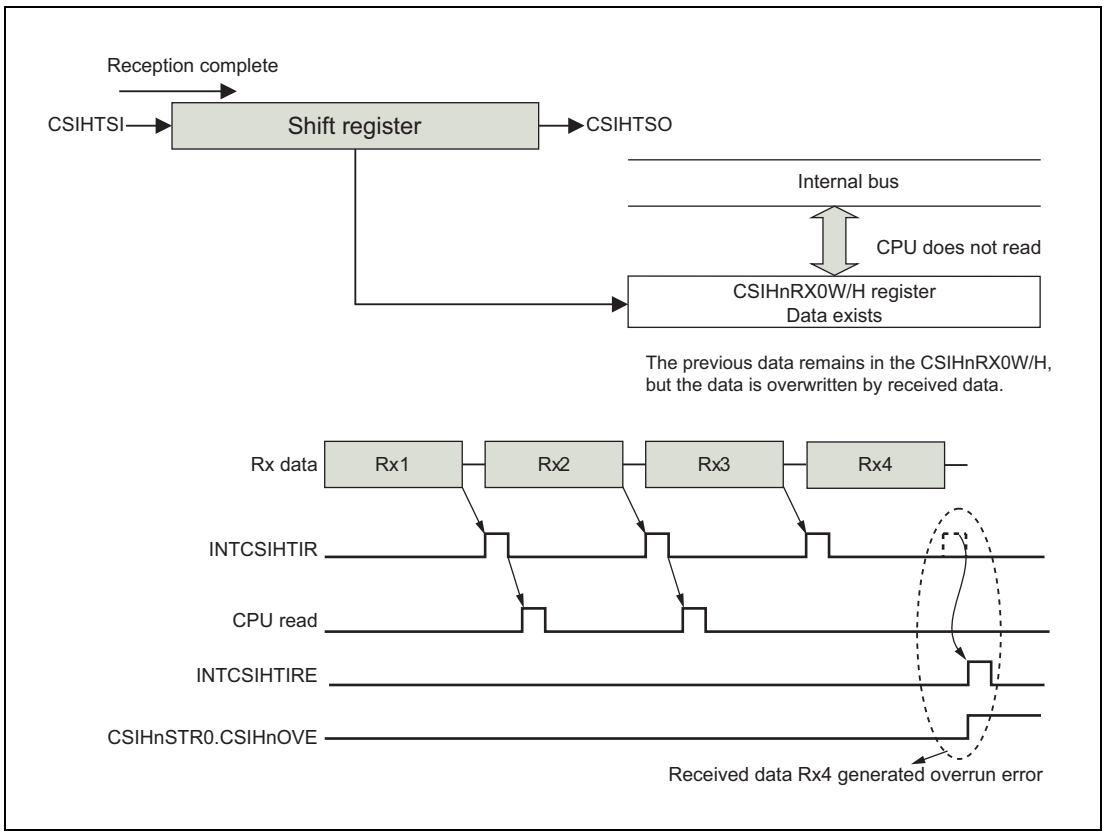

Figure 19.41 Overrun Error Detection in Direct Access and Transmit-Only Buffer Mode

NOTE

An overrun error can be avoided in slave mode by using handshake function. When handshake is used in slave mode, the receiver (slave) signals to the transmitter (master) that it is busy. The transmitter then waits until the receiver has read its reception register and is ready again.

(2) FIFO mode

In FIFO mode, this error occurs if:

1. Newly received data cannot be transferred from the shift register to the FIFO because the FIFO is full.

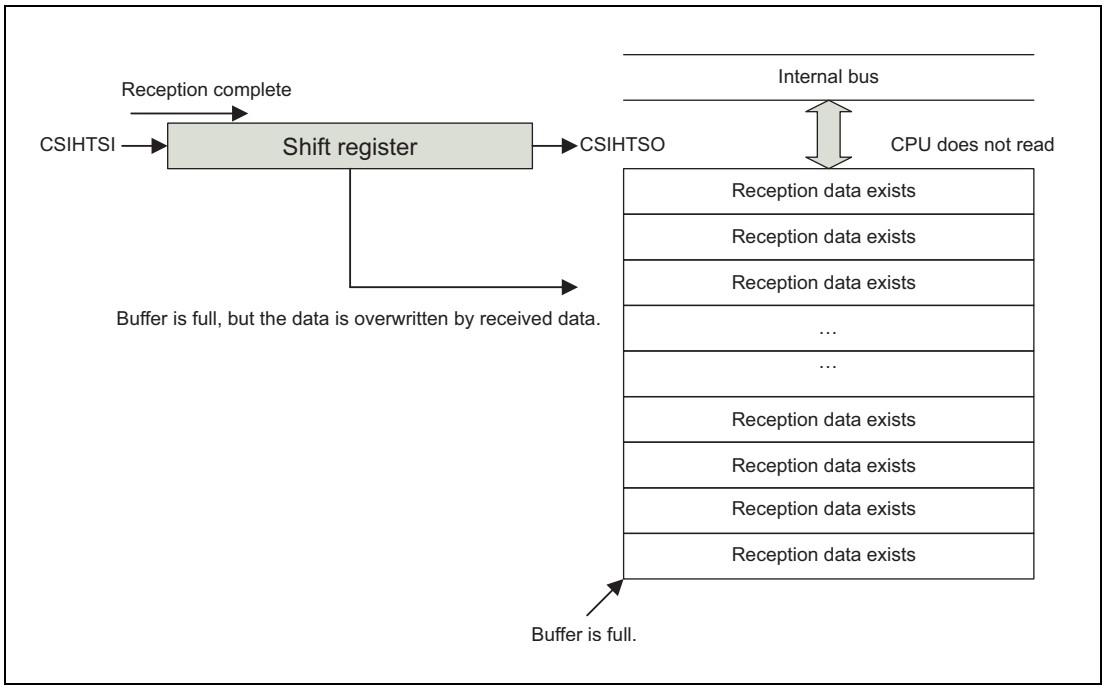

Figure 19.42 Overrun Error Detection in FIFO Mode (FIFO Full)

In FIFO mode, an overrun error is generated only when using received-only mode.

NOTE

An overrun error can be avoided in slave mode by using the handshake function. When handshake is used in slave mode, the receiver (slave) signals to the transmitter (master) that it is busy. The transmitter then waits until the receiver has read its reception register and is ready again.

2. The CPU attempts to read non existing reception data.

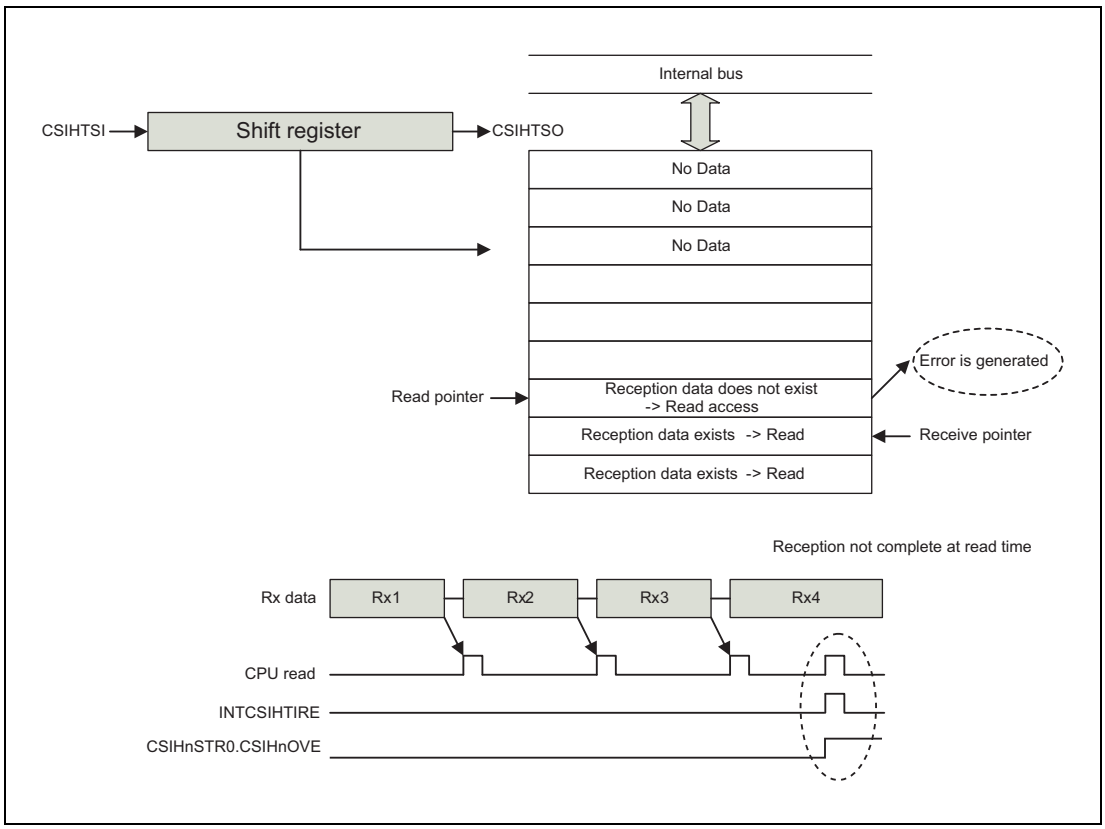

Figure 19.43 Overrun Error Detection in FIFO Mode (No Data)

In case of overrun error:

- Interrupt INTCSIHTIRE is generated.
- The CSIHnSTR0.CSIHnOVE bit is set.
- Received data is overwritten and the communication continues.
  (When the CPU tries to read non-existent data, the CPU starts reading again after a wait until reception is completed.)

For details see Section 19.5.11, Handshake Function.

19.5.13 Loop-Back Mode

Loop-back mode is a special mode for self-test. This feature is only available in master mode.

When this mode is active (CSIHnCTL1.CSIHnLBM = 1), CSIHTCSSx is fixed to the inactive level (the active level is defined by the CSIHnCTL1.CSIHnCSLx value). The transmit and receive signals are internally connected, as shown in the figures below.

The signals CSIHTSCK, CSIHTSO, and CSIHTSI are disconnected from the ports. In addition, the CSIHTSO output level is fixed to low, and CSIHTSCK is set to reset level (High) regardless of the value of the CSIHnCFGx.CSIHnCKPx. The rest of CSIH works as in normal operation.

In order to test CSIH, put it in loop-back mode and carry out normal transfer operations. Then check that the received data is the same as the transmitted data. Any connected device remains unaffected by the loop-back test.

Table 19.45 Pin Output Level in Loop-Back Mode

Pin Name	Output level
CSIHTSCK(out)	High level
CSIHTCSS[7:0]	Inactive level
CSIHTSO	Low level (not dependent on the previous value)
Interrupt	Normal function
CSIHTRYO	Normal function (Low level)

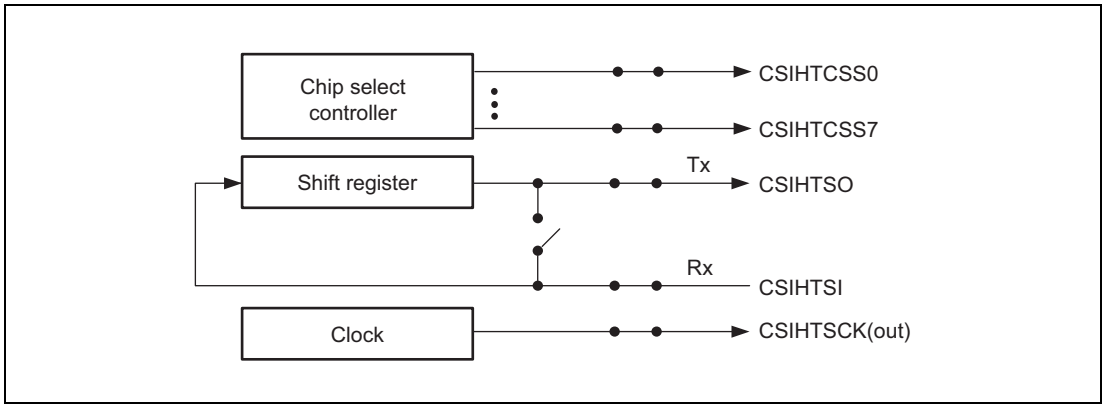

Figure 19.44 Normal Operation

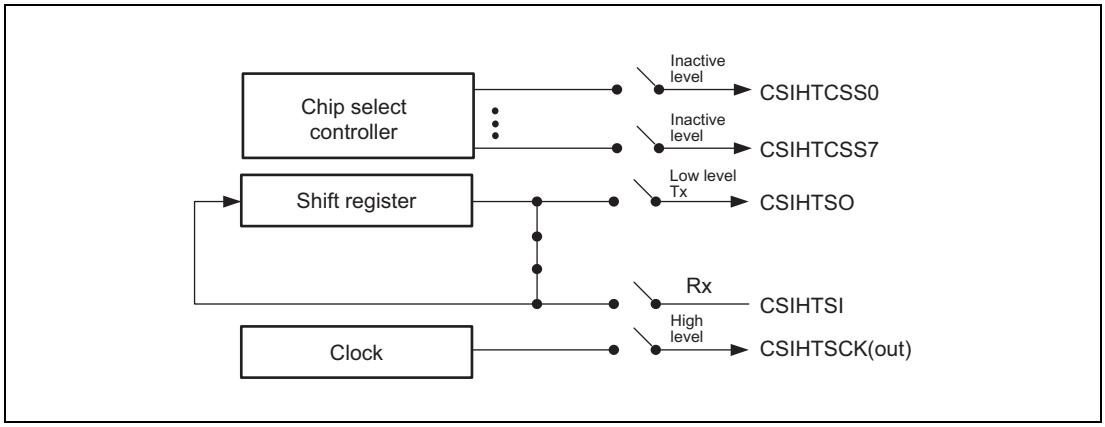

Figure 19.45 Loop-Back Mode Operation

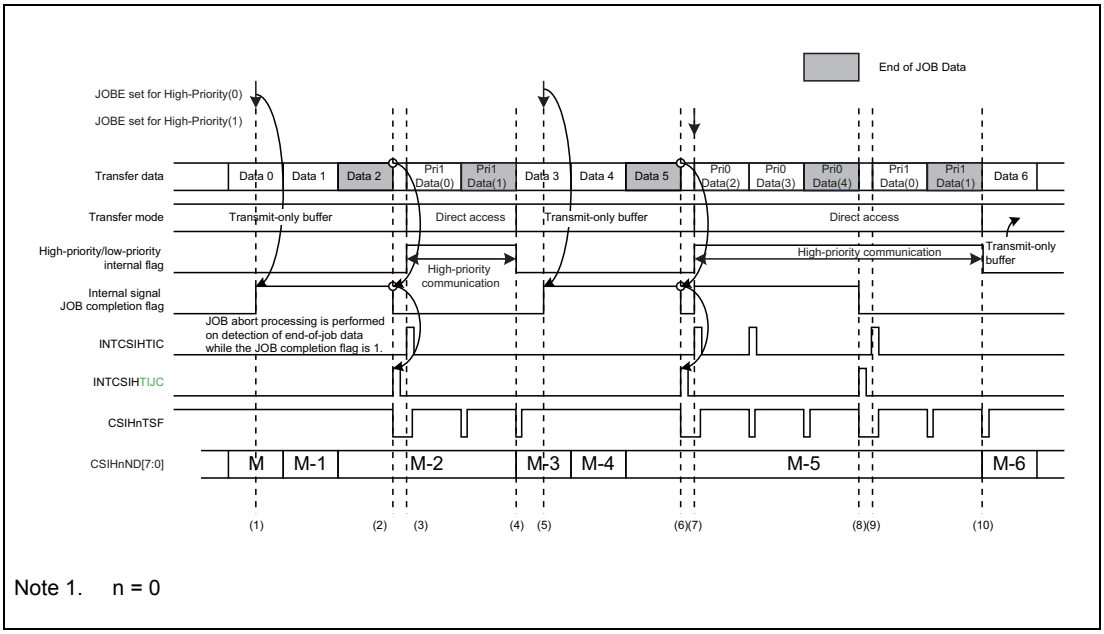
19.5.14 CPU-Controlled High Priority Communication Function (CSIH0 only)

CSIH has a function to abort low priority communication to perform high priority communication if it receives a high-priority communication request from the CPU while low-priority communication is being used. This function supports transmit-only buffer mode as low priority communication and direct access mode as high-priority communication only. To enable this function, CSIH0CTL1.CSIH0PHE and CSIH0CTL1.CSIH0JE must be set to 1.

The following figure illustrates CPU-controlled high-priority communication.



Note 1. n = 0

Figure 19.46 Example of CPU-Controlled High-Priority Communication

(1) By setting CSIH0CTL0.CSIH0JOBE = 1 during low-priority communication, start of high-priority communication following end-of-job data is notified, and the internal signal flag is set.

(2) When end-of-job data is detected, the current low-priority communication is aborted and the INTCSIH0TIJS interrupt occurs. An internal signal, the JOB completion flag is cleared due to the abort of communication, and memory mode is automatically switched to direct access mode for the subsequent high-priority communication.

(3) The CPU detects the interrupt and starts communication by writing the first transmission data of high-priority communication to CSIH0TX0W or CSIH0TX0H.

(4) When end-of-job data is detected, communication is aborted. At this time, because the internal signal, end-of-job flag is set to 0, the CSIH determines that the next communication is low-priority and switches memory mode to transmit-only buffer mode automatically, and then resumes the aborted low-priority communication.

(5) Same as (1) above.

(6) Same as (2) above.

(7) The CPU detects an interrupt and starts communication by writing the first transmission data of high-priority communication to CSIH0TX0W or CSIH0TX0H. The CPU sets CSIH0CTL0.CSIH0JOBE = 1 again to notify that the next communication is high-priority.

(8) When end-of-job data is detected, communication is aborted and the INT_CSIH0TIJC interrupt is generated. At this time, the CPU determines that the subsequent communication is high-priority because the internal signal JOB completion flag is 1, and waits for communication to start.

(9) Same as (3) above.

(10) Same as (4) above.

CAUTION

Memory mode is switched automatically when communication is changed from low priority to high priority (switch from transmit-only buffer mode to direct access mode) and from high priority to low priority (switch from direct access mode to transmit-only buffer mode).

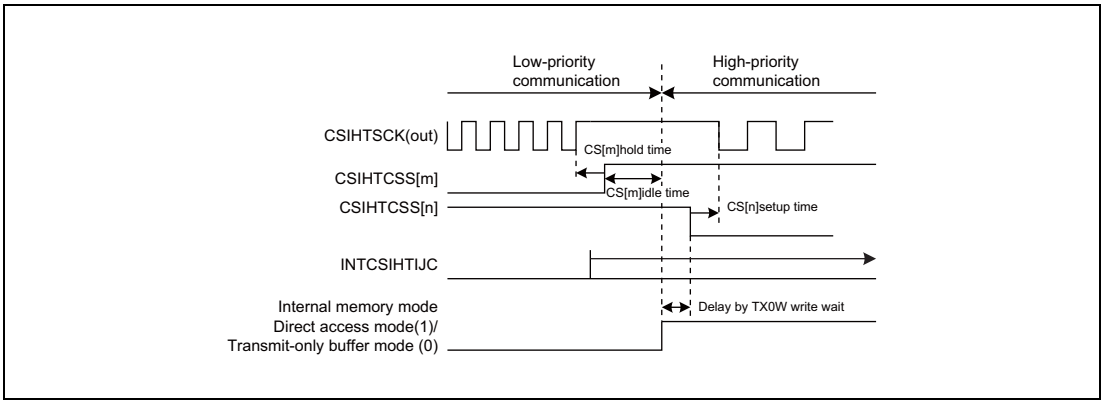


Figure 19.47 Transition from Low-Priority Mode to High-Priority Mode

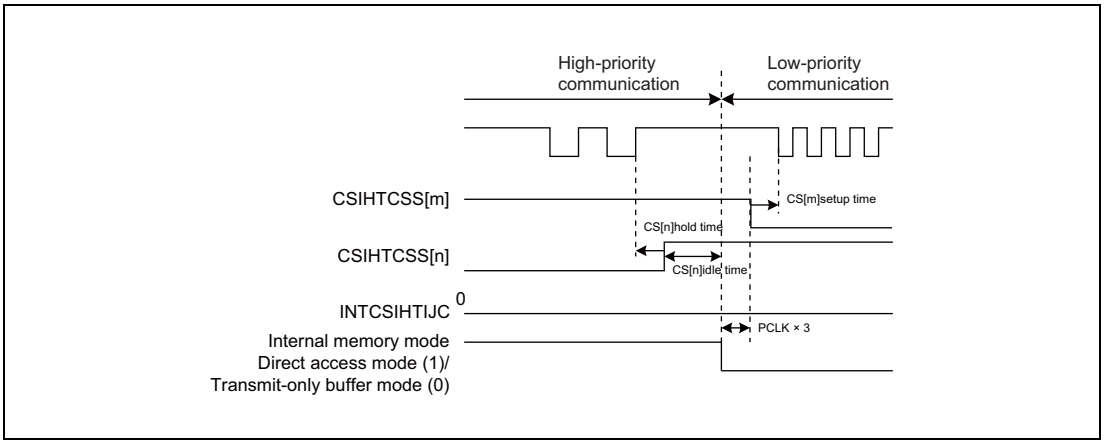

Figure 19.48 Transition from High-Priority Mode to Low-Priority Mode

Do not conduct write operation of communication data or CSIH0CTL0.CSIH0JOBE bit operation during setting prohibit period to switch low and high priority communication mode correctly.

CSIH0TX0W register write inhibited period:

- Period from when CSIH0JOBE bit is set for switching to high priority communication mode to when CSIHTIJC interrupt is detected.
- Period from when the last data of high priority communication (End of JOB data) is written to when the CSIH0HPST state = 0 is detected.

CSIH0JOBE register write inhibited period:

- Period from when CSIH0JOBE bit is set for switching to high priority communication mode to when INTCSIHTIJC interrupt is detected.

During high communication mode period, there is no setting prohibit period for CSIH0JOBE bit. It is possible to set CSIH0JOBE bit before writing communication data. For example, to communicate multiple JOB data in high priority mode, it is possible to set CSIH0JOBE bit before writing the first communication data.

CAUTION

For CSIH0 only:
When CSIH0JOBE bit is set right before the last communication of high priority communication ends, different operations are required depending on the internal detection timing of CSIH0JOBE bit setting. When CSIH0JOBE bit setting is detected before the last bit communication, high priority communication mode continues.

When setting of the CSIH0JOBE bit is detected after the transfer of the last bit is completed, the mode temporarily returns to low priority communications. After detection of End of JOB data in low priority communications, the mode changes back to high priority communications.

19.5.15 Enforced Chip Select Idle Setting

This macro is able to insert an idle state between the two consecutive transfer data by the setting of CSIHnCFGx.CSIHnIDLx. Detail is as follows.

1. When CSIHnCFGx.CSIHnIDLx = 0
   If a next CSIHTCSSx is the same as the previous one, an idle state is not inserted and an inter-data time is inserted.
   If a next CSIHTCSSx is different from the previous one, an idle state is inserted.
2. When CSIHnCFGx.CSIHnIDLx = 1
   An idle state is always inserted even if a next CSIHTCSSx is not different from the previous one.

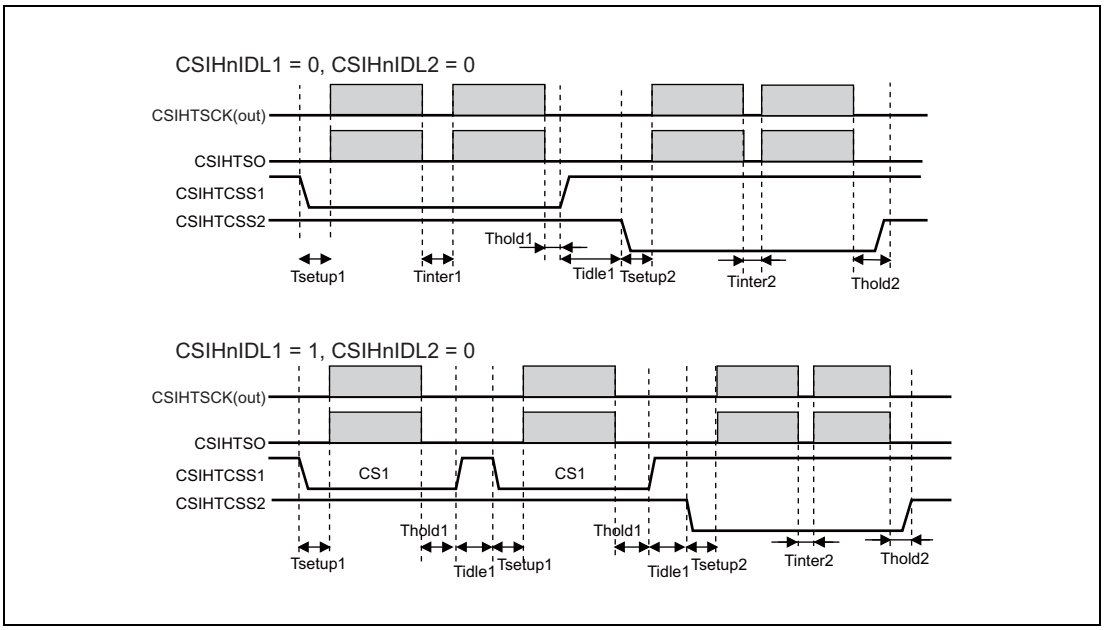

Figure 19.49 Enforced Chip Select Idle Example

CAUTION

CSIH0 only: If high priority communication function controlled by CPU is validated (CSIHnCTL1.CSIHnPHE = 1), when switch from low priority communication mode to high priority communication mode or switch from high priority communication mode to low priority communication mode, IDLE state is inserted regardless of the setting of IDLx bit.

19.6 Operating Procedures

The examples and procedures below are described according to the memory mode in the following order:

- Direct access mode
- Transmit-only buffer mode
- Dual buffer mode
- FIFO mode

19.6.1 Procedures in Direct Access Mode

Two examples for a master are provided, one with job mode disabled, and the other one with job mode enabled.

19.6.1.1 Transmit/Receive in Master Mode when Job Mode is Disabled

The procedures below is based on the assumption that:

- The transmission data length is 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = $1000_{B)}$.
- Transmission direction is MSB first (CSIHnCFGx.CSIHnDIRx = 0).
- Normal clock and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Job mode is disabled (CSIHnCTL1.CSIHnJE = 0).
- Normal INTCSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Direct access mode (CSIHnCTL0.CSIHnMBS = 1)

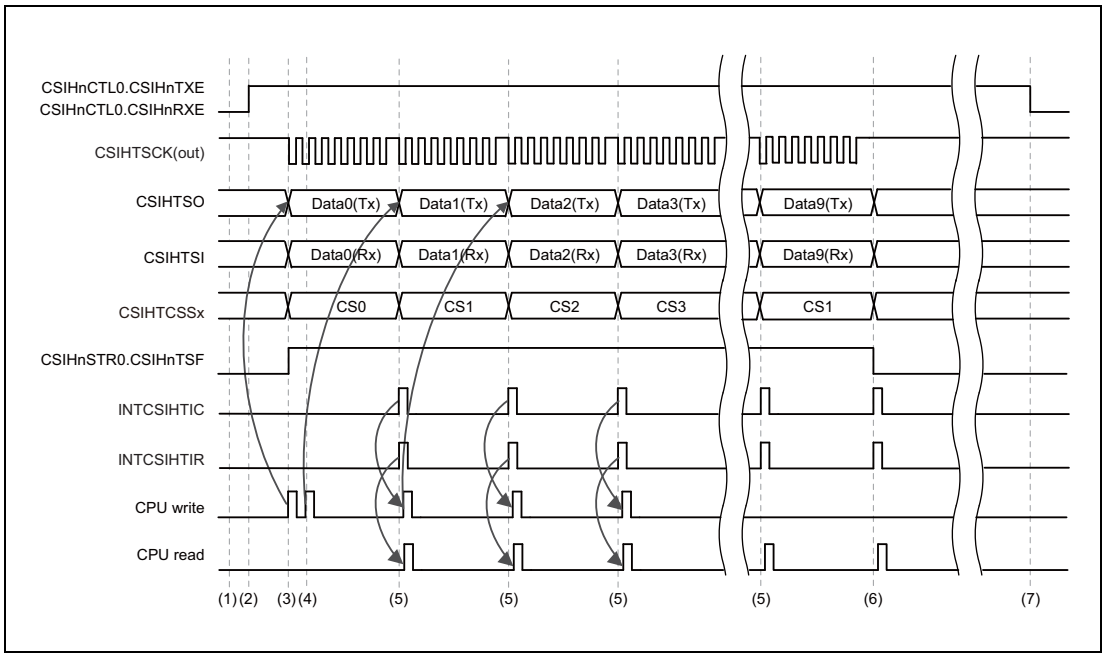

Figure 19.50 Master in Direct Access Mode, CSIHnCTL1.CSIHnJE = 0

Procedure:

1. Configure the communication protocol in the CSIHnCFGx register. This example uses chip select signals CSIHTCSS0 to CSIHTCSS3.
   Specify the transfer mode and job mode by setting the corresponding bits in registers CSIHnCTL1 and CSIHnCTL2.
2. In the CSIHnCTL0 register, set CSIHnPWR = 1 (enables the clock), CSIHnTXE = 1 (permits transmission), CSIHnRXE = 1 (permits reception), and CSIHnMBS = 1 (Direct access mode selection).
3. Write the first data to be sent to the transmission register, CSIHnTX0W. Within the same write operation, activate CS0. Transmission starts automatically when the first data becomes available.
4. Write the second data to CSIHnTX0W. If required, you can change the CS to address a different device. Writing the second data immediately after the first one avoids unnecessary delays between the data.
5. After every transmission of a data the interrupts INTCSIHTIC and INTCSIHTIR are generated:
   – INTCSIHTIC indicates that the next data can be written to CSIHnTX0W.
   – INTCSIHTIR indicates that the reception register, CSIHnRX0W must be read.
6. No more write action is required after completion of data 8. data 9 (the last data) has been written in advance.
   However, reception register CSIHnRX0W must be read after completion of writing data 8 and 9.
7. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to prohibit the transmit/receive operation. When no communication is conducted, set CSIHnCTL0.CSIHnPWR to 0 to minimize power consumption of the CSIHn.

19.6.1.2 Transmit/Receive in Master Mode when Job Mode is Enabled

The procedure below is based on the assumption that:

- The transmission data length is 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B).
- Transmission direction is MSB first (CSIHnCFGx.CSIHnDIRx = 0).
- Normal phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Job mode is enabled (CSIHnCTL1.CSIHnJE = 1).
- Normal INTCSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Direct access mode (CSIHnCTL0.CSIHnMBS = 1)
- Two jobs, each of them sends three data.

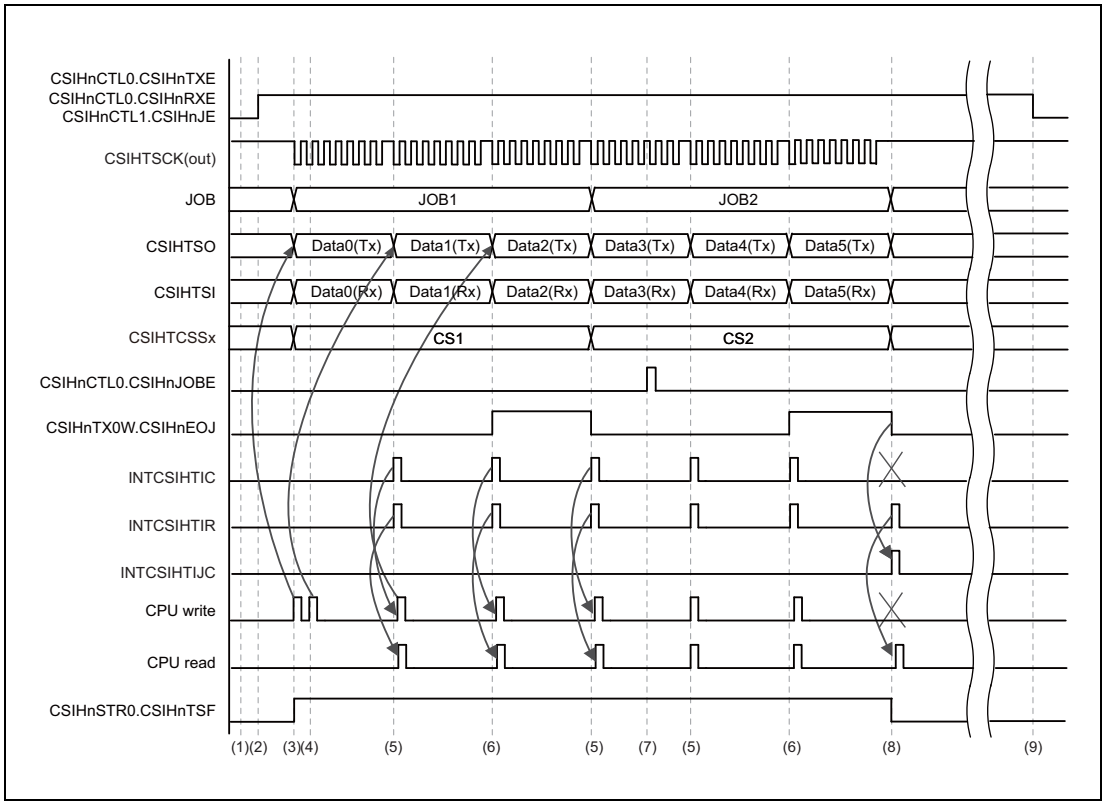

Figure 19.51 Master in Direct Access Mode, CSIHnCTL1.CSIHnJE = 1

Procedure:

1. Configure the communication protocol in the CSIHnCFGx register. This example uses chip select signals CS1 to CS2.
   Specify the transfer mode and job mode by setting the corresponding bits in registers CSIHnCTL1 and CSIHnCTL2.
2. In the CSIHnCTL0 register, set the bits CSIHnPWR = 1 (enables the clock), CSIHnTXE = 1 (permits transmission), CSIHnRXE = 1 (permits the reception), and CSIHnMBS = 1 (selects direct access mode).
3. Write the first data to be sent to the transmission register CSIHnTX0W. Transmission starts automatically when the first data becomes available.
   The CSIHnSTR0.CSIHnTSF flag indicates that communication is in progress.
4. Write the second data to CSIHnTX0W. Writing the second data immediately after the first one avoids unnecessary delays between the data.
5. After every data transmission/reception, the interrupt requests INTCSIHTIC and INTCSIHTIR are generated.
   - INTCSIHTIC indicates that the next data can be written to CSIHnTX0W.
   - INTCSIHTIR indicates that the reception register, CSIHnRX0W must be read.
6. Setting CSIHnTX0W.CSIHnEOJ = 1 indicates that the last data of the current job is sent. After that, the next job may begin.
7. By setting CSIHnCTL0.CSIHnJOBE = 1, communication is forced to stop at the end of the current job (JOB2).

8. After the forced stop of communication, the interrupt request, INTCSIHTIC is replaced by INTCSIHTIJC. INTCSIHTIR is generated as usual.
   The interrupt request, INTCSIHTIJC indicates a forced stop of communication at the end of the current job.
   The interrupt request, INTCSIHTIC is not generated. Additionally, the transmission data available in the CSIHnTX0W register is not sent.
9. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to prohibit the transmit/receive operation. When no communication is conducted, set CSIHnCTL0.CSIHnPWR to 0 to minimize power consumption of the CSIHn.
   To start another transmission without stopping communication, perform steps 3 and later.

19.6.2 Procedures in Transmit-Only Buffer Mode

Two examples for a master is provided, one with job mode disabled, and the other one with job mode enabled.

19.6.2.1 Transmit/Receive in Master Mode when Job Mode is Disabled

The procedure below is based on the assumption that:

- The transmission data length is 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B).
- The transmission direction is MSB first (CSIHnCFGx.CSIHnDIRx = 0).
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Job mode is disabled (CSIHnCTL1.CSIHnJE = 0).
- The number of data is 9 (CSIHnMCTL2.CSIHnND[7:0] = 09_H).
- The transfer start address is 10_H (CSIHnMCTL2.CSIHnSOP[6:0] = 10_H).
- Normal INTCSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Transmit-only buffer mode (CSIHnCTL0.CSIHnMBS = 0,CSIHnMCTL0.CSIHnMMS[1:0] = 10_B)

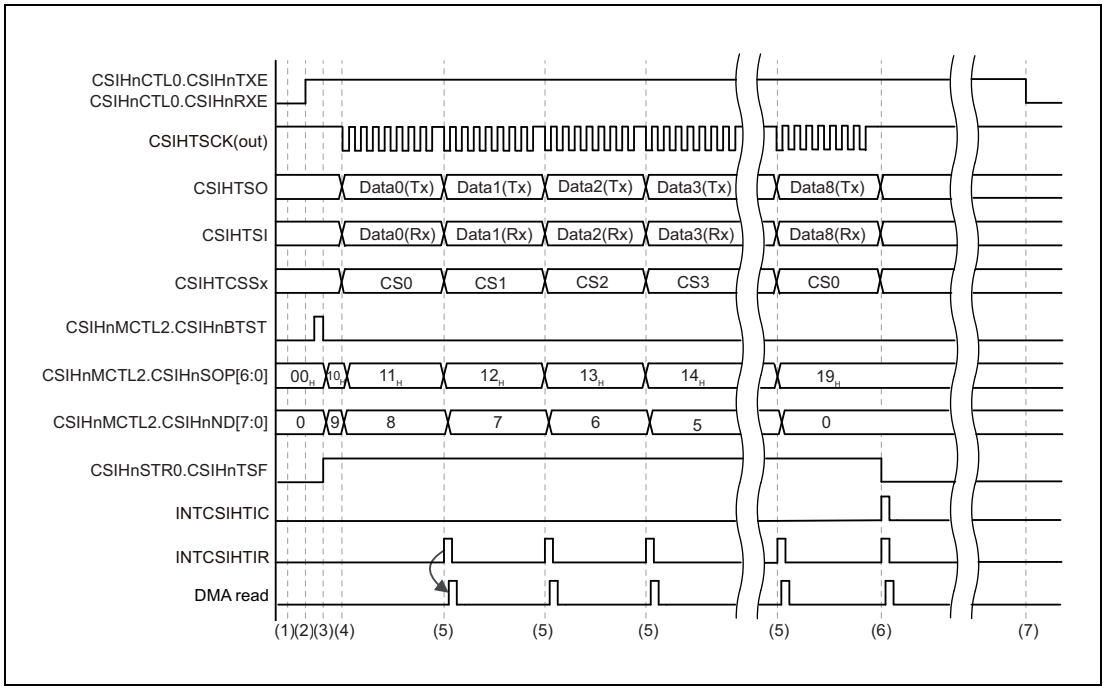

Figure 19.52 Master in Transmit-Only Buffer Mode, CSIHnCTL1.CSIHnJE = 0

NOTE

The procedure of writing the data into the buffer is not described.

Procedure:

1. Configure the communication protocol in the CSIHnCFGx register. This example uses chip select signals CSIHTCSS0 to CSIHTCSS3.
   Specify the transfer and operating modes by setting the corresponding bits in registers CSIHnCTL1 and CSIHnCTL2.
   Configure the memory mode in CSIHnMCTL0.CSIHnMMS[1:0].
   Set CSIHnMCTL0.CSIHnMMS[1:0] = 10_B (transmit-only buffer mode).
2. In the CSIHnCTL0 register, set CSIHnPWR = 1 (enables the clock), CSIHnTXE = 1 (permits transmission), and CSIHnRXE = 1 (permits reception). The CSIHnCTL0.CSIHnMBS bit must be cleared.
3. Configure the send pointer and the number of data by setting the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits. Start the buffer transfer by setting CSIHnMCTL2.CSIHnBTST.
4. Transmission/reception is started. The CSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented after each data transmission.
5. After every data reception, the interrupt request, INTCSIHTIR is generated. INTCSIHTIR indicates that the reception register, CSIHnRX0W must be read.
6. When all transmissions are complete, the interrupt request, INTCSIHTIC is generated.

7. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to prohibit the transmit/receive operation. When no communication is conducted, set CSIHnCTL0.CSIHnPWR to 0 to minimize power consumption of the CSIHn.

19.6.2.2 Transmit/Receive in Master Mode when Job Mode is Enabled

The procedure below is based on the assumption that:

- The transmission data length is 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B).
- The transmission direction is MSB first (CSIHnCFGx.CSIHnDIRx = 0).
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Job mode is enabled (CSIHnCTL1.CSIHnJE = 1).
- The number of data is 8 (CSIHnMCTL2.CSIHnND[7:0] = 08_H).
- The transfer start address is 10_H (CSIHnMCTL2.CSIHnSOP[6:0] = 10_H).
- Normal INTCSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Transmit-only buffer mode (CSIHnCTL0.CSIHnMBS = 0,CSIHnMCTL0.CSIHnMMS[1:0] = 10_B)

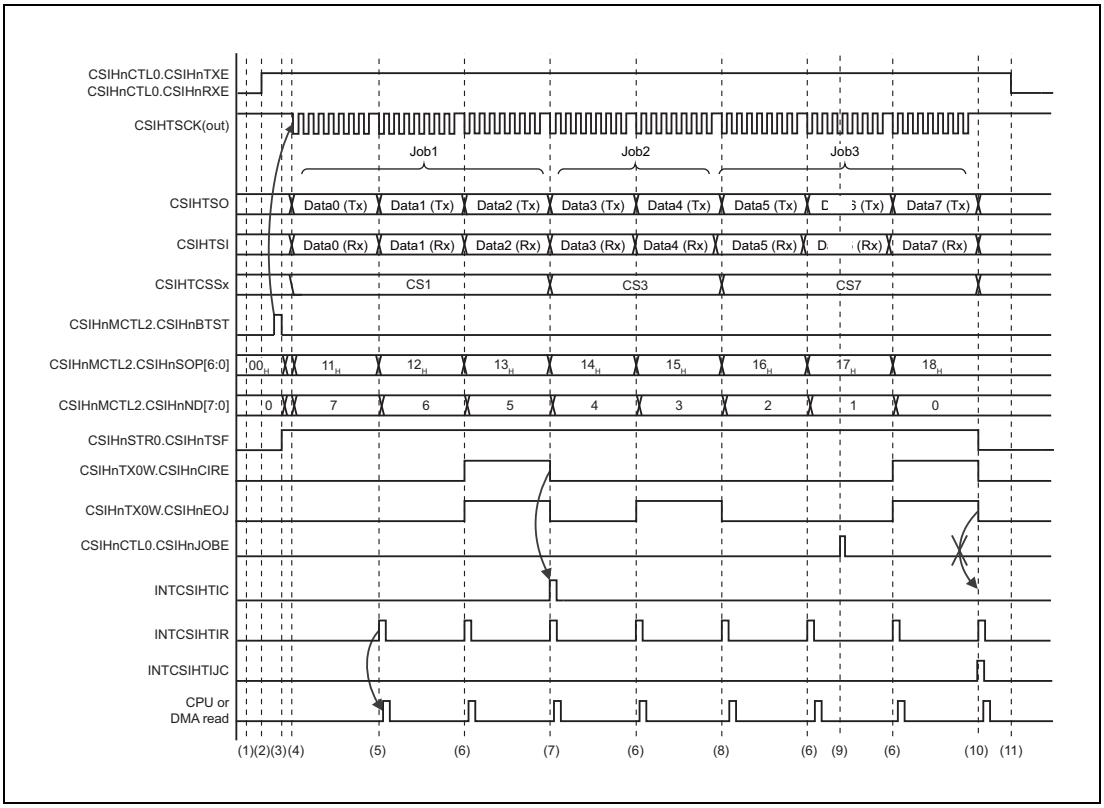

Figure 19.53 Master in Transmit-Only Buffer Mode, CSIHnCTL1.CSIHnJE = 1

NOTE

The process of writing the data into the buffer is not described.

Procedure:

1. Configure the communication protocol in the CSIHnCFGx register. This example uses chip select signals CSIHTCSS0, CSIHTCSS3, and CSIHTCSS7.
   Specify the transfer mode and job mode by setting the corresponding bits in registers CSIHnCTL1 and CSIHnCTL2.
   Configure the memory mode in CSIHnMCTL0.CSIHnMMS[1:0].
   Set CSIHnMCTL0.CSIHnMMS[1:0] = 10_B (transmit -only buffer mode).
2. In the CSIHnCTL0 register, set CSIHnPWR = 1 (enables the clock), CSIHnTXE = 1 (permits transmission), and CSIHnRXE = 1 (permits reception). The CSIHnCTL0.CSIHnMBS bit must be cleared.
3. Configure the send pointer and the number of data by setting the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits. Start the buffer transfer by setting CSIHnMCTL2.CSIHnBTST.
4. Transmission is started. The CSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented after each data transmission.
5. After every data reception, the interrupt request, INTCSIHTIR is generated. INTCSIHTIR indicates that the reception register, CSIHnRX0W must be read.
6. The CSIHnTX0W.CSIHnEOJ = 1 setting indicates that the last data of the current job is sent.
7. The interrupt request INTCSIHTIC is generated. INTCSIHTIC indicates that the last data of the current job (CSIHnTX0W.CSIHnEOJ = 1) was sent with CSIHnTX0W.CSIHnCIRE = 1.
8. The INTCSIHTIC interrupt request is not generated because the last data of the current job (CSIHnTX0W.CHABnEOJ = 1) was sent with CSIHnTX0W.CSIHnCIRE = 0.
9. By setting CSIHnCTL0.CSIHnJOBE = 1, communication is forced to stop at the end of JOB3.
10. After the forced stop of communication, interrupt requests INTCSIHTIJC and INTCSIHTIR are generated at the end of job3.
    The INTCSIHTIJC interrupt request indicates a forced stop of communication at the end of the current job.
    The INTCSIHTIC interrupt request is not generated because the INTCSIHTIJC interrupt request is generated instead of the INTCSIHTIC interrupt request. Additionally, the transmission data available in the CSIHnTX0W register is not sent.
11. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to prohibit the transmit/receive operation. When no communication is conducted, set CSIHnCTL0.CSIHnPWR to 0 to minimize power consumption of the CSIHn.

19.6.3 Procedures in Dual Buffer Mode

Examples when job mode is enabled in master mode, disabled in master mode, and disabled in slave mode are provided below.

19.6.3.1 Transmit/Receive in Master Mode when Job Mode is Disabled

The procedure below is based on the assumption that:

- The transmission data length is 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B).
- The transmission direction is MSB first (CHABnCFGx.CSIHnDIRx = 0).
- Default clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Job mode is disabled (CSIHnCTL1.CSIHnJE = 0).
- The number of data is 9 (CSIHnMCTL2.CSIHnND[7:0] = 09_H).
- The transfer start address is 10_H (CSIHnMCTL2.CSIHnSOP[6:0] = 10_H).
- Normal INTCSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Dual buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 01_B)

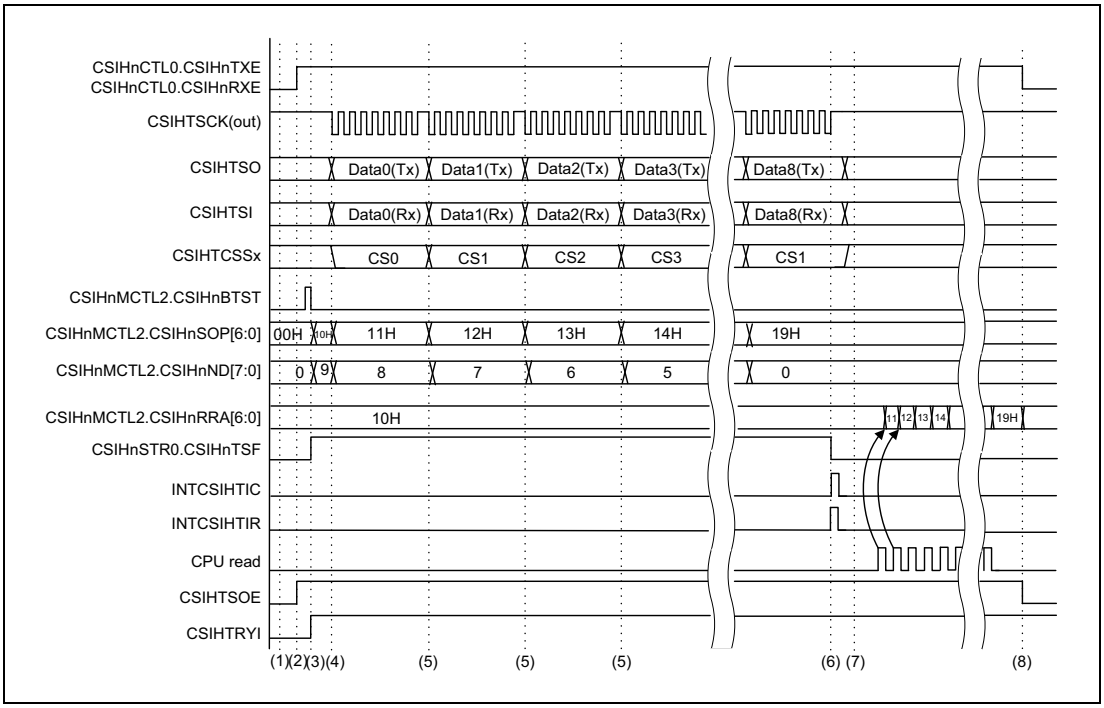

Figure 19.54 Master in Dual Buffer Mode, CSIHnCTL1.CSIHnJE = 0

NOTE

The process of writing the data into the buffer is not described.

Procedure:

1. Configure the communication protocol in the CSIHnCFGx register. This example uses chip select signals CSIHTCSS0 to CSIHTCSS3.
   Specify the transfer and operating modes by setting the corresponding bits in registers CSIHnCTL1 and CSIHnCTL2.
   Configure the memory mode in CSIHnMCTL0.CSIHnMMS[1:0]. Set CSIHnMCTL0.CSIHnMMS[1:0] = 01_B (dual buffer mode).
2. In the CSIHnCTL0 register, set CSIHnPWR = 1 (enables the clock), CSIHnTXE = 1 (permits transmission), and CSIHnRXE = 1 (permits the reception). The CSIHnCTL0.CSIHnMBS bit must be cleared.
3. Configure communication by setting the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits. Permit buffer transfer by setting CSIHnMCTL2.CSIHnBTST.
4. Transmission is started. TheCSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented after each data transmission.
5. This is repeated until the last data is transmitted/received.
   The interrupt requests, INTCSIHTIC and INTCSIHTIR are not generated.
6. When the last data is transmitted/received, the interrupt requests, INTCSIHTIC and INTCSIHTIR are generated.
   The CPU starts to read the received data from the receive buffer.
7. The start address of the read access is specified in CSIHnMRWP0.CSIHnRRA[6:0] (CSIHnRRA[6:0] is set to 10_H by the software in this figure). These bits are incremented after the reading of every data.
8. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to prohibit the transmit/receive operation. When no communication is conducted, set CSIHnCTL0.CSIHnPWR to 0 to minimize power consumption of the CSIHn.

19.6.3.2 Transmit/Receive in Master Mode when Job Mode is Enabled

The procedure below is based on the assumption that:

- The transmission data length is 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B).
- The transmission direction is MSB first (CSIHnCFGx.CSIHnDIRx = 0).
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Job mode is enabled (CSIHnCTL1.CSIHnJE = 1).
- The number of data is 8 (CSIHnMCTL2.CSIHnND[7:0] = 08_H).
- The transfer start address is 00_H (CSIHnMCTL2.CSIHnSOP[6:0] = 00_H).
- Normal INTCSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Dual buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 01_B)

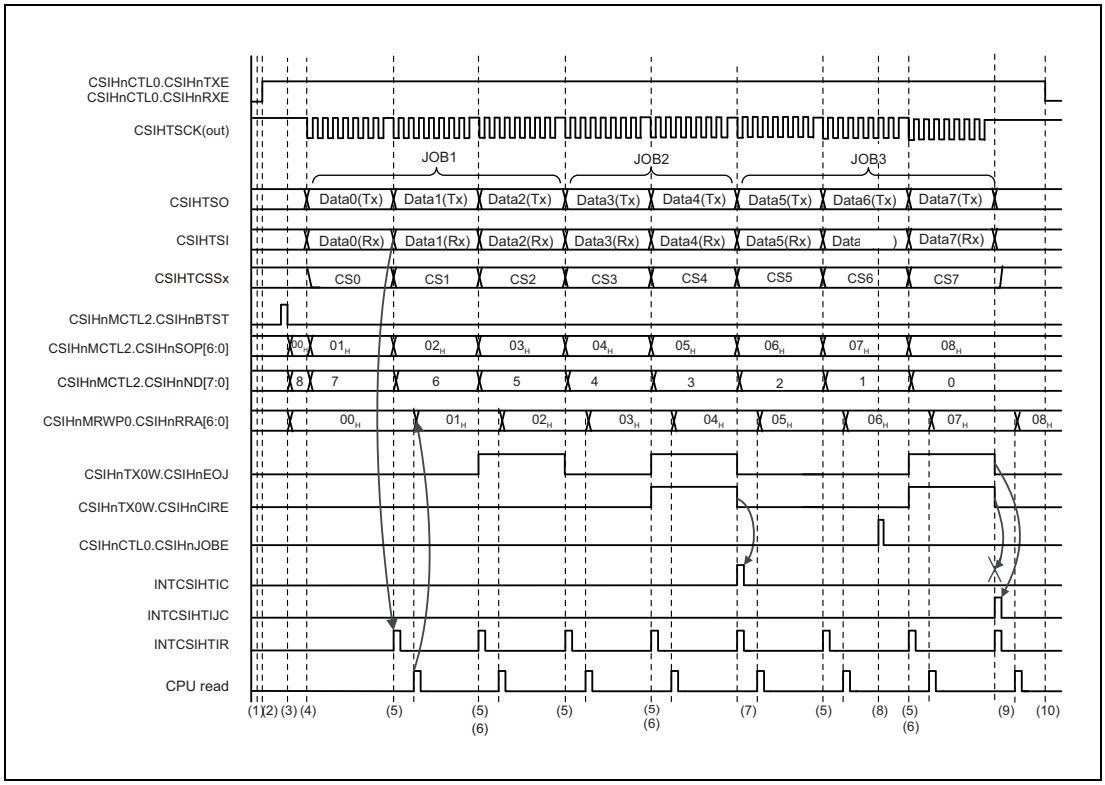

Figure 19.55 Master in Dual Buffer Mode, CSIHnCTL1.CSIHnJE = 1

NOTE

The process of writing the data into the buffer is not described.

Procedure:

1. Configure the communication protocol in the CSIHnCFGx register. This example uses chip select signals CSIHTCSS0 to CSIHTCSS7.
   Specify the transfer and operating modes by setting the corresponding bits in registers CSIHnCTL1 and CSIHnCTL2.
   Configure the memory mode in CSIHnMCTL0.CSIHnMMS[1:0].
   Set CSIHnMCTL0.CSIHnMMS[1:0] = 01_B (dual buffer mode).
2. In the CSIHnCTL0 register, set CSIHnPWR = 1 (enables the clock), CSIHnTXE = 1 (permits transmission), and CSIHnRXE = 1 (permits the reception). The CSIHnCTL0.CSIHnMBS bit must be cleared.
3. Configure communication by setting the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits. Start the buffer transfer by setting CSIHnMCTL2.CSIHnBTST.
4. Transmission is started.
   TheCSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented, and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented after each data transmission. This is repeated until the last data is transmitted/received.

5. The INTCSIHTIR interrupt request is generated everytime a data is received.
   The INTCSIHTIC interrupt request is not generated because the last data of the current job (CSIHnTX0W.CSIHnEOJ = 1) was sent with CSIHnTX0W.CSIHnCIRE = 0.
6. CSIHnTX0W.CSIHnEOJ = 1 indicates that the last data of the current job is sent.
7. The INTCSIHTIC interrupt request is generated. INTCSIHTIC indicates that the last data of the current job (CSIHnTX0W.CSIHnEOJ = 1) was sent with CSIHnTX0W.CSIHnCIRE = 1.
8. By setting CSIHnCTL0.CSIHnJOBE = 1, communication is forced to stop at the end of JOB3.
9. After the forced stop of communication, interrupt requests, INTCSIHTIJC and INTCSIHTIR are generated at the end of JOB3.
   The INTCSIHTIJC interrupt request indicates a forced stop of communication at the end of the current job.
   The INTCSIHTIC interrupt request is not generated because the INTCSIHTIJC interrupt request is generated instead of the INTCSIHTIC interrupt request. Additionally, the transmission data available in register CSIHnTX0W is not sent.
10. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to prohibit the transmit/receive operation. When no communication is conducted, set CSIHnCTL0.CSIHnPWR to 0 to minimize power consumption of the CSIHn.

19.6.3.3 Transmit/Receive in Slave Mode when Job Mode is Disabled

The procedure below is based on the assumption that:

- The transmission data length is 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B).
- The transmission direction is MSB first (CSIHnCFGx.CSIHnDIRx = 0).
- Normal clock phase and data phase (CSIHnCTL1.CSIHnCKR = 0, CSIHnCFG0.CSIHnDAP0 = 0)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Job mode is disabled (CSIHnCTL1.CSIHnJE = 0).
- The number of data is 9 (CSIHnMCTL2.CSIHnND[7:0] = 09_H).
- The transfer start address is 10_H (CSIHnMCTL2.CSIHnSOP[6:0] = 10_H).
- Dual buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 01_B)
- Handshake function enable (CSIHnCTL1.CSIHnHSE = 1)
- Normal INTCSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

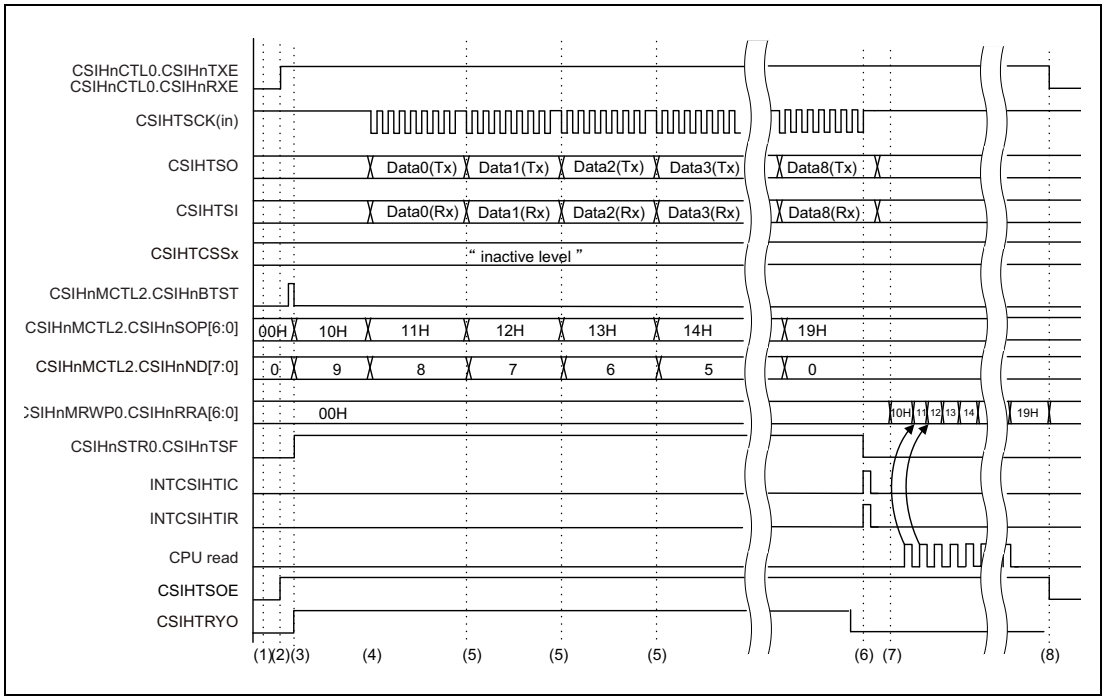

Figure 19.56 Slave in Dual Buffer Mode, CSIHnCTL1.CSIHnJE = 0

NOTE

The process of writing the data into the buffer is not described.

Procedure:

1. Configure the communication protocol in register CSIHnCFG0.
   Specify the transfer and operating modes by setting the corresponding bits in registers CSIHnCTL1 and CSIHnCTL2.
   Configure the memory mode in CSIHnMCTL0.CSIHnMMS[1:0].
   Set CSIHnMCTL0.CSIHnMMS[1:0] = 01_B (dual buffer mode).
2. In the CSIHnCTL0 register, set CSIHnPWR = 1 (enables the clock), CSIHnTXE = 1 (permits transmission), and CSIHnRXE = 1 (permits the reception). The CSIHnCTL0.CSIHnMBS bit must be cleared.
3. Specify the transfer start address by setting the CSIHnMCTL2.CSIHnSOP[6:0] bits and the number of data by setting the CSIHnMCTL2.CSIHnND[7:0] bits. Permit the buffer transfer by setting CSIHnMCTL2.CSIHnBTST.
4. Transmission is started when the input clock from the master is received. The CSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented after each data transmission.
5. This is repeated until the last data is transmitted/received.
   The interrupt requests, INTCSIHTIC and INTCSIHTIR are not generated because transmission data is sent from the buffer, and received data is stored in the buffer.
6. When the last data is transmitted/received, the interrupt requests, INTCSIHTIC and INTCSIHTIR are generated.
   The CPU starts to read the received data that is stored in the receive buffer.

7. The start address of the read access is specified in CSIHnMRWP0.CSIHnRRA[6:0] (CSIHnRRA[6:0] is set to 10_H by the software in this figure). These bits are incremented after the reading of every data.
8. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to prohibit the transmit/receive operation. When no communication is conducted, set CSIHnCTL0.CSIHnPWR to 0 to minimize power consumption of the CSIHn.

19.6.4 Procedures in FIFO Mode

Two examples for a master is provided, one with job mode disabled, the other one with job mode enabled.

19.6.4.1 Transmit/Receive in Master Mode when Job Mode is Disabled

The procedure below is based on the assumption that:

- The transmission data length is 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B).
- The transmission direction is MSB first (CSIHnCFGx.CSIHnDIRx = 0).
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Job mode is disabled (CSIHnCTL1.CSIHnJE = 0).
- Normal INTCSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- FIFO mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 00_B)

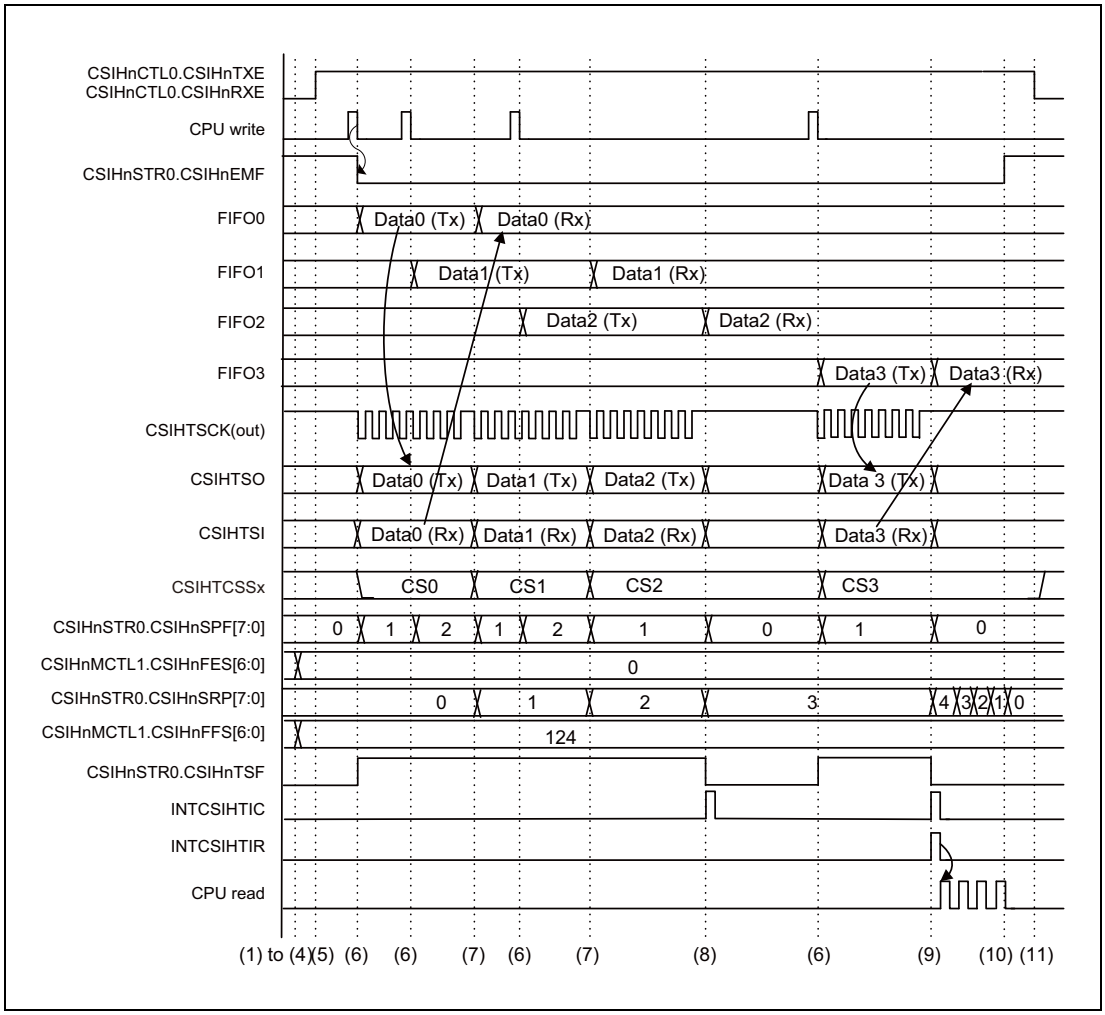

Figure 19.57 Master in FIFO Mode, CSIHnCTL1.CSIHnJE = 0

Procedure:

1. Configure the communication protocol in the CSIHnCFGx register. Specify the job mode disable and master mode by setting the corresponding bits in registers CSIHnCTL1 and CSIHnCTL2. Specify the FIFO mode by CSIHnMCTL0.CSIHnMMS[1:0] = 00B. This example uses chip select signals CSIHTCSS0 to CSIHTCSS3.
2. Set CSIHnSTCR0.CSIHnPCT = 1 to clear all buffer pointers.
3. Check that CSIHnSTR0.CSIHnFLF = 0, CSIHnSTR0.CSIHnEMF = 1, and CSIHnSTR0.CSIHnSPF[7:0] = 00_H.
4. The CSIHnMCTL1.CSIHnFES [6:0] bits specify the condition for the INTCSIHTIC interrupt output.
   The CSIHnFFS[6:0] bits in the same register specify the condition for the INTCSIHTIR interrupt.
5. Set CSIHnCTL0.CSIHnPWR = 1 (enables the clock), CSIHnTXE = 1 (permits transmission), and CSIHnRXE = 1 (permits reception). The CSIHnCTL0.CSIHnMBS bit must be cleared.

6. Write the first transmit data to the transmit register CSIHnTX0W. Transmission starts automatically when the first data becomes available.
   Check that CSIHnSTR0.CSIHnEMF = 0.
7. The current transmission is completed. As the CSIHnFES[6:0] bits are not the same as the CSIHnSPF[7:0] bits, the interrupt request INTCSIHTIC is not generated.
8. As the CSIHnFES[6:0] bits are the same as the CSIHnSPF[7:0] bits, the interrupt request INTCSIHTIC is generated.
9. When CSIHnFFS[6:0] = 128 - CSIHnSRP[7:0], the interrupt request INTCSIHTIR is generated. Since CSIHnFES[6:0] is CSIHnSPF[7:0], the interrupt request INTCSIHTIC is generated. After the generation of an interrupt, the CPU starts reading received data that is stored in the receive buffer.
10. When the CPU completes reading the received data that is stored in the receive buffer, CSIHnSTR0.CSIHnEMF is set to 1 and the FIFO buffer will be empty.
11. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to prohibit the transmit/receive operation. In addition, if communication is not performed, set CSIHnCTL0.CSIHnPWR = 0 to minimum the power consumption of CSIHn.

19.6.4.2 Transmit/Receive Mode when Job Mode is Enabled in Master Mode

The procedure below is based on the assumption that:

- The transmission data length is 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B).
- The transmission direction is MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Job mode is enabled (CSIHnCTL1.CSIHnJE = 1).
- JOB1 consists of four data, JOB2 consists of three data, and JOB3 consists of five data.
- Normal INTCSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- FIFO mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 00_B)

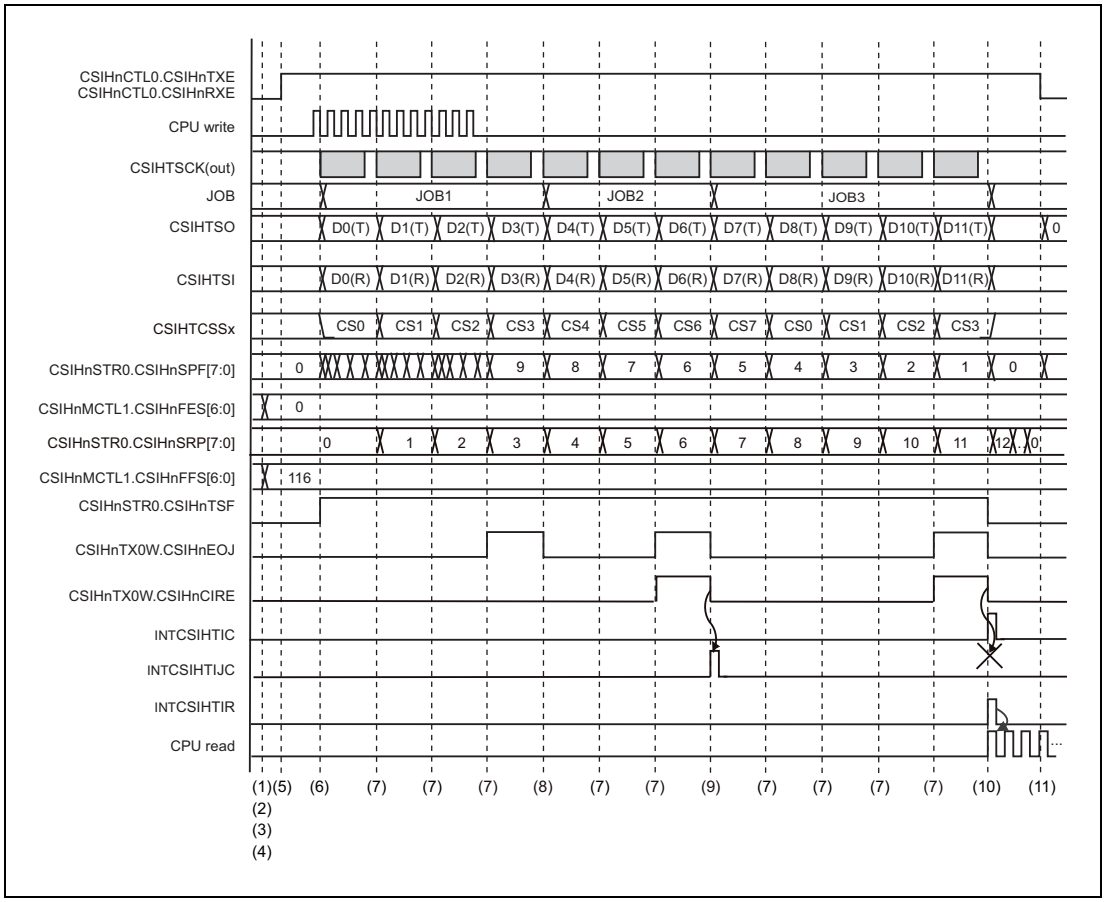

Figure 19.58 Master in FIFO Mode, CSIHnCTL1.CSIHnJE = 1

Procedure:

1. Configure the communication protocol in the CSIHnCFGx register. Set job mode disenable and master mode in the bits corresponding to CSIHnCTL1 and CSIHnCTL2 registers. Set FIFO mode by setting CSIHnMCTL0.CSIHnMMS[1:0] to 00_B. This example uses chip select signals CSIHTCSS0 to CSIHTCSS7.
2. Set CSIHnSTCR0.CSIHnPCT to 1 to clear all buffer pointers.
3. Make sure that CSIHnSTR0.CSIHnFLF is set to 0, CSIHnSTR0.CSIHnEMF is set to 1, and CSIHnSTR0.CSIHnSPF[7:0] is set to 00_H.
4. With CSIHnMCTL1.CSIHnFES[6:0], specify the conditions for generating the INTCSIHTIC interrupt request. With CSIHnMCTL1.CSIHnFFS[6:0], specify the conditions for generating the INTCSIHTIR interrupt request.
5. In the CSIHnCTL0 register, set CSIHnPWR = 1 (enables the clock), CSIHnTXE = 1 (permits transmission), and CSIHnRXE = 1 (permits reception). The CSIHnCTL0.CSIHnMBS bit must be cleared.
6. Write the first data to be sent to the CSIHnTX0W transmission register. Transmission starts automatically when the first data becomes available.
   Make sure CSIHnSTR0.CSIHnEMF is set to 0.

7. The current transmission is completed. Since CSIHnFES[6:0] is not CSIHnSPF[7:0], the interrupt request INTCSIHTIC is not generated.
8. The INTCSIHTIJC interrupt request is not generated because the last data of the current job (CSIHnTX0W.CSIHnEOJ = 1) was sent with CSIHnTX0W.CSIHnCIRE = 0.
9. The INTCSIHTIJC interrupt request is generated because the last data of the current job (CSIHnTX0W.CSIHnEOJ = 1) was sent with CSIHnTX0W.CSIHnCIRE = 1.
10. The INTCSIHTIC interrupt request is generated because CSIHnFES[6:0] is CSIHnSPF[7:0]. INTCSIHTIC is generated so that INTCSIHTIJC is not generated.
    When CSIHnFFS[6:0] is 128 - CSIHnSRP[7:0], the interrupt request INTCSIHTIR is generated. After the generation of the INTCSIHTIR interrupt, CPU starts reading the received data stored in received buffer.
11. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to prohibit the transmit/receive operation. When no communication is conducted, set CSIHnCTL0.CSIHnPWR to 0 to minimize power consumption of the CSIHn.

Section 20 LIN/UART Interface (RLIN3)

This section contains a generic description of the LIN/UART interface (RLIN3).

The first part of this section describes all RH850/D1L/D1M specific properties, such as the number of units, register base addresses, etc. The remainder of the section describes the functions and registers of RLIN3.

20.1 Features of RH850/D1L/D1M RLIN3

20.1.1 Number of Units and Channels

This microcontroller has the following number of RLIN3 units.

RLIN3 unit has one channel interface. “Number of channels” is used with the same meaning as “number of units” in this section.

Table 20.1 Number of Units

Product Name	All products
Number of units	4
Name	RLIN3n (n = 0 to 3)

Table 20.2 Unit Configurations and Channels

Unit Name (Channel Name) RLIN3n	Channels per Unit	All products
RLIN30	1	√
RLIN31	1	√
RLIN32	1	√
RLIN33	1	√

The channel names are same as those of the corresponding units.

Table 20.3 Index

Index	Meaning
n	Throughout this section, the individual RLIN3 units are identified by the index “n” (n = 0 to 3): for example, RLN3nLCUC is the LIN control register.
b	Throughout this section, the individual transmit/receive data buffers of RLIN3n are identified by the index “b” (b = 1 to 8): for example, RLN3nLDBRb is the first stage data buffer register.

The following lists the index corresponding to each product.

Table 20.4 Index Correspondence of Each Product

Index Correspondence of Each Product
All products
b = 1 to 8

20.1.2 Register Base Address

RLIN3 base addresses are listed in the following table.

RLIN3 register addresses are given as offsets from the base addresses in general.

Table 20.5 Register Base Address

Base Address Name	Base Address
<RLIN30_base>	FFCE 0000_H
<RLIN31_base>	FFCE 1000_H
<RLIN32_base>	FFCE 2000_H
<RLIN33_base>	FFCE 3000_H

20.1.3 Clock Supply

The RLIN3 clock supply is shown in the following table.

Table 20.6 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
RLIN3n	PCLK	Clock Controller C_ISO_PCLK
	LIN communication clock sources	Clock Controller C_ISO_RLIN

CAUTION

The frequency of the C_ISO_RLIN clock must not exceed the C_ISO_PCLK clock frequency. Thus the clock frequencies must fulfill following condition:

$$f_{C\_ISO\_RLIN} < f_{C\_ISO\_PCLK}$$

20.1.4 Interrupt Request

RLIN3 interrupt requests are listed in the following table.

Table 20.7 Interrupt Requests (1/2)

RLIN3n signals	Function	Connected to
RLIN30		
INTRLIN30	RLIN30 interrupt	not connected
INTRLIN30UR0	RLIN30 transmit interrupt	Interrupt Controller INTRLIN30UR0 DMA Controller trigger ID 87
INTRLIN30UR1	RLIN30 receive completion interrupt	Interrupt Controller INTRLIN30UR1 DMA Controller trigger ID 88
INTRLIN30UR2	RLIN30 status interrupt	Interrupt Controller INTRLIN30UR2
RLIN31		
INTRLIN31	RLIN31 interrupt	not connected
INTRLIN31UR0	RLIN31 transmit interrupt	Interrupt Controller INTRLIN31UR0 DMA Controller trigger ID 89
INTRLIN31UR1	RLIN31 receive completion interrupt	Interrupt Controller INTRLIN31UR1 DMA Controller trigger ID 90
INTRLIN31UR2	RLIN31 status interrupt	Interrupt Controller INTRLIN31UR2

Table 20.7 Interrupt Requests (2/2)

RLIN3n signals	Function	Connected to
RLIN32		
INTRLIN32	RLIN32 interrupt	not connected
INTRLIN32UR0	RLIN32 transmit interrupt	Interrupt Controller INTRLIN32UR0 DMA Controller trigger ID 91
INTRLIN32UR1	RLIN32 receive completion interrupt	Interrupt Controller INTRLIN32UR1 DMA Controller trigger ID 92
INTRLIN32UR2	RLIN32 status interrupt	Interrupt Controller INTRLIN32UR2
RLIN33		
INTRLIN33	RLIN33 interrupt	not connected
INTRLIN33UR0	RLIN33 transmit interrupt	Interrupt Controller INTRLIN33UR0 DMA Controller trigger ID 93
INTRLIN33UR1	RLIN33 receive completion interrupt	Interrupt Controller INTRLIN33UR1 DMA Controller trigger ID 94
INTRLIN33UR2	RLIN33 status interrupt	Interrupt Controller INTRLIN33UR2

20.1.5 Reset Sources

RLIN3 reset sources are listed in the following table. RLIN3 is initialized by these reset sources.

Table 20.8 Reset Sources

Unit Name	Reset Source
RLIN3n	• Reset Controller SYSRES • reset upon wake-up from DEEPSTOP mode

20.1.6 External Input/output Signals

External input/output signals of RLIN3 are listed below.

Table 20.9 External Input/Output Signals

Unit Signal Name	Outline	Alternative Port Pin Signal
RLIN30		
RLIN30RX	RLIN30 receive data input	RLIN30RX
RLIN30TX	RLIN30 transmit data output	RLIN30TX
RLIN31		
RLIN31RX	RLIN31 receive data input	RLIN31RX
RLIN31TX	RLIN31 transmit data output	RLIN31TX
RLIN32		
RLIN32RX	RLIN32 receive data input	RLIN32RX
RLIN32TX	RLIN32 transmit data output	RLIN32TX
RLIN33		
RLIN33RX	RLIN33 receive data input	RLIN33RX
RLIN33TX	RLIN33 transmit data output	RLIN33TX

20.2 Overview

20.2.1 Functional Overview

The LIN/UART interface is a hardware LIN communication controller that supports LIN Specification Package Revision 1.3, 2.0, 2.1, 2.2, and SAE J2602, and automatically performs frame communication and error determination.

The LIN/UART interface is provided with UART mode and can also be used as a UART.

The appropriate mode should be used for the LIN/UART interface according to the application: LIN master or UART.

LIN master

- LIN reset mode
- LIN mode (LIN master mode)
  - LIN wake-up mode
  - LIN operation mode
- LIN self-test mode

UART

- LIN reset mode
- UART mode

Table 20.10 gives the LIN/UART interface specifications.

Table 20.10 LIN/UART Interface Specifications (1/3)

Item		Specifications
	Channel count	4 channels

Table 20.10 LIN/UART Interface Specifications (2/3)

Item		Specifications	
LIN communication function	Protocol	LIN Specification Package Revision 1.3, 2.0, 2.1, 2.2, and SAE J2602	
	Variable frame structure	Master	• Break transmission width: 13 to 28 Tbits • Break delimiter transmission width: 1 to 4 Tbits • Transmission inter-byte space width (header): 0 to 7 Tbits (space between Sync field and ID field)*1 • Transmission response space width: 0 to 7 Tbits*1 • Transmission inter-byte space width: 0 to 3 Tbits (space between data bytes in response area) • Transmission wake-up width: 1 to 16 Tbits
	Checksum	• Automatic operation for both transmission and reception • Classic or enhanced selectable (for each frame)	
	Response field data byte count	Variable from 0 to 8 bytes Multi-byte (9 or more bytes) response transmission and reception also possible	
	Frame communication modes	Master	• Mode in which header transmission and response transmission/reception is started with a single transmission start request • Mode in which header transmission and response transmission are started with separate transmission start requests (frame separate mode)
	Wake-up transmission and reception	LIN wake-up mode provided • Wake-up transmission (1 to 16 Tbits) • Wake-up reception Low-level width of input signals measured	
	Status	Master	• Successful frame/wake-up transmission • Successful header transmission • Successful frame/wake-up reception*2 • Successful data 1 reception • Error detection • Operation mode (LIN reset mode, LIN wake-up mode, LIN operation mode, LIN self-test mode)
	Error status	Master	• Bit error • Checksum error • Frame timeout error/response timeout error • Physical bus error • Framing error • Response preparation error
	Baud rate selection	Baud rate conforming to the LIN specifications generated using baud rate generator	
	Test mode	Self-test mode for user evaluation	
	Interrupt function	Master	• Successful header/frame/wake-up transmission • Successful frame/wake-up reception*2 • Error detection

Table 20.10 LIN/UART Interface Specifications (3/3)

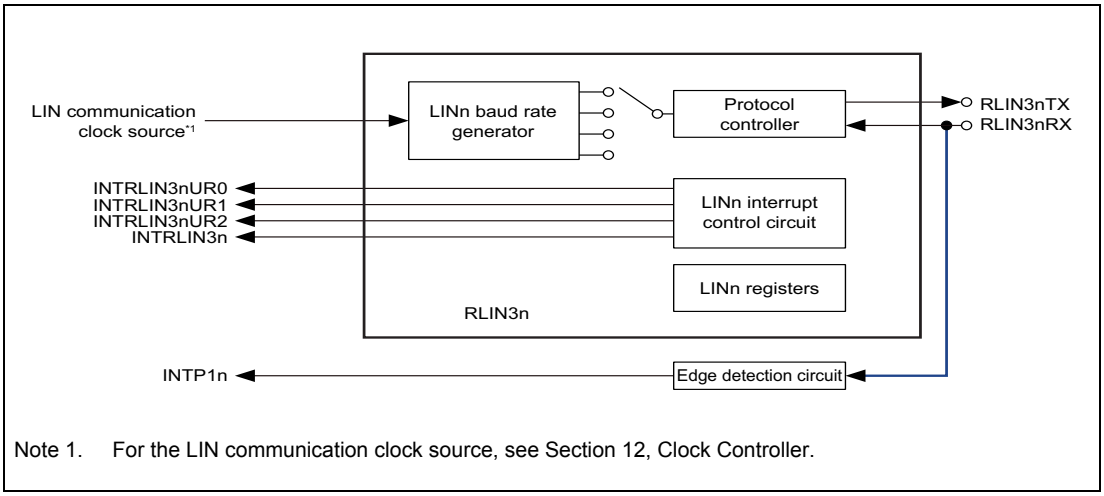
Item		Specifications
UART communication function	Data buffer	• Transmission data buffer/transmission data buffer for wait (exclusively for transmission; data length of 1. Character length of 7, 8, and 9 bits supported) • UART buffer (exclusively for transmission; variable data length from 1 to 9 bits; character length of 7 and 8 bits supported) • Reception data buffer (exclusively for reception; data length of 1. Character length of 7, 8, and 9 bits supported)
	Data format	Character length: 7 or 8 bits 9 bits including the expansion bit supported.
		Transmission stop bit: 1 or 2 bits
		Parity function: odd, even, 0, or none
		LSB- or MSB-first transfer selectable
		Reverse input/output of transmission/reception data
	Status	• Transmission status • Reception status • Successful UART buffer transmission • Error detection • Expansion bit detection • ID match • Reset mode status
	Error status	• Bit error • Framing error • Parity error • Overrun error
	Baud rate selection	With the baud rate generator incorporated, any baud rate can be set.
	When a certain expansion bit is at the expected level, the data received can be compared to the 8-bit data preset in the register.	
	The stop bit received is guaranteed (start of transmission can be delayed when start of transmission is attempted during reception of the stop bit).	
	Interrupt function	• Transmission start/complete • Reception complete • Status/error detection

Note 1. Since the same register is used for setting, the inter-byte space (header) = response space.

Note 2. For wake-up reception, the low level width of the input signal is indicated.

20.2.2 Block Diagram

Figure 20.1 shows a block diagram of the LIN/UART interface.



Note 1. For the LIN communication clock source, see Section 12, Clock Controller.

Figure 20.1 LIN/UART Interface Block Diagram

20.2.3 Description of Blocks

- RLIN3nTX, RLIN3nRX: LIN/UART interface I/O pins
- LINn baud rate generator: Generates the LIN/UART interface communication clock signal.
- LINn registers: LIN/UART interface registers
- LINn interrupt controller circuit: Controls interrupt requests generated by the LIN/UART interface

20.3 Registers

20.3.1 List of Registers

RLIN3 registers are listed in the following table.

For <RLIN3n_base>, see Section 20.1.2, Register Base Address.

Table 20.11 Registers (1/2)

Module	Register	Symbol	Address	LIN Master	UART
RLN3n	LIN wake-up baud rate selector register	RLN3nLWBR	<RLN3n_base> + 01_H	√	√
RLN3n	UART baud rate prescaler 01 register	RLN3nLBRP01	<RLN3n_base> + 02_H	—	√
RLN3n	LIN/ UART baud rate prescaler 0 register	RLN3nLBRP0	<RLN3n_base> + 02_H	√	√
RLN3n	LIN/ UART baud rate prescaler 1 register	RLN3nLBRP1	<RLN3n_base> + 03_H	√	√
RLN3n	LIN self-test control register	RLN3nLSTC	<RLN3n_base> + 04_H	√	—
RLN3n	LIN/ UART mode register	RLN3nLMD	<RLN3n_base> + 08_H	√	√
RLN3n	LIN break field configuration register/ UART configuration register	RLN3nLBFC	<RLN3n_base> + 09_H	√	√
RLN3n	LIN / UART space configuration register	RLN3nLSC	<RLN3n_base> + $0A_H$	√	√
RLN3n	LIN wake-up configuration register	RLN3nLWUP	<RLN3n_base> + $0B_H$	√	—
RLN3n	LIN interrupt enable register	RLN3nLIE	<RLN3n_base> + $0C_H$	√	—
RLN3n	LIN / UART error detection enable register	RLN3nLEDE	<RLN3n_base> + $0D_H$	√	√
RLN3n	LIN/ UART control register	RLN3nLCUC	<RLN3n_base> + $0E_H$	√	√
RLN3n	LIN / UART transmission control register	RLN3nLTRC	<RLN3n_base> + 10_H	√	√
RLN3n	LIN/ UART mode status register	RLN3nLMST	<RLN3n_base> + 11_H	√	√
RLN3n	LIN / UART status register	RLN3nLST	<RLN3n_base> + 12_H	√	√
RLN3n	LIN/ UART error status register	RLN3nLEST	<RLN3n_base> + 13_H	√	√
RLN3n	LIN data field configuration register	RLN3nLDFC	<RLN3n_base> + 14_H	√	√
RLN3n	LIN ID buffer register	RLN3nLIDB	<RLN3n_base> + 15_H	√	√
RLN3n	LIN checksum buffer register	RLN3nLCBR	<RLN3n_base> + 16_H	√	—
RLN3n	UART data 0 buffer register	RLN3nLUDB0	<RLN3n_base> + 17_H	—	√
RLN3n	LIN / UART data buffer 1 register	RLN3nLDBR1	<RLN3n_base> + 18_H	√	√
RLN3n	LIN/ UART data buffer 2 register	RLN3nLDBR2	<RLN3n_base> + 19_H	√	√
RLN3n	LIN/ UART data buffer 3 register	RLN3nLDBR3	<RLN3n_base> + $1A_H$	√	√
RLN3n	LIN / UART data buffer 4 register	RLN3nLDBR4	<RLN3n_base> + $1B_H$	√	√
RLN3n	LIN / UART data buffer 5 register	RLN3nLDBR5	<RLN3n_base> + $1C_H$	√	√
RLN3n	LIN / UART data buffer 6 register	RLN3nLDBR6	<RLN3n_base> + $1D_H$	√	√
RLN3n	LIN / UART data buffer 7 register	RLN3nLDBR7	<RLN3n_base> + $1E_H$	√	√
RLN3n	LIN/ UART data buffer 8 register	RLN3nLDBR8	<RLN3n_base> + $1F_H$	√	√
RLN3n	UART operation enable register	RLN3nLUOER	<RLN3n_base> + 20_H	—	√
RLN3n	UART option register 1	RLN3nLUOR1	<RLN3n_base> + 21_H	—	√
RLN3n	UART transmission data register	RLN3nLUTDR	<RLN3n_base> + 24_H	—	√
RLN3n	UART transmission data register L	RLN3nLUTDRL	<RLN3n_base> + 24_H	—	√
RLN3n	UART transmission data register H	RLN3nLUTDRH	<RLN3n_base> + 25_H	—	√
RLN3n	UART reception data register	RLN3nLURDR	<RLN3n_base> + 26_H	—	√
RLN3n	UART reception data register L	RLN3nLURDRL	<RLN3n_base> + 26_H	—	√

Table 20.11 Registers (2/2)

Module	Register	Symbol	Address	LIN Master	UART
RLN3n	UART reception data register H	RLN3nLURDRH	<RLN3n_base> + 27_H	—	√
RLN3n	UART wait transmission data register	RLN3nLUWTDR	<RLN3n_base> + 28_H	—	√
RLN3n	UART wait transmission data register L	RLN3nLUWTDRL	<RLN3n_base> + 28_H	—	√
RLN3n	UART wait transmission data register H	RLN3nLUWTDRH	<RLN3n_base> + 29_H	—	√

Note: √: Used, —: Not used
When writing to a register not used, write the value after reset.

20.3.2 LIN Master Related Registers

20.3.2.1 RLN3nLWBR — LIN Wake-Up Baud Rate Select Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 01_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	NSPB[3:0]				LPRS[2:0]			LWBR0
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.12 RLN3nLWBR Register Contents

Bit Position	Bit Name	Function
7 to 4	NSPB[3:0]	Bit Sampling Count Select b7 b4 0 0 0 0: 16 sampling 1 1 1 1: 16 sampling Settings other than the above are prohibited.
3 to 1	LPRS[2:0]	Prescaler Clock Select b3 b1 0 0 0: 1/1 0 0 1: 1/2 0 1 0: 1/4 0 1 1: 1/8 1 0 0: 1/16 1 0 1: 1/32 1 1 0: 1/64 1 1 1: 1/128
0	LWBR0	Wake-up Baud Rate Select 0: In LIN wake-up mode, the clock specified in the LCKS[1:0] bit of the RLN3nLMD register is used. (for LIN1.3) 1: In LIN wake-up mode, the clock fa is used regardless of the setting in the LCKS[1:0] bit of the RLN3nLMD register. (for LIN2.x)

Set the RLN3nLWBR register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

NSPB[3:0] Bits (Bit Sampling Count Select)

These bits select the number of sampling in one Tbit (reciprocal of the baud rate).
In LIN master mode (LIN/UART mode select bits in LIN mode register = 00_B), set these bits to 0000_B or 1111_B (16 sampling).

LPRS[2:0] Bits (Prescaler Clock Select)

These bits select the frequency division ratio for the prescaler.
The LIN communication clock source is divided by this prescaler.

LWBR0 Bit (Wake-up Baud Rate Select)

When LIN Specification Package Revision 1.3 is used, set the LWBR0 bit in the RLN3nLWBR register to 0. This allows the 2.5-Tbit or longer low-level width of the input signal to be measured.
When LIN Specification Package Revision 2.x is used, set the LWBR0 bit to 1. Setting the LWBR0 bit to 1 selects fa as the LIN system clock (fLIN) during LIN wake-up mode regardless of the setting of the

RLN3nLMD.LCKS[1:0] bit (the LCKS[1:0] bit is not changed). This allows the 2.5-Tbit or longer low-level width of the input signal to be measured.

Setting the baud rate to 19200 bps while fa is selected allows the 130 µs or longer low-level width of the input signal to be detected during LIN wake-up mode regardless of the setting of the RLN3nLMD.LCKS[1:0] bit.

20.3.2.2 RLN3nLBRP0 — LIN Baud Rate Prescaler 0 Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 02_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LBRP0[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.13 RLN3nLBRP0 Register Contents

Bit Position	Bit Name	Function
7 to 0	LBRP0[7:0]	Assuming that the value set in this register is N (0 to 255), the baud rate prescaler divides the frequency of the prescaler clock by N + 1. Setting range: 00_H to FF_H

Set the RLN3nLBRP0 register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

The value set in this register is used to control the frequency of baud rate clock sources fa, fb, and fc.

Assuming that the value set in this register is N, baud rate prescaler 0 divides the frequency of the clock that is selected by the LPRS[2:0] bits by N + 1.

20.3.2.3 RLN3nLBRP1 — LIN Baud Rate Prescaler 1 Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 03_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LBRP1[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.14 RLN3nLBRP1 Register Contents

Bit Position	Bit Name	Function
7 to 0	LBRP1[7:0]	Assuming that the value set in this register is M (0 to 255), the baud rate prescaler divides the frequency of the prescaler clock by M + 1. Setting range: 00_H to FF_H

Set the RLN3nLBRP1 register when the OMM0 bit in the RLN3LMST register is 0_B (in LIN reset mode).

The value set in this register is used to control the frequency of baud rate clock source fd.

Assuming that the value set in this register is M, baud rate prescaler 1 divides the frequency of the clock that is selected by the LPRS[2:0] bits (prescaler clock select bits) by M+1.

20.3.2.4 RLN3nLSTC — LIN Self-Test Control Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 04_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	LSTM
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.15 RLN3nLSTC Register Contents

Bit Position	Bit Name	Function
7 to 0	—	Writing $A7_H$, 58_H, and 01_H successively to the RLN3nLSTC register places the module into LIN self-test mode.
0	LSTM	LIN Self-Test Mode 0: The module is not in LIN self-test mode. 1: The module is in LIN self-test mode.

The RLN3nLSTC register cancels protection of LIN self-test mode.

Set the RLN3nLSTC register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

Writing $A7_H$, 58_H, and 01_H successively to the RLN3nLSTC register places the module into LIN self-test mode.

When successive writing is completed thus placing LIN self-test mode to be entered, the LSTM bit is set to 1.

Do not write any other value during successive writing.

For making transition to LIN self-test mode, see Section 20.9, LIN Self-Test Mode.

When read, bits 6 to 1 return "000000_B", and bit 7 returns an undefined value.

LSTM Bit (LIN Self-Test Mode)

When transition to LIN self-test mode is completed, the LSTM bit is set to 1.
For leaving LIN self-test mode, see Section 20.9, LIN Self-Test Mode.
Writing 1 to this bit does not affect the value of the RLN3nLSTC register if it is not a part of successive writing of $A7_H$, 58_H, and 01_H.

20.3.2.5 RLN3nLMD — LIN Mode Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base>+ 08_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	LRDNFS	LIOS	LCKS[1:0]		LMD[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.16 RLN3nLMD Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
5	LRDNFS	LIN Reception Data Noise Filtering Disable 0: The noise filter is enabled. 1: The noise filter is disabled.
4	LIOS	LIN Interrupt Output Select 0: RLIN3n interrupt is used. 1: RLIN3n transmission interrupt, RLIN3n successful reception interrupt, and RLIN3n status interrupt are used.
3, 2	LCKS[1:0]	LIN System Clock Select b3 b2 0 0: fa (Clock generated by baud rate prescaler 0) 0 1: fb (1/2 clock generated by baud rate prescaler 0) 1 0: fc (1/8 clock generated by baud rate prescaler 0) 1 1: fd (1/2 clock generated by baud rate prescaler 1)
1, 0	LMD[1:0]	LIN/UART Mode Select b1 b0 0 0: LIN master mode

Set the RLN3nLMD register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode)

LRDNFS Bit (LIN Reception Data Noise Filtering Disable)

The LRDNFS bit enables or disables the noise filter when receiving data.
With 0 set, the noise filter is enabled when receiving data.
With 1 set, the noise filter is disabled when receiving data.

LIOS Bit (LIN Interrupt Output Select)

The LIOS bit selects the number of interrupt outputs from the LIN/UART interface.
With 0 set, the RLIN3 interrupt is generated from the LIN/UART interface.
With 1 set, the RLIN3n transmission interrupt, RLIN3n successful reception interrupt, and RLIN3n status interrupt are generated from the LIN/UART interface.
For each interrupt source, see Section 20.4, Interrupt Sources.

LCKS[1:0] Bits (LIN System Clock Select)

The LCKS[1:0] bits select the clock to be input to the protocol controller.
With 00_B set, the protocol controller is provided with fa (clock generated by baud rate prescaler 0).
With 01_B set, the protocol controller is provided with fb (1/2 clock generated by baud rate prescaler 0).

With 10_B set, the protocol controller is provided with fc (1/8 clock generated by baud rate prescaler 0).
With 11_B set, the protocol controller is provided with fd (1/2 clock generated by baud rate prescaler 1).

With 1_B is set in the LWBR0 bit in the RLN3nLWBR register (LIN 2.x is used), and the RLN3nLMST register is 01_H (LIN wake-up mode), the protocol controller is provided with fa regardless of the setting of the bit (the LCKS[1:0] bit is not changed)

LMD[1:0] Bits (LIN/UART Mode Select)

The LMD[1:0] bits select the LIN/UART interface mode.
To use the LIN/UART interface as an LIN master, set these bits to 00_B.

20.3.2.6 RLN3nLBFC — LIN Break Field Configuration Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 09_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	BDT[1:0]		BLT[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.17 RLN3nLBFC Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
5, 4	BDT[1:0]	Transmission Break Delimiter (High Level) Width Select b5 b4 0 0: 1 Tbit 0 1: 2 Tbits 1 0: 3 Tbits 1 1: 4 Tbits
3 to 0	BLT[3:0]	Transmission Break (Low Level) Width Select b3 b0 0 0 0 0: 13 Tbits 0 0 0 1: 14 Tbits 0 0 1 0: 15 Tbits : 1 1 1 0: 27 Tbits 1 1 1 1: 28 Tbits

Set the RLN3nLBFC register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

Some combinations of the set values result in the length of a frame exceeding the timeout time. Set the appropriate values in this register.

BDT[1:0] Bits (Transmission Break Delimiter (High Level) Width Select)

The BDT[1:0] bits set the break delimiter (high level) width of transmission frame header.
1 Tbit to 4 Tbits can be set.

BLT[3:0] Bits (Transmission Break (Low Level) Width Select)

This BLT[3:0] bits set the break low level width of transmission frame header.
13 Tbits to 28 Tbits can be set.

20.3.2.7 RLN3nLSC — LIN Space Configuration Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base>+ $0A_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	IBS[1:0]		—	IBHS[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R/W	R/W	R/W

Table 20.18 RLN3nLSC Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
5, 4	IBS[1:0]	Inter-Byte Space Select b5 b4 0 0: 0 Tbit 0 1: 1 Tbit 1 0: 2 Tbits 1 1: 3 Tbits
3	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
2 to 0	IBHS[2:0]	Inter-Byte Space (Header)/Response Space Select b2 b0 0 0 0: 0 Tbit 0 0 1: 1 Tbit 0 1 0: 2 Tbits 0 1 1: 3 Tbits 1 0 0: 4 Tbits 1 0 1: 5 Tbits 1 1 0: 6 Tbits 1 1 1: 7 Tbits

Set the RLN3nLSC register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

Some combinations of the set values result in the length of a frame or a response exceeding the timeout time. Set the appropriate values in this register.

IBS[1:0] Bits (Inter-Byte Space Select)

The IBS[1:0] bits set the width of the inter-byte space of the transmission frame response field.
0 Tbit to 3 Tbits can be set.
These bits are enabled only during response transmission; these are disabled during response reception.

IBHS[2:0] Bits (Inter-Byte Space (Header)/Response Space Select)

The IBHS[2:0] bits set the width of the inter-byte space (header) of the transmission frame header field and the response space.
0 Tbit to 7 Tbits can be set.
The response space setting is enabled only during response transmission; setting is disabled during response reception.
The inter-byte space (header) is equal to the response space.

20.3.2.8 RLN3nLWUP — LIN Wake-Up Configuration Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base>+ $0B_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	WUTL[3:0]				—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R	R	R

Table 20.19 RLN3nLWUP Register Contents

Bit Position	Bit Name	Function
7 to 4	WUTL[3:0]	Wake-up Transmission Low Level Width Select b7 b4 0 0 0 0: 1 Tbit 0 0 0 1: 2 Tbits 0 0 1 0: 3 Tbits 0 0 1 1: 4 Tbits : 1 1 0 0: 13 Tbits 1 1 0 1: 14 Tbits 1 1 1 0: 15 Tbits 1 1 1 1: 16 Tbits
3 to 0	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.

Set the RLN3nLWUP register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

WUTL[3:0] Bits (Wake-up Transmission Low Level Width Select)

The WUTL[3:0] bits set the low level width of the wake-up signal transmission.
1 Tbit to 16 Tbits can be set.

With 1 is set in the LWBR0 bit in the RLN3nLWBR register (LIN 2.x is used), fa is selected as the LIN system clock (fLIN) regardless of the setting of the RLN3nLMD.LCKS[1:0] bit (the LCKS[1:0] bit is not changed).

20.3.2.9 RLN3nLIE — LIN Interrupt Enable Register

Occurrence factors are bit errors, physical bus errors, frame/response timeout errors, framing errors, checksum errors, and response preparation errors.

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + $0C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	SHIE	ERRIE	FRCIE	FTCIE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 20.20 RLN3nLIE Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	SHIE	Successful Header Transmission Interrupt Request Enable 0: Disables successful header transmission interrupt request. 1: Enables successful header transmission interrupt request.
2	ERRIE	Error Detection Interrupt Request Enable 0: Disables error detection interrupt request. 1: Enables error detection interrupt request.
1	FRCIE	Successful Frame/Wake-up Reception Interrupt Request Enable 0: Disables successful frame/wake-up reception interrupt request. 1: Enables successful frame/wake-up reception interrupt request.
0	FTCIE	Successful Frame/Wake-up Transmission Interrupt Request Enable 0: Disables successful frame/wake-up transmission interrupt request. 1: Enables successful frame/wake-up transmission interrupt request.

Set the RLN3nLIE register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

SHIE Bit (Successful Header Transmission Interrupt Request Enable)

The SHIE bit enables or disables interrupt request upon successful transmission of a header.
With 0 set, the interrupt request for RLIN3n transmission is not generated when the HTRC flag in the RLN3nLST register is set to 1.
With 1 set, the interrupt request for RLIN3n transmission is generated when the HTRC flag in the RLN3nLST register is set to 1.

ERRIE Bit (Error Detection Interrupt Request Enable)

The ERRIE bit enables or disables an interrupt request upon detection of an error.
With 0 set, the interrupt request for RLIN3n status not generated when the ERR flag in the RLN3nLST register is set to 1.
With 1 set, the interrupt request for RLIN3n status is generated when the ERR flag in the RLN3nLST register is set to 1.
Occurrence factors are bit errors, physical bus errors, frame/response timeout errors, framing errors, checksum errors, and response preparation errors.
Detection of the bit error, physical bus error, frame/response timeout error, and framing error can be enabled or disabled using the RLN3nLEDE register.

FRCIE Bit (Successful Frame/Wake-up Reception Interrupt Request Enable)

The FRCIE bit enables or disables an interrupt request upon successful reception of a frame or a wake-up signal (counting of low level width of the input signal).
With 0 set, the interrupt request for successful RLIN3n reception is not generated when the FRC flag in the RLN3nLST register is set to 1.
With 1 set, the interrupt request for successful RLIN3n reception is generated when the FRC flag in the RLN3nLST register is set to 1.

FTCIE Bit (Successful Frame/Wake-up Transmission Interrupt Request Enable)

The FTCIE bit enables or disables an interrupt request upon successful transmission of a frame or a wake-up signal.
With 0 set, the interrupt request for RLIN3n transmission is not generated when the FTC flag in the RLN3nLST register is set to 1.
With 1 set, the interrupt request for RLIN3n transmission is generated when the FTC flag in the RLN3nLST register is set to 1.

20.3.2.10 RLN3nLEDE — LIN Error Detection Enable Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + $0D_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LTES	—	—	—	FERE	FTERE	PBERE	BERE
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R/W	R/W	R/W	R/W

Table 20.21 RLN3nLEDE Register Contents

Bit Position	Bit Name	Function
7	LTES	Timeout Error Select 0: Frame timeout error 1: Response timeout error
6 to 4	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	FERE	Framing Error Detection Enable 0: Disables framing error detection. 1: Enables framing error detection.
2	FTERE	Timeout Error Detection Enable 0: Disables frame/response timeout error detection. 1: Enables frame/response timeout error detection.
1	PBERE	Physical Bus Error Detection Enable 0: Disables physical bus error detection. 1: Enables physical bus error detection.
0	BERE	Bit Error Detection Enable 0: Disables bit error detection. 1: Enables bit error detection.

Note: Set FERE bit and BERE bit to 1.

Set the RLN3nLEDE register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode)

LTES Bit (Timeout Error Select)

The LTES bit selects the timeout function to be used.
With 0 set, the timeout function applies to frame timeout.
With 1 set, the timeout function applies to response timeout.
For details on the timeout error, see Section 20.7.6, Error Status.

FERE Bit (Framing Error Detection Enable)

The FERE bit enables or disables detection of the framing error.
With 0 set, the framing error is not detected.
With 1 set, the framing error is detected.
When this bit is set to 1, the detection result is indicated in the FER flag in the RLN3nLEST register.
For details on the framing error, see Section 20.7.6, Error Status.

FTERE Bit (Timeout Error Detection Enable)

The FTERE bit enables or disables detection of the frame timeout error or the response timeout error.
With 0 set, the frame timeout error or response timeout error is not detected.
With 1 set, the frame timeout error or response timeout error is detected.
When this bit is set to 1, the detection result is indicated in the FTER flag in the RLN3nLEST register.
With the LTES bit, either the frame timeout error or response timeout error can be selected.
Do not use the timeout error if response data of 9 bytes or more is to be transmitted or received.
For details on the timeout error, see Section 20.7.6, Error Status.

PBERE Bit (Physical Bus Error Detection Enable)

The PBERE bit enables or disables detection of the physical bus error.
With 0 set, the physical bus error is not detected.
With 1 set, the physical bus error is detected.
When this bit is set to 1, the detection result is indicated in the PBER flag in the RLN3nLEST register.
For details on the physical bus error, see Section 20.7.6, Error Status.

BERE Bit (Bit Error Detection Enable)

The BERE bit enables or disables detection of the bit error.
With 0 set, the bit error is not detected.
With 1 set, the bit error is detected.
When this bit is set to 1, the detection result is indicated in the BER flag in the RLN3nLEST register.
For details on the bit error, see Section 20.7.6, Error Status.

20.3.2.11 RLN3nLCUC — LIN Control Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + $0E_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OM1	OM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 20.22 RLN3nLCUC Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
1	OM1	LIN Mode Select 0: LIN wake-up mode is caused. 1: LIN operation mode is caused.
0	OM0	LIN Reset 0: LIN reset mode is caused. 1: LIN reset mode is canceled.

Set the RLN3nLCUC register to 01_H to cause a transition to LIN wake-up mode after canceling LIN reset mode, and set the register to 03_H to cause a transition to LIN operation mode.

In LIN self-test mode, set the RLN3nLCUC register to 03_H after a transition to LIN self-test mode is completed.

After a value is written to this register, confirm that the value written is actually indicated in the RLN3nLMST register before writing another value.

OM1 Bit (LIN Mode Select)

The OM1 bit selects the specific operation mode (either LIN wake-up mode or LIN operation mode) after canceling LIN reset mode.
With 0 set, LIN wake-up mode is caused.
With 1 set, LIN operation mode is caused.
This bit is valid only when the OMM0 bit in the RLN3nLMST register is 1.
Writing a value to this bit is disabled while the FTS bit in the RLN3nLTRC register is 1.

OM0 Bit (LIN Reset)

The OM0 bit selects either causing a transition to LIN reset mode or canceling LIN reset mode.
With 0 set, LIN reset mode is caused.
With 1 set, LIN reset mode is canceled.

20.3.2.12 RLN3nLTRC — LIN Transmission Control Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 10_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	RTS	FTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 20.23 RLN3nLTRC Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
1	RTS	Response Transmission/Reception Start 0: Response transmission/reception is stopped in frame separate mode. 1: Response transmission/reception is started in frame separate mode.
0	FTS	Frame Transmission/Wake-up Transmission /Reception Start 0: Frame Transmission/wake-up transmission/reception is stopped. 1: Frame Transmission/wake-up transmission/reception is started.

RTS Bit (Response Transmission/Reception Start)

Set the RTS bit to 1 in frame separate mode after header transmission is started (FTS bit is 1) and response transmission data is ready. Once set, this bit is automatically cleared to 0 upon completion of frame communication (including error detection) or transition to LIN reset mode.
Only 1 can be written to this bit; 0 cannot be written.
To write 1 to this bit, write 02_H to the RLN3nLTRC register using the store instruction.
Writing a value to this bit is disabled when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).
Writing a value to this bit is disabled when the FTS bit is 0 (frame transmission or wake-up transmission/reception is halted).
When response data of 9 bytes or more is to be transmitted or received, set this bit to 1 each time a data group (variable from 0 to 8 bytes) is transmitted or received. Once set, this bit is automatically cleared to 0 at the end of communication or transition to LIN reset mode.

FTS Bit (Frame Transmission/Wake-up Transmission/Reception Start)

Set the FTS bit to 1 to start frame transmission and reception.
Also set this bit to 1 to allow wake-up transmission and reception (counting of the low level width of the input signal).
Only 1 can be written to this bit; 0 cannot be written.
Writing a value to this bit is disabled when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

This bit is set to 0 upon completion of frame or wake-up communication (including error detection) and transition to LIN reset mode.

20.3.2.13 RLN3nLMST — LIN Mode Status Register

Access: This register can only be read in 8-bit units

Address: <RLIN3n_base> + 11_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OMM1	OMM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 20.24 RLN3nLMST Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned.
1	OMM1	LIN Mode Status Monitor 0: The module is in LIN wake-up mode. 1: The module is in LIN operation mode.
0	OMM0	LIN Reset Status Monitor 0: The module is in LIN reset mode. 1: The module is not in LIN reset mode.

OMM1 Bit (LIN Mode Status Monitor)

The OMM1 bit indicates the current operating mode.

OMM0 Bit (LIN Reset Status Monitor)

The OMM0 bit indicates the current operating mode.

20.3.2.14 RLN3nLST — LIN Status Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 12_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	HTRC	D1RC	—	—	ERR	—	FRC	FTC
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R/W	R/W

Table 20.25 RLN3nLST Register Contents

Bit Position	Bit Name	Function
7	HTRC	Successful Header Transmission Flag 0: Header transmission has not been completed. 1: Header transmission has been completed.
6	D1RC	Successful Data 1 Reception Flag 0: Data 1 reception has not been completed. 1: Data 1 reception has been completed.
5, 4	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	ERR	Error Detection Flag 0: No error has been detected. 1: Error has been detected.
2	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
1	FRC	Frame/Wake-up Reception Complete Flag 0: Frame or wake-up reception has not been completed. 1: Frame or wake-up reception has been completed.
0	FTC	Frame/Wake-up Transmission Complete Flag 0: Frame or wake-up transmission has not been completed. 1: Frame or wake-up transmission has been completed.

The RLN3nLST register is automatically cleared to 00_H upon transition to LIN reset mode and start of the next communication (when the FTS bit of the RLN3nLTRC register is 1).

In LIN reset mode, this register cannot be written to. In LIN reset mode, the register retains 00_H.

To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

HTRC Flag (Successful Header Transmission Flag)

Only 0 can be written to the HTRC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The HTRC flag is set to 1 upon completion of header transmission. Here, an interrupt request for RLN3n transmission is generated if the SHIE bit in the RLN3nLIE register is 1 (interrupt is enabled).
To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode.

D1RC Flag (Successful Data 1 Reception Flag)

Only 0 can be written to the D1RC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The D1RC flag is set to 1 upon completion of data 1 reception. Here, an interrupt request is not

generated. To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode.
When response data of 9 bytes or more is to be received, this bit is set to 1 each time data 1 of a data group (variable from 0 to 8 bytes) is received. Write 0 before starting reception of the next data group.

ERR Flag (Error Detection Flag)

The ERR flag is set to 1 upon detection of an error (when the value of at least one of the flags of the RLN3nLEST register is set to 1). Here, an interrupt request for RLN3n status is generated if the ERRIE bit in the RLN3nLIE register is 1 (interrupt is enabled). To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the RPER, CSER, FER, FTER, PBER, and BER flags in the RLN3nLEST register in LIN operation mode or LIN wake-up mode. This clears the ERR flag to 0.

FRC Flag (Frame/Wake-up Reception Complete Flag)

Only 0 can be written to the FRC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The FRC flag is set to 1 upon completion of frame or wake-up reception. Here, an interrupt request for RLN3n reception complete is generated if the FRCIE bit in the RLN3nLIE register is 1 (interrupt is enabled). To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.
When response data of 9 bytes or more is to be received, this bit is set to 1 each time a data group (variable from 0 to 8 bytes) is received. Write 0 before starting reception of the next data group.

FTC Flag (Frame/Wake-up Transmission Complete Flag)

Only 0 can be written to the FTC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The FTC flag is set to 1 upon completion of frame or wake-up transmission. Here, an interrupt request for RLN3n transmission is generated if the FTCIE bit in the RLN3nLIE register is 1 (interrupt is enabled). To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.
When response data of 9 bytes or more is to be transmitted, this bit is set to 1 each time a data group (variable from 0 to 8 bytes) is transmitted. Write 0 before starting transmission of the next data group.

20.3.2.15 RLN3nLEST — LIN Error Status Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 13_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	RPER	—	CSER	—	FER	FTER	PBER	BER
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R/W	R	R/W	R/W	R/W	R/W

Table 20.26 RLN3nLEST Register Contents

Bit Position	Bit Name	Function
7	RPER	Response Preparation Error Flag 0: Response preparation error has not been detected. 1: Response preparation error has been detected.
6	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
5	CSER	Checksum Error Flag 0: Checksum error has not been detected. 1: checksum error has been detected.
4	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
3	FER	Framing Error Flag 0: Framing error has not been detected. 1: Framing error has been detected.
2	FTER	Timeout Error Flag 0: Frame/response timeout error has not been detected. 1: Frame/response timeout error has been detected.
1	PBER	Physical Bus Error Flag 0: Physical bus error has not been detected. 1: Physical bus error has been detected.
0	BER	Bit Error Flag 0: Bit error has not been detected. 1: Bit error has been detected.

The RLN3nLEST register is automatically cleared to 00_H upon transition to LIN reset mode and start of the next communication (when the FTS bit of the RLN3nLTRC register is 1).

In LIN reset mode, this register cannot be written to. In LIN reset mode, the register retains 00_H.

When the FTS bit in the RLN3nLTRC register is 1 (frame transmission or wake-up transmission/reception is started), do not write a value to this register.

To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

RPER Flag (Response Preparation Error Flag)

Only 0 can be written to the RPER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The RPER flag is set to 1 upon response preparation error detection. To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode.

CSER Flag (Checksum Error Flag)

Only 0 can be written to the CSER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The CSER flag is set to 1 upon checksum error detection. To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode.

FER Flag (Framing Error Flag)

Only 0 can be written to the FER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
When the value of the FERE bit of the RLN3nLEDE register is 1 (framing error detection enabled), the FER flag is set to 1 upon framing error detection. To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode.

FTER Flag (Timeout Error Flag)

Only 0 can be written to the FTER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
When the FTERE bit of the RLN3nLEDE register is 1 (frame/response timeout error detection enabled), the FTER flag is set to 1 upon frame timeout error or response timeout error detection. To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode.

PBER Flag (Physical Bus Error Flag)

Only 0 can be written to the PBER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
When the PBERE bit of the RLN3nLEDE register is 1 (physical bus error detection enabled), the PBER flag is set to 1 upon physical bus error detection. To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.

BER Flag (Bit Error Flag)

Only 0 can be written to the BER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
When the BERE bit of the RLN3nLEDE register is 1 (bit error detection enabled), the BER flag is set to 1 upon bit error detection. To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.

20.3.2.16 RLN3nLDFC — LIN Data Field Configuration Register

Access: This register can be read/written in 8-bit units.

Address: <RLIN3n_base> + 14_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LSS	FSM	CSM	RFT	RFDL[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.27 RLN3nLDFC Register Contents

Bit Position	Bit Name	Function
7	LSS	Transmission/Reception Continuation Select 0: The data group to be transmitted/received next is the last one. 1: The data group to be transmitted/received next is not the last one. (Checksum is not included.)
6	FSM	Frame Separate Mode Select 0: Frame separate mode is not set. 1: Frame separate mode is set.
5	CSM	Checksum Select 0: Classic checksum mode 1: Enhanced checksum mode
4	RFT	Response Field Communication Direction Select 0: Reception 1: Transmission
3 to 0	RFDL[3:0]	Response Field Length Select b3 b0 0 0 0 0: 0 byte (+ checksum) 0 0 0 1: 1 byte (+ checksum) 0 0 1 0: 2 bytes (+ checksum) : 0 1 1 1: 7 bytes (+ checksum) 1 0 0 0: 8 bytes (+ checksum) Settings other than the above are prohibited.

LSS Bit (Transmission/Reception Continuation Select)

The LSS bit indicates that the data group to be transmitted or received next is not the last data group when response data of 9 bytes or more is to be transmitted or received.
With 0 set, data and checksum are transmitted or received because the next data group to be transmitted or received is the last one.
With 1 set, only data is transmitted or received, and the checksum is not included because the next data group to be transmitted or received is not the last one.
Set the LSS bit only when the FSM bit is 1 (frame separate mode) and response data of 9 bytes or more is to be transmitted or received.

Set the LSS bit only when the RTS bit in the RLN3nLTRC is 0 (response transmit/receive is stopped).

FSM Bit (Frame Separate Mode Select)

The FSM bit sets the response communication mode.
With 0 set, frame separate mode is not selected. In this case, after header transmission is started (the FTS bit in the RLN3nLTRC register is 1), response is transmitted/received without the RTS bit in the RLN3nLTRC register being set.

With 1 set, frame separate mode is selected. If the RTS bit of the RLN3nLTRC register is set to 1 during header transmission, response transmission is executed after header transmission is completed.

For response reception which is 8 bytes or less (the RFT bit is 0), set the FSM bit to 0.
When causing a transition to LIN self-test mode, set this bit to 0 before transition.
For details on frame separate mode, see Section 20.7.3.1, Transmission of LIN Frames.
Set this bit when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).
When response data of 9 bytes or more is to be transmitted or received, set the FSM bit to 1.

CSM Bit (Checksum Select)

The CSM bit sets the checksum mode.
With 0 set, classic checksum mode is selected.
With 1 set, enhanced checksum mode is selected.
When the timeout error is used (the FTERE bit in the RLN3nLEDE register is 1), the specific timeout time depends on the setting of this bit. For details on the bit error, see Section 20.7.6, Error Status.
Set this bit when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).
When response data of 9 bytes or more is to be transmitted or received, do not change the CSM bit setting after the first data group through the last data group.
During communication of response data of 9 bytes or more, only the last data group (the LSS bit is 0) includes the checksum, and no other groups (the LSS bit is 1) include the checksum.

RFT Bit (Response Field Communication Direction Select)

The RFT bits set the direction of the response field/wake-up signal communication.
With 0 set, reception is performed in the response field. In LIN wake-up mode, wake-up reception is performed (low level width of the input signal is counted).
With 1 set, transmission is performed in the response field. In LIN wake-up mode, wake-up transmission is performed.
Set this bit when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).
When response data of 9 bytes or more is to be transmitted or received, do not change the RFT bit setting after the first data group through the last data group.

RFDL[3:0] Bits (Response Field Length Select)

The RFDL[3:0] bits set the length of the response field data.
The data length can be 0 to 8 bytes excluding the checksum size.
To transmit response data with the FSM bit set to 0 (not frame separate mode), set the RFDL[3:0] bits before header transmission (the FTS bit in the RLN3nLTRC register is 0).
To transmit response data with the FSM bit set to 1 (frame separate mode), set the RFDL[3:0] bits before response transmission (the RTS bit in the RLN3nLTRC register is 0).
To receive response data, set the RFDL[3:0] bits before header transmission (the FTS bit in the RLN3nLTRC register is 0).
When response data of 9 bytes or more is to be transmitted or received, set the RFDL[3:0] bits before data group transmission/reception (RTS bit in the RLN3nLTRC register is 0).
Only the last data group (the LSS bit is 0) includes the checksum, and no other groups (the LSS bit is 1) include the checksum.

20.3.2.17 RLN3nLIDB — LIN ID Buffer Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 15_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	IDP1	IDP0	ID[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.28 RLN3nLIDB Register Contents

Bit Position	Bit Name	Function
7	IDP1	Parity Setting (P1) Sets the parity bits (P1) to be transmitted in the ID field.
6	IDP0	Parity Setting (P0) Sets the parity bits (P0) to be transmitted in the ID field.
5 to 0	ID[5:0]	ID Setting Sets the 6-bit ID value to be transmitted in the ID field.

Set the RLN3nLIDB register when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

In LIN self-test mode, this register operates as described below.

Write the value to be transmitted before communication. After completion of frame transmission/reception (after loopback), the reversed value of the received value can be read.

For details about the LIN self-test mode, see Section 20.9, LIN Self-Test Mode.

IDP[1:0] Bits (Parity Setting)

The IDP bits set the parity bits (P0 and P1) to be transmitted in the ID field of the LIN frame. IDP0 is for P0, and IDP1 is for P1.

Since parity is not automatically calculated, set the calculation result. Note that if the erroneous result is set, it is transmitted as is.

ID[5:0] Bits (ID Setting)

The ID bit sets the 6-bit ID value to be transmitted in the ID field of the LIN frame.

20.3.2.18 RLN3nLCBR — LIN Checksum Buffer Register

Access: This register can only be read in 8-bit units. In LIN self-test mode, this register can be read/written in 8-bit units.

Address: <RLIN3n_base> + 16_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	CKSM[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.29 RLN3nLCBR Register Contents

Bit Position	Bit Name	Function
7 to 0	CKSM[7:0]	Holds the checksum value transmitted or received.

In LIN mode, this register operates as follows:

- When the RFT bit in the RLN3nLDFC register is 1 (transmission):
  The value transmitted can be read from the register. Read the value after transmission is completed.
  Writing to this register is invalid.
- When the RFT bit in the RLN3nLDFC register is 0 (reception):
  The value received can be read from the register. Read the value after reception is completed.
  Writing to this register is invalid.

When response data of 9 bytes or more is to be transmitted or received, the checksum is appended only to the last data group; this register is not updated for the other data groups.

In LIN self-test mode, this register operates as follows:

- When the RFT bit in the RLN3nLDFC register is 1 (transmission):
  After completion of the frame transmission (after loopback), the reversed value of the received value can be read.
- When the RFT bit in the RLN3nLDFC register is 0 (reception):
  Write the value to be received before communication. After completion of frame transmission/reception (after loopback), the reversed value of the received value can be read.

For details about the LIN self-test mode, see Section 20.9, LIN Self-Test Mode.

Set the RLN3nLCBR register when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

20.3.2.19 RLN3nLDBRb — LIN Data Buffer b Register (b = 1 to 8)

Access: This register can be read/written in 8-bit units.

Address: RLN3nLDBR1: <RLIN3n_base> + 18_H
RLN3nLDBR2: <RLIN3n_base> + 19_H
RLN3nLDBR3: <RLIN3n_base> + $1A_H$
RLN3nLDBR4: <RLIN3n_base> + $1B_H$
RLN3nLDBR5: <RLIN3n_base> + $1C_H$
RLN3nLDBR6: <RLIN3n_base> + $1D_H$
RLN3nLDBR7: <RLIN3n_base> + $1E_H$
RLN3nLDBR8: <RLIN3n_base> + $1F_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LDB[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.30 RLN3nLDBRb Register Contents

Bit Position	Bit Name	Function
7 to 0	LDB[7:0]	Sets the data to be transmitted or holds the received data. Setting range: 00_H to FF_H

- For response transmission:
  The LDBRn registers set the data to be transmitted in the response field.
  Use these registers with the following settings.
  - RFT in RLN3nLDFC register is 1 (transmission)
  - FSM in RLN3nLDFC register is 0 (not frame separate mode)
  - FTS bit in RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted)

  or
  - RFT in RLN3nLDFC register is 1 (transmission)
  - FSM in RLN3nLDFC register is 1 (frame separate mode)
  - RTS in RLN3nLTRC register is 0 (response transmission/reception is halted)
- For response reception:
  The LDBRn registers hold the data received in the response field.
  The received data is overwritten. If an error is detected, the data up to the byte in which the error was detected are stored in the register.
  Do not read these registers when the FTS bit is 1 (frame transmission or wake-up transmission/reception is started)
- For transmission of response data of 9 bytes or more:
  Use the LDBRn registers with the following settings.
  - RFT in RLN3nLDFC register is 1 (transmission)
  - FSM in RLN3nLDFC register is 1 (frame separate mode)
  - RTS in RLN3nLTRC register is 0 (response transmission/reception is halted)
- For reception of response data of 9 bytes or more:
  Do not read these registers when the RTS bit is 1 (response transmission/reception is started).

In LIN self-test mode, these registers operate as described below.

Write the value to be transmitted before communication. After completion of frame transmission/reception (after loopback), the reversed value of the received value can be read.

For details about the LIN self-test mode, see Section 20.9, LIN Self-Test Mode.

20.3.3 UART Related Registers

20.3.3.1 RLN3nLWBR — LIN Wake-Up Baud Rate Select Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 01_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	NSPB[3:0]				LPRS[2:0]			—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 20.31 RLN3nLWBR Register Contents

Bit Position	Bit Name	Function
7 to 4	NSPB[3:0]	Bit Sampling Count Select b7 b4 0 0 0 0: 16 sampling 0 1 0 1: 6 sampling 0 1 1 0: 7 sampling 0 1 1 1: 8 sampling 1 0 0 0: 9 sampling 1 0 0 1: 10 sampling 1 0 1 0: 11 sampling 1 0 1 1: 12 sampling 1 1 0 0: 13 sampling 1 1 0 1: 14 sampling 1 1 1 0: 15 sampling 1 1 1 1: 16 sampling Settings other than the above are prohibited.
3 to 1	LPRS[2:0]	Prescaler Clock Select b3 b1 0 0 0: 1/1 0 0 1: 1/2 0 1 0: 1/4 0 1 1: 1/8 1 0 0: 1/16 1 0 1: 1/32 1 1 0: 1/64 1 1 1: 1/128
0	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.

Set the LN3nLWBR register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

NSPB[3:0] Bits (Bit Sampling Count Select)

The NSPB[3:0] bits select the number of sampling in one Tbit (reciprocal of the bit rate).
In UART mode, it is possible to set the NSPB[3:0] bits from 6 sampling to 16 sampling.

LPRS[2:0] Bits (Prescaler Clock Select)

The LPRS[2:0] bits select the frequency division ratio for the prescaler.

The LIN communication clock source is divided by this prescaler.

20.3.3.2 RLN3nLBRP01 — UART Baud Rate Prescaler 01 Register

Access: RLN3nLBRP01 register can be read/written in 16-bit units.
RLN3nLBRP0 register can be read/written in 8-bit units.
RLN3nLBRP1 register can be read/written in 8-bit units.

Address: RLN3nLBRP01: <RLIN3n_base> + 02_H
RLN3nLBRP0: <RLIN3n_base> + 02_H
RLN3nLBRP1: <RLIN3n_base> + 03_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BRP[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.32 RLN3nLBRP01 Register Contents

Bit Position	Bit Name	Function
15 to 0	BRP[15:0]	Assuming that the value set in this register is L (0 to 65535), the baud rate prescaler divides the frequency of the prescaler clock by L + 1. Setting range: 0000_H to $FFFF_H$

Set the RLN3nLBRP01 register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

Assuming that the value set in this register is L, the baud rate prescaler divides the frequency of the clock that is selected by the LPRS[2:0] bits (prescaler clock select bits) in the RLN3nLWBR register by
L + 1.

The RLN3nLBRP01 register can be accessed in 8-bit units by the registers RLN3nLBRP0 and RLN3nLBRP1.

20.3.3.3 RLN3nLMD — UART Mode Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 08_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	LRDNFS	—	—	—	LMD[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R	R	R	R/W	R/W

Table 20.33 RLN3nLMD Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
5	LRDNFS	LIN Reception Data Noise Filtering Disable 0: The noise filter is enabled. 1: The noise filter is disabled.
4 to 2	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
1, 0	LMD[1:0]	LIN/UART Mode Select b1 b0 0 1: UART mode

Set the RLN3nLMD register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

LRDNFS Bit (UART Reception Data Noise Filtering Disable)

The LRDNFS bit enables or disables the noise filter when receiving data.
With 0 set, the noise filter is enabled when receiving data.
With 1 set, the noise filter is disabled when receiving data.

LMD[1:0] Bits (LIN/UART Mode Select)

The LMD[1:0] bits select the LIN/UART interface mode.
To use the LIN/UART interface as an UART, set these bits to 01_B.

20.3.3.4 RLN3nLBFC — UART Configuration Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 09_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	UTPS	URPS	UPS[1:0]		USBLS	UBOS	UBLS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.34 RLN3nLBFC Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
6	UTPS	UART Output Polarity Switch 0: Transmit data normal output 1: Transmit data with inversion output
5	URPS	UART Input Polarity Switch 0: Reception data normal output 1: Reception data with inversion output
4, 3	UPS[1:0]	UART Parity Select 00: Parity prohibited 01: Even Parity 10: 0 Parity 11: Odd parity
2	USBLS	UART Stop Bit length Select 0: Stop bit:1 bit 1: Stop bit: 2 bits
1	UBOS	UART Transfer Format Order Select 0: LSB First 1: MSB First
0	UBLS	UART Character Length Select 0: UART 8 bits communication 1: UART 7 bits communication

Set the RLN3nLBFC register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

UTPS Bit (UART Output Polarity Switch)

Sets the output polarity for UART communication.
With 0 set, transmit data is output without inversion.
With 1 set, inverted transmit data is output.
The setting of this bit is valid in all the bits of the UART frame.
In half-duplex communication, this setting should match with the setting of URPS bit.

URPS Bit (UART Input Polarity Switch)

Sets the input polarity for UART communication.
With 0 set, receive data is input without inversion.
With 1 set, receive data is input with inversion.
The setting of this bit is valid in all the bits of the UART frame.
In half-duplex communication, this setting should match with the setting of UTPS bit.

When setting this bit to “1” and expansion bit reception (with expansion bit comparison) or (with data comparison) is performed, set the reversed value of the expected value to the UEBDL bit in the RLN3nLUOR1 register and RLN3nLIDB register for comparison of the reversed values of the received values.

UPS[1:0] Bits (UART Parity Select)

Sets the UART parity.

- When these bits are set to “00_B”, data is communicated without the parity.

  [Transmission]

  A parity bit is not added to transmit data.

  [Reception]

  Data is received without parity processing. Therefore, a parity error does not occur.

- When these bits are set to “01”, data is communicated with the even parity.

  [Transmission]

  If the number of 1s in transmit data is odd, “1” is added to the parity bit. If the number of 1s in transmit data is even, “0” is added to the parity bit.

  [Reception]

  If the number of 1s in receive data including the parity bit is odd, a parity error occurs.

- When these bits are set to “10”, data is communicated with 0 parity.

  [Transmission]

  Regardless of the number 1s in transmit data, “0” is added to the parity bit.

  [Reception]

  The value of the parity bit is not judged. Therefore, no parity error occurs.

- When these bits are set to “11”, data is communicated with the odd parity.

  [Transmission]

  If the number of 1s in transmit data is odd, “0” is added to the parity bit. If the number of 1s in transmit data is even, “1” is added to the parity bit.

  [Reception]

  If the number of 1s in receive data including the parity bit is even, a parity error occurs.

USBLS Bit (UART Stop Bit Length Select)

Sets the stop bit length of data for UART communication.
With 0 set, stop bit length of 1 bit is selected.
With 1 set, stop bit length of 2 bits is selected.

UBOS Bit (UART Transfer Format Select)

Sets the bit order of data for UART communication.
With 0 set, LSB first is selected.
With 1 set, MSB first is selected.

UBLS Bit (UART Character Length Select)

Sets the character length of one frame for UART communication.
With 0 set, the character length is 8 bits.
With 1 set, the character length is 7 bits.
When the character length of one frame is 9 bits (the UEBE bit in the RLN3nLUOR1 register is 1), the setting of this bit is ignored.

20.3.3.5 RLN3nLSC — UART Space Configuration Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + $0A_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	IBS[1:0]		—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R	R	R

Table 20.35 RLN3nLSC Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
5, 4	IBS[1:0]	Inter-Byte Space Select b5 b4 0 0: 0 Tbit 0 1: 1 Tbit 1 0: 2 Tbits 1 1: 3 Tbits
3 to 0	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.

Set the RLN3nLSC register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

IBS[1:0] Bits (Inter-Byte Space Select)

The IBS[1:0] bits set the width of the space between the UART frame in UART buffer transmit 0 Tbit to 3 Tbits can be set.

Set IBS[1:0] bits to "00_B" when UART buffer is not used.

When data is transferred from the UART transmit data register (RLN3nLUTDR) and the UART wait transmit data register (RLN3nLUWTDR), the setting of these bits is ignored.Set these bits to "00_B".

20.3.3.6 RLN3nLEDE —UART Error Detection Enable Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + $0D_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	FERE	OERE	—	BERE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R	R/W

Table 20.36 RLN3nLEDE Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	FERE	Framing Error Detection Enable 0: Disables framing error detection. 1: Enables framing error detection.
2	OERE	Overrun Error Detection Enable 0: Disables overrun error detection. 1: Enables overrun error detection.
1	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
0	BERE	Bit Error Detection Enable 0: Disables bit error detection. 1: Enables bit error detection.

Set the RLN3nLEDE register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

FERE Bit (Framing Error Detection Enable)

The FERE bit enables or disables detection of the framing error.
With 0 set, the framing error is not detected.
With 1 set, the framing error is detected.
When this bit is set to 1, the detection result is indicated in the FER flag in the RLN3nLEST register.
For details on the framing error, see Section 20.7.6, Error Status.

OERE Bit (Overrun Error Detection Enable)

This bit enables or disables detection of the overrun error.
With 0 set, the overrun error is not detected.
With 1 set, the overrun error is detected.
When this bit is set to 1, the detection result is reflected in the OER flag in the RLN3nLEST register.
For details on the overrun error, see Section 20.7.6, Error Status.

BERE Bit (Bit Error Detection Enable)

The BERE bit enables or disables detection of the bit error.
With 0 set, the bit error is not detected.
With 1 set, the bit error is detected.
When this bit is set to 1, the detection result is indicated in the BER flag in the RLN3nLEST register.
In full-duplex communication, do not set this bit to “1”.

Do not set this register when the NSPB[3:0] bits in the RLN3nLWBR register is 0101_B (6 sampling) and the LRDNFS bit in the RLN3nLMD register is 0 (noise filter is enabled).

For details on the bit error, see Section 20.7.6, Error Status.

20.3.3.7 RLN3nLCUC — UART Control Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + $0E_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 20.37 RLN3nLCUC Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	OM0	LIN Reset 0: LIN reset mode is caused. 1: LIN reset mode is canceled.

After a value is written to this register, confirm that the value written is actually indicated in the RLN3nLMST register before writing another value.

OM0 Bit (LIN Reset)

The OM0 bit selects whether to transition to or exit LIN reset mode.
With 0 set, reset mode.
With 1 set, reset mode is canceled.

20.3.3.8 RLN3nLTRC — UART Transmission Control Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 10_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	RTS	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R

Table 20.38 RLN3nLTRC Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
1	RTS	UART Buffer Transmission Start 0: UART Buffer transmission is stopped. 1: UART Buffer transmission is started.
0	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.

RTS Bit (UART Buffer Transmission Start)

When transmitting data from the UART buffer, set this bit to “1”.
Only 1 can be written to this bit; 0 cannot be written.
Write to this bit when the UTOE bit in the RLN3nLUOER register is 1 (transmission enable) and the UTS bit in the RLN3nLST register is 0 (transmission is not in progress).
Once set, regardless of errors, this bit is automatically cleared to 0 upon completion of the number of data transmission specified by the MDL bit in the RLN3nLDFC register. Moreover, this bit is automatically cleared to 0 upon transition to reset mode.
Writing a value to this bit is disabled when the OMM0 bit of the RLN3nLMST register is 0_B (in LIN reset mode).
When writing 1 to this bit while the UTSW bit in the RLN3nLDFC register is 1 (when UART buffer transmission is requested, the start of transmission is delayed until the stop bit of reception data is completed), write only during the reception of stop bit.

20.3.3.9 RLN3nLMST — UART Mode Status Register

Access: This register can only be read in 8-bit units

Address: <RLIN3n_base> + 11_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OMM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 20.39 RLN3nLMST Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned.
0	OMM0	LIN Reset Status Monitor 0: The module is in LIN reset mode. 1: The module is not in LIN reset mode.

OMM0 Bit (LIN Reset Status Monitor)

The OMM0 bit indicates the current operating mode.

20.3.3.10 RLN3nLST — UART Status Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 12_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	URS	UTS	ERR	—	—	FTC
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 20.40 RLN3nLST Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
5	URS	Data Reception Status 0:Reception is not operated. 1:Reception is operated.
4	UTS	Transmission Status 0: Transmission is not operated. 1: Transmission is operated.
3	ERR	Error Detection Flag 0: No error has been detected. 1: Error has been detected.
2, 1	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	FTC	Successful UART Buffer Transmission Flag 0: UART buffer transmission has not been completed. 1: UART buffer transmission has been completed.

The RLN3nLST register is automatically cleared to "00_H" upon transition to LIN reset mode. In LIN reset mode, this register cannot be written to. In LIN reset mode, the register retains "00_H". To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

URS Bit (Data Reception Status)

At the start of the reception, this flag is set to 1.
The reception is started under the following condition.

- When the start bit is detected

At the end of reception, this flag is cleared to 0. While reception is stopped, this flag retains 0.
The reception is ended under the following conditions.

- Sampling point of the first bit of the stop bits

UTS Bit (Transmission Status Flag)

At the start of the transmission, this flag is set to 1. During the transmission, this flag retains 1.
The transmission is started under the following conditions.

- When transmission data is set to the RLN3nLUTDR or RLN3nLUWTDR register
- When the RTS bit in the RLN3nLTRC register is set to 1

This flag is cleared to 0 at the end of transmission.
The transmission is ended under the following conditions.

- When transmission of data set in the RLN3nLUTDR or RLN3nLUWTDR register is completed and next data is not set
- When transmission from UART buffer is completed (when the RTS bit in the RLN3nLTRC register is cleared to 0)

ERR Flag (Error Detection Flag)

This flag is set to 1 upon detection of an error, detection of an expansion bit, or upon ID matching (when the value of at least one of the flags of the RLN3nLEST register is 1). At this time, an interrupt request for RLIN3n status is generated. However, when this bit is 1, an interrupt is not generated upon detection of an error, detection of an expansion bit, or upon ID matching. To clear the bit to 0, write 0 to the UPER, IDMT, EXBT, FER, OER, and BER flags in the RLN3nLEST register.

FTC Flag (Successful Frame/Wake-up Transmission Flag)

Only 0 can be written to the FTC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
Regardless of errors, this bit is set to 1 upon completion of the number of data transmission specified by the MDL bit in the RLN3nLDFC register from the UART buffer. At this time, an interrupt request for RLIN3n transmission is generated.
Write 0 to the bit to be cleared.

20.3.3.11 RLN3nLEST — UART Error Status Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 13_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	UPER	IDMT	EXBT	FER	OER	—	BER
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R	R/W

Table 20.41 RLN3nLEST Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
6	UPER	Parity Error Flag 0: Parity error has not been detected. 1: Parity error has been detected.
5	IDMT	ID Matching Flag 0: The receive data does not match with the ID value. 1: The receive data matches with the ID value.
4	EXBT	Expanded Bit Detection Flag 0: Expanded bit has not been detected. 1: Expanded bit has been detected.
3	FER	Framing Error Flag 0: Framing error has not been detected. 1: Framing error has been detected.
2	OER	Overrun Error Flag 0: Overrun error has not been detected. 1: Overrun error has been detected.
1	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
0	BER	Bit Error Flag 0: Bit error has not been detected. 1: Bit error has been detected.

The RLN3nLEST register is automatically cleared to 00_H when the module transitions to LIN reset mode. In LIN reset mode, this register cannot be written to, and the value of 00_H is held. To clear certain bits in this register, write 0 to those bits, and write 1 to the bits not to be cleared by using the store instruction.

UPER Flag (Parity Error Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
This flag is set to 1 upon parity error detection. To clear the bit, write 0 to the bit.

IDMT Flag (ID Matching Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The IDMT flag becomes 1 when all the following conditions are met:

- The UEBE bit in the RLN3nLUOR1 register is 1 (expansion bit enabled)

- The UECD bit in the RLN3nLUOR1 register is 0 (expansion bit comparison enabled)
- The UEBDCE bit in the RLN3nLUOR1 register is 1 (expansion bit/data comparison enabled)
  - The received expansion bit and the value of the UEBDL bit of the RLN3nLUOR1 register are matched.
  - The 8-bit receive data excluding the expansion bit and the value of the RLN3nLIDB register are matched.

To clear the bit, write 0 to the bit.

EXBT Flag (Expanded Bit Detection Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
When the UEBE bit in the RLN3nLUOR1 register is 1 (expansion bit enable), if the received expansion bit matches with the UEBDL bit in the RLN3nLUOR1 register, this flag is set to 1.
To clear the bit, write 0 to the bit.

FER Flag (Framing Error Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The FER flag is set to 1 upon framing error detection while the FERE bit of the RLN3nLEDE register is 1 (framing error detection enabled). To clear the bit, write 0 to the bit.

OER Flag (Overrun Error Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The 0ER flag is set to 1 upon overrun error detection while the OERE bit of the RLN3nLEDE register is 1 (overrun error detection enabled). To clear the bit, write 0 to the bit.

BER Flag (Bit Error Flag)

Only 0 can be written to the BER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The BER flag is set to 1 when the transmitted data and the data monitored by the receive pin do not match while the BERE bit of the RLN3nLEDE register is 1 (bit error detection enabled).
To clear the bit, write 0 to the bit.

20.3.3.12 RLN3nLDFC — UART Data Field Configuration Register

Access: This register can be read/written in 8-bit units.

Address: <RLIN3n_base> + 14_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	UTSW	—	MDL[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R	R/W	R/W	R/W	R/W

Table 20.42 RLN3nLDFC Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
5	UTSW	Transmission Start Wait 0: When UART transmission is requested, transmission is started immediately. 1: When UART transmission is requested, transmission is not started until reception of the stop bit is completed.
4	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
3 to 0	MDL[3:0]	UART Buffer Data Length Select b3 b0 0 0 0 0: 9 data 0 0 0 1: 1 data 0 0 1 0: 2 data 0 0 1 1: 3 data 0 1 0 0: 4 data 0 1 0 1: 5 data 0 1 1 0: 6 data 0 1 1 1: 7 data 1 0 0 0: 8 data 1 0 0 1: 9 data Settings other than the above are prohibited.

UTSW Bit (Transmission Start Wait)

This bit controls the transmission start timing of UART buffer.
With 0 set, transmission is started as soon as the start of UART buffer transmit is requested.
With 1 set, transmission is started after the completion of the stop bit reception.
Note that the wait time is only 1 bit even if the stop bit length is set to 2 bits with the USBLS bit in the RLN3nLBFC register.
This bit is enabled when the RTS bit in the RLN3nLTRC register is set to 1. In addition, writing a value to this bit is disabled when the RTS bit is 1 (UART buffer transmission started).
Set this bit to 1 only to switch from reception to transmission in half-duplex communication.

MDL[3:0] Bits (UART Buffer Data Length Select)

This bit specifies the data length of the UART buffer.
Writing a value to these bits is disabled when the RTS bit in the RLN3nLTRC register is 1 (UART buffer transmission started).

20.3.3.13 RLN3nLIDB — UART ID Buffer Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 15_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	ID[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.43 RLN3nLIDB Register Contents

Bit Position	Bit Name	Function
7 to 0	ID[7:0]	ID value that is referred for the expansion bit data comparison is set

ID[7:0] Bit (ID Bit)

When the UEBE bit in the RLN3nLUOR1 register is set to 1 (expansion bit enabled), the UECD bit is set to 0 (expansion bit comparison enabled), and the UEBDCE bit is set to 1 (expansion bit/data comparison enabled), set the receive data and the value to be compared. Write to the RLN3nLIDB register when the URS bit in the RLN3nLST register is 0 (receive operation is not in progress).

20.3.3.14 RLN3nLUDB0 — UART Data 0 Buffer Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 17_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	UDB[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.44 RLN3nLUDB0 Register Contents

Bit Position	Bit Name	Function
7 to 0	UDB[7:0]	Transmission data is set Setting range: 00_H to FF_H.

If the data length selection corresponds to 9 data bytes (RLN3nLDFC.MDL bit is "0_H" or "9_H") for multi-byte UART transmission, then the first data value for UART communication is present in this buffer.

Write to the RLN3nLUDB0 register when the RTS bit of the RLN3nLTRC register is 0 (UART buffer transmission stopped).

Table 20.45, Bit Arrangement of the RLN3nLUDB0 Register According to Each Communication Format shows the bit arrangement according to the set communication format.

For details about the UART buffer, see Section 20.8.1.2, UART Buffer Transmission, (1) UART Buffer Transmission.

Table 20.45 Bit Arrangement of the RLN3nLUDB0 Register According to Each Communication Format

20.3.3.16 RLN3nLUOER — UART Operation Enable Register

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 20_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	UROE	UTOE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 20.48 RLN3nLUOER Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
1	UROE	Reception Enable 0: Disables reception. 1: Enables reception.
0	UTOE	Transmission Enable 0: Disables transmission. 1: Enables transmission.

The RLN3nLUOER register is automatically cleared to 00_H upon transition to LIN reset mode.
In LIN reset mode, this register cannot be written to.
In LIN reset mode, the register retains 00_H.

UROE Bit (Reception Enable)

The UROE bit enables or disables reception.
With 0 set, reception is disabled.
With 1 set, reception is enabled.
Do not clear this bit during reception. If the communication is suspended during reception, set the OM0 bit in the RLN3nLCUC register to 0 (LIN reset mode) to shift to the LIN reset mode. However, the transmit operation is also suspended at this time.
Do not set this bit to 1 when data transmission from the UART buffer is in progress.

UTOE Bit (Transmission Enable)

The UTOE bit enables or disables transmission.
With 0 set, transmission is disabled.
With 1 set, transmission is enabled.
Do not clear this bit during transmission. If the communication is suspended during transmission, set the OM0 bit in the RLN3nLCUC register to 0 (LIN reset mode) to shift to the LIN reset mode. However, the receive operation is also suspended at this time.

20.3.3.17 RLN3nLUOR1 — UART Option Register 1

Access: This register can be read/written in 8-bit units

Address: <RLIN3n_base> + 21_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	UECD	UTIGTS	UEBDCE	UEBDL	UEBE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 20.49 RLN3nLUOR1 Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
4	UECD	Expansion Bit Comparison Disable 0: Enables comparison between the received expansion bit and the UEBDL bit value. 1: Disables comparison between the received expansion bit and the UEBDL bit value.
3	UTIGTS	Transmission Interrupt Generation Timing Select 0: Transmission interrupt is generated at the start of transmission. 1: Transmission interrupt is generated at the completion of transmission.
2	UEBDCE	Expansion Bit Data Comparison Enable 0: Disables data comparison after an expansion bit is detected. 1: Enables data comparison after an expansion bit is detected.
1	UEBDL	Expansion Bit Detection Level Select 0: Selects expansion bit value 0 as the expansion bit detection level. 1: Selects expansion bit value 1 as the expansion bit detection level.
0	UEBE	Expansion Bit Enable 0: Disables expansion bit operation. 1: Enables expansion bit operation.

UECD Bit (Expansion Bit Comparison Disable)

The UECD bit enables or disables comparison between the received expansion bit and the UEBDL bit value when the UEBE bit is 1 (expansion bit operation is enabled).
With 0 set, comparison between the received expansion bit and the UEBDL bit value is enabled when the expansion bit is received.
With 1 set, comparison between the received expansion bit and the UEBDL bit value is disabled when the expansion bit is received.
Set this bit when the OMM0 bit of the RLN3nLMST register is 0_B (in LIN reset mode).
Do not set this bit to 1 when the UART buffer is used.
Do not set this bit to 1 when the UEBDCE bit is 1 (expansion bit/data comparison enable).

UTIGTS Bit (Transmission Interrupt Generation Timing Select)

The UTIGTS bit sets the generation timing of the transmission interrupt.
With 0 set, the transmission interrupt is generated at the start of transmission.
With 1 set, the transmission interrupt is generated at the completion of transmission.
When transmission from the UART buffer is performed with 0 set, the transmission interrupt is generated only at the start of the transmission of the last data (the data length is specified by the MDL bits in the RLN3nLDFC register).

When transmission from the UART buffer is performed with 1 set, the transmission interrupt is generated only at the completion of the transmission of the last data of the data length set with the MDL bits in the RLN3nLDFC register.

UEBDCE Bit (Expansion Bit Data Comparison Enable)

After an expansion bit is detected, this bit enables or disables the comparison between the 8-bit receive data excluding the expansion bit and the value of the RLN3nLIDB register.
With 0 set, when the level selected by the UEBDL bit is detected as an expansion bit, the comparison between the receive value in the RLN3nLURDR register and the value of the RLN3nLIDB register is disabled.
With 1 set, when the level selected by the UEBDL bit is detected as an expansion bit, the comparison between the receive value in the RLN3nLURDR register and the value of the RLN3nLIDB register is enabled.
Set this bit when the OMM0 bit of the RLN3nLMST register is 0_B (in LIN reset mode).
Do not set this bit to 1 when the UEBE bit is 0 (expansion bit operation disabled).
Do not set this bit to 1 when the UECD bit is 1 (expansion bit comparison disabled).
Do not set this bit to 1 when the UART buffer is used.

UEBDL Bit (Expansion Bit Detection Level Select)

The UEBDL bit sets the level to be detected as the expansion bit when the UEBE bit is 1 (expansion bit operation is enabled) and the UECD bit is 0 (comparison of the expansion bit is enabled).
With 0 set, expansion bit value 0 is the level to be detected as the expansion bit.
With 1 set, expansion bit value 1 is the level to be detected as the expansion bit.
Set this bit when the OMM0 bit of the RLN3nLMST register is 0_B (in LIN reset mode).
Do not set this bit to 1 when the UART buffer is used.

UEBE Bit (Expansion Bit Enable Bit)

The UEBE bit enables or disables expansion bit operation.
With 0 set, expansion bit operation is disabled.
With 1 set, expansion bit operation is enabled.
Set this bit when the OMM0 bit of the RLN3nLMST register is 0_B (in LIN reset mode).
Do not set this bit to 1 when the UART buffer is used.

20.3.3.18 RLN3nLUTDR — UART Transmission Data Register

Access: RLN3nLUTDR register can be read/written in 16-bit units.
RLN3nLUTDRL register can be read/written in 8-bit units.
RLN3nLUTDRH register can be read/written in 8-bit units.

Address: RLN3nLUTDR: <RLIN3n_base> + 24_H
RLN3nLUTDRL: <RLIN3n_base> + 24_H
RLN3nLUTDRH: <RLIN3n_base> + 25_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	UTD[8:0]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.50 RLN3nLUTDR Register Contents

Bit Position	Bit Name	Function
15 to 9	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
8 to 0	UTD[8:0]	Sets the data to be transmitted from the transmission buffer. Setting range: 000_H to $1FF_H$

The RLN3nLUTDR register sets the data to be transmitted from the transmit data register.

Writing data to this register with the UTOE bit in the RLN3nLUOER register set to 1 starts transmission.

This register can be accessed in 8 bits.

In 9-bit communication mode, do not attempt 8-bit access.

Do not write data to this register when data transmission from the UART buffer is in progress.

Also, do not write data to this register when a transmission request is being generated due to write access to the RLN3nLUWTDR register.

When transmitting data continuously, do not set another piece of transmission data in this register before the generation of transmission interrupt.

The table below shows the bit arrangement according to the set communication format.

Table 20.51 Bit Arrangement of the RLN3nLUTDR Register According to Each Communication Format

	RLN3nLUTDR								
	b8	b7	b6	b5	b4	b3	b2	b1	b0

20.3.3.19 RLN3nLURDR — UART Reception Data Register

Access: RLN3nLURDR register can only be read in 16-bit units.
RLN3nLURDRL register can only be read in 8-bit units.
RLN3nLURDRH register can only be read in 8-bit units.

Address: RLN3nLURDR: <RLIN3n_base> + 26_H
RLN3nLURDRL: <RLIN3n_base> + 26_H
RLN3nLURDRH: <RLIN3n_base> + 27_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	URD [8:0]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.52 RLN3nLURDR Register Contents

Bit Position	Bit Name	Function
15 to 9	Reserved	When read, the value after reset is returned.
8 to 0	URD [8:0]	Stores the received data Setting range: 000_H to $1FF_H$

The RLN3nLURDR allows the reception data to be read from the receive data register.

When the UROE bit in the RLN3nLUOER register is 1, the reception data is stored in this register and can be read out.

This register is updated at the stop bit of the reception data.

This register is also updated when an error is caused by the parity or stop bit.

However, the value of this register is not updated upon occurrence of an overrun error when the OERE bit of the RLN3nLEDE register is 1 (overrun detection enabled). The value of this register is updated upon occurrence of an overrun error when the OERE bit is 0 (overrun detection disabled).

Read this register upon occurrence of a receive error (overrun error, framing error, parity error) when the OERE bit of the RLN3nLEDE register is 1 (overrun error detection enabled). If the next data is received without reading this register, an overrun error occurs.

This register can be accessed in 8 bits.

However, during expansion bit use (UEBE bit of the RLN3nLUOR1 register is 1 (expansion bit operation enabled), do not attempt 8-bit access.

The table below shows the bit arrangement according to the set communication format.

Table 20.53 Bit Arrangement of the RLN3nLURDR Register According to Each Communication Format

	RLN3nLURDR								
	b8	b7	b6	b5	b4	b3	b2	b1	b0

Table 20.54 RLN3nLUWTDR Register Contents

Bit Position	Bit Name	Function
15 to 9	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
8 to 0	UWTD[8:0]	Sets the data to be transmitted from the wait transmit data register after waiting for the stop bit reception to be completed. Setting range: 000_H to $1FF_H$

The RLN3nLUWTDR register sets the data to be transmitted from the UART wait transmit data register.

Writing data to this register with the UTOE bit in the RLN3nLUOER register set to 1 starts transmission.

Use this register only to switch from reception to transmission in half-duplex communication.

The user should write to this register only while the stop bit is being received.

Note that the wait time is only 1 bit even if the stop bit length is set to 2 bits with the USBLS bit in the RLN3nLBFC register.

When this register is read, the RLN3nLUTDR register value is actually read.

In 9-bit communication mode, do not attempt 8-bit access.

Do not write data to this register when data transmission from the UART buffer is in progress.

The table below shows the bit arrangement according to the set communication format.

Table 20.55 Bit Arrangement of the RLN3nLUWTDR Register According to Each Communication Format

	RLN3nLUWTDR								
	b8	b7	b6	b5	b4	b3	b2	b1	b0

9-bit; LSB first	Bit8	Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
9-bit; MSB first	Bit0	Bit1	Bit2	Bit3	Bit4	Bit5	Bit6	Bit7	Bit8

20.4 Interrupt Sources

The LIN/UART interface generates four types of interrupt requests.

- RLIN3n transmission interrupt
- RLIN3n successful reception interrupt
- RLIN3n status interrupt
- RLIN3n interrupt

Setting the LIOS bit in the RLN3nLMD register to 0 allows to perform logical OR operation on all of the interrupt sources, outputting the interrupt request from the RLIN3n interrupt.

Setting the LIOS bit in the RLN3nLMD register to 1 allows to output the RLIN3n transmission interrupt, RLIN3n successful reception interrupt, or RLIN3n status interrupt depending on the interrupt request.

Table 20.56 lists the sources for each interrupt.

Table 20.56 Interrupt Sources

	LIOS bit in RLN3nLMD register is 0	LIOS bit in RLN3nLMD register is 1*1		
	RLIN3n Interrupt	RLIN3n Transmission Interrupt	RLIN3n Successful Reception Interrupt	RLIN3n Status Interrupt
LIN master mode	• Successful frame transmission • Successful frame reception • Successful wake-up transmission • Successful wake-up reception • Successful header transmission • Bit error • Physical bus error • Frame/response timeout error • Framing error • Checksum error • Response preparation error	• Successful frame transmission • Successful wake-up transmission • Successful header transmission	• Successful wake-up reception • Successful frame reception	• Bit error • Physical bus error • Frame/response timeout error • Framing error • Checksum error • Response preparation error
UART mode	—	• Transmission start/successful transmission	• Successful reception • Expansion bit mismatch	• Bit error • Overrun error • Framing error • Expansion bit match • ID match • Parity error

Note 1. The LIOS bit setting is valid in LIN Mode. In UART mode, setting the LIOS bit is not required.

In LIN mode, each interrupt request is output when the corresponding bit in the RLN3nLIE register is 1 (interrupt is enabled) and the corresponding flag in the RLN3nLST register is 1.

20.5 Modes

The LIN/UART interface provides the following four modes, depending upon the specific function to be performed:

- LIN reset mode
- LIN master mode
- UART mode
- LIN self-test mode

Figure 20.2 shows mode transitions. **Table 20.60** describes mode transition conditions. **Table 20.60** lists operations available in each mode.

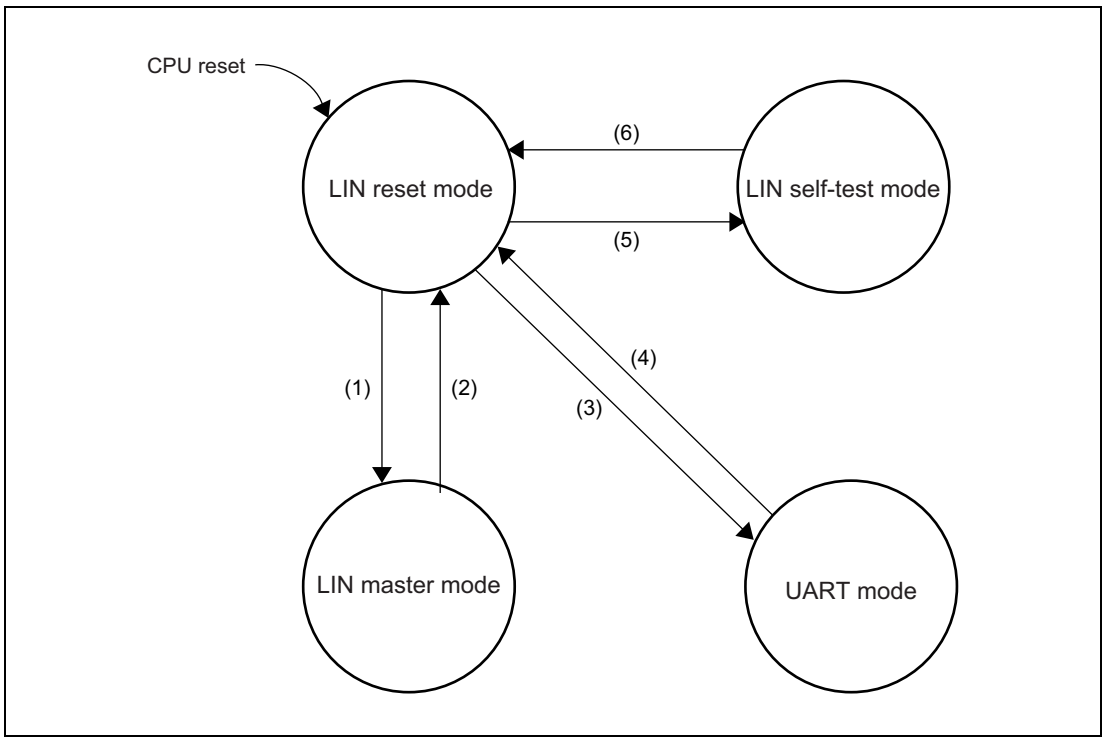

Figure 20.2 Mode Transitions

Table 20.57 Operations Available in Each Mode

LIN Master Mode	UART Mode	LIN Self-Test Mode
Header transmission Response transmission Response reception Wake-up transmission Wake-up reception Error detection	UART transmission UART reception Error detection	Self test

Whether a transition has been caused to LIN reset mode, the LIN mode, or the UART mode can be verified by reading the LMD[1:0] bits in the RLN3nLMD register or the OMM0 bit in the RLN3nLMST register.

For a description of the LIN self-test mode, see Section 20.9, LIN Self-Test Mode.

20.6 LIN Reset Mode

Setting the OM0 bit in the RLN3nLCUC register to 0 (LIN reset mode) causes a transition to LIN reset mode. The change to LIN reset mode can be verified by determining that the OMM0 bit in the RLN3nLMST register has been set to 0 (LIN reset mode). In this mode, the LIN communication and the UART communication functions are halted.

From LIN reset mode, transitions to LIN mode, UART mode, and LIN self-test mode can be made.

When the mode changes to LIN reset mode, the following registers are initialized to their reset values, and as long as LIN reset mode is in effect, they retain their initial values.

- RLN3nLTRC register
- RLN3nLST register
- RLN3nLEST register
- RLN3nLUOER register

The following registers retain their previous values even when a transition to LIN reset mode is made:

- RLN3nLWBR register
- RLN3nLBRP0 register
- RLN3nLBRP1 register
- RLN3nLMD register
- RLN3nLBFC register
- RLN3nLSC register
- RLN3nLWUP register
- RLN3nLIE register
- RLN3nLEDE register
- RLN3nLDFC register
- RLN3nLIDB register
- RLN3nLCBR register
- RLN3nLUDB0 register
- RLN3nLDBRb register (b = 1 to 8)
- RLN3nLUOR1 register
- RLN3nLUTDR register
- RLN3nLURDR register
- RLN3nLUWTDR register

20.7 LIN Mode

LIN mode can operate in LIN master mode.

In LIN master mode, the following operations can be performed: header transmission, response transmission, response reception, wake-up transmission, wake-up reception, and error detection. In LIN reset mode, setting the LMD[1:0] bits in the RLN3nLMD register to 00_B (LIN master mode) and the OM1 and OM0 bits in the RLN3nLCUC register to either 01_B or 11_B sets LIN master mode, turning the OMM1 and OMM0 bits in the RLN3nLMST register to either 01_B to 11_B.

When changing a submode to another submode within LIN mode, a transition to LIN reset mode should first be made and change the LMD[1:0] bits in the RLN3nLMD register.

The LIN mode provides the following two operation modes:

- LIN operation mode
- LIN wake-up mode

Figure 20.3 shows the transition of operation modes. **Table 20.58** describes the transition conditions of operation modes.

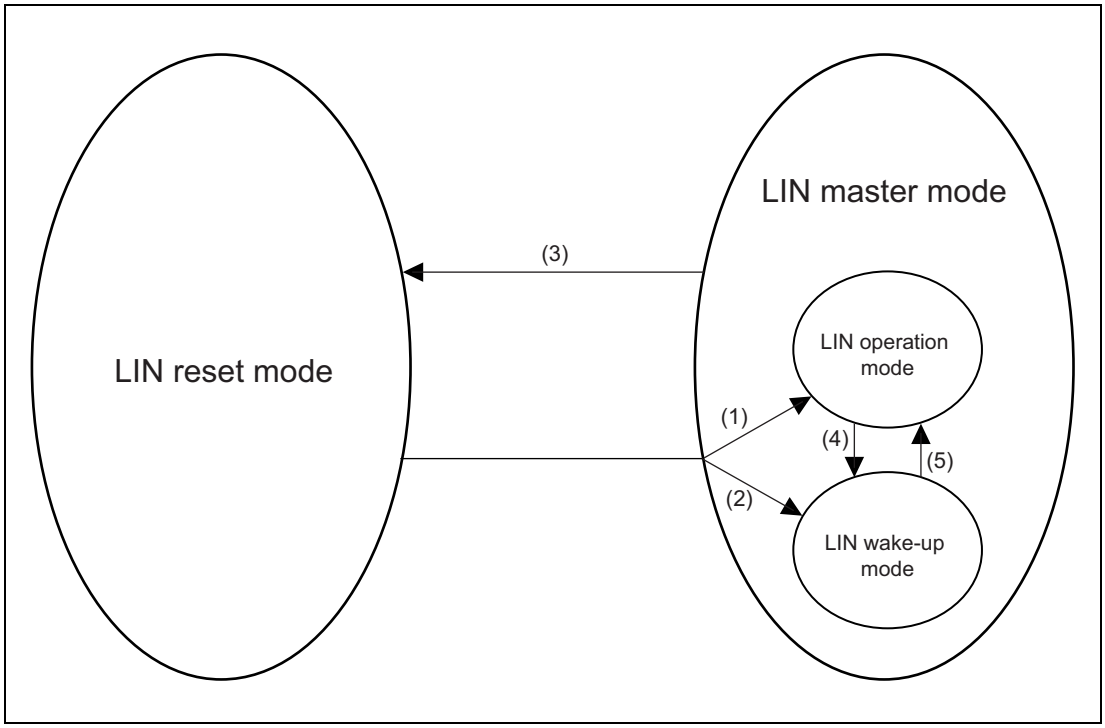

Figure 20.3 Transition of Operation Modes

Table 20.58 Transition Condition for Operation Mode

	Operation Mode Transition			Transition Condition
(1)	LIN reset mode	→	LIN mode • LIN operation mode	LMD[1:0] bit in RLN3nLMD register = 00_B and OM1 and OM0 bits in RLN3nLCUC register = 11_B
(2)	LIN reset mode	→	LIN mode • LIN wake-up mode	LMD[1:0] bit in RLN3nLMD register = 00_B and OM1 and OM0 bits in RLN3nLCUC register = 01_B
(3)	LIN mode • LIN operation mode • LIN wake-up mode	→	LIN reset mode	OM0 bit in RLN3nLCUC register = 0_B
(4) *1	LIN mode • LIN operation mode	→	LIN mode • LIN wake-up mode	OM1 and OM0 bits in RLN3nLCUC register = 01_B
(5) *1	LIN mode • LIN wake-up mode	→	LIN mode • LIN operation mode	OM1 and OM0 bits in RLN3nLCUC register = 11_B

Note 1. Transition between LIN operation mode and LIN wake-up mode cannot be made when communication is going on (when the FTS bit in the RLN3nLTRC register is 1).

(1) LIN Operation Mode

In LIN operation mode, frame processing (header transmission, header reception, response transmission, response reception, and error detection) can be performed.

During a transition from LIN reset mode to LIN mode, setting the OM1 and OM0 bits in the RLN3nLCUC register to 11_B changes the mode to LIN operation mode, changing the OMM1 and OMM0 bits in the RLN3nLMST register to 11_B. Communication settings should be performed after the OMM1 and OMM0 bits have become 11_B.

(2) LIN Wake-up Mode

In LIN wake-up mode, wake-up signal processing (wake-up transmission, wake-up reception, and error detection) can be performed.

During a transition from LIN reset mode to LIN mode, setting the OM1 and OM0 bits in the RLN3nLCUC register to 01_B changes the mode to LIN wake-up mode, changing the OMM1 and OMM0 bits in the RLN3nLMST register to 01_B. Communication settings should be performed after the OMM1 and OMM0 bits have become 01_B.

20.7.1 LIN Master Mode

20.7.1.1 Header Transmission

Figure 20.4 shows the operation of the LIN/UART interface (LIN master mode) in header transmission. **Table 20.59** shows processing in header transmission.

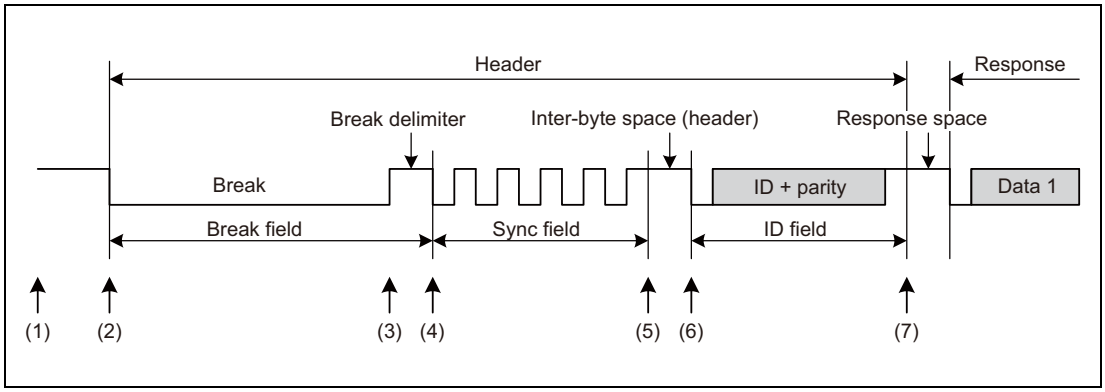

Figure 20.4 Operation in Header Transmission

Table 20.59 Processing in Header Transmission

	Software Processing	LIN/UART Interface Processing
(1)	• Sets a baud rate • Sets noise filter ON/OFF • Enables interrupt • Enables error detection • Sets frame configuration parameters • Changes the LIN/UART interface to the LIN master mode: LIN operation mode • Sets information on the frame to be transmitted (ID, parity, data length, response direction, Checksum method, and transmission data)	Waits for the setting of the FTS bit in the RLN3nLTRC register by software (idle)
(2)	Sets the FTS bit in the RLN3nLTRC register to 1 (frame transmission or wake-up transmission/reception started)	Transmits a break.
(3)	Waits for an interrupt request	Transmits a break delimiter.
(4)		Transmits a sync field (55_H).
(5)		Transmits an inter-byte space (header).
(6)		Transmits an ID field.
(7)		Sets a successful header transmission flag.

NOTE

For information about error detection conditions, see Section 20.7.6, Error Status.

20.7.1.2 Response Transmission

Figure 20.5shows the operation of the LIN/UART interface (LIN master mode) in response transmission. **Table 20.60** provides processing in response transmission.

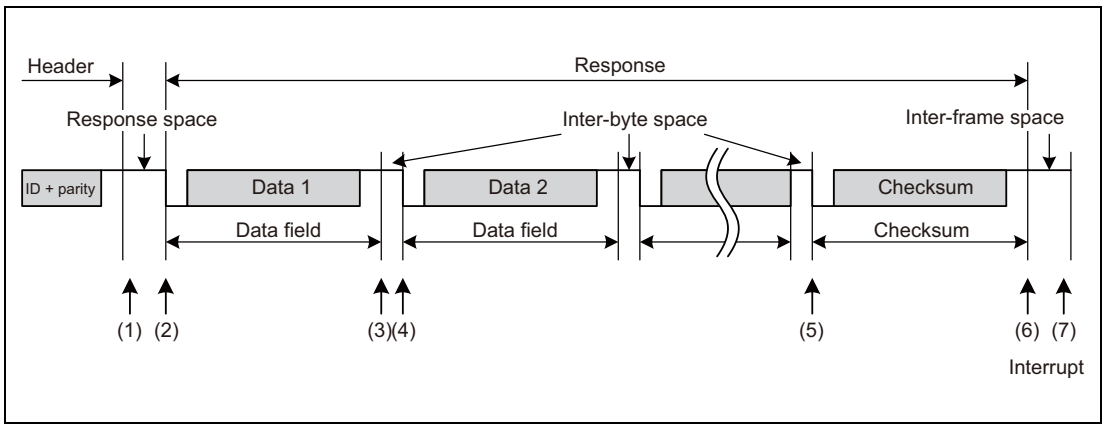

Figure 20.5 Operation in Response Transmission

Table 20.60 Processing in Response Transmission

	Software Processing	LIN/UART Interface Processing
(1)	[When in frame separate mode] • Sets the RTS bit in the RLN3nLTRC register to 1 (response transmission/reception started) [When not in frame separate mode] • Waits for an interrupt request	[When in frame separate mode] • Waits for the setting of the RTS bit in the RLN3nLTRC register to 1 by software. • When the bit is set to 1, sends a response space. [When not in frame separate mode] • Sends a response space.
(2)	Waits for an interrupt request	Transmits data 1.
(3)		Transmits an inter-byte space.
(4)		• Transmits data 2. • Transmits an inter-byte space • Transmits data 3. • Transmits an inter-byte space (Repeats the transmission of inter-byte spaces as many times as the data length specified in bits RFDL[3:0] in the RLN3nLDFC register). : :
(5)		Transmits the checksum.
(6)		• Sets a successful frame/wake-up transmission flag. • Sets the FTS bit in the RLN3nLTRC register to 0 (frame transmission or wake-up transmission/reception stopped) [When in frame separate mode] • Set the RTS bit in the RLN3nLTRC register to 0 (response transmission/reception stopped).
(7)	• Processing after communication Checks the RLN3nLST register, and clears flags.	Idle

NOTE

For information about error detection conditions, see Section 20.7.6, Error Status.

20.7.1.3 Response Reception

Figure 20.6 shows the operation of the LIN/UART interface (LIN master mode) on response reception. **Table 20.61** provides processing in response reception.

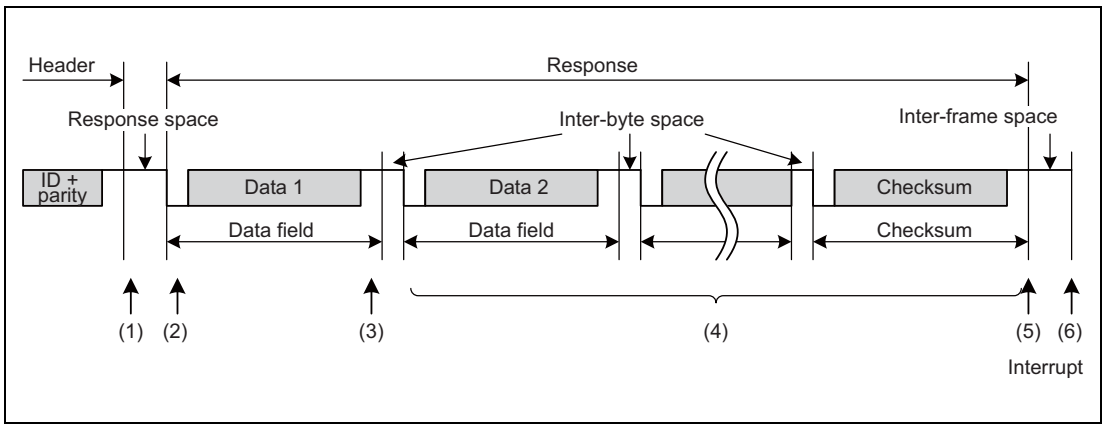

Figure 20.6 Operation in Response Reception

Table 20.61 Processing in Response Reception

	Software Processing	LIN/UART Interface Processing
(1)	Waits for an interrupt request (no processing)	Waits for detection of a start bit.
(2)		Receives data 1 when the start bit is detected.
(3)		Sets the successful data 1 reception flag.
(4)		• Receives data 2 when the start bit is detected. • Receives data 3 when the start bit is detected. Repeats the transmission of inter-byte spaces as many times as the data length specified in bits RFDL[3:0] in the RLN3nLDFC register). : : • Receives the checksum when the start bit is detected.
(5)		• Determines the checksum. • Sets the successful frame/wake-up reception flag. • Sets the FTS bit in the RLN3nLTRC register to 0 (frame transmission or wake-up transmission/reception stopped).
(6)	• Processing after communication Reads the received data. Checks the RLN3nLST register, and clears flags.	Idle

NOTE

For information about error detection conditions, see Section 20.7.6, Error Status.

20.7.2 Data Transmission/Reception

20.7.2.1 Data Transmission

One bit of data is transmitted per 1 Tbit.

The data that is transmitted returns to the reception data input pin via the LIN transceiver. The received data and the transmitted data is compared bit by bit, and the results are stored in the BER flag in the RLN3nLEST register (see Section 20.7.6, Error Status).

Figure 20.7 shows an example of data transmission timing.

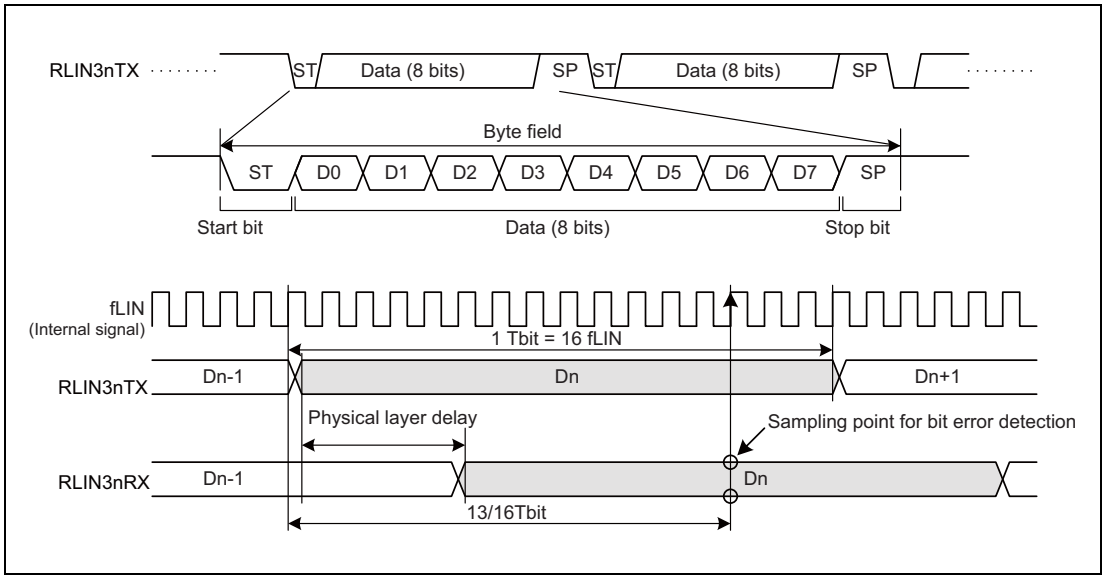

Figure 20.7 Example of Data Transmission Timing (LIN Master Mode)

20.7.2.2 Data Reception

Data reception is performed by using the synchronized RLIN3nRX signal (an internal signal) that is the input from the RLIN3nRX pin synchronized with prescaler clock.

The byte field is synchronized at the falling edge of the start bit for the synchronized RLIN3nRX signal. After the falling edge is detected, sampling is performed again 0.5 Tbit later, and the falling edge is recognized as a start bit if the synchronized RLIN3nRX signal is low level. The falling edge is not recognized as a start bit if the RLIN3nRX signal after the clearing of the resetting is low-level-fixed or if a high level is detected on re-sampling.

After the start bit is detected, the system samples 1 bit per Tbit.

The LIN/UART interface has a noise filter function with respect to reception data. If the LRDNFS bit in the RLN3nLMD register is 0, the LIN/UART interface uses a noise filter, and for a sampling value the value determined by a 3-sampling majority rule on prescaler clocks is used. If the LRDNFS bit in the RLN3nLMD register is 1, the LIN/UART interface does not use a noise filter, and for a sampling value the value of the synchronized RLIN3nRX value at the sampling position is used as is.

Figure 20.8 shows an example of data reception timing.

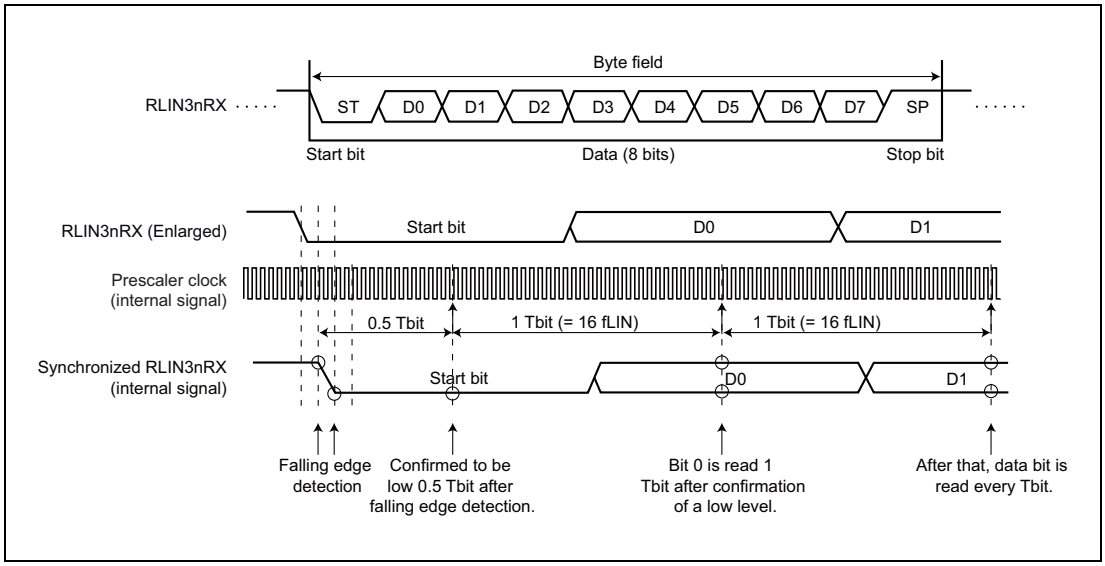

Figure 20.8 Example of Data Reception Timing (LIN Master Mode)

20.7.3 Transmission/Reception Data Buffering

This section explains the buffer processing that takes place when the LIN/UART interface sends or receives data continuously.

20.7.3.1 Transmission of LIN Frames

For an 8-byte transmission, the contents stored in registers RLN3nLDBR1 to RLN3nLDBR8 are sequentially transmitted to data areas 1 to 8 of the LIN frame. In the case of a 4-bytes transmission, the contents stored in registers RLN3nLDBR1 to RLN3nLDBR4 are transmitted to data areas 1 to 4 of the LIN frame, but the contents of registers RLN3nLDBR5 to RLN3nLDBR8 are not transmitted. The transmitted checksum data is stored in the RLN3nLCBR register.

Figure 20.9 depicts the LIN transmission processing and the required buffer.

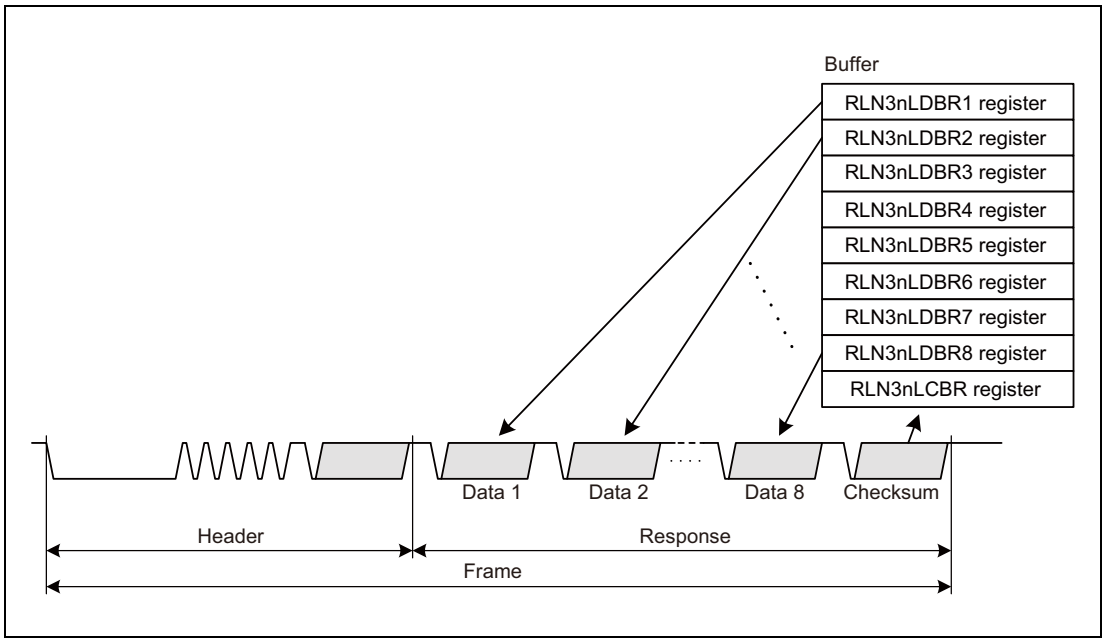

Figure 20.9 LIN Transmission Processing and Required Buffer

[Frame Separate Mode]

Setting the FSM bit in the RLN3nLDFC register to 1 turns on the frame separate mode.

In frame separate mode, the header and response are separately transmitted when prompted by respective transmission start requests.

When the transmission of a header is finished, the HTRC flag in the RLN3nLST register turns 1 (successful header transmission).

Use frame separate mode when sending or receiving response data of 9 bytes or greater in LIN master mode.

20.7.3.2 Reception of LIN Frames

For an 8-byte reception, the contents of data areas 1 to 8 of the LIN frame is stored in registers RLN3nLDBR1 to RLN3nLDBR8, respectively, upon receipt of a stop bit. In the case of a 4-byte reception, the contents of data areas 1 to 4 of the LIN frame are stored in registers RLN3nLDBR1 to RLN3nLDBR4, respectively; however, no data is stored in registers RLN3nLDBR5 to RLN3nLDBR8. Also, the received checksum data is stored in the RLN3nLCBR register.

Figure 20.10 depicts the LIN reception processing and the required buffer.

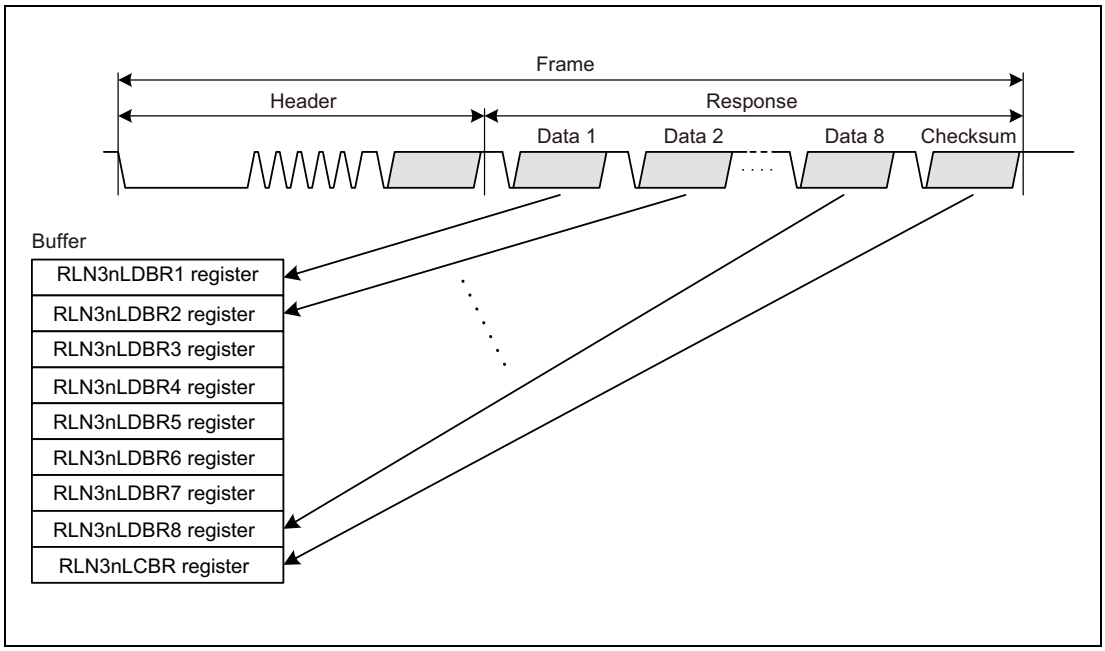

Figure 20.10 LIN Reception Processing and Required Buffer

[Reception of Data 1]

When the reception of the first byte of data is finished, the D1RC flag in the RLN3nLST register turns 1 (successful data 1 reception).

20.7.3.3 Multi-Byte Response Transmission/Reception Function

Normally in LIN communications, a response is 9 bytes or less including a checksum field; however, responses in 10 bytes or greater can also be sent and received.

In such a case, the bit error, framing error, response preparation error detection, and auto checksum functions are enabled.

If the data length is greater than 8 bytes, the LSS bit in RLN3nLDFC register should be set to 1 (indicating that the next data group to be transmitted or received is not the final data group) in the first data group (variable from 0 to 8 bytes) before transmitting or receiving the data group. After the transmission or reception, the user should determine whether the next data group is the final data group. If it is the final data group, the LSS bit in the RLN3nLDFC register should be set to 0 (indicating that the next data group to be transmitted or received is the final data group) before transmitting or receiving the data group, and a checksum should be appended to the final data group.

By changing the RFDL[3:0] bit in RLN3nLDFC register settings when the RTS bit in RLN3nLTRC register is 0, the user can change the data length for each data group.

When performing multi-byte response transmission/reception in LIN master mode, set the FSM bit in RLN3nLDFC register in the RLN3nLDFC register to 1 (frame separate mode).

20.7.4 Wake-up Transmission/Reception

The wake-up transmission/reception can be used in LIN wake-up mode.

20.7.4.1 Wake-up Transmission

In LIN wake-up mode, setting the RFT bit in the RLN3nLDFC register to 1 (LIN master mode: response transmission), and the FTS bit in the RLN3nLTRC register to 1 (frame transmission, header reception or wake-up transmission/reception started) causes a wake-up signal to be output from the output pin. The low width of the wake-up signal should be set using the WUTL[3:0] bits in the RLN3nLWUP register.

However, if the LWBR0 bit of the RLN3nLWBR register in LIN master mode is 1 (LIN2.x use), the LIN system clock (fLIN) becomes low level width at fa regardless of the setting of the LCKS[1:0] bit of the RLN3nLMD register. By setting the WUTL[3:0] bit of the RLN3nLWUP register to 0100_B (5 Tbits), 260 µs low width can be output in LIN wake-up mode regardless of the setting of the LCKS[1:0] bit of the RLN3nLMD register.

If a wake-up low is output without any bit error, the FTC flag in the RLN3nLST register turns 1 (successful frame response or wake-up transmission); when the FTCIE bit in the RLN3nLIE register is 1 (successful frame response/wake-up transmission interrupt enabled), an interrupt request for RLIN3n transmission is generated.

If RLN3nLEDE.BERE is set and a bit error is detected, wake-up transmission is canceled and the BER flag in the RLN3nLEST register is set to 1 (bit error detection).
When RLN3nLEDE.PBERE is set in LIN master mode, set RLN3nLEST.PBER flag to 1 (physical bus error detection) at the same time of a bit error.

Figure 20.11 shows the wake-up transmission timing.

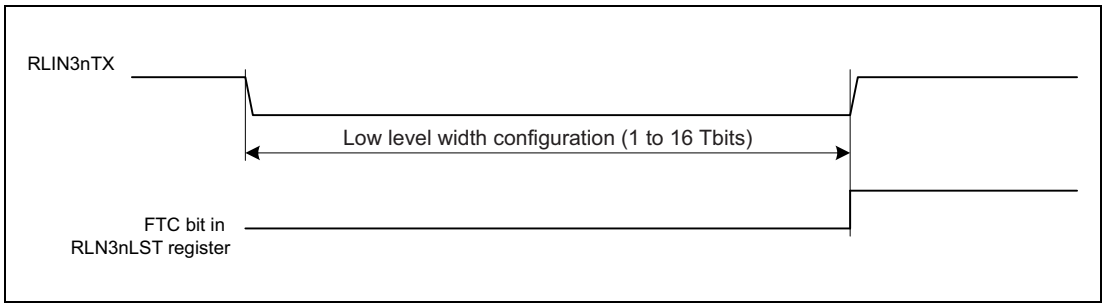

Figure 20.11 Wake-up Transmission Timing

20.7.4.2 Wake-up Reception

The detection of a wake-up involves the use of an input signal low level width count function. The input signal low level width count function measures the low level width of the input signal to the RLIN3nRX pin, using the same sampling point as data reception. This allows the 2.5-Tbit or longer low-level width of the input signal of fLIN to be measured.

In LIN master mode, by setting the LWBR0 bit in the RLN3nLWBR register, operation is executed without changing the baud rate generator setting at a transition between LIN operation mode and LIN wake-up mode.

When LIN Specification Package Revision 1.3 is used, set the LWBR0 bit in the RLN3nLWBR register to 0. When LIN Specification Package Revision 2.x is used, set the LWBR0 bit to 1. Setting the LWBR0 bit to 1 selects the LIN system clock (fLIN) to fa regardless of the setting of the LCKS[1:0] bit in the RLN3nLMD register. (The LCKS[1:0] bit is not changed). By setting the baud rate to 19200bps while fa is selected, the 130 µs or longer low-level width of the input signal to be measured regardless of the setting of the LCKS[1:0] bit in the RLN3nLMD register.

When using this function, in LIN wake-up mode set the RFT bit in the RLN3nLDFC register to 0 (LIN master mode: response reception), or the FTS bit in the RLN3nLTRC register to 1 (frame transmission (header reception) or wake-up transmission/reception started).

When the low level width to be measured is reached, the FRC flag in the RLN3nLST register turns 1 (successful frame response/wake-up reception). If the FRCIE bit in the RLN3nLIE register is 1 (successful frame response or wake-up reception interrupt enabled), an interrupt request for successful RLIN3n reception is generated.

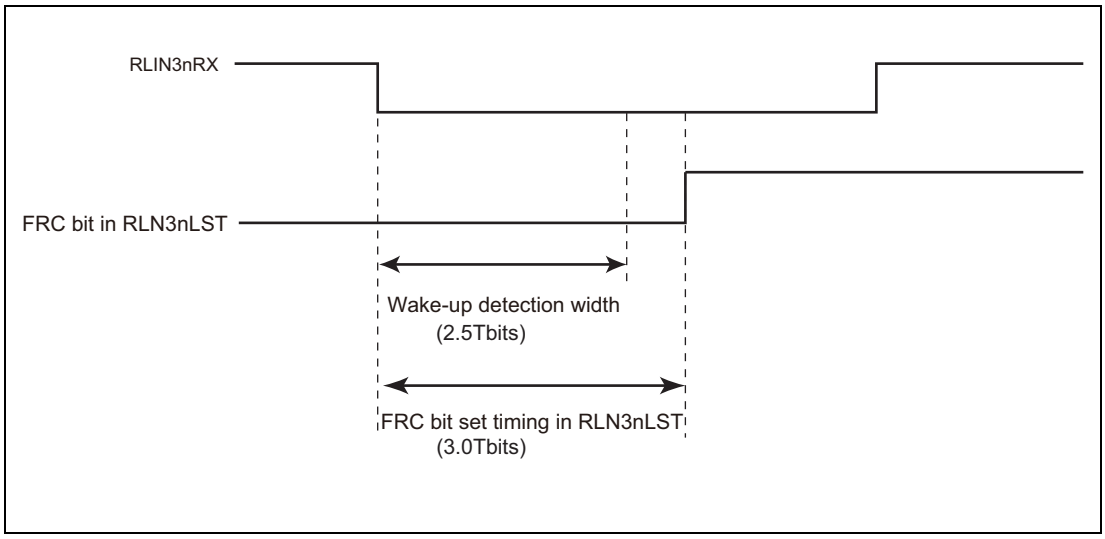

Figure 20.12 Input Signal Low level Count Function

20.7.4.3 Wake-up Collision

If the master node and the slave node transmit wake-up signals simultaneously, a collision will occur on the LIN bus, though a collision of wake-up signals is not detected in the LIN/UART interface.

20.7.5 Status

During LIN mode operation, the LIN/UART interface can detect seven types of statuses.

The four statuses, successful frame/wake-up transmission, successful frame/wake-up reception, error detection, successful header transmission/reception, can generate interrupt requests.

Table 20.62 shows the types of statuses available in LIN master mode.

Table 20.62 Types of Statuses in LIN Master Mode

Status	Status Set Condition	Status Clear Condition	Operation Mode Capable of Status Detection	Corresponding Bit	Interrupt
Reset	After the OM0 bit in the RLN3nLCUC register is set to not-LIN–reset-mode, if actually the LIN/UART interface is cleared from LIN reset mode.	After the OM0 bit in the RLN3nLCUC register is set to LIN reset mode, if actually the LIN/UART interface enters LIN reset mode.	All modes	OMM0 bit in RLN3nLMST register	—
Operation mode	After the OM1 bit in the RLN3nLCUC register is set to LIN operation mode, if actually the LIN/UART interface enters LIN operation mode.	After the OM1 bit in the RLN3nLCUC register is set to LIN wake-up mode, if actually the LIN/UART interface enters LIN wake-up mode.	• LIN operation mode • LIN wake-up mode	OMM1 bit in RLN3nLMST register	—
Frame/wake-up transmission end	When a frame (header transmission + response transmission), a wake-up signal, or a data group is transmitted successfully.	• When another communication is started (When the FTS bit in the RLN3nLTRC register is set) • When cleared by software • After transition to LIN reset mode	• LIN operation mode • LIN wake-up mode	FTC flag in RLN3nLST register	√
Frame/wake-up reception end	When a frame (header transmission + response reception), a wake-up signal, or a data group is received successfully.	• When another communication is started (When the FTS bit in the RLN3nLTRC register is set) • When cleared by software • After transition to LIN reset mode	• LIN operation mode • LIN wake-up mode	FRC flag in RLN3nLST register	√
Error detection	If any of the RPER flag, CSER flag, FER flag, FTER flag, PBER flag, and BER flags in the RLN3nLEST register turns 1 (error detected).	• When another communication is started (When the FTS bit in the RLN3nLTRC register is set) • When cleared by software**Note 1.** • After transition to LIN reset mode	• LIN operation mode • LIN wake-up mode	ERR flag in RLN3nLST register	√
Data 1 reception end	The RFT bit in the RLN3nLDFC register is 0 (reception) and the first byte of the response field or the first byte of each data group is received.*2	• When another communication is started (When the FTS bit in the RLN3nLTRC register is set) • • When cleared by software • After transition to LIN reset mode	LIN operation mode	D1RC flag in RLN3nLST register	—
Header transmission end	When a header field is transmitted successfully.	• When another communication is started (When the FTS bit in the RLN3nLTRC register is set) • When cleared by software • After transition to LIN reset mode	LIN operation mode	HTRC flag in RLN3nLST register	√

Note 1. In LIN operation mode, the ERR flag in the RLN3nLST register is cleared to 0 by writing 0 to the RPER flag, CSER flag, FER flag, FTER flag, PBER flag, or BER flags in the RLN3nLEST register.

Note 2. Not detected when the RFDL [3:0] bits in the RLN3nLDFC register are 0000_B (0-byte + checksum).

20.7.6 Error Status

(1) Types of Error Statuses

The LIN/UART interface can detect six types of error statuses in LIN master mode. The condition of these error statuses can be checked by means of the corresponding bits in the RLN3nLEST register.

All error statuses represent interrupt events.

Table 20.63 shows the types of error statuses.

Table 20.63 Types of Error Statuses in LIN Master Mode

Status	Error Detection Condition	Operation Mode Capable of Error Detection	Communication	Enable/Disable Detection	Corresponding Bit
Bit error	The transmitted data and the data on the LIN bus monitored by the receive pin do not match *1*2	• LIN operation mode • LIN wake-up mode	Cancel	Enabled	BER flag in RLN3nLEST register
Physical bus error	• LIN bus is detected to be high level when sending a break • LIN bus is detected to be low level when sending a break delimiter • LIN bus is detected to be high level when sending a wake-up	• LIN operation mode • LIN wake-up mode	Cancel	Enabled	PBER flag in RLN3nLEST register
Timeout error	A frame or response transmission/reception does not terminate within a given time*3	LIN operation mode	Cancel	Enabled	FTER flag in RLN3nLEST register
Framing error	In response field reception, a stop bit of each data byte is low level	LIN operation mode	Cancel	Enabled	FER flag in RLN3nLEST register
Checksum error	In response field reception, the result of checksum test gives an error	LIN operation mode	—	Disabled	CSER flag in RLN3nLEST register
Response preparation error	One of the following conditions occurs in frame separate mode during a multi-byte response reception: • The first reception data byte is received after completion of header transmission but before a response transmission/reception request is set • The first reception data byte is received after the completion of previous data group reception before a transmission/reception request for another data group is set.	LIN operation mode	Cancel	Disabled	RPER flag in RLN3nLEST register

Note 1. If a bit error is detected, the process is canceled after a stop bit is sent. If a bit error is detected in a non-data area, such as an inter-byte space, the transmission is canceled immediately after that area. If a bit error is detected during the transmission of a wake-up, the transmission of the wake-up is canceled after the error-causing bit is sent.

Note 2. In a multi-byte response transmission, bit errors are detected also between data groups.

Note 3. The timeout time depends on the response field data length (the RFDL [3:0] bits in the RLN3nLDFC register) and the checksum selection (the CSM bit in the RLN3nLDFC register), and this can be calculated according to the following formula:
When the FSM bit in the RLN3nLDFC register is set to 1 (frame separate mode), the timeout time is that of the 8 data bytes until the RTS bit of the RLN3nLTRC register is set. Once the RTS bit is set, the timeout time is changed to the time based on the response field data length (the RFDL[3:0] bits in the RLN3nLDFC register).

[Frame timeout]
On classic selection (when the CSM bit in RLN3nLDFC is 0): Timeout time = 49 + (number of data bytes + 1) × 14 [Tbit]
On enhanced selection (when the CSM bit in RLN3nLDFC is 1): Timeout time = 48 + (number of data bytes + 1) × 14 [Tbit]
The aforementioned timeout time is a time greater than the TFRAME_MAX of LIN Specification Package Revision 1.3 on classic selection, or the TFRAME_MAX of LIN Specification Package Revision 2.x on enhanced selection.
[Response timeout]
Timeout time = (number of data bytes + 1) × 14 [Tbit]

When an error is detected, time-out error detection function stops.

The error status is cleared when the next communication is started (when the FTS bit in the RLN3nLTRC register is set), by software, or at a transition to LIN reset mode.

(2) Target Time Area for LIN Error Detection

Figure 20.13 shows the time domain in which the LIN/UART interface in LIN master mode performs monitoring for error detection.

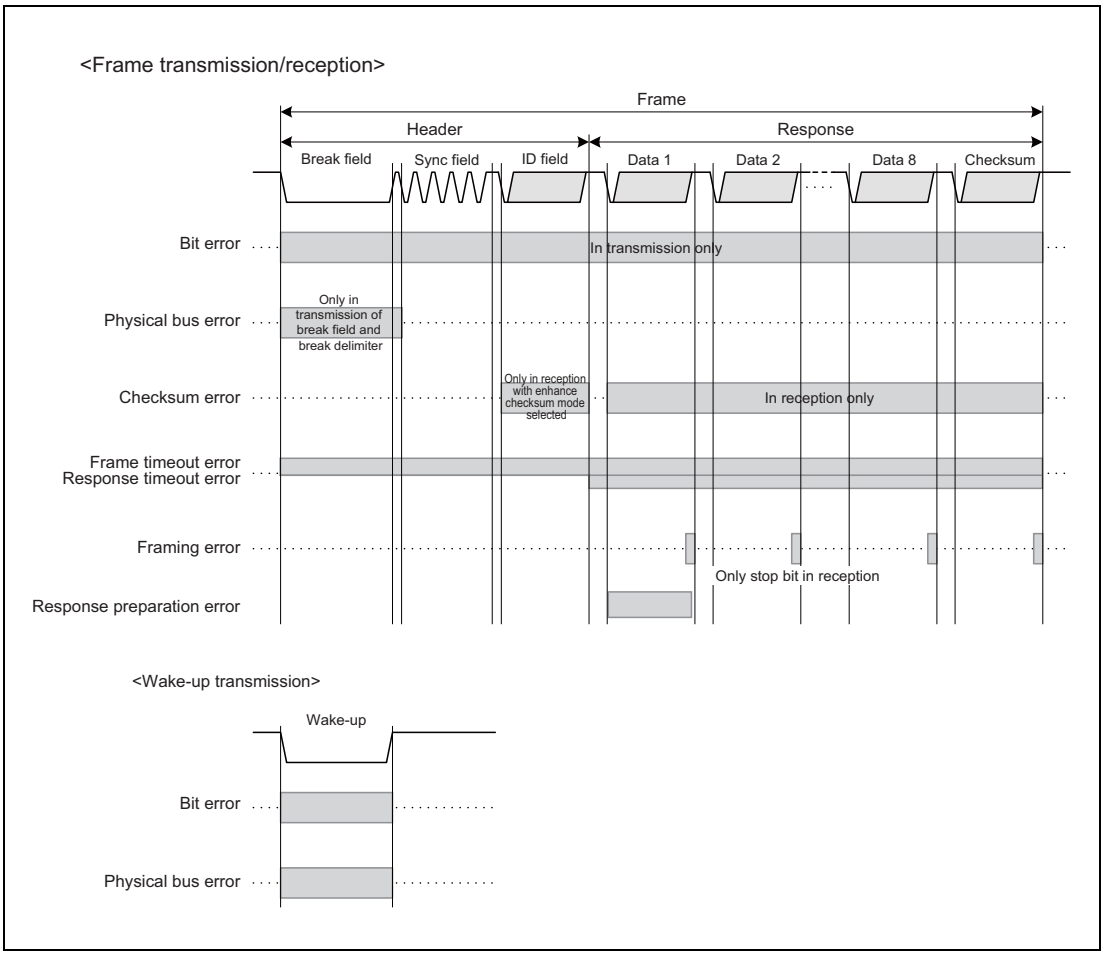

Figure 20.13 Target Time Area for LIN Error Detection (LIN Master Mode)

20.8 UART Mode

In LIN reset mode, setting the LMD[1:0] bits in the RLN3nLMD register to 01_B (UART mode) and the OM0 bit in the RLN3nLCUC register to 1 changes the mode to UART mode, turning the OMM0 bit in the RLN3nLMST register to 1.

20.8.1 Transmission

Figure 20.14 shows LIN/UART interface (in UART mode) transmission operations; **Table 20.64** shows LIN/UART interface (in UART mode) transmission processing.

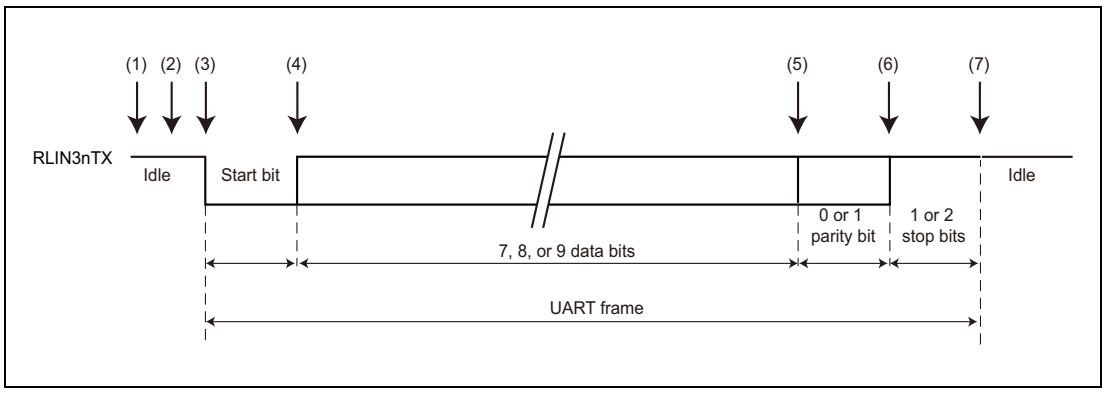

Figure 20.14 LIN/UART Interface (in UART Mode) Transmission Operation

Table 20.64 LIN/UART Interface (UART Mode) Transmission Processing (1/2)

	Software Processing	LIN/UART Interface Processing
(1)	• Sets a baud rate. • Sets noise filter ON/OFF. • Sets error detection enable. • Sets data format. • Sets an interrupt generation timing. • Clears the LIN/UART interface from LIN reset mode. • Sets the transmit enable bit (UTOE bit) to 1.	• Waits for a transmission trigger (RLN3nLUTDR register) by software.
(2)	• Sets the transmit data to the UART transmit data register (RLN3nLUTDR) or UART wait transmit data register (RLN3nLUWTDR).	• Sets the transmit status flag.
(3)	• Waits an interrupt request.	• Transmits a start bit (for switching between transmission and reception in half duplex communication, transmits a start bit after receiving 1 stop bit. For details about this function, see Section 20.8.1.4, Transmission Start Wait Function.
	[When the UTIGTS bit is 0 (a transmission interrupt request is generated upon start of transmission)] • When transmitting data continuously, sets another piece of transmission data in the UART transmit data register (RLN3nLUTDR register), waits for the generation of an interrupt request.	[When the UTIGTS bit is 0 (a transmission interrupt is generated)] • Generates a RLIN3n transmission interrupt request.
(4)		Transmits the data set in the UART (for wait) transmit data register.
(5)		Transmits a parity bit when parity is used.
(6)		Transmits 1 or 2 stop bits.

Table 20.64 LIN/UART Interface (UART Mode) Transmission Processing (2/2)

	Software Processing	LIN/UART Interface Processing
(7)	[When the UTIGTS bit is 0 (a transmission interrupt request is generated upon start of transmission)] • If another piece of transmission data is set, goes to step (3).	[When the UTIGTS bit is 0 (a transmission interrupt request is generated upon start of transmission)] • If another piece of transmission data is set, goes to step (3). • If another piece of transmission data is not set, clears the transmit status flag.
	[When the UTIGTS bit is 1 (a transmission interrupt is output upon end of transmission)] • When transmitting data continuously, goes to step (2).	[When the UTIGTS bit is 1 (a transmission interrupt is output upon end of transmission)] • Generates a RLIN3n transmission interrupt request. • Clears the transmission status flag.

NOTE

For information about error detection conditions, see Section 20.8.5, Error Status.

20.8.1.1 Continuous Transmission

The LIN/UART interface (in UART mode) can transmit multiple sets of data continuously by using the RLN3nLUTDR register. **Figure 20.15** shows an operation example where the transmission interrupt generation timing is the start of transmission and an operation example where the transmission interrupt generation timing is the end of transmission.

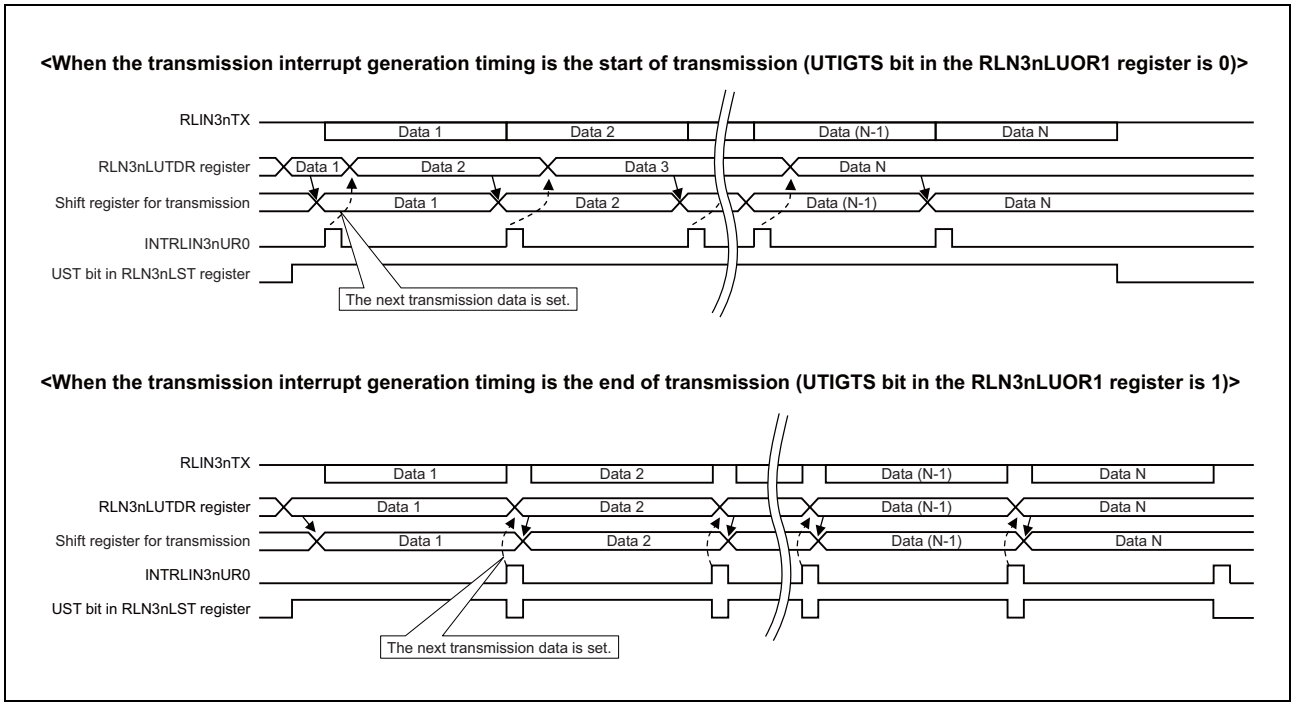

Figure 20.15 Operation Example of LIN/UART Interface (UART Mode) Continuous Transmission

An interrupt can be generated at the end of a transmission by changing the UTIGTS bit in the RLN3nLUOR1 register from 0 to 1 after the start of transmission of final data, provided only that the transmission interrupt generation timing is the start of transmission and the end of transmission of final data needs to be known.

20.8.1.2 UART Buffer Transmission

The LIN/UART interface (in UART mode) has a maximum of nine bytes of UART buffers, and thus it is capable of performing continuous transmissions through the use of UART buffers.

Figure 20.16 shows the UART buffer transmission operation in the LIN/UART interface (in UART mode). **Table 20.65** shows the UART buffer transmission processing.

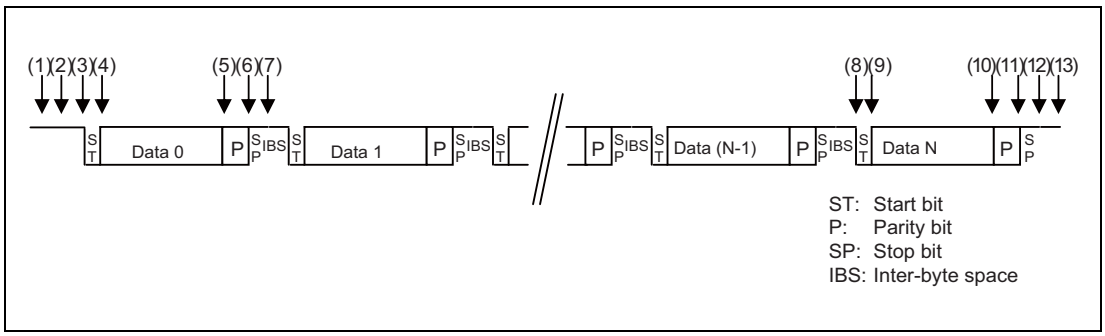

Figure 20.16 UART Buffer Transmission in LIN/UART Interface (in UART Mode)

Table 20.65 UART Buffer Transmission Processing in LIN/UART Interface (in UART Mode) (1/2)

	Software Processing	LIN/UART Interface Processing
(1)	• Sets a baud rate • Sets noise filter ON/OFF • Sets error detection enable • Sets data format • Sets an interrupt generation timing to the end of transmission. • Clears the LIN/UART interface from LIN reset mode. • Sets the transmit enable bit (UTOE bit) to 1	• Waits for a transmission trigger (RTS bit) by software
(2)	• Sets the UART buffer data length and whether the system must wait for the start of transmission. • Specifies the transmission data to be transmitted in the UART data 0 buffer register (RLN3nLUDB0) and the LIN data buffer b register (RLN3nLDBRb). (b =1 to 8) • Sets the UART buffer transmission start bit (RTS).	• Sets the transmit status flag.

Table 20.65 UART Buffer Transmission Processing in LIN/UART Interface (in UART Mode) (2/2)

	Software Processing	LIN/UART Interface Processing
(3)	Waits for an interrupt request.	Transmits a start bit. (When switching from reception to transmission during half-duplex communication, transmits the start bit upon completion of the stop bit for reception. For details about this function, see **Section 20.8.1.4, Transmission Start Wait Function**.)
(4)		Transmits the data specified in the UART data buffer 0 register (RLN3nLUDB0) or the LIN/UART data buffer b register (RLN3nLDBRb).
(5)		Transmits a parity bit when parity is used.
(6)		Transmits 1 or 2 stop bits (When the number of data set in UART buffer data length setting bit, proceed to (12).)
(7)		Transmits an inter-byte space (idle).
		Repeats steps (3) to (7) until the number of data -1 that was set in the UART buffer data length select bits is reached.
(8)		Transmits a start bit.
(9)		Transmits the data set in the LIN/UART data buffer b register (RLN3nLDBRb).
(10)		Transmits a parity bit when parity is used.
(11)		Transmits 1 or 2 stop bits.
(12)		• Sets the buffer transmission end flag. • Clears the UART buffer transmit start bit (RTS). • A transmission interrupt request signal. • Clears the transmission status flag.
(13)	• Checks the RLN3nLST register, and clears flags • In the case of continuous data transmission, goes to step (2).	

NOTE

For information about error detection conditions, see Section 20.8.5, Error Status.

(1) UART Buffer Transmission

For a 9-byte transmission, the contents stored in the RLN3nLUDB0 and RLN3nLDBR1 to RLN3nLDBR8 registers are transmitted to data areas 0 to 8. The RLN3nLUDB0 register is used only if 9-byte transmission is set. In other cases, the RLN3nLDBR1 to RLN3nLDBR8 registers are selected depending upon the length of data involved. For a 4-byte transmission, the contents stored in the RLN3nLDBR1 to RLN3nLDBR4 registers are transmitted to data areas 1 to 4, but the contents of the RLN3nLDBR5 to RLN3nLDBR8 registers are not transmitted. An RLIN3n transmission interrupt is generated after the transmission of the data that is set in the MDL[3:0] bits of the RLN3nLDFC register. The spaces between transmission data items can be set in the IBS[1:0] bit in the RLN3nLSC register.

Figure 20.17 shows a 9-byte UART buffer and the transmission processing.

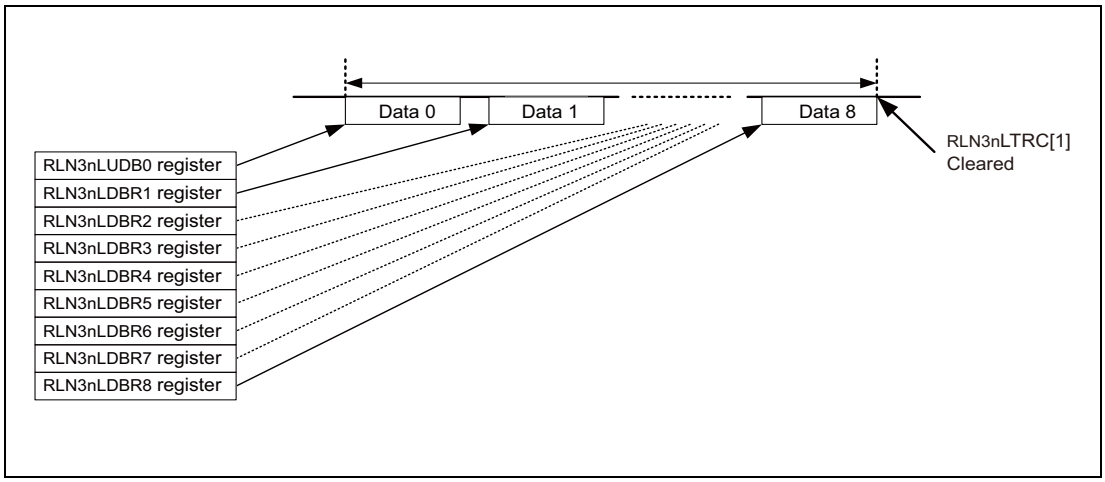

Figure 20.17 UART Buffer and Transmission Processing (for 9-Byte Transmission)

20.8.1.3 Data Transmission

One bit of data is transmitted per Tbit.

In half-duplex communication, if the BERE bit in the RLN3nLEDE register is 1 (bit error detection enabled), the transmission data and the input pin level are compared bit by bit during data transmission, and the results are stored in the BER flag in the RLN3nLEST register (see Section 20.7.6, Error Status). The timing at which the input pin is sampled during data transmission can vary depending upon the settings of the LPRS[2:0] and NSPB[3:0] bits in the RLN3nLWBR register.

The bit error detection timing in UART mode is shown in **Table 20.66**.

Table 20.66 Error Detection Timing in UART Mode

Sampling Count Per Bit	Bit Error Detection Timing
6 samples	3rd clock cycle + 1 prescaler clock
7 samples	4th clock cycle + 1 prescaler clock
8 samples	4th clock cycle + 1 prescaler clock
9 samples	5th clock cycle + 1 prescaler clock
10 samples	5th clock cycle + 1 prescaler clock
11 samples	6th clock cycle + 1 prescaler clock
12 samples	6th clock cycle + 1 prescaler clock
13 samples	7th clock cycle + 1 prescaler clock
14 samples	7th clock cycle + 1 prescaler clock
15 samples	8th clock cycle + 1 prescaler clock
16 samples	8th clock cycle + 1 prescaler clock

Example of Data Transmission Timing (when 1 Tbit = 16 Sampling) is shown in **Figure 20.18**

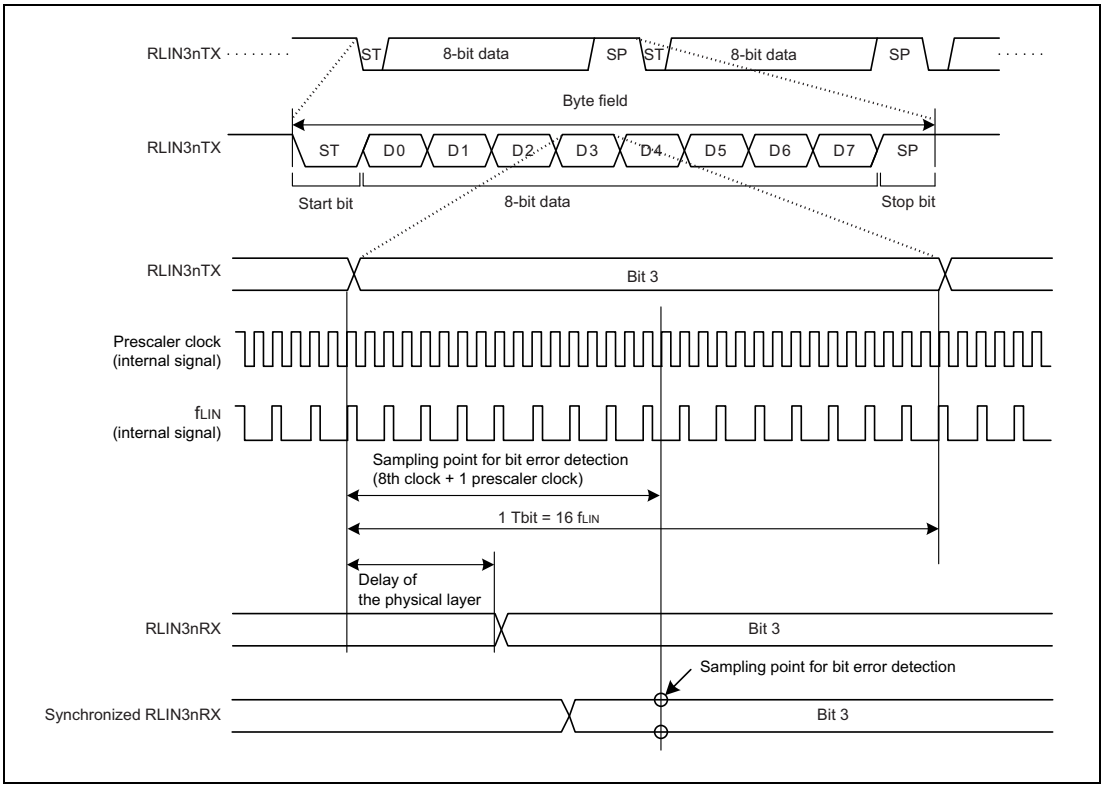

Figure 20.18 Example of Data Transmission Timing (When 1 Tbit = 16 Sampling)

20.8.1.4 Transmission Start Wait Function

For performing half-duplex communication, the LIN/UART interface (in UART mode) has the function of securing the reception stop bit length when switching from reception to transmission.

If it is desired to delay the start of transmission until the stop bits for the reception are completed, set data in the RLN3nLUWTDR register, which is used only for the wait function, instead of setting transmission data in the RLN3nLUTDR register as a start-of-transmission request. When transmitting from the UART buffer, set 1 (UART buffer transmission started) in the RTS bit in the RLN3nLTRC register with 1 set in the UTSW bit in the RLN3nLDFC register.

In such a case, the LIN/UART interface delays the start of transmission until the stop bits of reception data are completed.

It should be noted that even if the UART stop bit length select bit (USBLS) in RLN3nLBFC register is 1 (stop bits = 2 bits), delay is made only for 1 bits.

Figure 20.19 shows the operation of transmission wait function.

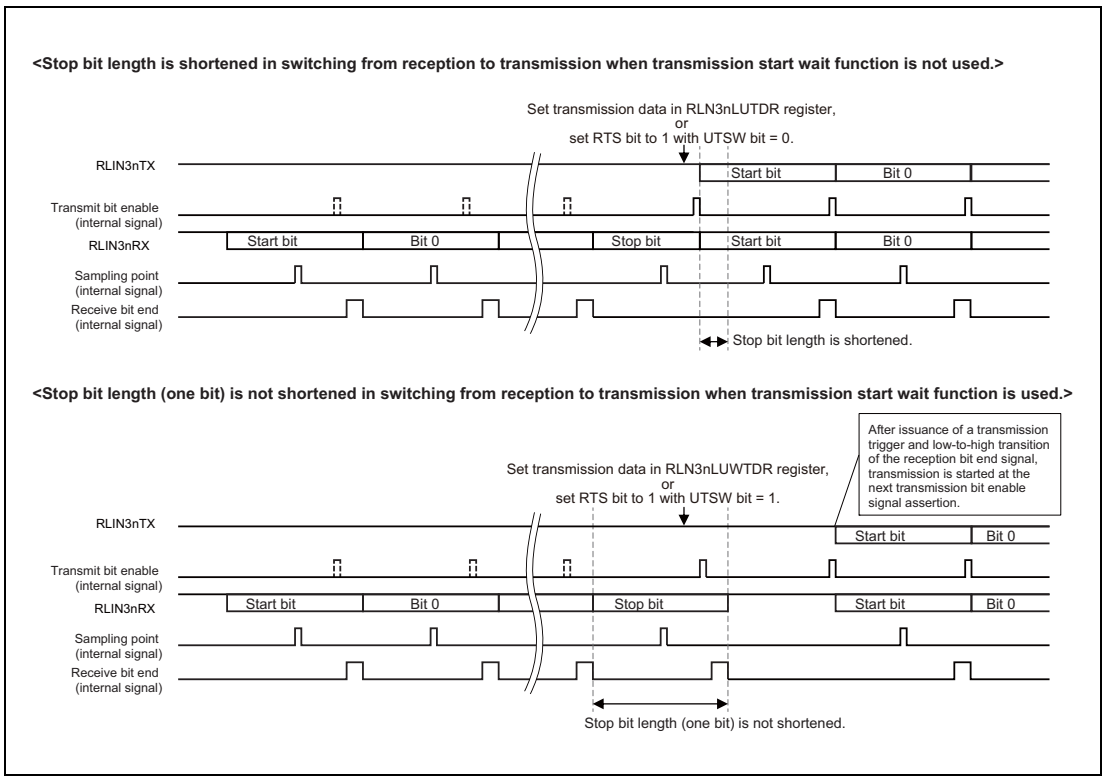

Figure 20.19 Transmission Wait Function (If Transmission Data is Set during the Stop Bits in the Received Data)

20.8.2 Reception

Figure 20.16 shows the LIN/UART interface (in UART mode) reception operation.**Table 20.67** shows the LIN/UART interface (in UART mode) reception processing.

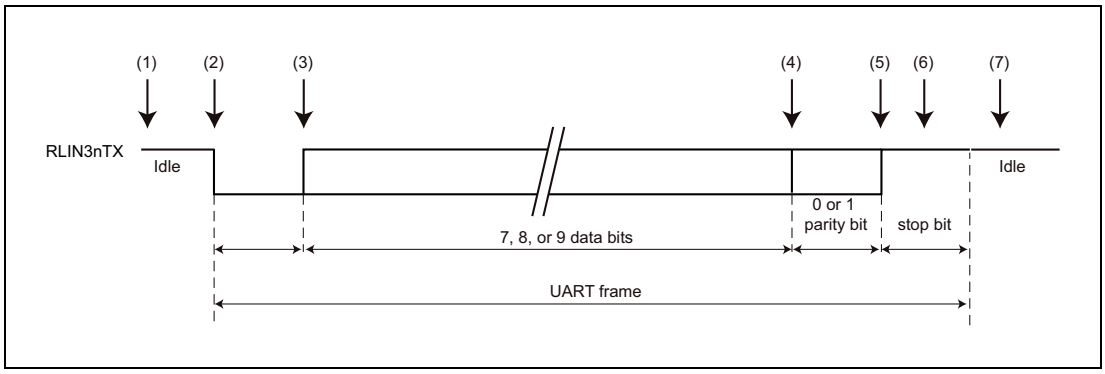

Figure 20.20 LIN/UART Interface (in UART Mode) Reception Operation

Table 20.67 LIN/UART Interface (in UART Mode) Reception Processing

	Software Processing	LIN/UART Interface Processing
(1)	• Sets a baud rate. • Sets noise filter ON/OFF. • Sets error detection enable. • Sets data format. • Clears the LIN/UART interface from LIN reset mode. • Sets the receive enable bit (UROE bit) to 1.	• Waits for reception enable state switching by software. • Waits for detection of a start bit.
(2)	Waits for an interrupt request.	• Waits for a falling edge from the reception pin, and detects a start bit. • Sets the reception status flag.
(3)		Receives data.
(4)		Receives a parity bit when parity is used.
(5)		Receives only 1 stop bit.
(6)		• Generates a successful RLIN3n reception interrupt request. • Clears the reception status flag.
(7)	Checks the RLN3nLST register, and clears flags	Waits for a falling edge from the reception pin.

NOTE

For information about error detection conditions, see Section 20.8.5, Error Status.

20.8.2.1 Data Reception

Data reception is performed by using the synchronized RLIN3nRX (an internal signal) that is the input from the RLIN3nRX pin synchronized with the prescaler clock.

The byte field is synchronized at the falling edge of the start bit for the synchronized RLIN3nRX signal. After the falling edge is detected, resampling is performed 0.5 Tbits later when the number of the sampling per 1 Tbit is even and {(the number of the sampling + 1) / 2} / (the number of sampling) Tbits later when the number is odd. If the synchronized RLIN3nRX signal is low level, the bit is recognized as a start bit. The bit is not recognized as a start bit if the RLIN3nRX signal is fixed at low level after the reset is cleared or if a high level is detected during the resampling.

After the start bit is detected, 1 bit is sampled per Tbit.

However, when the BERE bit in the RLN3nLEDE register is 1, the sampling point is the same as the bit error detection timing.

The LIN/UART interface has a noise filter function with respect to received data. If the LRDNFS bit in the RLN3nLMD register is 0, the noise filter is used. For a sampling value, the value determined by a 3-sampling majority rule by the prescaler clock is used. If the LRDNFS bit in the RLN3nLMD register is 1, the noise filter is not used. In this case, for a sampling value, the synchronized RLIN3nRX value at the sampling position is used as is.

Figure 20.21 shows an example of data reception timing.

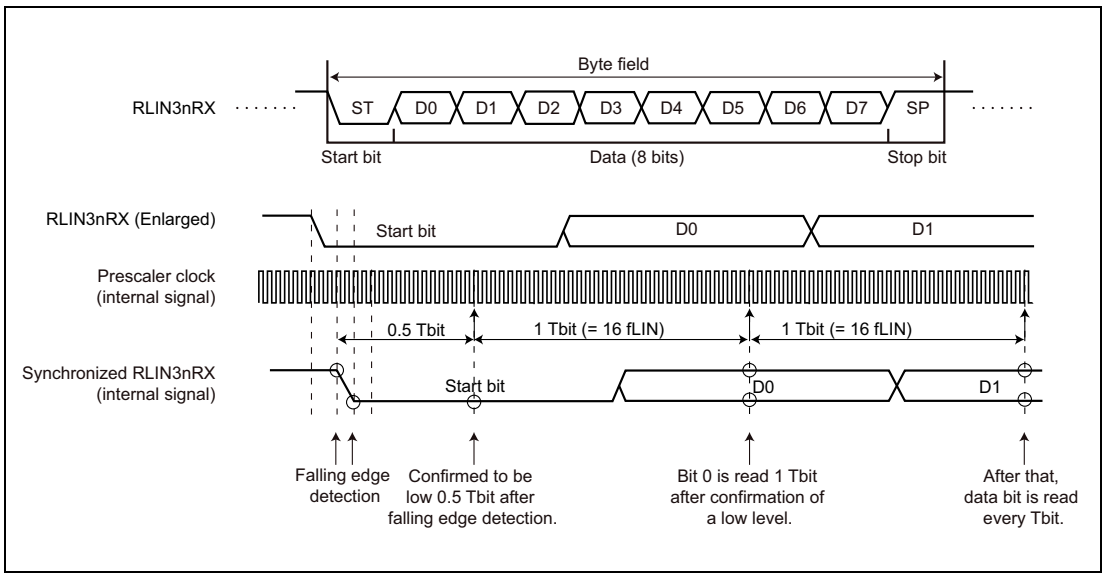

Figure 20.21 Example of Data Reception Timing (When Sampling Count is 16 in 1 Tbit)

20.8.3 Expansion Bits

The LIN/UART interface (in UART mode) can transmit and receive 9-bit long data by setting the UEBE bit in the RLN3nLUOR1 register to 1.

20.8.3.1 Expansion Bit Transmission

The LIN/UART interface (in UART mode) can transmit 9-bit long data when the expansion bit enable bit (UEBE) in the UART option register 1 (RLN3nLUOR1) is 1 and by writing the 9-bit data to either the UART transmission data register (RLN3nLUTDR) or the UART wait transmission data register (RLN3nLUWTDR).

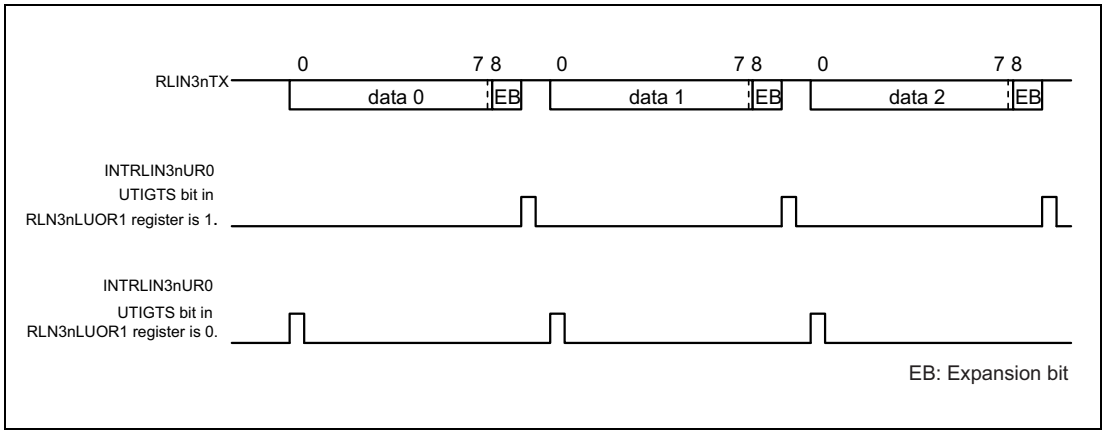

Figure 20.22 Transmission Example When Expansion Bit is Enabled (LSB First)

20.8.3.2 Expansion Bit Reception

With the LIN/UART interface (in UART mode), 9-bit data can always be received without requiring a comparison of expansion bits, provided that the expansion bit enable bit (UEBE) in the UART option register 1 (RLN3nLUOR1) is 1, the expansion bit comparison disable bit (UECD) is 1, and the expansion bit data comparison enable bit (UEBDCE) is 0. Irrespective of the particular setting of the expansion bit detection level select bit (UEBDL) in the UART option register 1 (RLN3nLUOR1), a successful RLIN3n reception interrupt is generated when 9-bit data is received.

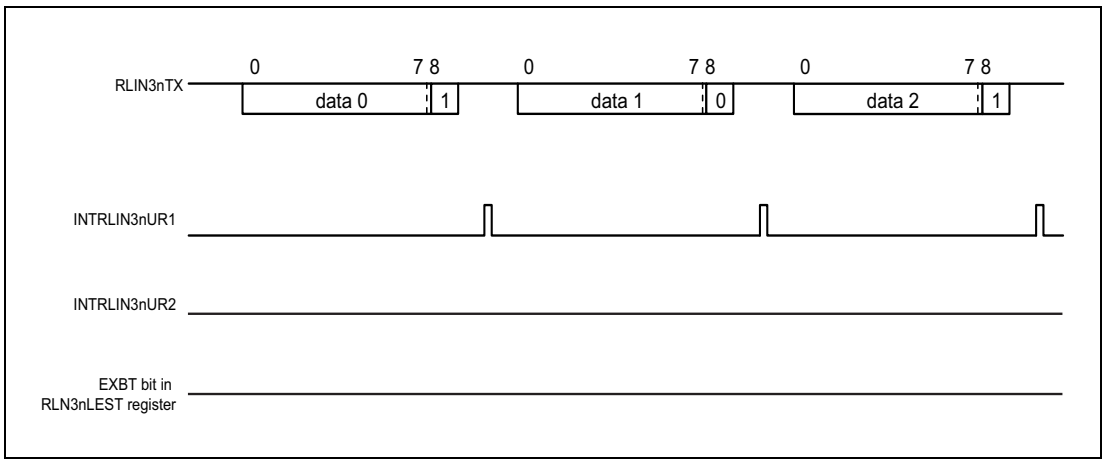

Figure 20.23 Expansion Bit Reception Example (LSB First)

20.8.3.3 Expansion Bit Reception (with Expansion Bit Comparison)

The LIN/UART interface (in UART mode) can compare received expansion bits and the UEBDL bits when the expansion bit enable bit (UEBE) in the UART option register 1 (RLN3nLUOR1) is 1 and the expansion bit comparison disable bit (UECD) is 0 and the expansion bit/data comparison enable bit (UEBDCE) is 0.

If the level that was set in the expansion bit detection level select bit (UEBDL) is detected, an RLIN3n status interrupt request is generated upon completion of data reception, and the expansion bit detection flag (EXBT) in the LIN error status register (RLN3nLEST) is set. If the reversed value of an expansion bit detection level is detected, a successful RLIN3n reception interrupt request is generated. In either case, the received data is stored in the UART reception data register (RLN3nLURDR), unless there was an overrun error.

Figure 20.24 shows an example when the expansion bit detection level select bit (UEBDL) is set to 0.

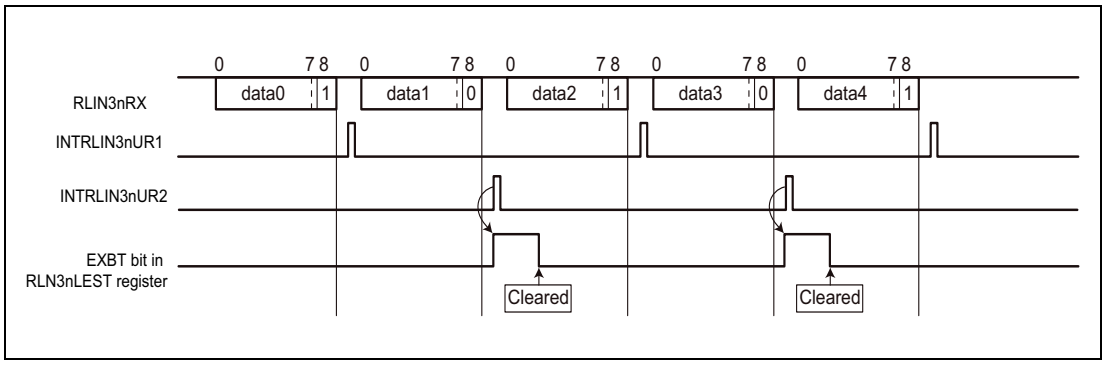

Figure 20.24 Expansion Bit Reception Example (with Expansion Bit Comparison) (LSB First, UEBDL = 0)

NOTE

- If a reception error (parity error, framing error, or overrun error) occurs in received data 0, 2, or 4 (if a reversed value of an expansion bit detection level is detected), an RLIN3n status interrupt is generated, and the error flag is updated. In this case, a successful RLIN3n reception interrupt is not generated.
- If a reception error (parity error, framing error, or overrun error) occurs in received data 1 or 3 (if an expansion bit detection level is detected), an RLIN3n status interrupt is generated, and the error flag is updated. If the overrun error occurs, the expansion bit detection flag (EXBT) is also set.

20.8.3.4 Expansion Bit Reception (with Data Comparison)

If the expansion bit enable bit (UEBE) in the UART option register 1 (RLN3nLUOR1) is 1 and the expansion bit comparison disable bit (UECD) is 0 and the expansion bit/data comparison enable bit (UEBDCE) is 1, when the level that was set by the expansion bit detection level select bit (UEBDL) is detected, the LIN/UART interface (in UART mode) compares the 8 bits of the received data excluding the expansion bit, exclusive of the expansion bit in the received data, with the a preset RLN3nLIDB register value.

If the result of the comparison is a match, the LIN/UART interface performs the following operations:

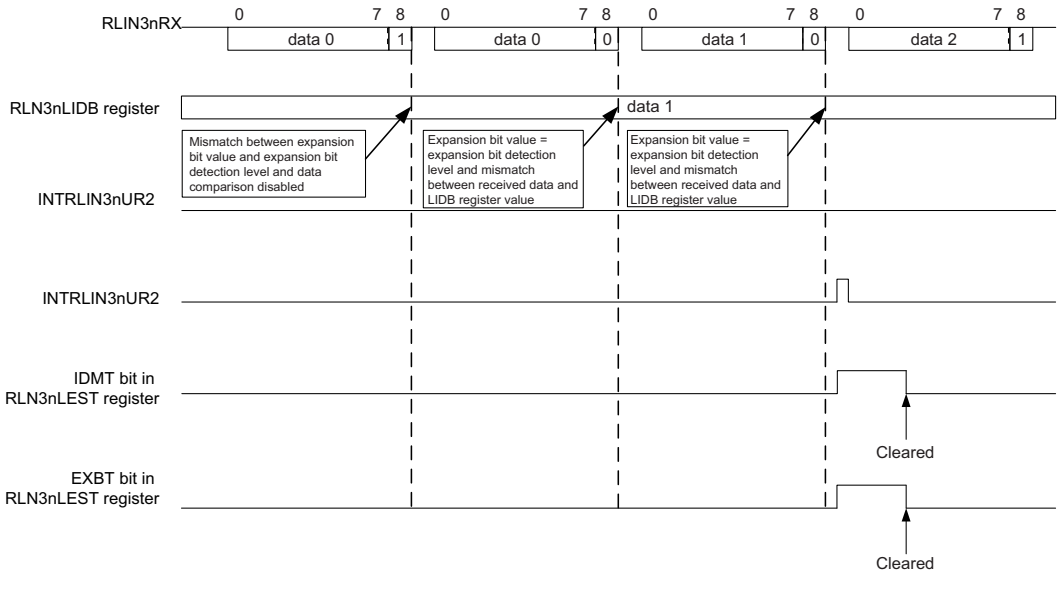
- Generates an RLIN3n status interrupt
- Sets an expansion bit detection flag (EXBT)
- Sets an ID match flag (IDMT)
- Stores the received data in the UART reception data register (RLN3nLURDR)

Even when the result of the comparison is a match, a successful RLIN3n reception interrupt is not generated.

If the result of the comparison is not a match, no RLIN3n successful reception interrupt or RLIN3n status interrupt is generated, and the EXBT and IDMT flags are not set to 1. The received data is not stored in the UART reception data register (RLN3nLURDR).

When changing the UEBDCE bit to 0, make the change before the reception of another set of data is finished.

Figure 20.25 shows an example when the expansion bit detection level select bit (UEBDL) is set to 0.



Note: If a reception error (parity error or overrun error) occurs, an RLIN3n status interrupt is generated and the error flag is updated. If the overrun error occurs and the results of the comparison is a match, the EXBT and IDMT are also set to 1.

Figure 20.25 Expansion Bit Reception Example (with Data Comparison) (LSB First, UEBDL = 0)

20.8.4 Status

In UART mode, the LIN/UART interface can detect five types of statuses.

Two statuses, successful UART buffer transmission and error detection, can generate interrupt requests.

Table 20.68 shows the types of statuses available in UART mode.

Table 20.68 Types of Statuses in UART Mode

Status	Status Set Condition	Status Clear Condition	Corresponding Bit	Interrupt
Reset	After the OM0 bit in the RLN3nLCUC register is set to not-LIN–reset-mode, if actually the LIN/UART interface is cleared from LIN reset mode.	After the OM0 bit in the RLN3nLCUC register is set to LIN reset mode, if actually the LIN/UART interface enters LIN reset mode.	OMM0 bit in RLN3nLMST register	—
Successful UART buffer transmission	• When the UTIGTS bit in the RLN3nLUOR1 register is 0 (transmission interrupt request is generated upon start of transmission), the transmission of the last data of the data length set by the MDL bit in the RLN3nLDFC register is started. • When the UTIGTS bit in the RLN3nLUOR1 register is 1 (transmission interrupt request is generated upon end of transmission), the transmission of the data length set by the MDL bit in the RLN3nLDFC register is ended.	• When cleared by software • After transition to LIN reset mode	FTC flag in RLN3nLST register	√
Error detection	If any of the UPER flag, IDMT flag, EXBT flag, FER flag, OER flag, and BER flags in the RLN3nLEST register turns 1 (error detected).	• When cleared by software*1 • After transition to LIN reset mode	ERR flag in RLN3nLST register	√
Transmission status	• When data is written to the RLN3nLUTDR or RLN3nLUWTDR register. • When a 1 is written to the RTS bit in the RLN3nLTRC register.	• The transmission of the data set in the RLN3nLUTDR or RLN3nLUWTDR register is complete, but another transmission data item is not set • The transmission of the data in the UART buffer is complete, and the RTS bit in the RLN3nLTRC register is cleared • After transition to LIN reset mode	UTS flag in RLN3nLST register	—
Reception status	• When a start bit is detected.	• When a sampling point for stop bits is detected • After transition to LIN reset mode	URS flag in RLN3nLST register	—

Note 1. Writing a 0 to the UPER, IDMT, EXBT, FER, OER, and BER flags in the RLN3nLEST register when the LIN reset mode is being canceled turns the ERR flag in the RLN3nLST register to 0.

20.8.5 Error Status

Types of Error Statuses

In UART mode, the LIN/UART interface can detect four types of errors and two types of statuses. The condition of these statuses can be checked by means of the corresponding bits in the RLN3nLEST register.

Table 20.69 lists applicable status types.

Table 20.69 Types of Statuses in UART Mode

Status	Error Detection Condition	Communication	Enable/Disable Detection	Corresponding Bit
Bit error	The transmitted data and the data monitored on the receive pin do not match*1	Continues until the transmission of the set transmission data is finished.	Enabled	BER flag in RLN3nLEST register
Overrun error	After received data is stored in the RLN3nLURDR register, another data item is received before the data is read. (In this case, no data is stored in the RLN3nLURDR register).	— (Reception is finished by the time this error is detected)	Enabled	OER flag in RLN3nLEST register
Framing error	When the first stop bit is low level in the reception processing.	— (Reception is finished by the time this error is detected)	Enabled	FER flag in RLN3nLEST register
Parity error	The received parity value fails to match the parity value calculated from the received data	Continues until the data reception is finished.	Disabled *2	UPER flag in RLN3nLEST register
Expansion bit detection	The value of the received expansion bit matches the value of the UEBDL bit in the RLN3nLUOR1 register.	—	Enabled	EXBT flag in RLN3nLEST register
ID match detection	The value of the received expansion bit matches the value of the UEBDL bit in the RLN3nLUOR1 register and the 8-bit receive data excluding the expansion bit matches the value of the RLN3nLIDB register.	—	Enabled	IDMT flag in RLN3nLEST register

Note 1. In the case of transmission from the UART buffer, bit errors are detected even in the space between UART frames (inter-byte space).

Note 2. Setting the UPS[1:0] bits in the RLN3nLBFC register to 10_B (0 parity) disables the checking of parity bit values. In this case, no parity error is generated.

The error status is cleared by software or at a transition to LIN reset mode.

20.9 LIN Self-Test Mode

The LIN/UART interface provides a LIN self-test mode. When the LIN/UART interface enters the LIN self-test mode, RLIN3nTX and RLIN3nRX are disconnected from external pins and they are internally connected within the LIN/UART interface. Therefore, the frame transmitted from RLIN3nTX is looped back to RLIN3nRX. The LIN self-test mode can perform tests exclusively in LIN mode.

The self-test can be performed in the following two types.

- LIN master self-test mode (transmission): Header transmission and response transmission
- LIN master self-test mode (reception): Header transmission and response reception

In LIN self-test mode, the operate is at the fastest baud rate, regardless of the setting of the baud rate generator.

Regardless of the setting of the baud rate related registers, the baud rate operates at the LIN communication clock source/16 [bps]. (The NSPB[3:0] bits in the RLN3nLWBR register should be set to 0000_B or 1111_B.)

In addition, in LIN self-test mode, the following functions are not supported.

- LIN wake-up mode
- Frame separate mode
- Multi-byte response transmission/reception
- Frame/response timeout error

Do not use these functions.

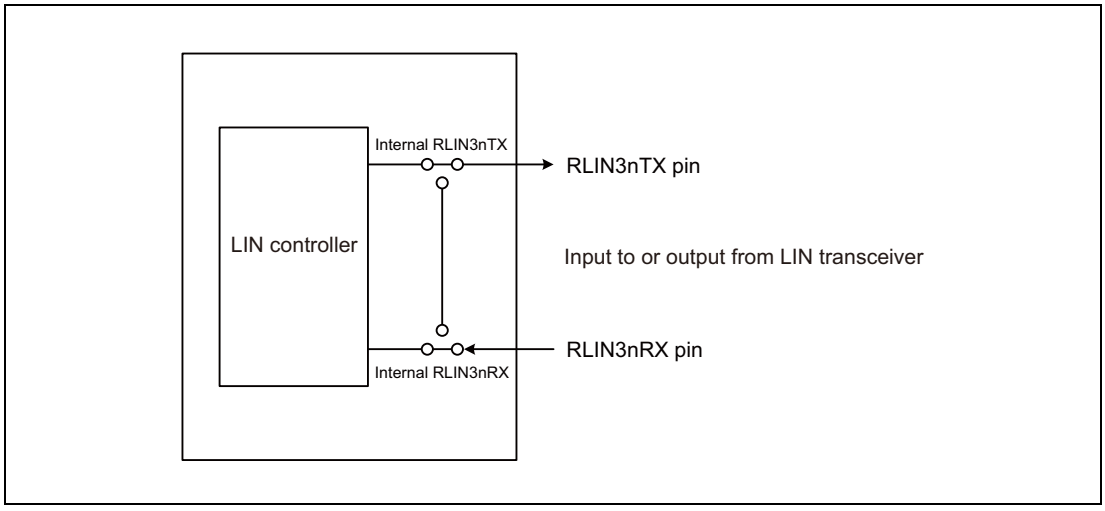


Figure 20.26 Connection in LIN Reset Mode, LIN Mode, and UART Mode

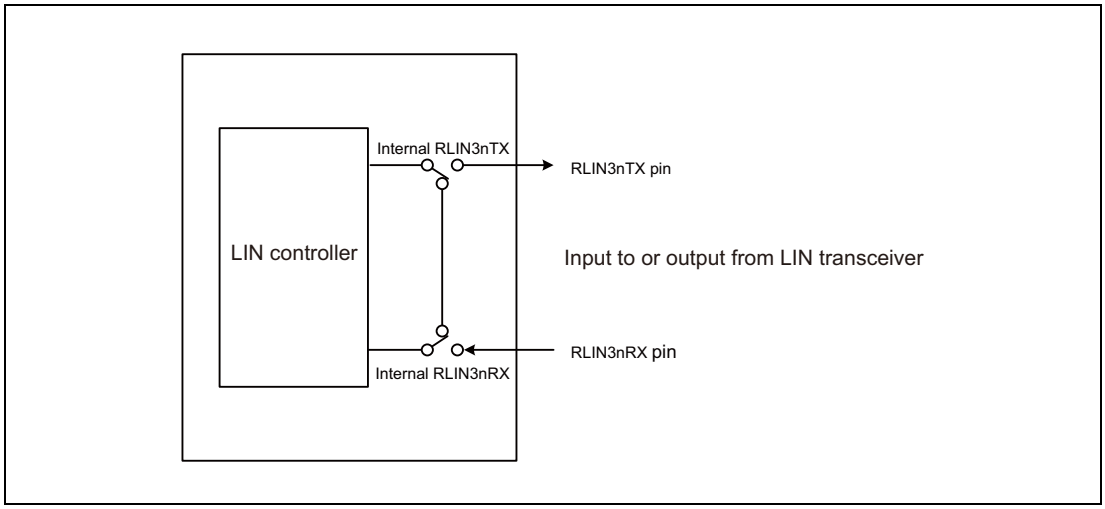

Figure 20.27 Connection in LIN Self-Test Mode

20.9.1 Change to LIN Self-Test Mode

Writing to the RLN3nLSTC register makes a transition to the LIN self-test mode.
When the LSTM bit in the RLN3nLSTC register is set to 1, the shift to the LIN self-test mode is checked.

When changing to LIN self-test mode, be sure to execute a specific sequence. In that sequence, information must be written three times consecutively to the LIN self-test control register, as follows:

- Change to LIN reset mode
  Set the OM0 bit in the RLN3nLCUC register to 0 (LIN reset mode).
  Read the OMM0 bit in the RLN3nLMST register; verify that it is 0 (LIN reset mode).
- Select a LIN mode
  LMD[1:0] bits in RLN3nLMD = 00_B (LIN master mode)
- 1st write: RLN3nLSTC register = $1010\ 0111_B$ ($A7_H$)
- 2nd write: RLN3nLSTC register = $0101\ 1000_B$ (58_H)
- 3rd write: RLN3nLSTC register = $0000\ 0001_B$ (01_H)
- Verify the transition to LIN self-test mode
  Read the LSTM bit in the RLN3nLSTC register; verify that it is 1 (LIN self-test mode).

If the key of the first write ($A7_H$) is written twice by mistake, the transition to LIN self-test mode is canceled. The above sequence should be retried from the step of first write. In addition, if a write to another LIN-related register is performed during transition to LIN self-test mode (three consecutive write operations to the RLN3nLSTC register), the transition is also canceled.

20.9.2 Transmission in LIN Master Self-Test Mode

To execute a self-test on LIN master transmission, perform the procedure below:

- Set the baud rate, noise filter, and interrupt output related registers.
  RLN3nLWBR register = 0000 $xxxx_B$*1
  RLN3nLBRP0 register = xxxx $xxxx_B$*1
  RLN3nLBRP1 register = xxxx $xxxx_B$*1
  RLN3nLMD register = 00xx $xx00_B$*1
- Set the interrupt enable and error enable related registers.
  RLN3nLIE register = 0000 $xxxx_B$*2
  RLN3nLEDE register = x000 x0xx
- Set the break field and space related registers.
  RLN3nLBFC register = 00xx $xxxx_B$
  RLN3nLSC register = 00xx $0xxx_B$
- Cancel the LIN reset mode.
  Write 11_B to the OM1 and OM0 bits in the RLN3nLCUC register, and check that the OMM1 and OMM0 bits in the RLN3nLMST register are 11_B.
- Set the transmit frame related registers.
  RLN3nLDFC register = 00x1 $xxxx_B$
  RLN3nLIDB register = xxxx $xxxx_B$
  RLN3nLDRB1 to RLN3nLDRB8 registers = xxxx $xxxx_B$
- Header transmission → response transmission started
  Set the FTS bit in the RLN3nLTRC register to 1 (frame transmission or wake-up transmission/reception started).
  The LIN master self-test mode (transmission) is executed. In this mode, interrupt are generated, and status and error status are also updated. The checksum is automatically calculated by the LIN/UART interface.
  To suspend the LIN master self-test mode (transmission) being executed, write 0 (LIN reset mode) to the OM0 bit in the RLN3nLCUC register for transition to LIN reset mode.
- When the transmission is completed, the reversed value of the looped-back frame data is stored in the RLN3nLIDB, RLN3nLDBRb (b = 1 to 8), and RLN3nLCBR registers (the data is reversed before being stored because the transmitted value should be compared with the looped-back value). Then, the FTS bit in the RLN3nLTRC register is cleared.
- If the transmission fails to complete due to an error, the applicable error flag is set and the FTS bit in the RLN3nLTRC register is cleared.

Note: x: Don't care

Note 1. The following register settings are not reflected to the operation of the LIN self-test mode. The LPRS[2:0] bit in the RLN3nLWBR register, the RLN3nLBRP0 register, the RLN3nLBRP1 register and the LCKS[1:0] bit in the RLN3nLMD register. Therefore, those settings are not necessary.

Note 2. If necessary, set the related registers described in Section 7, Interrupt.

Note 3. When the successful header transmission interrupt and the successful frame transmission interrupt are used in the same interrupt processing, if the software processing of the successful header transmission interrupt is not completed before the generation of the successful frame transmission interrupt, the SHIE bit in the RLN3nLIE register should not be

set to 1 (successful header transmission interrupt enabled). The time required from the set of the successful header transmission flag to the set of the successful frame/wake-up transmission flag is calculated by the following formula.

10 × (number of data bytes + 1) [Tbit]

1 Tbit = frequency of LIN communication clock source × 16

20.9.3 Reception in LIN Master Self-Test Mode

To execute a self-test on LIN master reception, perform the procedure below:

- Set the baud rate, noise filter, and interrupt output related registers.
  RLN3nLWBR register = 0000 $xxxx_B$*1
  RLN3nLBRP0 register = xxxx $xxxx_B$*1
  RLN3nLBRP1 register = xxxx $xxxx_B$*1
  RLN3nLMD register = 00xx $xx00_B$*1
- Set the interrupt enable and error enable related registers.
  RLN3nLIE register = 0000 $xxxx_B$*2
  RLN3nLEDE register = x000 $x0xx_B$
- Set the break field and space related registers.
  RLN3nLBFC register = 00xx $xxxx_B$
  RLN3nLSC register = 00xx $0xxx_B$*1
- Cancel the LIN reset mode.
  Write 11_B to the OM1 and OM0 bits in the RLN3nLCUC register, and check that the OMM1 and OMM0 bits in the RLN3nLMST register are 11_B.
- Configure the reception frame related registers.
  RLN3nLDFC register = 00x0 $xxxx_B$
  RLN3nLIDB register = xxxx $xxxx_B$
  RLN3nLDRB1 to RLN3nLDRB8 registers = xxxx $xxxx_B$
  RLN3nCBR register = xxxx $xxxx_B$
  Since the checksum value to be transmitted is not automatically calculated, perform the calculation value in the RLN3nLCBR register.
- Header transmission → response reception started
  Set the FTS bit in the RLN3nLTRC register to 1 (frame transmission or wake-up transmission/reception started).
  The LIN master self-test mode (reception) is executed. In this mode, interrupt are generated, and status and error status are also updated.
  To suspend the LIN master self-test mode (reception) being executed, write 0 (LIN reset mode) to the OM0 bit in the RLN3nLCUC register for transition to LIN reset mode.
- When the reception is completed, the reversed value of the looped-back frame data is stored in the RLN3nLIDB, RLN3nLDBRb (b = 1 to 8), and RLN3nLCBR registers (the data is reversed before being stored because the set value should be compared with the looped-back value). Then, the FTS bit in the RLN3nLTRC register is cleared.
- If the reception fails to complete due to an error, the applicable error flag is set and the FTS bit in the RLN3nLTRC register is cleared.

Note: x: Don't care

Note 1. The following register settings are not reflected to the operation of the LIN self-test mode. The LPRS[2:0] bit in the RLN3nLWBR register, the RLN3nLBRP0 register, the RLN3nLBRP1

register, the LCKS[1:0] bit in the RLN3nLMD register, and the IBS[1:0] bit in the RLN3nLSC register. Therefore, those settings are not necessary.

Note 2. If necessary, set the related registers described in Section 7, Interrupt.

Note 3. When the successful header transmission interrupt and the successful frame reception interrupt are used in the same interrupt processing, if the software processing of the successful header transmission interrupt is not completed before the generation of the successful frame reception interrupt, the SHIE bit in the RLN3nLIE register should not be set to 1 (successful header transmission interrupt enabled).
The time required from the set of the successful header transmission flag to the set of the successful frame/wake-up reception flag is calculated by the following formula.

10 × (number of data bytes + 1) [Tbit]

1 Tbit = 1/LIN communication clock source × 16

20.9.4 Terminating LIN Self-Test Mode

To terminate LIN self-test mode, perform the procedure below:

- Write 0 (LIN reset mode) to the OM0 bit in the RLN3nLCUC register.
  If the OMM1 and OMM0 bits in the RLN3nLMST register are not 11_B, write 11_B to the OM1 and OM0 bits in the RLN3nLCUC register. After confirming that the OMM1 and OMM0 bits in the RLN3nLMST register have turned 11_B, change to LIN reset mode.
- Verify the cancelation of LIN self-test mode.
  Read the LSTM bit in the RLN3nLSTC register; confirm that it is not 0 (not in LIN self-test mode)
- Verify the transition to LIN reset mode.
  Read the OMM0 bit in the RLN3nLMST register; verify that it is 0 (LIN reset mode).

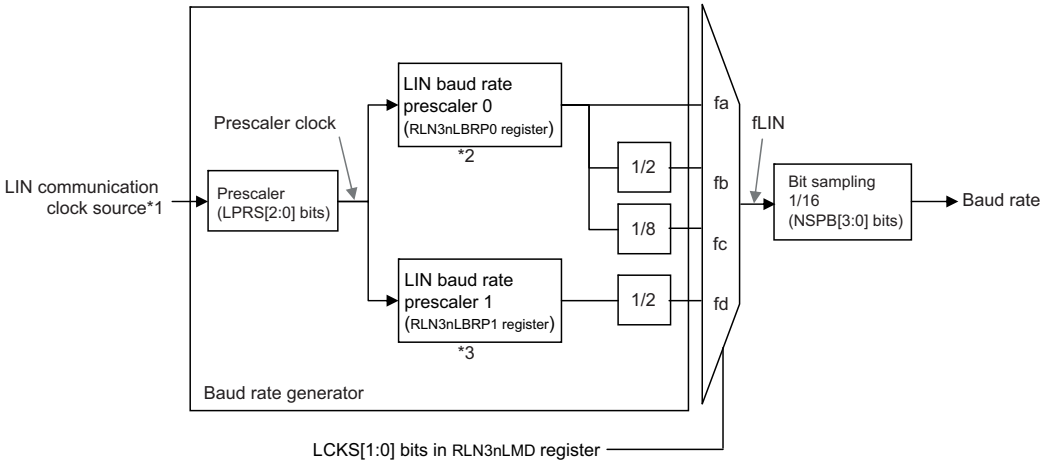
20.10 Baud Rate Generator

The prescaler clock is obtained by frequency-dividing the LIN communication clock source by the prescaler, and the LIN system clock (fLIN) is obtained by frequency-dividing the prescaler clock by the baud rate generator. The clock obtained by frequency-dividing the LIN system clock (fLIN) by the number of samples is the baud rate. The inverse of this baud rate is called the bit time (Tbit).

The LIN/UART interface has two kinds of baud rate generators. The baud rate generators switch over according to the mode used.

20.10.1 LIN Master Mode

Figure 20.28 shows a block diagram of baud rate generation in LIN master mode.



Note 1. For the LIN communication clock source, see Section 12, Clock Controller.
Note 2. When the value in RLN3nLBRP0 register is N (N = 0 to 255), the clock frequency is divided by N + 1.
Note 3. When the value in RLN3nLBRP1 register is M (M = 0 to 255), the clock frequency is divided by M + 1.

Figure 20.28 Block Diagram of Baud Rate Generation in LIN Master Mode

By setting the RLN3nLBRP0 register so that fa is 307200 Hz (= 19200 × 16), the resulting bit rates are fa = 19200 × 16, fb = 9600 × 16, and fc = 2400 × 16. These bit rates are frequency-divided by 16 in the bit timing generator, enabling baud rates of 19200 bps, 9600 bps and 2400 bps, to be generated. Also, by setting the RLN3nLBRP1 register so that fd is 166672 Hz (= 10417 × 16), the resulting bit rate is fd = 10417 × 16. This bit rate is frequency-divided by 16 in the bit timing generator, enabling 10417 bps to be generated.

Baud rate of LIN master

= {Frequency of LIN communication clock source} × (RLN3nLWBR.LPRS[2:0] selection clock)
÷ (RLN3nLBRP0+ 1) ÷ 16 [bps] (When fa is selected for fLIN)

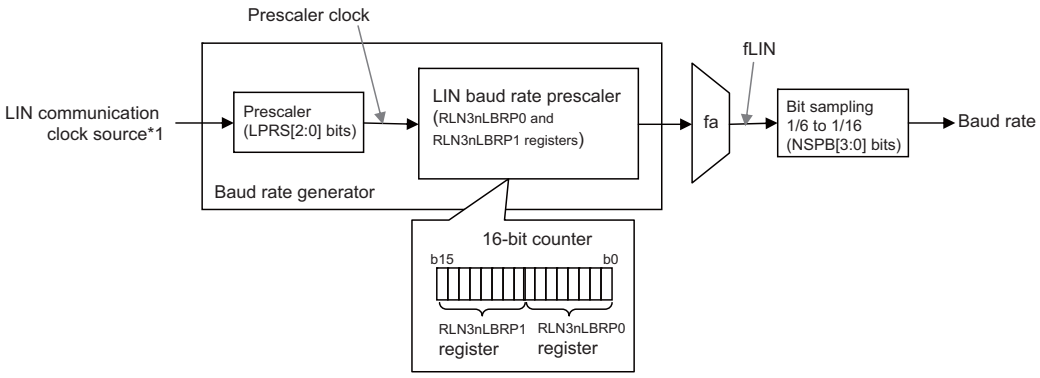
= {Frequency of LIN communication clock source} × (RLN3nLWBR.LPRS[2:0] selection clock)
÷ (RLN3nLBRP0 + 1) ÷ 2 ÷ 16 [bps] (When fb is selected for fLIN)

= {Frequency of LIN communication clock source} × (RLN3nLWBR.LPRS[2:0] selection clock)
÷ (RLN3nLBRP0 + 1) ÷ 8 ÷ 16 [bps] (When fc is selected for fLLIN)

= {Frequency of LIN communication clock source} × (RLN3nLWBR.LPRS[2:0] selection clock)
÷ (RLN3nLBRP1 + 1) ÷ 2 ÷ 16 [bps] (When fd is selected for fLIN)

20.10.2 UART Mode

Figure 20.29 shows a block diagram of baud rate generation in UART mode.



Note 1. For the LIN communication clock source, see Section 12, Clock Controller.

Figure 20.29 Block Diagram of Baud Rate Generation in UART Mode

UART baud rate is calculated with the following formula:

UART baud rate
= {LIN communication clock source frequency} × (RLN3nLWBR.LPRS[2:0] select clock) ÷ (RLN3nLBRP01 + 1) ÷ {RLN3nLWBR.NSPB[3:0] select count} [bps]

20.11 Noise Filter

The LIN/UART interface has a noise filter for reducing erroneous receiving of data due to noise. By setting the LRDNFS bit in the RLN3nLMD register to 0 (to use the noise filter), the noise filter is activated. The noise filter samples the level of the synchronized RLIN3nRX with the prescaler clock, and outputs the sampling value determined by a 3-sampling majority rule. The value of each bit of the receive data is determined based on the noise filter output.

Figure 20.30 shows the configuration of the noise filter, **Figure 20.31** shows an example of a noise filter circuit, and **Figure 20.32** shows the determination of the received data when the noise filter is used.

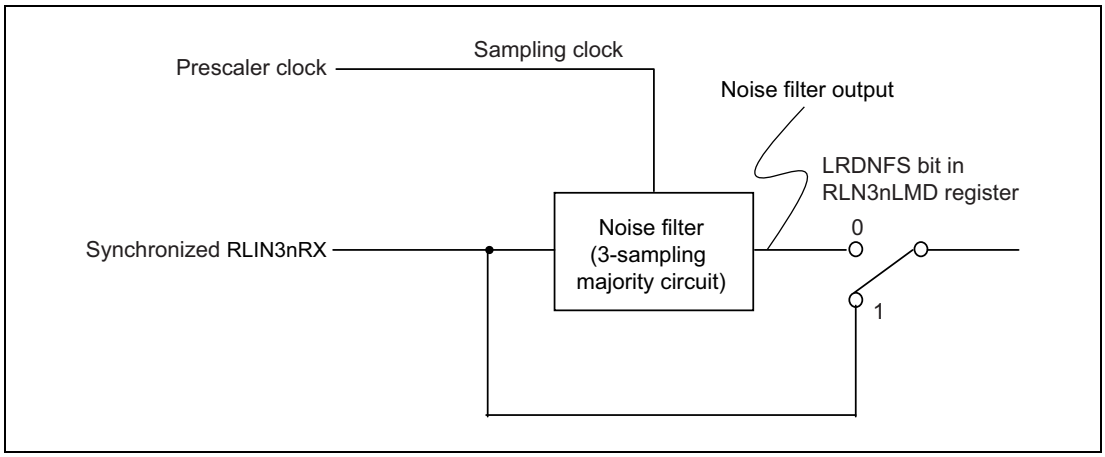


Figure 20.30 Configuration of Noise Filter

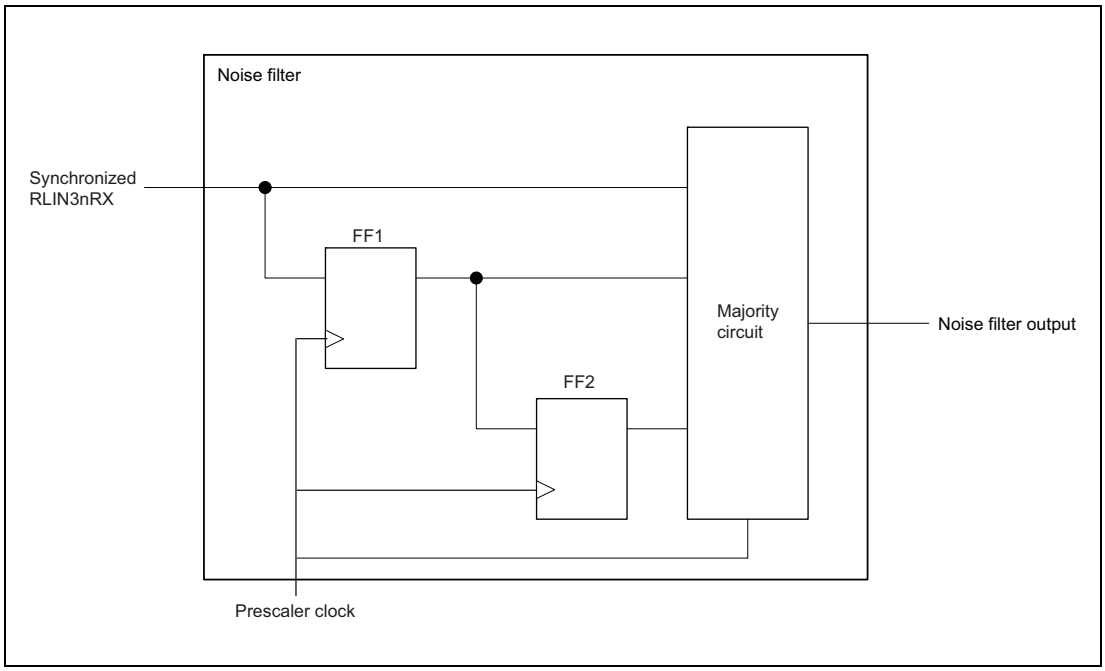

Figure 20.31 Example of Noise Filter Circuit

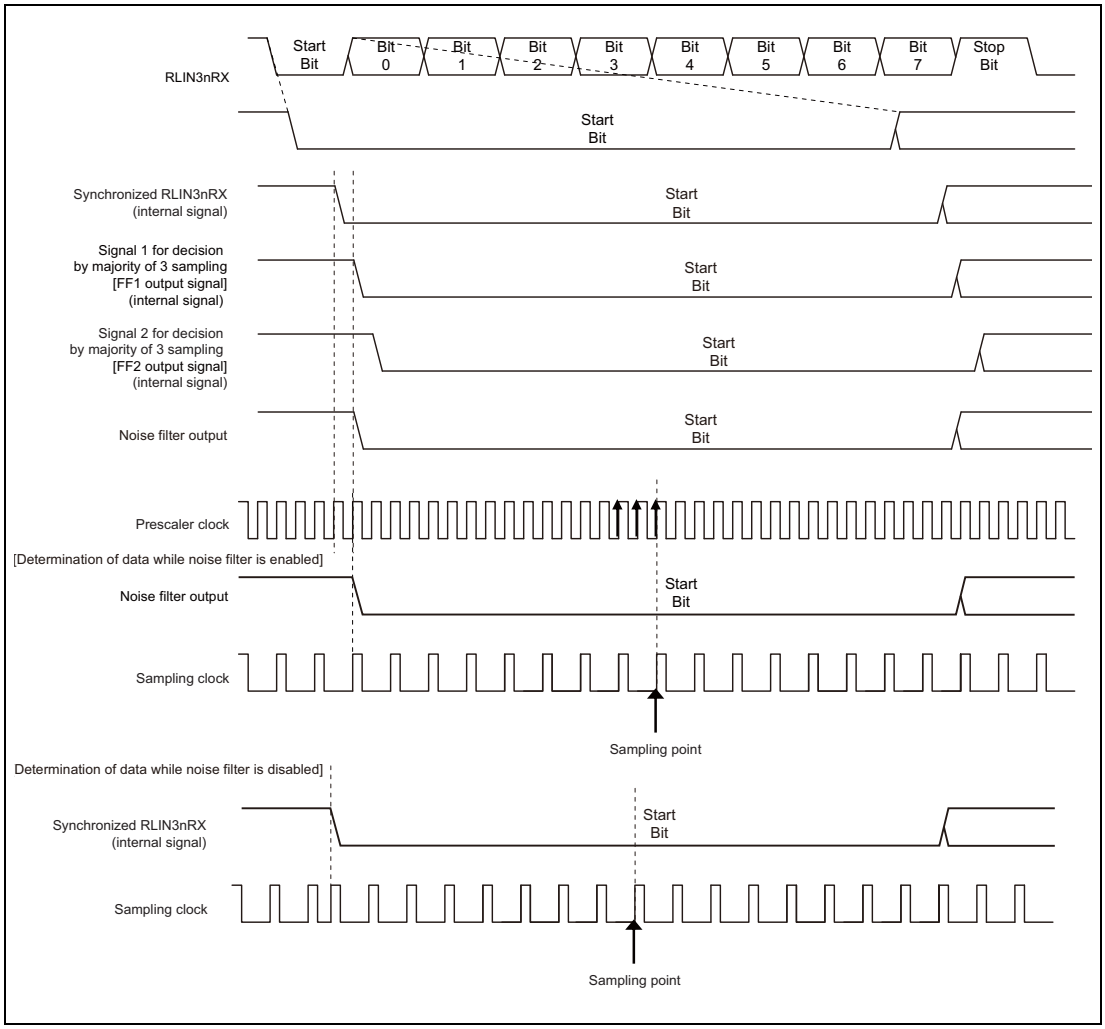

Figure 20.32 Determination of Received Data when Noise Filter is Used

Section 21 I2C Bus Interface (RIIC)

This section contains a generic description of the I2C Bus Interface (RIIC).

The first part of this section describes all RH850/D1L/D1M specific properties, such as the number of units, register base addresses, etc. The remainder of the section describes the functions and registers of RIIC.

21.1 Features of RH850/D1L/D1M RIIC

21.1.1 Number of Units and Channels

This microcontroller has the following number of RIIC units.

Each RIIC unit has one channel interface. “Number of channels” is used with the same meaning as “number of units” in this section.

Table 21.1 Number of Units

Product Name	All products
Number of Units	2
Name	RIICn (n = 0, 1)

Table 21.2 Index

Index	Meaning
n	Throughout this section, the individual RIIC units are identified by the index “n” (n = 0, 1): for example, RIICnCR1 is the I2C bus control register1.

21.1.2 Register Base Address

RIIC base addresses are listed in the following table.

RIIC register addresses are given as offsets from the base addresses in general.

Table 21.3 Register Base Address

Base Address Name	Base Address
<RIIC0_base>	FFDB 0000_H
<RIIC1_base>	FFDB 1000_H

21.1.3 Clock Supply

The RIIC clock supply is shown in the following table.

Table 21.4 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
RIICn	PCLK	Clock Controller CLKJIT

Note 1. Set the period of PCLK no greater than 1/2 of the width at high level of the SCL clock.

21.1.4 Interrupt Requests

RIIC interrupt requests are listed in the following table.

Table 21.5 Interrupt Requests

RIICn signals	Function	Connected to
RIIC0		
INTIICnEE	Transfer Error/Event Generation	Interrupt Controller INTRIIC0LEE
INTIICnRI	Receive complete	Interrupt Controller INTRIIC0RI DMA Controller trigger ID 110
INTIICnTI	Transmit data empty	Interrupt Controller INTRIIC0TI DMA Controller trigger ID 109
INTIICnTEI	Transmit end	Interrupt Controller INTRIIC0TEI
RIIC1		
INTIICnEE	Transfer Error/Event Generation	Interrupt Controller INTRIIC1LEE
INTIICnRI	Receive complete	Interrupt Controller INTRIIC1RI DMA Controller trigger ID 112
INTIICnTI	Transmit data empty	Interrupt Controller INTRIIC1TI DMA Controller trigger ID 111
INTIICnTEI	Transmit end	Interrupt Controller INTRIIC1TEI

21.1.5 Reset Sources

RIIC reset sources are listed in the following table. RIIC is initialized by these reset sources.

Table 21.6 Reset Sources

Unit Name	Reset Source
RIICn	• Reset Controller SYSRES • reset upon wake-up from DEEPSTOP mode

21.1.6 External Input/Output Signals

External input/output signals of RIIC are listed below.

Table 21.7 External Input/Output Signals

Unit Signal Name	Outline	Alternative Port Pin Signal
RIIC0		
RIICnSCL	Serial clock I/O pin	RIIC0SCL
RIICnSDA	Serial data I/O pin	RIIC0SDA
RIIC1		
RIICnSCL	Serial clock I/O pin	RIIC1SCL
RIICnSDA	Serial data I/O pin	RIIC1SDA

When using these ports, the PBDCn register for the corresponding port and the corresponding bit in the PODCn register must be set to 1.

21.2 Overview

21.2.1 Functional Overview

Communications format

- I2C bus format
- Master mode or slave mode selectable
- Automatic securing of the various set-up times, hold times, and bus-free times for the transfer rate

Transfer rate

Up to 400 kbps

SCL clock

- For master operation, the duty cycle of the SCL clock is selectable in the following range:
  – 0%< Duty < 100%

Issuing and detecting conditions

Start, restart, and stop conditions are automatically generated. Start conditions (including restart conditions) and stop conditions are detectable.

Slave address

- Up to three slave-address settings can be made.
- Seven- and ten-bit address formats are supported (along with the use of both at once).
- General call addresses and device ID addresses are detectable.

Acknowledgement

- For transmission, the acknowledge bit is automatically loaded
  - Transfer of the next data for transmission can be automatically suspended on detection of a not-acknowledge bit.
- For reception, the acknowledge bit is automatically transmitted
  - If a wait between the eighth and ninth clock cycles has been selected, software control of the value in the acknowledge field in response to the received value is possible.

Wait function

- In reception, the following periods of waiting can be obtained by holding the clock signal (SCL) at the low level:
  - Waiting between the eighth and ninth clock cycles
  - Waiting between the ninth clock cycle and the first clock cycle of the next transfer (WAIT function)

SDA output delay function

Timing of the output of transmitted data, including the acknowledge bit, can be delayed.

Arbitration

- For multi-master operation
  - Operation to synchronize the SCL (clock) signal in cases of conflict with the SCL signal from another master is possible.
  - When issuing the start condition would create conflict on the bus, loss of arbitration is detected by testing for non-matching between the internal signal for the SDA line and the level on the SDA line.
  - In master operation, loss of arbitration is detected by testing for non-matching of internal and line levels for transmit data.
- Loss of arbitration due to detection of the start condition while the bus is busy is detectable (to prevent the issuing of double start conditions).
- Loss of arbitration in transfer of a not-acknowledge bit due to the internal signal for the SDA line and the level on the SDA line not matching is detectable.
- Loss of arbitration due to non-matching of internal and line levels for data is detectable in slave transmission.

Timeout function

The internal time-out function is capable of detecting long-interval stop of the SCL (clock signal).

Noise removal

The interface incorporates digital noise filters for both the SCL and SDA signals, and the width for noise cancellation by the filters is adjustable by software.

Interrupt sources

- Four sources:
  - Error in transfer or occurrence of events (detection of arbitration lost, NACK, time-out, a start condition including a restart condition, or a stop condition)
  - Receive complete (including matching with a slave address)
  - Transmit data empty (including matching with a slave address)
  - Transmission end

21.2.2 Block Diagram

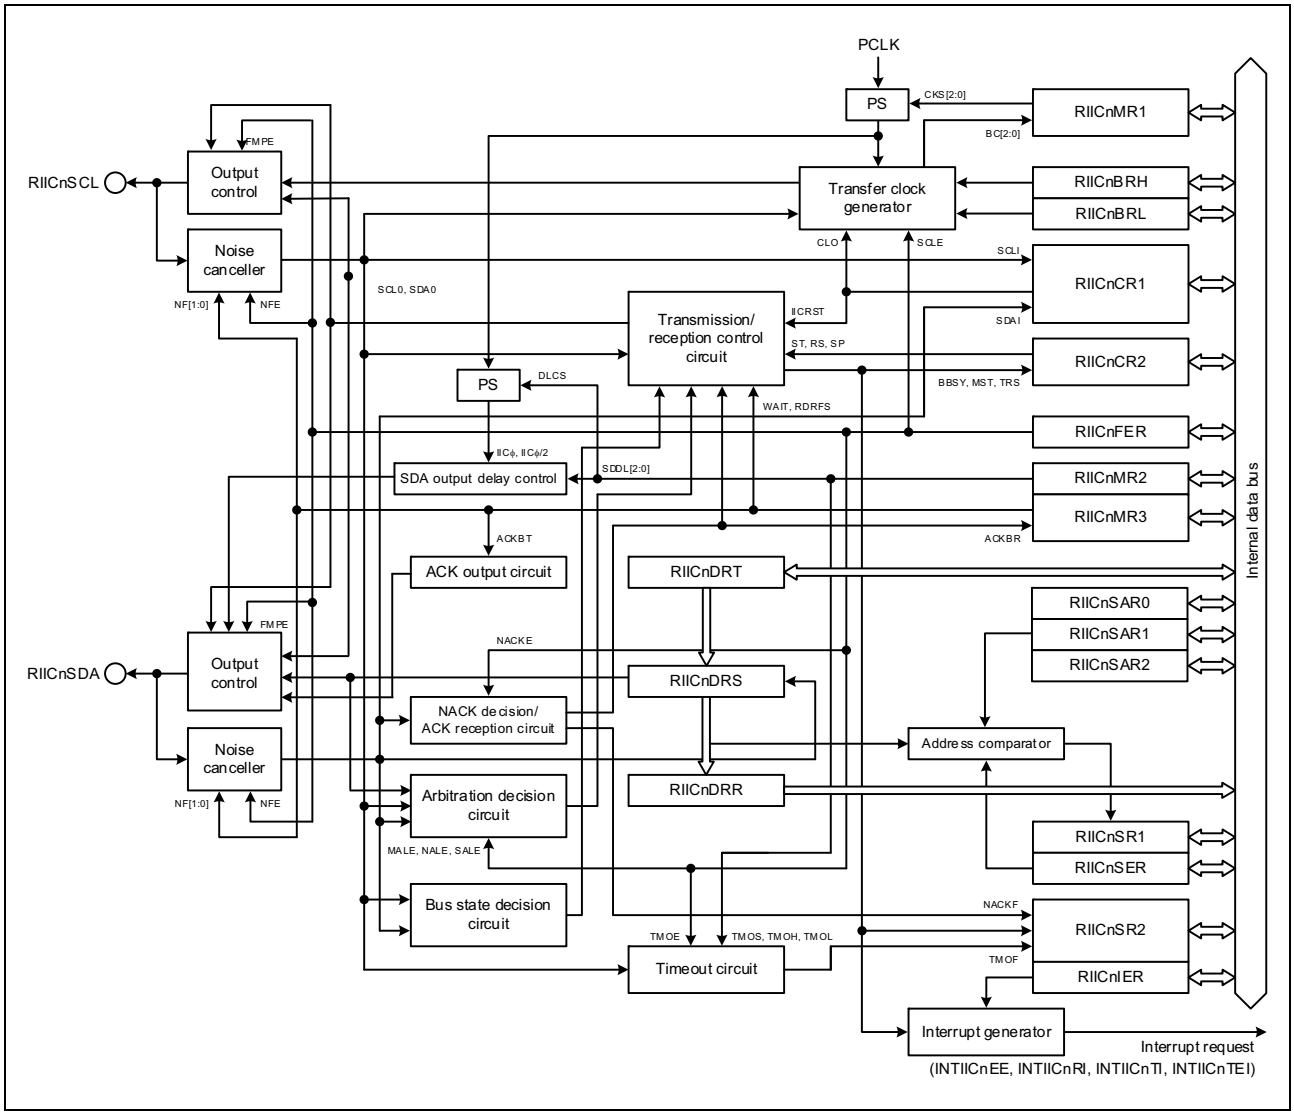

Figure 21.1 Block Diagram of RIIC

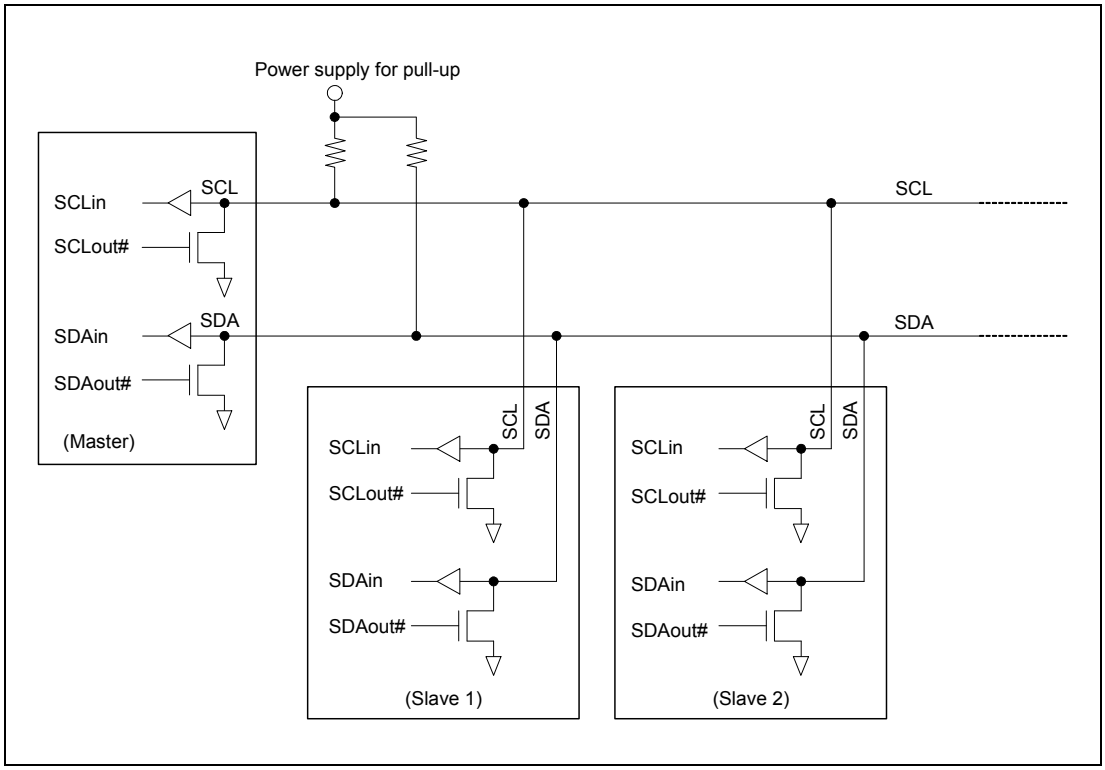

Figure 21.2 Connections to the External Circuit by the I/O Pins (I2C Bus Configuration Example)

21.3 Registers

21.3.1 List of Registers

RIIC registers are listed in the table below.

For details about <RIICn_base>, see Section 21.1.2, Register Base Address.

Table 21.8 List of Registers

Module Name	Register Name	Symbol	Address
RIICn	I2C Bus Control Register 1	RIICnCR1	<RIICn_base> + 0000_H
RIICn	I2C Bus Control Register 2	RIICnCR2	<RIICn_base> + 0004_H
RIICn	I2C Bus Mode Register 1	RIICnMR1	<RIICn_base> + 0008_H
RIICn	I2C Bus Mode Register 2	RIICnMR2	<RIICn_base> + $000C_H$
RIICn	I2C Bus Mode Register 3	RIICnMR3	<RIICn_base> + 0010_H
RIICn	I2C Bus Function Enable Register	RIICnFER	<RIICn_base> + 0014_H
RIICn	I2C Bus Status Enable Register	RIICnSER	<RIICn_base> + 0018_H
RIICn	I2C Bus Interrupt Enable Register	RIICnIER	<RIICn_base> + $001C_H$
RIICn	I2C Bus Status Register 1	RIICnSR1	<RIICn_base> + 0020_H
RIICn	I2C Bus Status Register 2	RIICnSR2	<RIICn_base> + 0024_H
RIICn	I2C Slave Address Register 0	RIICnSAR0	<RIICn_base> + 0028_H
RIICn	I2C Slave Address Register 1	RIICnSAR1	<RIICn_base> + $002C_H$
RIICn	I2C Slave Address Register 2	RIICnSAR2	<RIICn_base> + 0030_H
RIICn	I2C Bus Bit Rate Low-Level Register	RIICnBRL	<RIICn_base> + 0034_H
RIICn	I2C Bus Bit Rate High-Level Register	RIICnBRH	<RIICn_base> + 0038_H
RIICn	I2C Bus Transmit Data Register	RIICnDRT	<RIICn_base> + $003C_H$
RIICn	I2C Bus Receive Data Register	RIICnDRR	<RIICn_base> + 0040_H
RIICn	I2C Bus Shift Register	RIICnDRS	—

21.3.2 RIICnCR1 — I2C Bus Control Register 1

Access: RIICnCR1 is a 32-bit readable/writable register.
RIICnCR1L and RIICnCR1H are 16-bit readable/writable registers.
RIICnCR1LL, RIICnCR1LH, RIICnCR1HL, and RIICnCR1HH are 8-bit readable/writable registers.

Address: RIICnCR1: <RIICn_base> + 0000_H

RIICnCR1L: <RIICn_base> + 0000_H, RIICnCR1H: <RIICn_base> + 0002_H

RIICnCR1LL: <RIICn_base> + 0000_H, RIICnCR1LH: <RIICn_base> + 0001_H,
RIICnCR1HL: <RIICn_base> + 0002_H, RIICnCR1HH: <RIICn_base> + 0003_H

Value after reset: 0000 $001F_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 21.9 RIICnCR1 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 8	Reserved	These bits are read as the value after reset. The write value should be the value after reset.
7	ICE	I2C Bus Interface Enable 0: Disabled (the RIICnSCL and RIICnSDA pins are not driven). 1: Enabled (the RIICnSCL and RIICnSDA pins driven). (This bit selects an RIIC reset or internal reset in combination with the IICRST bit.)
6	IICRST	I2C Bus Interface Internal Reset 0: Clears the RIIC reset or internal reset. 1: Initiates the RIIC reset or internal reset. (Clears the bit counter and the SCL/SDA output latch)
5	CLO	Extra SCL Clock Cycle Output 0: Does not output an extra SCL clock cycle (default). 1: Outputs an extra SCL clock cycle. (The CLO bit is cleared automatically after one clock cycle is output.)
4	SOWP	SCLO/SDAO Write Protect 0: Bits SCLO and SDAO can be written. 1: Bits SCLO and SDAO are protected. (This bit is read as 1.)
3	SCLO	SCL Output Control/Monitor • Read: 0: The RIIC has driven the RIICnSCL pin low. 1: The RIIC has released the RIICnSCL pin. • Write: 0: The RIIC drives the RIICnSCL pin low. 1: The RIIC releases the RIICnSCL pin.

Table 21.9 RIICnCR1 Register Contents (2/2)

Bit Position	Bit Name	Function
2	SDAO	SDA Output Control/Monitor • Read: 0: The RIIC has driven the RIICnSDA pin low. 1: The RIIC has released the RIICnSDA pin. • Write: 0: The RIIC drives the RIICnSDA pin low. 1: The RIIC releases the RIICnSDA pin.
1	SCLI	SCL Line Monitor 0: RIICnSCL line is low. 1: RIICnSCL line is high.
0	SDAI	SDA Line Monitor 0: RIICnSDA line is low. 1: RIICnSDA line is high.

SDAO Bit (SDA Output Control/Monitor) and SCLO Bit (SCL Output Control/Monitor)

These bits are used to directly control the RIICnSDA and RIICnSCL signals output from the RIIC.

When writing to these bits, also write 0 to the SOWP bit.

The result of setting these bits is input to the RIIC via the input buffer. When slave mode is selected, a START condition may be detected and the bus may be released depending on the bit settings.

Do not rewrite these bits during a START condition, STOP condition, repeated START condition, or during transmission or reception. Operation after rewriting under the above conditions is not guaranteed.

When reading these bits, the state of signals output from the RIIC can be read.

CLO Bit (Extra SCL Clock Cycle Output)

This bit is used to output an extra SCL clock cycle for debugging or error processing.

Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error.

For details on this function, see Section 21.13.2, Extra SCL Clock Cycle Output Function.

IICRST Bit (I2C Bus Interface Internal Reset)

This bit is used to reset the internal states of the RIIC.

Setting this bit to 1 initiates an RIIC reset or internal reset.

Whether an RIIC reset or internal reset is initiated is determined according to the combination with the ICE bit. **Table 21.10** lists the types of RIIC reset.

The RIIC reset resets all registers (except ICE and IICRST) including the RIICnCR2.BBSY flag and internal states of the RIIC, and the internal reset resets the bit counter (RIICnMR1.BC[2:0] bits), the I2C bus shift register (RIICnDRS), and the I2C bus status registers (RIICnSR1 and RIICnSR2) as well as the internal states of the RIIC. For the reset conditions for each register, see Section 21.14, Reset Function of RIIC.

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the RIIC without initializing the port settings and the control and setting registers of the RIIC when the bus or RIIC hangs up due to a communication error.

If the RIIC hangs up in a low level output state, resetting the internal states cancels the low level output state and releases the bus with the RIICnSCL pin and RIICnSDA pin at a high impedance.

CAUTION

If an internal reset is initiated using the IICRST bit for a bus hang-up occurred during communication with the master device in slave mode, the states may become different between the slave device and the master device (due to the difference in the bit counter information). For this reason, do not initiate an internal reset in slave mode, but initiate restoration processing from the master device. If an internal reset is necessary because the RIIC hangs up with the SCL line in a low level output state in slave mode, initiate an internal reset and then issue a restart condition from the master device or resume communication from the start condition issuance after issuing a stop condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start condition or restart condition from the master device, synchronization will be lost because the master and slave devices operate asynchronously.

Table 21.10 RIIC Resets

IICRST	ICE	State	Specifications
1	0	RIIC reset	Resets all registers (except ICE and IICRST) and internal states of the RIIC.
	1	Internal reset	Reset the RIICnMR1.BC[2:0] bits, and the RIICnSR1, RIICnSR2, RIICnDRS registers and the internal states of the RIIC.

ICE Bit (I2C Bus Interface Enable)

The ICE bit selects driving or non-driving of the RIICnSCL and RIICnSDA pins. Moreover, this bit can perform two types of reset in combination with the IICRST bit. For the types of reset, see Table 21.10, RIIC Resets.

Set the ICE bit to 1 when using RIIC. Setting the ICE bit to 1 selects driving of the RIICnSCL and RIICnSDA pins.

Set the ICE bit to 0 when RIIC is not to be used. Clearing the ICE bit to 0 stops driving of the RIICnSCL and RIICnSDA pins.

CAUTION

Though the output from RIICnSDA or RIICnSCL is disabled while the ICE bit is 0, the input to RIICnSDA or RIICnSCL is enabled. The RIICnSCL and RIICnSDA pin functions should not be assigned to the RIIC. If assigned, it causes the slave addresses to be compared.

21.3.3 RIICnCR2 — I2C Bus Control Register 2

Access: RIICnCR2 is a 32-bit readable/writable register.
RIICnCR2L and RIICnCR2H are 16-bit readable/writable registers.
RIICnCR2LL, RIICnCR2LH, RIICnCR2HL, and RIICnCR2HH are 8-bit readable/writable registers.

Address: RIICnCR2: <RIICn_base> + 0004_H

RIICnCR2L: <RIICn_base> + 0004_H, RIICnCR2H: <RIICn_base> + 0006_H

RIICnCR2LL: <RIICn_base> + 0004_H, RIICnCR2LH: <RIICn_base> + 0005_H,
RIICnCR2HL: <RIICn_base> + 0006_H, RIICnCR2HH: <RIICn_base> + 0007_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	BBSY	MST	TRS	—	SP	RS	ST	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R/W	R/W	R/W	R

Table 21.11 RIICnCR2 Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	These bits are read as the value after reset. The write value should be the value after reset.
7	BBSY	Bus Busy Detection Flag 0: The I2C bus is released (the bus is free). 1: The I2C bus is occupied (the bus is busy).
6	MST*1	Master/Slave Mode 0: Slave mode 1: Master mode
5	TRS*1	Transmit/Receive Mode 0: Receive mode 1: Transmit mode
4	Reserved	This bit is read as the value after reset. The write value should be the value after reset.
3	SP	Stop Condition Issuance Request 0: Does not request to issue a stop condition. 1: Requests to issue a stop condition.
2	RS	Restart Condition Issuance Request 0: Does not request to issue a restart condition. 1: Requests to issue a restart condition.
1	ST	Start Condition Issuance Request 0: Does not request to issue a start condition. 1: Requests to issue a start condition.
0	Reserved	This bit is read as the value after reset. The write value should be the value after reset.

Note 1. When the RIICnMR1.MTWP bit is set to 1, the MST and TRS bits can be written to.

ST Bit (Start Condition Issuance Request)

This bit is used to request transition to master mode and issuance of a start condition.

When this bit is set to 1 to request to issue a start condition, a start condition is issued when the BBSY flag is set to 0 (bus free).

For details on the start condition issuance, see Section 21.12, Start Condition/Restart Condition/Stop Condition Issuing Function.

[Setting condition]

When 1 is written to the ST bit

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition has been issued
- When the RIICnSR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

CAUTION

Set the ST bit to 1 (start condition issuance request) when the BBSY flag is set to 0 (bus free).
Note that arbitration may be lost as the start condition issuance error if the ST bit is set to 1 (start condition issuance request) when the BBSY flag is set to 1 (bus busy).

RS Bit (Restart Condition Issuance Request)

This bit is used to request that a restart condition be issued in master mode.

When this bit is set to 1 to request to issue a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy) and the MST bit is set to 1 (master mode).

For details on the restart condition issuance, see Section 21.12, Start Condition/Restart Condition/Stop Condition Issuing Function.

[Setting condition]

When 1 is written to the RS bit with the RIICnCR2.BBSY flag set to 1

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition has been issued or a start condition is detected
- When a stop condition is detected
- When the RIICnCR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

CAUTIONS

1. Do not set the RS bit to 1 while issuing a stop condition.
2. It is commended to issue a restart condition in master transmit mode. If the RS bit is set to 1 (restart condition issuance request) in mode other than master mode, the restart condition is not issued in this mode but the RS bit remains set. If the operating mode changes to master mode with the bit not being cleared, the restart condition may be issued.

SP Bit (Stop Condition Issuance Request)

This bit is used to request that a stop condition be issued in master mode.

When this bit is set to 1 to request to issue a stop condition, a stop condition is issued when the BBSY flag is set to 1 (bus busy) and the MST bit is set to 1 (master mode).

For details on the stop condition issuance, see Section 21.12, Start Condition/Restart Condition/Stop Condition Issuing Function.

[Setting condition]

When 1 is written to the SP bit with both the RIICnCR2.BBSY flag and the RIICnCR2.MST bit set to 1

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition has been issued or a stop condition is detected
- When the RIICnSR2.AL (arbitration-lost) flag is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

CAUTIONS

1. Writing to the SP bit is not possible while the setting of the BBSY flag is 0 (bus free).
2. Do not set the SP bit to 1 while a restart condition is being issued.

TRS Bit (Transmit/Receive Mode)

This bit indicates transmit or receive mode.

The RIIC is in receive mode when the TRS bit is set to 0 and is in transmit mode when the bit is set to 1. Combination of this bit and the MST bit indicates the operating mode of the RIIC.

The value of the TRS bit is automatically changed to the value for transmission mode or reception mode (1 or 0) by detection or issuing of a start condition, setting or clearing of the R/W# bit, etc. Although writing to the TRS bit is possible when the RIICnMR1.MTWP bit is set to 1, writing to this bit is not necessary during normal usage.

[Setting conditions]

- When a start condition is issued normally according to the start condition issuance request (when a start condition is detected with the ST bit set to 1)
- When the address received in slave mode matches the address enabled in RIICnSER, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the RIICnMR1.MTWP bit set to 1

[Clearing conditions]

- When a stop condition is detected
- The RIICnSR2.AL (arbitration-lost) flag being set to 1
- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended
- In slave transmit mode, a restart condition is detected (a restart condition is detected with RIICnCR2.BBSY = 1 and RIICnCR2.MST = 0)

- When 0 is written to the TRS bit with the RIICnMR1.MTWP bit set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

MST Bit (Master/Slave Mode)

This bit indicates master or slave mode.

The RIIC is in slave mode when the MST bit is set to 0 and is in master mode when the bit is set to 1. Combination of this bit and the TRS bit indicates the operating mode of the RIIC.

The value of the MST bit is automatically changed to the value for master mode or slave mode (1 or 0) by detection or issuing of a start condition, etc. Although writing to the MST bit is possible when the RIICnMR1.MTWP bit is set to 1, writing to this bit is not necessary during normal usage.

[Setting conditions]

- When a start condition is issued normally according to the start condition issuance request (when a start condition is detected with the ST bit set to 1)
- When 1 is written to the MST bit with the RIICnMR1.MTWP bit set to 1

[Clearing conditions]

- When a stop condition is detected
- When the RIICnSR2.AL (arbitration-lost) flag is set to 1
- When 0 is written to the MST bit with the RIICnMR1.MTWP bit set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

BBSY Flag (Bus Busy Detection)

The BBSY flag indicates whether the I2C bus is occupied (bus busy) or released (bus free).

This bit is set to 1 when the SDA line changes from high to low under the condition of SCL = high, assuming that a start condition has been issued.

When the SDA line changes from low to high under the condition of SCL = high, this bit is cleared to 0 after the bus free time (specified in RIICnBRL) start condition is not detected, assuming that a stop condition has been issued.

[Setting condition]

When a start condition is detected

[Clearing conditions]

- When the bus free time (specified in RIICnBRL) start condition is not detected after detecting a stop condition
- When 1 is written to the RIICnCR1.IICRST bit with the RIICnCR1.ICE bit set to 0 (RIIC reset)

CAUTIONS

1. **When an internal reset is applied while the bus is free after detection of a stop condition, the setting of the BBSY flag is 0 while the bus is free following de-assertion of the internal reset signal.**
2. **When an internal reset is applied while the bus is not free, the BBSY flag is not cleared.**

21.3.4 RIICnMR1 — I2C Bus Mode Register 1

Access: RIICnMR1 is a 32-bit readable/writable register.
RIICnMR1L and RIICnMR1H are 16-bit readable/writable registers.
RIICnMR1LL, RIICnMR1LH, RIICnMR1HL, and RIICnMR1HH are 8-bit readable/writable registers.

Address: RIICnMR1: <RIICn_base> + 0008_H

RIICnMR1L: <RIICn_base> + 0008_H, RIICnMR1H: <RIICn_base> + $000A_H$

RIICnMR1LL: <RIICn_base> + 0008_H, RIICnMR1LH: <RIICn_base> + 0009_H,
RIICnMR1HL: <RIICn_base> + $000A_H$, RIICnMR1HH: <RIICn_base> + $000B_H$

Value after reset: 0000 0008_H

Table 21.12 RIICnMR1 Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	These bits are read as the value after reset. The write value should be the value after reset.
7	MTWP	MST/TRS Write Protect 0: Disables writing to the RIICnCR2.MST and TRS bits. 1: Enables writing to the RIICnCR2.MST and TRS bits.
6 to 4	CKS[2:0]	Internal Reference Clock Selection (IICϕ) b6 b4 0 0 0: PCLK/1 clock 0 0 1: PCLK/2 clock 0 1 0: PCLK/4 clock 0 1 1: PCLK/8 clock 1 0 0: PCLK/16 clock 1 0 1: PCLK/32 clock 1 1 0: PCLK/64 clock 1 1 1: PCLK/128 clock
3	BCWP*1	BC[2:0] Write Protect 0: Enables a value to be written in the BC[2:0] bits. 1: Protects the BC[2:0] bits (This bit is read as 1.)
2 to 0	BC[2:0]	Bit Counter b2 b0 0 0 0: 9 bits 0 0 1: 2 bits 0 1 0: 3 bits 0 1 1: 4 bits 1 0 0: 5 bits 1 0 1: 6 bits 1 1 0: 7 bits 1 1 1: 8 bits

Note 1. When rewriting the BC[2:0] bits, write 0 to the BCWP bit simultaneously.

BC[2:0] Bits (Bit Counter)

These bits function as a counter that indicates the number of bits remaining to be transferred at the detection of a rising edge on the SCL line. Although these bits are writable and readable, it is not necessary to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one (data is transferred with an additional acknowledge bit) between transferred frames. When setting any value other than 000_B, set the value while the SCL line is at a low level.

[Clearing conditions]

- When 1 is written to the RIICnCR1.IICRST bit and a RIIC reset or internal reset is initiated.
- Data transfer including the acknowledge bit being completed.
- A start condition including a restart condition being detected.

21.3.5 RIICnMR2 — I2C Bus Mode Register 2

Access: RIICnMR2 is a 32-bit readable/writable register.
RIICnMR2L and RIICnMR2H are 16-bit readable/writable registers.
RIICnMR2LL, RIICnMR2LH, RIICnMR2HL, and RIICnMR2HH are 8-bit readable/writable registers.

Address: RIICnMR2: <RIICn_base> + $000C_H$

RIICnMR2L: <RIICn_base> + $000C_H$, RIICnMR2H: <RIICn_base> + $000E_H$

RIICnMR2LL: <RIICn_base> + $000C_H$, RIICnMR2LH: <RIICn_base> + $000D_H$,
RIICnMR2HL: <RIICn_base> + $000E_H$, RIICnMR2HH: <RIICn_base> + $000F_H$

Value after reset: $0000\ 0006_H$

Table 21.13 RIICnMR2 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 8	Reserved	These bits are read as the value after reset. The write value should be the value after reset.
7	DLCS	SDA Output Delay Clock Source Selection 0: The internal reference clock (IICϕ) is selected as the clock source of the SDA output delay counter. 1: The internal reference clock divided by 2 (IICϕ/2) is selected as the clock source of the SDA output delay counter.*1
6 to 4	SDDL[2:0]	SDA Output Delay Counter • When RIICnMR2.DLCS = 0 (IICϕ) b6 b4 0 0 0: No output delay 0 0 1: 1 IICϕ cycle 0 1 0: 2 IICϕ cycles 0 1 1: 3 IICϕ cycles 1 0 0: 4 IICϕ cycles 1 0 1: 5 IICϕ cycles 1 1 0: 6 IICϕ cycles 1 1 1: 7 IICϕ cycles • When RIICnMR2.DLCS = 1 (IICϕ/2) b6 b4 0 0 0: No output delay 0 0 1: 1 or 2 IICϕ cycles 0 1 0: 3 or 4 IICϕ cycles 0 1 1: 5 or 6 IICϕ cycles 1 0 0: 7 or 8 IICϕ cycles 1 0 1: 9 or 10 IICϕ cycles 1 1 0: 11 or 12 IICϕ cycles 1 1 1: 13 or 14 IICϕ cycles
3	Reserved	This bit is read as the value after reset. The write value should be the value after reset.
2	TMOH	Timeout H Count Control 0: Disables counting while the SCL line is at a high level. 1: Enables counting while the SCL line is at a high level.

Table 21.13 RIICnMR2 Register Contents (2/2)

Bit Position	Bit Name	Function
1	TMOL	Timeout L Count Control 0: Disables counting while the SCL line is at a low level. 1: Enables counting while the SCL line is at a low level.
0	TMOS	Timeout Detection Time Selection 0: Long mode is selected. 1: Short mode is selected.

Note 1. The setting DLCS = 1 (IICϕ/2) only becomes valid when SCL is at the low level. When SCL is at the high level, the setting DLCS = 1 becomes invalid and the clock source becomes the internal reference clock (IICϕ).

TMOS Bit (Timeout Detection Time Selection)

This bit is used to select long mode or short mode for the timeout detection time when the timeout function is enabled (RIICnFER.TMOE bit = 1). When this bit is set to 0, long mode is selected. When this bit is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a 14 bit-counter. While the SCL line is in the state that enables this counter as specified by bits TMOH and TMOL, the counter counts up in synchronization with the internal reference clock (IICϕ) as a count source.

For details on the timeout function, see Section 21.13.1, Timeout Function.

TMOL Bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL line is held low when the timeout function is enabled (RIICnFER.TMOE bit = 1).

TMOH Bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL line is held high when the timeout function is enabled (RIICnFER.TMOE bit = 1).

SDDL[2:0] Bits (SDA Output Delay Setup Counter)

The SDA output can be delayed by the SDDL[2:0] setting. This counter works with the clock source selected by the DLCS bit. The setting of this function can be used for all types of SDA output, including the transmission of the acknowledge bit.

For details on this function, see Section 21.7, Facility for Delaying SDA Output.

CAUTION

Set the SDA output delay time to meet the I2C bus standard (within the data enable time/acknowledge enable time*1). Note that, if a value outside the standard is set, communication with communication devices may malfunction or it may seemingly become a start condition or stop condition depending on the bus state.

Note 1. Data enable time/acknowledge enable time
3,450 ns (up to 100 kbps: standard mode [Sm])
900 ns (up to 400 kbps: fast mode [Fm])

21.3.6 RIICnMR3 — I2C Bus Mode Register 3

Access: RIICnMR3 is a 32-bit readable/writable register.
RIICnMR3L and RIICnMR3H are 16-bit readable/writable registers.
RIICnMR3LL, RIICnMR3LH, RIICnMR3HL, and RIICnMR3HH are 8-bit readable/writable registers.

Address: RIICnMR3: <RIICn_base> + 0010_H

RIICnMR3L: <RIICn_base> + 0010_H, RIICnMR3H: <RIICn_base> + 0012_H

RIICnMR3LL: <RIICn_base> + 0010_H, RIICnMR3LH: <RIICn_base> + 0011_H,
RIICnMR3HL: <RIICn_base> + 0012_H, RIICnMR3HH: <RIICn_base> + 0013_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R/W

Table 21.14 RIICnMR3 Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	These bits are read as the value after reset. The write value should be the value after reset.
6	WAIT*2	WAIT 0: No WAIT (The period between ninth clock cycle and first clock cycle is not held low.) 1: WAIT (The period between ninth clock cycle and first clock cycle is held low.) Low-hold is released by reading RIICnDRR.
5	RDRFS*2	RDRF Flag Set Timing Selection 0: The RDRF flag is set at the rising edge of the ninth SCL clock cycle. (The SCL line is not held low at the falling edge of the eighth clock cycle.) 1: The RDRF flag is set at the rising edge of the eighth SCL clock cycle. (The SCL line is held low at the falling edge of the eighth clock cycle.) Low-hold is released by writing a value to the ACKBT bit.
4	ACKWP*1	ACKBT Write Protect 0: Modification of the ACKBT bit is disabled. 1: Modification of the ACKBT bit is enabled.
3	ACKBT*1	Transmit Acknowledge 0: A 0 is sent as the acknowledge bit (ACK transmission). 1: A 1 is sent as the acknowledge bit (NACK transmission).
2	ACKBR	Receive Acknowledge 0: A 0 is received as the acknowledge bit (ACK reception). 1: A 1 is received as the acknowledge bit (NACK reception).
1, 0	NF[1:0]	Digital noise Filter Stage Selection b1 b0 0 0: Noise of up to one IICϕ cycle is filtered out (single-stage filter). 0 1: Noise of up to two IICϕ cycles is filtered out (2-stage filter). 1 0: Noise of up to three IICϕ cycles is filtered out (3-stage filter). 1 1: Noise of up to four IICϕ cycles is filtered out (4-stage filter).

Note 1. If it is attempted to write 1 to both ACKWP and ACKBT bits, the ACKBT bit cannot be set to 1.

Note 2. The WAIT and RDRFS bits are valid only in receive mode (invalid in transmit mode).

NF[1:0] Bits (Digital noise Filter Stage Selection)

These bits are used to select the number of stages of the digital noise filter.

CAUTION

Set the noise range to be filtered out by the noise filter within a range less than the SCL line high-level period or low-level period. If the noise range is set to a value of (SCL clock width: high-level period or low-level period, whichever is shorter) - [1.5 internal reference clock synchronized (IICϕ) cycles] or more, the SCL clock is regarded as noise by the noise filter function of the RIIC, which may prevent the RIIC from operating normally.

ACKBR Bit (Receive Acknowledge)

This bit is used to store the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

When 1 is received as the acknowledge bit with the RIICnCR2.TRS bit set to 1

[Clearing conditions]

- When 0 is received as the acknowledge bit with the RIICnCR2.TRS bit set to 1
- When 1 is written to the RIICnCR1.IICRST bit while the RIICnCR1.ICE bit is 0 (RIIC reset)

ACKBT Bit (Transmit Acknowledge)

This bit is used to set the bit to be sent at the acknowledge timing in receive mode.

[Setting condition]

When 1 is written to this bit with the ACKWP bit set to 1

[Clearing conditions]

- When 0 is written to this bit after ACKWP reading while the ACKWP bit is set to 1
- When stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit while the RIICnCR1.ICE bit is 0 (RIIC reset)

CAUTION

The ACKBT bit must be written to while the ACKWP bit is 1. If the ACKBT bit is written to with the ACKWP bit cleared to 0, writing to the ACKBT bit is disabled.

ACKWP Bit (ACKBT Write Protect)

This bit is used to control the modification of the ACKBT bit.

RDRFS Bit (RDRF Flag Set Timing Selection)

This bit is used to select the RDRF flag set timing in receive mode and also to select whether to hold the SCL line low at the falling edge of the eighth SCL clock cycle.

When the RDRFS bit is 0, the SCL line is not held low at the falling edge of the eighth SCL clock cycle, and the RDRF flag is set to 1 at the rising edge of the ninth SCL clock cycle.

When the RDRFS bit is 1, the RDRF flag is set to 1 at the rising edge of the eighth SCL clock cycle and the SCL line is held low at the falling edge of the eighth SCL clock cycle. The low-hold of the SCL line is released by writing a value to the ACKBT bit.

After data is received with this setting, the SCL line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1) according to receive data.

WAIT Bit (WAIT)

This bit is used to control whether to hold the period between the ninth SCL clock cycle and the first SCL clock cycle low until the receive data buffer (RIICnDRR) is completely read each time single-byte data is received in receive mode.

When the WAIT bit is 0, the receive operation is continued without holding the period between the ninth and the first SCL clock cycle low. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCL line is held low from the falling edge of the ninth clock cycle until the RIICnDRR value is read each time single-byte data is received. This enables receive operation in byte units.

CAUTION

When the value of the WAIT bit is cleared to 0, be sure to read the RIICnDRR beforehand.

21.3.7 RIICnFER — I2C Bus Function Enable Register

Access: RIICnFER is a 32-bit readable/writable register.
RIICnFERL and RIICnFERH are 16-bit readable/writable registers.
RIICnFERLL, RIICnFERLH, RIICnFERHL, and RIICnFERHH are 8-bit readable/writable registers.

Address: RIICnFER: <RIICn_base> + 0014_H

RIICnFERL: <RIICn_base> + 0014_H, RIICnFERH: <RIICn_base> + 0016_H

RIICnFERLL: <RIICn_base> + 0014_H, RIICnFERLH: <RIICn_base> + 0015_H,
RIICnFERHL: <RIICn_base> + 0016_H, RIICnFERHH: <RIICn_base> + 0017_H

Value after reset: 0000 0072_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.15 RIICnFER Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	These bits are read as the value after reset. The write value should be the value after reset.
6	SCLE	SCL Synchronous Circuit Enable 0: No SCL synchronous circuit is used. 1: An SCL synchronous circuit is used.
5	NFE	Digital Noise Filter Circuit Enable 0: No digital noise filter circuit is used. 1: A digital noise filter circuit is used.
4	NACKE	NACK Reception Transfer Suspension Enable 0: Transfer operation is not suspended during NACK reception (transfer suspension disabled). 1: Transfer operation is suspended during NACK reception (transfer suspension enabled).
3	SALE	Slave Arbitration-Lost Detection Enable 0: Slave arbitration-lost detection is disabled. 1: Slave arbitration-lost detection is enabled.
2	NALE	NACK Transmission Arbitration-Lost Detection Enable 0: NACK transmission arbitration-lost detection is disabled. 1: NACK transmission arbitration-lost detection is enabled.
1	MALE	Master Arbitration-Lost Detection Enable 0: Master arbitration-lost detection is disabled. (Disables the arbitration-lost detection function and does not clear the RIICnCR2.MST and TRS bits automatically when arbitration is lost.) 1: Master arbitration-lost detection is enabled. (Enables the arbitration-lost detection function and clears the RIICnCR2.MST and TRS bits automatically when arbitration is lost.) If 1 is written to the ST bit while the BBSY flag is 1 in slave transmit mode, the TRS bit is not cleared.
0	TMOE	Timeout Function Enable 0: The timeout function is disabled. 1: The timeout function is enabled.

TMOE Bit (Timeout Function Enable)

This bit is used to enable or disable the timeout function.

For details on the timeout function, see Section 21.13.1, Timeout Function.

MALE Bit (Master Arbitration-Lost Detection Enable)

This bit is used to select enabling or disabling of the arbitration-lost detection function. Normally, set this bit to 1.

NALE Bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit is used to specify whether the detection of ACK during transmission of NACK in reception (such as when slaves with the same address are present on the bus and each is transmitting different data, or when two or more masters select the same slave device simultaneously with different numbers of bytes for reception) is judged to represent a loss in arbitration.

SALE Bit (Slave Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

NACKE Bit (NACK Reception Transfer Suspension Enable)

This bit is used to specify whether to continue or discontinue the transfer operation when NACK is received in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended.

When the NACKE bit is 0, the next transfer operation is continued regardless of the received acknowledge content.

SCLE Bit (SCL Synchronous Circuit Enable)

This bit is used to specify whether to synchronize the SCL clock with a rising or falling edge on the SCL line. Normally, set this bit to 1.

When the SCLE bit is cleared to 0 (SCL synchronous circuit not used), the RIIC does not synchronize the SCL clock with the SCL input clock. In this setting, the RIIC outputs the SCL clock with the transfer rate set in RIICnBRH and RIICnBRL regardless of the SCL line state. For this reason, if the bus load of the I2C bus line is much larger than the specification value or if the SCL clock output overlaps in multiple masters, the short-cycle SCL clock that does not meet the specification may be output. When no SCL synchronous circuit is used, it also affects the issuance of a start condition, restart condition, and stop condition, and the continuous output of extra SCL clock cycles.

This bit must not be cleared to 0 except for checking the output of the transfer rate.

21.3.8 RIICnSER — I2C Bus Status Enable Register

Access: RIICnSER is a 32-bit readable/writable register.
RIICnSERL and RIICnSERH are 16-bit readable/writable registers.
RIICnSERLL, RIICnSERLH, RIICnSERHL, and RIICnSERHH are 8-bit readable/writable registers.

Address: RIICnSER: <RIICn_base> + 0018_H

RIICnSERL: <RIICn_base> + 0018_H, RIICnSERH: <RIICn_base> + $001A_H$

RIICnSERLL: <RIICn_base> + 0018_H, RIICnSERLH: <RIICn_base> + 0019_H,
RIICnSERHL: <RIICn_base> + $001A_H$, RIICnSERHH: <RIICn_base> + $001B_H$

Value after reset: 0000 0009_H

Table 21.16 RIICnSER Register Contents

Bit Position	Bit Name	Function
31 to 6	Reserved	These bits are read as the value after reset. The write value should be the value after reset.
5	DIDE	Device-ID Address Detection Enable 0: Device-ID address detection is disabled. 1: Device-ID address detection is enabled.
4	Reserved	This bit is read as the value after reset. The write value should be the value after reset.
3	GCE	General Call Address Enable 0: General call address detection is disabled. 1: General call address detection is enabled.
2	SAR2	Slave Address Register 2 Enable 0: Slave address in RIICnSAR2 is disabled. 1: Slave address in RIICnSAR2 is enabled.
1	SAR1	Slave Address Register 1 Enable 0: Slave address in RIICnSAR1 is disabled. 1: Slave address in RIICnSAR1 is enabled.
0	SAR0	Slave Address Register 0 Enable 0: Slave address in RIICnSAR0 is disabled. 1: Slave address in RIICnSAR0 is enabled.

SARy Bit (Slave Address Register y Enable) (y = 0 to 2)

This bit is used to enable or disable the slave address set in RIICnSARy.

When this bit is set to 1, the slave address set in RIICnSARy is enabled and is compared with the received slave address.

When this bit is cleared to 0, the slave address set in RIICnSARy is disabled and is ignored even if it matches the received slave address.

GCAE Bit (General Call Address Enable)

This bit is used to specify whether to ignore the general call address ($0000\ 000_B$ + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the RIIC recognizes the received slave address as the general call address independently of the slave addresses set in RIICnSARy (y = 0 to 2) and performs data receive operation.

When this bit is cleared to 0, the received slave address is ignored even if it matches the general call address.

DIDE Bit (Device-ID Address Detection Enable)

This bit is used to specify whether to recognize and execute the Device-ID address when a device ID ($1111\ 100_B$) is received in the first frame after a start condition or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the RIIC recognizes that the Device-ID address has been received. When the following R/W# bit is 0 [W], the RIIC recognizes the second and the following frames as slave addresses and continues the receive operation.

When this bit is cleared to 0, the RIIC ignores the received first frame even if it matches the device ID address and recognizes the first frame as a normal slave address.

For details on the device-ID address detection, see **Section 21.9.3, Device-ID Address Detection**.

21.3.9 RIICnIER — I2C Bus Interrupt Enable Register

Access: RIICnIER is a 32-bit readable/writable register.
RIICnIERL and RIICnIERH are 16-bit readable/writable registers.
RIICnIERLL, RIICnIERLH, RIICnIERHL, and RIICnIERHH are 8-bit readable/writable registers.

Address: RIICnIER: <RIICn_base> + $001C_H$

RIICnIERL: <RIICn_base> + $001C_H$, RIICnIERH: <RIICn_base> + $001E_H$

RIICnIERLL: <RIICn_base> + $001C_H$, RIICnIERLH: <RIICn_base> + $001D_H$,
RIICnIERHL: <RIICn_base> + $001E_H$, RIICnIERHH: <RIICn_base> + $001F_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 21.17 RIICnIER Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	These bits are read as the value after reset. The write value should be the value after reset.
7	TIE	Transmit Data Empty Interrupt Enable 0: Transmit data empty interrupt request (INTIICnTI) is disabled. 1: Transmit data empty interrupt request (INTIICnTI) is enabled.
6	TEIE	Transmit End Interrupt Enable 0: Transmit end interrupt request (INTIICnTEI) is disabled. 1: Transmit end interrupt request (INTIICnTEI) is enabled.
5	RIE	Receive Complete Interrupt Enable 0: Receive complete interrupt request (INTIICnRI) is disabled. 1: Receive complete interrupt request (INTIICnRI) is enabled.
4	NAKIE	NACK Reception Interrupt Enable 0: NACK reception interrupt request (NAKI) is disabled. 1: NACK reception interrupt request (NAKI) is enabled.
3	SPIE	Stop Condition Detection Interrupt Enable 0: Stop condition detection interrupt request (SPI) is disabled. 1: Stop condition detection interrupt request (SPI) is enabled.
2	STIE	Start Condition Detection Interrupt Enable 0: Start condition detection interrupt request (STI) is disabled. 1: Start condition detection interrupt request (STI) is enabled.
1	ALIE	Arbitration-Lost Interrupt Enable 0: Arbitration-lost interrupt request (ALI) is disabled. 1: Arbitration-lost interrupt request (ALI) is enabled.
0	TMOIE	Timeout Interrupt Enable 0: Timeout interrupt request (TMOI) is disabled. 1: Timeout interrupt request (TMOI) is enabled.

TMOIE Bit (Timeout Interrupt Enable)

This bit is used to enable or disable timeout interrupt requests (TMOI) when the RIICnSR2.TMOF flag is set to 1. A TMOI interrupt request is canceled by clearing the TMOF flag or the TMOIE bit to 0.

ALIE Bit (Arbitration-Lost Interrupt Enable)

This bit is used to enable or disable arbitration-lost interrupt requests (ALI) when the RIICnSR2.AL flag is set to 1. An ALI interrupt request is canceled by clearing the AL flag or the ALIE bit to 0.

STIE Bit (Start Condition Detection Interrupt Enable)

This bit is used to enable or disable start condition detection interrupt requests (STI) when the RIICnSR2.START flag is set to 1. An STI interrupt request is canceled by clearing the START flag or the STIE bit to 0.

SPIE Bit (Stop Condition Detection Interrupt Enable)

This bit is used to enable or disable stop condition detection interrupt requests (SPI) when the RIICnSR2.STOP flag is set to 1. An SPI interrupt request is canceled by clearing the STOP flag or the SPIE bit to 0.

NAKIE Bit (NACK Reception Interrupt Enable)

This bit is used to enable or disable NACK reception interrupt requests (NAKI) when the RIICnSR2.NACKF flag is set to 1. An NAKI interrupt request is canceled by clearing the NACKF flag or the NAKIE bit to 0.

RIE Bit (Receive Complete Interrupt Enable)

This bit is used to enable or disable receive complete interrupt requests (INTIICnRI) when the RIICnSR2.RDRF flag is set to 1.

TEIE Bit (Transmit End Interrupt Enable)

This bit is used to enable or disable transmit end interrupts (INTIICnTEI) when the RIICnSR2.TEND flag is set to 1. An INTIICnTEI interrupt request is canceled by clearing the TEND flag or the TEIE bit to 0.

TIE Bit (Transmit Data Empty Interrupt Enable)

This bit is used to enable or disable transmit data empty interrupts (INTIICnTI) when the RIICnSR2.TDRE flag is set to 1.

21.3.10 RIICnSR1 — I2C Bus Status Register 1

Access: RIICnSR1 is a 32-bit readable/writable register.
RIICnSR1L and RIICnSR1H are 16-bit readable/writable registers.
RIICnSR1LL, RIICnSR1LH, RIICnSR1HL, and RIICnSR1HH are 8/1-bit readable/writable registers.

Address: RIICnSR1: <RIICn_base> + 0020_H

RIICnSR1L: <RIICn_base> + 0020_H, RIICnSR1H: <RIICn_base> + 0022_H

RIICnSR1LL: <RIICn_base> + 0020_H, RIICnSR1LH: <RIICn_base> + 0021_H,
RIICnSR1HL: <RIICn_base> + 0022_H, RIICnSR1HH: <RIICn_base> + 0023_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note 1. Only 0 can be written to this bit.

Table 21.18 RIICnSR1 Register Contents

Bit Position	Bit Name	Function
31 to 6	Reserved	These bits are read as the value after reset. The write value should be the value after reset.
5	DID	Device-ID Address Detection Flag 0: Device-ID address is not detected. 1: Device-ID address is detected.
4	Reserved	This bit is read as the value after reset. The write value should be the value after reset.
3	GCA	General Call Address Detection Flag 0: General call address is not detected. 1: General call address is detected.
2	AAS2	Slave Address 2 Detection Flag 0: Slave address 2 is not detected. 1: Slave address 2 is detected.
1	AAS1	Slave Address 1 Detection Flag 0: Slave address 1 is not detected. 1: Slave address 1 is detected.
0	AAS0	Slave Address 0 Detection Flag 0: Slave address 0 is not detected. 1: Slave address 0 is detected.

AASy Flag (Slave Address y Detection) (y = 0 to 2)

[Setting conditions]

<For 7-bit address format: RIICnSARy.FSy = 0>

When the received slave address matches the RIICnSARy.SVA[7:1] value with the RIICnSER.SARy bit set to 1 (slave address y detection enabled)
This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

<For 10-bit address format: RIICnSARy.FSy = 1>

When the received slave address matches a value of (1111 0_B + RIICnSARy.SVA[9:8]) and the following address matches the RIICnSARy.SVA[7:0] value with the RIICnSER.SARy bit set to 1 (slave address y detection enabled)
This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the AASy bit after reading AASy = 1
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

<For 7-bit address format: RIICnSARy.FSy = 0>

- When the received slave address does not match the RIICnSARy.SVA[7:1] value with the RIICnSER.SARy bit set to 1 (slave address y detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.

<For 10-bit address format: RIICnSARy.FSy = 1>

- When the received slave address does not match a value of (1111 0_B + RIICnSARy.SVA[9:8]) with the RIICnSER.SARy bit set to 1 (slave address y detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When the received slave address matches a value of (1111 0_B + RIICnSARy.SVA[9:8]) and the following address does not match the RIICnSARy.SVA[7:0] value with the RIICnSER.SARy bit set to 1 (slave address y detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.

GCA Flag (General Call Address Detection)

[Setting condition]

- When the received slave address matches the general call address ($0000\ 000_B$ + 0 [W]) with the RIICnSER.GCE bit set to 1 (general call address detection enabled)
  This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the GCA bit after reading GCA = 1
- When a stop condition is detected
- When the received slave address does not match the general call address ($0000\ 000_B$ + 0 [W]) with the RIICnSER.GCE bit set to 1 (general call address detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

DID Flag (Device-ID Address Detection)

[Setting condition]

- When the first frame received immediately after a start condition or restart condition is detected matches a value of (device ID ($1111\ 100_B$) + 0 [W]) with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled). This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.
- When a restart condition is detected after a match with the device ID address and the device ID address ($1111\ 100_B$) plus 1[R] has matched while the setting of the RIICnSER.DIDE bit is 1 (device ID address detection enabled). This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the DID bit after reading DID = 1
- When a stop condition is detected
- When the first frame received immediately after a start condition or restart condition is detected does not match a value of (device ID ($1111\ 100_B$)) with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When the first frame received immediately after a start condition or restart condition is detected matches a value of (device ID ($1111\ 100_B$) + 0 [W]) and the second frame does not match any of slave addresses 0 to 2 with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

21.3.11 RIICnSR2 — I2C Bus Status Register 2

Access: RIICnSR2 is a 32-bit readable/writable register.
RIICnSR2L and RIICnSR2H are 16-bit readable/writable registers.
RIICnSR2LL, RIICnSR2LH, RIICnSR2HL, and RIICnSR2HH are 8/1-bit readable/writable registers.

Address: RIICnSR2: <RIICn_base> + 0024_H

RIICnSR2L: <RIICn_base> + 0024_H, RIICnSR2H: <RIICn_base> + 0026_H

RIICnSR2LL: <RIICn_base> + 0024_H, RIICnSR2LH: <RIICn_base> + 0025_H,
RIICnSR2HL: <RIICn_base> + 0026_H, RIICnSR2HH: <RIICn_base> + 0027_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	TDRE	TEND	RDRF	NACKF	STOP	START	AL	TMOF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R(/W)*1	R(/W)*1	R(/W)*1	R(/W)*1	R(/W)*1	R(/W)*1	R(/W)*1

Note 1. Only 0 can be written to this bit.

Table 21.19 RIICnSR2 Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	These bits are read as the value after reset. The write value should be the value after reset.
7	TDRE	Transmit Data Empty Flag 0: RIICnDRT contains transmit data. 1: RIICnDRT contains no transmit data.
6	TEND	Transmit End Flag 0: Data is being transmitted. 1: Data has been transmitted.
5	RDRF	Receive Complete Flag 0: RIICnDRR contains no receive data. 1: RIICnDRR contains receive data.
4	NACKF	NACK Detection Flag 0: NACK is not detected. 1: NACK is detected.
3	STOP	Stop Condition Detection Flag 0: Stop condition is not detected. 1: Stop condition is detected.
2	START	Start Condition Detection Flag 0: Start condition is not detected. 1: Start condition is detected.
1	AL	Arbitration-Lost Flag 0: Arbitration is not lost. 1: Arbitration is lost.
0	TMOF	Timeout Detection Flag 0: Timeout is not detected. 1: Timeout is detected.

TMOF Flag (Timeout Detection)

This flag is set to 1 when the RIIC recognizes timeout after the SCL line state remains unchanged for a certain period.

[Setting condition]

The timeout function is enabled when the RIICnFER.TMOE bit is 1. It detects an abnormal bus state that the SCL line is stuck low or high during the following conditions:

- The bus is busy (the RIICnCR2.BBSY flag is 1) in master mode (the RIICnCR2.MST bit is 1).
- The RIIC's own slave address matches (the RIICnSR1 register is not 00_H) and the bus is busy (the RIICnCR2.BBSY bit is 1) in slave mode (the RIICnCR2.MST bit is 0).
- The bus is free (the RIICnCR2.BBSY flag is 0) while generation of a start condition is requested (the RIICnCR2.ST bit is 1).

[Clearing conditions]

- When 0 is written to the TMOF bit after reading TMOF = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

AL Flag (Arbitration-Lost)

This flag shows that bus mastership has been lost (loss in arbitration) due to a bus conflict or some other reason when a start condition is issued or an address and data are transmitted. The RIIC monitors the level on the SDA line during transmission and, if the level on the line does not match the value of the bit being output, sets the value of the AL bit to 1 to indicate that the bus is occupied by another device.

The RIIC can also set the flag to indicate the detection of loss of arbitration during NACK transmission in receive mode or during data transmission in slave mode.

[Setting conditions]

<When master arbitration-lost detection is enabled: RIICnFER.MALE = 1>

- When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock except for the ACK period during data (including slave address) transmission in master transmit mode (when the SDA line is driven low while the internal SDA output is at a high level (the SDA pin is in the high impedance state))
- When a start condition is detected while the RIICnCR2.ST bit is 1 (start condition issuance request) or the internal SDA output state does not match the SDA line level
- When the RIICnCR2.ST bit is set to 1 (start condition issuance request) with the RIICnCR2.BBSY flag set to 1.

<When NACK arbitration-lost detection is enabled: RIICnFER.NALE = 1>

When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock in the ACK period during NACK transmission in receive mode

<When slave arbitration-lost detection is enabled: RIICnFER.SALE = 1>

When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock except for the ACK period during data transmission in slave transmit mode

[Clearing conditions]

- When 0 is written to the AL bit after reading AL = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

Table 21.20 Relationship between Arbitration-Lost Generation Sources and Arbitration-Lost Enable Functions

RIICnFER			RIICnSR2		
MALE	NALE	SALE	AL	Error	Arbitration-Lost Generation Source
1	—	—	1	Start condition issuance error	When internal SDA output state does not match SDA line level when a start condition is detected while the RIICnCR2.ST bit is 1
					When RIICnCR2.ST is set to 1 with RIICnCR2.BBSY set to 1
			1	Transmit data mismatch	When transmit data (including slave address) does not match the bus state in master transmit mode
—	1	—	1	NACK transmission mismatch	When ACK is detected during transmission of NACK in master receive mode or slave receive mode
—	—	1	1	Transmit data mismatch	When transmit data does not match the bus state in slave transmit mode

—: Don't care

START Flag (Start Condition Detection)

[Setting condition]

When a start condition (or a restart condition) is detected

[Clearing conditions]

- When 0 is written to the START bit after reading START = 1
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

STOP Flag (Stop Condition Detection)

[Setting condition]

When a stop condition is detected

[Clearing conditions]

- When 0 is written to the STOP bit after reading STOP = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

NACKF Flag (NACK Detection)

[Setting condition]

When acknowledge is not received (NACK is received) from the receive device in transmit mode with the RIICnFER.NACKE bit set to 1 (transfer suspension enabled)

[Clearing conditions]

- When 0 is written to the NACKF bit after reading NACKF = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

CAUTION

When the NACKF flag is set to 1, the RIIC suspends data transmission/reception. Writing to RIICnDRT in transmit mode or reading from RIICnDRR in receive mode with the NACKF flag set to 1 does not enable data transmit/receive operation. To restart data transmission/reception, clear the NACKF flag to 0.

RDRF Flag (Receive Complete)

[Setting conditions]

- When receive data has been transferred from RIICnDRS to RIICnDRR
  This flag is set to 1 at the rising edge of the eighth or ninth SCL clock cycle (selected by the RIICnMR3.RDRFS bit)
- When the received slave address matches the address enabled in RIICnSER after a start condition (or a restart condition) is detected with the RIICnCR2.TRS bit cleared to 0
- In master mode, transition to master reception while the R/W# bit appended to the slave address is set to 1

[Clearing conditions]

- When 0 is written to the RDRF bit after reading RDRF = 1
- When data is read from RIICnDRR
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

TEND Flag (Transmit End)

[Setting condition]

At the rising edge of the ninth SCL clock cycle while the TDRE flag is 1

[Clearing conditions]

- When 0 is written to the TEND bit after reading TEND = 1
- When data is written to RIICnDRT
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

TDRE Flag (Transmit Data Empty)

[Setting conditions]

- When data has been transferred from RIICnDRT to RIICnDRS and RIICnDRT becomes empty
- When the RIICnCR2.TRS bit is set to 1
  - When the RIICnCR2.MST bit is set to 1 after a start condition is detected
  - When the RIIC enters transmit mode from receive mode
  - When 1 is written to the RIICnCR2.TRS bit while the RIICnMR1.MTWP bit is 1
  - When the received slave address matches the address enabled in RIICnSER after a start condition including a restart condition is detected with the RIICnCR2.TRS bit set to 1
- When the received slave address matches while the TRS bit is 1

[Clearing conditions]

- When data is written to RIICnDRT
- When the RIICnCR2.TRS bit is cleared to 0
  - When a stop condition is detected
  - When the RIIC enters receive mode from transmit mode
  - When 0 is written to the RIICnCR2.TRS bit while the RIICnMR1.MTWP bit is 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

CAUTION

When the NACKF flag is set to 1 while the RIICnFER.NACKE bit is 1, the RIIC suspends data transmission/reception. Here, if the TDRE flag is 0 (next transmit data has been written), data is transferred to the RIICnDRS register and the RIICnDRT register becomes empty at the rising edge of the ninth clock cycle, but the TDRE flag is not set to 1.

21.3.12 RIICnSARy — I2C Slave Address Register y (y = 0 to 2)

Access: RIICnSARy is a 32-bit readable/writable register.
RIICnSARyL and RIICnSARyH are 16-bit readable/writable registers.
RIICnSARyLL, RIICnSARyLH, RIICnSARyHL, and RIICnSARyHH are 8-bit readable/writable registers.

Address: RIICnSAR0: <RIICn_base> + 0028_H

RIICnSAR0L: <RIICn_base> + 0028_H, RIICnSAR0H: <RIICn_base> + $002A_H$

RIICnSAR0LL: <RIICn_base> + 0028_H, RIICnSAR0LH: <RIICn_base> + 0029_H,
RIICnSAR0HL: <RIICn_base> + $002A_H$, RIICnSAR0HH: <RIICn_base> + $002B_H$

RIICnSAR1: <RIICn_base> + $002C_H$

RIICnSAR1L: <RIICn_base> + $002C_H$, RIICnSAR1H: <RIICn_base> + $002E_H$

RIICnSAR1LL: <RIICn_base> + $002C_H$, RIICnSAR1LH: <RIICn_base> + $002D_H$,
RIICnSAR1HL: <RIICn_base> + $002E_H$, RIICnSAR1HH: <RIICn_base> + $002F_H$

RIICnSAR2: <RIICn_base> + 0030_H

RIICnSAR2L: <RIICn_base> + 0030_H, RIICnSAR2H: <RIICn_base> + 0032_H

RIICnSAR2LL: <RIICn_base> + 0030_H, RIICnSAR2LH: <RIICn_base> + 0031_H,
RIICnSAR2HL: <RIICn_base> + 0032_H, RIICnSAR2HH: <RIICn_base> + 0033_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FSy	—	—	—	—	—	SVA[9:1]									SVA0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.21 RIICnSARy Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	These bits are read as the value after reset. The write value should be the value after reset.
15	FSy	7-Bit/10-Bit Address Format Selection 0: The 7-bit address format is selected. 1: The 10-bit address format is selected.
14 to 10	Reserved	These bits are read as the value after reset. The write value should be the value after reset.
9 to 1	SVA[9:1]	7-Bit Address/10-Bit Address Upper Bits A slave address is set. • When the FSy bit is 0 (7-bit address format), the SVA[7:1] bits are valid and form a 7-bit slave address. • When the FSy bit is 1 (10-bit address format), SVA[9:1] bits form a 10-bit slave address (combined with the SVA0 bit).
0	SVA0	10-Bit Address LSB The least significant bit (LSB) of a 10-bit slave address is set. • When the FSy bit is 0 (7-bit address format), this bit is invalid. • When the FSy bit is 1 (10-bit address format), this bit is a 10-bit slave address (combined with the SVA[9:1] bits).

SVA0 Bit (10-Bit Address LSB)

When the 10-bit address format is selected (RIICnSARy.FSy = 1), this bit functions as the LSB of a 10-bit address and forms a 10-bit address in combination with the SVA[9:1] bits.

When the RIICnSER.SARy bit is set to 1 (RIICnSARy enabled) and the RIICnSARy.FSy bit is 1, this bit is valid. While the RIICnSARy.FSy bit or SARy bit is 0, the setting of this bit is ignored.

SVA[9:1] Bits (7-Bit Address/10-Bit Address Upper Bits)

When the 7-bit address format is selected (RIICnSARy.FSy = 0), these bits function as a 7-bit address. When the 10-bit address format is selected (RIICnSARy.FSy = 1), these bits function as a 10-bit address in combination with the SVA0 bit.

While the RIICnSER.SARy bit is 0, the setting of these bits is ignored.

FSy Bit (7-Bit/10-Bit Address Format Selection)

This bit is used to select 7-bit address or 10-bit address for slave address y (in RIICnSARy).

When the RIICnSER.SARy bit is set to 1 (RIICnSARy enabled) and the RIICnSARy.FSy bit is 0, the 7-bit address format is selected for slave address y, the RIICnSARy.SVA[7:1] setting is valid, and the settings of the SVA[9:8] bits and the RIICnSARy.SVA0 bit are ignored.

When the RIICnSER.SARy bit is set to 1 (RIICnSARy enabled) and the RIICnSARy.FSy bit is 1, the 10-bit address format is selected for slave address y and the settings of the SVA[9:1] bits and the SVA0 bit are valid.

While the RIICnSER.SARy bit is 0 (RIICnSARy disabled), the setting of the RIICnSARy.FSy bit is invalid.

21.3.13 RIICnBRL — I2C Bus Bit Rate Low-Level Register

Access: RIICnBRL is a 32-bit readable/writable register.
RIICnBRLL and RIICnBRLH are 16-bit readable/writable registers.
RIICnBRLLL, RIICnBRLLH, RIICnBRLHL, and RIICnBRLHH are 8-bit readable/writable registers.

Address: RIICnBRL: <RIICn_base> + 0034_H

RIICnBRLL: <RIICn_base> + 0034_H, RIICnBRLH: <RIICn_base> + 0036_H

RIICnBRLLL: <RIICn_base> + 0034_H, RIICnBRLLH: <RIICn_base> + 0035_H,
RIICnBRLHL: <RIICn_base> + 0036_H, RIICnBRLHH: <RIICn_base> + 0037_H

Value after reset: 0000 $00FF_H$

Table 21.22 RIICnBRL Register Contents

Bit Position	Bit Name	Function
31 to 5	Reserved	These bits are read as the value after reset. The write value should be the value after reset.
4 to 0	BRL[4:0]	Bit Rate Low-Level Period Low-level period of SCL clock

The RIICnBRL[4:0] register is a 5-bit register that is used to set the width at low level for the SCL clock.

It also works to generate the data setup time for automatic SCL low-hold operation (see Section 21.10, Automatic Low-Hold Function for SCL); when the RIIC is used only in slave mode, this register needs to be set to a value longer than the data setup time*1.

RIICnBRL[4:0] counts the low-level period with the internal reference clock source (IICϕ) specified by the RIICnMR1.CKS[2:0] bits.

Note 1. Data setup time (tSU: DAT)
250 ns (up to 100 kbps: standard mode [Sm])
100 ns (up to 400 kbps: fast mode [Fm])

21.3.14 RIICnBRH — I2C Bus Bit Rate High-Level Register

Access: RIICnBRH is a 32-bit readable/writable register.
RIICnBRHL and RIICnBRHH are 16-bit readable/writable registers.
RIICnBRHLL, RIICnBRHLH, RIICnBRHHL, and RIICnBRHHH are 8-bit readable/writable registers.

Address: RIICnBRH: <RIICn_base> + 0038_H

RIICnBRHL: <RIICn_base> + 0038_H, RIICnBRHH: <RIICn_base> + $003A_H$

RIICnBRHLL: <RIICn_base> + 0038_H, RIICnBRHLH: <RIICn_base> + 0039_H,
RIICnBRHHL: <RIICn_base> + $003A_H$, RIICnBRHHH:<RIICn_base> + $003B_H$

Table 21.23 RIICnBRH Register Contents

Bit Position	Bit Name	Function
31 to 5	Reserved	These bits are read as the value after reset. The write value should be the value after reset.
4 to 0	BRH[4:0]	Bit Rate High-Level Period High-level period of SCL clock

RIICnBRH[4:0] is a 5-bit register to set the high-level period of SCL clock. RIICnICBRH is valid in master mode. If the RIIC is used only in slave mode, this register need not to set the high-level period.

RIICnBRH[4:0] counts the high-level period with the internal reference clock source (IICϕ) specified by the RIICnMR1.CKS[2:0] bits.

The I2C transfer rate and the SCL clock duty are calculated using the following expression.

(1) When RIICnFER.SCLE = 0
Transfer rate = 1 / {[(RIICnBRH+1) + (RIICnBRL+1)] / IICφ*1 + tr + tf}
Duty cycle = {tr+[(RIICnBRH+1)/ IICφ]}/{ tr + tf + [(RIICnBRH+1) + (RIICnBRL+1)]/IICφ}

(2) When RIICnFER.SCLE=1, RIICnFER.NFE=0, IICφ = PCLK
Transfer rate = 1 / {[(RIICnBRH+3) + (RIICnBRL+3)] / IICφ*1 + tr + tf}
Duty cycle = {tr +[(RIICnBRH+3)/ IICφ]}/{ tr + tf + [(RIICnBRH+3) + (RIICnBRL+3)]/IICφ}

(3) When RIICnFER.SCLE=1, RIICnFER.NFE=1, IICφ = PCLK
Transfer rate =1 / {[(RIICnBRH+3+nf) + (RIICnBRL+3+nf)] / IICφ*1 + tr + tf}
Duty cycle = {tr +[(RIICnBRH+3+nf)/ IICφ]}/{ tr + tf + [(RIICnBRH+3+nf) + (RIICnBRL+3+nf)]/ IICφ}

(4) RIICnFER.SCLE=1, RIICnFER.NFE=0, IICφ < PCLK
Transfer rate =1 / {[(RIICnBRH+2) + (RIICnBRL+2)] / IICφ*1+ tr + tf}
Duty cycle = {tr +[(RIICnBRH+2)/ IICφ]}/{ tr + tf + [(RIICnBRH+2) + (RIICnBRL+2)]/IICφ}

(5) When RIICnFER.SCLE=1, RIICnFER.NFE=1, IICφ < PCLK
Transfer rate =1 / {[(RIICnBRH+2+nf) + (RIICnBRL+2+nf)] / IICφ*1+ tr + tf}
Duty cycle = {tr +[(RIICnBRH+2+nf)/ IICφ]}/{ tr + tf + [(RIICnBRH+2+nf) + (RIICnBRL+2+nf)]/ IICφ}

tf: SCL line falling time [ns]*2

tr: SCL line rising time [ns]*2

nf: Digital noise filter stage

Duty cycle: 0% < Duty < 100%

NOTES

1. As for IICφ, see CKS[2:0] in Section 21.3.4, RIICnMR1 — I2C Bus Mode Register 1.
2. The SCL line rising time [tr] and SCL line falling time [tf] depend on the total bus line capacitance [Cb] and the pull-up resistor [Rp]. For details, see the I2C bus standard from NXP Semiconductors.

Table 21.24 lists examples of RIICnBRH/RIICnBRL settings.

Table 21.24 Examples of RIICnBRH/RIICnBRL Settings for Transfer Rate (1)

Transfer Rate (kbps)	Operating Frequency PCLK (MHz)							
	40				80			
	CKS[2:0]	CKS	RIICnBRH	RIICnBRL	CKS[2:0]	CKS	RIICnBRH	RIICnBRL
10	111b	128	14 (EEh)	15 (EFh)	111b	128	29 (FDh)	31 (FFh)
50	100b	16	21 (F5h)	24 (F8h)	101b	32	21 (F5h)	24 (F8h)
100	011b	8	20 (F4h)	22 (F6h)	100b	16	19 (F3h)	23 (F7h)
400	001b	2	17 (F1h)	19 (F3h)	011b	8	7 (E7h)	10 (EAh)

CAUTION

CBRH/ICBRL settings in these tables are calculated using the following values:
SCL line rising time (tr): 100 kbps or less, [Sm]: 1000 ns, 400 kbps or less, [Fm]: 300 ns
SCL line falling time (tf): 400 kbps or less, [Sm/Fm]: 300 ns
For the specified values of SCL line rising time (tr) and SCL line falling time (tf), see the I2C bus standard from NXP Semiconductors.

21.3.15 RIICnDRT — I2C Bus Transmit Data Register

Access: RIICnDRT is a 32-bit readable/writable register.
RIICnDRTL and RIICnDRTH are 16-bit readable/writable registers.
RIICnDRTLL, RIICnDRTLH, RIICnDRTHL, and RIICnDRTHH are 8-bit readable/writable registers.

Address: RIICnDRT: <RIICn_base> + $003C_H$

RIICnDRTL: <RIICn_base> + $003C_H$, RIICnDRTH: <RIICn_base> + $003E_H$

RIICnDRTLL: <RIICn_base> + $003C_H$, RIICnDRTLH: <RIICn_base> + $003D_H$,
RIICnDRTHL: <RIICn_base> + $003E_H$, RIICnDRTHH: <RIICn_base> + $003F_H$

Value after reset: $0000\ 00FF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DRT[7:0]							
Value after reset	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When RIICnDRT detects a space in the I2C bus shift register (RIICnDRS), it transfers the transmit data that has been written to RIICnDRT to RIICnDRS and starts transmitting data in transmit mode.

The double-buffer structure of RIICnDRT and RIICnDRS allows continuous transmit operation if the next transmit data has been written to RIICnDRT while the RIICnDRS data is being transmitted.

RIICnDRT can always be read and written. Write transmit data to RIICnDRT once when a transmit data empty interrupt (INTIICnTI) request is generated. When writing to bit 31 to 8, write 0.

21.3.16 RIICnDRR — I2C Bus Receive Data Register

Access: RIICnDRR is a 32-bit readable register.
RIICnDRRL and RIICnDRRH are 16-bit readable registers.
RIICnDRRLL, RIICnDRRLH, RIICnDRRHL, and RIICnDRRHH are 8-bit readable registers.

Address: RIICnDRR: <RIICn_base> + 0040_H

RIICnDRRL: <RIICn_base> + 0040_H, RIICnDRRH: <RIICn_base> + 0042_H

RIICnDRRLL: <RIICn_base> + 0040_H, RIICnDRRLH: <RIICn_base> + 0041_H,
RIICnDRRHL: <RIICn_base> + 0042_H, RIICnDRRHH: <RIICn_base> + 0043_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DRR[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

When 1 byte of data has been received, the received data is transferred from the I2C bus shift register (RIICnDRS) to RIICnDRR to enable the next data to be received.

The double-buffer structure of RIICnDRS and RIICnDRR allows continuous receive operation if the received data has been read from RIICnDRR while RIICnDRS is receiving data.

RIICnDRR cannot be written. Read data from RIICnDRR once when a receive complete interrupt (INTIICnRI) request is generated.

If RIIC receives the next receive data before the current data is read from RIICnDRR (while the RIICnSR2.RDRF flag is 1), the RIIC automatically holds the SCL clock low one cycle before the RDRF flag is set to 1 next.

21.3.17 RIICnDRS — I2C Bus Shift Register

Access: This register is not accessible.

Address: —

Value after reset: 0000 00FF$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DRS[7:0]							
Value after reset	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

RIICnDRS is a shift register to transmit and receive data.

During transmission, transmit data is transferred from RIICnDRT to RIICnDRS and is sent from the SDA pin. During reception, data is transferred from RIICnDRS to RIICnDRR after 1 byte of data has been received.

RIICnDRS cannot be accessed directly.

21.4 Interrupt Sources

The RIIC issues four types of interrupt request: transfer error or event generation (arbitration-lost detection, NACK detection, timeout detection, start condition detection, and stop condition detection), receive complete, transmit data empty, and transmit complete.

Table 21.25 lists details of the several interrupt requests. The receive complete and transmit data empty interrupt request are both capable of launching data transfer by the DMAC.

Table 21.25 Interrupt Sources

Symbol	Interrupt Source	Interrupt Flag	DMACA Launching	Interrupt Condition
INTIICnTI	Transmit Data Empty	TDRE	Possible	TDRE = 1 and TIE = 1
INTIICnTEI	Transmit End	TEND	Not possible	TEND = 1 and TEIE = 1
INTIICnRI	Receive Complete	RDRF	Possible	RDRF = 1 and RIE = 1
INTIICnEE	Transfer Error/ Event Generation	AL	Not possible	AL = 1 and ALIE = 1
		NACKF		NACKF = 1 and NAKIE = 1
		TMOF		TMOF = 1 and TMOIE = 1
		START		START = 1 and STIE = 1
		STOP		STOP = 1 and SPIE = 1

Clear or mask the each flag during interrupt handling.

CAUTIONS

1. **There is a latency (delay) between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared or masked, read the relevant flag again to check whether clearing or masking has been completed, and then return from interrupt processing. Returning from interrupt processing without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.**
2. **Since INTIICnTI is an edge-detected interrupt, it does not require clearing. Furthermore, the RIICnSR2.TDRE flag (a condition for INTIICnTI) is automatically cleared to 0 when data for transmission are written to RIICnDRT or a stop condition is detected (RIICnSR2.STOP flag = 1).**
3. **Since INTIICnRI is an edge-detected interrupt, it does not require clearing. Furthermore, the RIICnSR2.RDRF flag (a condition for INTIICnRI) is automatically cleared to 0 when data are read from RIICnDRR.**
4. **When using the INTIICnTEI interrupt, clear the RIICnSR2.TEND flag in the INTIICnTEI interrupt processing.**
   Note that the RIICnSR2.TEND flag is automatically cleared to 0 when data for transmission are written to RIICnDRT or a stop condition is detected (RIICnSR2.STOP flag = 1).

21.5 Operation

21.5.1 Communication Data Format

The I2C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a start condition or restart condition is an address frame used to specify a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is issued.

Figure 21.3 shows the I2C bus format, and **Figure 21.4** shows the I2C bus timing.

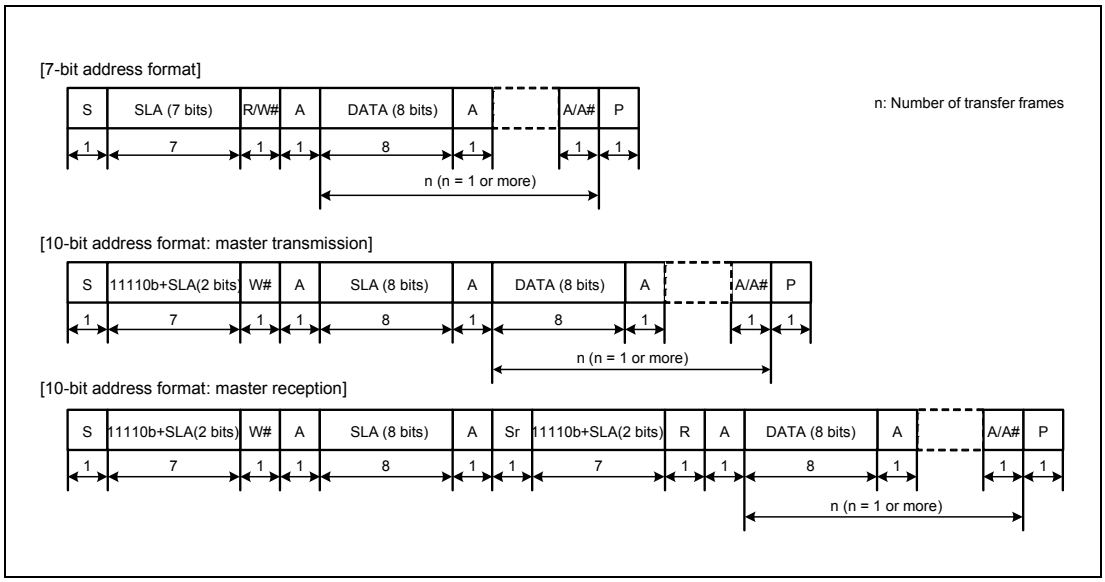

Figure 21.3 I2C Bus Format

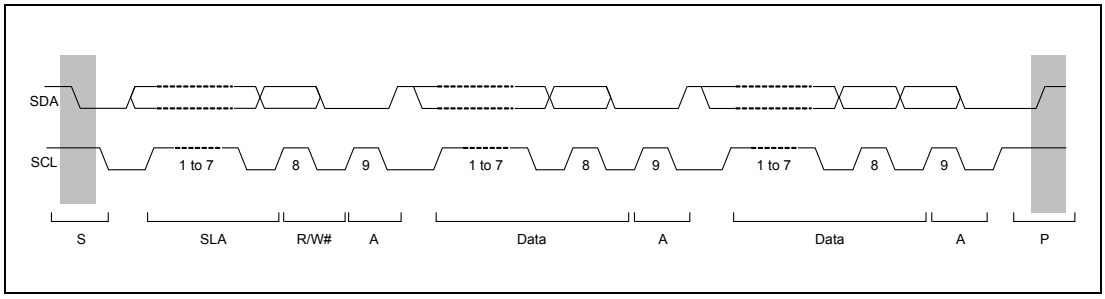

Figure 21.4 I2C Bus Timing (SLA = 7 Bits)

S: Start condition. The master device drives the SDA line low from high level while the SCL line is at a high level.

SLA: Slave address, by which the master device selects a slave device.

R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W is 1, or from the master device to the slave device when R/W is 0.

A: Acknowledge. The receive device drives the SDA line low. (In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.)

A#: Not-acknowledge. The receiving device has not returned a response or is not present so the SDA line has remained at the high level.

Sr: Restart condition. The master device drives the SDA line low from the high level after the setup time has elapsed with the SCL line at the high level.

DATA: Transmitted or received data

P: Stop condition. The master device drives the SDA line high from low level while the SCL line is at a high level.

21.5.2 Initial Settings

Before starting data transmission and reception, initialize the RIIC according to the procedure in **Figure 21.5**. Make initial settings for the RIIC once when starting the RIIC.

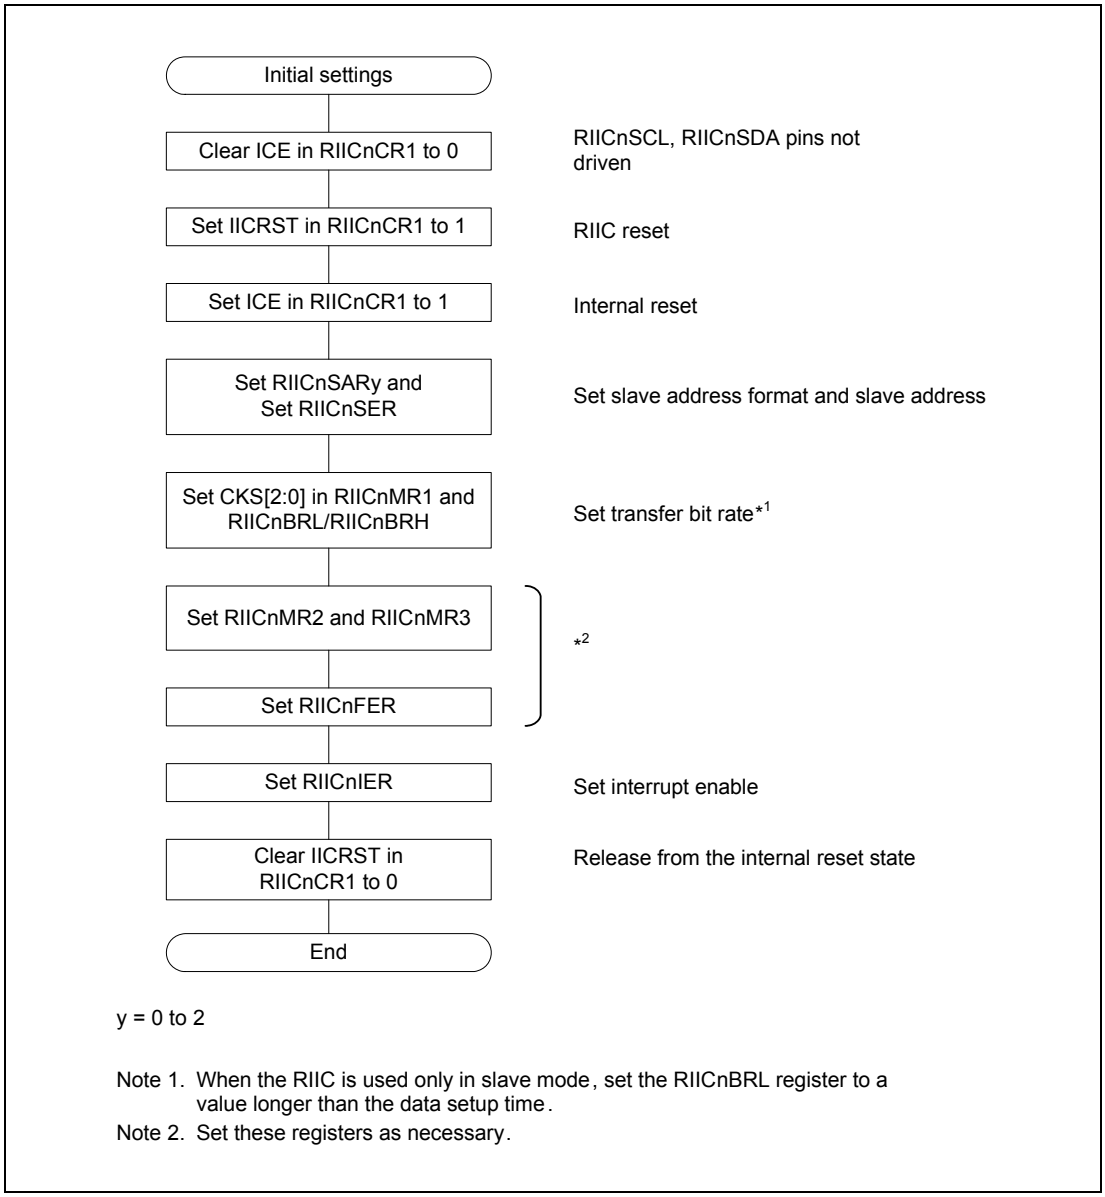

Figure 21.5 Example of RIIC Initialization Flowchart

21.5.3 Master Transmit Operation

In master transmit operation, the RIIC outputs the SCL (clock) and transmitted data signals as the master device, and the slave device returns acknowledgements. **Figure 21.6** shows an example of usage of master transmission and **Figure 21.7** to **Figure 21.9** show the timing of operations in master transmission.

The following describes the procedure and operations for master transmission.

(1) Set the RIICnCR1.IICRST bit 1 to 1 (RIIC reset) and then set the RIICnCR1.ICE bit to 1 (internal reset) with the RIICnCR1.ICE bit cleared to 0 (RIICnSCL and RIICnSDA pins not driven). This initializes the internal state and the various flags of RIICnSR1. After that, set registers RIICnSARy, RIICnSER, RIICnMR1, RIICnBRH, and RIICnBRL (y = 0 to 2), and set the other registers as necessary (for initial settings of the RIIC, see **Figure 21.5**). When the necessary register settings have been completed, set the RIICnCR1.IICRST bit to 0 (for release from the reset state). This step is not necessary if initialization of the RIIC has already been completed.

(2) Read the RIICnCR2.BBSY flag to check that the bus is open, and then set the RIICnCR2.ST bit to 1 (start condition issuance request). Upon receiving the request, the RIIC issues a start condition. At the same time, the BBSY flag and the RIICnSR2.START flag are automatically set to 1 and the ST bit is automatically cleared to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDA line have matched while the ST bit is 1, the RIIC recognizes that issuing of the start condition as requested by the ST bit has been successfully completed, and the RIICnCR2.MST and TRS bits are automatically set to 1, placing the RIIC in master transmit mode. The RIICnSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS and MST bits to 1.

(3) Check that the RIICnSR2.TDRE flag is 1, and then write the value for transmission (the slave address and the R/W# bit) to RIICnDRT. Once the data for transmission are written to RIICnDRT, the TDRE flag is automatically cleared to 0, the data are transferred from RIICnDRT to RIICnDRS, and the TDRE flag is again set to 1. After the slave address including the R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the RIIC continues in master transmit mode.
Since the RIICnSR2.NACKF flag being 1 at this time indicates that the slave address has not been recognized or there was an error in communications, write 1 to the RIICnCR2.SP bit to issue a stop condition.
For data transmission with an address in the 10-bit format, start by writing 1111 0_B, the two higher-order bits of the slave address, and W# to RIICnDRT as the first address transmission. Then, as the second address transmission, write the eight lower-order bits of the slave address to RIICnDRT.

(4) After confirming that the RIICnSR2.TDRE flag is 1, write the data for transmission to the RIICnDRT register. The RIIC automatically holds the SCL line low until the data for transmission are ready or a stop condition is issued.

(5) After all bytes of data for transmission have been written to the RIICnDRT register, wait until the value of the RIICnSR2.TEND flag returns to 1, and then set the RIICnCR2.SP bit to 1 (stop condition issuance request). Upon receiving a stop condition issuance request, the RIIC issues the stop condition.

(6) Upon detecting the stop condition, the RIIC automatically clears the RIICnCR2.MST and TRS bits to 00_B and enters slave receive mode. Furthermore, it automatically clears the RIICnSR2.TDRE and TEND flags to 0, and sets the RIICnSR2.STOP flag in to 1.

(7) After checking that the RIICnSR2.STOP flag is 1, clear the RIICnSR2.NACKF and STOP flags to 0 for the next transfer operation.

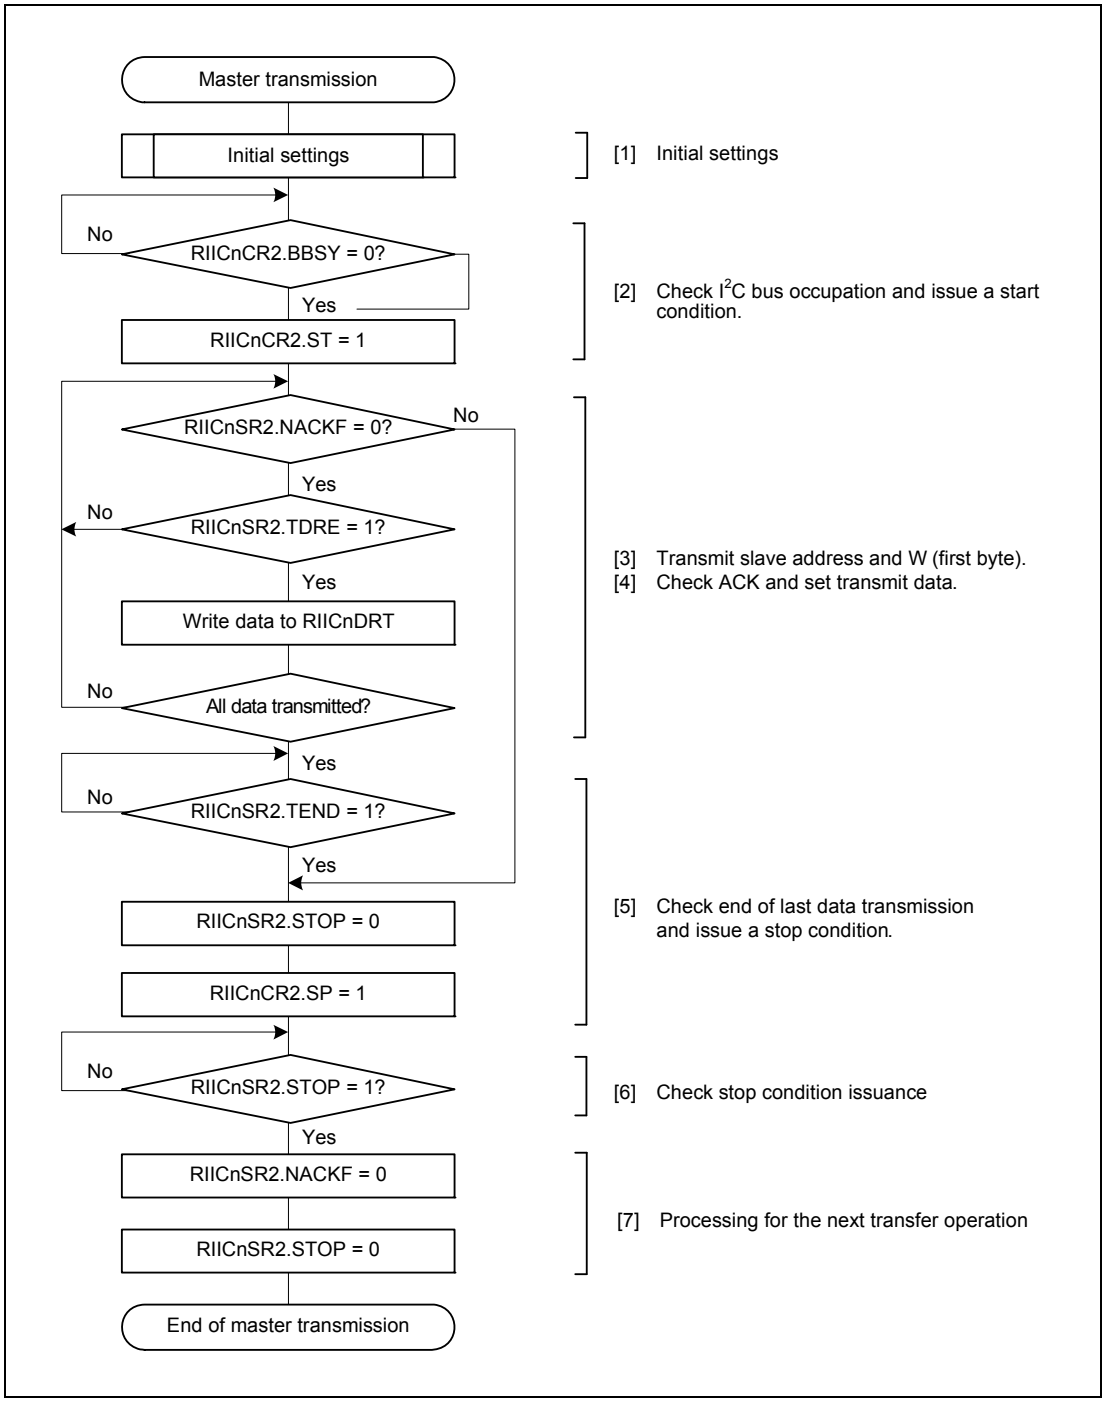

Figure 21.6 Example of Master Transmission Flowchart

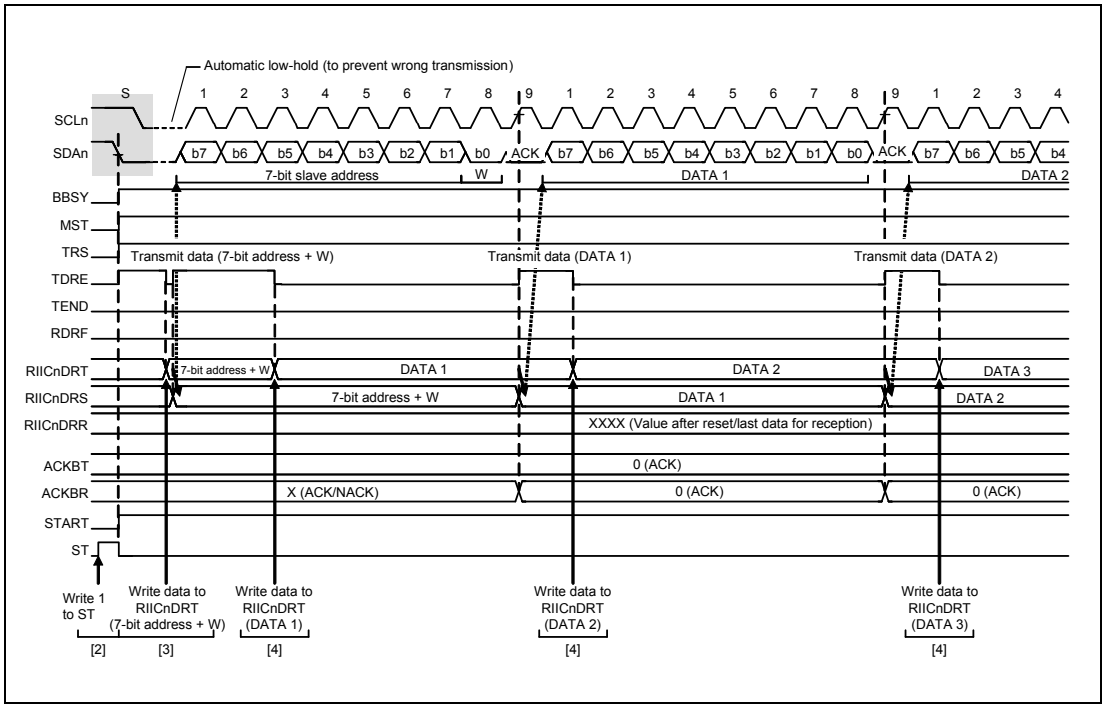

Figure 21.7 Master Transmit Operation Timing (1) (7-Bit Address Format)

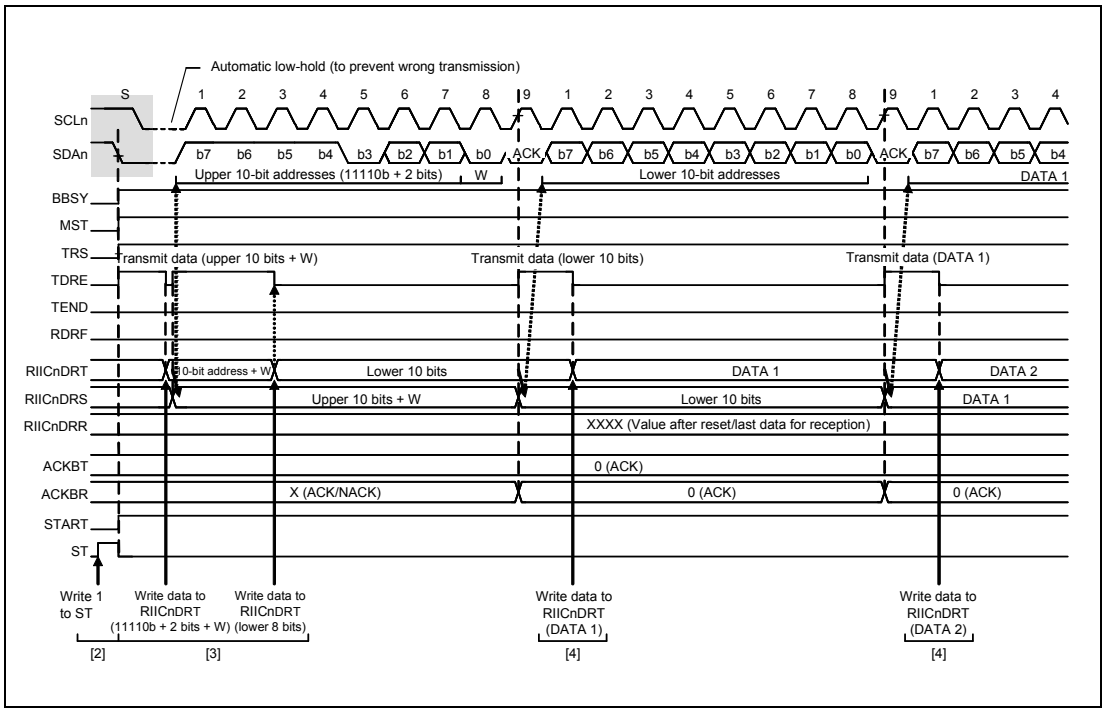

Figure 21.8 Master Transmit Operation Timing (2) (10-Bit Address Format)

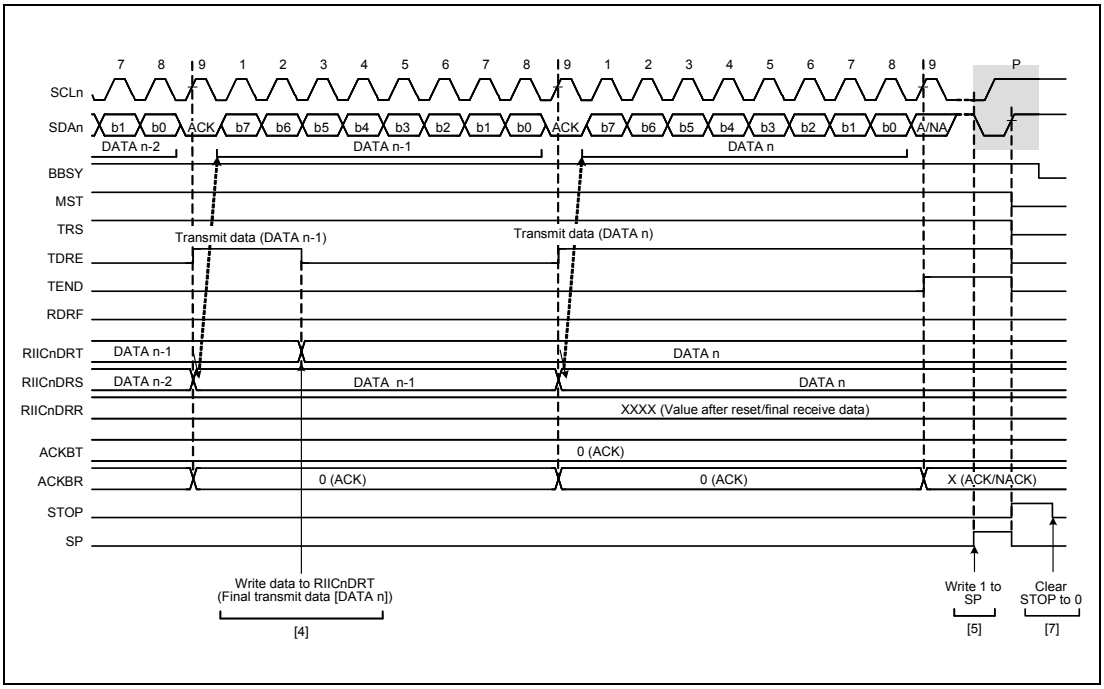

Figure 21.9 Master Transmit Operation Timing (3)

21.5.4 Master Receive Operation

In master receive operation, the RIIC as a master device outputs the SCL (clock) signal, receives data from the slave device, and returns acknowledgements. Since the RIIC must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 21.10 shows an example of master reception flowchart (7-bit address format, 1 or 2 bytes), **Figure 21.11** shows an example of master reception flowchart (7-bit address format, 3 bytes or more), and **Figure 21.12** to **Figure 21.14** show the timing of operations in master reception.

The following describes the procedure and operations for master reception.

(1) Set the RIICnCR1.IICRST bit to 1 (RIIC reset) and then set the RIICnCR1.ICE bit to 1 (internal reset) with the RIICnCR1.ICE bit cleared to 0 (RIICnSCL and RIICnSDA pins not driven). This initializes the internal state and the various flags of RIICnSR1. After that, set registers RIICnSARy, RIICnSER, RIICnMR1, RIICnBRH, and RIICnBRL (y = 0 to 2), and set the other registers as necessary (for initial settings of the RIIC, see **Figure 21.5**). When the necessary register settings have been completed, set the RIICnCR1.IICRST bit to 0 (for release from the reset state). This step is not necessary if initialization of the RIIC has already been completed.

(2) Read the RIICnCR2.BBSY flag to check that the bus is open, and then set the RIICnCR2.ST bit to 1 (start condition issuance request). Upon receiving the request, the RIIC issues a start condition. When the RIIC detects the start condition, the BBSY flag and the RIICnSR2.START flag are automatically set to 1 and the ST bit is automatically cleared to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDA line have matched while the ST bit is 1, the RIIC recognizes that issuing of the start condition as requested by the ST bit has been successfully completed, and the RIICnCR2.MST and TRS bits are automatically set to 1, placing the RIIC in master transmit mode. The RIICnSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS bit to 1.

(3) Check that the RIICnSR2.TDRE flag is 1, and then write the value for transmission (the slave address and value of the R/W# bit) to RIICnDRT. Once the data for transmission are written to RIICnDRT, the TDRE flag is automatically cleared to 0, the data are transferred from RIICnDRT to RIICnDRS, and the TDRE flag is again set to 1. After the slave address including the R/W# bit has been transmitted, the value of the RIICnCR2.TRS bit is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the RIICnCR2.TRS bit is cleared to 0 on the rising edge of the ninth cycle of SCL (the clock signal), placing the RIIC in master receive mode. At this time, the TDRE flag is automatically cleared to 0 and the RIICnSR2.RDRF flag is automatically set to 1.
Since the RIICnSR2.NACKF flag being 1 at this time indicates that the slave address has not been recognized or there was an error in communications, write 1 to the RIICnCR2.SP bit to issue a stop condition.
For master reception from a device with a 10-bit address, start by using master transmission to transmit the two higher-order bits of the slave address and then the eight lower-order bits of the slave address, and issue a restart condition following generation of the transmission end interrupt (or after TEND = 1) (see **Figure 21.13** for operation timing).
After that, transmitting 1111 0B plus the two higher-order bits of the slave address and the R bit places the RIIC in master receive mode.

(4) Dummy read RIICnDRR after confirming that the RIICnSR2.RDRF flag is 1; this makes the RIIC start output of the SCL (clock) signal and start data reception.

(5) After 1 byte of data has been received, the RIICnSR2.RDRF flag is set to 1 on the rising edge of the eighth or ninth cycle of SCL clock (the clock signal) as selected by the RIICnMR3.RDRFS bit. Reading out RIICnDRR at this time will produce the received data, and the RDRF flag is automatically cleared to 0 at the same time. Furthermore, the value of the acknowledgement field received during the ninth cycle of SCL clock is returned as the value set in the RIICnMR3.ACKBT bit. Furthermore, if the next byte to be received is the next to last byte, set the RIICnMR3.WAIT bit to 1 (for wait insertion) before reading the RIICnDRR (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the RIICnMR3.ACKBT bit to 1 (NACK) in step (6), due to other interrupts, etc., this fixes the SCL line to the low level on the rising edge of the ninth clock cycle in reception of the last byte, so the state is such that issuing a stop condition is possible.

(6) When the RIICnMR3.RDRFS bit is 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the RIICnMR3.ACKBT bit to 1 (NACK).

(7) After reading out the byte before last from the RIICnDRR register, if the value of the RIICnSR2.RDRF flag is confirmed to be 1, write 1 to the RIICnCR2.SP bit (stop condition issuance request) and then read the last byte from RIICnDRR. When RIICnDRR is read, the RIIC is released from the wait state and issues the stop condition after low-level output in the ninth clock cycle is completed or the SCL line is released from the low-hold state.

(8) Upon detecting the stop condition, the RIIC automatically clears the RIICnCR2.MST and TRS bits to 00_B and enters slave receive mode. Furthermore, detection of the stop condition leads to setting of the RIICnSR2.STOP flag to 1.

(9) After checking that the RIICnSR2.STOP flag is 1, clear the RIICnSR2.NACKF and STOP flags to 0 for the next transfer operation.

21.5.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL (clock) signal, the RIIC transmits data as a slave device, and the master device returns acknowledgements.

Figure 21.5 shows an example of usage of slave transmission and **Figure 21.16** and **Figure 21.17** show the timing of operations in slave transmission.

The following describes the procedure and operations for slave transmission.

(1) Follow the procedure in **Figure 21.5** to make initial settings for the RIIC. This step is not necessary if initialization of the RIIC has already been completed. After initial settings, the RIIC automatically sets the BBSY and RIICnSR2.START flags to 1 and automatically clears the ST bit to 0 on detection of a start condition.

(2) After receiving a matching slave address, the RIIC sets one of the corresponding bits RIICnSR1.GCA, and AASy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and returns the value set in the RIICnMR3.ACKBT bit to the acknowledge bit on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 1, the RIIC automatically places itself in slave transmit mode by setting both the RIICnCR2.TRS bit and the RIICnSR2.TDRE flag to 1.

(3) After the RIICnSR2.TDRE flag is confirmed to be 1, write the data for transmission to the RIICnDRT register. At this time, if the RIIC receives no acknowledge from the master device (receives an NACK signal) while the RIICnFER.NACKE bit is 1, the RIIC suspends transfer of the next data.

(4) Wait until the RIICnSR2.TEND flag is set to 1 while the RIICnSR2.TDRE flag is 1, after the RIICnSR2.NACKF flag is set to 1 or the last byte for transmission is written to the RIICnDRT register. When the RIICnSR2.NACKF flag or the TEND flag is 1, the RIIC drives the SCL line low on the ninth falling edge of SCL clock.

(5) When the RIICnSR2.NACKF flag or the RIICnSR2.TEND flag is 1, dummy read RIICnDRR to complete the processing. This releases the SCL line.

(6) Upon detecting the stop condition, the RIIC automatically clears bits RIICnSR1.GCA, and AASy (y = 0 to 2), flags RIICnSR2.TDRE and TEND, and the RIICnCR2.TRS bit to 0, and enters slave receive mode. Furthermore, it automatically sets the RIICnSR2.STOP flag to 1.

(7) After checking that the RIICnSR2.STOP flag is 1, clear the RIICnSR2.NACKF and STOP flags to 0 for the next transfer operation.

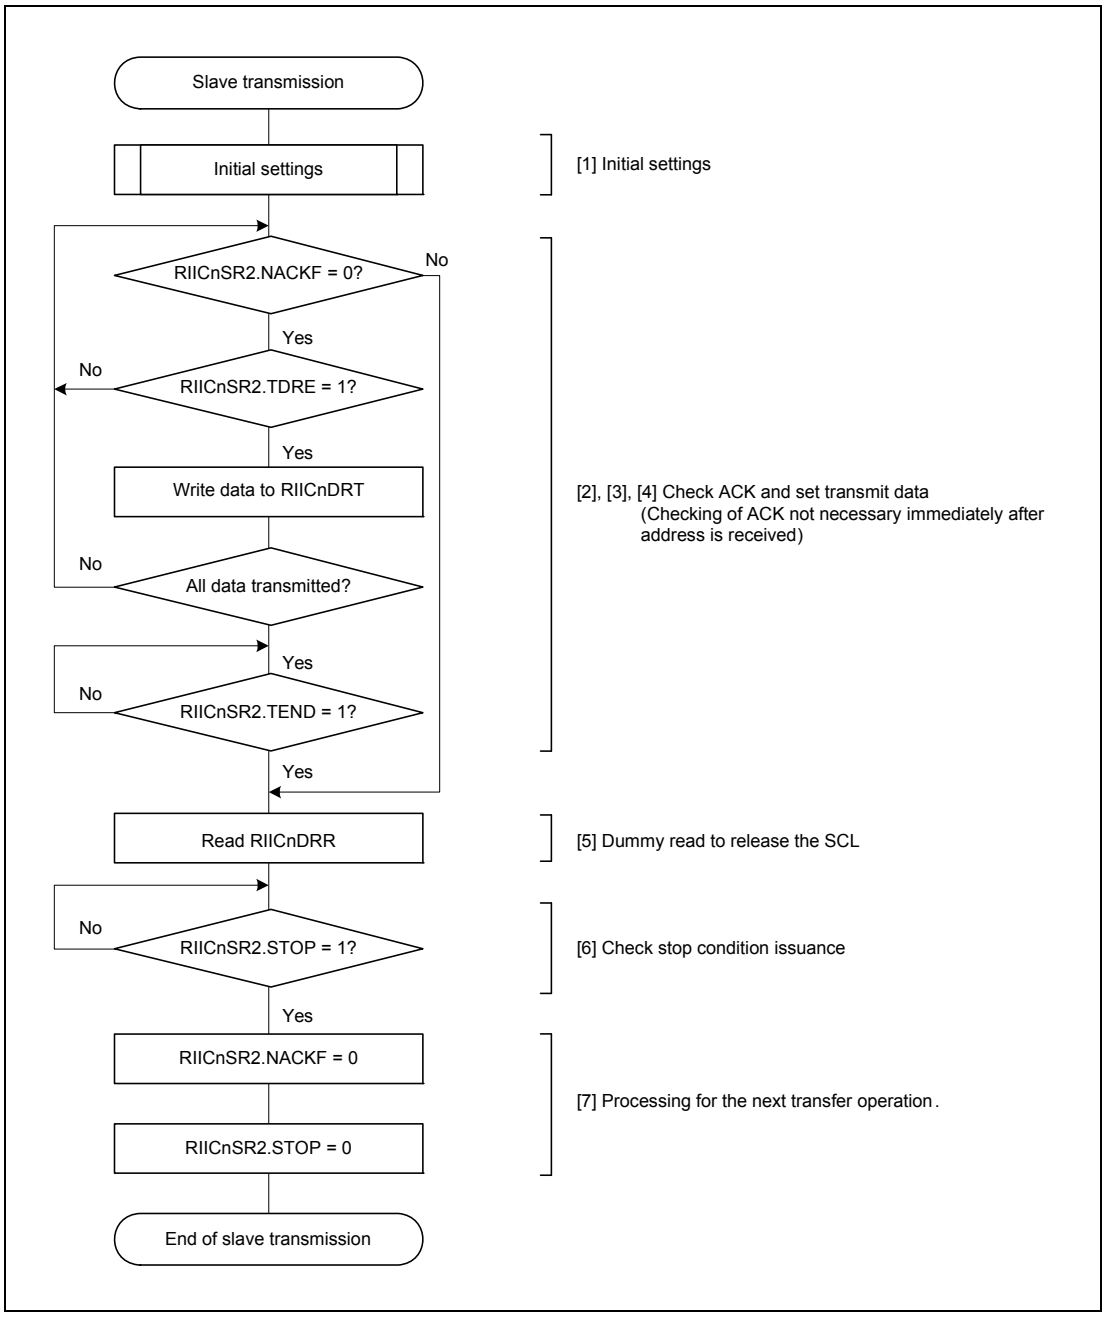

Figure 21.15 Example of Slave Transmission Flowchart

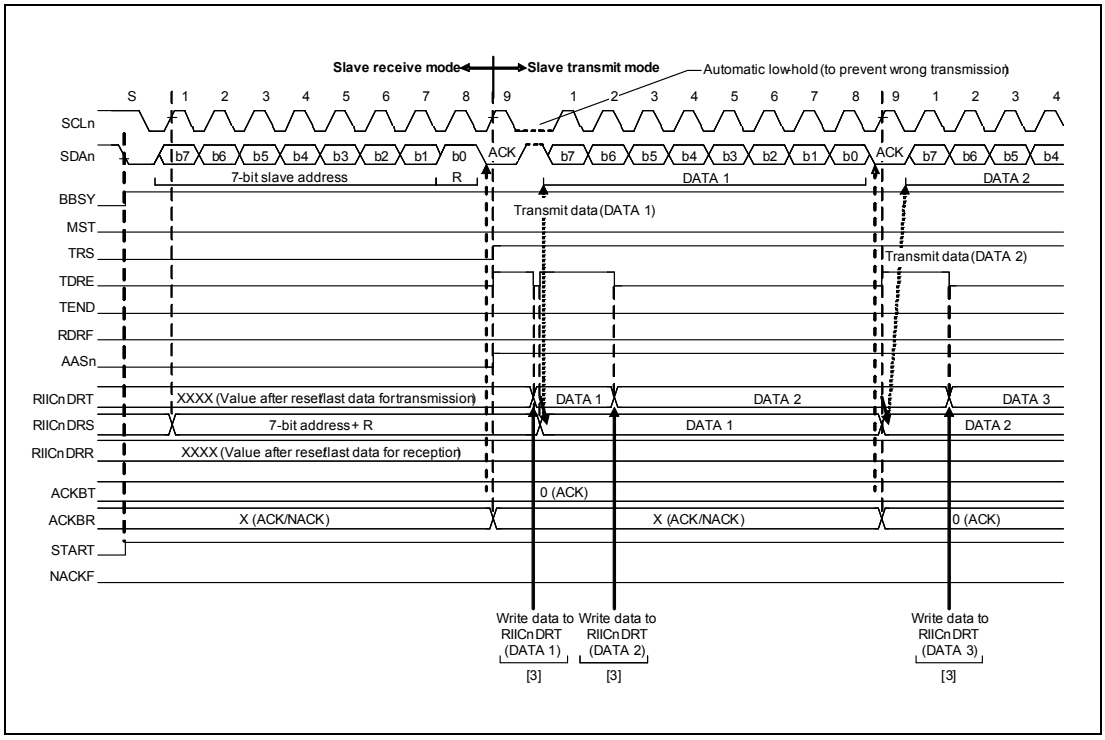

Figure 21.16 Slave Transmit Operation Timing (1) (7-Bit Address Format)

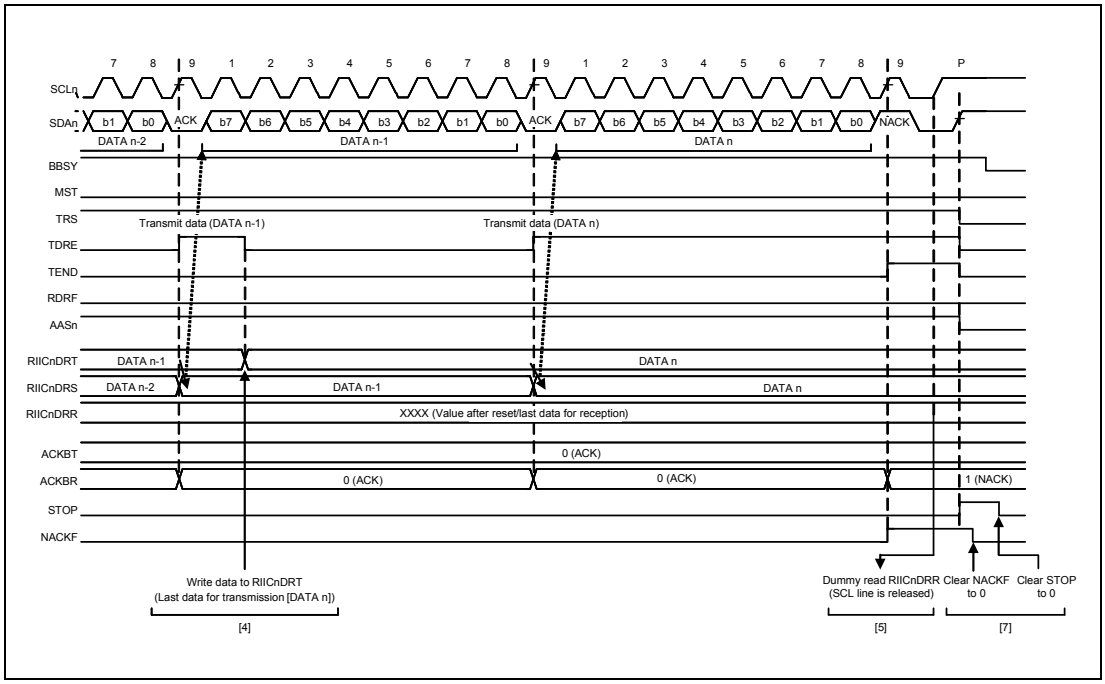

Figure 21.17 Slave Transmit Operation Timing (2)

21.5.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the RIIC returns acknowledgements as a slave device.

Figure 21.18 shows an example of usage of slave reception and **Figure 21.19** and **Figure 21.20** show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

(1) Follow the procedure in **Figure 21.5** to make initial settings for the RIIC. This step is not necessary if initialization of the RIIC has already been completed. After initial settings, the RIIC automatically sets the BBSY and RIICnSR2.START flags to 1 and automatically clears the ST bit to 0 on detection of a start condition.

(2) After receiving a matching slave address, the RIIC sets one of the corresponding bits RIICnSR1.GCA, and AASy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and returns the value set in the RIICnMR3.ACKBT bit to the acknowledge bit on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 0, the RIIC continues to place itself in slave receive mode and sets the RIICnSR2.RDRF flag to 1.

(3) After the RIICnSR2.STOP flag is confirmed to be 0 and the RIICnSR2.RDRF flag to be 1, dummy read RIICnDRR as the first read operation (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower eight bits when the 10-bit address format is selected).

(4) When RIICnDRR is read, the RIIC automatically clears the RIICnSR2.RDRF flag to 0. If reading of RIICnDRR is delayed and a next byte is received while the RDRF flag is still set to 1, the RIIC holds the SCL line low from one SCL cycle before the timing with which RDRF should be set. In this case, reading RIICnDRR releases the SCL line from being held at the low level.
When the RIICnSR2.STOP flag is 1 and the RIICnSR2.RDRF flag is also 1, read RIICnDRR until all the data is completely received.

(5) Upon detecting the stop condition, the RIIC automatically clears bits RIICnSR1.GCA, and AASy (y = 0 to 2) to 0. Furthermore, it automatically sets the RIICnSR2.STOP flag to 1.

(6) After checking that the RIICnSR2.STOP flag is 1, clear the RIICnSR2.STOP flag to 0 for the next transfer operation.

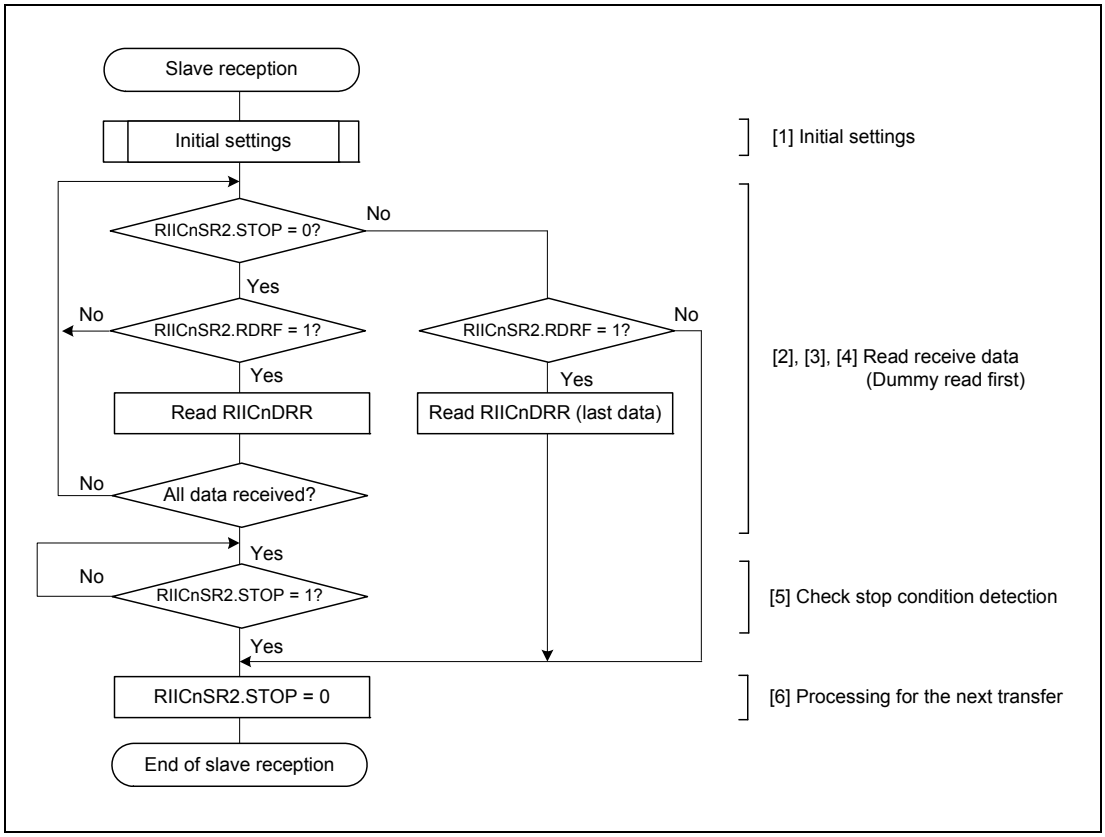

Figure 21.18 Example of Slave Reception Flowchart

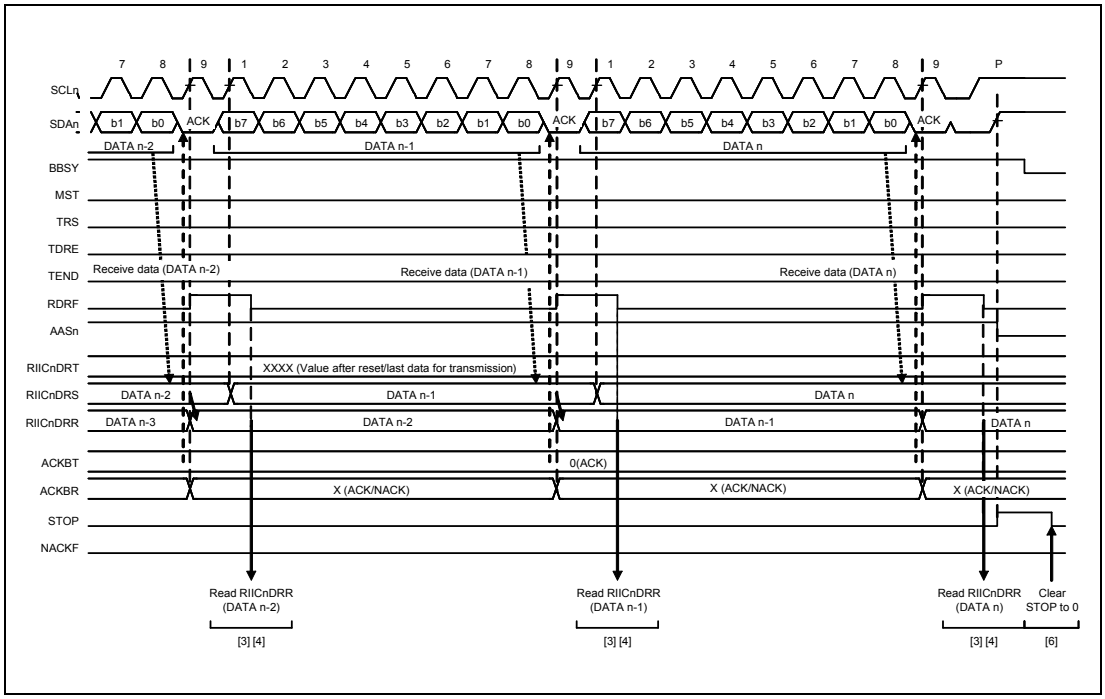

Figure 21.20 Slave Receive Operation Timing (2) (when RDRFS = 0)

21.6 SCL Synchronization Circuit

In generation of the SCL (clock) signal, the RIIC starts counting out the value for width at high level specified in RIICnBRH when it detects a rising edge on the SCL line and drives the SCL line low once counting of the width at high level is complete. When the RIIC detects the falling edge of the SCL line, it starts counting out the width at low level period specified in RIICnBRL, and then stops driving the SCL line (releases the line) once counting of the width at low level is complete. The SCL (clock) signal is thus generated.

If multiple master devices are connected to the I2C bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since this synchronization of SCL signals must be bit by bit, the RIIC is equipped with a facility (the SCL synchronization circuit) to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCL line during communication.

When the RIIC has detected a rising edge on the SCL line and thus started counting out the width at high level specified in RIICnBRH, and the level on the SCL line falls because an SCL signal is being generated by another master device, the RIIC stops counting when it detects the falling edge, drives the level on the SCL line low, and starts counting out the width at low level specified in RIICnBRL. When the RIIC finishes counting out the width at low level, it stops driving the SCL line to the low level (i.e. releases the line). At this time, if the width at low level of the SCL clock signal from the other master device is longer than the width at low level set in the RIIC, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the SCL line has been released. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the RIICnFER.SCLE bit is set to 1.

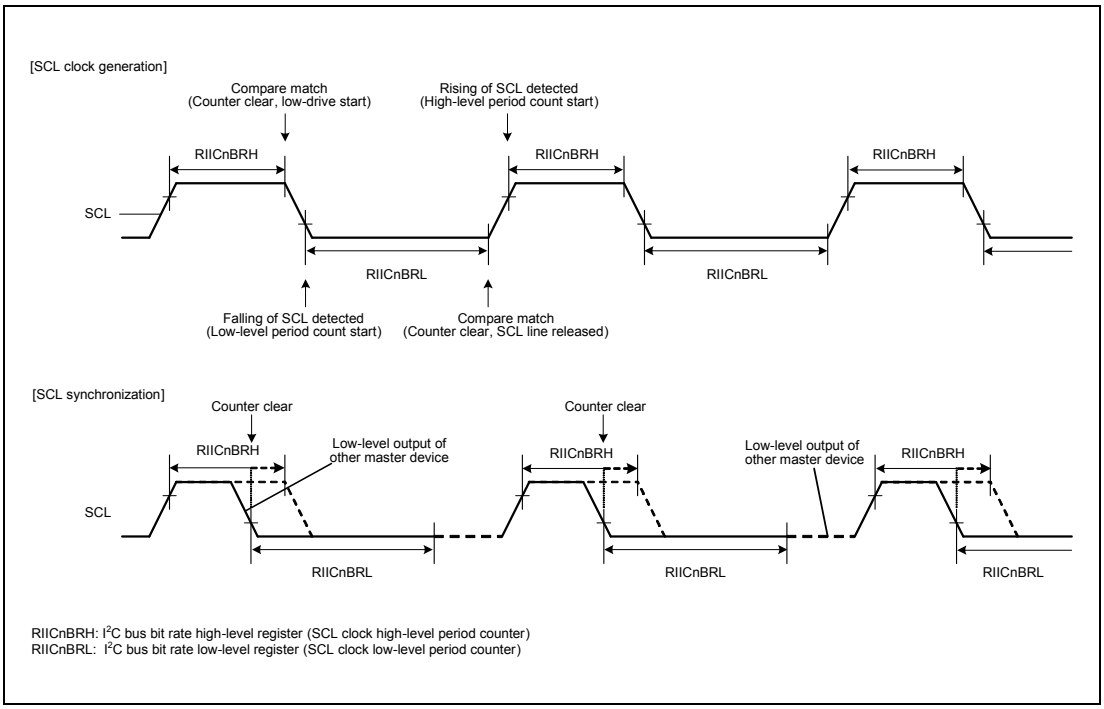

Figure 21.21 Generation and Synchronization of the SCL Signal from the RIIC

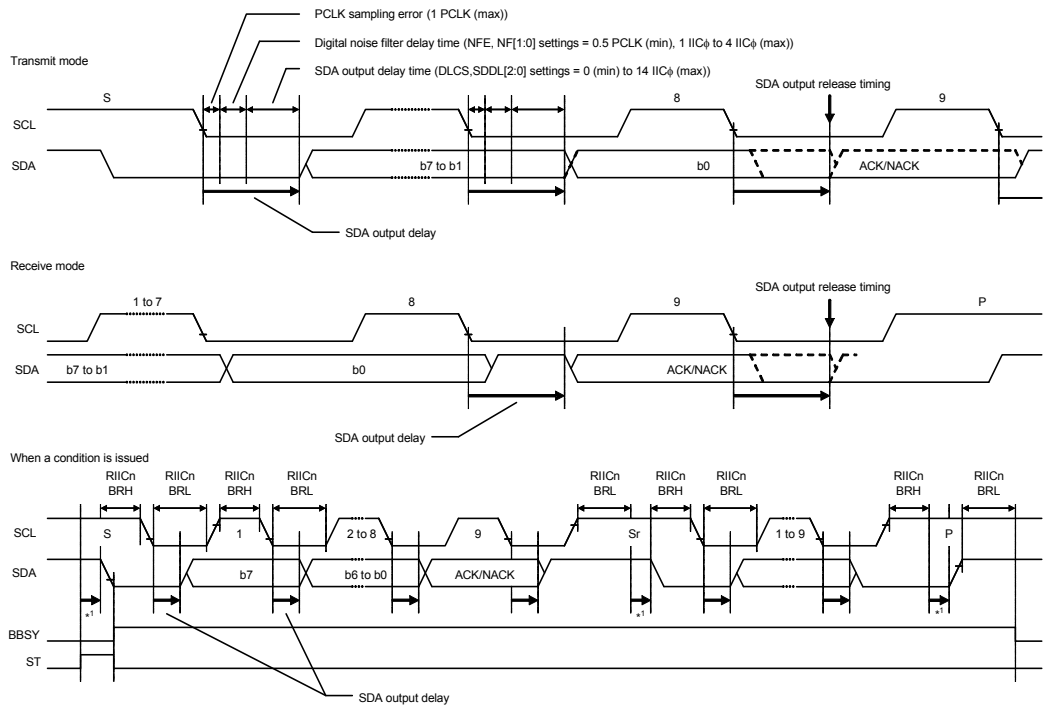
21.7 Facility for Delaying SDA Output

The RIIC module incorporates a facility for delaying output on the SDA line. The delay can be applied to all output (issuing of the start, restart, and stop conditions, data, and the ACK and NACK signals) on the SDA line.

With the SDA output delay facility, SDA output is delayed from detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval over which the SCL (clock) signal is at the low level. Doing this leads to usage with the aim of preventing erroneous operation of communications devices.

The output delay facility is enabled by setting the RIICnMR2.SDDL[2:0] bits to any value other than 000_B, and disabled by setting the same bits to 000_B.

While the SDA output delay facility is enabled (i.e. while the SDDL[2:0] bits are set to any value other than 000_B), the RIICnMR2.DLCS bit selects the clock source for counting by the SDA output delay counter as the internal base clock (IICϕ) for the RIIC module or as a clock signal derived by dividing the frequency of the internal base clock by two (IICϕ/2). The counter counts the number of cycles set in the SDDL[2:0] bits. After counting of the set number of cycles of delay is completed, the RIIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.



Note: The output delay facility is set by the SDDL[2:0] bits when a start (S), restart (Sr), or stop (P) condition is issued.

Figure 21.22 SDA Output Delay Facility

21.8 Digital Noise-Filter Circuits

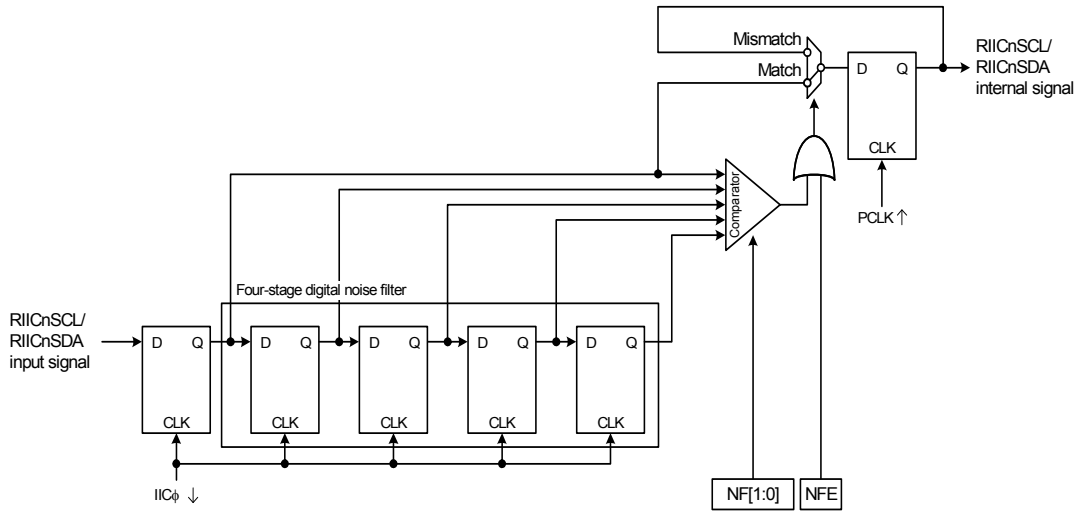
The states of the RIICnSCL and RIICnSDA pins are conveyed to the internal circuitry through the digital noise-filter circuit. **Figure 21.23** is a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of the RIIC consists of four flip-flop circuit stages connected in series and a match-detection circuit.

The number of effective stages in the digital noise filter is selected by the RIICnMR3.NF[1:0] bits. The selected number of effective stages determines the noise-filtering capability as a period from one to four IICϕ cycles.

The input signal to the RIICnSCL pin (or RIICnSDA pin) is sampled on falling edges of the IICϕ signal. When the input signal level matches the output level of the number of effective flip-flop circuit stages as selected by the RIICnMR3.NF[1:0] bits, the signal level is conveyed as an internal signal. If the signal levels do not match, the previous value is retained.

If the ratio between the frequency of the internal operating clock (PCLK) and the transfer rate is small, the characteristics of the digital noise filter may lead to the elimination of needed signals as noise. In such cases, it is possible to disable the digital noise-filter circuit (by clearing the RIICnFER.NFE bit to 0).



Note: NFE: Digital noise filter circuit enable bit
NF[1:0]: Digital noise filter stage selection bit

Figure 21.23 Block Diagram of Digital Noise Filter Circuit

21.9 Address Match Detection

The RIIC can set three unique slave addresses in addition to the general call address and device ID address, and also can set 7-bit or 10-bit slave addresses.

21.9.1 Slave-Address Match Detection

The RIIC can set three unique slave addresses, and has a slave address detection function for each unique slave address. When the RIICnSER.SARy bit (y = 0 to 2) is set to 1, the slave addresses set in RIICnSARy (y = 0 to 2) can be detected.

When the RIIC detects a match of the set slave address, the corresponding RIICnSR1.AASy flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL clock cycle and returns the value set in the RIICnMR3.ACKBT bit to the acknowledge bit on the ninth cycle of SCL clock. The RIICnSR2.RDRF flag or the RIICnSR2.TDRE flag is set to 1 by the following R/W# bit. This causes a receive complete interrupt (INTIICnRI) or transmit data empty interrupt (INTIICnTI) to be generated. The AASy flag is used to identify which slave address has been specified.

Figure 21.24 to **Figure 21.26** show the AASy flag set timing in three cases.

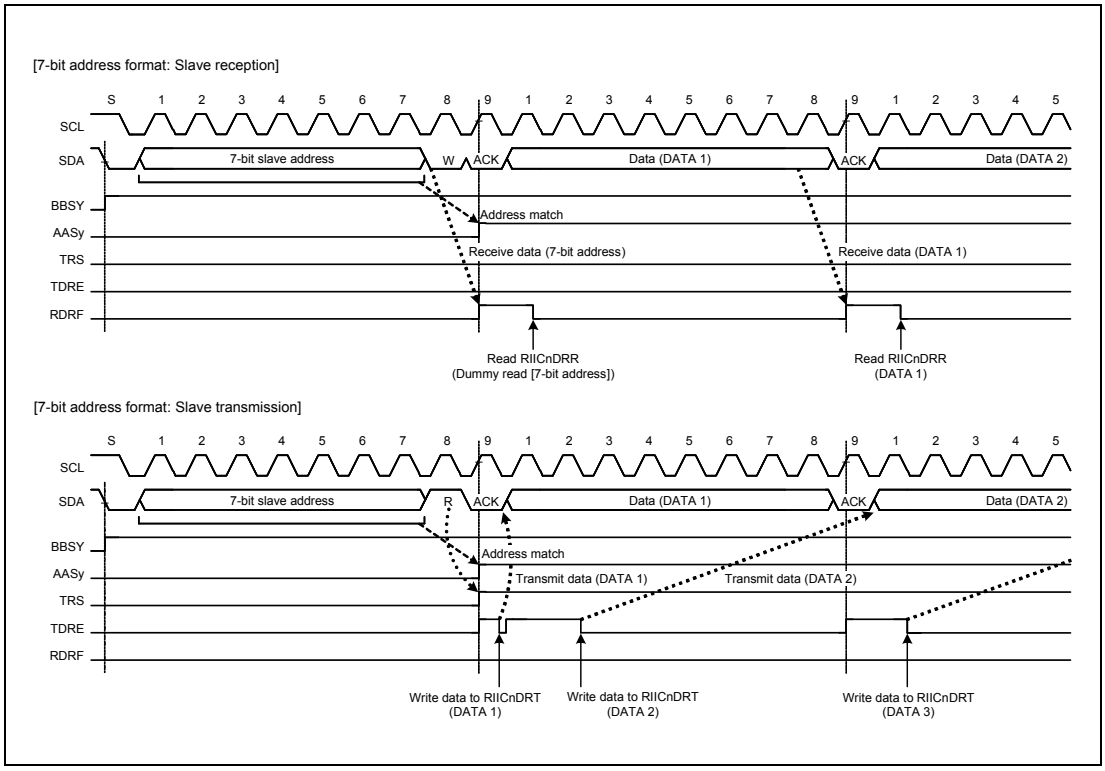


Figure 21.24 AASy Flag Set Timing with 7-Bit Address Format Selected

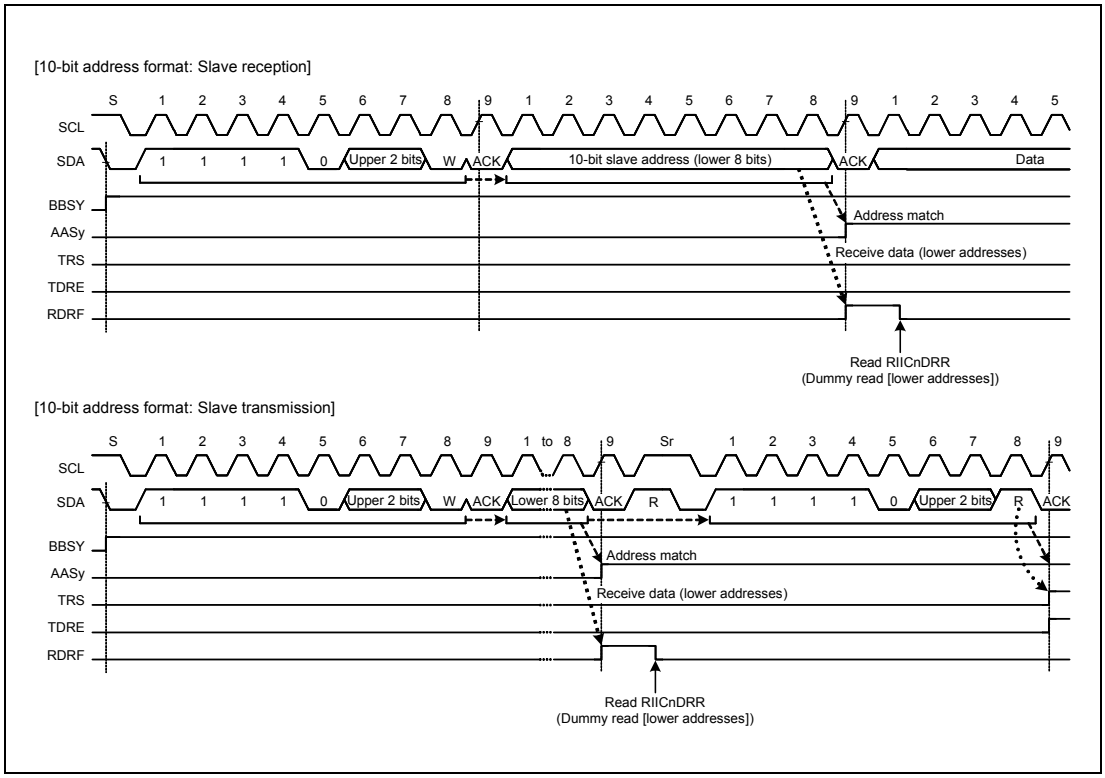

Figure 21.25 AASy Flag Set Timing with 10-Bit Address Format Selected

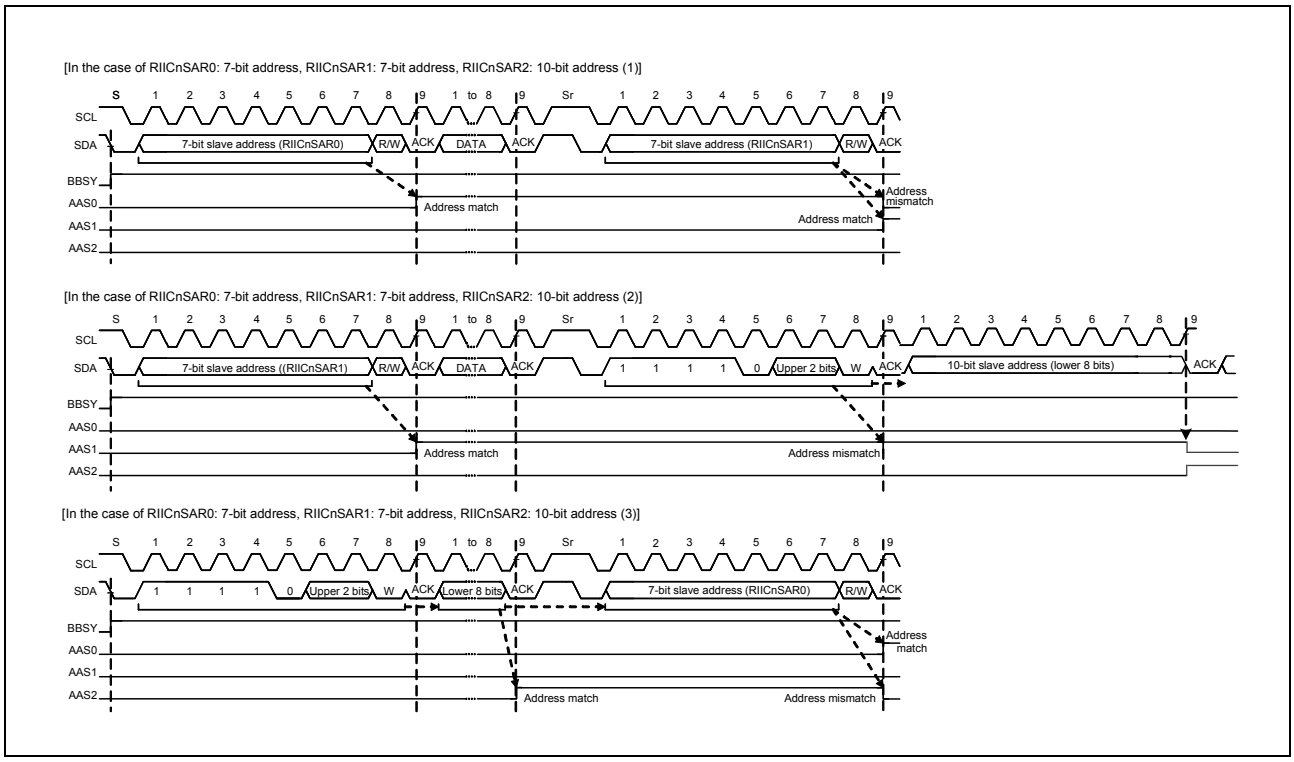

Figure 21.26 AASy Flag Set/Clear Timing with 7-Bit/10-Bit Address Formats Mixed

21.9.2 Detection of the General Call Address

The RIIC has a facility for detecting the general call address ($0000\ 000_B$ + 0 [W]). This is enabled by setting the RIICnSER.GCAE bit to 1.

If the address received after a start or restart condition is issued is 0000 000_B + 1[R] (start byte), the RIIC recognizes this as the address of a slave device with an “all-zero” address but not as the general call address.

When the RIIC detects the general call address, both the RIICnSR1.GCA flag and the RIICnSR2.RDRF flag are set to 1 on the rising edge of the ninth cycle of SCL clock. This leads to the generation of a receive complete interrupt (INTIICnRI). The value of the GCA flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

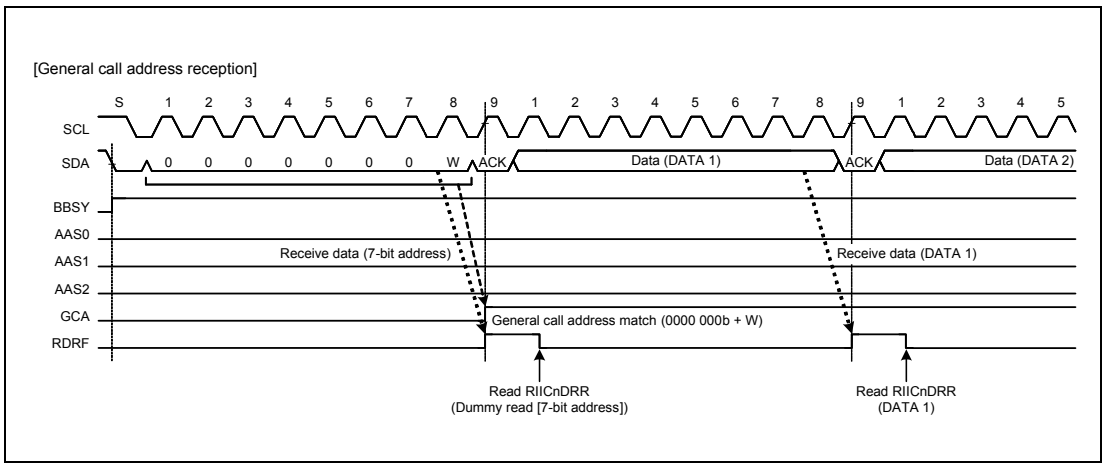

Figure 21.27 Timing of GCA Flag Setting during Reception of General Call Address

21.9.3 Device-ID Address Detection

The RIIC module has a facility for detecting device-ID addresses conforming with the I2C bus specification (Rev. 03). When the RIIC receives 1111 100_B as the first byte after a start condition or restart condition was issued with the RIICnSER.DIDE bit set to 1, the RIIC recognizes the address as a device ID, sets the RIICnSR1.DID flag to 1 on the rising edge of the ninth SCL clock cycle when the following R/W# bit is 0, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the RIIC sets the corresponding RIICnSR1.AASy flag (y = 0 to 2) to 1.

After that, when the first byte received after a start or restart condition is issued matches the device ID address (1111 100_B) again and the following R/W# bit is 1, the RIIC does not compare the second and subsequent bytes and sets the RIICnSR2.TDRE flag to 1.

In the device-ID address detection function, the RIIC clears the DID flag to 0 if a match with the RIIC’s own slave address is not obtained or a match with the device ID address is not obtained after a match with the RIIC’s own slave address and the detection of a restart condition. If the first byte after detection of a start or restart condition matches the device ID address (1111 100_B) and the R/W# bit is 0, the RIIC sets the DID flag to 1 and compares the second and subsequent bytes with the RIIC’s slave address. If the R/W# bit is 1, the DID flag holds the previous value and the RIIC does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DID flag after confirming that TDRE = 1.

Furthermore, prepare the device-ID fields (three bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details, see I2C Bus Standard from NXP Semiconductors.

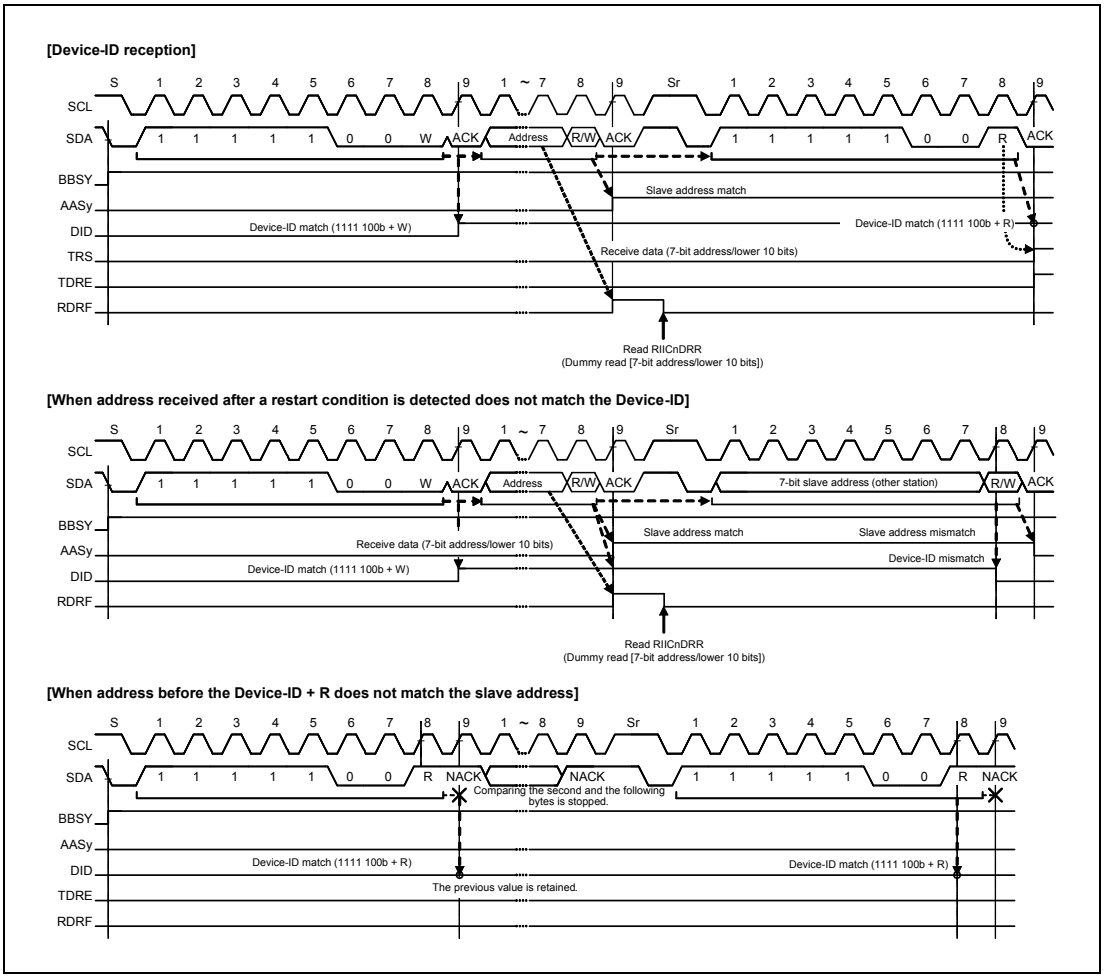

Figure 21.28 AASy/DID Flag Set/Clear Timing during Reception of Device-ID

21.10 Automatic Low-Hold Function for SCL

21.10.1 Function to Prevent Wrong Transmission of Transmit Data

If the shift register (RIICnDRS) is empty when data have not been written to the transmit data register (RIICnDRT) with the RIIC in transmission mode (RIICnCR2.TRS bit = 1), the SCL signal is automatically held at the low level over the intervals shown below. To prevent the unintended transmission of erroneous data, this low-hold period is extended until data for transmission have been written. In addition, the RIIC holds the SCL line low over the period until a stop condition is issued and also over the period until the RIICnDRR register is dummy read.

<Master transmit mode>

- Low-level interval after a start condition or restart condition is issued
- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next
- Low-level interval from the ninth clock cycle until a stop condition is issued

<Slave transmit mode>

- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next
- Low-level interval from the ninth clock cycle and the RIICnDRR register is dummy read

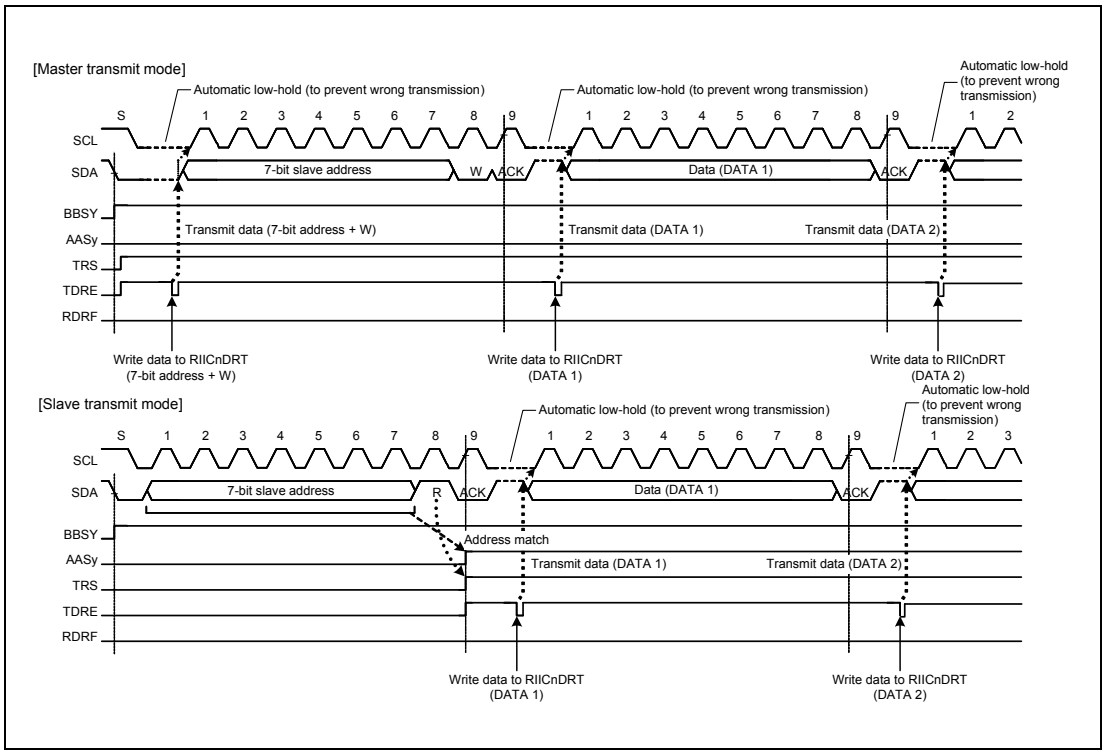

Figure 21.29 Automatic Low-Hold Operation in Transmit Mode

21.10.2 NACK Reception Transfer Suspension Function

The RIIC has a function to suspend transfer operation when NACK is received in transmit mode (RIICnCR2.TRS bit = 1). This function is enabled when the RIICnFER.NACKE bit is set to 1 (transfer suspension enabled). If the next transmit data has already been written (RIICnSR2.TDRE flag = 0) when NACK is received, next data transmission at the falling edge of the ninth SCL clock cycle is automatically suspended. This prevents the SDA line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (RIICnSR2.NACKF flag = 1), transmit operation and receive operation are discontinued. To restore transmit/receive operation, be sure to clear the NACKF flag to 0. In master transmit mode, clear the NACKF flag to 0, issue a restart or stop condition, and then issue a start condition again.

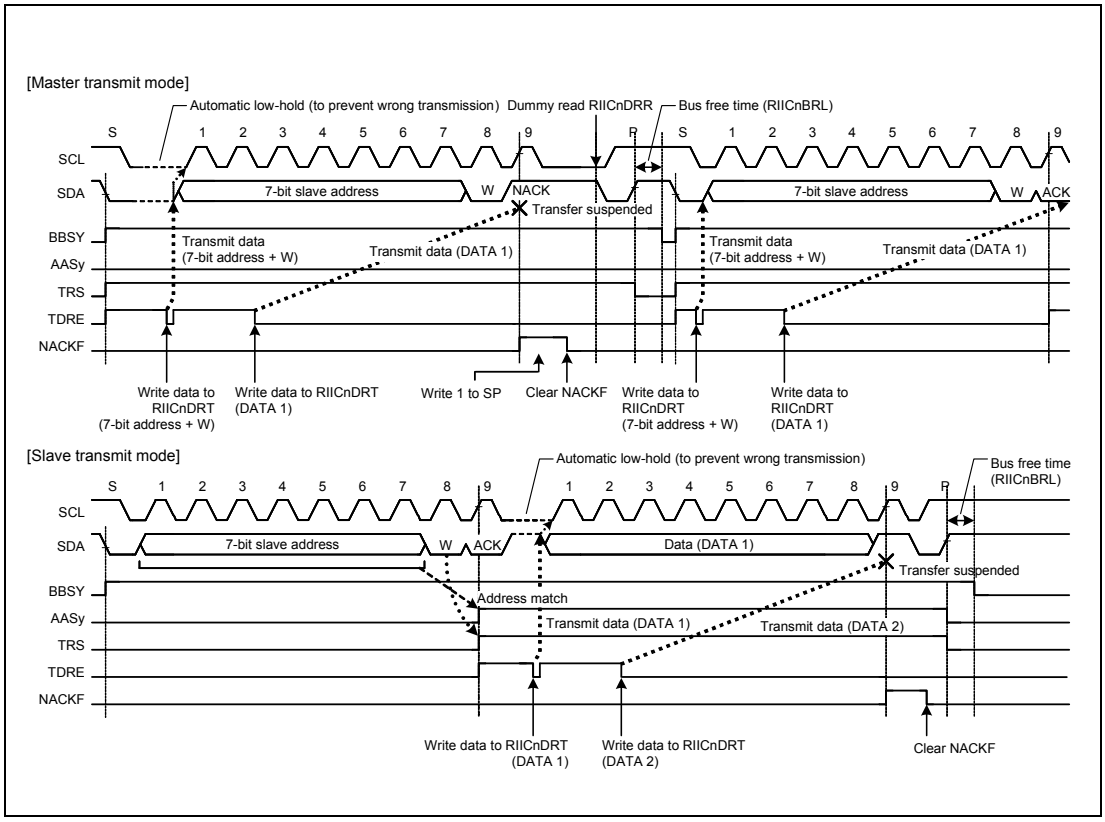

Figure 21.30 Suspension of Data Transfer when NACK is Received (NACKE = 1)

21.10.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (RIICnDRR) read is delayed for a period of one transfer frame or more with receive complete (RIICnSR2.RDRF flag = 1) in receive mode (RIICnCR2.TRS = 0), the RIIC holds the SCL line low automatically immediately before the next data is received to prevent failure to receive data.

This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, the RIIC's own slave address is designated after a stop condition is issued. This function does not disturb other communication because the RIIC does not hold the SCL line low when a mismatch with its own slave address occurs after a stop condition is issued.

Sections in which the SCL line is held low can be selected with a combination of the RIICnMR3.WAIT and RDRFS bits.

(1) One-Byte Receive Operation and Automatic Low-Hold Function Using the WAIT Bit

When the RIICnMR3.WAIT bit is set to 1, the RIIC performs one-byte receive operation using the WAIT bit function.
Furthermore, when the RIICnMR3.RDRFS bit is 0, the RIIC automatically sends the RIICnMR3.ACKBT bit value for the acknowledge bit in the period from the falling edge of the eighth SCL clock cycle to the falling edge of the ninth SCL clock cycle, and automatically holds the SCL line low at the falling edge of the ninth SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from RIICnDRR, which enables bytewise receive operation.

The WAIT bit function is enabled for receive frames after a match with the RIIC's own slave address (including the general call address and device ID address) is obtained in master receive mode or slave receive mode.

(2) One-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the RDRFS Bit

When the RIICnMR3.RDRFS bit is set to 1, the RIIC performs one-byte receive operation using the RDRFS bit function.
When the RIICnSR2.RDRFS bit is set to 1, the RDRF flag (receive complete) in RIICnSR2 is set to 1 at the rising edge of the eighth SCL clock cycle, and the SCL line is automatically held low at the falling edge of the eighth SCL clock cycle. This low-hold is released by writing a value to the RIICnMR3.ACKBT bit, but cannot be released by reading data from RIICnDRR, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.

The RDRFS bit function is enabled for receive frames after a match with the RIIC's own slave address (including the general call address and device ID address) is obtained in master receive mode or slave receive mode.

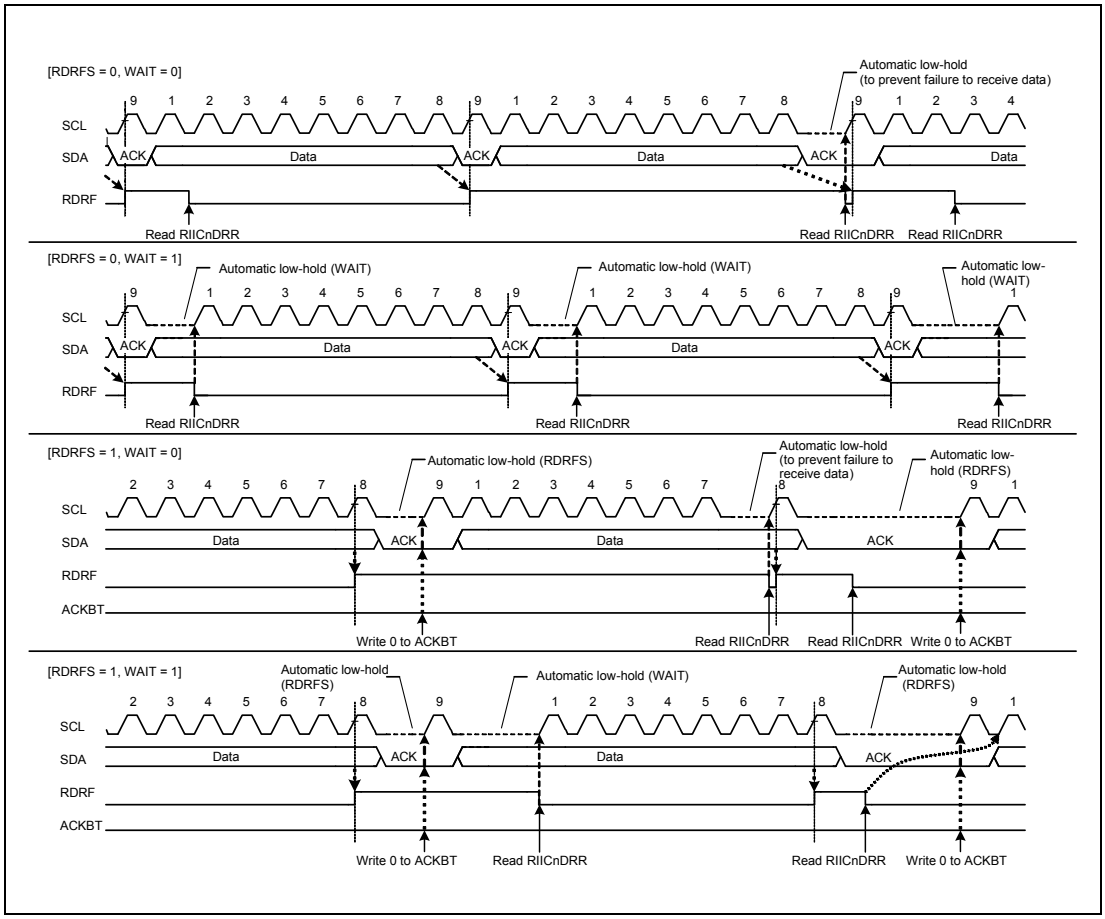

Figure 21.31 Automatic Low-Hold Operation in Receive Mode (Using RDRFS and WAIT Bits)

21.11 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I2C bus standard, the RIIC has functions to prevent double-issue of a start condition, to detect arbitration-lost during transmission of NACK, and to detect arbitration-lost in slave transmit mode.

21.11.1 Master Arbitration-Lost Detection (MALE Bit)

The RIIC drives the SDA line low to issue a start condition. However, if the SDA line has already been driven low by another master device issuing a start condition, the RIIC considers this a loss in arbitration, so priority is given to transfer by the other master device. Similarly, if the RIICnCR2.ST bit is set to 1 while the bus is busy (RIICnCR2.BBSY flag = 1), the RIIC considers itself to have lost in arbitration, so priority is given to transfer by the other master device and no start condition is generated.

When a start condition is issued successfully, if the data for transmission including the address bits (i.e. the internal SDA output level) and the level on the SDA line do not match (the high output as the internal SDA output; i.e. the SDA pin is in the high impedance state, and the low level is detected on the SDA line), the RIIC loses in arbitration.

After a loss in arbitration of mastership, the RIIC immediately enters slave receive mode. If a slave address (including the general call address) matches its own address at this time, the RIIC continues in slave operation.

A loss in arbitration of mastership is detected when the following conditions are met while the RIICnFER.MALE bit is 1 (master arbitration-lost detection enabled).

[Master arbitration-lost conditions]

- Non-matching of the internal level for output on SDA and the level on the SDA line after a start condition was issued by setting the RIICnCR2.ST bit to 1 while the RIICnCR2.BBSY flag was cleared to 0 (erroneous issuing of a start condition)
- Setting of the RIICnCR2.ST bit to 1 (start condition double-issue error) while the RIICnCR2.BBSY flag is set to 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDA line in master transmit mode (RIICnCR2.MST and TRS bits = 11_B)

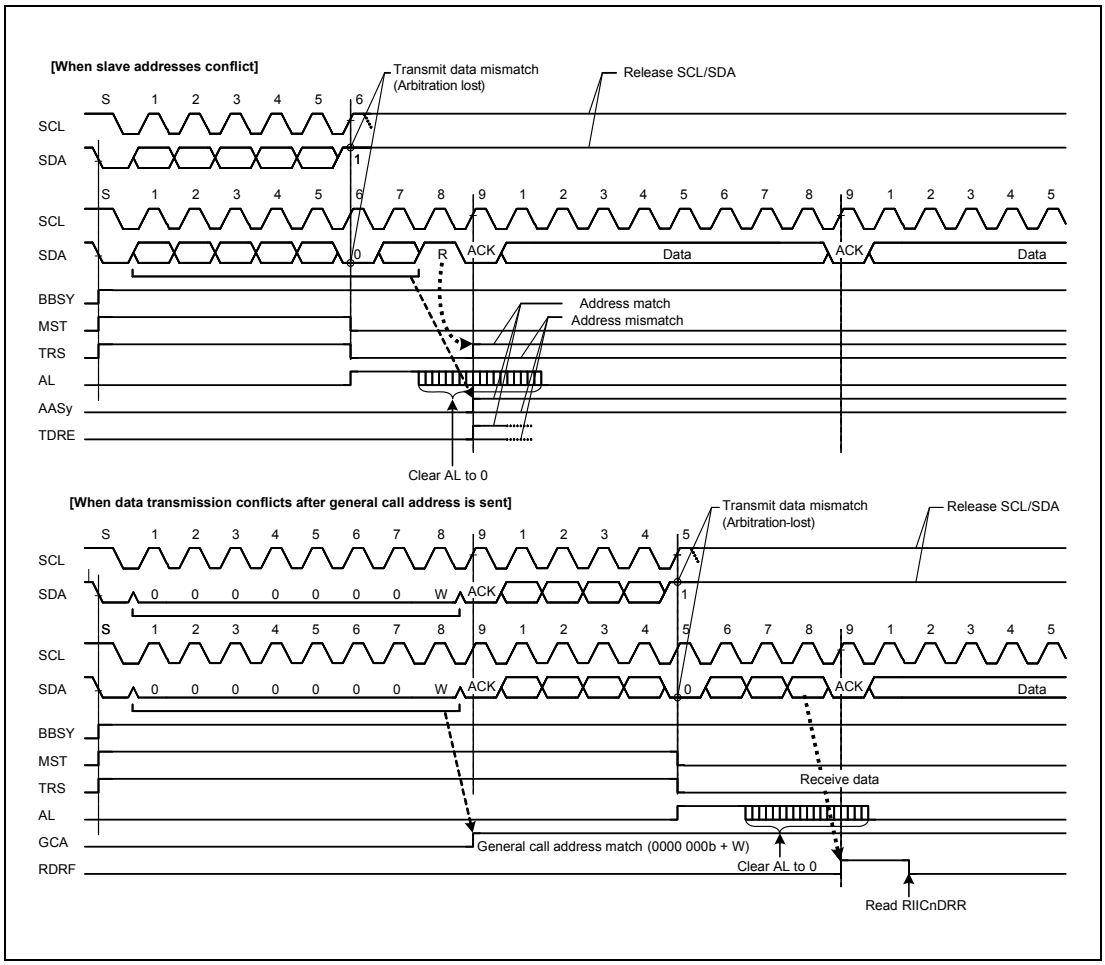

Figure 21.32 Examples of Master Arbitration-Lost Detection (MALE = 1)

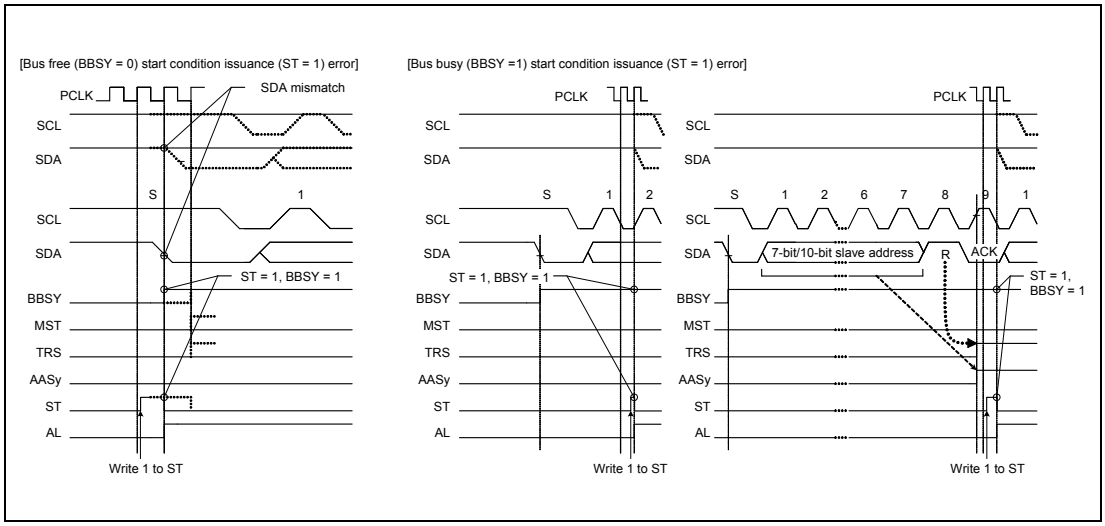

Figure 21.33 Arbitration-Lost when a Start Condition is Issued (MALE = 1)

The TRS bit is not cleared if 1 is written to the ST bit while the BBSY flag is 1 in slave transmit mode.

21.11.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit)

The RIIC has a function to cause arbitration to be lost if the internal SDA output level does not match the level on the SDA line (the high output as the internal SDA output; i.e. the SDA pin is in the high impedance state, and the low level is detected on the SDA line) during transmission of NACK in receive mode. Arbitration is lost due to a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send/receive the same information through a single slave device. **Figure 21.34** shows an example of arbitration-lost detection during transmission of NACK.

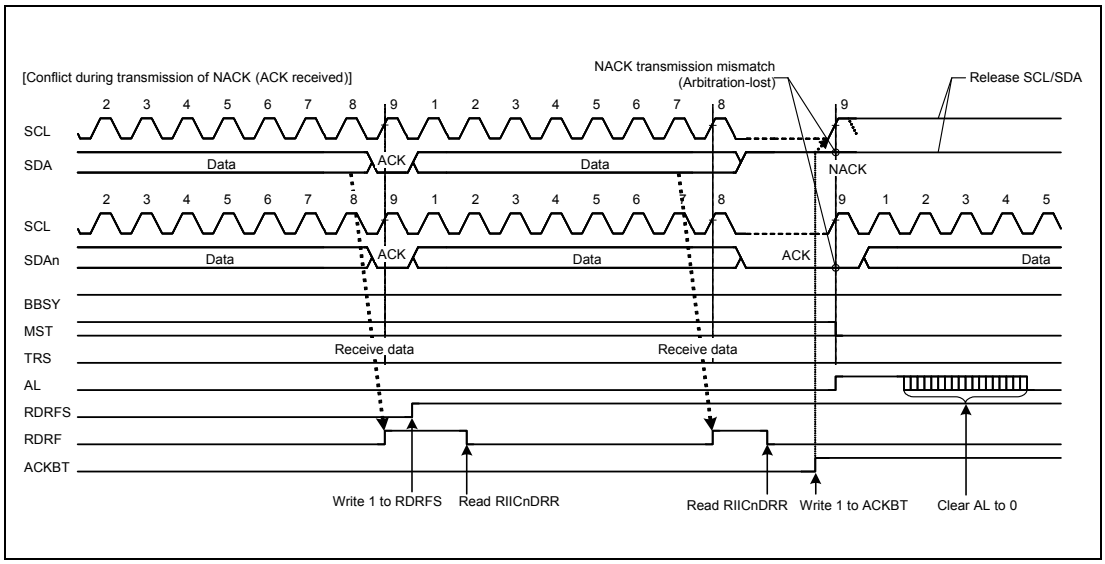

Figure 21.34 Example of Arbitration-Lost Detection during Transmission of NACK (NALE = 1)

The following explains arbitration-lost detection using an example where two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives two bytes of data from the slave device, and master B receives four bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in both master A and master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Here, master A sends NACK when it has received two final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received necessary four bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect ACK transmitted by master B and issues a stop condition.

Therefore, the issuance of the stop condition conflicts with the SCL clock output of master B, which disturbs communication.

When the RIIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost.

If arbitration is lost during transmission of NACK, the RIIC enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

The RIIC detects arbitration-lost during transmission of NACK when the following condition is met with the RIICnFER.NALE bit set to 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

When the internal SDA output level does not match the SDA line (ACK is received) during transmission of NACK (RIICnMR3.ACKBT bit = 1)

21.11.3 Slave Arbitration-Lost Detection (SALE Bit)

The RIIC has a function to cause arbitration to be lost if the data for transmission (i.e. the internal SDA output level) and the level on the SDA line do not match (the high output as the internal SDA output; i.e. the SDA pin is in the high impedance state, and the low level is detected on the SDA line) in slave transmit mode.

When it loses slave arbitration, the RIIC enters slave receive mode.

The RIIC detects slave arbitration-lost when the following condition is met with the RIICnFER.SALE bit set to 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

When transmit data excluding acknowledge (internal SDA output level) does not match the SDA line in slave transmit mode (RIICnCR2.MST and TRS bits = 01_B)

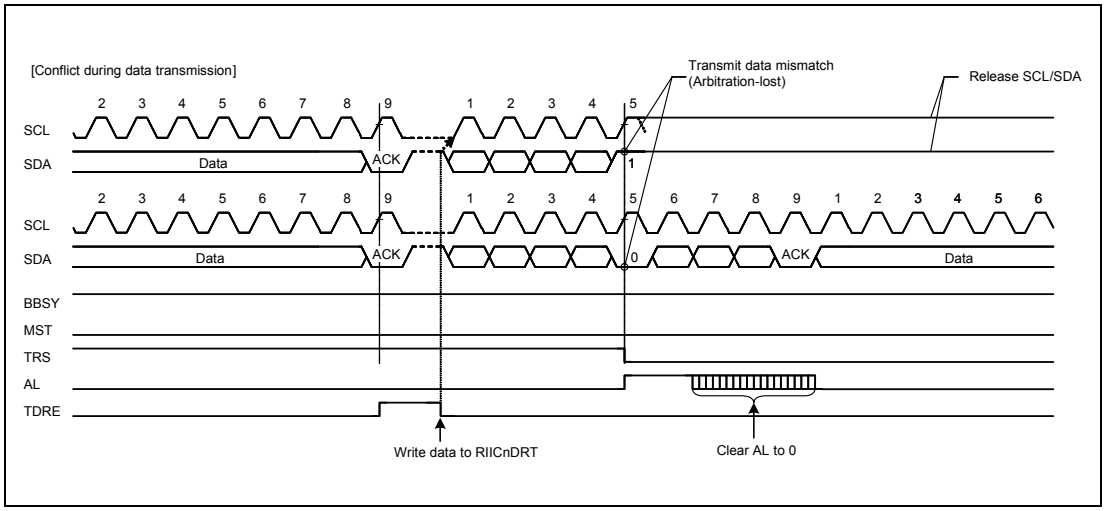

Figure 21.35 Example of Slave Arbitration-Lost Detection (SALE = 1)

21.12 Start Condition/Restart Condition/Stop Condition Issuing Function

21.12.1 Issuing a Start Condition

The RIIC issues a start condition when the RIICnCR2.ST bit is set to 1.

When the ST bit is set to 1, a start condition issuance request is made and the RIIC issues a start condition when the RIICnCR2.BBSY flag is 0 (bus free). When a start condition is issued normally, the RIIC automatically shifts to the master transmit mode.

A start condition is issued in the following sequence.

[Start condition issuance]

- Drive the SDA line low (high level to low level).
- Ensure the time set in RIICnBRH and the start condition hold time.
- Drive the SCL line low (high level to low level).
- Detect low level of the SCL line and ensure the low-level period of SCL line set in RIICnBRL.

21.12.2 Issuing a Restart Condition

The RIIC issues a restart condition when the RIICnCR2.RS bit is set to 1.

When the RS bit is set to 1, a restart condition issuance request is made even during communication and the RIIC issues a restart condition when the RIICnCR2.BBSY flag is 1 (bus busy) and the RIICnCR2.MST bit is 1 (master mode).

(To detect the issuance of a restart condition, clear the RIICnSR2.START flag before a restart condition is issued.)

A restart condition is issued in the following sequence.

[Restart condition issuance]

- Release the SDA line.
- Ensure the low-level period of SCL line set in RIICnBRL.
- Release the SCL line (low level to high level).
- Detect a high level of the SCL line and ensure the time set in RIICnBRL and the restart condition setup time.
- Drive the SDA line low (high level to low level).
- Ensure the time set in RIICnBRH and the restart condition hold time.
- Drive the SCL line low (high level to low level).
- Detect a low level of the SCL line and ensure the low-level period of SCL line set in RIICnBRL.

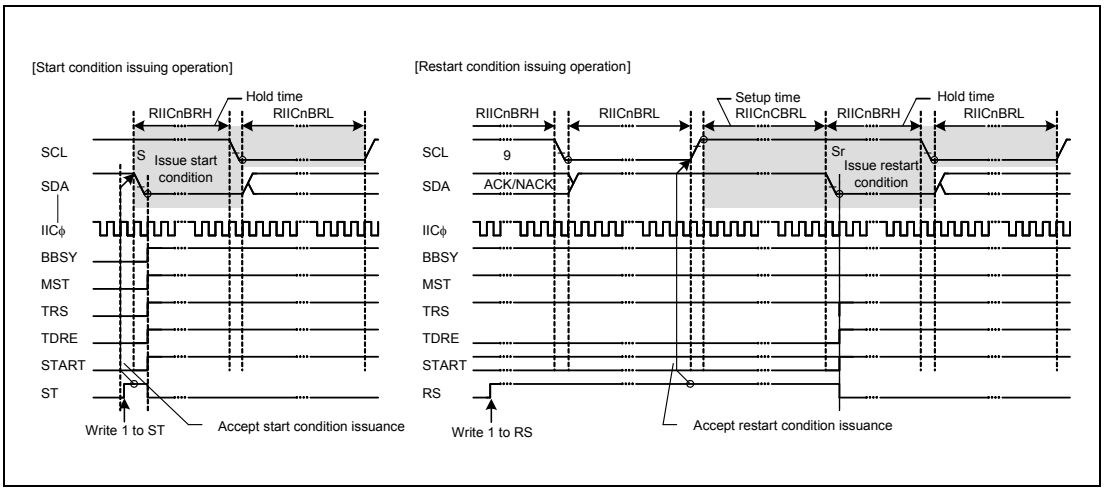

Figure 21.36 Start Condition/Restart Condition Issue Timing (ST and RS Bits)

21.12.3 Issuing a Stop Condition

The RIIC issues a stop condition when the RIICnCR2.SP bit is set to 1.

When the SP bit is set to 1, a stop condition issuance request is made and the RIIC issues a stop condition when the RIICnCR2.BBSY flag is 1 (bus busy) and the RIICnCR2.MST bit is 1 (master mode).

A stop condition is issued in the following sequence.

[Stop condition issuance]

- Drive the SDA line low (high level to low level).
- Ensure the low-level period of SCL line set in RIICnBRL.
- Release the SCL line (low level to high level).
- Detect a high level of the SCL line and ensure the time set in RIICnBRH and the stop condition setup time.
- Release the SDA line (low level to high level).
- Ensure the time set in RIICnBRL and the bus free time.
- Clear the BBSY flag to 0 (to release the bus mastership).

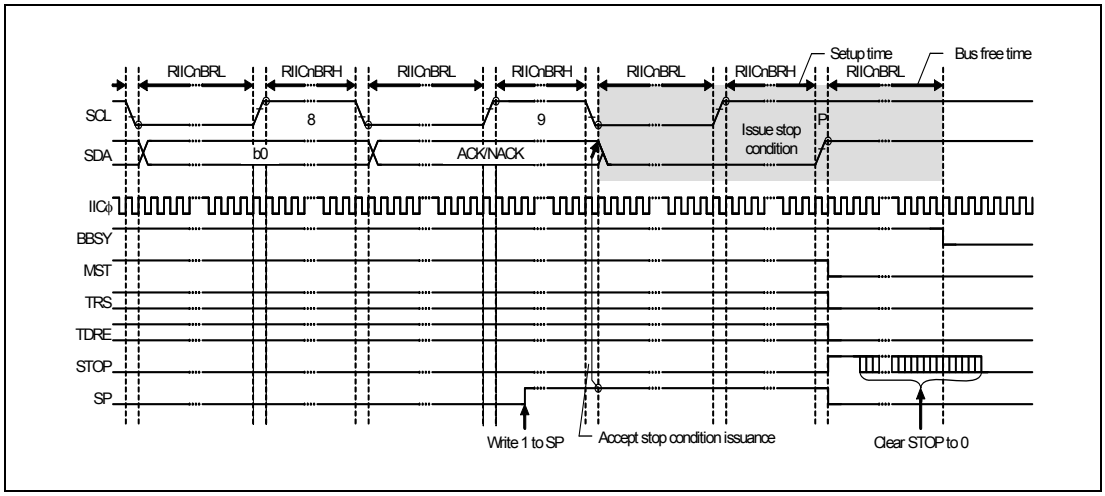

Figure 21.37 Stop Condition Issue Timing (SP Bit)

21.13 Bus Hanging

If the clock signals from the master and slave devices go out of synchronization due to noise or other factors, the I2C bus might hang with a fixed level on the SCL line and/or SDA line.

As measures against the bus hanging, the RIIC has a timeout function to detect hanging by monitoring the SCL line, a function for the output of an extra SCL clock cycle to release the bus from a hung state due to clock signals being out of synchronization, and the RIIC/internal reset function.

By checking the RIICnCR1.SCLO, SDAO, SCLI, and SDAI bits, it is possible to see whether the RIIC or its partner in communications is placing the low level on the SCL or SDA lines.

21.13.1 Timeout Function

The RIIC has the timeout function to detect an abnormality that the SCL line is held for a certain period of time. The RIIC can detect an abnormal bus state by monitoring that the SCL line is held low or high for a predetermined time.

The timeout function monitors the SCL line state and counts the low-level period or high-level period using the internal counter. The timeout function resets the internal counter each time the SCL line changes (rising or falling), but continues to count unless the SCL line changes. If the internal counter overflows due to no SCL line change, the RIIC can detect the timeout and report the bus abnormality.

The internal counter is cleared when one of the conditions is met.

(1) When RIICnMR2.TMOH=0, and RIICnMR2.TMOL=1:
The internal counter is cleared by SCL rising

(2) When RIICnMR2.TMOH=1, and RIICnMR2.TMOL=0:
The internal counter is cleared by SCL falling

(3) When RIICnMR2.TMOH=RIICnMR2.TMOL=1:
The internal counter is cleared by SCL rising or falling

This timeout function is enabled when the RIICnFER.TMOE bit is 1. It detects an abnormal bus state that the SCL line is stuck low or high during the following conditions:

- The bus is busy (RIICnCR2.BBSY flag is 1) in master mode (RIICnCR2.MST bit is 1).
- The RIIC's own slave address matches (RIICnSR1 register is not 00_H) and the bus is busy (RIICnCR2.BBSY flag is 1) in slave mode (RIICnCR2.MST bit is 0).
- The bus is free (RIICnCR2.BBSY flag is 0) while generation of a START condition is requested (RIICnCR2.ST bit is 1).

The internal counter of the timeout function works using the internal reference clock (IICϕ) set by the RIICnMR1.CKS[2:0] bits as a count source. It functions as a 16-bit counter when long mode is selected (RIICnMR2.TMOS bit = 0) or a 14-bit counter when short mode is selected (TMOS bit = 1).

The SCL line level (low/high or both levels) during which this counter is activated can be selected by the setting of the RIICnMR2.TMOH and TMOL bits. If both TMOL and TMOH bits are cleared to 0, the internal counter does not work.

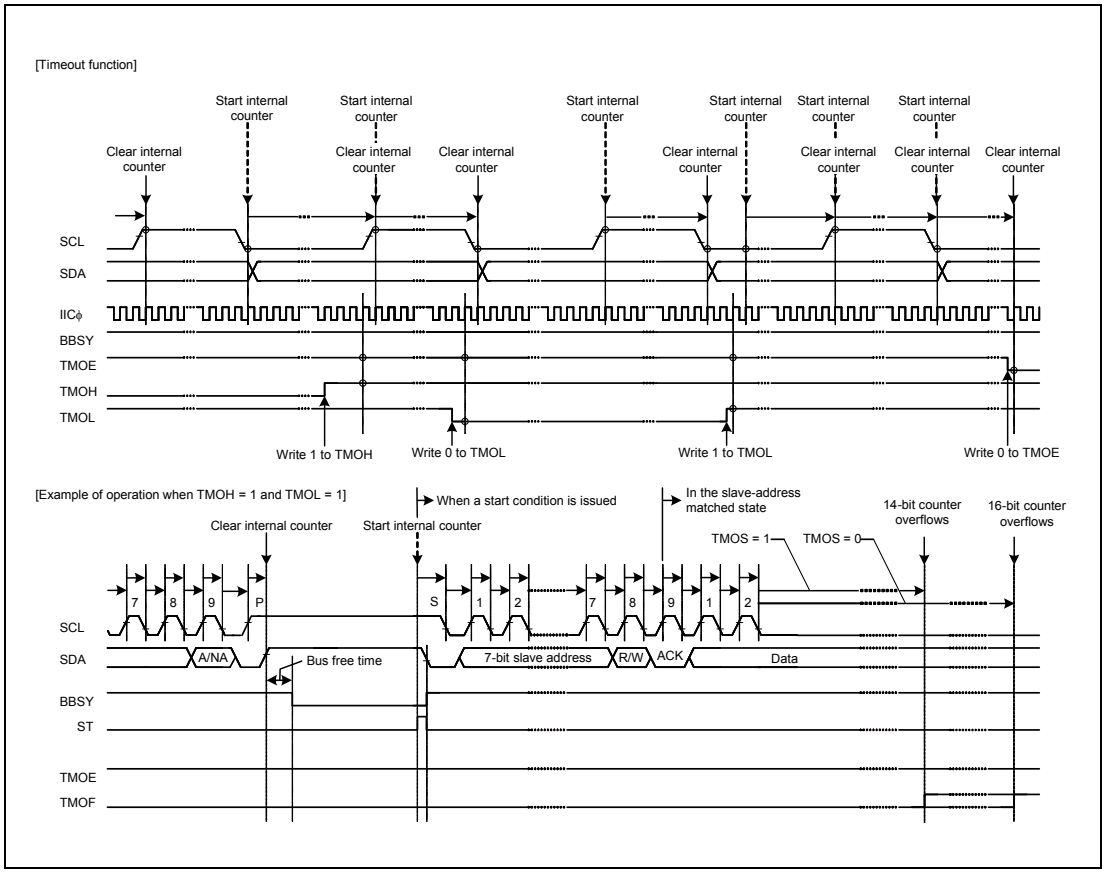

Figure 21.38 Timeout Function (TMOE, TMOS, TMOH, and TMOL Bits)

21.13.2 Extra SCL Clock Cycle Output Function

In master mode, the RIIC module has a facility for the output of extra SCL (clock) cycles to release the SDA line of the slave device from being held at the low level due to the master being out of synchronization with the slave device.

This function is mainly used in master mode to release the SDA line of the slave device from the state of being fixed to the low level by including extra cycles of SCL output from the RIIC with single cycles of the SCL (clock) signal as the unit in the case of a bus error where the RIIC cannot issue a stop condition because the slave device is holding the SDA line at the low level. Do not use this facility in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.

When the RIICnCR1.CLO bit is set to 1 in master mode, a single cycle of the SCL clock at the frequency corresponding to the transfer rate settings (settings of the RIICnMR1.CKS[2:0] bits, and of the RIICnBRH and RIICnBRL registers) is output as an extra clock cycle. After output of this single cycle of the SCL clock, the CLO bit is automatically cleared to 0. Therefore, further extra clock cycles can be output consecutively by the software program writing 1 to the CLO bit after having read CLO = 0.

When the RIIC module is in master mode and the slave device is holding the SDA line at the low level because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a stop condition is not possible. The facility for output of an extra cycle of the SCL (clock) signal can be used to output extra cycles of SCL one by one to make the slave device release the SDA line from being held at the low level, thus recovering the bus from an unusable state. Release of the SDA line by the slave device can be monitored by reading the RIICnCR1.SDAI bit. After confirming release of the SDA line by the slave device, complete communications by reissuing the stop condition.

Use this facility with the RIICnFER.MALE bit (master arbitration-lost detection disabled) cleared to 0. If the MALE bit is set to 1 (master arbitration-lost detection enabled), arbitration is lost when the value of the RIICnCR1.SDAO bit does not match the state of the SDA line, so take care on this point.

[Additional output conditions for the SCL clock]

- In master mode and when the bus is free
- In master mode and the SCL line is not held low (the bus is busy)

Figure 21.39 shows the operation timing of the extra SCL clock cycle output function (CLO bit).

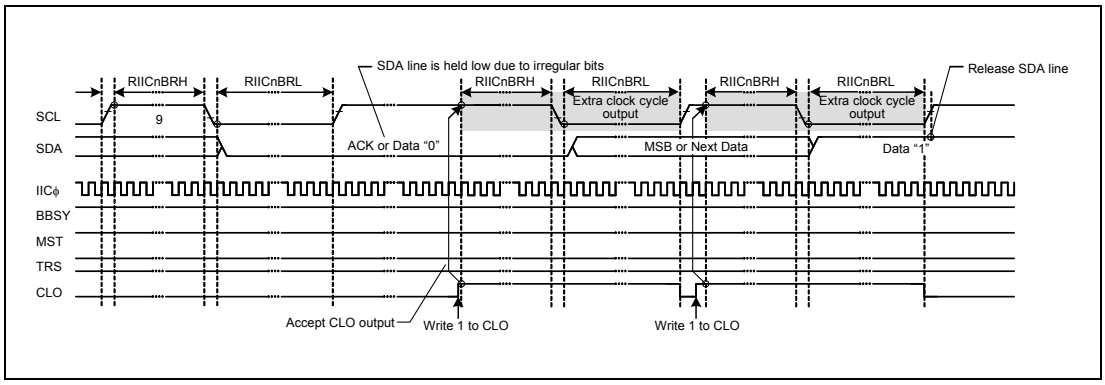

Figure 21.39 Extra SCL Clock Cycle Output Function (CLO Bit)

21.13.3 RIIC Reset and Internal Reset

The RIIC module incorporates a function for resetting itself. There are two types of reset. One is referred to as an RIIC reset; this initializes all registers including the RIICnCR2.BBSY flag. The other is referred to as an internal reset; this releases the RIIC from the slave-address matched state and initializes the internal counter while retaining other settings.

After issuing a reset, be sure to clear the RIICnCR1.IICRST bit to 0.

Both types of reset are effective for release from bus-hung states since both restore the output state of the SCL and SDA pins to the high impedance state.

Issuing a reset during slave operation may lead to a loss of synchronization between the master device clock and the slave device clock, so avoid this where possible. Note that monitoring of the bus state, such as for the presence of a start condition, is not possible during an RIIC reset (RIICnCR1.ICE and IICRST bits = 01_B).

For a detailed description of the RIIC and internal resets, see Section 21.14, Reset Function of RIIC.

21.14 Reset Function of RIIC

The RIIC has RIIC reset, and internal reset functions. In addition RIIC is cleared by ISORES. **Table 21.26** lists the scope of each reset and reset conditions.

Table 21.26 RIIC Reset Functions (1/2)

UM		SYSRES/ wake-up from DEEPSTOP mode	RIIC Reset (ICE = 0, IICRST = 1)	Internal Reset (ICE = 1, IICRST = 1)	Start/Restart Condition Detection	Stop Condition Detection

Note 1. When an internal reset is applied while the bus is free after detection of a stop condition, the setting of the BBSY flag is 0 while the bus is free following de-assertion of the internal reset signal.
When an internal reset is applied while the bus is not free, the BBSY flag is not cleared.

Section 22 CAN Interface (RSCAN)

This section contains a generic description of the CAN Interface (RSCAN).

The first part of this section describes all RH850/D1L/D1M specific properties, such as the number of units, register base addresses, etc. The remainder of the section describes the functions and registers of RSCAN.

22.1 Features of RH850/D1L/D1M RSCAN

22.1.1 Number of Units and Channels

This microcontroller has the following number of RSCAN units.

Table 22.1 Number of Units for D1L Devices

	D1L1		D1L2(H)	
Product Name	**R7F701401**	**R7F701421**	**R7F701402 R7F701403**	**R7F701422 R7F701423**
Number of Units	1	0	1	0

Table 22.5 Index

Index	Meaning
n	Throughout this section, the individual RSCAN units are generically indicated by the index “n” (n = 0); for example, RSCANnGCTR is the global control register of the RSCANn unit.
m	Throughout this section, the individual channels of RSCAN units are generically indicated by the index “m” (m = 0 to 2); for example, RSCAN0CmSTS is the channel m status register.
j	The individual registers associated with receive rule table are generically indicated by the index “j” (j = 0 to 15); for example, RSCAN0GAFLIDj is the receive rule ID register.
k	The individual transmit/receive FIFO buffers are generically indicated by the index “k” (k = 0 to 8); for example, RSCAN0CFCCk is the transmit/receive FIFO buffer configuration/control register.
x	The individual receive FIFO buffers in the RSCAN units are identified by the index “x” (x = 0 to 7): for example, RSCAN0RFSTSx is the receive FIFO buffer status register.
q	The individual receive buffers are generically indicated by the index “q” (q = 0 to 47); for example, RSCAN0RMIDq is the receive buffer ID register.
p	The individual transmit buffers are generically indicated by the index “p” (p = 0 to 47); for example, RSCAN0TMCp is the transmit buffer control register.
r	The individual RAM tests for CAN are generically indicated by the index “r” (r = 0 to 63); for example, RSCAN0RPGACCr is the RAM test page access register.
y	The registers not covered above are indicated by the index “y” (y = 0, 1); for example, RSCAN0RMNDy is a receive buffer new data register.

22.1.2 Register Base Address

RSCAN0 base addresses are listed in the following table.

RSCAN0 register addresses are given as offsets from the base addresses in general.

Table 22.6 Register Base Address

Base Address Name	Base Address
<RSCAN0_base>	$FFD0\ 0000_H$

22.1.3 Clock Supply

The RSCAN0 clock supply is shown in the following table.

Table 22.7 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
RSCAN0	clk_xincan	Clock Controller C_ISO_RSCANXIN
	clkc	Clock Controller C_ISO_RSCAN
	PCLK	Clock Controller RSCANPCLK

The operating frequency of the RSCAN0 depends on the transfer rate and the number of channels in use. **Table 22.8** shows the range of the frequency.

Table 22.8 Range of Operating Frequency Depending on the Transfer Rate and the Number of Channels in Use in the RH850/D1L/D1M

Condition		Range of Operating Frequency	
Transfer Rate	No. of Channels in Use	pclk	clkc/clk_xincan*[1]
1 Mbps	3ch	pclk ≥ 32MHz	8 MHz ≤ clk_xincan ≤ pclk/2
	2ch	pclk ≥ 26MHz	
	1ch	pclk ≥ 18MHz	
500 kbps	3ch	pclk ≥ 16MHz	4 MHz ≤ clk_xincan ≤ pclk/2
	2ch	pclk ≥ 13MHz	
	1ch	pclk ≥ 8MHz	
125 kbps	3ch	pclk ≥ 8MHz	4 MHz ≤ clk_xincan ≤ pclk/2
	2ch		
	1ch		

Note 1. Setting the DCS bit in RSCAN0GCFG enables to select either clk_xincan or clkc. Set clocks less than or equal to pclk/2.

22.1.4 Interrupt Request

RSCAN0 interrupt requests are listed in the following table.

Table 22.9 Interrupt Requests

Unit Interrupt Signal	Outline	Connected to
RSCAN0		
INTRCANGERR	CAN global error interrupt	Interrupt Controller INTRCANGERR
INTRCANGRECC	CAN receive FIFO interrupt	Interrupt Controller INTRCANGRECC
RSCAN0		
INTRCANmERR (m = 0)	CAN0 error interrupt	Interrupt Controller INTRCAN0ERR
INTRCANmREC (m = 0)	CAN0 transmit/receive FIFO receive completion interrupt	Interrupt Controller INTRCAN0REC
INTRCANmTRX (m = 0)	CAN0 transmit interrupt	Interrupt Controller INTRCAN0TRX
RSCAN0		
INTRCANmERR (m = 1)	CAN1 error interrupt	Interrupt Controller INTRCAN1ERR
INTRCANmREC (m = 1)	CAN1 transmit/receive FIFO receive completion interrupt	Interrupt Controller INTRCAN1REC
INTRCANmTRX (m = 1)	CAN1 transmit interrupt	Interrupt Controller INTRCAN1TRX
RSCAN0		
INTRCANmERR (m = 2)	CAN2 error interrupt	Interrupt Controller INTRCAN2ERR
INTRCANmREC (m = 2)	CAN2 transmit/receive FIFO receive completion interrupt	Interrupt Controller INTRCAN2REC
INTRCANmTRX (m = 2)	CAN2 transmit interrupt	Interrupt Controller INTRCAN2TRX

22.1.5 Reset Sources

RSCAN0 reset sources are listed in the following table. RSCAN0 is initialized by these reset sources.

Table 22.10 Reset Sources

Unit Name	Reset Source
RSCAN0	• Reset Controller SYSRES • reset upon wake-up from DEEPSTOP mode

22.1.6 External Input/Output Signals

External input/output signals of RSCAN0 are listed below.

Table 22.11 External Input/Output Signals

Unit Signal Name	Outline	Alternative Port Pin Signal
CAN0		
CANmRX (m = 0)	CAN0 receive data input	CAN0RX
CANmTX (m = 0)	CAN0 transmit data output	CAN0TX
CAN1		
CANmRX (m = 1)	CAN1 receive data input	CAN1RX
CANmTX (m = 1)	CAN1 transmit data output	CAN1TX
CAN2		
CANmRX (m = 2)	CAN2 receive data input	CAN2RX
CANmTX (m = 2)	CAN2 transmit data output	CAN2TX

22.2 Overview

22.2.1 Functional Overview

The RH850/D1L/D1M incorporates one unit of the CAN interface (RSCAN) which consists of three channels (CAN0 to CAN2) of the CAN controller conforming to the ISO11898-1 specifications. **Table 22.12** shows the RSCAN module specifications. **Figure 22.1** shows the RSCAN module block diagram.

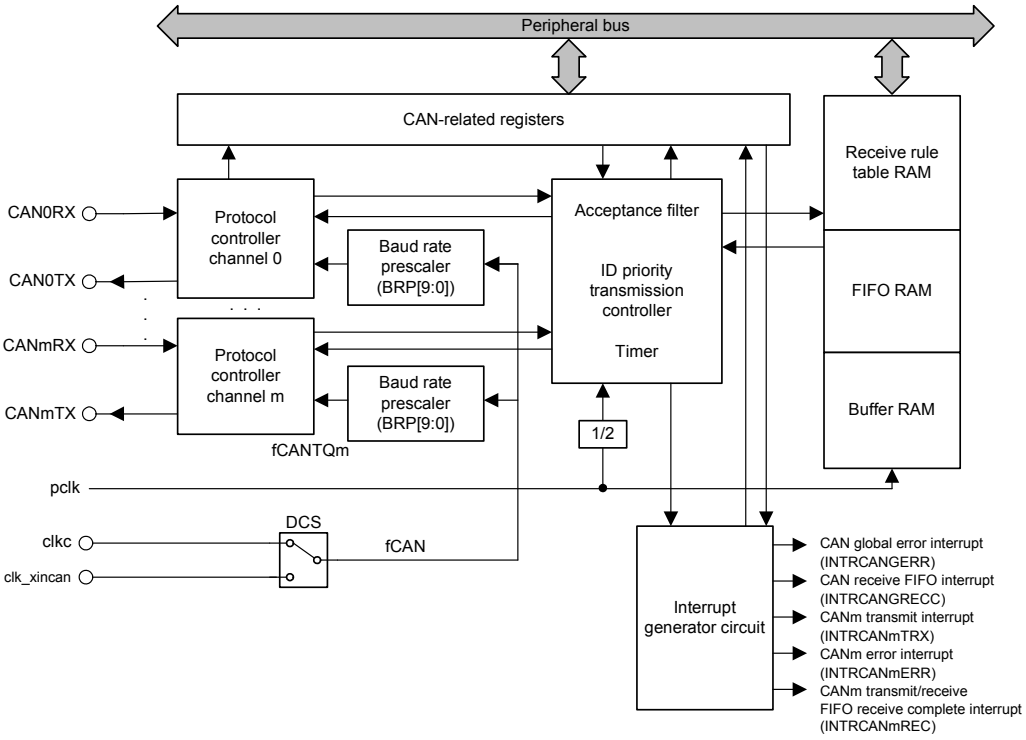
Table 22.12 RSCAN Module Specifications (1/2)

Item	Specification
Number of channels	3
Protocol	ISO11898-1 compliant
Communication speed	• Maximum 1 Mbps $\text{Commnucation speed (CANm bit time clock)} = \frac{1}{\text{CANm bit time}}$ CANm bit time = CANmTq × Tq count per bit $\text{CANmTq} = \frac{\text{(BRP[9:0] bits in the RSCAN0CmCFG register + 1)}}{\text{fCAN}}$ m = 0 to 2 Tq: Time quantum fCAN: Frequency of CAN clock (selected by the DCS bit in the RSCAN0GCFG register)
Buffer	240 buffers in total • Individual buffers: 48 buffers (16 buffers × 3 channels) Transmit buffer: 16 buffers per channel Transmit queue: Single queue per channel (shared with the transmit buffer; up to 16 buffers allocatable) • Shared buffers: 192 buffers for all channels Receive buffer: 48 buffers Receive FIFO buffer: 8 FIFO buffers (up to 128 buffers allocatable to each) Transmit/receive FIFO buffer: 3 FIFO buffers per channel (up to 128 buffers allocatable to each) • ECC included The 7-bit ECC value is calculated for each 32-bit transfer.
Reception function	• Receives data frames and remote frames. • Selects ID format (standard ID, extended ID, or both IDs) to be received. • Sets interrupt enable/disable for each FIFO. • Mirror function (reception of messages transmitted from the own CAN node) • Timestamp function (to record message reception time as a 16-bit timer value)
Reception filter function	• Selects receive messages according to 192 receive rules. • Sets the number of receive rules (0 to 127) for each channel. • Acceptance filter processing: Sets ID and mask for each receive rule. • DLC filter processing: Enables DLC filter check for each acceptance rule.
Receive message transfer function	• Routing function Transfers receive messages to arbitrary destinations (can be transferred to up to 8 buffers) Transfer destination: Receive buffer, receive FIFO buffer, and/or transmit/receive FIFO buffer • Label addition function Stores label information together with a message in a receive buffer and FIFO buffer.
Transmission function	• Transmits data frames and remote frames. • Selects ID format (standard ID, extended ID, or both IDs) to be transmitted. • Sets interrupt enable/disable for each transmit buffer and transmit/receive FIFO buffer. • Selects ID priority transmission or transmit buffer number priority transmission. • Transmit request can be aborted (possible to confirm with a flag) • One-shot transmission function

Table 22.12 RSCAN Module Specifications (2/2)

Item	Specification
Interval transmission function	Transmit messages at configurable intervals (transmit mode or gateway mode of transmit/receive FIFO buffers)
Transmit queue function	Transmits all stored messages according to the ID priority.
Transmit history function	Stores the history information of transmission-completed messages
Gateway function	Transmits a received message automatically.
Bus off recovery mode selection	Selects the method for returning from bus off state. • ISO11898-1 compliant • Automatic entry to channel halt mode at bus-off entry • Automatic entry to channel halt mode at bus-off end • Transition to channel halt mode by program request • Transition to the error-active state by program request (forcible return from the bus off state)
Error status monitoring	• Monitors CAN protocol errors (stuff error, form error, ACK error, CRC error, bit error, ACK delimiter error, and bus dominant lock). • Detects error status transitions (error warning, error passive, bus off entry, and bus off recovery) • Reads the error counter. • Monitors DLC errors.
Interrupt source	11 sources • Global Interrupts (2 sources) Receive FIFO interrupt Global error interrupt • Channel interrupts (3 sources/channel) CANm transmit interrupt (m = 0 to 2) – CANm transmit complete interrupt – CANm transmit abort interrupt – CANm transmit/receive FIFO transmit complete interrupt (in transmit mode, gateway mode) – CANm transmit history interrupt – CANm transmit queue interrupt CANm transmit/receive FIFO receive complete interrupt (in receive mode, gateway mode) CANm error interrupt
CAN stop mode	Reduces power consumption by stopping clock supply to the RSCAN module.
CAN clock source	Selects the clkc or the clk_xincan. As for the range of operating frequency, see **Table 22.8**.
Test function	Test function for user evaluation • Listen-only mode • Self-test mode 0 (external loopback) • Self-test mode 1 (internal loopback) • RAM test (read/write test) • Inter-channel communication test

22.2.2 Block Diagram



Note: m = 0 to 2
BRP[9:0]: Bits in the RSCAN0CmCFG register
DCS: Bits in the RSCAN0GCFG register
fCANTQm: CANmTq clock
fCAN: CAN clock

Figure 22.1 RSCAN Module Block Diagram

22.3 Registers

22.3.1 List of Registers

RSCAN registers are listed in the following table.

For details about <RSCAN0_base>, see Section 22.1.2, Register Base Address.

Table 22.13 Registers (1/19)

Module	Register	Symbol	Address
RSCAN0	Channel 0 configuration register	RSCAN0C0CFG	<RSCAN0_base> + 0000_H
RSCAN0	Channel 0 control register	RSCAN0C0CTR	<RSCAN0_base> + 0004_H
RSCAN0	Channel 0 status register	RSCAN0C0STS	<RSCAN0_base> + 0008_H
RSCAN0	Channel 0 error flag register	RSCAN0C0ERFL	<RSCAN0_base> + $000C_H$
RSCAN0	Channel 1 configuration register	RSCAN0C1CFG	<RSCAN0_base> + 0010_H
RSCAN0	Channel 1 control register	RSCAN0C1CTR	<RSCAN0_base> + 0014_H
RSCAN0	Channel 1 status register	RSCAN0C1STS	<RSCAN0_base> + 0018_H
RSCAN0	Channel 1 error flag register	RSCAN0C1ERFL	<RSCAN0_base> + $001C_H$
RSCAN0	Channel 2 configuration register	RSCAN0C2CFG	<RSCAN0_base> + 0020_H
RSCAN0	Channel 2 control register	RSCAN0C2CTR	<RSCAN0_base> + 0024_H
RSCAN0	Channel 2 status register	RSCAN0C2STS	<RSCAN0_base> + 0028_H
RSCAN0	Channel 2 error flag register	RSCAN0C2ERFL	<RSCAN0_base> + $002C_H$
RSCAN0	Global configuration register	RSCAN0GCFG	<RSCAN0_base> + 0084_H
RSCAN0	Global control register	RSCAN0GCTR	<RSCAN0_base> + 0088_H
RSCAN0	Global status register	RSCAN0GSTS	<RSCAN0_base> + $008C_H$
RSCAN0	Global error flag register	RSCAN0GERFL	<RSCAN0_base> + 0090_H
RSCAN0	Global timestamp counter register	RSCAN0GTSC	<RSCAN0_base> + 0094_H
RSCAN0	Receive rule entry control register	RSCAN0GAFLECTR	<RSCAN0_base> + 0098_H
RSCAN0	Receive rule configuration register 0	RSCAN0GAFLCFG0	<RSCAN0_base> + $009C_H$
RSCAN0	Receive buffer number register	RSCAN0RMNB	<RSCAN0_base> + $00A4_H$
RSCAN0	Receive buffer new data register 0	RSCAN0RMND0	<RSCAN0_base> + $00A8_H$
RSCAN0	Receive buffer new data register 1	RSCAN0RMND1	<RSCAN0_base> + $00AC_H$
RSCAN0	Receive FIFO buffer configuration and control register 0	RSCAN0RFCC0	<RSCAN0_base> + $00B8_H$
RSCAN0	Receive FIFO buffer configuration and control register 1	RSCAN0RFCC1	<RSCAN0_base> + $00BC_H$
RSCAN0	Receive FIFO buffer configuration and control register 2	RSCAN0RFCC2	<RSCAN0_base> + $00C0_H$
RSCAN0	Receive FIFO buffer configuration and control register 3	RSCAN0RFCC3	<RSCAN0_base> + $00C4_H$
RSCAN0	Receive FIFO buffer configuration and control register 4	RSCAN0RFCC4	<RSCAN0_base> + $00C8_H$
RSCAN0	Receive FIFO buffer configuration and control register 5	RSCAN0RFCC5	<RSCAN0_base> + $00CC_H$
RSCAN0	Receive FIFO buffer configuration and control register 6	RSCAN0RFCC6	<RSCAN0_base> + $00D0_H$
RSCAN0	Receive FIFO buffer configuration and control register 7	RSCAN0RFCC7	<RSCAN0_base> + $00D4_H$
RSCAN0	Receive FIFO buffer status register 0	RSCAN0RFSTS0	<RSCAN0_base> + $00D8_H$
RSCAN0	Receive FIFO buffer status register 1	RSCAN0RFSTS1	<RSCAN0_base> + $00DC_H$
RSCAN0	Receive FIFO buffer status register 2	RSCAN0RFSTS2	<RSCAN0_base> + $00E0_H$
RSCAN0	Receive FIFO buffer status register 3	RSCAN0RFSTS3	<RSCAN0_base> + $00E4_H$
RSCAN0	Receive FIFO buffer status register 4	RSCAN0RFSTS4	<RSCAN0_base> + $00E8_H$
RSCAN0	Receive FIFO buffer status register 5	RSCAN0RFSTS5	<RSCAN0_base> + $00EC_H$
RSCAN0	Receive FIFO buffer status register 6	RSCAN0RFSTS6	<RSCAN0_base> + $00F0_H$
RSCAN0	Receive FIFO buffer status register 7	RSCAN0RFSTS7	<RSCAN0_base> + $00F4_H$

Table 22.13 Registers (2/19)

Module	Register	Symbol	Address
RSCAN0	Receive FIFO buffer pointer control register 0	RSCAN0RFPCTR0	<RSCAN0_base> + $00F8_H$
RSCAN0	Receive FIFO buffer pointer control register 1	RSCAN0RFPCTR1	<RSCAN0_base> + $00FC_H$
RSCAN0	Receive FIFO buffer pointer control register 2	RSCAN0RFPCTR2	<RSCAN0_base> + 0100_H
RSCAN0	Receive FIFO buffer pointer control register 3	RSCAN0RFPCTR3	<RSCAN0_base> + 0104_H
RSCAN0	Receive FIFO buffer pointer control register 4	RSCAN0RFPCTR4	<RSCAN0_base> + 0108_H
RSCAN0	Receive FIFO buffer pointer control register 5	RSCAN0RFPCTR5	<RSCAN0_base> + $010C_H$
RSCAN0	Receive FIFO buffer pointer control register 6	RSCAN0RFPCTR6	<RSCAN0_base> + 0110_H
RSCAN0	Receive FIFO buffer pointer control register 7	RSCAN0RFPCTR7	<RSCAN0_base> + 0114_H
RSCAN0	Transmit/receive FIFO buffer configuration and control register 0	RSCAN0CFCC0	<RSCAN0_base> + 0118_H
RSCAN0	Transmit/receive FIFO buffer configuration and control register 1	RSCAN0CFCC1	<RSCAN0_base> + $011C_H$
RSCAN0	Transmit/receive FIFO buffer configuration and control register 2	RSCAN0CFCC2	<RSCAN0_base> + 0120_H
RSCAN0	Transmit/receive FIFO buffer configuration and control register 3	RSCAN0CFCC3	<RSCAN0_base> + 0124_H
RSCAN0	Transmit/receive FIFO buffer configuration and control register 4	RSCAN0CFCC4	<RSCAN0_base> + 0128_H
RSCAN0	Transmit/receive FIFO buffer configuration and control register 5	RSCAN0CFCC5	<RSCAN0_base> + $012C_H$
RSCAN0	Transmit/receive FIFO buffer configuration and control register 6	RSCAN0CFCC6	<RSCAN0_base> + 0130_H
RSCAN0	Transmit/receive FIFO buffer configuration and control register 7	RSCAN0CFCC7	<RSCAN0_base> + 0134_H
RSCAN0	Transmit/receive FIFO buffer configuration and control register 8	RSCAN0CFCC8	<RSCAN0_base> + 0138_H
RSCAN0	Transmit/receive FIFO buffer status register 0	RSCAN0CFSTS0	<RSCAN0_base> + 0178_H
RSCAN0	Transmit/receive FIFO buffer status register 1	RSCAN0CFSTS1	<RSCAN0_base> + $017C_H$
RSCAN0	Transmit/receive FIFO buffer status register 2	RSCAN0CFSTS2	<RSCAN0_base> + 0180_H
RSCAN0	Transmit/receive FIFO buffer status register 3	RSCAN0CFSTS3	<RSCAN0_base> + 0184_H
RSCAN0	Transmit/receive FIFO buffer status register 4	RSCAN0CFSTS4	<RSCAN0_base> + 0188_H
RSCAN0	Transmit/receive FIFO buffer status register 5	RSCAN0CFSTS5	<RSCAN0_base> + $018C_H$
RSCAN0	Transmit/receive FIFO buffer status register 6	RSCAN0CFSTS6	<RSCAN0_base> + 0190_H
RSCAN0	Transmit/receive FIFO buffer status register 7	RSCAN0CFSTS7	<RSCAN0_base> + 0194_H
RSCAN0	Transmit/receive FIFO buffer status register 8	RSCAN0CFSTS8	<RSCAN0_base> + 0198_H
RSCAN0	Transmit/receive FIFO buffer pointer control register 0	RSCAN0CFPCTR0	<RSCAN0_base> + $01D8_H$
RSCAN0	Transmit/receive FIFO buffer pointer control register 1	RSCAN0CFPCTR1	<RSCAN0_base> + $01DC_H$
RSCAN0	Transmit/receive FIFO buffer pointer control register 2	RSCAN0CFPCTR2	<RSCAN0_base> + $01E0_H$
RSCAN0	Transmit/receive FIFO buffer pointer control register 3	RSCAN0CFPCTR3	<RSCAN0_base> + $01E4_H$
RSCAN0	Transmit/receive FIFO buffer pointer control register 4	RSCAN0CFPCTR4	<RSCAN0_base> + $01E8_H$
RSCAN0	Transmit/receive FIFO buffer pointer control register 5	RSCAN0CFPCTR5	<RSCAN0_base> + $01EC_H$
RSCAN0	Transmit/receive FIFO buffer pointer control register 6	RSCAN0CFPCTR6	<RSCAN0_base> + $01F0_H$
RSCAN0	Transmit/receive FIFO buffer pointer control register 7	RSCAN0CFPCTR7	<RSCAN0_base> + $01F4_H$
RSCAN0	Transmit/receive FIFO buffer pointer control register 8	RSCAN0CFPCTR8	<RSCAN0_base> + $01F8_H$
RSCAN0	FIFO empty status register	RSCAN0FESTS	<RSCAN0_base> + 0238_H
RSCAN0	FIFO full status register	RSCAN0FFSTS	<RSCAN0_base> + $023C_H$
RSCAN0	FIFO Msg lost status register	RSCAN0FMSTS	<RSCAN0_base> + 0240_H
RSCAN0	Receive FIFO buffer interrupt flag status register	RSCAN0RFISTS	<RSCAN0_base> + 0244_H
RSCAN0	Transmit/receive FIFO buffer RX interrupt flag status register	RSCAN0CFRISTS	<RSCAN0_base> + 0248_H
RSCAN0	Transmit/receive FIFO buffer TX interrupt flag status register	RSCAN0CFTISTS	<RSCAN0_base> + $024C_H$
RSCAN0	Transmit buffer control register 0	RSCAN0TMC0	<RSCAN0_base> + 0250_H
RSCAN0	Transmit buffer control register 1	RSCAN0TMC1	<RSCAN0_base> + 0251_H
RSCAN0	Transmit buffer control register 2	RSCAN0TMC2	<RSCAN0_base> + 0252_H

Table 22.13 Registers (3/19)

Module	Register	Symbol	Address
RSCAN0	Transmit buffer control register 3	RSCAN0TMC3	<RSCAN0_base> + 0253_H
RSCAN0	Transmit buffer control register 4	RSCAN0TMC4	<RSCAN0_base> + 0254_H
RSCAN0	Transmit buffer control register 5	RSCAN0TMC5	<RSCAN0_base> + 0255_H
RSCAN0	Transmit buffer control register 6	RSCAN0TMC6	<RSCAN0_base> + 0256_H
RSCAN0	Transmit buffer control register 7	RSCAN0TMC7	<RSCAN0_base> + 0257_H
RSCAN0	Transmit buffer control register 8	RSCAN0TMC8	<RSCAN0_base> + 0258_H
RSCAN0	Transmit buffer control register 9	RSCAN0TMC9	<RSCAN0_base> + 0259_H
RSCAN0	Transmit buffer control register 10	RSCAN0TMC10	<RSCAN0_base> + $025A_H$
RSCAN0	Transmit buffer control register 11	RSCAN0TMC11	<RSCAN0_base> + $025B_H$
RSCAN0	Transmit buffer control register 12	RSCAN0TMC12	<RSCAN0_base> + $025C_H$
RSCAN0	Transmit buffer control register 13	RSCAN0TMC13	<RSCAN0_base> + $025D_H$
RSCAN0	Transmit buffer control register 14	RSCAN0TMC14	<RSCAN0_base> + $025E_H$
RSCAN0	Transmit buffer control register 15	RSCAN0TMC15	<RSCAN0_base> + $025F_H$
RSCAN0	Transmit buffer control register 16	RSCAN0TMC16	<RSCAN0_base> + 0260_H
RSCAN0	Transmit buffer control register 17	RSCAN0TMC17	<RSCAN0_base> + 0261_H
RSCAN0	Transmit buffer control register 18	RSCAN0TMC18	<RSCAN0_base> + 0262_H
RSCAN0	Transmit buffer control register 19	RSCAN0TMC19	<RSCAN0_base> + 0263_H
RSCAN0	Transmit buffer control register 20	RSCAN0TMC20	<RSCAN0_base> + 0264_H
RSCAN0	Transmit buffer control register 21	RSCAN0TMC21	<RSCAN0_base> + 0265_H
RSCAN0	Transmit buffer control register 22	RSCAN0TMC22	<RSCAN0_base> + 0266_H
RSCAN0	Transmit buffer control register 23	RSCAN0TMC23	<RSCAN0_base> + 0267_H
RSCAN0	Transmit buffer control register 24	RSCAN0TMC24	<RSCAN0_base> + 0268_H
RSCAN0	Transmit buffer control register 25	RSCAN0TMC25	<RSCAN0_base> + 0269_H
RSCAN0	Transmit buffer control register 26	RSCAN0TMC26	<RSCAN0_base> + $026A_H$
RSCAN0	Transmit buffer control register 27	RSCAN0TMC27	<RSCAN0_base> + $026B_H$
RSCAN0	Transmit buffer control register 28	RSCAN0TMC28	<RSCAN0_base> + $026C_H$
RSCAN0	Transmit buffer control register 29	RSCAN0TMC29	<RSCAN0_base> + $026D_H$
RSCAN0	Transmit buffer control register 30	RSCAN0TMC30	<RSCAN0_base> + $026E_H$
RSCAN0	Transmit buffer control register 31	RSCAN0TMC31	<RSCAN0_base> + $026F_H$
RSCAN0	Transmit buffer control register 32	RSCAN0TMC32	<RSCAN0_base> + 0270_H
RSCAN0	Transmit buffer control register 33	RSCAN0TMC33	<RSCAN0_base> + 0271_H
RSCAN0	Transmit buffer control register 34	RSCAN0TMC34	<RSCAN0_base> + 0272_H
RSCAN0	Transmit buffer control register 35	RSCAN0TMC35	<RSCAN0_base> + 0273_H
RSCAN0	Transmit buffer control register 36	RSCAN0TMC36	<RSCAN0_base> + 0274_H
RSCAN0	Transmit buffer control register 37	RSCAN0TMC37	<RSCAN0_base> + 0275_H
RSCAN0	Transmit buffer control register 38	RSCAN0TMC38	<RSCAN0_base> + 0276_H
RSCAN0	Transmit buffer control register 39	RSCAN0TMC39	<RSCAN0_base> + 0277_H
RSCAN0	Transmit buffer control register 40	RSCAN0TMC40	<RSCAN0_base> + 0278_H
RSCAN0	Transmit buffer control register 41	RSCAN0TMC41	<RSCAN0_base> + 0279_H
RSCAN0	Transmit buffer control register 42	RSCAN0TMC42	<RSCAN0_base> + $027A_H$
RSCAN0	Transmit buffer control register 43	RSCAN0TMC43	<RSCAN0_base> + $027B_H$
RSCAN0	Transmit buffer control register 44	RSCAN0TMC44	<RSCAN0_base> + $027C_H$
RSCAN0	Transmit buffer control register 45	RSCAN0TMC45	<RSCAN0_base> + $027D_H$
RSCAN0	Transmit buffer control register 46	RSCAN0TMC46	<RSCAN0_base> + $027E_H$

Table 22.13 Registers (4/19)

Module	Register	Symbol	Address
RSCAN0	Transmit buffer control register 47	RSCAN0TMC47	<RSCAN0_base> + $027F_H$
RSCAN0	Transmit buffer status register 0	RSCAN0TMSTS0	<RSCAN0_base> + $02D0_H$
RSCAN0	Transmit buffer status register 1	RSCAN0TMSTS1	<RSCAN0_base> + $02D1_H$
RSCAN0	Transmit buffer status register 2	RSCAN0TMSTS2	<RSCAN0_base> + $02D2_H$
RSCAN0	Transmit buffer status register 3	RSCAN0TMSTS3	<RSCAN0_base> + $02D3_H$
RSCAN0	Transmit buffer status register 4	RSCAN0TMSTS4	<RSCAN0_base> + $02D4_H$
RSCAN0	Transmit buffer status register 5	RSCAN0TMSTS5	<RSCAN0_base> + $02D5_H$
RSCAN0	Transmit buffer status register 6	RSCAN0TMSTS6	<RSCAN0_base> + $02D6_H$
RSCAN0	Transmit buffer status register 7	RSCAN0TMSTS7	<RSCAN0_base> + $02D7_H$
RSCAN0	Transmit buffer status register 8	RSCAN0TMSTS8	<RSCAN0_base> + $02D8_H$
RSCAN0	Transmit buffer status register 9	RSCAN0TMSTS9	<RSCAN0_base> + $02D9_H$
RSCAN0	Transmit buffer status register 10	RSCAN0TMSTS10	<RSCAN0_base> + $02DA_H$
RSCAN0	Transmit buffer status register 11	RSCAN0TMSTS11	<RSCAN0_base> + $02DB_H$
RSCAN0	Transmit buffer status register 12	RSCAN0TMSTS12	<RSCAN0_base> + $02DC_H$
RSCAN0	Transmit buffer status register 13	RSCAN0TMSTS13	<RSCAN0_base> + $02DD_H$
RSCAN0	Transmit buffer status register 14	RSCAN0TMSTS14	<RSCAN0_base> + $02DE_H$
RSCAN0	Transmit buffer status register 15	RSCAN0TMSTS15	<RSCAN0_base> + $02DF_H$
RSCAN0	Transmit buffer status register 16	RSCAN0TMSTS16	<RSCAN0_base> + $02E0_H$
RSCAN0	Transmit buffer status register 17	RSCAN0TMSTS17	<RSCAN0_base> + $02E1_H$
RSCAN0	Transmit buffer status register 18	RSCAN0TMSTS18	<RSCAN0_base> + $02E2_H$
RSCAN0	Transmit buffer status register 19	RSCAN0TMSTS19	<RSCAN0_base> + $02E3_H$
RSCAN0	Transmit buffer status register 20	RSCAN0TMSTS20	<RSCAN0_base> + $02E4_H$
RSCAN0	Transmit buffer status register 21	RSCAN0TMSTS21	<RSCAN0_base> + $02E5_H$
RSCAN0	Transmit buffer status register 22	RSCAN0TMSTS22	<RSCAN0_base> + $02E6_H$
RSCAN0	Transmit buffer status register 23	RSCAN0TMSTS23	<RSCAN0_base> + $02E7_H$
RSCAN0	Transmit buffer status register 24	RSCAN0TMSTS24	<RSCAN0_base> + $02E8_H$
RSCAN0	Transmit buffer status register 25	RSCAN0TMSTS25	<RSCAN0_base> + $02E9_H$
RSCAN0	Transmit buffer status register 26	RSCAN0TMSTS26	<RSCAN0_base> + $02EA_H$
RSCAN0	Transmit buffer status register 27	RSCAN0TMSTS27	<RSCAN0_base> + $02EB_H$
RSCAN0	Transmit buffer status register 28	RSCAN0TMSTS28	<RSCAN0_base> + $02EC_H$
RSCAN0	Transmit buffer status register 29	RSCAN0TMSTS29	<RSCAN0_base> + $02ED_H$
RSCAN0	Transmit buffer status register 30	RSCAN0TMSTS30	<RSCAN0_base> + $02EE_H$
RSCAN0	Transmit buffer status register 31	RSCAN0TMSTS31	<RSCAN0_base> + $02EF_H$
RSCAN0	Transmit buffer status register 32	RSCAN0TMSTS32	<RSCAN0_base> + $02F0_H$
RSCAN0	Transmit buffer status register 33	RSCAN0TMSTS33	<RSCAN0_base> + $02F1_H$
RSCAN0	Transmit buffer status register 34	RSCAN0TMSTS34	<RSCAN0_base> + $02F2_H$
RSCAN0	Transmit buffer status register 35	RSCAN0TMSTS35	<RSCAN0_base> + $02F3_H$
RSCAN0	Transmit buffer status register 36	RSCAN0TMSTS36	<RSCAN0_base> + $02F4_H$
RSCAN0	Transmit buffer status register 37	RSCAN0TMSTS37	<RSCAN0_base> + $02F5_H$
RSCAN0	Transmit buffer status register 38	RSCAN0TMSTS38	<RSCAN0_base> + $02F6_H$
RSCAN0	Transmit buffer status register 39	RSCAN0TMSTS39	<RSCAN0_base> + $02F7_H$
RSCAN0	Transmit buffer status register 40	RSCAN0TMSTS40	<RSCAN0_base> + $02F8_H$
RSCAN0	Transmit buffer status register 41	RSCAN0TMSTS41	<RSCAN0_base> + $02F9_H$
RSCAN0	Transmit buffer status register 42	RSCAN0TMSTS42	<RSCAN0_base> + $02FA_H$

Table 22.13 Registers (5/19)

Module	Register	Symbol	Address
RSCAN0	Transmit buffer status register 43	RSCAN0TMSTS43	<RSCAN0_base> + $02FB_H$
RSCAN0	Transmit buffer status register 44	RSCAN0TMSTS44	<RSCAN0_base> + $02FC_H$
RSCAN0	Transmit buffer status register 45	RSCAN0TMSTS45	<RSCAN0_base> + $02FD_H$
RSCAN0	Transmit buffer status register 46	RSCAN0TMSTS46	<RSCAN0_base> + $02FE_H$
RSCAN0	Transmit buffer status register 47	RSCAN0TMSTS47	<RSCAN0_base> + $02FF_H$
RSCAN0	Transmit buffer transmit request status register 0	RSCAN0TMTRSTS0	<RSCAN0_base> + 0350_H
RSCAN0	Transmit buffer transmit request status register 1	RSCAN0TMTRSTS1	<RSCAN0_base> + 0354_H
RSCAN0	Transmit buffer transmit abort request status register 0	RSCAN0TMTARSTS0	<RSCAN0_base> + 0360_H
RSCAN0	Transmit buffer transmit abort request status register 1	RSCAN0TMTARSTS1	<RSCAN0_base> + 0364_H
RSCAN0	Transmit buffer transmit complete status register 0	RSCAN0TMTCSTS0	<RSCAN0_base> + 0370_H
RSCAN0	Transmit buffer transmit complete status register 1	RSCAN0TMTCSTS1	<RSCAN0_base> + 0374_H
RSCAN0	Transmit buffer transmit abort status register 0	RSCAN0TMTASTS0	<RSCAN0_base> + 0380_H
RSCAN0	Transmit buffer transmit abort status register 1	RSCAN0TMTASTS1	<RSCAN0_base> + 0384_H
RSCAN0	Transmit buffer interrupt enable configuration register 0	RSCAN0TMIEC0	<RSCAN0_base> + 0390_H
RSCAN0	Transmit buffer interrupt enable configuration register 1	RSCAN0TMIEC1	<RSCAN0_base> + 0394_H
RSCAN0	Transmit queue configuration and control register 0	RSCAN0TXQCC0	<RSCAN0_base> + $03A0_H$
RSCAN0	Transmit queue configuration and control register 1	RSCAN0TXQCC1	<RSCAN0_base> + $03A4_H$
RSCAN0	Transmit queue configuration and control register 2	RSCAN0TXQCC2	<RSCAN0_base> + $03A8_H$
RSCAN0	Transmit queue status register 0	RSCAN0TXQSTS0	<RSCAN0_base> + $03C0_H$
RSCAN0	Transmit queue status register 1	RSCAN0TXQSTS1	<RSCAN0_base> + $03C4_H$
RSCAN0	Transmit queue status register 2	RSCAN0TXQSTS2	<RSCAN0_base> + $03C8_H$
RSCAN0	Transmit queue pointer control register 0	RSCAN0TXQPCTR0	<RSCAN0_base> + $03E0_H$
RSCAN0	Transmit queue pointer control register 1	RSCAN0TXQPCTR1	<RSCAN0_base> + $03E4_H$
RSCAN0	Transmit queue pointer control register 2	RSCAN0TXQPCTR2	<RSCAN0_base> + $03E8_H$
RSCAN0	Transmit history configuration and control register 0	RSCAN0THLCC0	<RSCAN0_base> + 0400_H
RSCAN0	Transmit history configuration and control register 1	RSCAN0THLCC1	<RSCAN0_base> + 0404_H
RSCAN0	Transmit history configuration and control register 2	RSCAN0THLCC2	<RSCAN0_base> + 0408_H
RSCAN0	Transmit history status register 0	RSCAN0THLSTS0	<RSCAN0_base> + 0420_H
RSCAN0	Transmit history status register 1	RSCAN0THLSTS1	<RSCAN0_base> + 0424_H
RSCAN0	Transmit history status register 2	RSCAN0THLSTS2	<RSCAN0_base> + 0428_H
RSCAN0	Transmit history pointer control register 0	RSCAN0THLPCTR0	<RSCAN0_base> + 0440_H
RSCAN0	Transmit history pointer control register 1	RSCAN0THLPCTR1	<RSCAN0_base> + 0444_H
RSCAN0	Transmit history pointer control register 2	RSCAN0THLPCTR2	<RSCAN0_base> + 0448_H
RSCAN0	Global TX interrupt status register 0	RSCAN0GTINTSTS0	<RSCAN0_base> + 0460_H
RSCAN0	Global test configuration register	RSCAN0GTSTCFG	<RSCAN0_base> + 0468_H
RSCAN0	Global test control register	RSCAN0GTSTCTR	<RSCAN0_base> + $046C_H$
RSCAN0	Global lock key register	RSCAN0GLOCKK	<RSCAN0_base> + $047C_H$
RSCAN0	Receive rule ID register 0	RSCAN0GAFLID0	<RSCAN0_base> + 0500_H
RSCAN0	Receive rule mask register 0	RSCAN0GAFLM0	<RSCAN0_base> + 0504_H
RSCAN0	Receive rule pointer 0 register 0	RSCAN0GAFLP00	<RSCAN0_base> + 0508_H
RSCAN0	Receive rule pointer 1 register 0	RSCAN0GAFLP10	<RSCAN0_base> + $050C_H$
RSCAN0	Receive rule ID register 1	RSCAN0GAFLID1	<RSCAN0_base> + 0510_H
RSCAN0	Receive rule mask register 1	RSCAN0GAFLM1	<RSCAN0_base> + 0514_H
RSCAN0	Receive rule pointer 0 register 1	RSCAN0GAFLP01	<RSCAN0_base> + 0518_H

Table 22.13 Registers (6/19)

Module	Register	Symbol	Address
RSCAN0	Receive rule pointer 1 register 1	RSCAN0GAFLP11	<RSCAN0_base> + 051C$_H$
RSCAN0	Receive rule ID register 2	RSCAN0GAFLID2	<RSCAN0_base> + 0520$_H$
RSCAN0	Receive rule mask register 2	RSCAN0GAFLM2	<RSCAN0_base> + 0524$_H$
RSCAN0	Receive rule pointer 0 register 2	RSCAN0GAFLP02	<RSCAN0_base> + 0528$_H$
RSCAN0	Receive rule pointer 1 register 2	RSCAN0GAFLP12	<RSCAN0_base> + 052C$_H$
RSCAN0	Receive rule ID register 3	RSCAN0GAFLID3	<RSCAN0_base> + 0530$_H$
RSCAN0	Receive rule mask register 3	RSCAN0GAFLM3	<RSCAN0_base> + 0534$_H$
RSCAN0	Receive rule pointer 0 register 3	RSCAN0GAFLP03	<RSCAN0_base> + 0538$_H$
RSCAN0	Receive rule pointer 1 register 3	RSCAN0GAFLP13	<RSCAN0_base> + 053C$_H$
RSCAN0	Receive rule ID register 4	RSCAN0GAFLID4	<RSCAN0_base> + 0540$_H$
RSCAN0	Receive rule mask register 4	RSCAN0GAFLM4	<RSCAN0_base> + 0544$_H$
RSCAN0	Receive rule pointer 0 register 4	RSCAN0GAFLP04	<RSCAN0_base> + 0548$_H$
RSCAN0	Receive rule pointer 1 register 4	RSCAN0GAFLP14	<RSCAN0_base> + 054C$_H$
RSCAN0	Receive rule ID register 5	RSCAN0GAFLID5	<RSCAN0_base> + 0550$_H$
RSCAN0	Receive rule mask register 5	RSCAN0GAFLM5	<RSCAN0_base> + 0554$_H$
RSCAN0	Receive rule pointer 0 register 5	RSCAN0GAFLP05	<RSCAN0_base> + 0558$_H$
RSCAN0	Receive rule pointer 1 register 5	RSCAN0GAFLP15	<RSCAN0_base> + 055C$_H$
RSCAN0	Receive rule ID register 6	RSCAN0GAFLID6	<RSCAN0_base> + 0560$_H$
RSCAN0	Receive rule mask register 6	RSCAN0GAFLM6	<RSCAN0_base> + 0564$_H$
RSCAN0	Receive rule pointer 0 register 6	RSCAN0GAFLP06	<RSCAN0_base> + 0568$_H$
RSCAN0	Receive rule pointer 1 register 6	RSCAN0GAFLP16	<RSCAN0_base> + 056C$_H$
RSCAN0	Receive rule ID register 7	RSCAN0GAFLID7	<RSCAN0_base> + 0570$_H$
