

Highly Versatile, Regulated Single-Output, Buck-Boost Ambient Energy Manager For AC/DC Sources with Optional Primary Battery

Features

Ultra-low power start-up

- Cold start from 275 mV input voltage and 3 μ W input power (typical)

Very efficient energy extraction

- Open-circuit voltage sensing for Maximum Power Point Tracking (MPPT)
- Selectable open-circuit voltage ratios from 35% to 80% or fixed impedance
- Programmable MPPT sensing period
- MPPT voltage operation range from 100 mV to 4.5 V

Adaptive and smart energy management with optional primary battery

- Switches automatically between boost, buck-boost and buck operation, to maximize energy transfer from its input to the output
- Automatically selects between the source, storage element and an optional primary battery
- Automatically select the output between the internal supply, the load and the storage element

Load supply voltage

- Current drive capability: 30 mA in low power mode, 60 mA in high power mode
- Selectable load voltage from 1.2 V to 3.3 V

Battery protection features

- Selectable over-charge and over-discharge protection for any type of rechargeable battery or (super-)capacitor
- Fast super-capacitor charging
- Dual cell super-capacitor balancing circuit

Smallest footprint, smallest BOM

- Only four external components are required
- One 10 μ H inductor
- Three capacitors: one 10 μ F, one 15 μ F, one at least 40 μ F

Description

The AEM30330 is an integrated energy management circuit that extracts DC power from an ambient energy harvesting source to simultaneously supply an application and store energy in a storage element. The AEM30330 allows to extend battery lifetime and ultimately eliminates the primary energy storage element in a large range of applications.

Thanks to its Maximum Power Point Tracking system, the AEM30330 extracts the maximum energy available from the source. It integrates an ultra-low power DCDC converter which operates with input voltages ranging from 100 mV to 4.5 V.

Two different storage elements can be connected: one for storing energy and another one for coupling the load output voltage. At start-up, user can choose to charge the storage element first or the load capacitor first.

With its unique cold start circuit, the AEM30330 can start harvesting with an input voltage as low as 275 mV and from an input power of 3 μ W. The preset protection levels determine the storage element voltages protection thresholds to avoid over-charging and over-discharging the storage element and thus avoiding damaging it. Those are set through configuration pins. Moreover, special modes can be obtained at the expense of a few configuration resistors.

The load voltage can be selected to cover most application needs, with a maximum available load current of 60 mA.

The chip integrates all active elements for powering a typical wireless sensor. Only three capacitors and one inductor are required.

Applications

- Asset Tracking/Monitoring
- Industrial applications
- Retail ESL/ Smart sensors
- Aftermarket automotive
- Smart home/building

1. Introduction

The AEM30330 is a full-featured energy efficient power management circuit able to harvest energy from an energy source (connected to **SRC**) to supply an application circuit (connected to **LOAD**) and use any excess of energy to charge a storage element (connected to **STO**). This is done with a minimal bill of material: only 3 capacitors and one inductor are needed for a basic setup.

The heart of the AEM30330 is a regulated switching DCDC converter with high power conversion efficiency.

At first start-up, as soon as a required cold start voltage of 275 mV and a sparse amount of power of at least 3 μ W is available at the source, the AEM30330 cold starts. After the cold start, the AEM extracts the power available from the source if the working input voltage is at least 100 mV.

Through four configuration pins (**STO_CFG[3:0]**), the user can select a specific operating mode out of 15 modes that cover most application requirements without any dedicated external component. Those operating modes define the protection levels of the storage element. If none of those 15 modes fit the user's storage element, a custom mode is also available to allow the user to define a mode with custom specifications.

Status pins **ST_STO**, **ST_STO_RDY** and **ST_STO_OVDIS** provide information about the voltage levels of the storage element. **ST_STO** is asserted when the voltage of the storage element V_{STO} is above V_{CHRDY} and is reset when the voltage drops below V_{OVDIS} . **ST_STO_RDY** is asserted when V_{STO} is above V_{CHRDY} , and reset when V_{STO} drops below V_{CHRDY} . **ST_STO_OVDIS** is asserted when V_{STO} drops below V_{OVDIS} or

when the AEM30330 enters on **PRIMARY BATTERY STATE**, and reset when V_{STO} is above V_{OVDIS} . Status pin **ST_LOAD** is asserted when the load voltage V_{LOAD} rises above $V_{LOAD,TYP}$, and is reset when V_{LOAD} drops below $V_{LOAD,MIN}$.

The Maximum Power Point (MPP) ratio is configurable thanks to three configuration pins (**R_MPP[2:0]**) and ensures an optimum biasing of the harvester to maximize power extraction. Depending on the harvester, it is possible to adapt the timings of the MPP evaluations with the two configuration pins (**T_MPP[1:0]**) that sets the periodicity and the duration of the MPP evaluation.

Once started, if at any time the load requires more power than can be harvested from the energy source, the AEM30330 automatically uses the storage element to keep the load supplied.

The AEM30330's DCDC converter can work in two modes: **LOW POWER MODE** and **HIGH POWER MODE**, each one of these being optimized for a power range on **SRC** and **LOAD**.

The charging of the storage element can be prevented by pulling **EN_STO_CH** to **GND**, typically to protect the storage element if the temperature is too low/high to safely charge it.

The AEM30330 also implements a **SLEEP STATE**, which reduces the quiescent current to avoid wasting the energy stored on the storage element when **EN_SLEEP** is asserted.

At start-up, user can choose to prioritize starting the application circuit connected on **LOAD**, or charging the storage element connected on **STO**. This is set by the **STO_PRIO** pin.

Figure 2: Pinout Diagram QFN 40-pin

NAME	PIN NUMBER	FUNCTION
	QFN40	
Power pins		
CS_IN	1	Input for the cold start circuit.
ZMPP	2	Used for the configuration of the ZMPP (optional). Must be left floating if not used.
SRC	3	Connection to the harvested energy source.
PRIM	4	Input for primary battery. Must be connected to GND if not used.
BUFSRC	7	Connection to an external capacitor buffering the DCDC converter input.
LIN	8	DCDC inductance connection.
LOUT	9	DCDC inductance connection.
VINT	13	Internal voltage supply.
LOAD	17	Output voltage to supply on application load.
BAL	18	Connection to mid-point of a dual-cell supercapacitor (optional). Must be connected to GND if not used.
STO	19	Connection to the energy storage element - battery or (super-)capacitor. Cannot be left floating. Must be connected to a minimum capacitance of 100 μF or to a rechargeable battery.
Status pins		
ST_LOAD	36	Logic output. Asserted when the LOAD voltage V_{LOAD} rises above the $V_{LOAD,TYP}$ threshold. Reset when V_{LOAD} drops below $V_{LOAD,MIN}$ threshold. High level is V_{LOAD} .
ST_STO_RDY	37	Logic output. Asserted when V_{STO} is above V_{CHRDY} , reset when V_{STO} drops below V_{CHRDY} . High level is V_{LOAD} .
ST_STO_OVDIS	38	Logic output. Asserted when the AEM30330 state is SHUTDOWN STATE or PRIMARY BATTERY STATE, reset when in any other state. High level is V_{LOAD} .
ST_STO	40	Logic output. Asserted when the storage device voltage V_{STO} rises above the V_{CHRDY} threshold, reset when V_{STO} drops below the V_{OVDIS} threshold. High level is V_{STO} .

Table 1: Power and Status Pins

NAME	PIN NUMBER	Function
	QFN40	
Configuration pins		
R_MPP[0]	15	Used for the configuration of the MPP ratio.
R_MPP[1]	12	
R_MPP[2]	11	
T_MPP[0]	30	Used for the configuration of the MPP timings.
T_MPP[1]	32	
LOAD_CFG[0]	24	Used for the configuration of LOAD output voltage V_{LOAD} .
LOAD_CFG[1]	25	
LOAD_CFG[2]	26	
STO_CFG[0]	33	Used for the configuration of the threshold voltages for the energy storage element (V_{OVDIS} , V_{CHRDY} and V_{OVCH}).
STO_CFG[1]	34	
STO_CFG[2]	35	
STO_CFG[3]	27	
STO_PRIO	29	- Pulled up to VINT: storage device (STO) has highest priority at start-up. - Pulled down to GND: load (LOAD) has highest priority at start-up.
STO_OVCH	23	Used for the configuration of the threshold voltages (V_{OVDIS} , V_{CHRDY} and V_{OVCH}) for the energy storage element when STO_CFG[3:0] are set to custom mode (optional). Must be left floating if not used.
STO_OVDIS	21	
STO_RDY	22	
EN_SLEEP	39	- Pulled up to LOAD: SLEEP STATE enabled. - Pulled down to GND: SLEEP STATE disabled.
EN_STO_FT	31	- Pulled up to VINT: allows charges flowing directly from SRC to STO when SRC is above 5V. - Pulled down to GND: normal operation.
EN_STO_CH	20	- Pulled up to LOAD: enables the charging of the storage element. - Pulled down to GND: disables the charging of the storage element.
EN_HP	28	- Pulled up to VINT: HIGH POWER MODE enabled. - Pulled down to GND: HIGH POWER MODE disabled.
PRIM_CUT	5	Used for the configuration of the primary battery. Must be left floating if not used.
PRIM_FB	6	Used for the configuration of the primary battery. Must be connected to GND if not used.
Other		
GND	10, 14, 16	Ground connection, best possible connection to PCB ground plane.
	Exposed pad

6. Functional Block Diagram

Figure 3: Functional Block Diagram

Figure 4: Simplified Schematic View of the AEM30330

7. Theory of Operation

7.1. DCDC Converter

The DCDC converter converts the voltage available at **BUFSRC** or at **STO** to a level suitable for charging the storage element **STO** or to regulate the **LOAD** and the internal supply **VINT**. The switching transistors of the DCDC converter are M2 or M3, M4, M5 and M6. Thanks to M7, M8 and M9, the controller selects between **LOAD**, **STO** and **VINT** respectively as the converter output. M1 and M10 selects respectively the source or the primary battery as main input of energy. The internal supply **VINT** is regulated with priority over **LOAD**. **STO** is selected as an output only when neither **VINT** nor **LOAD** needs to be supplied. The converter has two possible inputs: **BUFSRC** or **STO**. **BUFSRC** is used by default as an input via M3. If the energy available on **SRC** is not sufficient to maintain the **LOAD** or **VINT** voltage, for instance because of a sudden current peak on **LOAD**, the converter uses **STO** instead as an input via M2 to keep **LOAD** and **VINT** regulated.

The reactive power component of this converter is the external inductor **LDCDC**. Periodically, the MPP control circuit

disconnects the source from the **BUFSRC** pin with the transistor M1 in order to let the harvester on **SRC** rise to its open-circuit voltage V_{OC} and measure it. This is done to define the optimal voltage level V_{MPP} , which is determined by applying the MPP ratio on V_{OC} . **BUFSRC** is decoupled by the capacitor **CSRC**, which smooths the voltage against the current pulses pulled by the DCDC converter. The storage element is connected to the **STO** pin.

Depending on its input voltage and its output voltage, the DCDC converter will work as a boost converter, a buck converter or a buck-boost converter. The maximum power that can be harvested and supplied to the output **LOAD** depends on the power mode (**HIGH POWER MODE** or **LOW POWER MODE**), which is configured through the **EN_HP** pin (see Section 8.1).

DCDC converter mode	Input Voltage / Output Voltage
Boost	$V_{IN} < V_{OUT} - 250\text{mV}$
Buck	$V_{IN} > V_{OUT} + 250\text{mV}$
Buck - Boost	$V_{OUT} - 250\text{mV} < V_{IN} < V_{OUT} + 250\text{mV}$

Table 8: DCDC Converter Modes

7.2. Reset, Wake Up and Start States

The **RESET STATE** is a state where all nodes are deeply discharged and there is no available energy to be harvested. As soon as the required cold start voltage of 275 mV and a sparse amount of power of just 3 μ W become available on **CS_IN** (usually connected to **SRC**), the AEM30330 switches to **WAKE-UP STATE**, and energy is extracted from **SRC** to make V_{VINT} rise to 2.2 V. When V_{VINT} reaches those 2.2 V, the AEM30330 switches to **START STATE**. In **START STATE**, two scenarios are possible: in the first scenario, **STO_Prio** is asserted, the storage element connected to **STO** has the priority on the one connected to **LOAD**. In the second scenario, **STO_Prio** is reset and the **LOAD** has the priority.

When the AEM30330 is in **RESET STATE**, **WAKE-UP STATE** or **START STATE**, the DCDC converter's input is always **BUFSRC**: **STO** is never used as input. This guarantees that the storage element is not used until a minimum amount of energy has been stored in it.

7.2.1. Storage Element Priority

This paragraph covers the AEM30330 behaviour when **STO_Prio** is pulled up to **VINT**, so that the storage element connected on **STO** has priority over **LOAD**.

Supercapacitor as a Storage Element

If the storage element is a supercapacitor, it may be fully discharged at first and thus need to be charged from 0 V. The DCDC converter charges **STO** from the input source (**SRC**). When V_{STO} reaches V_{CHRDY} , the circuit enters **SUPPLY STATE**.

Battery as a Storage Element

If the storage element is a battery, but its voltage is lower than V_{CHRDY} , then the storage element needs to be charged first until it reaches V_{CHRDY} . Once V_{STO} reaches V_{CHRDY} , or if the battery was initially charged above V_{CHRDY} , the circuit enters **SUPPLY STATE**.

7.2.2. Load Priority

If **STO_Prio** is connected to GND, the AEM charges first the **LOAD** to $V_{LOAD,MAX}$ (see Table 10) using energy from the source (**SRC**). This allows to first supply the application circuit connected to **LOAD**. If the storage element was initially charged above V_{CHRDY} , the circuit enters **SUPPLY STATE** as soon as **LOAD** reaches $V_{LOAD,TYP}$. If the storage element is a supercapacitor or a battery which voltage is lower than V_{CHRDY} , the AEM keeps regulating **LOAD** between $V_{LOAD,MAX}$ and $V_{LOAD,TYP}$. Meanwhile, any excess charges on the source is used to charge the storage element until it reaches V_{CHRDY} . Once V_{STO} exceeds V_{CHRDY} , the circuit enters into **SUPPLY STATE**.

This configuration is useful when a large storage element is connected to **STO** and a smaller one is connected to **LOAD**: the application starts as soon as **CLOAD** is charged and does not have to wait for the large storage element on **STO** to be charged.

7.3. Supply State

In **SUPPLY STATE**, four scenarios are possible:

- There is enough power provided by the source (**SRC**) to keep V_{LOAD} near $V_{LOAD,TYP}$ with a small hysteresis and V_{VINT} at 2.2 V. The excessive power is used to charge the storage element on **STO**. In that case, the circuit remains in **SUPPLY STATE**. If **STO** is fully charged, **LOAD** will be maintained at $V_{LOAD,MAX}$ instead of $V_{LOAD,TYP}$.
- If the circuit connected to **LOAD** consumes more energy than the energy that the AEM30330 is able to extract from the source, the **LOAD** circuit will be

supplied by the storage element connected to the **STO** terminal. In this case, the circuit stays in **SUPPLY STATE**.

- Due to a lack of power from the source, V_{STO} falls below V_{OVDIS} . In this case, the circuit enters **SHUTDOWN STATE** as explained in Section 7.4.
- If **EN_SLEEP** is asserted and conditions (shown on Figure 5) on V_{LOAD} and V_{VINT} are satisfied, the AEM enters **SLEEP STATE** (see section 7.5).

Figure 5: Diagram of the AEM30330 States

7.4. Shutdown State

If the storage element gets depleted ($V_{STO} < V_{OVDIS}$), the AEM30330 goes to **SHUTDOWN STATE**. As long as the AEM30330 is in this state, the **ST_STO_OVDIS** is asserted. In **SHUTDOWN STATE**, if V_{STO} recovers within 680 ms, the AEM30330 goes back to **SUPPLY STATE**. This prevents false detection of the storage element being empty because of a **LOAD** current peak. However, if V_{STO} remains lower than

V_{OVDIS} for at least 680 ms, the circuit enters then **PRIMARY BATTERY STATE** if a suitable primary battery has been detected on **PRIM**, else it enters **RESET STATE**.

7.5. Sleep State

SLEEP STATE reduces the AEM30330 quiescent current by disabling the DCDC converter and by reducing the controller clock frequency. If **VINT** voltage or **V_{LOAD}** fall below their regulation value, the AEM30330 temporarily exits **SLEEP STATE** to wake up the DCDC converter and supply **VINT** or **LOAD**. Exiting **SLEEP STATE** and waking up the DCDC converter takes up to 1 ms. Depending on the expected **LOAD** current, **C_{LOAD}** value must be adapted to act as an energy buffer during the 1 ms required to wake up the DCDC converter. Therefore, this mode should be used when **LOAD** current is small. As the DCDC is enabled, no energy is harvested from **SRC** while in **SLEEP STATE**.

The AEM30330 enters **SLEEP STATE** if all the following conditions are satisfied:

- **EN_SLEEP** pin pulled up to **LOAD**
- $V_{INT} > 2.2 \text{ V}$
- $V_{LOAD} > V_{LOAD, TYP}$

The AEM30330 leaves **SLEEP STATE** and switches back to **SUPPLY STATE** if one of the following conditions is satisfied:

- **EN_SLEEP** pin pulled down to **GND**
- $V_{INT} < 2.2 \text{ V}$
- $V_{LOAD} < V_{LOAD, TYP}$

The AEM30330 will then stay in **SUPPLY STATE** until the **SLEEP STATE** conditions are all satisfied again.

7.6. Primary Battery State

When **V_{STO}** drops below **V_{OVDIS}**, the circuit compares the voltage on **PRIM_FB** to a 1V voltage reference to determine whether a charged primary battery is connected on **PRIM**. The voltage on **PRIM_FB** is set thanks to two optional resistances as explained in Section 8.9. If the voltage on **PRIM_FB** is higher than 1V, the circuit considers the primary battery as available and the circuit enters **PRIMARY BATTERY STATE** as shown on Figure 5.

In that mode, transistor M1 is opened and the primary battery is connected to **BUFSRC** through transistor M10 to become the energy source for the AEM30330. The chip remains in **PRIMARY BATTERY STATE** until **V_{STO}** reaches **V_{CHRDY}**, where the circuit switches to **SUPPLY STATE**. As long as the AEM30330 is in **PRIMARY BATTERY STATE**, **ST_STO_OVDIS** is asserted.

7.7. Maximum Power Point Tracking

During **SUPPLY STATE**, **SHUTDOWN STATE** and **START STATE**, the voltage on **SRC** is regulated by an internal Maximum Power Point Tracking (MPPT) module. The MPPT module evaluates **V_{MPP}**, the voltage at which the source provides the highest possible power, as a given fraction of the open-circuit voltage of the source **V_{OC}**. This ratio is set by the **R_MPP[2:0]** terminals according to Table 7. The sampling period and duration are set according to Table 8 by the **T_MPP[1:0]** terminals. The AEM30330 supports any **V_{MPP}** levels in the range from 100 mV to 4.5 V. It offers a choice of seven values for the **V_{MPP} / V_{OC}** fraction. It can also match the input impedance of the DCDC converter with an impedance connected to the **ZMPP** terminal as explained in section 8.7.

7.8. Balancing for Dual-Cell Supercapacitor

The balancing circuit allows the user to balance the internal voltage of the dual-cell supercapacitor connected to **STO** in order to avoid damaging the supercapacitor because of excessive voltage on one cell.

If **BAL** is connected to **GND**, the balancing circuit is disabled. This configuration must be used if a battery, a capacitor or a single-cell supercapacitor is connected on **STO**.

If **BAL** is connected to the node between both cells of a supercapacitor, the balancing circuit compensates for any mismatch of the two cells that could lead to the over-charge of one of two cells. The balancing circuit ensures that **BAL** remains close to **V_{STO} / 2**. This configuration must be used if a dual-cell supercapacitor is connected to **STO**, and that this supercapacitor requires cells balancing.

8. System Configuration

8.1. High Power / Low Power Mode

When **EN_HP** is pulled to **VINT**, the DCDC converter is configured to **HIGH POWER MODE**. This allows higher currents to be extracted from the DCDC converter input (**SRC**, **STO** or **PRIM**) to the DCDC converter output (**LOAD** or **STO**).

Figure 6 shows the maximum current that the DCDC converter can supply to **LOAD**, depending on the storage voltage **V_{STO}**, for every available load voltage **V_{LOAD}**, for both **HIGH POWER MODE** and **LOW POWER MODE**.

Figure 6: Maximum LOAD Current Depending on V_{STO} and on V_{LOAD}

8.2. Storage Element Configuration

Through four configuration pins (**STO_CFG[3:0]**), the user can set a particular operating mode from a range that covers most application requirements, without any dedicated external component as shown in Table 9. The three threshold levels are defined as:

- **V_{OVCH}**: maximum voltage accepted on the storage element before disabling its charging.
- **V_{CHRDY}**: minimum voltage required on the storage element before starting to supply the **LOAD** (if **STO_PRIO** is asserted) and entering supply state after start-up.

- **V_{OVDIS}**: minimum voltage accepted on the storage element before considering the storage element as depleted resetting **ST_STO**.

A large-size storage element is not mandatory on **STO**:

- If the harvested energy source is permanently available and covers the application needs or
- If the application does not need to store energy when the harvested energy source is not available

The storage element may then be replaced by an external capacitor **CSTO** with a minimum value of 100 μ F.

CAUTION: running the AEM30330 without this 100 μ F minimum capacitance on STO will permanently damage the circuit.

Configuration pins				Storage element threshold voltages			Typical use
STO_CFG[3]	STO_CFG[2]	STO_CFG[1]	STO_CFG[0]	V_{OVDIS}	V_{CHRDY}	V_{OVCH}	
0	0	0	0	3.00 V	3.50 V	4.05 V	Li-ion battery
0	0	0	1	2.80 V	3.10 V	3.60 V	LiFePO4 battery
0	0	1	0	1.85 V	2.40 V	2.70 V	NiMH battery
0	0	1	1	0.20 V	1.00 V	4.65 V	Dual-cell supercapacitor
0	1	0	0	0.20V	1.00 V	2.60 V	Single-cell supercapacitor
0	1	0	1	1.00 V	1.20 V	2.95 V	Single-cell supercapacitor
0	1	1	0	1.85 V	2.30 V	2.60 V	NGK
0	1	1	1	Custom Mode			
1	0	0	0	1.10 V	1.25 V	1.50 V	Ni-Cd 1 cells
1	0	0	1	2.20 V	2.50 V	3.00 V	Ni-Cd 2 cells
1	0	1	0	1.45 V	2.00 V	4.65 V	Dual-cell supercapacitor
1	0	1	1	1.00 V	1.20 V	2.60 V	Single-cell supercapacitor
1	1	0	0	2.00 V	2.30 V	2.60 V	ITEN / Umal Murata
1	1	0	1	3.00 V	3.50 V	4.35 V	Li-Po battery
1	1	1	0	2.60 V	2.70 V	4.00 V	Tadiran TLI1020A
1	1	1	1	2.60 V	3.50 V	3.90 V	Tadiran HLC1020

Table 9: Storage Element Configuration Pins

8.3. Load Configuration

The **LOAD** output voltage V_{LOAD} can be configured thanks to the **LOAD_CFG[2:0]** configuration pins covering most application cases (see Table 10). V_{LOAD} is regulated to

$V_{LOAD,TYP}$. However, if V_{LOAD} falls below $V_{LOAD,MID}$, the controller forces **STO** as an input of the DCDC converter to supply **LOAD**.

Configuration pins			LOAD output voltage			
LOAD_CFG[2]	LOAD_CFG[1]	LOAD_CFG[0]	$V_{LOAD,MIN}$	$V_{LOAD,MID}$	$V_{LOAD,TYP}$	$V_{LOAD,MAX}$
0	0	0	3.15 V	3.23 V	3.28 V	3.34 V
0	0	1	2.35 V	2.47 V	2.50 V	2.53 V
0	1	0	1.64 V	1.75 V	1.79 V	1.82 V
0	1	1	1.14 V	1.16 V	1.20 V	1.23 V
1	0	0	1.39 V	1.56 V	1.61 V	2.63 V
1	0	1	1.39 V	1.56 V	1.61 V	4.65 V
1	1	0	Reserved, do not use			
1	1	1				

Table 10: Load Configuration Pins

8.4. Custom Mode Configuration

Figure 7: Custom Mode Settings

When **STO_CFG[3:0] = 0111**, the custom mode is selected and all four configuration resistors must be wired as shown in Figure 7.

V_{OVCH} , V_{CHRDY} and V_{OVDIS} are defined thanks to R1, R2, R3 and R4, which can be determined within the following constraints:

- $RT = R1 + R2 + R3 + R4$
- $1\text{ M}\Omega \leq RT \leq 100\text{ M}\Omega$
- $R1 = RT (1\text{ V} / V_{OVCH})$
- $R2 = RT (1\text{ V} / V_{CHRDY} - 1\text{ V} / V_{OVCH})$
- $R3 = RT (1\text{ V} / V_{OVDIS} - 1\text{ V} / V_{CHRDY})$

$$- R4 = RT (1 - 1\text{ V} / V_{OVDIS})$$

The resistors should have high values to make the additional power consumption negligible. Moreover, the following constraints must be adhered to ensure the functionality of the chip:

- $V_{CHRDY} + 0.05\text{ V} \leq V_{OVCH} \leq 4.5\text{ V}$
- $V_{OVDIS} + 0.05\text{ V} \leq V_{CHRDY} \leq V_{OVCH} - 0.05\text{ V}$
- $1\text{ V} \leq V_{OVDIS}$

8.5. Disable Storage Element Charging

Pulling down **EN_STO_CH** pin to **GND** disables the charging of the storage element connected to **STO**, either from **SRC** or from **PRIM**. This can be done for example to protect the storage element when the system detects that the environment temperature is too low or too high to safely charge the storage element.

While **EN_STO_CH** is pulled down, **VINT** and **LOAD** can still be supplied either from **SRC**, from **STO** or from **PRIM**.

To enable charging the storage element on **STO**, **EN_STO_CH** must be pulled up to **LOAD**.

NOTE: **STO** will still be charged to V_{CHRDY} during the **START STATE**

8.6. MPPT Configuration

There are two kinds of pins to configure the maximum point tracking. The first configuration pins allows for selecting the MPP tracking ratio based on the characteristic of the input power source. The configuration pins are **R_MPP[2:0]**.

Configuration pins			MPPT ratio
R_MPP[2]	R_MPP[1]	R_MPP[0]	V_{MPP} / V_{OC}
0	0	0	35%
0	0	1	50%
0	1	0	60%
0	1	1	65%
1	0	0	70%
1	0	1	75%
1	1	0	80%
1	1	1	ZMPP

Table 11: MPP Ratio Configuration Pins

The second kind of configuration pins allows for configuring the duration of an MPP evaluation and the time between two MPP evaluations. The configurations pins are **T_MPP[1:0]**

Configuration pins		MPPT timing	
T_MPP[1]	T_MPP[0]	Sampling duration	Sampling period
0	0	3.82 ms	18.28 ms
0	1	5.1 ms	280.0 ms
1	0	71.6 ms	1.12 s
1	1	1.12 s	71.7 s

Table 12: MPP Timing Configuration Pins

8.7. ZMPP Configuration

Instead of working at a ratio of the open-circuit voltage, the AEM30330 can regulate the input impedance of the DCDC converter so that it matches a constant impedance **R_{ZMPP}** connected to the **ZMPP** pin. In this case, the AEM30330 regulates **V_{SRC}** at a voltage that is the product of the **ZMPP** resistance **R_{ZMPP}** and the current available at the **SRC** input.

$$- 10 \Omega \leq R_{ZMPP} \leq 100 \text{ k}\Omega$$

Figure 8: **R_{ZMPP}** Connection to the AEM30330

8.8. Source to Storage Element Feed-Through

When the harvester connected to **SRC** delivers a high amount of power, the AEM might not be able to pull enough current to regulate **V_{SRC}** to the MPP voltage. The voltage on **SRC** thus increases, eventually above 5V. To maximize the energy extracted in that case, the AEM30330 can be configured to create a direct feed-through current path from **SRC** to **STO** when **V_{SRC}** is above 5V. This is measured when the AEM is pulling current from the source (not during an MPP evaluation).

If the MPPT module detects that **V_{SRC}** is higher than 4 V and **EN_STO_FT** is set, the **SRC** is monitored. From that moment, if the AEM30330 detects that **V_{SRC}** rises above 5 V and if the storage element is not fully charged, the switch between the **SRC** and **STO** pins is closed until **V_{SRC}** drops below 5 V or until the storage element is fully charged.

This feature is enabled by pulling up **EN_STO_FT** pin to **VINT**. However, it is disabled if the storage element is fully charged, or when a MPP evaluation is occurring. Therefore the circuit must still be protected from any overshoot voltage on **SRC** above 5.5 V, for instance by a zener diode.

8.9. Primary Battery Configuration

To use the primary battery, it is mandatory to determine $V_{\text{PRIM,MIN}}$, the voltage of the primary battery at which it has to be considered as empty. This is to prevent over-discharging the primary battery, which could lead to hazardous behaviour of the primary battery.

The circuit uses a resistive divider between **PRIM** and **PRIM_CUT** to define the voltage on **PRIM_FB**. $V_{\text{PRIM,MIN}}$ is evaluated by comparing the voltage on **PRIM_FB** to an internal 1V voltage reference.

During the evaluation of $V_{\text{PRIM,MIN}}$, the circuit connects **PRIM_CUT** to GND, thus letting current flow in the resistive voltage divider. When $V_{\text{PRIM,MIN}}$ is not evaluated, **PRIM_CUT** is left floating to avoid quiescent current on the resistive divider.

We define the total resistance ($R6 + R5$) as R_P . $R6$ and $R5$ are calculated as:

- $100\text{ k} \leq R_P \leq 500\text{ k}$
- $R5 = R_P * 1\text{V} / V_{\text{PRIM,MIN}}$

$$- R6 = R_P - R5$$

*NOTE: **PRIM** and **PRIM_FB** must be tied to GND if no primary battery is used. **PRIM_CUT** can then be left floating.*

Figure 9: $V_{\text{PRIM,MIN}}$ Configuration Through a Resistive Divider

8.10. External Components

Refer to Figure 3 to have an illustration of the external components wiring.

8.10.1. Storage element information

The energy storage element of the AEM30330 can be a rechargeable battery, a supercapacitor or a capacitor. The size of the storage element must be determined so that its voltage does not fall below V_{OVDIS} even during current peaks pulled by the application circuit connected to **LOAD**. If the internal resistance of the storage element cannot sustain this voltage limit, it is advisable to decouple the battery with a capacitor.

If the application expects a disconnection of the battery (e.g. because of a user removable connector), the PCB should include a capacitor **CSTO** of at least 100 μ F connected between **STO** and **GND**. The leakage current of the storage element should be small as leakage currents directly impact the quiescent current of the whole subsystem.

8.10.2. External inductor information

The AEM30330 operates with one standard miniature

inductor. **LDCDC** must sustain a peak current of at least 1 A and a switching frequency of at least 10 MHz. Low equivalent series resistance (ESR) favours the power conversion efficiency of the DCDC converter. The recommended value is 10 μ H.

8.10.3. External capacitors information

CSRC

This capacitor acts as an energy buffer at the input of the DCDC converter. It prevents large voltage fluctuations when the DCDC converter is switching. The recommended value is 15 μ F.

CINT

This capacitor acts as an energy buffer for the internal voltage supply. The recommended value is 10 μ F.

CLOAD

This capacitor acts as an energy buffer for **LOAD**. It also reduces the voltage ripple induced by the current pulses inherent to the switched behaviour of the converter. The recommended value is at least 40 μ F.

9. Typical Application Circuits

9.1. Example Circuit 1

Figure 10: Typical Application Circuit 1

The circuit is an example of a system with Radio Frequency (RF) energy harvesting. It uses a pre-defined operating mode that use standard components, and a supercapacitor as energy storage.

- Energy source: RF source
- $R_MPP[2:0] = 111$: the MPP tracker system is set to ZMPP, so that the AEM30330 will regulate SRC input resistance to $R_{ZMPP} = 3.5\text{ k}\Omega$ (see Section 8.7)
- $T_MPP[1:0] = 01$: the MPP sampling period is 280 ms and the MPP sampling duration is 5.1 ms
- $STO_CFG[3:0] = 0011$: the storage element is a dual-cell supercapacitor, with:
 - $V_{OVCH} = 4.65\text{ V}$
 - $V_{CHRDY} = 1.00\text{ V}$
 - $V_{OVDIS} = 0.20\text{ V}$
- The balancing pin of the dual-cell supercapacitor is connected to BAL
- $LOAD_CFG[2:0] = 001$: the micro-controller and the radio transceiver are supplied by the LOAD terminal, which is regulated at $V_{LOAD} = 2.5\text{ V}$
- There is no primary battery connected to PRIM: PRIM_FB and PRIM are connected to GND
- STO_Prio is connected to VINT: at start-up STO will be charged and before LOAD
- EN_SLEEP is connected to GND: the AEM30330 will never switch to SLEEP STATE
- EN_STO_CH is connected to GND : the charging of the storage element on STO is disabled
- EN_HP is connected to GND: the DCDC converter is in LOW POWER MODE

9.2. Example Circuit 2

Figure 11: Typical Application Circuit 2

The circuit is an example of a system with vibration energy harvesting. It uses a Li-Po rechargeable battery as energy storage, which voltages thresholds are set by the custom mode.

Please note that the custom mode is used for the sake of the example, but most applications that use a Li-Po battery as storage element could use a pre-defined mode that does not require to implement the resistive divider (R1-R2-R3-R4), and thus have a reduced bill of material compared to the circuit shown on Figure 21.

- Energy source: piezoelectric vibration harvester
- **R_MPP[2:0]** = 010: the MPP ratio is set to 60%
- **T_MPP[1:0]** = 10: the MPP sampling period is 1.12 s and the MPP sampling duration is 71.6 ms.

- **STO_CFG[3:0]** = 0111: the storage element is a Li-Po rechargeable battery, used with custom mode (in this example we set V_{CHRDY} to 4.0V instead of the 3.51V on **STO_CFG[3:0]** = 1101 preset):

- V_{OVCH} = 4.35V
- V_{CHRDY} = 4.00V
- V_{OVDIS} = 3.03V

- Custom mode resistor divider calculations (values have been rounded to the closest available value):

- $R_T = 70M\Omega$
- $R_1 = 70M\Omega * (1V / 4.35V) \approx 16M\Omega$
- $R_2 = 70M\Omega * (1V / 4.00V - 1V / 4.35V) \approx 1.4M\Omega$
- $R_3 = 70M\Omega * (1V / 3.03V - 1V / 4.00V) \approx 5.6M\Omega$
- $R_4 = 70M\Omega * (1 - 1V / 3.03V) \approx 47M\Omega$

- **BAL** is not used (not a dual-cell storage element) so it is connected to GND.

- **LOAD_CFG[2:0]** = 010: the micro-controller and the radio transceiver are supplied by the **LOAD** terminal, which is regulated at $V_{LOAD} = 1.8V$
- **PRIM** is a Li/MnO₂ battery which has an over-discharge voltage of 2.1V. Thus we set R5 and R6 so that $V_{PRIM,MIN} = 2.1V$:
 - $R_P = 400k\Omega$
 - $R_5 = 1V * 400k\Omega / 2.1V \approx 191k\Omega$
 - $R_6 = 400k\Omega - 191k\Omega \approx 210k\Omega$
- **STO_PRI0** is connected to **VINT**: at start-up **STO** will be charged and before **LOAD**
- **EN_SLEEP** is controlled by the application circuit, typically by a micro-controller GPIO output
- connected to **LOAD**: the charging of the storage element present on **STO** is enabled
- **EN_HP** is connected to **VINT**: the DCDC converter is in **HIGH POWER MODE**
