

Coreless, High Precision, Hall-Effect Current Sensor IC with Common-Mode Field Rejection, Overcurrent and Overtemperature Detection

FEATURES AND BENEFITS

- Eliminates need for concentrator core or shield
- · Contactless, lossless, noninvasive current sensing
- Suited for applications where current flows through busbar or PCB
- High operating bandwidth: DC to 200 kHz
- Overcurrent (OCF) and overtemperature (OTF) detection on the fault pin
- Differential Hall sensing rejects common-mode magnetic fields
- Very fast response time (<2 µs typical)
- Very high sensitivity (40 to 60 mV/G)
 □ Ideal for sensing currents on a PCB from 50 A
- Factory-programmed segmented linear temperature compensation (TC) provides low thermal drift
 Sensitivity ±1% (typical)
 - \Box Offset $\pm 3 \text{ mV}$ (typical)
- Customer-programmable, high-resolution offset and sensitivity trim
- Wide Hall-element spacing for improved SNR and thermal performance
- Ultra-sensitive Hall elements for improved noise performance

PACKAGE:

8-pin TSSOP package (suffix LU)

Not to scale

DESCRIPTION

The Allegro ACS37610 current sensor IC enables low-cost solutions for AC and DC current sensing without the need for an external field concentrator core or a U-shaped magnetic shield. It is designed for applications where hundreds of amperes or more flow through a busbar or PCB.

Current flowing through a busbar or PCB trace generates a magnetic field that is sensed by the monolithic, low-offset, linear Hall IC. The differential sensing topology virtually eliminates all types of errors caused by common-mode stray magnetic fields. The wide spacing between the differential Hall elements (2.58 mm) coupled with the increased sensitivity of each Hall element enable the ACS37610 to achieve superior signal-to-noise ratio (SNR) and improved resolution. While not mandatory, a notch or slit in the current-carrying busbar or PCB copper trace provides further improvements to system SNR. High isolation is achieved via the no-contact nature of this simple assembly.

The ACS37610 is offered with regular and low-power modes, enabling customers to achieve optimal SNR and power consumption. A dedicated user-programmable overcurrent and overtemperature fault pin and a slew of built-in diagnostics,

TYPICAL APPLICATIONS

- High-voltage traction motor inverter
- 48 V/12 V auxiliary inverter
- · Heterogeneous redundant battery monitoring
- Overcurrent detection
- DC-to-DC converter
- Smart fuse
 - Power distribution unit (PDU)
- Power supply

ACS37610H-DS, Rev. 2 MCO-0001428

FEATURES AND BENEFITS (continued)

- Wide ambient temperature range: -40°C to 150°C
- 3.3 or 5 V single-supply operation
- Programmable through output pin or through dedicated programming pin for easier device programming
- AEC-Q100 Grade 0, automotive qualified
- Monolithic Hall IC for high reliability
- Surface-mount, small-footprint, low-profile TSSOP-8 package

DESCRIPTION (continued)

including broken ground and VCC detection, make it ideal for safety-critical applications. The accuracy and flexibility of this device is enhanced by user programmability, performed via the output pin or through the dedicated programming pin, which allows the device to be optimized in the application and cancels errors caused by mechanical assembly tolerances on the PCB. Device specifications apply across an extended ambient temperature range: -40° C to 150° C.

The ACS37610 is suitable for space-constrained applications because of its low-profile eight-pin surface-mount thin-shrink smalloutline package (TSSOP; Allegro suffix LU) that is lead (Pb) free, with 100% matte tin leadframe plating. The sensor can be mounted in a horizontal or vertical orientation relative to the busbar, providing superior flexibility in mechanical assemblies.

SELECTION GUIDE

TYPICAL APPLICATION CIRCUITS

The ACS37610 outputs an analog signal, V_{OUT}, that varies linearly with the bidirectional AC or DC field sensed, within the range specified. C_L is for optimal noise management, with values that depend on the application. R_L is an optional pulldown to GND or pullup to VCC for broken-wire detection. For broken-GND function, it is recommended to tie the PROG pin to VCC when not used. R_F is an optional pull-up resistor to V_F, to be used when disabling the device internal pull-up in memory.

PINOUT DIAGRAM AND PINOUT LIST

Temperature Error	VOUT(Q)TC	$T_A = 25^{\circ}C$ to $150^{\circ}C$, $\pm 20\%$ sensitivity change	-20	±4	20	mV	
		$T_A = -40^{\circ}C$ to 25°C, ±20% sensitivity change	-20	±4	20	mV	
LIFETIME DRIFT CHARACTERISTICS [2]							
QVO Lifetime Drift	V _{OUT(Q)LIFE}	Initial sensitivity	_	±31.5	_	mV	
Sens Lifetime Drift	Sens _{LIFE}	Initial sensitivity	_	1.9	_	%	

^[1] For lower V_{CC} variations than test conditions, ratiometry error linearly scales with V_{CC}; e.g., $\pm 1.5\%$ variations on V_{CC}, instead of $\pm 3\%$, leads to Rat_{ErrSens} and V_{RatErrQVO} to be divided by 2.

[2] Lifetime drift characteristics are based on the AEC-Q100 qualification results from reads at zero hours. Typical values are the worst-case observed mean ±3-sigma drift during AEC-Q100 qualification from any of the -40°C, 25°C, or 150°C temperatures.

Coreless, High-Precision, Hall-Effect Current Sensor IC with Common-Mode Field Rejection, Overcurrent and Overtemperature Detection

FUNCTIONAL DESCRIPTION

Principle of Operation

When AC or DC current flows through a PCB copper trace or a busbar, as shown in Figure 8, the ACS37610 device senses the magnetic-field difference induced between its two Hall elements, H_L and H_R , represented by the field components B_L and B_R , respectively. The device output is proportional to the differential field sensed, B_{diff} , which is proportional to the applied current. The relationship between applied current and generated field is described as:

$B_{diff} = CF \times I$,

where B_{diff} is the differential field $(H_L - H_R)$, CF is the differential coupling factor (G/A), and I is the current through the busbar/ PCB trace. As demonstrated in this equation, the differential coupling factor (CF) is the linear relationship between the differential field sensed and the current flowing in the conductor. Different busbar shapes can be used to best answer application requirements; for more details, see the Application Information section.

Figure 8: Current-Sensing Principle

Device Diagnostics

The ACS37610 device offers multiple built-in diagnostics with the effects and programmability described in Table 1.

Table 1: Device Diagnostics Table

Diagnostic	Effect on V _{OUT}	Effect on FAULT	Note
Overvoltage Detection	If V_{CC} exceeds V_{OVDE} for more than t_{OVDE} (64 µs typical), V_{OUT} goes to the high-impedance state.	FAULT remains in the high-impedance state (or goes to high-impedance in case of FAULT pin asserted), pulledup to $V_{F(PULLUP)}$.	NOTE 1: When V_{OUT} goes to the high- impedance state, the voltage on V_{OUT} is pulled down to GND or pulled up to V_{CC} , depending on the application wiring. If the COM_LOCK bit is set, the OVD feature is disabled.
Undervoltage Detection	If V_{CC} drops below V_{UVLOE} for more than t_{UVLOE} (64 µs typical), V_{OUT} is pulled to GND. if V_{CC} drops farther below V_{PORL} , V_{OUT} goes to the high- impedance state.	FAULT remains in the high-impedance state (or goes to high-impedance in case of FAULT pin asserted), pulledup to $V_{F(PULLUP)}$.	See NOTE 1.
Broken Wire	V _{OUT} goes to the high- impedance state.	FAULT remains in the high-impedance state (or goes to high-impedance in case of FAULT pin asserted), pulledup to $V_{F(PULLUP)}$.	See NOTE 1.
Overcurrent	No effect.	FAULT pin is pulled to GND.	Overcurrent threshold is programmable and can be enabled/disabled in EEPROM.
Overtemperature	No effect.	FAULT pin is pulled to GND.	Overtemperature threshold is programmable and can be enabled/disabled in EEPROM.
Clamps	V_{OUT} can range from $V_{CLP(Low)}$ to $V_{CLP(High)}$	No effect.	Clamps can be enabled/disabled in EEPROM.
EEPROM Error Checking and Correction	If an uncorrectable error occurrs in EEPROM, V _{OUT} goes to a high-impedance state.	FAULT goes to a high-impedance state.	See NOTE 1.

Broken-Wire Detection

If the GND pin is disconnected, such that node A becomes open (Figure 9), the VOUT pin and FAULT pin go to a high-impedance state. If load resistor $R_{L(PULLUP)}$ is connected to VCC, the output voltage goes to $V_{BRK(HIGH)}$; if load resistor $R_{L(PULLDOWN)}$ is connected to GND, the output voltage goes to $V_{BRK(LOW)}$.

If the VCC pin is disconnected, such that node B becomes open (Figure 9), the VOUT pin and FAULT pin go to a high-impedance state. If load resistor $R_{L(PULLDOWN)}$ is connected to GND, the output voltage goes to $V_{BRK(LOW)}$.

Detection for broken VCC can only be guaranteed when a pulldown resistor is used.

Following a broken-wire event, the device does not respond to any applied magnetic field. If load resistor $R_{F(PULLUP)}$ is connected to the FAULT pin, the fault voltage goes to the $V_{F(PULLUP)}$ voltage.

If the disconnected wire is reconnected, the device resumes typical operation.

Figure 9: Connection for Detecting Broken Ground Wire

Coreless, High-Precision, Hall-Effect Current Sensor IC with Common-Mode Field Rejection, Overcurrent and Overtemperature Detection

DEVICE PROGRAMMING

- The serial interface uses Manchester protocol to communicate.
- Device programming can be achieved with bidirectional communication on VOUT or on the dedicated PROG pin.
- The device has an internal charge pump to generate the EEPROM pulses.
- When not used, the PROG pin can be left unconnected or tied to GND or VCC.

Serial Communication

The serial interface allows an external controller to read from and write to registers, including EEPROM, in the device using a point-to-point command/acknowledge protocol. The device does not initiate communication; it only responds to commands from the external controller. Each transaction consists of a command from the controller. If the command is a write, there is no acknowledgement from the device. If the command is a read, the device responds by transmitting the requested data. Two modes are available for device communication.

Mode 1, Programming on VOUT pin (see Figure 10): To enable bidirectional programming on VOUT, voltage is raised on V_{CC} (V_{OVDE}) for at least t_{OVDE} , followed by the access code on VOUT. If the COM_LOCK bit is set (value = 1), bidirectional programming on VOUT is disabled. If the COM_LOCK bit is not set (value = 0), there is no timeout limit to send the access code as long as V_{CC} stays above V_{OVDE} for at least t_{OVDE} . To ensure a reset of the Manchester state machine occurs, the start of any Manchester command should begin by holding the output low for t_{BIT} . If an incorrect access code is sent, VOUT remains in the typical analog mode (responds to magnetic stimulus) and the device remains locked for communication on VOUT until a power reset occurs.

To ensure safe EEPROM writing, when writing to nonvolatile memory (EEPROM), V_{CC} must not exceed 5 V. To achieve this, two methods can be used:

Method 1 (to write to EEPROM in Mode 1):

Locks VOUT into communication mode such that VCC can be returned to the typical supply voltage (5 V/3.3 V):

- 1. Set V_{CC} to V_{OVDE} (OVD)
- 2. Send access code + COMM_EN
- 3. Set V_{CC} back to typical level (5 V/3.3 V)
- 4. Send EEPROM write commands
- 5. Power-cycle the device to re-enable analog output on VOUT

Method 2 (to write to EEPROM in Mode 1):

Reduces VCC back to typical supply voltage (5 V/3.3 V) after sending the EEPROM write sequence:

- 1. Set V_{CC} to V_{OVDE} (OVD)
- 2. Send access code
- 3. Send EEPROM write commands
- 4. Set V_{CC} to typical level (5 V/3.3 V)
- 5. Wait 20 ms for EEPROM write

With method 2, the PROG pin must not be connected to GND (can be left floating or can be connected to VCC).

For more details, see the Access section and the figures in the Manchester Protocol section. When not used, it is recommended to tie the PROG pin to VCC (for the broken-GND feature).

Figure 10: Programming Connection—Mode 1

Mode 2, Programming on PROG Pin (see Figure 11):

 V_{CC} remains 5 V (below V_{OVDE}), and bidirectional programming is achieved on the PROG pin by sending an access code (independently of the COM_LOCK value). No pull-up is required on the PROG pin.

Coreless, High-Precision, Hall-Effect Current Sensor IC with Common-Mode Field Rejection, Overcurrent and Overtemperature Detection

Manchester Protocol

The serial interface uses a Manchester-encoding-based protocol per G.E. Thomas (0 = rising edge, 1 = falling edge), with address and data transmitted MSB first. Four commands are recognized by the device: write access code, write to volatile memory, write to nonvolatile memory (EEPROM), and read. In response to a read command, one frame type, read acknowledge, is sent by the device.

Figure 12: General Format For Serial Interface Commands

Read (Controller to Device)

The fields for the read command are:

- Sync (2 bits, both set to 0)
- Read/Write (1 bit; must be set to 1 for read)
- CRC (3 bits)

The sequence for a read command is shown in Figure 13.

Figure 13: Read Sequence

Read Acknowledge (Device to Controller)

The fields for the data return frame are:

- Sync (2 bits, both set to 0)
- Data (32 bits):
 - □ [31:28] Not relevant
 - □ [27:26] ECC pass/fail
 - □ [25:0] Data

The read acknowledge sequence is shown in Figure 14. For instructions about how to detect read/write synchronize memory address data (32 bits) and ECC failure, refer to the Detecting ECC Error section.

Figure 14: Read Acknowledge Sequence

Write (Controller to Device)

The fields for the write command are:

- Sync (2 bits, both set to 0)
- Read/Write (1 bit; must be set to 0 for write)
- Address (6 bits)
- Data (32 bits):
 - □ [31:26] Not relevant
 - □ [25:0] Data
- CRC (3 bits)

The sequence for a write command is shown in Figure 15. Bits [31:26] are not relevant because the device automatically generates 6 ECC bits based on the content of bits [25:0]. These ECC bits are later stored in EEPROM at locations [31:26].

Figure 15: Write Sequence

Write Access Code (Controller to Device)

The fields for the access code command are:

- Sync (2 bits, both set to 0)
- Read/Write (1 bit; must be set to 0 for write)
- Address (6 bits)
- Data (32 bits)
- CRC (3 bits)

The sequence for an access code command is shown in Figure 16.

Figure 16: Write Access Code

The controller must open the serial communication with the device by sending an access code. To enable communication on the PROG pin, an access code can be sent at any time on the PROG pin. For VOUT communication, an OVD event must be sent followed by an access code on VOUT. The OVD event must be maintained during the first full transaction.

Register Address	Address(Hex)	Data(Hex)
Customer Access	0x31	0x2C413736
Customer Access + COM_ENABLE	0x31	0x2C413737

The LSB of the 32-bit customer access code is used to disable the output and leave the device in communication mode until a reset occurs. When the output is disabled, V_{CC} can be restored to a level inferior to V_{OVDE} without altering the Manchester communication and, thus, until a reset occurs.

Using the COM_LOCK bit

This bit prevents VOUT from changing state following an unwanted OVD event in the application. If the COM_LOCK bit is set, the OVD is disabled and the device can only be programmed using the PROG pin (communication mode 2).

WRITE_LOCK bit

This is the lock bit used after EEPROM has been programmed by the user. When the WRITE_LOCK bit is set to 1 and VCC is power-cycled, the ability to write to any EEPROM register is permanently disabled; writing to the volatile register is still possible.

EEPROM Error Checking and Correction (ECC)

Hamming code methodology is implemented for EEPROM checking and correction. The device has ECC enabled after power-up. The device always returns 32 bits. The message received from the controller is analyzed by the device EEPROM driver, and the ECC bits are added. The first 6 bits received from device to controller are dedicated to ECC.

The Manchester serial interface uses a 3-bit cyclic redundancy check (CRC) for data-bit error checking (sychronized bits are ignored during the check). The CRC algorithm is based on the polynomial $g(x) = x^3 + x + 1$ and is initialized to 111 when first powered up. Write commands written to the peripheral controller are checked against the embedded CRC field.

Detecting ECC Error

If an uncorrectable error has occurred, bits [27:26] are set to 10, the VOUT pin goes to a high-impedance state, and the device does not respond to the applied magnetic field.

Bits	Name	Description
31:28	_	No meaning
27:26	ECC	00 = No error 01 = Error detected and message corrected 10 = Uncorrectable error 11 = No meaning
25:0	Data [25:0]	EEPROM data

Quantity of Bits	Name	Values	Description
2	Synchronization	00	Used to identify the beginning of a serial interface command
1	Pood/M/rito	0	[As required] Write operation
	I Read/write		[As required] Read operation
6	Address	0/1 [Read/Write] Register address (volatile memory or EEPROM)	
32	32 Data 0/1		26 data bits and 6 ECC bits. For a read command frame, the data consists of 32 bits: [31:28] not relevant, [27:26] ECC pass/fail, and [25:0] data, where bit 0 is the LSB. For a write command frame, the data consists of 32 bits: [31:26] not relevant and [25:0] data, where bit 0 is the LSB.
3	CRC	0/1	Bits to check the validity of frame.

[2] Real programming range can exceed this range; programming sensitivity beyond ±20% of change from initial value causes V_{OUT(Q)TC} and ΔSens_{TC}

drift to deteriorate beyond the specified values.

Coreless, High-Precision, Hall-Effect Current Sensor IC with Common-Mode Field Rejection, Overcurrent and Overtemperature Detection

Lock Bits Mechanism (WRITE_LOCK/COM_LOCK)

The device has two lock bits to disable communication and EEPROM programming. The achieved behavior is summarized Table 3.

WRITE_LOCK	COM_LOCK	EEPROM Write	EEPROM Read
0	0	Yes: PROG pin or VOUT with OVD	Yes: PROG pin or VOUT with OVD
0	1	Yes: PROG pin	Yes: PROG pin
1	0	No	Yes: PROG pin or VOUT with OVD
1	1	No	Yes: PROG pin

Table 3: Lock Bit Mechanism

Programming Sensitivity (SENS_FINE) and Quiescent Voltage Output (QVO)

Sensitivity and $V_{OUT(Q)}$ can be adjusted by programming the SENS_FINE and QVO bits, as illustrated in Figure 28 and Figure 29. The SENS_FINE and QVO codes use a two's complement encoding to either reduce or increase sensitivity and $V_{OUT(Q)}$. Neither sensitivity nor $V_{OUT(Q)}$ should be programmed beyond the maximum or minimum programming ranges specified in the Operating Characteristics table. Exceeding the specified limits causes the sensitivity and $V_{OUT(Q)}$ drift over the temperature range (E_{Drift} and V_{OED}) to deteriorate beyond the specified values. Programming sensitivity might cause a small drift in $V_{OUT(Q)}$. As a result, it is recommended that sensitivity be programmed first, then $V_{OUT(Q)}$.

Figure 28: Sensitivity Trim Range

Figure 29: QVO Trim Range

Coreless, High-Precision, Hall-Effect Current Sensor IC with Common-Mode Field Rejection, Overcurrent and Overtemperature Detection

Polarity (POL)

The device output polarity (POL) bit is programmable to 1 (default) or 0; this allows output polarity to be reversed. The default polarity (POL = 1) corresponds to an increasing output from 2.5 to 4.5 V typical (0.5 to 4.5 V on unidirectional versions) when positive current flows from pin 1 to pin 4 (or from pin 8 to pin 5), as shown in Figure 30 and Figure 31.

NOTE: Changing device polarity from the initial programmed value can cause offset error $V_{OUT(Q)TC}$ to exceed specification limits.

Figure 30: Polarity Definition in Planar Configuration

Figure 31: Polarity Definition in Vertical Configuration

Positive Overcurrent Fault Threshold (OCF_P_THRES)

This sets the threshold for the overcurrent fault (OCF) when current induces a positive output response on VOUT (increasing V_{OUT} value from 2.5 to 4.5 V on 5 V bidirectional variant or 0.5 to 4.5 V for 5 V unidirectional variant); see Figure 32. Threshold can be set independently using the OCF_N_THRES bit and can be disabled in device memory by setting the OCF_P_DIS bit to 1.

Figure 32: Positive OCF Threshold

Negative Overcurrent Fault Threshold (OCF_N_THRES)

The negative overcurrent fault threshold (OCF_N_THRES) bit sets the threshold for the OCF when current induces a negative output response on VOUT (decreasing V_{OUT} value from 2.5 to 0.5 V for the 5 V bidirectional variant); see Figure 33. Threshold can be set independently from the OCF_P_THRES bit and can be disabled in device memory by setting the OCF_N_DIS bit to 1. The negative overcurrent fault threshold feature is only usable in the bidirectional variant.

Fault Latch (FAULT_LATCH)

When the FAULT_LATCH bit is set to 1, the device needs to be power-cycled to release the fault condition (following an overcurrent or overtemperature event). By default, this bit is set to 0 (disabled).

When the FAULT_LATCH bit is disabled, the device relies on the programmed hysteresis value to release the fault.

The fault output behavior following an overcurrent condition is shown in Figure 34. When the FAULT_LATCH bit is set to 1, the fault remains activated (low state) until the device is powercycled.

The fault output behavior following an overcurrent condition is shown in Figure 35. When the FAULT_LATCH bit is set to 0, the fault is released once the current has reduced below the overcurrent threshold hysteresis level (for positive OCF threshold, OCF_{PTHRES} minus OCF_{HYST} ; for negative OCF threshold, OCF_{NTHRES} minus OCF_{HYST}).

Coreless, High-Precision, Hall-Effect Current Sensor IC with Common-Mode Field Rejection, Overcurrent and Overtemperature Detection

Figure 34: Fault Behavior with FAULT_LATCH = 1

Figure 35: Fault Behavior with FAULT_LATCH = 0

Overcurrent Fault Qualifier (OCF_QUAL)

The overcurrent fault qualifier sets the amount of time the overcurrent condition must be detected before triggering the fault output. This acts as a filter on the fault condition to prevent incorrect triggering of the fault output in case of quick current spikes or ripples.

Overcurrent must exceed the specified threshold for the duration of the fault qualifier (OCF_{QUAL}) in order to be flagged, as shown in the example in Figure 36 and Figure 37.

This delay does not apply to the condition for releasing the fault. Once the hysteresis condition is fulfilled and $t_{C(F)}$ has elapsed, the fault is released.

OCF_QUAL range is described in Table 4.

Figure 36: Fault not triggered if current exceeds the OCF threshold for less than OCF_{QUAL}.

Figure 37: Fault triggered when current exceeds the OCF threshold for more than OCF_{QUAL}; the fault is then released when current is below the hysteresis level

Table 4: Overcurrent Fault Qualifier

Setting	Typ. Added Delay	Typ. Delay to Fault	Units
0	0	2.5	μs
1	0.4	2.9	μs
2	2.2	4.7	μs
3	4.2	6.7	μs
4	6.2	8.7	μs
5	8.2	10.7	μs
6	10.3	12.8	μs
7	12.7	15.2	μs

Overcurrent Fault Hysteresis (OCF_HYST)

The overcurrent fault hysteresis bit (OCF_HYST) sets the hysteresis value applied to the OCF threshold such that, once triggered, the current must return below the hysteresis level to release the fault output. This feature prevents chattering of the FAULT pin due to noise.

The hysteresis principle is shown in Figure 38; e.g.,

 $OCF_{PTHRES} = 110\%$, where $OCF_{HYST} = 12.5\%$ corresponds to a fault trip point at 110% (2.2 V output sweep if $V_{CC} = 5$ V) and a release point at 97.5% (1.95 V output sweep if $V_{CC} = 5$ V).

Programming values of the OCF_HYST bit are shown in Table 5.

Figure 38: Hysteresis Effect on Fault

 Table 5: Overcurrent Fault Hysteresis

Setting	Typ. Value ^[1]	Units
0	11	%
1	22	%
2	42	%
3	75	%

^[1] Hysteresis value cannot be greater than the minimum OCF threshold specified minus 25%; e.g., if OCF_P is set at 50%, the maximum hysteresis value is 50 - 25 = 25%, such that OCF_HYST = 2 or 3 results in a maximum hysteresis value of 25%.

Temperature Output (TEMP_OUT)

This feature allows reading of the device temperature stored as a 12-bit digital value.

The following formula can be used to convert the digital temperature value into the ambient temperature in degree Celsius:

$$Temp_{AMBIENT}$$
 [°C] = ($TEMP_{OUT} - 2200$)/13.5 + 25

NOTE: Due to device self-heating, the temperature reaches 90% of its steady state approximately 10 seconds after power-on.

Temperature accuracy is indicated in the Fault Characteristics section and is guaranteed by characterization only.

Coreless, High-Precision, Hall-Effect Current Sensor IC with Common-Mode Field Rejection, Overcurrent and Overtemperature Detection

^[1] Shadow registers are volatile memory; upon startup, device loads EEPROM memory into shadow registers. Shadow registers can be used to test different programming options without erasing EEPROM (e.g., finding sensitivity and QVO codes before writing into EEPROM).

Coreless, High-Precision, Hall-Effect Current Sensor IC with Common-Mode Field Rejection, Overcurrent and Overtemperature Detection

DEFINITIONS OF ACCURACY CHARACTERISTICS

SENSITIVITY (Sens)

The amount of the output voltage increase is proportional to the magnitude of the magnetic field applied. This proportionality is specified as the magnetic sensitivity, Sens (mv/G), of the device, and it is defined as:

$$Sens = \frac{V_{\text{OUT}(B1)} - V_{\text{OUT}(B2)}}{B1 - B2}$$

where B1 and B2 are two different magnetic field levels.

SENSITIVITY ERROR

The sensitivity error is the percent difference between the measured sensitivity and the ideal sensitivity. For example, in the case of $V_{CC} = 5$ V:

$$E_{\text{Sens}} = \frac{Sens_{\text{Meas}(5V)} - Sens_{\text{Ideal}(5V)}}{Sens_{\text{Ideal}(5V)}} \times 100 \,(\%)$$

NONLINEARITY (ELIN)

Nonlinearity is a measure of how linear the output of the sensor IC is over the full current measurement range. The nonlinearity is calculated as:

$$E_{\text{LIN}} = \left\{ 1 - \left[\frac{Sens_{\text{BPRMax}}}{Sens_{\text{BPRHalf}}} \right] \right\} \times 100 \ (\%)$$

where $Sens_{BPRMax}$ is the sensitivity measured at the full range output level, and $Sens_{BPRHalf}$ is the sensitivity measured at half of the full range output level.

RATIOMETRY

The device features a ratiometric output. This means that the quiescent voltage output, $V_{OUT(Q)}$, and the magnetic sensitivity, Sens, are proportional to the supply voltage, V_{CC} .

The ratiometric change in the quiescent voltage output is defined as:

$$V_{\text{RatERRQVO}} = \left[\left(V_{\text{OUTQ(5V)}} \times \frac{V_{\text{CC}}}{5 \text{ V}} \right) - V_{\text{OUTQ(VCC)}} \right] \times 1000 \text{ (mV)}$$

The ratiometric change (%) in sensitivity is defined as:

$$Rat_{ERRSens} = \left[1 - \frac{\left(\frac{Sens_{(VCC)}}{Sens_{(5V)}}\right)}{\left(\frac{V_{CC}}{5V}\right)}\right] \times 100 \,(\%)$$

QUIESCENT OUTPUT VOLTAGE—QVO (ZERO FIELD OUTPUT VOLTAGE)

The quiescent output voltage is the output of the sensor when the sensed differential field is zero (in typical applications when no current is flowing in the busbar/PCB). It nominally remains at $0.5 \times V_{CC}$ for a bidirectional device and $0.1 \times V_{CC}$ for a unidirectional device. For example, in the case of a bidirectional output device, $V_{CC} = 5$ V translates into $V_{OUT(Q)} = 2.5$ V. Variation in $V_{OUT(Q)}$ can be attributed to the resolution of the Allegro linear IC quiescent voltage trim and thermal drift.

ACS37610H Coreless, High-Precision, Hall-Effect Current Sensor IC with Common-Mode Field Rejection, Overcurrent and Overtemperature Detection

POWER-ON RESET VOLTAGE (VPOR)

On power-up, to initialize to a known state and avoid current spikes, the device is held in the reset state. The reset signal is disabled when V_{CC} reaches V_{PORH} and time t_{PORR} has elapsed, allowing the output voltage to go from a high-impedance state into typical operation. After t_{PORR} , the output remains in a high-impedance state until V_{CC} exceeds V_{UVLOD} for more than t_{UVLOD} . During power-down, the reset signal is enabled when V_{CC} reaches V_{PORL} , causing the output voltage to go into a high-impedance state.

POWER-ON RESET RELEASE TIME (t_{PORR})

When V_{CC} rises to V_{PORH} , the power-on reset counter starts. The device output voltage transitions from a high-impedance state to typical operation only when the power-on reset counter has reached t_{PORR} and V_{CC} has been maintained above V_{PORH} .

OVERVOLTAGE DETECTION (V_{OVD})

When V_{CC} is raised above the overvoltage detection enable voltage (V_{OVDE}), the ACS37610 output stage enters a highimpedance state. With pull-up R_{L} , V_{OUT} floats to V_{CC} ; with pulldown R_{L} , V_{OUT} floats to GND when (V_{OVDE}) is reached. When programming the ACS37610 using V_{OUT} (Mode 1), overvoltage detection must be active for communication. The device output resumes typical operation after V_{CC} is below the overvoltage detection disable voltage (V_{OVDD}).

If the COM_LOCK bit is set, overvoltage detection is disabled and the device output does not respond to the overvoltage condition. NOTE: Supply voltage limits still apply for operating characteristics. Following an overvoltage condition, the supply voltage should not exceed 7.5 V for more than 1 minute. For more details, refer to the Overvoltage Detection section.

OUTPUT SATURATION VOLTAGE (V_{SAT})

When output voltage clamps are disabled, the output voltage can swing to a maximum of $V_{SAT(HIGH)}$ and to a minimum of $V_{SAT(LOW)}.$

BROKEN-WIRE VOLTAGE (VBRK)

If the GND pin is disconnected (broken wire event), output voltage goes to $V_{BRK(HIGH)}$ (if a load resistor is connected to VCC) or to $V_{BRK(LOW)}$ (if a load resistor is connected to GND).

UNDERVOLTAGE DETECTION (VUVLO)

When V_{CC} reduces below the undervoltage detection enable voltage (V_{UVLOE}), the ACS37610 output stage reduces beyond the clamp or saturation voltage—almost to GND. Once V_{CC} exceeds the undervoltage detection disable voltage (V_{UVLOD}), the device output resumes typical operation.

Undervoltage detection is only active on the 5 V variant.

For more details, refer to the Undervoltage Detection section

LOW-POWER MODE

The device is available in a low-power-mode variant, where the current drawn by the IC is reduced through factory programing. In this variant, the output noise is increased by \sim 30% compared to the full-power-mode variant.

ACS37610H Coreless, High-Precision, Hall-Effect Current Sensor IC with Common-Mode Field Rejection, Overcurrent and Overtemperature Detection

DEFINITIONS OF DYNAMIC RESPONSE CHARACTERISTICS

Power-On Time (t_{PO}). When the supply is ramped to its operating voltage, the device requires a finite time to power its internal components before responding to an input magnetic field. Poweron time, t_{PO} , is defined as the time it takes for the output voltage to settle within $\pm 10\%$ of its steady-state value under an applied magnetic field, after the power supply has reached its minimum specified operating voltage, $V_{CC}(min)$, as shown in Figure 39.

Temperature Compensation Power-On Time (t_{TC}). After the power-on time (t_{PO}) has elapsed, t_{TC} is also required before there can be a valid temperature-compensated output.

Response Time (t_{RESPONSE}). The time interval between a) when the sensed current reaches 90% of its final value, and b) when the sensor output reaches 90% of its full-scale value, as shown in Figure 41.

Rise Time (t_r). The time interval between a) when the sensor reaches 10% of its full-scale value, and b) when it reaches 90% of its full-scale value, as shown in Figure 40.

Propagation Delay (t_{pd}). The time interval between a) when the sensed current reaches 20% of its full-scale value, and b) when the sensor output reaches 20% of its full-scale value, as shown in Figure 40.

Delay to Clamp (t_{CLP}). A large magnetic input step may cause the clamp to overshoot its steady-state value. The delay-to-clamp time, t_{CLP} , is defined as: the time it takes for the output voltage to settle within $\pm 1\%$ of the clamp voltage dynamic range, after initially passing through its steady-state voltage, as shown in Figure 42.

Figure 42: Delay to Clamp

Figure 40: Propagation Delay (t_{PD}) and Rise Time (t_r)

POWER-ON RESET, UNDERVOLTAGE, AND OVERVOLTAGE DETECTION OPERATION

The descriptions in this section assume: temperature = 25° C, no output load (R_L, C_L), and no significant magnetic field is present.

Power-Up. At power-up, as V_{CC} ramps up, the output is in a high-impedance state. When V_{CC} crosses V_{PORH} (location [1] in Figure 43 and [1'] in Figure 44), the POR release counter starts counting for t_{PORR} . At this point, if V_{CC} exceeds V_{UVLOD} [2'], the output goes to $V_{CC}/2$ after t_{UVLOD} [3'].

If V_{CC} does not exceed V_{UVLOD} [2], the output remains in the high-impedance state until V_{CC} reaches V_{UVLOD} [3], then goes to $V_{CC}/2$ after t_{UVLOD} [4].

 V_{CC} drops below V_{CC} (min) = 4.5 V. If V_{CC} drops below V_{UVLOE} [4', 5], the UVLO enable counter starts counting. If V_{CC} is still below V_{UVLOE} when the counter reaches t_{UVLOE} , the UVLO function is enabled and the output is pulled near GND [6]. If V_{CC} exceeds V_{UVLOE} before the UVLO enable counter reaches t_{UVLOE} [5'], the output continues to be $V_{CC}/2$.

Coming out of UVLO. If V_{CC} exceeds V_{UVLOD} [7] while UVLO is enabled [6], UVLO becomes disabled after t_{UVLOD} and the output becomes $V_{CC}/2$ [8].

Power-Down. As V_{CC} ramps down below V_{UVLOE} [6', 9], the UVLO enable counter starts counting. If V_{CC} is higher than V_{PORL} when the counter reaches t_{UVLOE} , the UVLO function becomes enabled and the output becomes pulled near GND [10]. The output enters a high-impedance state as V_{CC} goes below V_{PORL} [11]. If V_{CC} falls below V_{PORL} before the UVLO enable counter reaches t_{UVLOE} , the output transitions directly into a high-impedance state [7'].

Overvoltage. If V_{CC} rises above V_{OVDE} , the OVD enable counter starts counting. If the internal pull-up mode is used, the fault pull-up voltage follows V_{CC} ; otherwise, it remains at the V_F level. If V_{CC} continues to exceed V_{OVDE} when the counter reaches t_{OVDE} , the OVD function is enabled and the output goes into a high-impedance state. Upon entering a high-impedance state, the FAULT pin becomes disabled.

Coming Out of OVD. While OVD is enabled, if V_{CC} drops below V_{OVDD} , OVD becomes disabled after t_{OVDD} , and the output returns to typical operation in analog mode $V_{CC}/2$. The FAULT pin becomes active and returns to typical operation.

Coreless, High-Precision, Hall-Effect Current Sensor IC with Common-Mode Field Rejection, Overcurrent and Overtemperature Detection

Power-On Reset (POR); Undervoltage Lockout (UVLO) Disabled— Nominal Supply Voltage = 3.3 V

Power-Up

At power-up, as V_{CC} ramps up, the output is in a high-impedance state. When V_{CC} crosses V_{PORH} (location [1] in Figure 45 and [1'] in Figure 46), the POR release counter starts counting for t_{PORR} [2], [2'], and the output goes to $V_{CC}/2$ after t_{PORD} [3], [3']. The temperature-compensation engine then adjusts the device sensitivity and QVO after time t_{TC} [4], [4'].

V_{CC} drops below $V_{CC}(min) = 3 V$

If V_{CC} drops below V_{PORH} [5'] but remains higher than V_{PORL} [6'], the output continues to be $V_{CC}/2$.

Power-Down

As V_{CC} ramps down below V_{PORL} [5],[7'], the output enters a high-impedance state.

APPLICATION INFORMATION

Typical Application—Busbar Current Sensing

Figure 47: Busbar Current-Sensing Application—Reference Busbar Design with Notch

The ACS37610 is ideal for busbar current-sensing applications. For a given current flowing through the busbar, the magnitude of the differential magnetic field sensed by the IC depends on the air gap between the busbar and the IC. Adding a notch (width reduction) to the busbar at the location where the sensor is placed significantly increases the magnitude of the magnetic field, improving SNR.

Keeping the notch length short (2 to 3 mm) results in virtually no increase in the resistance of the busbar or degradation of its thermal performance.

Different busbar and notch dimensions can be used to optimize system performance and respond to application constraints. The dimensions of an Allegro evaluation board designed to measure ± 1000 A are highlighted in Figure 47 and Table 6.

NOTE: Comparing the busbar described in Figure 47 to a bare busbar (without notch), the busbar with the 3 mm notch increases the overall impedance by less than 10 $\mu\Omega$, increasing busbar temperature by only few degrees during testing.

Skin-Effect Consideration

Skin effect in the conductor tends to reduce the magnitude of the differential magnetic field measured by the IC at high frequencies (coupling factor) and therefore influences the bandwidth of the system and the response time to transient current.

Skin effect depends on busbar dimensions, sensor mounting orientation, and distance between the busbar and the IC.

Table 6: Current Range Based on Reference Busbar Design

Busbar Application	Cross Section	Notch Cross	Max. Current ^[2]	Coupling Factor ^[1]	Diff. Field ^[1]	IC Sensitivity ^[1]
	[mm ²]	Section [mm ²]	[A]	[G/A]	[G]	[mV/G]
16 × 4 mm Busbar + 4.5 mm Notch	64	18	±1100	0.17	±200	10

^[1] Considering a distance from Hall elements to busbar of 3 mm.

^[2] Full-scale current is required to cover the full-scale output range (bidirectional = ± 2 V).

ACS37610H Coreless, High-Precision, Hall-Effect Current Sensor IC with Common-Mode Field Rejection, Overcurrent and Overtemperature Detection

Multiple Busbar Design Options

The ACS37610 offers many different mounting possibilities, addressing different needs (bandwidth, mounting tolerances, and crosstalk). Different mounting options are shown in Figure 48 through Figure 51.

Figure 48: Rift Busbar Design

High mounting tolerances, medium coupling factor, high skin effect. For DC to low-frequency AC applications <1 kHz.

Figure 50: Dual Vertical-Slit Busbar Design High mounting tolerances, high coupling factor, low skin effect. For DC to high-frequency AC applications >100 kHz. For application notes explaining the tradeoffs between different topologies, refer to Allegro's website (https://www.allegromicro. com).

Figure 49: Slit Busbar Design

High mounting tolerances, medium coupling factor, medium skin effect. For DC to medium-frequency AC applications <100 kHz.

Figure 51: Vertical-Slit Busbar Design High mounting tolerances, high coupling factor, low skin effect. For DC to high-frequency AC applications >100 kHz.

Coreless, High-Precision, Hall-Effect Current Sensor IC with Common-Mode Field Rejection, Overcurrent and Overtemperature Detection

Figure 52: PCB Current-Sensing Application—Six-Layer Reference PCB Example

The ACS37610 can also be used in PCB applications where the current flows directly in the PCB instead of on a busbar.

Multiple copper layers can be used to carry the current. Reducing the width of the copper traces under the sensor (neck-down) increases the magnitude of the differential magnetic field measured by the IC.

Different copper layer dimensions and stack-ups can be used to optimize performance and are specific to the constraints of the application. For example, in higher-voltage applications, the top layer is only used for signal routing in order to use the PCB replaced by dielectric layer for isolation.

The dimensions of three Allegro evaluation boards designed to measure a wide current range are highlighted in Figure 52 and Table 7.

Care must be taken when routing the device signal to prevent noise coupling to the supply or output lines.

The power plane in the neck-down area should also be avoided to prevent disturbing the magnetic field measured.

Skin Effect Consideration

Skin effect in the PCB current-carrying traces tends to reduce the differential magnetic field measured by the IC at high frequencies (coupling factor) and therefore influences the bandwidth of the system and the response time to transient current.

The skin effect is generally limited in PCB applications due to the thinness of the copper-layer; however, the effect depends on the PCB copper trace dimensions, number of layers, and layer thickness.

Table 7: Current range based on reference PCB design:

PCB Application ^[1]	Maximum Current (A) [2]	Coupling Factor (G/A) [1]	Differential Field (G) [1]	IC Sensitivity (mV/G) [1]
8 Lovera Reference Designs [3]	±100	0.9	±90	22.2
8 Layers—Reference Designs [3]	±200	0.9	±180	11.1

^[1] Typical values, not including device placement and PCB manufacturing tolerances.

^[3] Maximum continuous current without proper cooling on this Allegro evaluation PCB design should not exceed 150 A.

^[2] Full-scale current required to serve the full-scale output range (bidirectional = ± 2 V).

Coreless, High-Precision, Hall-Effect Current Sensor IC with Common-Mode Field Rejection, Overcurrent and Overtemperature Detection

Revision History

Number	Date	Description
-	August 16, 2023	Initial release
1	February 6, 2024	Aligned EEPROM programmable parameters table (page 20) with memory map table (page 26: SNS_FINE changed to SENS_FINE, FAULTPUP_DIS changed to FAULTR_DIS, FAULT_LAT changed to FAULT_LATCH, and OTF_THRES changed to OTF_THRESH), corrected hysteresis principle example (page 25), corrected active area depth (page 35), and made minor editorial corrections throughout.
2	October 14, 2024	Added footnote to output voltage clamp characteristic (page 9); corrected effects described in Device Diagnostic Table (page 13); and corrected X-axis name in QVO range figure (Figure 29) from "SENS_FINE code" to "QVO_FINE code" (page 21).
