

CAR2548DC series dc - dc converter

Input: $-36V_{dc}$ to $-75V_{dc}$; Output: $48V_{dc}$ @ 2500W; $3.3V_{dc}$ or $5V_{dc}$ @ 1A

RoHS Compliant

Description

The CAR2548DC series of DC-DC Converters provide highly efficient isolated power from DC input mains in a compact 1U industry standard form factor in an unprecedented power density of $27W/in^3$. These converters complement the CAR2548FP rectifier providing comprehensive solutions for systems connected either to commercial ac mains, $48/60V_{dc}$ power plants or telecom central offices. This plug and play approach offers significant advantages since systems can be reconfigured and repositioned

readily by simply replacing the power supply. The high-density, front-to-back airflow is designed for minimal space utilization and is highly expandable for future growth. The industry standard PMBus compliant I²C communications buss offers a full range of control and monitoring capabilities. The SMBus Alert signal pin alerts customers automatically of any state change within the power supply.

Applications

- $48V_{dc}$ distributed power architectures
- Cellular Base Stations
- Satellite Hubs
- Network Equipment
- Network Attached Storage
- Telecom Access Nodes
- Routers/Switches/ATE Equipment

Features

- 3 front panel LEDs: 1-input; 2-output; 3 - fault
- Output programmable from $43.2 - 56V_{dc}$
- Remote ON/OFF control of the $48V_{dc}$ output
- Remote sense (up to $0.25V$) on the $48V_{dc}$ output
- No minimum load requirements
- Redundant parallel operation
- Active load sharing (single wire)
- Efficiency: typically 91%
- Standby orderable either as $3.3V_{dc}$ or $5V_{dc}$
- Auto recoverable OC & OT protection
- Operating temperature: $-10 - 70^{\circ}C$ (de-rated above $50^{\circ}C$)
- Digital status & control: I²C and PMBus serial bus
- EN/IEC/UL62368-1 2nd edition; UL, CSA and VDE
- EMI: class B FCC docket 20780 part 15, EN55032
- Meets EN6100 immunity and transient standards
- Shock & vibration: NEBS GR-63-CORE, level 3
- Compliant to RoHS Directive 2011/65/EU and amended Directive (EU) 2015/863.
- Compliant to REACH Directive (EC) No 1907/2006

See Footnote on Page 16

Technical Specifications

Absolute Maximum Ratings

Stresses in excess of the absolute maximum ratings can cause permanent damage to the device. These are absolute stress ratings only, functional operation of the device is not implied at these or any other conditions in excess of those given in the operations sections of the data sheet. Exposure to absolute maximum ratings for extended periods can adversely affect the device reliability.

Parameter	Symbol	Min	Max	Unit
Input Voltage :Continues	V_{IN}	0	264	V_{AC}
Operating Ambient Temperature	T_A	-10	70 ¹	°C
Storage Temperature	T_{stg}	-40	85	°C

Technical Specifications (continued)

Control and Status

Control hierarchy: Some features, such as output voltage, can be controlled both through hardware and firmware. For example, the output voltage is controlled both by the signal pin (V_{prog}) and the PMBus command, ($V_{out_command}$).

Using output voltage as an example; the V_{prog} signal pin has ultimate control of the output voltage until the V_{prog} is either $> 3V_{dc}$ or a no connect. When the programming signal via V_{prog} is either a no connect or $> 3V_{dc}$, it is ignored, the output voltage is set at its nominal $12V_{dc}$ and the unit output voltage can be controlled via the PMBus command, ($V_{out_command}$).

Analog controls: Details of analog controls are provided in this data sheet under Signal Definitions.

Common ground: All signals and outputs are referenced to Output return. These include 'Vstb return' and 'Signal return'.

Control Signals

Voltage programming (V_{prog}): An analog voltage on this signal can vary the output voltage from $43.2V_{dc}$ to $56V_{dc}$. The equation of this signal is:

$$V_{out} = 42.67 + (V_{prog} * 5.33) \text{ where } V_{prog} = 0.1 \text{ to } 2.5V$$

For $V_{prog} > 2.5V$ the output reverts back to $48V_{dc}$.

Load share (I_{share}): This is a single wire analog signal that is generated and acted upon automatically by power supplies connected in parallel. The I_{share} pins should be tied together for power supplies if active current share among the power supplies is desired. No resistors or capacitors should get connected to this pin.

Able to current share with CAR2548FP rectifiers.

Remote_ON/OFF: Controls presence of the $48V_{dc}$ output voltage. This is an open collector, TTL level control signal that needs to be pulled HI externally through a resistor.

A turn OFF command either through this signal (Remote ON/OFF) or firmware commanded would turn OFF the $48V$ output.

Enable: This is a short signal pin that controls the presence of the $48V_{dc}$ main output. This pin should be connected to 'output return' on the system side of the output connector. The purpose of this pin is to ensure that the output turns ON after engagement of the power blades and turns OFF prior to disengagement of the power blades.

Write protect (WP): This signal protects the contents of the EEPROM from accidental over writing. When left open the EEPROM is write protected. A LO (TTL compatible) permits writing to the EEPROM. This signal is pulled HI internally by the power supply.

Status signals

Output current monitor (Imon): A voltage level proportional to the delivered output current is present on this pin. The signal level is $0.1V$ per amp $\pm 0.25V$.

Input_OK: A TTL compatible status signal representing whether the input voltage is within the anticipated range. This signal needs to be pulled HI externally through a resistor.

DC_OK: A TTL compatible status signal representing whether the output voltage is present. This signal needs to be pulled HI externally through a resistor.

Over_temp_warning: A TTL compatible status signal representing whether an over temperature exists. This signal needs to be pulled HI externally through a resistor.

If an over temperature should occur, this signal would pull LO approximately 10 seconds prior to shutting down the power supply. The unit would restart if internal temperatures recover within normal operational levels. At that time the signal reverts back to its open collector (HI) state.

Fault: A TTL compatible status signal representing whether a Fault occurred. This signal needs to be pulled HI externally through a resistor.

This signal activates for OTP, OVP, OCP, INPUT fault or No output.

PS_Present: This pin is connected to 'output return' within the power supply. Its intent is to indicate to the system that a power supply is present. This signal may need to be pulled HI externally through a resistor.

Interrupt (SMBAlert): A TTL compatible status signal, representing the SMBusAlert# feature of the PMBus compatible i²C protocol in the power supply. This signal needs to be pulled HI externally through a resistor.

Technical Specifications (continued)

Serial Bus Communications

The I²C interface facilitates the monitoring and control of various operating parameters within the unit and transmits these on demand over an industry standard I²C Serial bus.

All signals are referenced to 'Signal Return'.

Device addressing: The microcontroller (MCU) and the EEPROM have the following addresses:

Device	Address	Address Bit Assignments (Most to Least Significant)							
MCU	0xBx	1	0	1	1	A2	A1	A0	R/W
Broadcast	0x00	0	0	0	0	0	0	0	0
EEPROM	0xAx	1	0	1	0	A2	A1	A0	R/W

The Global Broadcast instruction executes a simultaneous **write** instruction to all power supplies. A **read** instruction cannot be accessed globally. The three programmable address bits are the same for all I²C accessible devices within the power supply.

Address lines (A2, A1, A0): These signal pins allow up to eight (8) modules to be addressed on a single I²C bus. The pins are pulled HI internal to the power supply. For a logic LO these pins should be connected to 'Output Return'

Serial Clock (SCL): The clock pulses on this line are generated by the host that initiates communications across the I²C Serial bus. This signal is pulled up internally to 3.3V by a 10k Ω resistor. The end user should add additional pull up resistance as necessary to ensure that rise and fall time timing and the maximum sink current is in compliance to the I²C specifications.

Serial Data (SDA): This line is a bi-directional data line. This signal is pulled up internally to 3.3V by a 10k Ω resistor. The end user should add additional pull up resistance as necessary to ensure that rise and fall time timing and the maximum sink current is in compliance to the I²C specifications.

Digital Feature Descriptions

PMBus™ compliance: The power supply is fully compliant to the Power Management Bus (PMBus™) rev1.2 requirements.

Manufacturer specific commands located between addresses 0xD0 to 0xEF provide instructions that either do not exist in the general PMBus specification or make the communication interface simpler and more efficient.

See Footnote on Page 16

Master/Slave: The 'host controller' is always the MASTER. Power supplies are always SLAVES. SLAVES cannot initiate communications or toggle the Clock. SLAVES also must respond expeditiously at the command of the MASTER as required by the clock pulses generated by the MASTER.

Clock stretching: The 'slave' μ Controller inside the power supply may initiate clock stretching if it is busy and it desires to delay the initiation of any further communications. During the clock stretch the 'slave' may keep the clock LO until it is ready to receive further instructions from the host controller. The maximum clock stretch interval is 25ms.

The host controller needs to recognize this clock stretching, and refrain from issuing the next clock signal, until the clock line is released, or it needs to delay the next clock pulse beyond the clock stretch interval of the power supply.

Note that clock stretching can only be performed after completion of transmission of the 9th ACK bit, the exception being the START command.

Figure 1. Example waveforms showing clock stretching.

I²C Bus Lock-Up detection: The device will abort any transaction and drop off the bus if it detects the bus being held low for more than 35ms.

Communications speed: Both 100kHz and 400kHz clock rates are supported. The power supplies default to the 100kHz clock rate. The minimum clock speed specified by SMBus is 10 kHz.

Technical Specifications (continued)

Digital Feature Descriptions (continued)

Packet Error Checking (PEC): Although the power supply will respond to commands with or without the trailing PEC, it is highly recommended that PEC be used in all communications. The integrity of communications is compromised if packet error correction is not employed. There are many functional features, including turning OFF the main output, that should require validation to ensure that the correct command is executed.

PEC is a CRC-8 error-checking byte, based on the polynomial $C(x) = x^8 + x^2 + x + 1$, in compliance with PMBus™ requirements. The calculation is based in all message bytes, including the originating write address and command bytes preceding read instructions. The PEC is appended to the message by the device that supplied the last byte.

SMBAlert#: The μ C driven SMBAlert# signal informs the 'master/host' controller that either a STATE or ALARM change has occurred. Normally this signal is HI. The signal will change to its LO level if the power supply has changed states and the signal will be latched LO until the power supply either receives a 'clear' instruction as outlined below or executes a READ STATUS_WORD. If the alarm state is still present after the STATUS registers were reset, then the signal will revert back into its LO state again and will latch until a subsequent reset signal is received from the host controller.

The signal will be triggered for any state change, including the following conditions;

- V_{IN} under or over voltage
- V_{OUT} under or over voltage
- I_{OUT} over current
- Over Temperature warning or fault
- Fan Failure
- Communication error
- PEC error
- Invalid command
- Detected internal faults

The power supply will clear the SMBAlert# signal (release the signal to its HI state) upon the following events:

- Receiving a CLEAR_FAULTS command
- The main output recycled (turned OFF and then ON) via the ENABLE signal pin
- The main output recycled (turned OFF and then ON) by the OPERATION command
- Execution of a READ of the STATUS_WORD register

See Footnote on Page 16

Global broadcast: This is a powerful command because it can instruct all power supplies to respond simultaneously in one command. But it does have a serious disadvantage. Only a single power supply needs to pull down the ninth acknowledge bit. To be certain that each power supply responded to the global instruction, a READ instruction should be executed to each power supply to verify that the command properly executed. The GLOBAL BROADCAST command should only be executed for write instructions to slave devices.

Read back delay: The power supply issues the SMBAlert # notification as soon as the first state change occurred. During an event a number of different states can be transitioned to before the final event occurs. If a read back is implemented rapidly by the host a successive SMBAlert# could be triggered by the transitioning state of the power supply. In order to avoid successive SMBAlert#s and read back and to avoid reading a transitioning state, it is prudent to wait more than 2 seconds after the receipt of an SMBAlert# before executing a read back. This delay will ensure that only the final state of the power supply is captured.

Successive read backs: Successive read backs to the power supply should not be attempted at intervals faster than every one second. This time interval is sufficient for the internal processors to update their data base so that successive reads provide fresh data.

PMBus™ Commands

Standard instruction: Up to two bytes of data may follow an instruction depending on the required data content. Analog data is always transmitted as LSB followed by MSB. PEC is optional and includes the address and data fields.

1	8	1	8	1
S	Slave address	Wr	A	Command Code

8	1	8	1	8	1	1
Low data byte	A	High data byte	A	PEC	A	P

Technical Specifications (continued)

PMBus™ Commands (continued)

□ Master to Slave □ Slave to Master

SMBUS annotations; S – Start, Wr – Write, Sr – re-Start, Rd – Read,

A – Acknowledge, NA – not-acknowledged, P – Stop

Standard READ: Up to two bytes of data may follow a READ request depending on the required data content. Analog data is always transmitted as LSB followed by MSB. PEC is mandatory and includes the address and data fields.

1	7	1	1	8	1
S	Slave address	Wr	A	Command Code	A

1	7	1	1	8	1
Sr	Slave address	Rd	A	LSB	A

8	1	8	1	1
MSB	A	PEC	No-ack	P

Block communications: When writing or reading more than two bytes of data at a time BLOCK instructions for WRITE and READ commands must be used instead of the Standard Instructions **Error!**
Reference source not found. write any number of bytes greater than two.

Block write format:

1	7	1	1	8	1
S	Slave address	Wr	A	Command Code	A

8	1	8	1	8	1
Byte count = N	A	Data 1	A	Data 2	A

8	1	8	1	8	1	1
.....	A	Data 48	A	PEC	A	P

Block read format:

1	7	1	1	8	1
S	Slave address	Wr	A	Command	A

1	7	1	1
Sr	Slave address	Rd	A

See Footnote on Page 16

8	1	8	1	8	1
Byte count = N	A	Data 1	A	Data 2	A

8	1	8	1	8	1	1
.....	A	Data 48	A	PEC	NoAck	P

Linear Data Format: The definition is identical to Part II of the PMBus Specification. All standard PMBus values, with the exception of output voltage related functions, are represented by the linear format described below. Output voltage functions are represented by a 16 bit mantissa. Output voltage has an E=9 constant exponent. The Linear Data Format is a two byte value with an 11-bit, two's complement mantissa and a 5-bit, two's complement exponent or scaling factor, its format is shown below.

Data Byte High									Data Byte Low								
Bit	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	
	Exponent (E)								Mantissa (M)								

The relationship between the Mantissa, Exponent, and Actual Value (V) is given by the following equation:

$V = M * 2^E$, where: V is the value, M is the 11-bit, 2's complement mantissa, E is the 5-bit, two's complement exponent

PMBus™ Command set:

Command	Hex Code	Data Byte	Function
Operation	01	1	Output ON/OFF
ON_OFF_config	02	1	09, output ON
Clear_faults	03	0	Clear Status
Write_protect	10	1	Write control

Command Descriptions

Operation (01) : By default the Power supply is turned **ON** at power up as long as Power ON/OFF signal pin is active HI. The Operation command is used to turn the Power Supply ON or OFF via the PMBus. The data byte below follows the OPERATION command.

FUNCTION	DATA BYTE
Unit ON	80
Unit OFF	00

To **RESET** the power supply, cycle the power supply OFF, wait at least 2 seconds, and then turn back ON. All alarms and shutdowns are cleared during a restart.

Clear_faults (03): This command clears all STATUS and FAULT registers and resets the SMBAlert# line.

If a fault still persists after the issuance of the clear_faults command the specific registers indicating the fault are reset and the SMBAlert# line is activated again.

WRITE_PROTECT register (10): Used to control writing to the PMBus device. The intent of this command is to provide protection against accidental changes. All supported command parameters may have their parameters read, regardless of the write_protect settings. The contents of this register can be stored to non-volatile memory using the Store_default_code command. The default setting of this register is disable_all_writes except write_protect 0x80h.

FUNCTION	DATA BYTE
Enable all writes	00
Disable all writes except write_protect	80
Disable all writes except write_protect and OPERATION	40

Vout_Command (21): This command is used to change the output voltage of the power supply. Changing the output voltage should be performed simultaneously to all power supplies operating in parallel using the Global Address (Broadcast) feature. If only a single power supply is instructed to change its output, it may attempt to source all the required power which can cause either a power limit or shutdown condition.

Software programming of output voltage permanently overrides the set point voltage configured by the **V_{prog}** signal pin. The program no longer looks at the '**V_{prog}** pin' and will not respond to any hardware voltage settings. If power is removed from the μ Controller it will reset itself into its default configuration looking at the **V_{prog}** signal for output voltage control. In many applications, the **V_{prog}** pin is used for setting initial conditions, if different than the factory setting. Software programming then takes over once I2C communications are established.

To properly hot-plug a power supply into a live backplane, the system generated voltage should get re-configured into either the factory adjusted firmware level, or the voltage level reconfigured by the margin pin. Otherwise, the voltage state of the plugged-in power supply could be significantly different than the powered system.

Technical Specifications (continued)

Command Descriptions (continued)

Vout_OV_warn_limit (42): OV_warning is extremely useful because it gives the system controller a heads up that the output voltage is drifting out of regulation and the power supply is close to shutting down. Pre-emptive action may be taken before the power supply would shut down and potentially disable the system.

OC and OT_fault_response (47, 50): The default response for both OC and OT is auto-restart (hiccup). Each register, individually, can be reconfigured into a latched state. Latched and hiccup are the only supported states.

Restart after a latch off: Either of four restart possibilities are available. The hardware pin **Remote ON/OFF** may be turned OFF and then ON. The unit may be commanded to restart via i2c through the Operation command by first turning OFF then turning ON. The third way to restart is to remove and reinsert the unit. The fourth way is to turn OFF and then turn ON AC power to the unit. The fifth way is by changing firmware from **latch off** to **restart**. Each of these commands must keep the power supply in the OFF state for at least 2 seconds, with the exception of changing to **restart**.

A power system that is comprised of a number of power supplies could have difficulty restarting after a shutdown event because of the non-synchronized behavior of the individual power supplies. Implementing the latch-off mechanism permits a synchronized restart that guarantees the simultaneous restart of the entire system.

A synchronous restart can be implemented by;

1. Issuing a GLOBAL OFF and then ON command to all power supplies,
2. Toggling Off and then ON the Remote ON/OFF signal
3. Removing and reapplying input commercial power to the entire system.

The power supplies should be turned OFF for at least 20 – 30 seconds in order to discharge all internal bias supplies and reset the soft start circuitry of the individual power supplies.

Auto_restart: Auto-restart is the default configuration for recovering from over-current and over-temperature shutdowns.

An overvoltage shutdown is followed by three attempted restarts, each restart delayed 1 second, within a 1 minute window. If within the 1 minute window three attempted restarts failed, the unit will latch OFF. If less than 3 shutdowns occur within the 1 minute window then the count for latch OFF resets and the 1 minute window starts all over again.

Vin_UV_warn_limit (58): This is another warning flag indicating that the input voltage is decreasing dangerously close to the low input voltage shutdown level.

Status_word (79): returns two bytes of information. The upper byte bit functionality is tabulated in the Status_word section. The lower byte bit functionality is identical to Status_byte.

Fan_speed (D7): This register can be used to 'read' the fan speed in adjustment percent (0 – 100%) or set the fan speed in adjustment percent (0 – 100%). The speed of the fan cannot be reduced below what the power supply requires for its operation. The register value is the percent number, it is not in linear format.

Invalid commands or data: The power supply notifies the MASTER if a non-supported command has been sent or invalid data has been received. Notification is implemented by setting the appropriate STATUS and ALARM registers and setting the SMBAlert# flag.

If a non-supported read is requested the power supply will return all 0x00h.

Restart after a lachoff: To restart after a latch_off either of four restart mechanisms are available. The hardware pin **Remote ON/OFF** may be turned OFF and then ON. The unit may be commanded to restart via i2c through the Operation command by first turning OFF then turning ON. The third way to restart is to remove and reinsert the unit. The fourth way is to turn OFF and then turn ON AC power to the unit. The fifth way is by changing firmware from **latch off** to **restart**. Each of these commands must keep the power supply in the OFF state for at least 2 seconds, with the exception of changing to **restart**.

A successful restart shall clear all alarm registers.

A power system that is comprised of a number of power supplies could have difficulty restarting after a shutdown event because of the non-synchronized behavior of the individual power supplies. Implementing the latch-off mechanism permits a synchronized restart that guarantees the simultaneous restart of the entire system.

See Footnote on Page 16

Technical Specifications (continued)

Command Descriptions (continued)

A synchronous restart can be implemented by;

1. Issuing a GLOBAL OFF and then ON command to all power supplies,
2. Toggling Off and then ON the **Remote ON/OFF** signal
3. Removing and reapplying input commercial power to the entire system.

It is good practice to turn OFF the power supplies for about 20 – 30 seconds in order to discharge all internal bias supplies and reset the soft start circuitry of the individual power supplies.

Control and Read accuracy:

The estimates below are believed to be reasonable under most operating conditions. However, these are typical numbers and not hard bound values that cannot be exceeded. In most nominal operating conditions, the returned values are significantly better than these estimates.

FUNCTION	ACCURACY
Vout_command	± 2%
Vout_OV_fault_limit	± 3%
Iout_OC_warn_limit	± 4% of FL
OT_warn_limit	± 5°C
Vin_UV_warn_limit	± 3%
Vin_UV_fault_limit	± 3%
Read_Vout	± 2%
Read_Iout	± 4% of FL
Read_temperature	± 5°C
Read_Pout	±5%

EEPROM

The microcontroller has 96 bytes of EEPROM memory available for the system host.

A separate EEPROM IC, with write protect features, provides another 128 bytes of memory. This EEPROM contains the following FRU_ID information:

EEPROM: model number, revision, date code, serial number etc.

Offset	Length	Value	Description
00	7		Serial number
07	1	20	ASCII space
08	4		Date code [YY, WW], ASCII
0C	1	20	ASCII space
0D	17		Model#, ASCII alphanumeric
1E	1	20	ASCII space
1F	1		Revision, ASCII value
20-FF	224	FF	

LEDs

Three LEDs are located on the front faceplate. When the LEDs are ON GREEN then input and output are normal.

When the FAULT_LED is RED then a fault condition exists, and the power supply may not provide output power. The table below further defines these states:

Alarm Table

Test Condition		LED Indicator				Monitoring Signals		
		INPUT OK	DC OK	FAULT	FAULT	DC OK	INPUT OK	TEMP OK
1	Normal Operation	Green	Green	OFF	High	High	High	High
2	Low or NO INPUT	OFF	OFF	Red	Low	Low	Low	High
3	OVP	Green	OFF	Red	Low	Low	High	High
4	Over Current	Green	OFF	Red	Low	Low	High	High
5	Over Temp Alarm	Green	Green	Red	Low	High	High	Low
6	Over Temp Fault	Green	OFF	Red	Low	Low	High	Low

Note: Test condition #2 has 2 modules working in parallel. One module is running and the other has no INPUT.
