

MAX20077 Evaluation Kit

Evaluates: MAX20077/MAX25277

General Description

The MAX20077 evaluation kit (EV kit) provides a proven design to evaluate the MAX20077/MAX25277 2.1MHz/400kHz high-voltage mini-buck converter in a 12-pin side-wettable TDFN package. All components are rated for the automotive temperature range. Various test points and jumpers are included for evaluation.

The standard EV kit comes with the MAX20077ATCA/VY+ installed (5V, 2.1MHz), but it can also be used to evaluate other MAX20077/MAX25277 variants with minimal component changes (e.g., IC replacement of U1).

Benefits and Features

- 3.5V to 36V Input Supply Range
- 5V or 3.3V Fixed Output Voltage, or Adjustable Between 1V and 10V
- Delivers Up to 2.5A Output Current
- Frequency-Synchronization Input
- Enable Input
- Voltage-Monitoring PGOOD Output
- Proven PCB Layout
- Fully Assembled and Tested

Quick Start

Required Equipment

- MAX20077 EV kit
- Power supply
- Voltmeter
- Electronic load

Procedure

The EV kit is fully assembled and tested. Follow the steps below to verify board operation:

- 1) Verify that all jumpers are in their default positions, as shown in [Table 1](#).
- 2) Connect the positive and negative terminals of the power supply to the SUP and GND test pads, respectively.
- 3) Connect the positive terminal of the voltmeter to OUT and the negative terminal to GND2.
- 4) Set the power supply to 14V and 2A current limit. Turn on the power supply.
- 5) With the PU and LED headers shorted, the green LED lights up. The voltmeter should display an output voltage of 5V.

[Ordering Information](#) appears at end of data sheet.

Table 1. Default Jumper Settings

JUMPER	SHUNT POSITION	FUNCTION
EN	ON-Middle	Buck controller enabled
SPS	Middle-OFF	Spread spectrum disabled
PU, LED	Installed	PGOOD is pulled up by V _{BIAS} when OUT is in regulation
SYNC	Middle-FPWM	Forced-PWM mode

Detailed Description

The MAX20077 EV kit provides a proven layout for evaluating all variants of the MAX20077/MAX25277 family of small, current-mode-controlled buck converter ICs. Each device accepts input voltages as high as 36V and delivers up to 2.5A. The EV kit can handle an input-supply transient up to 40V.

Switching Frequency and External Synchronization

The ICs can operate in two modes, forced-PWM or skip. Skip mode has better efficiency for light-load conditions. When SYNC is pulled low, the device operates in skip mode for light loads, and in PWM mode for larger loads. When SYNC is pulled high, the device is forced to operate in PWM across all load conditions.

SYNC can be used to synchronize with other supplies if a clock source is present. The device is forced to operate in PWM when SYNC is connected to a clock source.

Buck Output Monitoring (PGOOD)

The EV kit provides a power-good output test point (PGOOD) to monitor the status of the buck output (OUT). PGOOD is low impedance when the output voltage is in regulation. PGOOD is high impedance when the output voltage drops below 8% (typ) of its nominal regulated voltage.

To obtain a logic signal, pull up PGOOD to V_{BIAS} by installing shunts on jumpers PU and LED.

Evaluating Other Variants

The EV kit comes installed with the fixed-output, 5V/2.1MHz variant (MAX20077ATCA/VY+). The 2.1MHz and 400kHz

variants can be installed and tested with minimal component changes. For the 2.1MHz variants, install the appropriate IC on the EV kit (U1), while keeping all other components the same. For 400kHz parts, the inductor should be increased to 10μH, and the output capacitance must be a minimum 44μF after derating is accounted for. For MAX20077ATCE2 and MAX20077ATCD2 high-bandwidth parts, increase the output capacitance as per the guidelines in the IC datasheet.

The MAX20077ATCC/VY+ can be installed for output voltages between 1V and 3V (2.1MHz). The inductor should be set to 4.7μH, and the output capacitance must be a minimum 44μF after derating is accounted for. The output voltage must be externally adjusted.

Setting the Output Voltage in the Buck Converters

To externally adjust the output voltage, remove R1 and install a 0Ω resistor on R4. Place appropriate resistors in positions R5 and R6 according to the following equation:

$$R5 = R6 \left[\left(\frac{V_{OUT}}{V_{FB}} \right) - 1 \right]$$

where V_{FB} = 1V (typ) and R6 = 50kΩ.
