

## MAX20429

# Dual 6A High-Efficiency Low Voltage Buck Converter

## General Description

The MAX20429 is a high-efficiency dual switching regulator that delivers up to 6A (peak) load current per output from 0.5V to 1.5875V in 12.5mV steps and 1.6V to 3.8V in 50mV steps. The IC operates from 3V to 5.5V, making it ideal for on-board point-of-load and post-regulation applications. Total output error is less than  $\pm 1.0\%$  over load, line, and temperature.

The MAX20429 features fixed-frequency PWM mode operation with a switching frequency of 2.1MHz or 3.2MHz. High-frequency operation allows for an all-ceramic capacitor design with small external components.

The low-resistance on-chip switches ensure high efficiency at heavy loads while minimizing critical inductances, making the layout a much simpler task with respect to discrete solutions. Following a simple layout and footprint ensures first-pass success in new designs.

The device features the MAXQ™ technology, which provides precision transient performance and phase margin. This allows obtaining the maximum power, performance, and precision from the converter over a very wide range of configurations.

The MAX20429 has separate enable inputs and status outputs for each buck converter. The output voltage is preset at the factory to allow customers to achieve  $\pm 1\%$  output-voltage accuracy without using expensive 0.1% resistors. The devices offer factory programmable soft-start and RESET times.

The devices include over-temperature shutdown and over-current limiting. All devices are designed to operate from  $-40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$  ambient temperature range.

## Applications

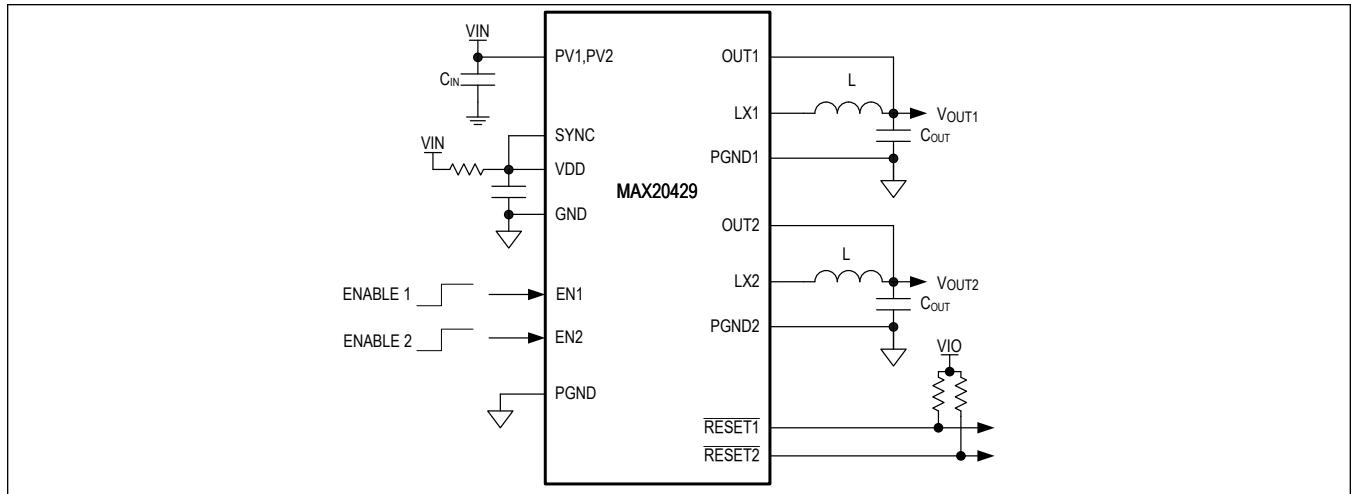

- Secondary Regulator for SoC / MCU Supply

## Benefits and Features

- High-Feature Set in an Ultra-Small Footprint
  - High-Efficiency DC-DC Converter
  - Two Independent Outputs, up to 6A per Output
  - 3.0V to 5.5V Operating Supply Voltage
  - Resistor-Adjustable Output Voltage
  - Optional Factory-Preset Output Voltage
  - 2.1MHz/3.2MHz Options
  - Enable Input
  - Individual RESET Outputs
  - Spread-Spectrum Option
  - Peak Current-Mode Architecture
  - 3mm x 3.5mm FCQFN
- High-Precision
  - 108/92% OV/UV Monitor
  - $\pm 3\%$  OV/UV Accuracy
  - $\pm 1\%$  Output Voltage Accuracy
  - Excellent Load-Transient Performance
  - PWM and SKIP Mode Operation
  - MAXQ™ Power Architecture
- High Efficiency
  - Up to 96% Efficiency 5V to 3.3V
  - Up to 90% Efficiency 5V to 1V
- $-40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$  Operating Temperature Range
- AEC-Q100 Qualified

*Ordering Information appears at end of data sheet.*

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

**Package Information****FC2QFN**

Package Code	F183A3FY+1
Outline Number	<a href="#">21-100428</a>
Land Pattern Number	<a href="#">90-100155</a>
<b>Thermal Resistance, Four-Layer Board:</b>	
Junction to Ambient ( $\theta_{JA}$ )	19.3°C/W
Junction to Case ( $\theta_{JC}$ )	5.0°C/W

For the latest package outline information and land patterns (footprints), go to [www.maximintegrated.com/packages](#). Note that a "+" or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to [www.maximintegrated.com/thermal-tutorial](#).

**Pin Description**

PIN	NAME	FUNCTION
1	EN2	OUT2 Active-High Enable Input. Drive EN2 HIGH for normal operation. The device enters soft-start on the rising edge enters soft-shutdown on the falling edge.
2	RESET2	OUT2 Active-Low Open Drain RESET Output. External pullup resistor required if used.
3	PV2	OUT2 Power Input Supply. Connect a 10 $\mu$ F or larger ceramic capacitor from PV2 to PGND2.
4	LX2	OUT2 Inductor Connection. Connect LX2 to the switched side of the inductor.
5,6	PGND2	OUT2 Power Ground
7	PGND	Power Ground
8,9	PGND1	OUT1 Power Ground
10	LX1	OUT1 Inductor Connection. Connect LX1 to the switched side of the inductor.
11	PV1	OUT1 Power Input Supply. Connect a 10 $\mu$ F or larger ceramic capacitor from PV1 to PGND1.
12	RESET1	OUT1 Active-Low Open Drain RESET Output. External pullup resistor required if used.
13	EN1	OUT1 Active-High Enable Input. Drive EN1 HIGH for normal operation. The device enters soft-start on the rising edge enters soft-shutdown on the falling edge.
14	OUT1	OUT1 Feedback Input. Connect to the output capacitor of Output 1.
15	SYNC	SYNC Input. Connect SYNC to GND or leave unconnected to enable skip-mode operation under light loads. Connect SYNC to PV or an external clock to enable fixed-frequency FPWM operation.
16	V <sub>DD</sub>	Internal Analog Supply. Connect a 2.2 $\mu$ F capacitor between this pin and GND.
17	GND	Analog Ground
18	OUT2	OUT2 Feedback Input. Connect to the output capacitor of Output 2.

## Functional Diagrams

### Internal Block Diagram

## Detailed Description

### MAXQ Power Architecture (No Wasted Performance)

The MAXQ power architecture allows the MAX20429 to achieve the maximum dynamic performance under all worst-case conditions. Without the MAXQ power architecture, typical AC performance must be lowered below the device capabilities to guarantee that the device will be stable under all worst-case application conditions. The MAXQ power architecture keeps the device operating at peak performance.

### Enable Input (EN1, EN2)

The enable control input EN1/EN2 activates the device channel from its low-power shutdown state. EN1/EN2 have an input-high threshold of 1.5V (typ), an input-low threshold of 0.5V, and a hysteresis of 50mV (typ). When an enable input goes high, the output voltage ramps up with the soft-start time. When an enable input goes low, the output voltage ramps down with the soft-start time or enters a Hi-Z state depending on the factory programmed setting of the device. See Soft-Start and Soft-Shutdown section for more detail.

### RESET Output

The device features open-drain reset outputs that assert low when the corresponding output voltage is outside of the OV/UV window. The OV/UV comparators run from a separate reference to provide drift detection on the outputs. RESET\_ remains asserted for a fixed timeout period after the corresponding output returns to its regulated voltage. The fixed timeout period for 2.1 MHz is selectable between 0.5ms, 3.9ms, 7.8ms, or 15.6ms. The fixed timeout period for 3.2 MHz is selectable between 0.3ms, 2.5ms, 5.1ms, or 10.2ms. To obtain a logic signal, place a pullup resistor between the RESET\_ pins to the system I/O voltage.

### Internal Oscillator

The device has a spread-spectrum oscillator that varies the internal operating frequency by  $\pm 3\%$  relative to the internally generated operating frequency of 2.1MHz/3.2MHz (typ). This function does not apply to externally applied oscillation frequency on the SYNC pin.

### Synchronization (SYNC)

A logic-high on SYNC enables fixed-frequency, forced-PWM mode. Apply an external clock on the SYNC input to synchronize the internal oscillator to an external clock. The SYNC input accepts signal frequencies in the range of  $1.9\text{MHz} < f_{\text{SYNC}} < 2.3\text{MHz}$  when  $f_{\text{SW}} = 2.1\text{MHz}$ , and  $2.9\text{MHz} < f_{\text{SYNC}} < 3.6\text{MHz}$  when  $f_{\text{SW}} = 3.2\text{MHz}$ . When the pin is open-circuited or logic-low, the SYNC input enables the device to enter a low-power skip mode under light-load conditions if the IC is configured to allow that behavior.

### Soft-Start and Soft-Shutdown

The device includes a factory-programmable fixed soft-start time. Soft-start time limits startup inrush current by forcing the output voltage to ramp up towards its regulation point. The soft-start ramp rate can be factory programmed with four different options: 32, 16, 8, or 4 clocks per step, where step size = 12.5mV for  $V_{\text{OUT}} \leq 1.6\text{V}$  (50mV step size when  $V_{\text{OUT}} > 1.6\text{V}$ ).

When an EN pin goes low, the associated output enters shutdown. There are factory programmable options available that will either simply disable switching and activate a  $50\Omega$  (typ) discharge resistor, or perform a soft-shutdown by ramping down the reference at a fixed rate until a minimum on-time of 20ns is reached, at which point the switching stops and the discharge resistor is activated. The soft-shutdown ramp rate is fixed at 32 clocks per step, where step size = 12.5mV for  $V_{\text{OUT}} \leq 1.6\text{V}$  (50mV step size when  $V_{\text{OUT}} > 1.6\text{V}$ ) when not configured as a simple discharge resistor.

### Current Limit / Short-Circuit Protection

The device features a current limit that protects the device against short-circuit and overload conditions at the output. In the event of a short-circuit or overload condition, the high-side MOSFET remains on until the inductor current reaches

the high-side MOSFET's current-limit threshold. The converter then turns on the low-side MOSFET to allow the inductor current to ramp down. Once the inductor current crosses below the low-side MOSFET current-limit threshold, the converter turns on the high-side MOSFET again. This cycle repeats until the short or overload condition is removed.

If the device crosses the current limit with the output voltage below 50% of the target, hiccup mode will be enabled and the output will turn off for 10ms, then the channel will attempt to power up through soft-start.

### PWM/SKIP Modes

The device features an input (SYNC) that puts the converter either in SKIP mode or forced-PWM mode of operation. See [Pin Descriptions](#) for mode detail. In FPWM mode of operation, the converter switches at a constant frequency with variable on-time. In SKIP mode, the converter's switching frequency is load-dependent until the output load reaches a set threshold. At higher load current, the switching frequency does not change, and the operating mode is similar to the FPWM mode. SKIP mode helps improve efficiency in light-load applications by allowing the converter to turn on the high-side switch only when the output voltage falls below a set threshold. As such, the converter does not switch MOSFETs on and off, as is often the case in the PWM mode. Consequently, the gate charge and switching losses are much lower in SKIP mode.

### Overtemperature Protection

Thermal overload protection limits the total power dissipation in the MAX20429. When the junction temperature exceeds 165°C (typ), an internal thermal sensor shuts down both outputs, allowing the IC to cool. The thermal sensor turns on the outputs again after the junction temperature cools by 15°C.

### Spread Spectrum

The spread-spectrum option is enabled/disabled based on the part number. See the ordering table. If the spread spectrum is enabled and an external clock is applied to the SYNC pin, then the spread-spectrum circuit is bypassed, effectively disabling the option.

### Resistor-Adjustable Output

MAX20429 output voltage can be set by external resistors in addition to the factory programmed  $V_{OUT}$  options. See the [Typical Application Diagram](#) for placement of R1 and R2 external resistors. Desired output voltage can be calculated using the following method:

$$V_{OUT} = \frac{R1 + R2}{R2} * V_{REF}$$

where  $V_{REF} = 0.6V$  when using the device specified for adjustable output voltage.

Fixed output voltage devices can use external resistors to achieve output voltages higher than the factory setting. When using a fixed output voltage device, use the factory preset output voltage as  $V_{REF}$  to calculate the resistor values.

## Applications Information

### Input Capacitor Selection

An input filter capacitor reduces peak currents drawn from the upstream power source and reduces noise and voltage ripple on the input (caused by the circuit's switching behavior). One  $10\mu\text{F}$  X7R ceramic capacitor each is recommended for the PV1 and PV2 pins. The  $V_{DD}$  pin is the input to the analog circuitry and should be connected to the same supply as PV1/2 through a series  $2\Omega$  resistor IC to a  $2.2\mu\text{F}$  X7R bypass capacitor.

### Inductor Selection

Three key inductor parameters must be specified for operation with the MAX20429: inductance value ( $L$ ), peak inductor current ( $I_{PEAK}$ ), and inductor saturation current ( $I_{SAT}$ ). The minimum required inductance is a function of operating frequency, input-to-output voltage differential, and the maximum output current capability of the output. A lower inductor value minimizes size and cost, improves large-signal and transient response, but reduces efficiency due to higher peak currents and higher peak-to-peak output-voltage ripple for the same output capacitor. On the other hand, higher inductance increases efficiency by reducing the ripple current. Resistive losses due to extra wire turns can exceed the benefit gained from lower ripple current levels especially when the inductance is increased without also allowing for larger inductor dimensions.

Soft-saturating inductors are recommended for use with the MAX20429. The gradual decrease in inductance means that the IC will respond to overcurrent conditions before the  $L_X$  current reaches dangerously high levels that might otherwise result in damage to the IC. If a hard-saturating inductor is used, its saturation current must be above the maximum  $L_X$  current limit. For a soft-saturation inductor, only the current limit for temperature must be above the maximum  $L_X$  current limit.

The MAX20429 is designed for nominal  $\Delta I_{PK-PK}$  equal to approximately 33% of the full load current. Use the following equation to calculate the typical inductance with respect to ripple current:

$$L = \frac{(V_{IN} - V_{OUT}) \times V_{OUT}}{V_{IN} \times f_{SW} \times I_{MAX} \times \Delta_{PK-PK}}$$

The  $V_{IN}$  and  $V_{OUT}$  terms are typical values to optimize inductor selection for expected operating conditions. The switching frequency  $f_{SW}$  is 2.1MHz, 3.2MHz, or a different value if the synchronization function is utilized. The maximum current  $I_{MAX}$  is the channel's rated output current (2A, 3A, 4A, or 6A), not the expected application maximum load current. Calculate the minimum inductance  $L_{MIN1}$  with  $\Delta_{PK-PK} = 40\%$ , and the typical inductance  $L_{TYP1}$  with  $\Delta_{PK-PK} = 30\%$ .

The second bound on minimum inductance is with respect to slope compensation. This applies only to peak current control, not to adaptive COT control. The absolute minimum inductance allowable must ensure that the inductor current downslope is less than twice the downslope of the compensation ramp:

$$-m \geq \frac{m2}{2}$$

**Table 1. Slope Compensation Terms**

TERM	VALUE
m2	Inductor current downslope: $\frac{V_{OUT}}{L} \times R_{CS}$
-m	Compensating ramp: $OTP\_SLP * 0.680 \text{ V} / \mu\text{sec}$
OTP_SLP	1/2, 2/3, 4/3 (factory programmed)
R <sub>CS</sub>	0.330Ω for 2A channel
	0.240Ω for 3A channel
	0.185Ω for 4A channel
	0.133Ω for 6A channel

For margin of error, the worst-case inductance (largest derating for current and temperature, plus lowest value for percent tolerance) should result in the inductor down-slope being 25% greater than half the slope compensation ramp:

$$L_{MIN2} = V_{OUT} \times \frac{R_{CS}}{2 \times m} \times 1.25$$

Nominally, the inductor current down-slope should be approximately equal to the compensating ramp. Equal down-slopes will result in current waveform perturbations being eliminated in a single switching cycle:

$$L_{TYP2} = V_{OUT} \times \frac{R_{CS}}{m}$$

Two equations must therefore be fulfilled: one equation for minimum worst-case inductance (required) and one for typical inductance (recommended):  $L_{MIN} > \max(L_{MIN1}, L_{MIN2})$  and  $L_{TYP} > \max(L_{TYP1}, L_{TYP2})$ . The maximum inductance should be less than  $2 \times L_{TYP2}$  to avoid degrading the control performance.

### Output Capacitors

The MAX20429 is designed to be stable with low-ESR ceramic capacitors. Other capacitor types are not recommended as the ESR zero can affect stability of the device. The output capacitor calculations below are guidelines based on nominal conditions. The phase margin must be measured on the final circuit to verify proper stability is achieved.

Conditions:

- Feed-forward zero enabled,  $GMZ = 116\mu S$ ,  $FFR = 300k\Omega$
- Nominal inductor value based on the Inductor Selection section

For  $V_{OUT} < 1.6V$

$$C_{OUT\_{MIN}} = 11.5\mu sec \times I_{MAX} \times \frac{R_{COMP}}{140k\Omega}$$

$$C_{OUT\_{TYP}} = 24.5\mu sec \times I_{MAX} \times \frac{R_{COMP}}{140k\Omega}$$

For  $V_{OUT} \geq 1.6V$

$$C_{OUT\_{MIN}} = 8.0\mu sec \times I_{MAX} \times \frac{R_{COMP}}{140k\Omega}$$

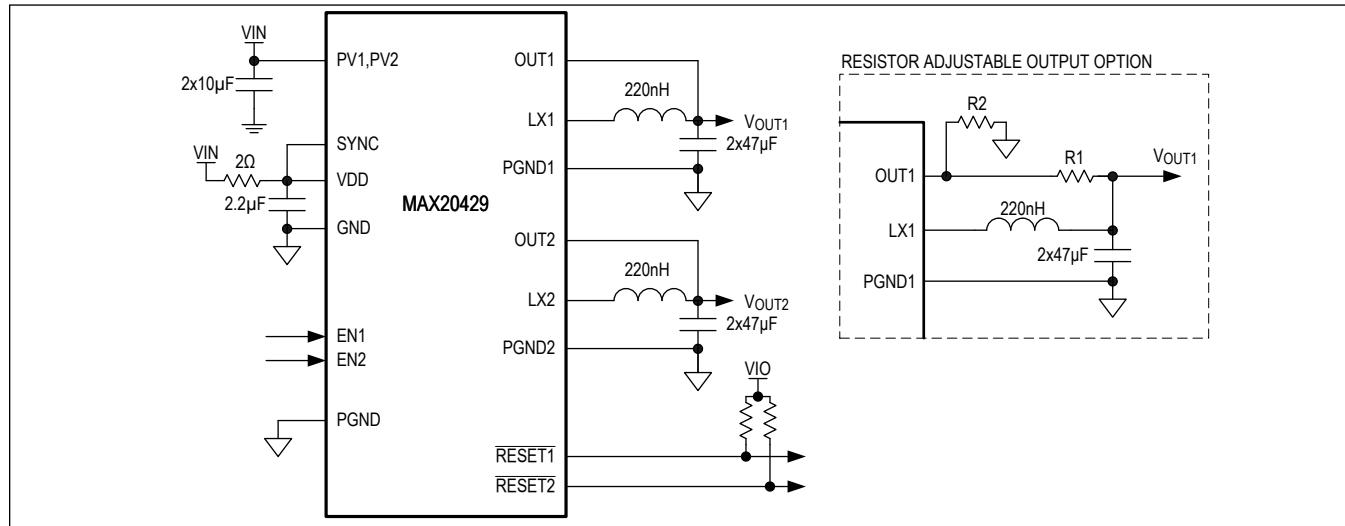

$$C_{OUT\_{TYP}} = 21.0\mu sec \times I_{MAX} \times \frac{R_{COMP}}{140k\Omega}$$

**Table 2. Output Capacitor Terms**

TERM	DESCRIPTION
$C_{OUT\_{MIN}}$	Minimum fully-derated capacitance necessary for phase margin of approximately 45 degrees
$C_{OUT\_{TYP}}$	Nominal output capacitance for a UGBW of 200kHz
$I_{MAX}$	The IC channel's maximum DC current capability: 2A, 3A, 4A, or 6A
$V_{OUT}$	Nominal output voltage
$R_{COMP}$	Compensation Resistor setting. Default = 140k $\Omega$ . Can be factory set from 35k $\Omega$ to 297.5k $\Omega$ in 17.5k $\Omega$ increments.

## Typical Application Circuits

### Typical Application Diagram

### Ordering Information

PART	V <sub>OUT1</sub> (V) (1)	I <sub>OUT1</sub> (A) (2)	V <sub>OUT2</sub> (V) (1)	I <sub>OUT2</sub> (A) (2)	SPREAD SPECTRUM (3)	f <sub>SW</sub> (MHz) (4)	t <sub>HOLD</sub> (ms) (5)	Soft-Start	Soft- Shutdown	R <sub>COMP</sub> (kΩ)
MAX20429AAFNA/VY+	0.85	3	0.72	6	ON	2.1	15.6	1.64 mv/us	0.82 mv/us	122.5
MAX20429CAFNA/VY+	ADJ (6)	6	ADJ (6)	6	ON	2.1	3.9	730 us (fixed)	730 us (fixed)	140

For variants with different options, contact the factory

/V Denotes an AEC-Q100 automotive-qualified part.

+ Denotes lead(Pb)-free/RoHS-compliant package.

T Denotes tape-and-reel.

Y Denotes side-wettable package.

(1) Fixed factory setting, 0.5V to 1.5875V in 12.5mV steps or 1.6V to 3.8V in 50mV steps.

(2) 2, 3, 4, or 6

(3) ON or OFF

(4) 2.1 or 3.2

(5) 0.5, 3.9, 7.8, 15.6 for f<sub>SW</sub> = 2.1MHz or 0.3, 2.5, 5.1, 10.2 for f<sub>SW</sub> = 3.2MHz.

(6) ADJ (adjustable externally)

## Revision History

REVISION NUMBER	REVISION DATE	DESCRIPTION	PAGES CHANGED
0	6/20	Initial release	—
1	12/20	Updated General Description, Benefits and Features, Absolute Maximum Ratings, Electrical Characteristics, Detailed Description, and Ordering Information	1, 4, 5, 12, 13, 16
