

General Description

The MAX24104 restores high-frequency signal level at the decision-feedback equalizer (DFE) receiver for high-loss backplane and cable channels. This permits the DFE receiver to meet BER goals. At 15Gbps, the MAX24104 can operate in channels with FR4 and cable HF loss of more than 30dB at 7.5GHz. The linear transfer function is transparent to Adaptive DFE equalizers, permitting DFE adaptation to track temperature and changing channel conditions.

Together with the DFE, integrated into Serializer/Deserializer (SERDES), the device adds increased margin rather than full signal regeneration. Unlike conventional equalizers with limiting output stages, the device preserves the linear channel characteristics, allowing the DFE to operate linearly over the entire channel. This permits extending total channel reach and/or improving signal-to-noise ratio (SNR). The device typically compensates for up to 19dB of the total loss in a long channel, effectively reducing the channel length seen by the DFE receiver.

The device has four channels and is packaged in a space-saving, 4mm x 6.5mm, FCLGA package.

Applications

- 1Gbps to 15Gbps High-Speed Backplanes and Cables
- 12.5Gbps Quad XAUI Interconnect
- 14Gbps 16G Fiber Channel
- 12Gbps SAS III

Benefits and Features

- Low Power Consumption Reduces Operating Cost
 - Single 2.5V Supply
 - 131mW Per Channel (typ) at 700mV_{P-P} Output
 - Lower Power, Lower Cost and Smaller Board Footprint than CDR Solutions
- Linear Performance for Greater System Flexibility
 - 1Gbps to 15Gbps Linear Equalization
 - Increases High-Frequency Signal Level to Help Rx DFE Achieve BER Goals
 - Selectable Output Linear Swing from 700mV_{P-P} to 1000mV_{P-P}
 - Input Return Loss Better than 16dB Up to 7.5GHz
- Adjustable Features for Greater Flexibility
 - Selectable EQ Peaking Spanning +6dB to +19dB at 7.5GHz
 - Selectable Flat Gain Spanning -2.9dB to +1.7dB
- Integration Allows Greater Design Flexibility
 - I²C Daisy-Chain for Addressing Up to 63 ICs
 - Plug and Play – Set Control Pins (All Channels Set the Same) or Independent Control of Each Channel through I²C Bus
 - Transparent to Link Training, OOB and Idle and Data-Rate and Coding Agnostic
 - 4mm x 6.5mm FCLGA Package

Typical Application Circuit

Ordering Information appears at end of data sheet.

For related parts and recommended products to use with this part, refer to www.maximintegrated.com/MAX24104.related.

Absolute Maximum Ratings

Power-Supply Voltage -0.5V to +4.0V
 DC Input Voltage Applied (all control pins except SDA
 and SCL) -0.5V to ($V_{CC} + 0.3V$)
 DC Input Voltage Applied (SDA, SCL) -0.5V to +4.0V

Output Current -90mA to +90mA
 Operating Junction Temperature +125°C
 Storage Temperature Range -40°C to +150°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Package Thermal Characteristics (Note 1)

FCLGA

Junction-to-Case Thermal Resistance (θ_{JC}) 10°C/W
 Junction-to-Ambient Thermal Resistance
 (θ_{JA}) (EIA/JESD51-2 standard) 29°C/W

Note 1: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to www.maximintegrated.com/thermal-tutorial.

Note 2: The MAX24104 is 100% production tested at $T_A = +25^{\circ}C$ and $T_A = +85^{\circ}C$. Specification at $T_A = -40^{\circ}C$ is guaranteed by design or characterization, unless otherwise noted.

Note 3: Guaranteed by design and characterization.

Note 4: Measured with circuit board loss optimized for best DJ. Residual jitter is the difference in deterministic jitter between the reference data source and device output. $DJ_{RESIDUAL} = DJ_{OUTPUT} - DJ_{SOURCE}$. The deterministic jitter at the output of the transmission line must be from media induced loss. Measured at point D in [Figure 2](#). Test Pattern: 66 Zeroes, 1010, PRBS7, 66 ones, 0101 Inverted PRBS7.

Note 5: The output voltage range in which a linear relationship between the input and output maintains less than or equal to 1dB compression.

Note 6: Measured using a vector-network analyzer (VNA N5245A) with -15dBm power level applied to the adjacent input. The VNA detects the signal at the output of the victim channel. All other inputs and outputs are terminated with 50 Ω .

Note 7: Refer to UM10204: I²C-bus specification and user manual, Rev. 03 – 19 June 2007.

Pin Configuration

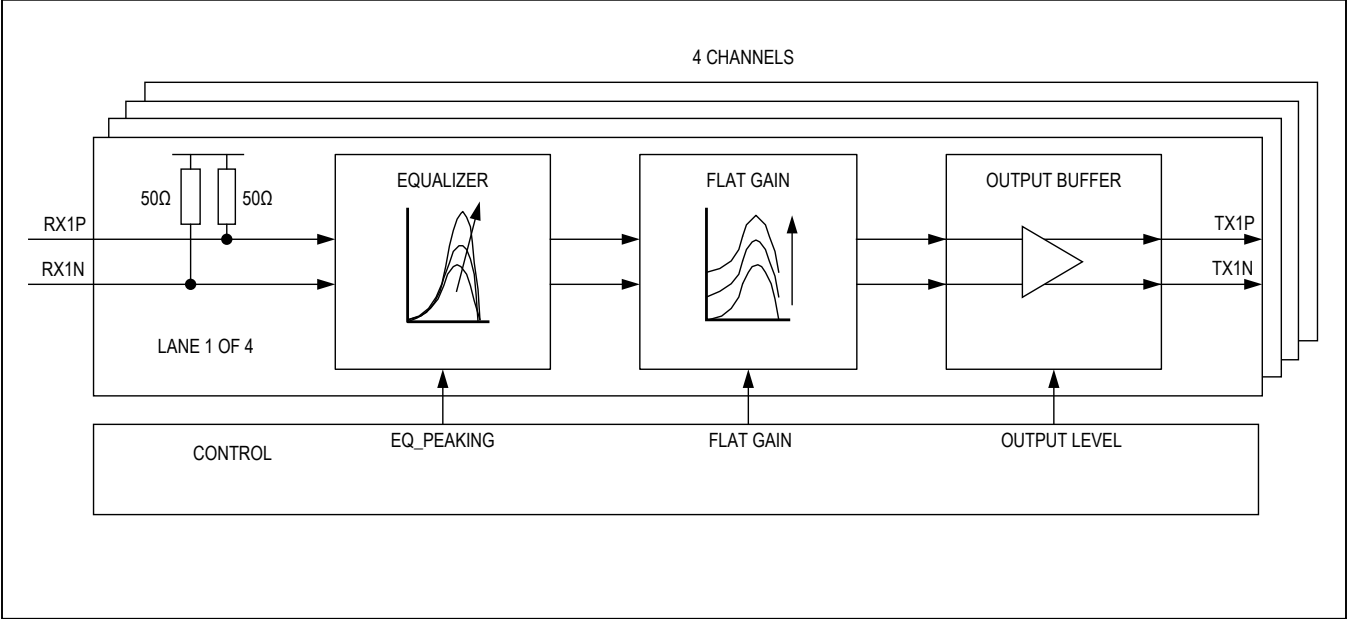

Pin Description

PIN	NAME	FUNCTION
1, 2	RX1P, RX1N	Differential Channel 1 Input, CML
3, 6, 9	VCCR	Positive Receive Power Supply, 2.5V. Filter each pin with a 0.1μF capacitor to GND.
4, 5	RX2P, RX2N	Differential Channel 2 Input, CML
7, 8	RX3P, RX3N	Differential Channel 3 Input, CML
10, 11	RX4P, RX4N	Differential Channel 4 Input, CML
12	I2C_EN	I ² C Enable Input, LVCMOS. Hardwire low for pin control. Hardwire high for I ² C control. User must select mode of operation before power-on reset.
13	VCCP	Positive Power Supply, 2.5V. Filter each pin with a 0.1μF capacitor to GND.
14	LDO_DIG	Compensation capacitor pin for internal LDO. Bypass pin with a 0.22μF capacitor to GND.
15	SCL	Analog I ² C Serial-Interface Clock Input. Use external 4.7kΩ pullup to V _{CC} .
16	SDA	Analog I ² C Serial-Interface Data Input and Output. Use external 4.7kΩ pullup to V _{CC} .
17	PGM_OUT	Cascadable I ² C Output. LVCMOS. See the <i>Slave Address Configuration</i> section.

Pin Description (continued)

PIN	NAME	FUNCTION
18, 19	TX4N, TX4P	Differential Channel 4 Output, CML
20, 23, 26	VCCT	Positive Transmit Power Supply, 2.5V. Filter each pin with a 0.1µF capacitor to GND.
21, 22	TX3N, TX3P	Differential Channel 3 Output, CML
24, 25	TX2N, TX2P	Differential Channel 2 Output, CML
27, 28	TX1N, TX1P	Differential Channel 1 Output, CML
29	PGM_IN	Cascadable I ² C Input. Has 30kΩ pulldown, see the <i>I²C Address Configuration</i> section.
30	ENABLE	Power-Down Enable Pin, LVCMOS. Three-state pin to program the power mode of the part at startup. For high and open, see Table 5 for settings. Set low for reset. Reset, disables all communication to the chip along with resetting the registers to their default states.
31	APPLICATION	Application Select Input, LVCMOS. Select between channel cases: short and long. Set low or open for long. Set high for short.
32	OUTPUT_LEVEL	Output Level Control, LVCMOS. Three-state pin to program the output level of all channels. See Table 4 for settings.
33	EQ_PEAKING	Equalization Control Pin, LVCMOS. Three-state pin to program the equalization level of all channels. See Table 2 for settings.
34	FLAT_GAIN	Gain Adjust Control Pin, LVCMOS. Three-state pin to program the flat gain level of all channels. See Table 3 for settings.
—	EP	Exposed Pad. Internally connected to GND. Ground reference for power supplies, three-state, and other low-speed pins. Connect EP to a large ground plane to maximize thermal performance.

Functional Diagram

Detailed Description

The MAX24104 is a 4-channel linear equalizer (EQ) functioning up to 15Gbps. Each channel has a programmable equalization network and programmable flat gain adjust. All controls for equalization, gain, output enable/disable, etc., are individually programmed through the on-chip programming block. The programming block can be controlled either through pin controls or the I²C serial bus.

APPLICATION Pin Control

The placement range of a linear equalizer is limited by its dynamic range and noise performance. To allow the widest placement range, the MAX24104 has two optimizations. The two cases are Short and Long Channels. By selecting the case based on channel loss as shown in [Table 1](#), the best dynamic range and noise operating points can be selected for the application.

Input Termination

The input termination consists of two 50Ω resistors forming a differential termination between the input pins. The excellent return loss minimizes reflections in a channel.

Table 1. APPLICATION Pin Control

INPUT LEVEL	CHANNEL LENGTH
High	Short Channel. 0dB to 18dB channel loss before MAX24104.
Low, Open	Long Channel. 18dB to 33dB channel loss before MAX24104.

Receive Equalizer

For the MAX24104, the input data goes into a selectable equalization stage. The receive equalizer is designed to compensate losses up to 19dB (at 7.5GHz). The selectable equalization can be controlled using commands sent over the I²C serial bus or pin control. With pin control the equalization setting has three available compensation levels and all the channels are controlled globally. See [Table 2](#) for details. With the I²C serial bus, the equalization has 16 settings and each channel can be adjusted independently.

Gain Stage

The MAX24104 data path goes through a wideband flat gain stage. With pin control, the flat gain can be adjusted globally from -2.9dB to +1.7dB as shown in [Table 3](#). With

I²C control, the flat gain can be adjusted independently for each channel.

Output Stage

The MAX24104 data path transitions from the gain stages into a linear output buffer with selectable output levels. With pin control the output levels can be adjusted globally as shown in [Table 4](#). With I²C control, the output levels can be adjusted independently for each channel.

Power Saving

The MAX24104 features a power-down enable input (ENABLE) pin to shut down the device and reduce supply current at startup. Set high to power down the output stage of all channels. Set open to power up all channels. Set low for reset. Reset disables all communication to the chip along with resetting the registers to their default states.

Table 2. EQ_PEAKING Pin Control (refer to Table 6)

CONTROL PIN INPUT LEVEL	LONG CHANNEL (APPLICATION = LOW, OPEN)	SHORT CHANNEL (APPLICATION = HIGH)	UNITS
High	(EQx[3:0] = 1110)	(EQx[3:0] = 1001)	dB
Open	(EQx[3:0] = 1001)	(EQx[3:0] = 0101)	
Low	(EQx[3:0] = 0101)	(EQx[3:0] = 0011)	

Table 3. FLAT_GAIN Pin Control (refer to Table 7)

CONTROL PIN INPUT LEVEL	LONG CHANNEL (APPLICATION = LOW, OPEN)	SHORT CHANNEL (APPLICATION = HIGH)	UNITS
High	(FGx[1:0] = 11)	(FGx[1:0] = 10)	dB
Open	(FGx[1:0] = 10)	(FGx[1:0] = 01)	
Low	(FGx[1:0] = 01)	(FGx[1:0] = 00)	

Table 4. OUTPUT_LEVEL Pin Control (refer to Table 8)

CONTROL PIN INPUT LEVEL	OUTPUT AMPLITUDE	UNITS
High	(TXAx[1:0] = 11)	mV _{P-P}
Open	(TXAx[1:0] = 10)	
Low	(TXAx[1:0] = 01)	

Table 5. ENABLE and Reset Pin Control

CONTROL PIN INPUT LEVEL (ENABLE)	I ² C CONTROL MODE (I2C_EN = high)	PIN CONTROL MODE (I2C_EN = low)
High	Upon POR or reset, power down all channels	Power down all channels
Open	Upon POR or reset, power on all channels	Power on all channels
Low	Reset (POR)	Reset (POR)

Applications Information

Linear Equalizer (EQ) Placement and Use, in 3 Steps

Placement of linear equalizers in lossy channels is bounded by output linearity and input noise (I_{RN}). See [Figure 5](#). Although placement is quite flexible, it is important to maintain linear operation with sufficient SNR, hence the boundary conditions stated in the following two sections.

Definitions

dBV is defined as dB relative to $1V_{P-P}$ (differential). Hence, the Tx level of $1V_{P-P}$ is 0dBV, and a Tx level of $0.5V_{P-P}$ is -6dBV.

Source Tx Level [dBV] is the total measured Tx V_{P-P} , including pre-emphasis.

Desired Margin is a user decision regarding margin needed to account for all system min/max variations, including source Tx, MAX24104, and ASIC receiver.

Figure 5. Linear Equalizer Placement

Step 1—Maintain EQ Linearity at Low Frequency (LF)

The source Tx low frequency (LF) amplitude needs to be considered to keep linear EQ within its linear range. The source Tx low-frequency (LF) amplitude is the differential peak-peak amplitude after any pre-emphasis has fully settled, e.g., the level of long CID (continuous identical digits) sequences. The primary controls over LF levels in Linear EQ are the Used ASIC Source Tx pre-emphasis (or de-emphasis) and the Linear EQ Flat Gain (MAX24104).

Figure 5 shows a typical example with ASIC Source Tx having 6dB pre-emphasis, with 1V_{P-P} peak swing and 0.5V_{P-P} swing after pre-emphasis (e.g., long CID LF content). Note that 0.5V_{P-P} fits easily under the -1dB Compression line. If the Source Tx were to have higher LF swing, driving linear EQ into nonlinearity, the linear EQ flat-gain control can be used to attenuate input signal level, as needed, to maintain linearity.

For example:

Maximum Linear EQ Flat Gain setting =

Linear EQ Output Level setting (-1dB compression) [dBV] -
Source Tx Level [dBV] +
Source Tx Pre-Emphasis (De-emphasis) [dB] -
User System Margin [dB]

For example:

Linear EQ Output Level setting (-1dB compression) [dBV] = -3dBV
Source Tx Level [dBV] = 0dB
Source Tx Pre-Emphasis (De-emphasis) [dB] = 6dB
User System Margin = 2dB

Then:

Maximum Linear EQ Flat Gain setting = (-3) - 0 + 6 - 2 = 1dB

(There are three Flat Gain settings available lower than +1dB: They are -3dB, -1.5dB, 0dB)

Step 2—Maintain EQ Linearity at High Frequency (Nyquist)

A linear equalizer when placed too close to a Source Tx is vulnerable to nonlinear compression at high frequency (Nyquist), especially if the EQ peaking gain is higher than the preceding channel loss. The -1dB compression specification gives maximum output level that guarantees linear operation. As a function of the EQ settings, the minimum placement distance from the Source Tx is calculated as follows: (see Position 1 in Figure 5).

Minimum Distance (Nyquist Loss) from Source Tx [dB] =

Source Tx Level [dBV] +
Linear EQ Peaking Gain [dB] +
Linear EQ Flat Gain [dB] -
Linear EQ Output Level setting (-1dB Compression level) [dBV] +
User System Margin [dB]

For example:

Source Tx Level = 0dBV
Linear EQ Peaking Gain = 14dB
Linear EQ Flat Gain = 0dB
Linear EQ Output Level setting (-1dB Compression Point) = -3dBV
User System Margin = 2dB

Then:

Minimum Distance (Nyquist Loss) from Source Tx = 0 + 14 + 0 - (-3) + 2 = 19dB

Step 3—Keep Nyquist Level Sufficiently Above Noise Floor

The amplitude of the Nyquist sequence (10101010...) must be maintained sufficiently above noise floor to achieve BER goals. Hence, Nyquist level at input to the Linear EQ needs to be sufficiently above the Linear EQ self-noise, IRN (input referred noise). This sets the maximum Nyquist channel loss preceding the Linear EQ, e.g., farthest placement from Source Tx (see Position 2 in Figure 5).

Maximum Distance (Nyquist Loss) from Source Tx [dB] =

Source Tx Level (which is Nyquist level) [dBV] -
Linear EQ IRNpp at BER goal [dBV] -
Margin required to reduce RJ creation -
User System Margin [dB]

For example:

Source Tx Level = 0dBV
Linear EQ IRNpp at BER goal (0.5mVrms x 15.9 at BER 1E-15) [dBV] = -43dB
Margin required to reduce RJ creation (to 0.2UIpp at BER) = 10dB
User System Margin = 3dB

Then:

Maximum Distance (Nyquist Loss) from Source Tx = 0 - (-43) - 10 - 3 = 30dB

Tools—Frequency Response Plotting and EQ Placement in Channel Calculator

Several simple Microsoft® Excel spreadsheet tools are available to assist in the application of the MAX24104 Linear EQs. Please visit www.maximintegrated.com to access the latest version of these spreadsheets:

I²C Interface

The SDA and SCL pins are referred to as the slave I²C. The slave I²C provides external access to the register set within the MAX24104. Typically, an MCU is connected to the slave I²C.

Framing and Data Transfer

An individual transaction is framed by a START condition and a STOP condition. A START condition occurs when a bus master pulls SDA low while SCL is high. A STOP condition occurs when the bus master allows SDA to transition low-to-high when SCL is high. Within the frame the master has exclusive control of the bus. The MAX24104 supports Repeated START conditions whereby the master may simultaneously end one frame and start another without releasing the bus by replacing the STOP condition with a START condition.

Within a frame, the state of SDA only changes when SCL is low. A data bit is transferred on a low-to-high transition

of SCL. Data is arranged in packets of 9 bits. The first 8 bits represent data to be transferred (most significant bit (MSB) first). The last bit is an acknowledge bit from the slave. The recipient of the data holds SDA low during the ninth clock cycle of a data packet to acknowledge (ACK) the byte. Leaving SDA left open on the ninth bit signals a not-acknowledged (NACK) condition. The interpretation of the acknowledge bit by the sender depends on the type of transaction and the nature of the byte being received. SDA is bidirectional so that the master may send data bytes during write transactions and the slave may send data bytes during reads.

Device Addressing

The first byte to be sent after a START condition is a slave address byte. The first seven bits of the byte contain the target slave address (MSB first). The eighth bit indicates the transaction type – ‘0’ = write, ‘1’ = read. Each slave interface on the bus is assigned a 7-bit slave address. If no slave matches the address broadcast by the master then SDA will be left open during the acknowledge bit and the master receives a NACK. The master must then assert a STOP condition. If a slave identifies the address then it acknowledges it by pulling SDA low. The master then proceeds with the transaction identified by the type bit. The two-wire interface of the MAX24104 decodes slave addresses ranging from 00h to 3Fh.

 P = Peaking Gain (HF re LF) [dB]
 F = Flat Gain (LF) [dB]

ASIC RX

N = Input Referred Noise [dBVpp @BER]

MEASUREMENT DEFINITIONS:
 HF = 0101010101 Sq Wave (Nyquist)
 LF = Long CID Sq Wave (100MHz)
 Peaking Gain = Gain @ HF relative to LF
 Noise BW = 10MHz to Nyquist

Entry Box in Yellow: **Entry Box**

Pull Down Box in Pink: **Pull Down**

Entry Box in Yellow: **Entry Box**

ASIC TX SETTINGS

T = Tx HF Level [mVpp] **1000**
 [dBVpp] **0.00**

D = Tx De-Emphasis [dB] **3.0**

STEP 1: Make sure that L (Tx LF Level) is less than EQ LF compression level:

L = Tx LF Level [mVpp] **708** < **800**
 [dBVpp] **-3.00**

LINEAR EQ SETTINGS

P = Peaking Gain (HF re LF) [dB] **15**
 F = Flat Gain (LF) [dB] **0**

Input Ref	n = Refer'd Noise [mVrms]	Mult	Output Ref
0.50		2	1.00
7.9	[mVpp]		15.8
-42.0	[dBVpp]		-36.0
-1.94			-1.94
142	CL = LF -1dB Compress [mVpp]		800
-16.9	[dBVpp]		-1.94
	CH = HF -1dB Compress [mVpp]		800
	[dBVpp]		-1.94

12.0 m = Margin [dB]: Nyquist above n [dBVpp@BER]
 (recommend ≥ 16 dB for RJ ≤ 0.10 U/lpp)
 (recommend ≥ 12 dB for RJ ≤ 0.16 U/lpp)

ASIC RX SETTINGS

N = Input Ref Noise [dBVrms] **0.5**
 [Vpp] **7.9**
 [dBVpp] **-42.0**

M = Margin [dB]: **12.0**
 Nyquist (010101) [Vpp] above N [Vpp@BER]
 (recommend ≥ 16 dB for RJ ≤ 0.10 U/lpp)
 (recommend ≥ 12 dB for RJ ≤ 0.16 U/lpp)

BER Target = 1E-xx, where xx= **15**
 Vpp/Vrms Multiplier = **15.85**
 (for BER in 1E-12 to 1E-17 range)

RESULTS:

EQ PLACEMENT [Loss@Nyquist]

A = Nearest to Tx [dB] \geq 16.94 Over PVT \geq 18.94 = T - CH (Input Ref) = Keeps Nyquist (010101) level below EQ HF compression level.	B = Farthest from Tx [dB] \leq 30.02 dB Over PVT \leq 28.02 dB = T - n (Input Ref) - m = Keeps Nyquist (010101) level above above EQ IRN (input referred noise) to meet BER and constrain RJ gen.	C = Longest Channel [dB] \leq 45.02 dB Over PVT \leq 43.02 dB = T + F + P - N - M = Keeps Nyquist (010101) level sufficiently above DFE IRN (input referred noise) to meet BER and constrain RJ generation
A = Farthest from Rx [dB] \leq 28.08 Over PVT \leq 26.08 = CH (Output Ref) - N - M = Keeps Nyquist above DFE IRN to meet BER and constrain RJ gen.	B = Nearest to Rx [dB] \geq 6.02 dB Over PVT \geq 8.02 dB = n (output) - N = Keeps EQ ORN (output ref noise) below DFE IRN (input ref noise), including channel loss on noise.	If using "Typical" specs, add Margin for PVT Variation +/- 2 dB

Figure 7. EQ Placement Calculator

Write Transaction

In a write transaction, the address byte is successfully acknowledged by the slave, and the type bit is set low. After the first acknowledge, the master sends a single data byte. All signaling is controlled by the master except for the SDA line during the acknowledge bits. During the acknowledge cycle the direction of the SDA line is reversed and the slave pulls SDA low to return a '0' (ACK) to the master.

The MAX24104 interprets the first data byte as a register address. This is used to set an internal memory pointer. Subsequent data bytes within the same transaction will then be written to the memory location addressed by the pointer. The pointer is auto-incremented after each byte. There is no limit to the number of bytes which may be written in a single burst to the internal registers of the MAX24104.

Read Transaction

In a read transaction, the slave address byte is successfully acknowledged by the slave, and the type bit is set high. After the ACK the slave returns a byte from the location identified by the internal memory pointer. This pointer is then auto-incremented. The slave then releases SDA so that the master can ACK the byte. If the slave receives an ACK then it will send another byte. The master identifies the last byte by sending a NACK to the slave. The master then issues a STOP to terminate the transaction.

Thus, to implement a random access read transaction, a write must first be issued by the master containing a slave address byte and a single data byte (the register address). This sets up the memory pointer. A read is then sent to retrieve data from this address.

Figure 8. Device Addressing

I²C Access Destination

The MAX24104 does not provide any security level on the I²C serial bus. Accesses to unimplemented registers in the device are discarded in the case of a write, and return an unpredictable value in the case of a read. During burst mode accesses, destination addresses are tested on a byte-by-byte basis.

Slave Address Configuration

The slave address of the MAX24104 I²C can be set using an initialization procedure involving PGM_IN and PGM_OUT, in conjunction with the standard I²C signals. This procedure facilitates the assignment of a large number of slave addresses, enabling several MAX24104s to be controlled by a single I²C serial bus and commands. All transactions on the I²C bus follow standard protocol, allowing simple firmware development.

There is little difference between a normal I²C serial bus and the MAX24104 solution except that there is a new signal which controls the programming of the device addresses. This signal is daisy-chained through all of the devices on the I²C bus via the PGM_IN and the PGM_OUT pins. The programming of device addresses is done as a single parallel write to all devices 1 to N.

The I²C bus is the usual “SCL” and bidirectional “SDA” with the pullup. The “program_reset” signal is a single bit passed through each device as a flying enable. The input pin for this signal is PGM_IN and the corresponding output pin is PGM_OUT. The PGM_IN pin on the first MAX24104 in the chain can be tied low or left unconnected because the PGM_IN pin has an internal pulldown resistor.

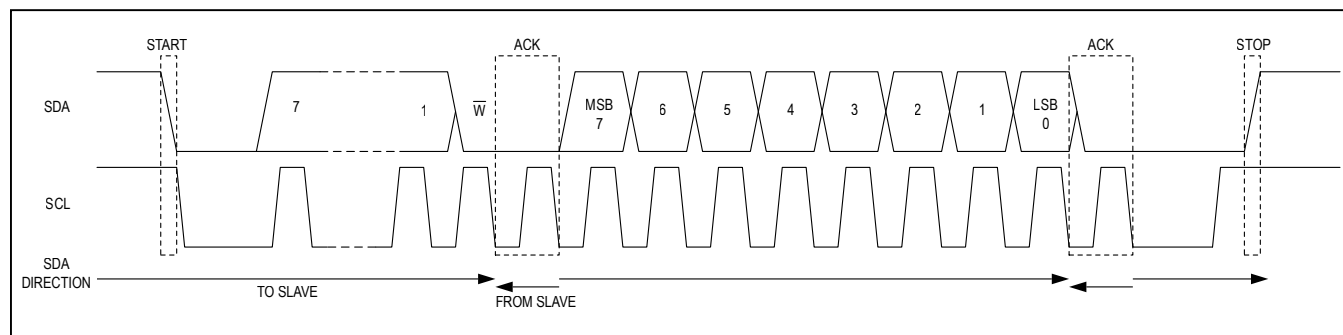

Figure 9. Write Transaction

Figure 10. Read Transaction

I²C Address Configuration

The new features of this interface compared to a conventional I²C interface are:

- The daisy chain $\overline{\text{PGM_IN}}$ and $\overline{\text{PGM_OUT}}$ pins
- A device_address register (7 bits[7:1]). Bit[0] in this register is used as a I²C read/write bit
- An internal “write_once” bit

At power-up, the “write_once” bit will be set to ‘1’ and the device I²C address will be set to its default value (A2h). All MAX24104 devices will respond to read and writes to this slave address until a write to register 3Ch is performed. The required I²C address of device 1 (“7 bit

address” x 2) is then assigned by writing to pgm_register (3Ch) at I²C address A2h. All devices accept the new address value (for example: 10h). Each device then starts to increment it on SCL edges while $\overline{\text{PGM_IN}}$ is high. The “program_reset” signal ripples down the chain, fixing the I²C address such that device N has an I²C address of (“address”x2)+2 x (N-1) (for example: device 1 at (10h), device 2 at (12h) and device 3 at (14h)).

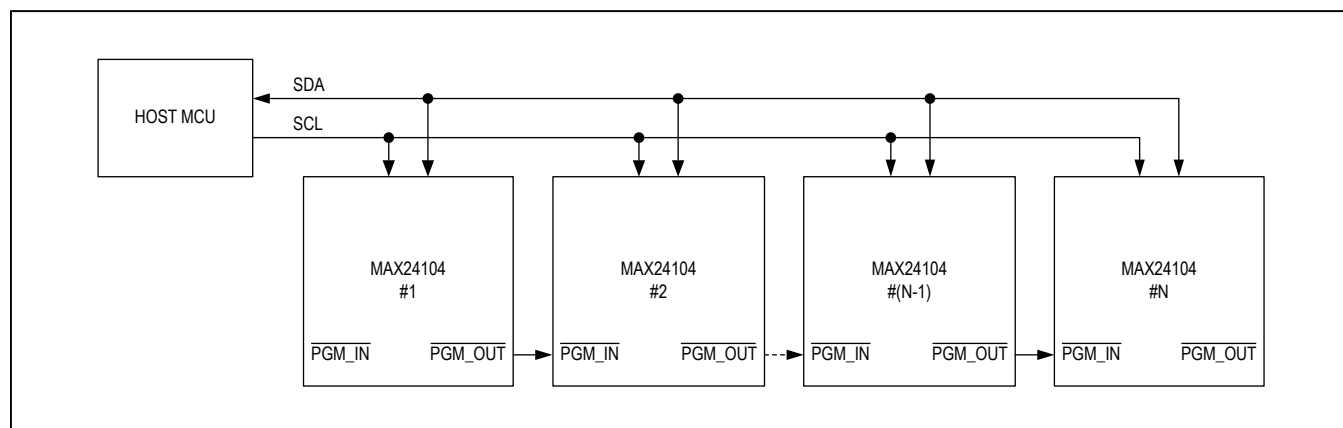

Figure 11. Slave Address Configuration

Startup Sequence

In this example, a chain of MAX24104s are loaded with the required I²C slave address.

- 1) Power up the devices.
- 2) Write I²C sequence < “A2h” ack “3Ch” ack “address” and ‘0’ ack>.
- 3) The first device is now accessible at its given address.
- 4) By accessing the first device, the SCL pin is toggled and hence the “program_reset” signal is propagated through the devices using the PGM_IN and PGM_OUT pins. For long chains, a number of accesses may be needed before all devices have an assigned address since each access results in 27 SCL transitions and hence 13 devices are allocated an address

To reset the slave address requires a power cycle or setting the ENABLE pin low.

ACCESS	RW	RW	RW	RW	RW	RW	RW	RW

EQ4[3:0]: Sets the equalizer peaking for channel 3. See Table 6 for values.

FG4[1:0]: Sets the flat gain for channel 3. See Table 7 for values.

TXA4[1:0]: Sets the output amplitude for channel 3. See Table 8 for values.

Register 05h (I²C Address): Channel 1–4 Controls

BIT	7	6	5	4	3	2	1	0
NAME	Reserved	Reserved	Reserved	REGCONT14	CH1OFF	CH2OFF	CH3OFF	CH4OFF
DEFAULT VALUE	0	0	0	0	0	0	0	0
ACCESS	RW	RW	RW	RW	RW	RW	RW	RW

REGCONT14: Selects channel settings, for channels 1–4, from pin control or I²C accessible registers. 0 = pin control (equalizer peaking, flat gain and output amplitude), 1 = I²C accessible registers.

CH1OFF: Disables channel 1. 0 = enabled, 1 = disabled.

CH2OFF: Disables channel 2. 0 = enabled, 1 = disabled.

CH3OFF: Disables channel 3. 0 = enabled, 1 = disabled.

CH4OFF: Disables channel 4. 0 = enabled, 1 = disabled.

Exposed Pad Package

The exposed pad of the MAX24104 package incorporates features that provide a very low thermal resistance path for heat removal from the IC. The exposed pad on the MAX24104 must be soldered to the circuit board for proper thermal performance and correct electrical grounding. For more information on exposed-pad packages, refer to Maxim [Application Note 862: HFAN-08.1: Thermal Considerations of QFN and Other Exposed-Paddle Packages](#).

Layout Considerations

Circuit board layout and design can significantly affect the performance of the MAX24104. Use good high-frequency design techniques, including minimizing ground inductance and using controlled-impedance transmission lines on the data signals. Power-supply decoupling should also be placed as close to the V_{CC} pins as possible. There should be sufficient supply filtering. Always connect all V_{CC} s to a power plane. Take care to isolate the input from the output signals to reduce feed through.
