

# **DS34S101, DS34S102, DS34S104, DS34S108**

## **Single/Dual/Quad/Octal TDM-over-Packet Chip**

### **General Description**

These IETF PWE3 SAToP/CESoPSN/TDMoIP/HDLC compliant devices allow up to eight E1, T1 or serial streams or one high-speed E3, T3, STS-1 or serial stream to be transported transparently over IP, MPLS or Ethernet networks. Jitter and wander of recovered clocks conform to G.823/G.824, G.8261, and TDM specifications. TDM data is transported in up to 64 individually configurable bundles. All standards-based TDM-over-packet mapping methods are supported except AAL2. Frame-based serial HDLC data flows are also supported. The high level of integration available with the DS34S10x devices minimizes cost, board space, and time to market.

### **Applications**

TDM Circuit Extension Over PSN

- Leased-Line Services Over PSN
- TDM Over GPON/EPON
- TDM Over Cable
- TDM Over Wireless

Cellular Backhaul Over PSN

Multiservice Over Unified PSN

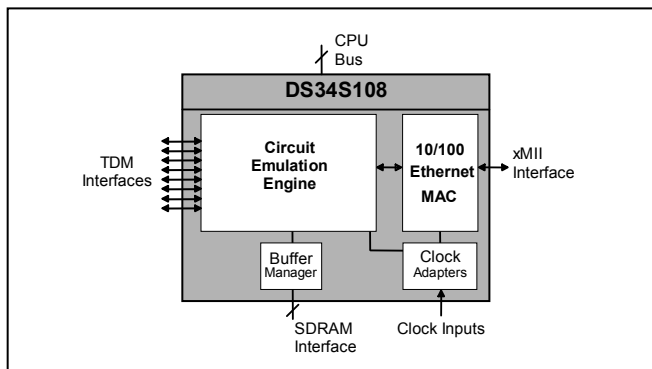

HDLC-Based Traffic Transport Over PSN

### **Features**

- ◆ Transport of E1, T1, E3, T3 or STS-1 TDM or Other CBR Signals Over Packet Networks
- ◆ Full Support for These Mapping Methods: SAToP, CESoPSN, TDMoIP (AAL1), HDLC, Unstructured, Structured, Structured with CAS
- ◆ Adaptive Clock Recovery, Common Clock, External Clock and Loopback Timing Modes
- ◆ On-Chip TDM Clock Recovery Machines, One Per Port, Independently Configurable
- ◆ Clock Recovery Algorithm Handles Network PDV, Packet Loss, Constant Delay Changes, Frequency Changes and Other Impairments
- ◆ 64 Independent Bundles/Connections
- ◆ Multiprotocol Encapsulation Supports IPv4, IPv6, UDP, RTP, L2TPv3, MPLS, Metro Ethernet
- ◆ VLAN Support According to 802.1p and 802.1Q
- ◆ 10/100 Ethernet MAC Supports MII/RMII/SSMII
- ◆ Selectable 32-Bit, 16-Bit or SPI Processor Bus
- ◆ Operates from Only Two Clock Signals, One for Clock Recovery and One for Packet Processing
- ◆ Glueless SDRAM Buffer Management
- ◆ Low-Power 1.8V Core, 3.3V I/O

See detailed feature list in Section 7.

### **Functional Diagram**

### **Ordering Information**

PART	PORTS	TEMP RANGE	PIN-PACKAGE
<b>DS34S101GN</b>	1	-40°C to +85°C	256 TECSBGA

## **1. Introduction**

The DS34S101/2/4/8 family of products provide single and multiport TDM-over-packet circuit emulation. Dedicated payload-type engines are included for TDMoIP (AAL1), CESoPSN, SAToP, and HDLC.

Products in the DS34S10x family provide the mapping/demapping ability to enable the transport of TDM data (Nx64kbps, E1, T1, J1, E3, T3, STS-1) over IP, MPLS or Ethernet networks. These products enable service providers to migrate to next generation networks while continuing to provide legacy voice, data and leased-line services. They allow enterprises to transport voice and video over the same IP/Ethernet network that is currently used only for LAN traffic, thereby minimizing network maintenance and operating costs.

Packet-switched networks, such as IP networks, were not designed to transport TDM data and have no inherent clock distribution mechanism. Therefore, when transporting TDM data over packet switched networks, the TDM demapping function needs to accurately reconstruct the TDM service clock(s). The DS34S10x devices perform this important clock recovery task, creating recovered clocks with jitter and wander levels that conform to ITU-T G.823/824 and G.8261, even for networks which introduce significant packet delay variation and packet loss.

The circuit emulation technology in the DS34S10x products that makes this possible is called TDM-over-Packet (TDMoP) and complements VoIP in those cases where VoIP is not applicable or where VoIP price/performance is not sufficient. Most importantly, TDMoP technology provides higher voice quality with lower latency than VoIP. Unlike VoIP, TDMoP can support all applications that run over E1/T1 circuits, not just voice. TDMoP can also provide traditional leased-line services over IP and is transparent to protocols and signaling. Because TDMoP provides an evolutionary, as opposed to revolutionary approach, investment protection is maximized.

## **2. Acronyms and Glossary**

### **Acronyms**

AAL1	ATM Adaptation Layer Type 1
AAL2	ATM Adaptation Layer Type 2
ATM	Asynchronous Transfer Mode
BGA	Ball Grid Array
BW	Bandwidth
CAS	Channel Associated Signaling
CBR	Constant Bit-Rate
CCS	Common channel signaling
CE	Customer Edge
CESoP	Circuit Emulation Service over Packet
CESoPSN	Circuit Emulation Services over Packet Switched Network
CLAD	Clock Rate Adapter
CPE	Customer Premises Equipment
CSMA	Carrier Sense Multiple Access
CSMA/CD	Carrier Sense Multiple Access with Collision Detection
DS0	Digital Signal Level 0
DS1	Digital Signal Level 1
DS3	Digital Signal Level 3
HDLC	High-Level data Link Control
IEEE	Institute of Electrical and Electronics Engineers
IETF	Internet Engineering Task Force
IP	Internet Protocol
JBC	Jitter Buffer Control
IWF	Interworking Function
LAN	Local Area Network
LOF	Loss of Frame (i.e. loss of frame alignment)
LOS	Loss of Signal
MAC	Media Access Control
MEF	Metro Ethernet Forum
MFA	MPLS / Frame Relay Alliance (Now called IP/MPLS Forum)
MII	Medium Independent Interface
MPLS	MULTI PROTOCOL LABEL SWITCHING
OC-3	Optical Carrier Level 3
OCXO	Oven Controlled Crystal Oscillator
OFE	Optical Front End
OSI	Open Systems Interconnection
OSI-RM	Open Systems Interconnection—Reference Model
PDH	Plesiochronous Digital Hierarchy
PDU	Protocol Data Unit
PDV	Packet Delay Variation
PE	Provider Edge
PRBS	Pseudo-Random Bit Sequence
PSN	Packet Switched Network
PSTN	Public Switched Telephone Network
PWE3	Pseudo-Wire Emulation Edge-to-Edge
QoS	Quality of Service
RMII	Reduced Medium Independent Interface
Rx or RX	Receive
SAR	Segmentation and Reassembly
SAToP	Structure-Agnostic TDM over Packet
SDH	Synchronous Digital Hierarchy
SMII	Serial Media Independent Interface
SN	Sequence Number
SONET	Synchronous Optical Network

SS7	Signaling System 7
SSMII	Source Synchronous Serial Media Independent Interface
STM-1	Synchronous Transport Module Level 1
TDM	Time Division Multiplexing
TDMoIP	TDM over Internet Protocol
TDMoP	TDM over Packet
TSA	Timeslot Assigner
Tx or TX	Transmit
UDP	User Datagram Protocol
VoIP	Voice over IP
VPLS	Virtual Private LAN Services
WAN	Wide Area Network

## ***Glossary***

**bundle** – a virtual path configured at two endpoint TDMoP gateways to carry TDM data over a PSN.

**CLAD** – Clock Rate Adapter, an analog PLL that creates an output clock signal that is phase/frequency locked to an input clock signal of a different frequency. A CLAD is said to “convert” one frequency to another or “adapt” (change) a clock’s rate to be a frequency that is useful to some other block on the chip.

**dword** – a 32-bit (4-byte) unit of information (also known as a doubleword)

## **4. Detailed Description**

The DS34S108 is an 8-port TDM-over-Packet (TDMoP) IC. The DS34S104, DS34S102 and DS34S101 have the same functionality as the DS34S108, except they have only 4, 2 or 1 ports, respectively. These sophisticated devices can map and demap multiple E1/T1 data streams or a single E3/T3/STS-1 data stream to and from IP, MPLS or Ethernet networks. A built-in MAC supports connectivity to a single 10/100 Mbps PHY over an MII, RMII or SSMII interface. The DS34S10x devices are controlled through a 16 or 32-bit parallel bus interface or a high-speed SPI serial interface.

The TDM-over-Packet (TDMoP) core is the enabling block for circuit emulation and other network applications. It performs transparent transport of legacy TDM traffic over Packet Switched-Networks (PSN). The TDMoP core implements payload mapping methods such as AAL1 for circuit emulation, HDLC method, structure-agnostic SAToP method, and the structure-aware CESoPSN method.

The AAL1 payload-type machine maps and demaps E1, T1, E3, T3, STS-1 and other serial data flows into and out of IP, MPLS or Ethernet packets, according to the methods described in ITU-T Y.1413, Y.1453, MEF 8, MFA 4.1 and IETF RFC 5087 (TDMoIP). It supports E1/T1 structured mode with or without CAS, using a timeslot size of 8 bits, or unstructured mode (carrying serial interfaces, unframed E1/T1 or E3/T3/STS-1 traffic).

The HDLC payload-type machine maps and demaps HDLC dataflows into and out of IP/MPLS packets according to IETF RFC 4618 (excluding clause 5.3 – PPP) and IETF RFC 5087 (TDMoIP). It supports 2-, 7- and 8-bit timeslot resolution (i.e. 16, 56, and 64 kbps respectively), as well as  $N \times 64$  kbps bundles ( $n=1$  to 32). Supported applications of this machine include trunking of HDLC-based traffic (such as Frame Relay) implementing Dynamic Bandwidth Allocation over IP/MPLS networks and HDLC-based signaling interpretation (such as ISDN D-channel signaling termination – BRI or PRI, V5.1/2, or GR-303).

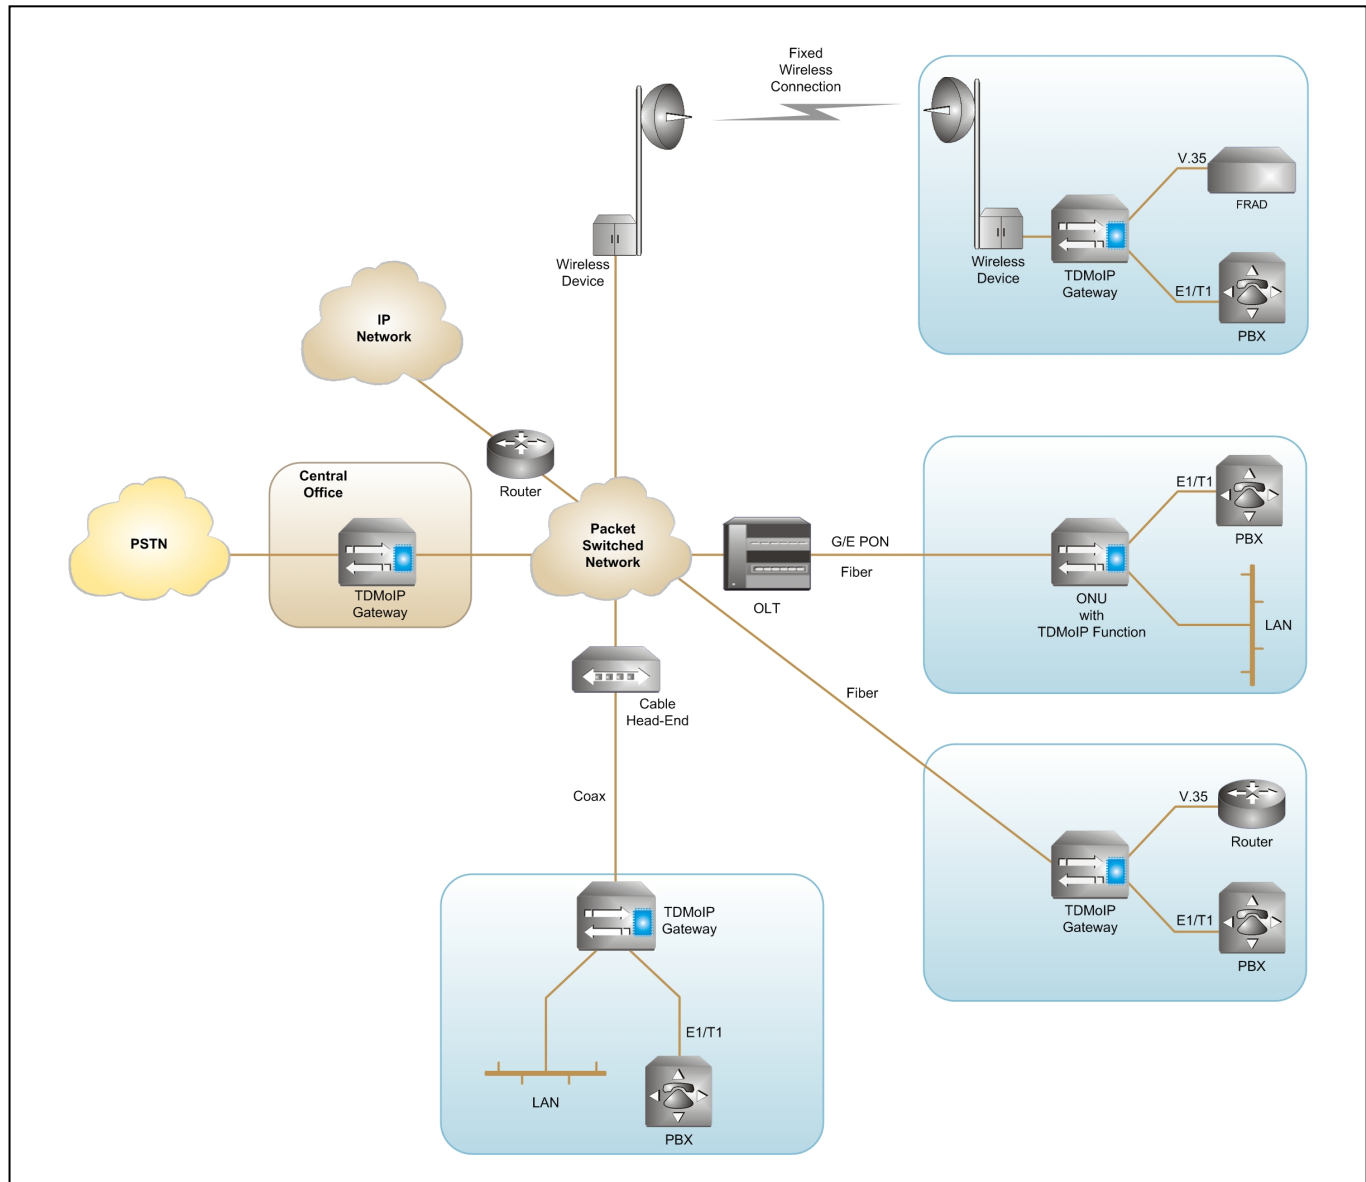

The SAToP payload-type machine maps and demaps unframed E1, T1, E3 or T3 data flows into and out of IP, MPLS or Ethernet packets according to ITU-T Y.1413, Y.1453, MEF 8, MFA 8.0.0 and IETF RFC 4553. It supports E1/T1/E3/T3 with no regard for the TDM structure. If TDM structure exists it is ignored, allowing this to be the simplest mapping/demapping method. The size of the payload is programmable for different services. This emulation suits applications where the provider edges have no need to interpret TDM data or to participate in the TDM signaling. The PSN network must have almost no packet loss and very low packet delay variation (PDV) for this method.

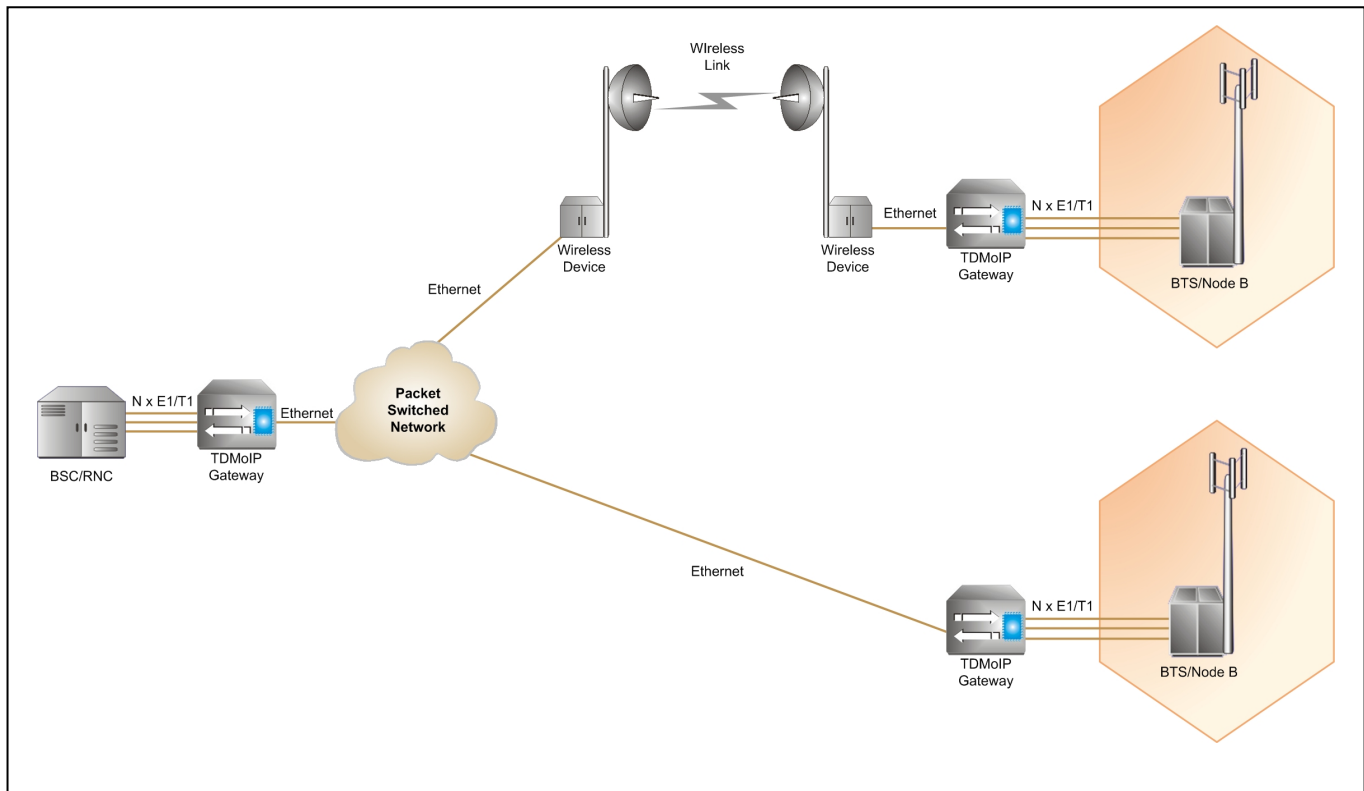

The CESoPSN payload-type machine maps and demaps structured E1, T1, E3 or T3 data flows into and out of IP, MPLS or Ethernet packets with static assignment of timeslots inside a bundle according to ITU-T Y.1413, Y.1453, MEF 8, MFA 8.0.0 and the IETF RFC 5086 (CESoPSN). It supports E1/T1/E3/T3 while taking into account the TDM structure. The level of structure must be chosen for proper payload conversion such as the framing type (i.e. frame or multiframe). This method is less sensitive to PSN impairments but lost packets could still cause service interruption.

## 5. Application Examples

In [Figure 5-1](#), a DS34S10x device is used in each TDMoP gateway to map TDM services into a packet-switched metropolitan network. TDMoP data is carried over various media: fiber, wireless, G/EPON, coax, etc.

Figure 5-1. TDMoP in a Metropolitan Packet Switched Network

**Figure 5-2. TDMoP in Cellular Backhaul**

## ***Other Possible Applications***

### ***Point-to-Multipoint TDM Connectivity over IP/Ethernet***

The DS34S10x devices support NxDS0 TDMoP connections (known as bundles) with or without CAS (Channel Associated Signaling). There is no need for an external TDM cross-connect, since the packet domain can be used as a virtual cross-connect. Any bundle of timeslots can be directed to another remote location on the packet domain.

### ***HDLC Transport over IP/MPLS***

TDM traffic streams often contain HDLC-based control channels and data traffic. These data streams, when transported over a packet domain, should be treated differently than the time-sensitive TDM payload. DS34S10x devices can terminate HDLC channels in the TDM streams and optionally map them into IP/MPLS/Ethernet for transport. All HDLC-based control protocols (ISDN BRI and PRI, SS7 etc.) and all HDLC data traffic can be managed and transported.

### ***Using a Packet Backplane for Multiservice Concentrators***

A communications device with all the above-mentioned capabilities can use a packet-based backplane instead of the more expensive TDM bus option. This enables a cost-effective and future-proof design of communication platforms with full support for both legacy and next-generation services.

## 6. Block Diagram

Figure 6-1. Top-Level Block Diagram

## **7. FEATURES**

### **Global Features**

- TDMoP Interfaces
  - DS34S101: 1 E1/T1/serial TDM interface
  - DS34S102: 2 E1/T1/serial TDM interfaces
  - DS34S104: 4 E1/T1/serial TDM interfaces
  - DS34S108: 8 E1/T1/serial TDM interfaces
  - All four devices: optionally 1 high-speed E3/DS3/STS-1 TDM interface
  - All four devices: each interface optionally configurable for serial operation for V.35 and RS530
- Ethernet Interface
  - One 10/100 Mbps port configurable for MII, RMII or SSMII interface format
  - Half or full duplex operation
  - VLAN support according to 802.1p and 802.1Q including stacked tags
  - Fully compatible with IEEE 802.3 standard
- End-to-end TDM synchronization through the IP/MPLS domain by on-chip, per-port TDM clock recovery
- 64 independent bundles/connections, each with its own:
  - Transmit and receive queues
  - Configurable jitter-buffer depth
  - Connection-level redundancy, with traffic duplication option
- Packet loss compensation and handling of misordered packets
- Glueless SDRAM interface
- Complies with MPLS-Frame Relay Alliance Implementation Agreements 4.1, 5.1 and 8.0
- Complies with ITU-T standards Y.1413 and Y.1414.
- Complies with Metro Ethernet Forum 3 and 8
- Complies with IETF RFC 4553 (SAToP), RFC 5086 (CESoPSN) and RFC 5087 (TDMoIP)
- IEEE 1146.1 JTAG boundary scan
- 1.8V and 3.3V Operation with 5.0V tolerant I/O

### **Clock Synthesizers**

- Clocks to operate the TDMoP clock recovery machines can be synthesized from a single clock input (10MHz, 19.44MHz, 38.88MHz or 77.76MHz on the CLK\_HIGH pin)
- Clock to operate TDMoP logic and SDRAM interface (50MHz or 75MHz) can be synthesized from a single 25MHz clock on the CLK\_SYS pin

### **TDM-over-Packet Block**

- Enables transport of TDM services (E1, T1, E3, T3, STS-1) or serial data over packet-switched networks
- SAToP payload-type machine maps/demaps unframed E1/T1/E3/T3/STS-1 or serial data flows to/from IP, MPLS or Ethernet packets according to ITU-T Y.1413, Y.1453, MEF 8, MFA 8.0.0 and IETF RFC 4553.
- CESoPSN payload-type machine maps/demaps structured E1/T1 data flows to/from IP, MPLS or Ethernet packets with static assignment of timeslots inside a bundle according to ITU-T Y.1413, Y.1453, MEF 8, MFA 8.0.0 and IETF RFC 5086.
- AAL1 payload-type machine maps/demaps E1/T1/E3/T3/STS-1 or serial data flows to/from IP, MPLS or Ethernet packets according to ITU-T Y.1413, MEF 8, MFA 4.1 and IETF RFC 5087. For E1/T1 it supports structured mode with/without CAS using 8-bit timeslot resolution, while implementing static timeslot allocation. For E1/T1, E3/T3/STS-1 or serial interface it supports unstructured mode.
- HDLC payload-type machine maps/demaps HDLC-based E1/T1/serial flow to/from IP, MPLS or Ethernet packets. It supports 2-, 7- and 8-bit timeslot resolution (i.e. 16, 56, and 64 kbps respectively), as well as N x 64 kbps bundles. This is useful in applications where HDLC-based signaling interpretation is required (such as ISDN D channel signaling termination, V.51/2, or GR-303), or for trunking packet-based applications (such as Frame Relay), according to IETF RFC 4618.

**TDMoP TDM Interfaces**

- Supports single high-speed E3, T3 or STS-1 interface on port 1 or one (DS34S101), two (DS34S102), four (DS34S104) or eight (DS34S108) E1, T1 or serial interfaces
- For single high-speed E3, T3 or STS-1 interface, AAL1 or SAToP payload type is used
- For E1 or T1 interfaces, the following modes are available:
  - Unframed – E1/T1 pass-through mode (AAL1, SAToP or HDLC payload type)
  - Structured – fractional E1/T1 support (all payloads)
  - Structured with CAS – fractional E1/T1 with CAS support (CESoPSN or AAL1 payload type)
- For serial interfaces, the following modes are available:
  - Arbitrary continuous bit stream (using AAL1 or SAToP payload type)
  - Single-interface high-speed mode on port 1 up to STS-1 rate (51.84 Mbps) using a single bundle/connection.
  - Low-speed mode with each interface operating at N x 64 kbps (N = 1 to 63) with an aggregate rate of 18.6Mbps
  - HDLC-based traffic (such as Frame Relay) at N x 64 kbps (N = 1 to 63) with an aggregate rate of 18.6Mbps).
- All serial interface modes are capable of working with a gapped clock.

**TDMoP Bundles**

- 64 independent bundles, each can be assigned to any TDM interface
- Each bundle carries a data stream from one TDM interface over IP/MPLS/Ethernet PSN from TDMoP source device to TDMoP destination device
- Each bundle may be for N x 64kbps, an entire E1, T1, E3, T3 or STS-1, or an arbitrary serial data stream
- Each bundle is unidirectional (but frequently coupled with opposite-direction bundle for bidirectional communication)
- Multiple bundles can be transported between TDMoP devices
- Multiple bundles can be assigned to the same TDM interface
- Each bundle is independently configured with its own:
  - Transmit and receive queues
  - Configurable receive-buffer depth
  - Optional connection-level redundancy (SAToP, AAL1, CESoPSN only).
- Each bundle can be assigned to one of the payload-type machines or to the CPU
- For E1/T1 the device provides internal bundle cross-connect functionality, with DS0 resolution

**TDMoP Clock Recovery**

- Sophisticated TDM clock recovery machines, one for each TDM interface, allow end-to-end TDM clock synchronization, despite the packet delay variation of the IP/MPLS/Ethernet network
- The following clock recovery modes are supported:
  - Adaptive clock recovery
  - Common clock (using RTP)
  - External clock
  - Loopback clock
- The clock recovery machines provide both fast frequency acquisition and highly accurate phase tracking:
  - Jitter and wander of the recovered clock are maintained at levels that conform to G.823/G.824 traffic or synchronization interfaces. (For adaptive clock recovery, the recovered clock performance depends on packet network characteristics.)
  - Short-term frequency accuracy (1 second) is better than 16 ppb (using OCXO reference), or 100 ppb (using TCXO reference)
  - Capture range is  $\pm 90$  ppm
  - Internal synthesizer frequency resolution of 0.5 ppb
  - High resilience to packet loss and misordering, up to 2% without degradation of clock recovery performance

- Robust to sudden significant constant delay changes
- Automatic transition to holdover when link break is detected

### ***TDMoP Delay Variation Compensation***

- Configurable jitter buffers compensate for delay variation introduced by the IP/MPLS/Ethernet network
- Large maximum jitter buffer depths:
  - E1: up to 256 ms
  - T1 unframed: up to 340 ms
  - T1 framed: up to 256 ms
  - T1 framed with CAS: up to 192 ms
  - E3: up to 60 ms
  - T3: up to 45 ms
  - STS-1: up to 40 ms.
- Packet reordering is performed for SAToP and CESoPSN bundles within the range of the jitter buffer
- Packet loss is compensated by inserting either a pre-configured conditioning value or the last received value.

### ***TDMoP CAS Support***

- On-chip CAS handler terminates E1/T1 CAS when using AAL1/CESoPSN in structured-with-CAS mode.
- CPU intervention is not required for CAS handling.

### ***Test and Diagnostics***

- IEEE 1149.1 JTAG support
- MBIST (memory built-in self test)

### ***CPU Interface***

- 32 or 16-bit parallel interface or optional SPI serial interface
- Byte write enable pins for single-byte write resolution
- Hardware reset pin
- Software reset supported
- Software access to device ID and silicon revision
- On-chip SDRAM controller provides access to SDRAM for both the chip and the CPU
- CPU can access transmit and receive buffers in SDRAM used for packets to/from the CPU (ARP, SNMP, etc.)

## ***8. OVERVIEW OF MAJOR OPERATIONAL MODES***

Globally, the resources of the device can be committed to either one high-speed E3, T3 or STS-1 TDM stream (high-speed mode) or one or more E1, T1 or serial streams (normal low-speed mode). In high-speed mode, the TDM signal is carried using an unstructured AAL1 or SAToP mapping. High-speed mode is enabled by setting [General\\_cfg\\_reg0.High\\_speed=1](#).

In normal, low-speed mode, each port can be configured for E1, T1 or serial (e.g. V.35) operation. Ports configured for E1 or T1 can be further configured for unframed, framed, or multiframed interface. In addition, each port can be configured to have the transmit and receive directions clocked by independent clocks (two-clock mode) or to have both directions clocked by the transmit clock (one-clock mode). All of this configuration is specified in the per-port [Port\[n\]\\_cfg\\_reg](#) register.

## 9. PIN DESCRIPTIONS

### 9.1 Short Pin Descriptions

Table 9-1. Short Pin Descriptions

PIN NAME <sup>(1)</sup>	TYPE <sup>(2)</sup>	PIN DESCRIPTION
<b>TDM Interface</b>		
TDMn_ACLK	O	TDMoP Recovered Clock Output
TDMn_TCLK	Ipu	TDMoP Transmit Clock Input (here transmit means “away from Ethernet MII”)
TDMn_TX	O	TDMoP Transmit Data Output
TDMn_TX_SYNC	Ipd	TDMoP Transmit Frame Sync Input
TDMn_TX_MF_CD	IOpd	TDMoP Transmit Multiframe Sync Input or Carrier Detect Output
TDMn_TSIG_CTS	O	TDMoP Transmit Signaling Output or Clear to Send Output
TDMn_RCLK	Ipu	TDMoP Receive Clock Input (here receive means “toward Ethernet MII”)
TDMn_RX	Ipu	TDMoP Receive Data Input
TDMn_RX_SYNC	Ipd	TDMoP Receive Frame/Multiframe Sync Input
TDMn_RSIG_RTS	Ipu	TDMoP Receive Signaling Input or Request To Send Input
<b>SDRAM Interface</b>		
SD_CLK	O	SDRAM Clock
SD_D[31:0]	IO	SDRAM Data Bus
SD_DQM[3:0]	O	SDRAM Byte Enable Mask
SD_A[11:0]	O	SDRAM Address Bus
SD_BA[1:0]	O	SDRAM Bank Select Outputs
SD_CS_N	O	SDRAM Chip Select (Active Low)
SD_WE_N	O	SDRAM Write Enable (Active Low)
SD_RAS_N	O	SDRAM Row Address Strobe (Active Low)
SD_CAS_N	O	SDRAM Column Address Strobe (Active Low)
<b>Ethernet PHY Interface (MII/RMII/SSMII)</b>		
CLK_MII_TX	I	MII Transmit Clock Input
CLK_SSMII_TX	O	SSMII Transmit Clock Output
MII_TXD[3:0]	O	MII Transmit Data Outputs
MII_TX_EN	O	MII Transmit Enable Output
MII_TX_ERR	O	MII Transmit Error Output
CLK_MII_RX	I	MII Receive Clock Input
MII_RXD[3:0]	I	MII Receive Data Inputs
MII_RX_DV	I	MII Receive Data Valid Input
MII_RX_ERR	I	MII Receive Error Input
MII_COL	I	MII Collision Input
MII_CRS	I	MII Carrier Sense Input
MDC	O	PHY Management Clock Output
MDIO	IOpu	PHY Management Data Input/Output
<b>Global Clocks</b>		
CLK_SYS_S	I	System Clock Selection Input
CLK_SYS	I	System Clock Input: 25, 50 or 75MHz
CLK_CMN	I	Common Clock Input (for common clock mode also known as differential mode)
CLK_HIGH	I	Clock High Input (for adaptive clock recovery machines and E1/T1 master clocks)
<b>CPU Interface</b>		
H_CPU_SPI_N	Ipu	Host Bus Interface (1=Parallel Bus, 0=SPI Bus)
DAT_32_16_N	Ipu	Data Bus Width (1=32-bit, 0=16-bit)
H_D[31:1]	IO	Host Data Bus
H_D[0] / SPI_MISO	IO	Host Data Lsb or SPI Data Output
H_AD[24:1]	I	Host Address Bus
H_CS_N	I	Host Chip Select (Active Low)
H_R_W_N / SPI_CP	I	Host Read/Write Control or SPI Clock Phase
H_WR_BE0_N / SPI_CLK	I	Host Write Enable Byte 0 (Active Low) or SPI Clock
H_WR_BE1_N / SPI_MOSI	I	Host Write Enable Byte 1 (Active Low) or SPI Data Input

PIN NAME <sup>(1)</sup>	TYPE <sup>(2)</sup>	PIN DESCRIPTION
<a href="#">H_WR_BE2_N / SPI_SEL_N</a>	I	Host Write Enable Byte 2 or SPI Chip Select (Active Low)
<a href="#">H_WR_BE3_N / SPI_CI</a>	I	Host Write Enable Byte 3 (Active Low) or SPI Clock Invert
<a href="#">H_READY_N</a>	Oz	Host Ready Output (Active Low)
<a href="#">H_INT</a>	O	Host Interrupt Output.
<b>JTAG Interface</b>		
<a href="#">JTRST_N</a>	Ipu	JTAG Test Reset
<a href="#">JTCLK</a>	I	JTAG Test Clock
<a href="#">JTMS</a>	Ipu	JTAG Test Mode Select
<a href="#">JTDI</a>	Ipu	JTAG Test Data Input
<a href="#">JTDO</a>	Oz	JTAG Test Data Output
<b>Reset and Factory Test Pins</b>		
<a href="#">RST_SYS_N</a>	Ipu	System Reset (Active Low)
<a href="#">HIZ_N</a>	I	High Impedance Enable (Active Low)
<a href="#">SCEN</a>	Ipd	Used for factory tests.
<a href="#">STMD</a>	Ipd	Used for factory tests.
<a href="#">MBIST_EN</a>	I	Used for factory tests.
<a href="#">MBIST_DONE</a>	O	Used for factory tests.
<a href="#">MBIST_FAIL</a>	O	Used for factory tests.
<a href="#">TEST_CLK</a>	O	Used for factory tests.
<a href="#">TST_CLD</a>	I	Used for factory tests. DS34S108 only.
<b>Power and Ground</b>		
<a href="#">DVDDC</a>	P	1.8V Core Voltage for TDM-over-Packet Digital logic (17 pins)
<a href="#">DVDDIO</a>	P	3.3V for I/O Pins (16 pins)
<a href="#">DVSS</a>	P	Ground for TDM-over-Packet logic and I/O Pins (31 pins)
<a href="#">ACVDD1, ACVDD2</a>	P	1.8V for CLAD Analog Circuits
<a href="#">ACVSS1, ACVSS2</a>	P	Ground for CLAD Analog Circuits

**Note 1:** In pin names, the suffix "n" stands for port number: n=1 to 8 for DS34S108; n=1 to 4 for DS34S104; n=2 for DS34S102; n=1 for DS34S101. All pin names ending in "\_N" are active low.

**Note 2:** All pins, except power and analog pins, are CMOS/TTL unless otherwise specified in the pin description.

#### PIN TYPES

I = input pin

I<sub>PD</sub> = input pin with internal 50k $\Omega$  pulldown to DVSS

I<sub>PU</sub> = input pin with internal 50k $\Omega$  pullup to DVDDIO

IO = input/output pin

IO<sub>PD</sub> = input/output pin with internal 50k $\Omega$  pulldown to DVSS

IO<sub>PU</sub> = input/output pin with internal 50k $\Omega$  pullup to DVDDIO

O = output pin

O<sub>Z</sub> = output pin that can be placed in a high-impedance state

P = power-supply or ground pin

## 9.2 Detailed Pin Descriptions

**Table 9-2. TDM-over-Packet Engine TDM Interface Pins**

In this table, the transmit direction is the packet-to-TDM direction while the receive direction is the TDM-to-packet direction. See [Figure 6-1](#).

PIN NAME <sup>(1)</sup>	TYPE <sup>(2)</sup>	PIN DESCRIPTION
TDMn_ACLK	O 8mA	<b>TDMoP Recovered Clock Output</b> The clock recovered by the TDMoP clock recovery machine is output on this pin. TDM1_ACLK (port 1) is used in high speed E3/T3/STS1 mode.
TDMn_TCLK	Ipu	<b>TDMoP Transmit Clock Input</b> This signal clocks the transmit TDM interface of the TDMoP engine. Depending on the value of <a href="#">Port[n]_cfg_reg:tx_sample</a> , outputs <a href="#">TDMn_TX</a> and <a href="#">TDMn_TSIG_CTS</a> are updated on the either the rising edge (0) or falling edge (1) of TDMn_TCLK. Inputs <a href="#">TDMn_TX_SYNC</a> and <a href="#">TDMn_TX_MF_CD</a> are latched on the opposite edge. See the timing diagrams in <a href="#">Figure 14-8</a> and <a href="#">Figure 14-9</a> .  In one-clock mode, TDMn_TCLK also clocks the receive TDM interface of the TDMoP engine. Depending on the value of <a href="#">Port[n]_cfg_reg:tx_sample</a> , outputs <a href="#">TDMn_RX</a> , <a href="#">TDMn_RX_SYNC</a> and <a href="#">TDMn_RSIG_RTS</a> are updated on the either the rising edge (0) or falling edge (1) of TDMn_TCLK.  <a href="#">Port[n]_cfg_reg.Two_clocks</a> specifies two-clock mode (1) or one-clock mode (0). This pin is only active in external mode ( <a href="#">GCR1.MODE=1</a> ). Only TDM1_TCLK (port 1) is used in high speed E3/T3/STS1 mode ( <a href="#">General_cfg_reg0.High_speed=1</a> ). See the timing diagrams in <a href="#">Figure 14-8</a> through <a href="#">Figure 14-13</a> .
TDMn_TX	O 8mA	<b>TDMoP Transmit Data Output</b> Serial data from the TDMoP engine is output on this pin. This signal is clocked by <a href="#">TDMn_TCLK</a> .  Only TDM1_TX (port 1) is used in high speed E3/T3/STS1 mode (i.e. when <a href="#">General_cfg_reg0.High_speed=1</a> ). This pin is only active in external mode ( <a href="#">GCR1.MODE=1</a> ). See the timing diagrams in <a href="#">Figure 14-8</a> through <a href="#">Figure 14-13</a> .
TDMn_TX_SYNC	Ipd	<b>TDMoP Transmit Frame Sync Input</b> Frame sync information is provided to the TDMoP engine from this pin. In two-clock mode, this signal specifies only transmit frame sync. In one-clock mode, this signal specifies frame sync for both the transmit and receive directions.  The signal on this pin must pulse high for one <a href="#">TDMn_TCLK</a> cycle when the first bit of a frame is expected to present on the <a href="#">TDMn_TX</a> pin (and the <a href="#">TDMn_RX</a> pin in one-clock mode). This pulse must be repeated every $N \times 125\mu\text{s}$ where N is a positive integer (example: if N=16, it pulses every 2ms).  <a href="#">Port[n]_cfg_reg.Two_clocks</a> specifies two-clock mode (1) or one-clock mode (0). This pin is only active in external mode ( <a href="#">GCR1.MODE=1</a> ). See the timing diagrams in <a href="#">Figure 14-8</a> through <a href="#">Figure 14-13</a> .
TDMn_TX_MF_CD	IOpd	<b>TDMoP Transmit Multiframe Sync Input</b> When the interface type is configured for E1 or T1, multiframe sync is provided to the TDMoP engine from this pin. The signal on this pin must pulse high for one <a href="#">TDMn_TCLK</a> cycle when the first bit the multiframe is expected to be present on the <a href="#">TDMn_TX</a> pin.  <b>TDMoP Transmit Carrier Detect Output</b> When the interface type is configured for serial, the carrier detect function of this pin is active. When <a href="#">Port[n]_cfg_reg.CD_en=1</a> , the state of this pin is controlled by the value stored in <a href="#">Port[n]_cfg_reg.CD</a> .

PIN NAME <sup>(1)</sup>	TYPE <sup>(2)</sup>	PIN DESCRIPTION
		<p><a href="#">Port[n]_cfg_reg.Int_type</a>=specifies serial (00), E1 (01) or T1 (10).  <a href="#">Port[n]_cfg_reg.Int_type</a>=specifies serial (00), E1 (01) or T1 (10) interface type.  This pin is only active in external mode (<a href="#">GCR1.MODE=1</a>).  See the timing diagrams in <a href="#">Figure 14-8</a> through <a href="#">Figure 14-13</a>.</p>
TDMn_TSIG_CTS	O 8mA	<p><b>TDMoP Transmit Signaling Output</b>  When the interface type is configured for E1 or T1, the transmit signaling function of this pin is active. Functional timing is shown in <a href="#">Figure 10-33</a> and <a href="#">Figure 10-34</a>.</p> <p><b>TDMoP Clear to Send Output</b>  When the interface type is configured for serial, the clear-to-send function of this pin is active. In this mode, the state of this pin is controlled by the value stored in <a href="#">Port[n]_cfg_reg.CTS</a>.</p> <p><a href="#">Port[n]_cfg_reg.Int_type</a> specifies serial (00), E1 (01) or T1 (10) interface type.  This pin is only active in external mode (<a href="#">GCR1.MODE=1</a>).  See the timing diagrams in <a href="#">Figure 14-8</a> through <a href="#">Figure 14-13</a>.</p>
TDMn_RCLK	Ipu	<p><b>TDMoP Receive Clock Input</b>  In two-clock mode, this signal clocks the receive TDM interface of the TDMoP engine: <a href="#">TDMn_RX</a>, <a href="#">TDMn_RX_SYNC</a> and <a href="#">TDMn_RSIG_RTS</a>.</p> <p>In one-clock mode, this signal is ignored, and the <a href="#">TDMn_TCLK</a> signal clocks both the transmit and receive interfaces of the TDMoP engine.</p> <p><a href="#">Port[n]_cfg_reg.Two_clocks</a> specifies two-clock mode (1) or one-clock mode (0).  <a href="#">Port[n]_cfg_reg.Rx_sample</a> specifies latching on the rising (1) or falling (0) edge.  TDM1_RCLK (port 1) is used in high speed E3/T3/STS1 mode.  This pin is only active in external mode (<a href="#">GCR1.MODE=1</a>).  See the timing diagrams in <a href="#">Figure 14-8</a> through <a href="#">Figure 14-13</a>.</p>
TDMn_RX	Ipu	<p><b>TDMoP Receive Data Input</b>  Serial data to the TDMoP engine is input on this pin.  In two-clock mode, this signal is clocked by <a href="#">TDMn_RCLK</a>.  In one-clock mode, this signal, is clocked by <a href="#">TDMn_TCLK</a>.</p> <p><a href="#">Port[n]_cfg_reg.Two_clocks</a> specifies two-clock mode (1) or one-clock mode (0).  TDM1_RX (port 1) is used in high speed E3/T3/STS1 mode.  This pin is only active in external mode (<a href="#">GCR1.MODE=1</a>).  See the timing diagrams in <a href="#">Figure 14-8</a> through <a href="#">Figure 14-13</a>.</p>
TDMn_RX_SYNC	Ipd	<p><b>TDMoP Receive Frame/Multiframe Sync Input</b>  In two-clock mode, this signal is clocked by <a href="#">TDMn_RCLK</a> and specifies frame or multiframe alignment for the receive interface of the TDMoP engine. The signal on this pin must pulse high for one <a href="#">TDMn_RCLK</a> cycle when the first bit of a frame is present on the <a href="#">TDMn_RX</a> pin. This pulse must be repeated every N*125µs where N is a positive integer (example: if N=16, it pulses every 2ms).</p> <p>In one-clock mode, this signal is ignored and <a href="#">TDMn_TX_SYNC</a> specifies frame alignment for both the transmit and receive interfaces of the TDMoP engine.</p> <p><a href="#">Port[n]_cfg_reg.Two_clocks</a> specifies two-clock mode (1) or one-clock mode (0).  This pin is only active in external mode (<a href="#">GCR1.MODE=1</a>).  See the timing diagrams in <a href="#">Figure 14-8</a> through <a href="#">Figure 14-13</a>.</p>
TDMn_RSIG_RTS	Ipu	<p><b>TDMoP Receive Signaling Input</b>  When the interface type is configured for E1 or T1, the transmit signaling function of this pin is active.  In two-clock mode, this signal is clocked by <a href="#">TDMn_RCLK</a>.  In one-clock mode, this signal, is clocked by <a href="#">TDMn_TCLK</a>.</p>

PIN NAME <sup>(1)</sup>	TYPE <sup>(2)</sup>	PIN DESCRIPTION
		<b>TDMoP Request To Send Input</b> When the interface type is configured for serial, the request-to-send function of this pin is active. In this mode, the real-time status of this pin can be read from <a href="#">Port[n]_stat_reg1.RTS_P</a> .  <a href="#">Port[n]_cfg_reg.Two_clocks</a> specifies two-clock mode (1) or one-clock mode (0). <a href="#">Port[n]_cfg_reg.Int_type</a> specifies serial (00), E1 (01) or T1 (10) interface type. This pin is only active in external mode ( <a href="#">GCR1.MODE=1</a> ). See the timing diagrams in <a href="#">Figure 14-8</a> through <a href="#">Figure 14-13</a> .

**Table 9-3. SDRAM Interface Pins**

PIN NAME <sup>(1)</sup>	TYPE <sup>(2)</sup>	PIN DESCRIPTION
SD_CLK	O 8mA	<b>SDRAM Clock</b> All SDRAM interface pins are updated or latched on the rising edge of SD_CLK. See the timing diagrams in <a href="#">Figure 14-6</a> and <a href="#">Figure 14-7</a> .
SD_D[31:0]	IO 8mA	<b>SDRAM Data</b> MSB is SD_D[31].
SD_DQM[3:0]	O 8mA	<b>SDRAM Byte Enable Mask</b> SD_DQM[0] is associated with the least significant byte. SD_DQM[3] is associated with the most significant byte. When a SD_DQM pin is high during a write cycle, the associated byte is not written to SDRAM. When a SD_DQM pin is high during a read cycle, the associated byte is not driven out of the SDRAM (the SD_D pins remain high-Z).
SD_A[11:0]	O 8mA	<b>SDRAM Address Bus</b> MSB is SD_A[11].
SD_BA[1:0]	O 8mA	<b>SDRAM Bank Select Outputs</b> The external SDRAMs used by the device have their memory organized into four banks. These pins specify the bank to be accessed. The bank must be specified on the same <a href="#">SD_CLK</a> edge that the row information is specified on <a href="#">SD_A[11:0]</a> .
SD_CS_N	O 8mA	<b>SDRAM Chip Select (Active Low)</b> Driven low by the device to initiate a memory access (read or write) to the external SDRAM.
SD_WE_N	O 8mA	<b>SDRAM Write Enable (Active Low)</b> Driven low by the device when data is to be written to the external SDRAM. Left high when data is to be read from the external SDRAM.
SD_RAS_N	O 8mA	<b>SDRAM Row Address Strobe (Active Low)</b> Driven low by the device during SD_CLK cycles in which <a href="#">SD_A[11:0]</a> indicates the SDRAM row address.
SD_CAS_N	O 8mA	<b>SDRAM Column Address Strobe (Active Low)</b> Driven low by the device during SD_CLK cycles in which <a href="#">SD_A[11:0]</a> indicates the SDRAM column address.

**Table 9-4. Ethernet PHY Interface Pins (MII/RMII/SSMII)**

The PHY interface type is configured by [General\\_cfg\\_reg0.Mii\\_mode\\_select\[1:0\]](#). 00=MII, 01=Reduced MII (RMII), 11=Source Synchronous Serial MII (SSMII). The MII interface is described in IEEE 802.3-2005 Section 22. The RMII interface is described in this document: [http://www.national.com/appinfo/networks/files/rmii\\_1\\_2.pdf](http://www.national.com/appinfo/networks/files/rmii_1_2.pdf). The Source Synchronous Serial MII is described in this document: <ftp://ftp-eng.cisco.com/smii/smii.pdf>.

PIN NAME <sup>(1)</sup>	TYPE <sup>(2)</sup>	PIN DESCRIPTION
CLK_MII_TX	I	<p><b>MII Transmit Clock Input</b></p> <p>In MII mode a 25MHz clock must be applied to this pin to clock the transmit side of the interface. <a href="#">MII_TXD[3:0]</a>, <a href="#">MII_TX_EN</a> and <a href="#">MII_TX_ERR</a> are clocked out of the device on the rising edge of CLK_MII_TX. See the timing diagram in Figure 14-15.</p> <p>In RMII mode a 50MHz clock must be applied to this pin to clock the transmit side of the interface. <a href="#">MII_TXD[3:2]</a> and <a href="#">MII_TX_EN</a> are clocked out of the device on the rising edge of CLK_MII_TX. See the timing diagram in Figure 14-17.</p> <p>In SSMII mode, a 125MHz clock must be applied to this pin. This clock is the reference for the <a href="#">CLK_SSMII_TX</a> output.</p>
CLK_SSMII_TX	O 12ma	<p><b>SSMII Transmit Clock Output</b></p> <p>In SSMII mode, the device provides a 125MHz clock on this pin to clock the transmit side of the interface. <a href="#">MII_TXD[0]</a> (SSMII_TXD) and <a href="#">MII_TXD[1]</a> (SSMII_TX_SYNC) are clocked out of the device on the rising edge of <a href="#">CLK_MII_TX</a>. See the timing diagram in Figure 14-19. This pin is not used in MII and RMII modes.</p>
MII_TXD[3:0]	O 8mA	<p><b>MII Transmit Data Outputs</b></p> <p>In MII mode, transmit data is passed to the PHY four bits at a time on MII_TXD[3:0] on the rising edge of <a href="#">CLK_MII_TX</a>. See the timing diagram in Figure 14-15.</p> <p>In RMII mode, transmit data is passed to the PHY two bits at a time on MII_TXD[3:2] on the rising edge of <a href="#">CLK_MII_TX</a> while MII_TXD[1:0] are not used. See the timing diagram in Figure 14-17.</p> <p>In SSMII mode, transmit data is passed to the PHY one bit at a time on MII_TXD[0] (SSMII_TXD) on the rising edge of <a href="#">CLK_SSMII_TX</a>. MII_TXD[1] (SSMII_TX_SYNC) indicates 10-bit segment alignment of the serial data stream.</p>
MII_TX_EN	O 8mA	<p><b>MII Transmit Enable Output</b></p> <p>In MII mode and RMII, this pin serves as the transmit enable output. In SSMII mode this pin is not used.</p>
MII_TX_ERR	O 8mA	<p><b>MII Transmit Error Output</b></p> <p>In MII mode this pin serves as the transmit error output. In RMII and SSMII modes this pin is not used.</p>
CLK_MII_RX	I	<p><b>MII Receive Clock Input</b></p> <p>In MII mode a 25MHz clock must be applied to this pin. <a href="#">MII_RXD[3:0]</a>, <a href="#">MII_RX_DV</a>, and <a href="#">MII_RX_ERR</a> are clocked into the device on the rising edge of CLK_MII_RX. See the timing diagram in Figure 14-16.</p> <p>In RMII mode this pin is not used, and a 50MHz clock applied to <a href="#">CLK_MII_TX</a> provides timing for both transmit and receive sides of the interface. <a href="#">MII_RXD[3:2]</a>, <a href="#">MII_RX_DV</a> and <a href="#">MII_RX_ERR</a> are clocked into the device on the rising edge of <a href="#">CLK_MII_TX</a>. See the timing diagram in Figure 14-18.</p> <p>In SSMII mode a 125MHz clock from the PHY must be applied to this pin. <a href="#">MII_RXD[0]</a> (SSMII_RXD) and <a href="#">MII_RXD[1]</a> (SSMII_RX_SYNC) are clocked into the device on the rising edge of CLK_MII_RX. See the timing diagram in Figure 14-20.</p>

PIN NAME <sup>(1)</sup>	TYPE <sup>(2)</sup>	PIN DESCRIPTION
MII_RXD[3:0]	I	<b>MII Receive Data Inputs</b> In MII mode, receive data comes from the PHY four bits at a time on MII_RXD[3:0], on the rising edge of <a href="#">CLK_MII_RX</a> . See the timing diagram in <a href="#">Figure 14-16</a> .  In RMII mode, receive data comes from the PHY two bits at a time on MII_RXD[3:2] and is latched on the rising edge of <a href="#">CLK_MII_TX</a> . MII_RXD[1:0] are not used. See the timing diagram in <a href="#">Figure 14-18</a> .  In SSMII mode, received data comes from the PHY one bit at a time on MII_RXD[0] (SSMII_RXD) on the rising edge of <a href="#">CLK_MII_RX</a> . MII_RXD[1] (SSMII_RX_SYNC) indicates 10-bit segment alignment of the serial data stream.
MII_RX_DV	I	<b>MII Receive Data Valid Input</b> In MII mode, this pin serves as the receive data valid input. In RMII mode, carrier sense and receive data valid alternate on this pin. See the RMII spec for details. In SSMII mode this pin is not used and should be pulled low or high.
MII_RX_ERR	I	<b>MII Receive Error Input</b> In MII mode and RMII mode, this pin serves as the receive error input. In SSMII mode this pin is not used and should be pulled low or high.
MII_COL	I	<b>MII Collision Input</b> In MII mode this pin serves as the collision detection input. In RMII mode and SSMII mode this pin is not used and should be pulled low or high.
MII_CRS	I	<b>MII Carrier Sense Input</b> In MII mode this pin serves as the carrier sense input. In RMII mode and SMII mode this pin is not used and should be pulled low or high.
MDC	O 8mA	<b>PHY Management Clock Output</b> This signal is the clock for the Ethernet PHY management interface, which consists of MDC and <a href="#">MDIO</a> . See the timing diagram in <a href="#">Figure 14-14</a> .
MDIO	IOpu 8mA	<b>PHY Management Data Input/Output</b> This signal is the serial data signal for the Ethernet PHY management interface, which consists of <a href="#">MDC</a> and MDIO. When MDIO is an output, it is updated on the rising edge of MDC. When MDIO is an input, it is latched into the device on the rising edge of MDC. See the timing diagram in <a href="#">Figure 14-14</a> .

**Table 9-5. Global Clock Pins**

PIN NAME <sup>(1)</sup>	TYPE <sup>(2)</sup>	PIN DESCRIPTION
CLK_SYS_S	lpd	<b>System Clock Selection Input</b> This pin specifies the frequency of the clock applied to the <a href="#">CLK_SYS</a> pin. See section <a href="#">10.4</a> . 0 = 50 or 75 MHz 1 = 25 MHz
CLK_SYS	I	<b>System Clock Input</b> A 25 MHz, 50 MHz or 75 MHz clock ( $\pm 50$ ppm or better) must be applied to this pin to clock TDM-over-Packet internal circuitry and the SDRAM interface ( <a href="#">SD_CLK</a> ). When a 25MHz clock is applied, it is internally multiplied by the CLAD2 block to 50MHz or 75MHz as specified by <a href="#">GCR1.SYSCLKS</a> . The <a href="#">CLK_SYS_S</a> pin specifies whether the CLK_SYS signal is 25MHz (and therefore needs to be multiplied up) or 50/75MHz (and therefore is used as-is). See section <a href="#">10.4</a> .
CLK_CMN	I	<b>Common Clock Input</b> When the TDMoP engine is configured for common clock mode (also known as differential mode), the common clock is applied to this pin. This clock signal has to be a multiple of 8kHz and in the range of 1MHz to 25MHz. The frequency should not be too close to an integer multiple of the service clock frequency. Based on these criteria, the following frequencies are suggested: For systems with access to a common SONET/SDH network, a frequency of 19.44 MHz (2430*8 kHz). For systems with access to a common ATM network, 9.72 MHz (1215*8 kHz) or

PIN NAME <sup>(1)</sup>	TYPE <sup>(2)</sup>	PIN DESCRIPTION
		19.44 MHz (2430*8 kHz). For systems using GPS, 8.184 MHz (1023*8 kHz). For systems connected by a single hop of 100 Mbit/s Ethernet where it is possible to lock the physical layer clock, 25 MHz (3125*8 kHz). For systems connected by a single hop of Gigabit Ethernet where it is possible to lock to the physical layer clock, 10MHz (1250*8 kHz). When a clock is not needed on this pin, pull it high or low. See section 10.4.
CLK_HIGH	I	<b>Clock High Input</b> A 10, 19.44, 38.88 or 77.76MHz clock can be applied to this pin. From the CLK_HIGH signal, an on-chip frequency converter block (called a clock adapter or CLAD, in this case CLAD1) produces the 38.88MHz reference clock required by the clock recovery machines in the TDMoP block. GCR1.FREQSEL specifies the frequency of the clock applied to CLK_HIGH. When GCR1.CLK_HIGHD=1, the CLAD disables the 38.88MHz reference clock to the clock recovery machines. When clock recovery is not required (i.e. when none of the recovered clock outputs TDMn_ACLK are used), CLK_HIGH can be held low. The required quality of the CLK_HIGH signal is discussed in section 10.6.3.

**Table 9-6. CPU Interface Pins**

See the parallel interface timing diagrams in Figure 14-2 and Figure 14-3 and the SPI timing diagrams in Figure 14-4 and Figure 14-5.

PIN NAME <sup>(1)</sup>	TYPE <sup>(2)</sup>	PIN DESCRIPTION
H_CPU_SPI_N	Ipu	<b>Host Bus Interface</b> 0 = SPI serial interface 1 = Parallel interface
DAT_32_16_N	Ipu	<b>Data Bus Width</b> 0 = 16-bit 1 = 32-bit In SPI bus mode this pin is ignored.
H_D[31:1]	IO 8mA	<b>Host Data Bus</b> When the device is configured for a 32-bit parallel interface, H_D[31:0] are the data I/O pins (HD[31] is the MSb). When the device is configured for a 16-bit parallel interface, H_D[15:0] are the data I/O pins (HD[15] is the MSb) and H_D[31:16] are ignored and should be pulled low or high. The DAT_32_16_N pin specifies bus width. In SPI bus mode these pins are ignored.
H_D[0] / SPI_MISO	IO 8mA	<b>H_D[0]: Host Data LSb</b> In parallel interface mode this pin is H_D[0], LSb of the data bus.  <b>SPI_MISO: SPI Data Output (Master In Slave Out)</b> In SPI bus mode this pin is the SPI data output.
H_AD[24:1]	I	<b>Host Address Bus</b> H_AD[24] is the MSb. When the host data bus is 32 bits (DAT_32_16_N=1), H_AD[1] should be held low. In SPI bus mode these pins are ignored.
H_CS_N	I	<b>Host Chip Select (Active Low)</b> In parallel interface mode this pin must be asserted (low) to read or write internal registers. In SPI bus mode this pin is ignored.
H_R_W_N / SPI_CP	I	<b>H_R_W_N: Host Read/Write Control</b> In parallel interface mode this pin controls whether an access to internal registers is a read or a write.  <b>SPI_CP: SPI Clock Phase</b> In SPI interface mode this pin specifies SPI clock phase. See the timing diagrams in Figure 14-4 and Figure 14-5 for details. 0 = input data is latched on the leading edge of the SCLK pulse; output data is updated on the trailing edge

PIN NAME <sup>(1)</sup>	TYPE <sup>(2)</sup>	PIN DESCRIPTION
		1 = input data is latched on the trailing edge of the SCLK pulse; output data is updated on the leading edge
H_WR_BE0_N / SPI_CLK	I	<b>H_WR_BE0_N: Host Write Enable Byte 0 (Active Low)</b> In parallel interface mode during a write access this pin specifies whether or not byte 0 ( <a href="#">H_D[7:0]</a> ) should be written to the device. This pin is active in both 32-bit and 16-bit modes. 0 = write byte 0 1 = don't write byte 0  <b>SPI_CLK: SPI Clock</b> In SPI interface mode this pin is the clock for the interface.
H_WR_BE1_N / SPI_MOSI	I	<b>H_WR_BE1_N: Host Write Enable Byte 1 (Active Low)</b> In parallel interface mode during a write access this pin specifies whether or not byte 1 ( <a href="#">H_D[15:8]</a> ) should be written to the device. This pin is active in both 32-bit and 16-bit modes. 0 = write byte 1 1 = don't write byte 1  <b>SPI_MOSI: SPI Data Input (Master Out Slave In)</b> In SPI interface mode this pin is the data input pin for the interface.
H_WR_BE2_N / SPI_SEL_N	I	<b>H_WR_BE2_N: Host Write Enable Byte 2 (Active Low)</b> In 32-bit parallel interface mode during a write access this pin specifies whether or not byte 2 ( <a href="#">H_D[15:8]</a> ) should be written to the device. In 16-bit parallel interface mode this pin is ignored and should be pulled high or low. 0 = write byte 2 1 = don't write byte 2  <b>SPI_SEL: SPI Chip Select (Active Low)</b> In SPI interface mode this pin must be asserted (low) to read or write internal registers.
H_WR_BE3_N / SPI_CI	I	<b>H_WR_BE3_N: Host Write Enable Byte 3 (Active Low)</b> In 32-bit parallel interface mode during a write access this pin specifies whether or not byte 3 ( <a href="#">H_D[15:8]</a> ) should be written to the device. In 16-bit parallel interface mode this pin is ignored and should be pulled high or low. 0 = write byte 3 1 = don't write byte 3  <b>SPI_CI: SPI Clock Invert</b> In SPI interface mode this pin specifies the polarity of the <a href="#">SPI_CLK</a> pin. See the timing diagrams in <a href="#">Figure 14-4</a> and <a href="#">Figure 14-5</a> for details. 0 = <a href="#">SPI_CLK</a> is normally low and pulses high (leading edge is rising edge) 1 = <a href="#">SPI_CLK</a> is normally high and pulses low (leading edge is falling edge)
H_READY_N	O 8mA	<b>Host Ready Output (Active Low)</b> In parallel interface mode the device pulls this pin low during a read or write access to signal that the device is ready for the access to be completed. The host processor should not pull <a href="#">H_CS_N</a> high (inactive) to complete the access until the device has pulled H_READY_N low. This pin requires the use of an external pull-up resistor. The device actively drives this pin high before allowing it to go high-impedance. See <a href="#">Figure 14-2</a> .
H_INT	O 8mA	<b>Host Interrupt Output (Active Low)</b> This pin indicates interrupt requests from the device. When <a href="#">GCR1.IPI</a> =1, H_INT is forced high (inactive). See section <a href="#">10.9</a> .

**Table 9-7. JTAG Interface Pins**See the JTAG interface timing diagram in [Figure 14-21](#).

PIN NAME <sup>(1)</sup>	TYPE <sup>(2)</sup>	PIN DESCRIPTION
JTRST_N	Ipu	<b>JTAG Test Reset (Active Low)</b> This signal is used to asynchronously reset the test access port controller. After power up, JTRST_N must be toggled from low to high. This action sets the device into the JTAG DEVICE ID mode. Pulling JTRST_N low restores normal device operation. If boundary scan is not used, this pin should be held low.
JTCLK	I	<b>JTAG Test Clock</b> This signal is used to shift data into <a href="#">JTDI</a> on the rising edge and out of <a href="#">JTDO</a> on the falling edge.
JTMS	Ipu	<b>JTAG Test Mode Select</b> This pin is sampled on the rising edge of <a href="#">JTCLK</a> and is used to place the test access port into the various defined IEEE 1149.1 states. If not used, JTMS should be held high.
JTDI	Ipu	<b>JTAG Test Data Input</b> Test instructions and data are clocked into this pin on the rising edge of <a href="#">JTCLK</a> . If not used, JTDI can be held low or high (DVDDIO).
JTDO	Oz 8mA	<b>JTAG Test Data Output</b> Test instructions and data are clocked out of this pin on the falling edge of <a href="#">JTCLK</a> . If not used, this pin should be left unconnected.

**Table 9-8. Reset and Factory Test Pins**

PIN NAME <sup>(1)</sup>	TYPE <sup>(2)</sup>	PIN DESCRIPTION
RST_SYS_N	Ipu	<b>System Reset (Active Low)</b> When this pin is held low the entire device is reset. This pin should be held low (active) for at least 200 $\mu$ s before going inactive. CLK_SYS and CLK_HIGH should be stable for at least 200 $\mu$ s before RST_SYS_N goes inactive. See <a href="#">section 10.5</a> for more information on system resets and block-level resets.
HIZ_N	I	<b>High Impedance Enable (Active Low)</b> When this signal is low while <a href="#">JTRST_N</a> is low, all of the digital output and bi-directional pins are placed in the high impedance state. For normal operation this signal is high. This is an asynchronous input.
SCEN	I	Used during factory test. This pin should be tied to DVSS.
STMD	I	Used during factory test. This pin should be tied to DVSS.
MBIST_EN	I	Used during factory test. This pin should be tied to DVSS.
MBIST_DONE	O	Used during factory test. This pin should be left floating.
MBIST_FAIL	O	Used during factory test. This pin should be left floating.
TEST_CLK	O	Used during factory test. This pin should be left floating.
TST_CLD	I	Used during factory test. This pin should be tied to DVSS.

**Table 9-9. Power and Ground Pins**

PIN NAME <sup>(1)</sup>	TYPE <sup>(2)</sup>	PIN DESCRIPTION
DVDDC	P	1.8V Core Voltage for TDM-over-Packet Digital Logic (17 pins)
DVDDIO	P	3.3V for I/O Pins (16 pins)
DVSS	P	Ground for TDM-over-Packet Logic and I/O Pins (31 pins)
ACVDD1	P	1.8V for CLAD Analog Circuits
ACVDD2	P	1.8V for CLAD Analog Circuits
ACVSS1	P	Ground for CLAD Analog Circuits
ACVSS2	P	Ground for CLAD Analog Circuits

## 10. Functional Description

### 10.1 Power-Supply Considerations

Due to the dual-power-supply nature of the device, some I/Os have parasitic diodes between a 1.8V supply and a 3.3V supply. When ramping power supplies up or down, care must be taken to avoid forward-biasing these diodes because it could cause latchup. Two methods are available to prevent this. The first method is to place a Schottky diode external to the device between the 1.8V supply and the 3.3V supply to force the 3.3V supply to be within one parasitic diode drop below the 1.8V supply (i.e.  $V_{DD3.3} > V_{DD1.8} - 0.4V$ ). The second method is to ramp up the 3.3V supply first and then ramp up the 1.8V supply.

### 10.2 CPU Interface

The CPU interface enables an external CPU to configure and control the device and collect statistics from the device. The CPU interface block identifies accesses (read or write) to on-chip registers and to external SDRAM, forwards accesses to the proper place, and replies to the CPU with the requested data during read accesses. See [Figure 10-1](#). AC timing for the CPU interface is specified in section [14.1](#).

Figure 10-1. CPU Interface Functional Diagram

To configure the device for CPU interface mode, the [H\\_CPU\\_SPI\\_N](#) pin must be high when the [RST\\_SYS\\_N](#) (system reset) pin is deasserted. The chip can be configured for 16-bit or 32-bit data bus width by wiring the [DAT\\_32\\_16\\_N](#) pin as shown in [Table 10-1](#):

Table 10-1. CPU Data Bus Widths

DAT_32_16_N Value	Data Bus Width	Access to Chip Internal Resources	Access to SDRAM	Data Bus Bits	MSB	H_WR_BE Pins Used
1	32 bits	32 bit only	8, 16, 32 bit	H_D[31:0]	H_D[31]	3:0
0	16 bits	16 bit only	8, 16 bit	H_D[15:0]	H_D[15]	1:0

Burst accesses are not supported. The device uses the big-endian byte order, as explained in section 11.1.

The CPU starts an access to the device by asserting the **H\_CS\_N** signal (active low), accompanied by the desired read/write state on **H\_R\_W\_N**, address on **H\_AD[24:1]**, write byte enables on the **H\_WR\_BE** pins and valid data (for a write access) on the **H\_D[31:0]** pins. In response, the device asserts **H\_READY\_N** to indicate that the access has been carried out. The ready assertion indicates that data from the CPU has been written into the device register or external SDRAM (for write access) or that valid data from register/SDRAM is present on the data bus (for read access). In response to **H\_READY\_N** assertion, the CPU de-asserts **H\_CS\_N**. This causes the chip to de-assert **H\_READY\_N**, and thereby finish the CPU access.

In order to make CPU operation more efficient, the device immediately asserts **H\_READY\_N** during a write access. On successive accesses (write or read) **H\_READY\_N** is asserted only after the previous write has been completed.

In 32-bit bus mode, **H\_WR\_BE0\_N** through **H\_WR\_BE3\_N** serve as write byte enable signals, replacing the functionality of **H\_AD[1:0]** in the address bus. In 16-bit bus mode, **H\_WR\_BE0\_N** and **H\_WR\_BE1\_N** serve as write byte enables, replacing the functionality of **H\_AD[0]** in the address bus. These signals enable byte-resolution write access to the external SDRAM.

When performing a write access to internal chip resources, all **H\_WR\_BE** pins should be asserted since write access to device registers must be done at the full bus width only.

Examples of read and write accesses on 32- and 16-bit buses are shown in the figures below.

Figure 10-2. Write Access, 32-Bit Bus

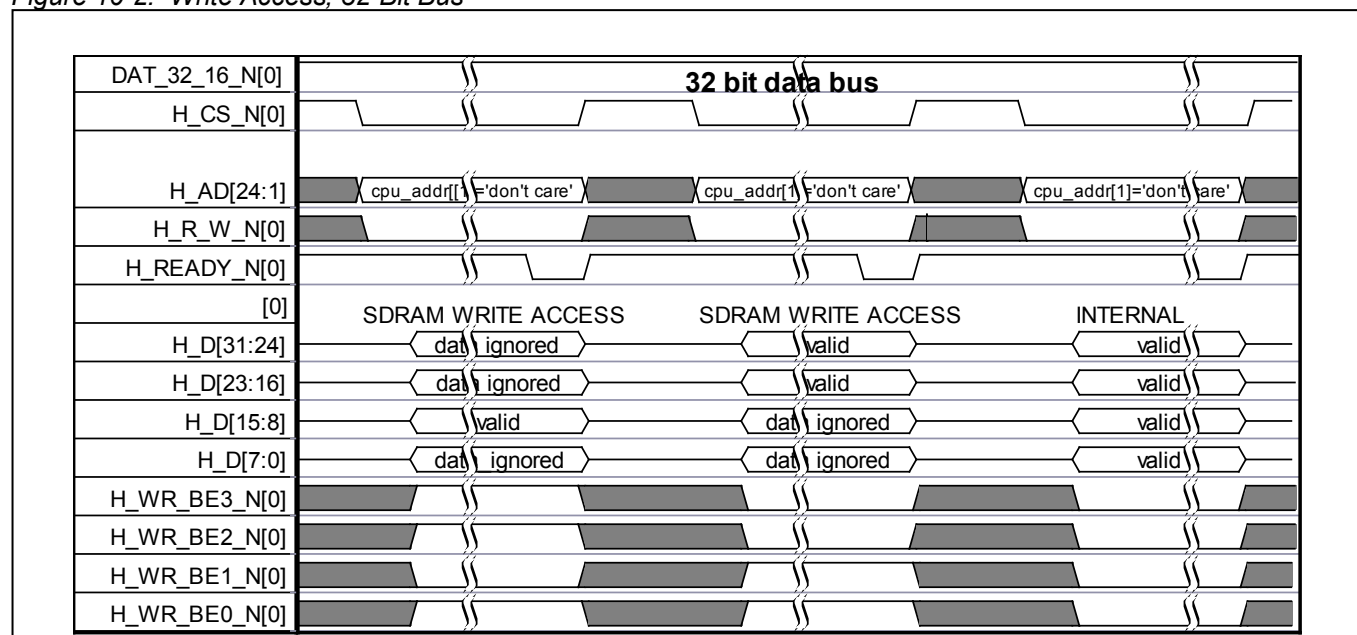

Figure 10-2 shows two write accesses to the SDRAM, one to a byte (at address 2) and the other to a word (at addresses 0 and 1), followed by a write access to the internal chip resources.

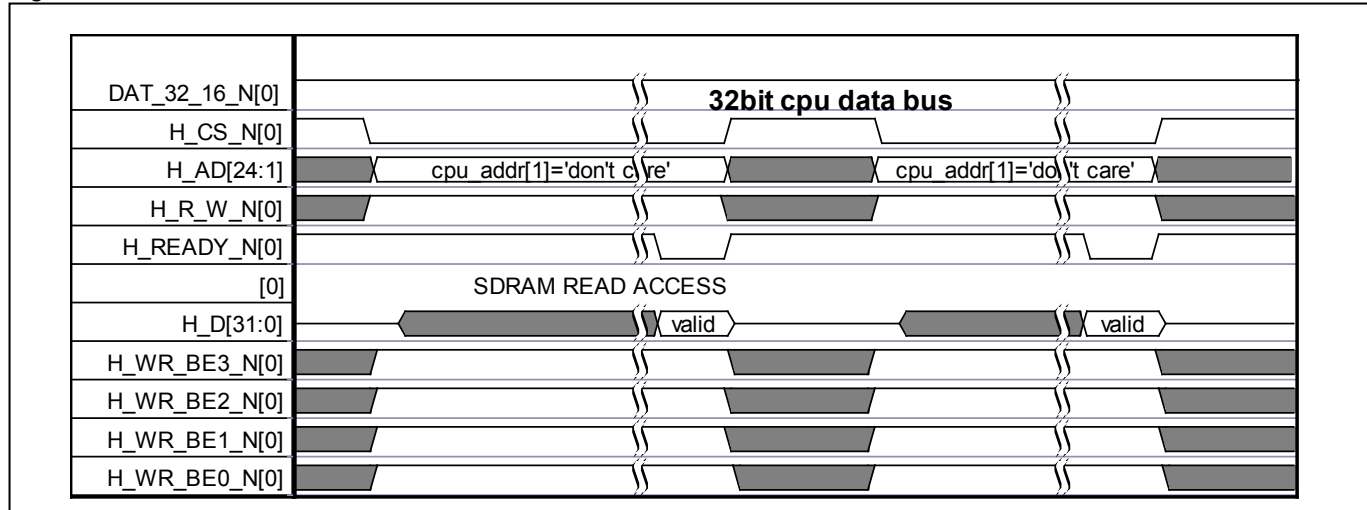

The write access to the SDRAM is different than the write access to the chip. The SDRAM can be written with byte resolution using the four byte write enables. In contrast, internal chip resources are always written at full CPU data bus width (32 bits in [Figure 10-2](#)). The write byte enable signals should always be asserted when writing to internal device registers.

For 32-bit CPU bus width, **H\_AD[1]** is ignored, since accesses are always on an even 4-byte boundary.

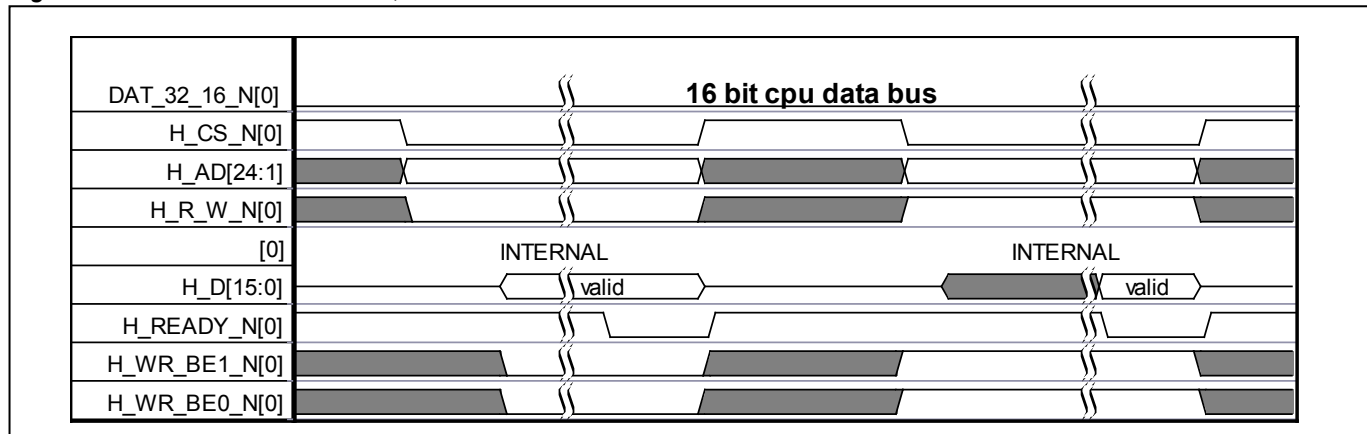

[Figure 10-3](#) shows a read access to the SDRAM followed by a read access to the internal chip resources. Read accesses always occur at CPU data bus width and the **H\_WR\_BE** pins are not used (and must be held high). Bytes that are not needed by the CPU can be ignored.

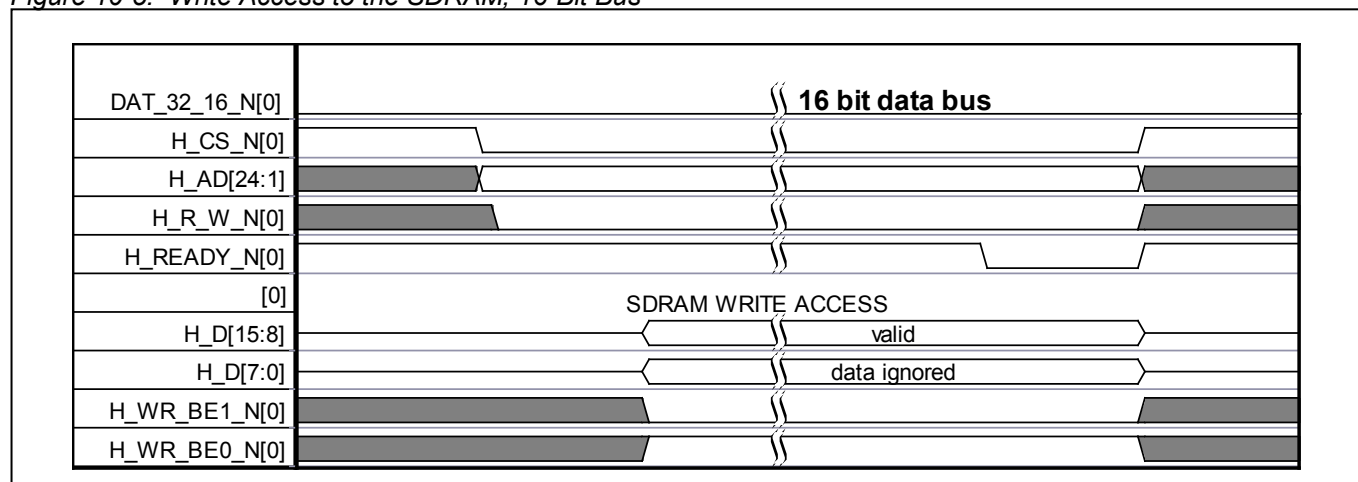

*Figure 10-3. Read Access, 32-Bit Bus*

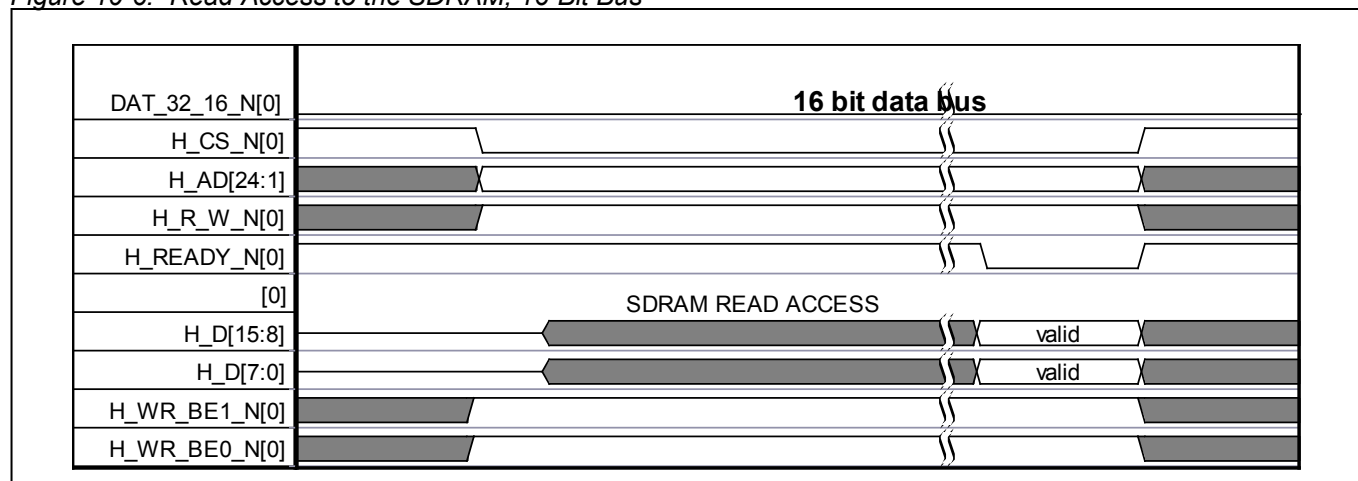

[Figure 10-4](#) shows a write access to the chip followed by a read access in 16-bit bus mode. In this mode the **H\_AD[1]** signal is used because accesses are on an even 2-byte boundary. Write access to the SDRAM can still be at byte resolution, as illustrated in [Figure 10-5](#).

*Figure 10-4. Read/Write Access, 16-Bit Bus*

**Figure 10-5. Write Access to the SDRAM, 16-Bit Bus**

In 16-bit bus mode, read accesses to SDRAM are always 16 bits, as in [Figure 10-6](#).

**Figure 10-6. Read Access to the SDRAM, 16-Bit Bus**

## 10.3 SPI Interface

The device optionally can be accessed by an external CPU through a Serial Peripheral Interface (SPI). To configure the device for SPI interface mode, the [H\\_CPU\\_SPI\\_N](#) pin must be low when the [RST\\_SYS\\_N](#) (system reset) pin is deasserted. In SPI mode, some of the parallel CPU bus pins take on an SPI-related function while the rest are disabled. See the CPU interface section of [Table 9-1](#) for details. The device functions as an SPI slave.

### 10.3.1 SPI Operation

The SPI is a 4-wire, full-duplex, synchronous interface. The SPI connects an SPI master (which initiates the data transfer) and an SPI slave.

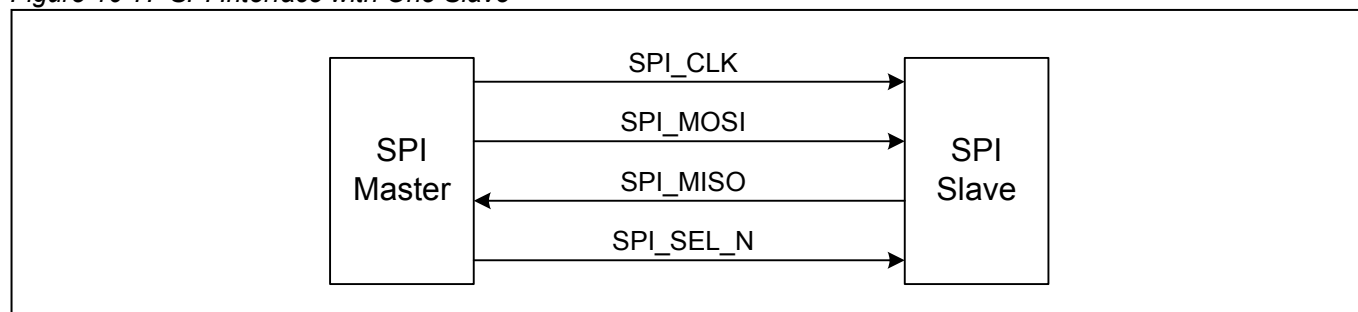

The SPI signal wires are as follows:

- [SPI\\_CLK](#) is the clock for the serial data (gated clock).
- [SPI\\_MOSI](#) is master data output, slave data input.

- **SPI\_MISO** is master data input, slave data output.
- **SPI\_SEL\_N** is the slave chip select.

The master initiates a data transfer by asserting **SPI\_SEL\_N** (low) and generating a sequence of **SPI\_CLK** cycles accompanied by serial data on **SPI\_MOSI**. During read cycles the slave outputs data on **SPI\_MISO**. Each additional slave requires an additional slave chip-select wire. [Figure 10-7](#) illustrates a typical connection between an SPI master and a single SPI slave.

Figure 10-7. SPI Interface with One Slave

### 10.3.2 SPI Modes

Two configuration pins define the SPI mode of operation.

- The polarity of **SPI\_CLK** is specified by the **SPI\_CI** (clock invert) input pin.
- The **SPI\_CP** (clock phase) input pin determines whether the first **SPI\_CLK** transition is used to sample the data on **SPI\_MISO/SPI\_MOSI** (which requires the first bit to be ready beforehand on these lines) or to updated the data on the **SPI\_MISO/SPI\_MOSI** lines. See [Figure 10-8](#) and [Figure 10-9](#).

Figure 10-8. SPI Interface Timing, **SPI\_CP=0**

Figure 10-9. SPI Interface Timing, **SPI\_CP=1**

### **10.3.3 SPI Signals**

In SPI mode, the following CPU bus pins change their functionality and operate as SPI signals.

- Inputs
  - [SPI\\_CLK](#) is shared with [H\\_WR\\_BE0\\_N](#)
  - [SPI\\_MOSI](#) is shared with [H\\_WR\\_BE1\\_N](#)
  - [SPI\\_SEL\\_N](#) is shared with [H\\_WR\\_BE2\\_N](#).
- Outputs
  - [SPI\\_MISO](#) is shared with [H\\_D\[0\]](#).

The SPI configuration is supplied on two external pins as follows:

- [SPI\\_CI](#) (clock invert) is shared with [H\\_WR\\_BE3\\_N](#)
- [SPI\\_CP](#) (clock phase) is shared with [H\\_R\\_W\\_N](#).

In the SPI mode the device operates internally in 32-bit mode.

### **10.3.4 SPI Protocol**

The external CPU communicates with the device over SPI by issuing commands. There are three command types:

1. Write – performs 32-bit write access
2. Read – performs 32-bit read access
3. Status – verifies that previous access has been finished

The [SPI\\_SEL\\_N](#) signal must be de-asserted between accesses to the device.

#### **10.3.4.1 Write Command**

The SPI write command proceeds as follows:

- The SPI master (CPU) starts a write access by asserting [SPI\\_SEL\\_N](#) (low).
- Then, during each [SPI\\_CLK](#) cycle a [SPI\\_MOSI](#) data bit is transmitted by the master (CPU), while a [SPI\\_MISO](#) bit is transmitted by the slave (the device).
- The first bit on [SPI\\_MOSI](#) and [SPI\\_MISO](#) is reserved (don't care).
- The master then transmits two opcode bits on [SPI\\_MOSI](#). These bits specify a read, write or status command. The value 01b represents a write command. At the same time, the slave transmits the opcode bits of the previous command on [SPI\\_MISO](#).
- The next four bits the master transmits on [SPI\\_MOSI](#) are byte-enable values: [byte\\_en\\_3](#), [byte\\_en\\_2](#), [byte\\_en\\_1](#), and [byte\\_en\\_0](#) which are equivalent to the function of the [H\\_WR\\_BE3\\_N](#) to [H\\_WR\\_BE0\\_N](#)

signals in CPU bus mode (including being active low). At the same time, the slave transmits the byte enable values of the previous access on [SPI\\_MISO](#).

- The next bit on [SPI\\_MOSI](#) and [SPI\\_MISO](#) is reserved (don't care).
- The next 24 bits the master transmits on [SPI\\_MOSI](#) are address bits, starting from A24 (MSB) and ending with A1 (LSB). At the same time, the slave transmits the address bits of the previous access on [SPI\\_MISO](#).
- The next 32 bits the master transmits on [SPI\\_MOSI](#) are 32 bits of data, starting from D31 (MSB) and ending with D0 (LSB). At the same time, the slave transmits 32 don't-care bits on [SPI\\_MISO](#).
- Finally the master transmits 8 don't care bits on [SPI\\_MOSI](#). During these clock periods the slave transmits 8 bits on [SPI\\_MISO](#). The first 7 [SPI\\_MISO](#) bits are don't-care. The 8<sup>th</sup> bit is a status bit that indicates whether the last access was completed successfully (1) or is still in progress (0). The 0 value indicates that the current operation has not yet completed and that the status command must follow (see section [10.3.4.3](#)).
- The master ends the write access by deasserting [SPI\\_SEL\\_N](#).

The total number of [SPI\\_CLK](#) cycles for a write command is 72. This is summarized in [Table 10-2](#).

**Table 10-2. SPI Write Command Sequence**

Bit Number	SPI_MOSI	SPI_MISO
1	Reserved	Reserved
2–3	opcode 01 (write)	Previous access opcode
4	H_WR_BE3_N value	Previous access H_WR_BE3_N value
5	H_WR_BE2_N value	Previous access H_WR_BE2_N value
6	H_WR_BE1_N value	Previous access H_WR_BE1_N value
7	H_WR_BE0_N value	Previous access H_WR_BE0_N value
8	Reserved	Reserved
9–32	Address [24 to 1]	Previous access address [24 to 1]
33–64	Data (32 bits)	Don't care (32 bits)
65–71	Don't care (7 bits)	Idle (7 bits)
72	Don't care (1 bit)	Status bit: 1=access has finished, 0=access has not finished

#### **10.3.4.2 Read Command**

The SPI read command proceeds as follows:

- The SPI master (CPU) starts a write access by asserting [SPI\\_SEL\\_N](#) (low).
- Then, during each [SPI\\_CLK](#) cycle a [SPI\\_MOSI](#) data bit is transmitted by the master (CPU), while a [SPI\\_MISO](#) bit is transmitted by the slave (the device).
- The first bit on [SPI\\_MOSI](#) and [SPI\\_MISO](#) is reserved (don't care).
- The master then transmits two opcode bits on [SPI\\_MOSI](#). These bits specify a read, write or status command. The value 10b represents a read command. At the same time, the slave transmits the opcode bits of the previous command on [SPI\\_MISO](#).
- The next four bits the master transmits on [SPI\\_MOSI](#) are byte-enable values: byte\_en\_3, byte\_en\_2, byte\_en\_1, and byte\_en\_0 which are equivalent to the function of the [H\\_WR\\_BE3\\_N](#) to [H\\_WR\\_BE0\\_N](#)

signals in CPU bus mode (including being active low). For a read access, all four of these bits should be 1. At the same time, the slave transmits the byte enable values of the previous access on **SPI\_MISO**.

- The next bit on **SPI\_MOSI** and **SPI\_MISO** is reserved (don't care).
- The next 24 bits the master transmits on **SPI\_MOSI** are address bits, starting from A24 (MSB) and ending with A1 (LSB). At the same time, the slave transmits the address bits of the previous access on **SPI\_MISO**.
- Next the master transmits 8 don't care bits on **SPI\_MOSI**. During these clock periods the slave transmits 8 bits on **SPI\_MISO**. The first 7 **SPI\_MISO** bits are don't-care. The 8<sup>th</sup> bit is a status bit that indicates whether the current read access was completed successfully (1) or is still in progress (0). Status=0 indicates that the current operation has not yet completed and that the status command must follow (see section 10.3.4.3).
- Status=1 indicates that the current read was completed successfully and 32 bits of data follow on **SPI\_MISO**, starting from D31 (MSB) and ending with D0 (LSB). During these 32 clock cycles, the master transmits 32 don't-care bits on **SPI\_MOSI**.
- Status=0 indicates that the current read was not completed and that the status command must follow (see section 10.3.4.3). During the next 32 clock cycles both the master and the slave must transmit don't-care bits to complete the read command. These 32 bits should be ignored.
- The master ends the write access by deasserting **SPI\_SEL\_N**.

The total number of **SPI\_CLK** cycles for a read command is 72.

**Table 10-3. SPI\_Read Command Sequence**

Bit Number	SPI_MOSI	SPI_MISO
1	Reserved	Reserved
2–3	opcode 10 (read)	Previous access opcode
4	1	Previous access H_WR_BE3_N value
5	1	Previous access H_WR_BE2_N value
6	1	Previous access H_WR_BE1_N value
7	1	Previous access H_WR_BE0_N value
8	Reserved	Reserved
9–32	Address [24 to 1]	Previous access Address [24 to 1]
33–39	Don't care	Idle (7 bits)
40	Don't care	Status bit: 1=access has finished, 0=access has not finished
41–72	Don't care	Data (32 bits)

#### **10.3.4.3 Status Command**

The status command differs from read or write commands, since it does not initiate an internal access. Usually a status command follows a read or write command that was not completed as described above.

The SPI status command proceeds as follows:

- The SPI master (CPU) starts a status command by asserting **SPI\_SEL\_N** (low).
- Then, during each **SPI\_CLK** cycle a **SPI\_MOSI** data bit is transmitted by the master (CPU), while a **SPI\_MISO** bit is transmitted by the slave (the device).

- The first bit on [SPI\\_MOSI](#) and [SPI\\_MISO](#) is reserved (don't care).
- The master then transmits two opcode bits on [SPI\\_MOSI](#). These bits specify a read, write or status command. The value 00b represents a status command. At the same time, the slave transmits the opcode bits of the previous command on [SPI\\_MISO](#).
- The master then transmits 4 don't care bits on [SPI\\_MOSI](#). During these clock periods the slave transmits 4 bits on [SPI\\_MISO](#). The first 3 [SPI\\_MISO](#) bits are don't-care. The 4<sup>th</sup> bit is a status bit that indicates whether the last access was completed successfully (1) or is still in progress (0). The 0 value indicates that the last access has not yet completed and that another status command must follow (see section 10.3.4.3).
- Status=1 indicates that the last access was completed successfully. If the last access was a read then 32 bits of data follow on [SPI\\_MISO](#), starting from D31 (MSB) and ending with D0 (LSB). During these 32 clock cycles, the master transmits 32 don't-care bits on [SPI\\_MOSI](#). If the last access was a write the during the next 32 clock cycles both the master and the slave must transmit don't-care bits to complete the status command. These 32 bits should be ignored.
- Status=0 indicates that the last access was not completed and that another status command must follow. During the next 32 clock cycles both the master and the slave must transmit don't-care bits to complete the status command. These 32 bits should be ignored.
- The master ends the write access by deasserting [SPI\\_SEL\\_N](#).

The total number of [SPI\\_CLK](#) cycles for a status command is 40.

**Table 10-4. SPI Status Command Sequence**

Bit Number	SPI_MOSI	SPI_MISO
1	Don't care	Don't care
2–3	opcode 00 (status)	Previous access opcode
4	Don't care	Don't care
5	Don't care	Don't care
6	Don't care	Don't care
7	Don't care	Don't care
8	Don't care	Status bit: 1=access has finished, 0=access has not finished
9–40*	Don't care*	Data*

\* only if previous access was a read (previous access opcode = 10b).

## 10.4 Clock Structure

When clock recovery is enabled ([Clock\\_recovery\\_en](#)=1 in [General\\_cfg\\_reg0](#)), the clock recovery machines of the TDM-over-packet block require a 38.88MHz clock. This clock can come directly from the [CLK\\_HIGH](#) pin, or the CLAD1 block (see [Figure 6-1](#)) can convert a 10MHz, 19.44MHz or 77.76MHz clock on [CLK\\_HIGH](#) to 38.88MHz using an analog PLL. The frequency of [CLK\\_HIGH](#) must be specified in [GCR1.FREQSEL](#).

When common clock (differential) mode is enabled ([RTP\\_timestamp\\_generation\\_mode](#)=1 in [General\\_cfg\\_reg1](#)), the clock recovery block requires a clock on the [CLK\\_CMN](#) pin *in addition to* the clock on the [CLK\\_HIGH](#) pin. See the [CLK\\_CMN](#) pin description for recommendations for the frequency of this clock. Often the same clock signal can be applied to both [CLK\\_CMN](#) and [CLK\\_HIGH](#), for example 19.44MHz.

When clock recovery is disabled ([Clock\\_recovery\\_en](#)=0 in [General\\_cfg\\_reg0](#)), CPU software can disable the 38.88MHz clock output from CLAD1 to save power by setting [GCR1.CLK\\_HIGHD](#). Clock recovery must be enabled whenever the TDMoP block must recover one or more service clocks from received packets using either adaptive mode or common clock (differential) mode.

The TDM-over-packet block also requires a 50 MHz or 75 MHz clock ( $\pm 50$  ppm or better) to clock its internal circuitry and the SDRAM interface ([SD\\_CLK](#)). When the [CLK\\_SYS\\_S](#) pin is low, a 50 MHz or 75 MHz clock applied to the CLK\_SYS pin is passed directly to the TDMoP block. When the [CLK\\_SYS\\_S](#) pin is high, a 25 MHz clock on the [CLK\\_SYS](#) pin is internally multiplied by an analog PLL in the CLAD2 block to either 50 MHz or 75 MHz as specified by [GCR1.SYSCLKS](#).

## 10.5 Reset and Power-Down

A hardware reset is issued by forcing the [RST\\_SYS\\_N](#) pin low. This pin resets the TDM-over-Packet block and the MAC. Note that not all registers are cleared to 0x00 on a reset condition. The register space must be reinitialized to appropriate values after hardware or software reset has occurred. This includes setting reserved locations to 0. Several block-specific resets are also available, as shown in [Table 10-5](#).

**Table 10-5. Reset Functions**

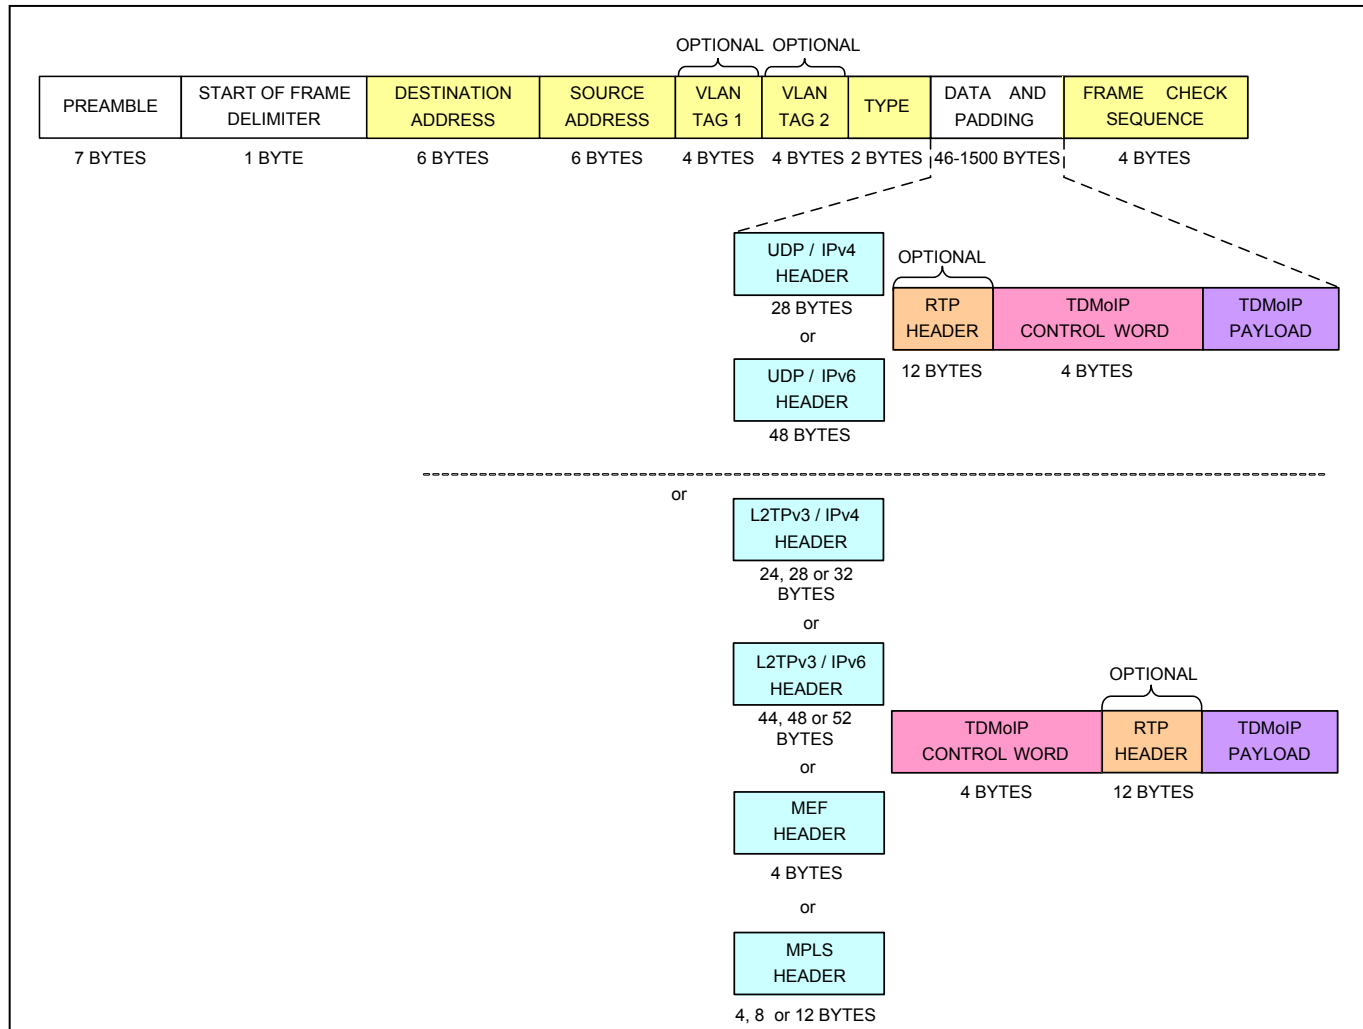

RESET FUNCTION	LOCATION	COMMENTS
Hardware Device Reset	<a href="#">RST_SYS_N</a> Pin	Transition to a 200us or more logic 0 level resets the device. CLK_SYS and CLK_HIGH/MCLK are recommended to be stable 200us before transitioning out of reset.
Hardware JTAG Reset	<a href="#">JTRST_N</a> Pin	Resets the JTAG test port.
Resets TDMoP TX, RX paths	<a href="#">Rst_reg</a>	Used to reset the transmit (TX) and receive (RX) paths of the TDM-over-Packet block.
Resets the SDRAM controller	<a href="#">General_cfg_reg0</a>	The <a href="#">Rst_SDRAM_n</a> bit resets the SDRAM controller.

## 10.6 TDM-over-Packet Block

### 10.6.1 Packet Formats

To transport TDM data through packet switched networks, the TDM-over-Packet block encapsulates the TDM data into Ethernet packets as depicted in [Figure 10-10](#).

**Figure 10-10. TDM-over-Packet Encapsulation Formats**

**Table 10-6. Ethernet Packet Fields**

Field	Description
Preamble	A sequence of 56 bits (alternating 1 and 0 values) Gives components in the network time to detect the presence of a signal and synchronize to the incoming bit stream.
Start of Frame Delimiter (SFD)	A sequence of 8 bits (10101011) that indicates the start of the packet.
Destination Address and Source Address	The Destination Address field identifies the station or stations that are to receive the packet. The Source Address identifies the station that originated the packet. A Destination Address may specify either an individual address destined for a single station, or a multicast address destined for a group of stations. A Destination Address of all 1s refers to all stations on the LAN and is called the broadcast address.
Type	Ethertype. The type of payload contained in the Ethernet frame.
Data and Padding	This field contains the payload data transferred from the source station to the destination station(s). The maximum size of this field is 1500 bytes. If the payload to be transported is less than 46 bytes, then padding is used to bring the packet size up to the minimum length. A minimum-length Ethernet packet is 64 bytes from the Destination Address field through the Frame Check Sequence.
Frame Check Sequence (FCS)	This field contains a 4-byte cyclical redundancy check (CRC) value used for error checking. When a source station assembles a packet, it performs a CRC calculation on all the bits in the packet from the Destination Address through the Pad fields (that is, all fields except the preamble, start frame delimiter, and frame check sequence). The source station stores the calculated value in the FCS field and transmits it as part of the packet. When the packet is received by the destination station, it performs an identical check. If the calculated value does not match the value in the FCS field, the destination station assumes an error has occurred during transmission and discards the packet.

### 10.6.1.1 VLAN Tag

As specified in IEEE Standard 802.1q, the twelve-bit VLAN identifier's tagged packets, enables the construction of a maximum of 4,096 distinct VLANs. For cases where this VLAN limit is inadequate VLAN stacking provides a two-level VLAN tag structure, which extends the VLAN ID space to over 16 million VLANs. Each packet may be sent without VLAN tags, with a single VLAN tag or with two VLAN tags (VLAN stacking).

Figure 10-11. Single VLAN Tag Format

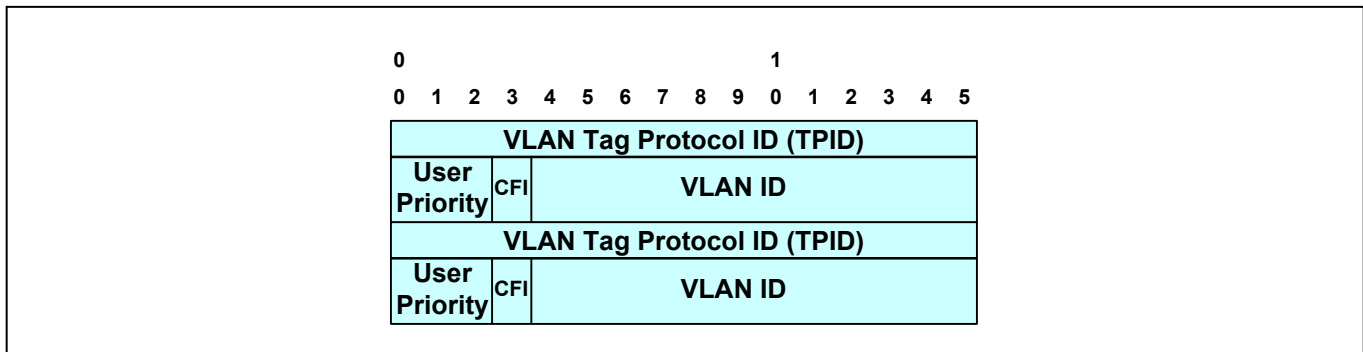

Figure 10-12. Stacked VLAN Tag Format

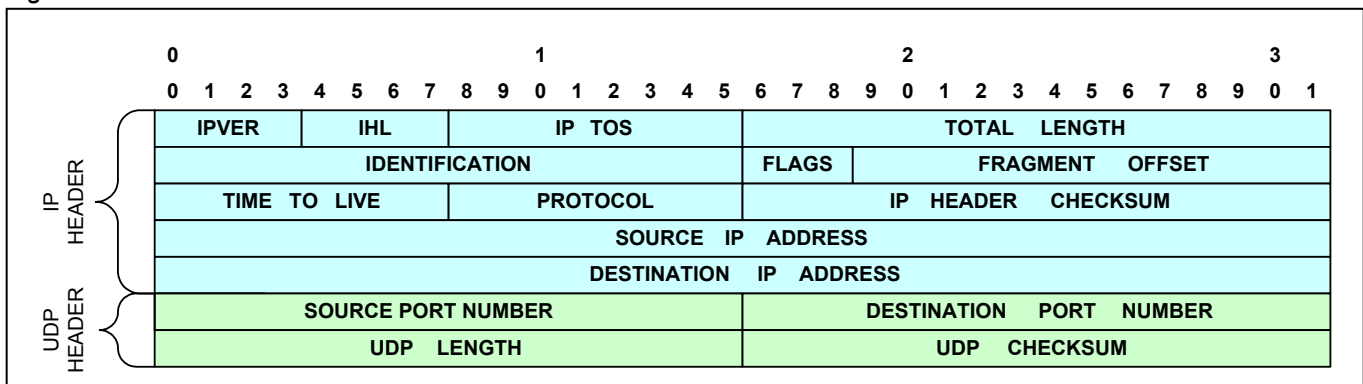

The VLAN tag's Protocol ID (TPID) can be either the typical value of 0x8100 or a value configured in the [vlan\\_2nd\\_tag\\_identifier](#) field in [Packet\\_classifier\\_cfg\\_reg7](#).

- The User Priority field is used to assign a priority level to the Ethernet packet.
- The CFI (Canonical Format Indicator) fields indicate the presence of a Router Information Field.
- The VLAN ID, uniquely identifies the VLAN to which the Ethernet packet belongs.

### 10.6.1.2 UDP/IPv4 Header

Figure 10-13. UDP/IPv4 Header Format

**Table 10-7. IPv4 Header Fields (UDP)**

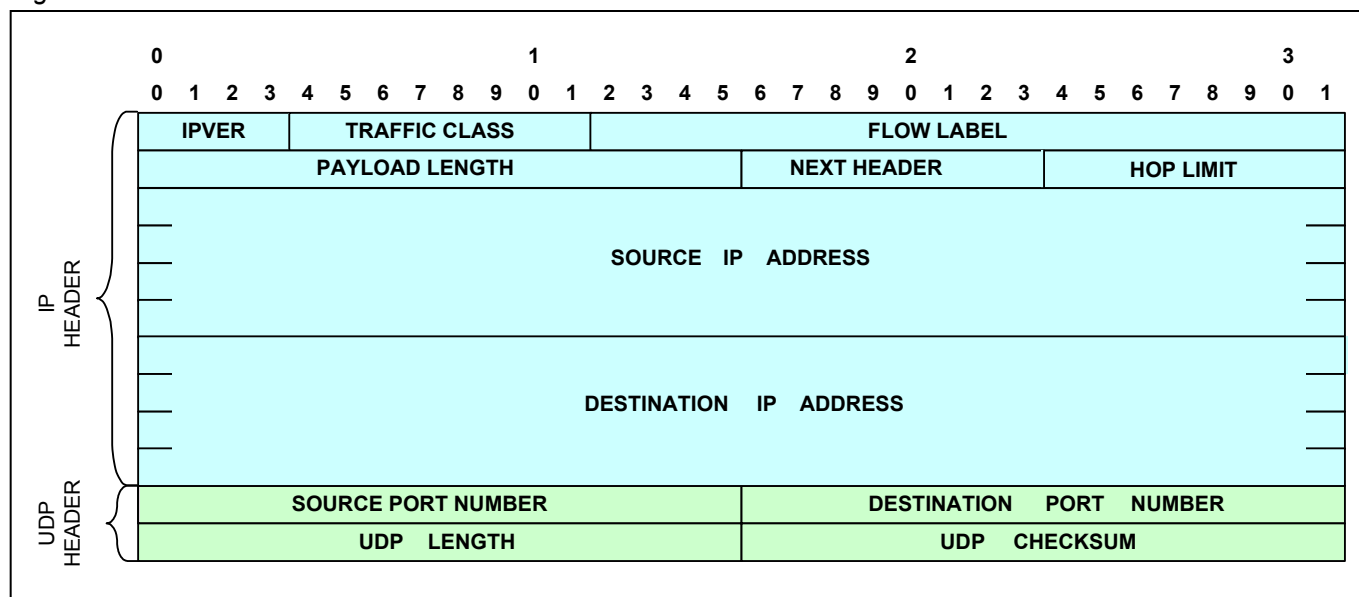

Field	Description
IPVER	IP version number. IPv4 IPVER=4
IHL	Length in 32-bit words of the IP header, IHL=5
IP TOS	IP type of service
Total Length	Length in octets of IP header and data
Identification	IP fragmentation identification
Flags	IP control flags; must be set to 010 to avoid fragmentation
Fragment Offset	Indicates where in the datagram the fragment belongs; not used for TDM-over-Packet
Time To Live	IP time-to-live field; datagrams with zero in this field are to be discarded
Protocol	Must be set to 0x11 to signify UDP
IP Header Checksum	Checksum for the IP header
Source IP Address	IP address of the source
Destination IP Address	IP address of the destination

**Table 10-8. UDP Header Fields**

Field	Description
Source Port Number, Destination Port Number	Either the source or the destination port number holds the bundle identifier. The unused field can be set to 0x85E (2142), which is the user port number assigned to TDM-over-Packet by the Internet Assigned Numbers Authority (IANA). For UDP/IP-specific OAM packets, the bundle identifier is all ones.
UDP length	Length in octets of UDP header and data
UDP checksum	Checksum of UDP/IP header and data. If not computed it must be set to zero.

### 10.6.1.3 UDP/IPv6 Header

Figure 10-14. UDP/IPv6 Header Format

**Table 10-9. IPv6 Header Fields (UDP)**

Field	Description
IPVER	IP version number, for IPv6 IPVER = 6
Traffic Class	An 8-bit field similar to the type of service (ToS) field in IPv4.
Flow Label	The 20-bit Flow Label field can be used to tag packets of a specific flow to differentiate the packets at the network layer.
Payload Length	Similar to the Total Length field in IPv4. This field indicates the total length of the IP header and data in octets.
Next Header	Similar to the Protocol field in IPv4. It determines the type of information following the basic IPv6 header. Must be set to 0x11 to signify UDP.
Hop Limit	Similar to the Time to Live field in IPv4.
Source IP Address	Similar to the Source Address field in IPv4, except that the field contains a 128-bit source address for IPv6 instead of a 32-bit source address for IPv4.
Destination Address	Similar to the Destination Address field in IPv4, except that the field contains a 128-bit destination address for IPv6 instead of a 32-bit destination address for IPv4.

**10.6.1.4 MPLS Header***Figure 10-15. MPLS Header Format***Table 10-10. MPLS Header Fields**

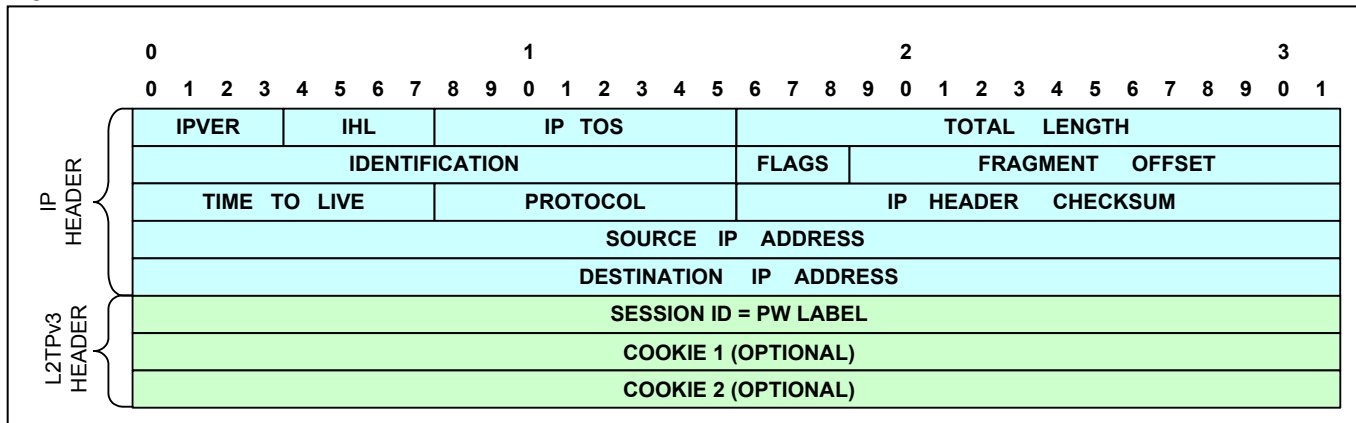

Field	Description
Outer Labels	MPLS labels, which identify the MPLS LSP, used to tunnel the TDMoMPLS packets through the MPLS network. Also known as tunnel label(s) or transport label(s). The label number can be assigned either manually or using the MPLS control protocol. There can be zero, one or two outer labels.
EXP	Experimental field
S	Stacking bit: S=1 indicates stack bottom (i.e. the inner label). S=0 for all outer labels.
TTL	MPLS time to live
Inner Label	MPLS inner label (also known as the PW label or the interworking label) contains the bundle identifier used to multiplex multiple bundles within the same tunnel. It is always be at the bottom of the MPLS label stack, and hence its stacking bit is set (S=1).

**10.6.1.5 MEF Header***Figure 10-16. MEF Header Format***Table 10-11. MEF Header Fields**

Field	Description
ECID	The Emulated Circuit Identifier (ECID) field. Contains the bundle identifier.

**10.6.1.6 L2TPv3/IPv4 Header**

Figure 10-17. L2TPv3/IPv4 Header Format

**Table 10-12. IPv4 Header Fields (L2TPv3)**

Field	Description
IPVER	
IHL	
IP TOS	
Total Length	See Table 10-7.
Identification	
Flags	
Fragment Offset	
Time To Live	
Protocol	Must be set to 0x73 to signify L2TPv3
IP Header Checksum	
Source IP Address	See Table 10-7.
Destination IP Address	

**Table 10-13. L2TPv3 Header Fields**

Field	Description
Session ID (32 bits)	Locally significant L2TP session identifier, Contains the bundle identifier. All bundle identifiers are available for use except 0, which is reserved.
Cookie (32 or 64 bits)	Optional field that contains a randomly selected value used to validate association of the packet with the expected bundle identifier

### 10.6.1.7 L2TPv3/IPv6 Header

Figure 10-18. L2TPv3/IPv6 Header Format

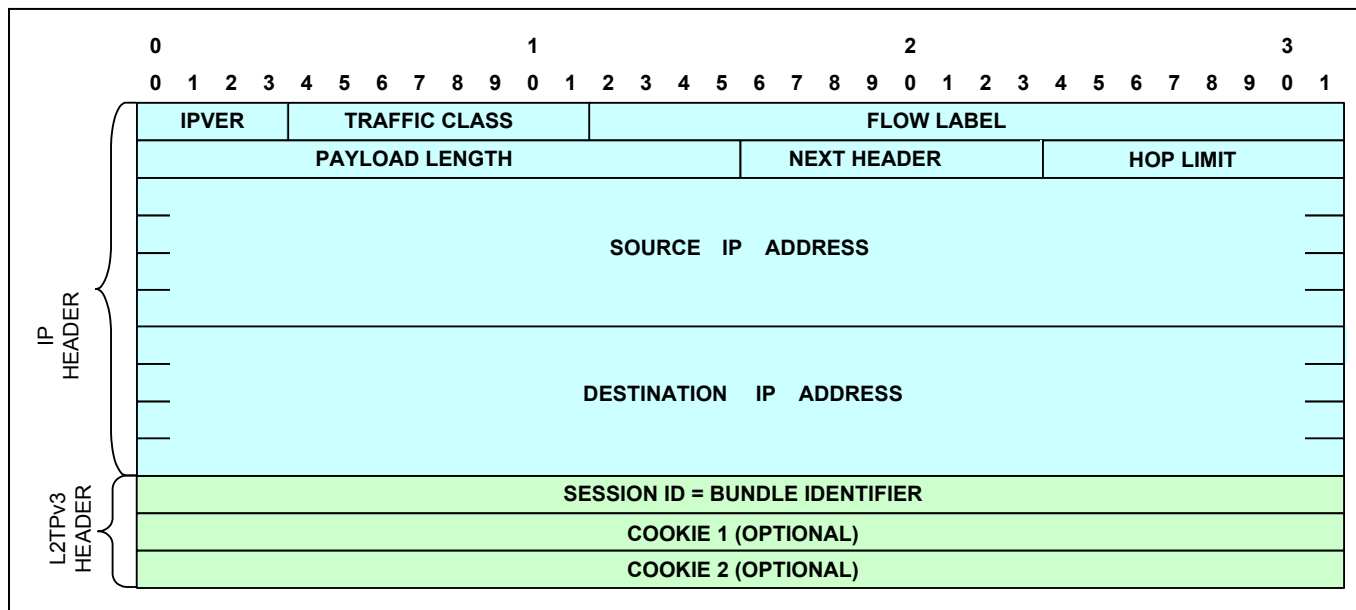

Table 10-14. IPv6 Header Fields (L2TPv3)

Field	Description
IPVER	See <a href="#">Table 10-9</a> .
Traffic Class	
Flow Label	
Payload Length	
Next Header	Must be set to 0x73 to signify LTPv3
Hop Limit	See <a href="#">Table 10-9</a> .
Source Address	
Destination Address	

### 10.6.1.8 Control Word

Figure 10-19. Control Word Format

Table 10-15. Control Word Fields

Field	Description
RES	Reserved bits. Must be set to zero.
L	Local loss of sync failure. This bit is set by CPU software ( <a href="#">Port[n]_cfg_reg.Loss</a> ) for packets transmitted out the Ethernet port. A set L bit indicates that the source has detected or has been informed of a TDM physical layer fault impacting the data to be transmitted. This bit can be used to indicate physical layer LOS that should trigger AIS generation at the far end. Once set, if the TDM fault is rectified, the L bit must be cleared.
R	Remote receive failure. This bit is set by CPU software ( <a href="#">Tx_R_bit</a> field in bundle configuration) for packets transmitted out the Ethernet port.. A set R bit indicates that the source is not receiving packets at the Ethernet port, i.e.,

Field	Description
	there is a failure of that direction of the bi-directional connection. This indication can be used to signal congestion or other network related faults. Receiving remote failure indication may trigger fall-back mechanisms for congestion avoidance. The R bit must be set after a preconfigured number of consecutive packets are not received, and must be cleared once packets are once again received.
M	Defect Modifier failure. These bits are set by CPU software ( <a href="#">Port[n]_cfg_reg.Tx_defect_modifier</a> ) for packets transmitted out the Ethernet port.. This field is optional. When used it supplements the L-bit meaning.
FRG	Fragmentation field This field is used for fragmenting multiframe structures into multiple packets in case of CESoPSN structured with CAS bundles. The field is used as follows: 00 = Indicates that the entire (unfragmented) multiframe structure is carried in a single packet. 01 = Indicates the packet carrying the first fragment. 10 = Indicates the packet carrying the last fragment. 11 = Indicates a packet carrying an intermediate fragment.
Length	Length field Includes control word, payload and RTP header (if present) unless it is a UDP/IP packet. It is only used when the total length of these fields is less than 64 bytes. Otherwise, it must be set to zero.
Sequence Number	TDM-over-Packet sequence number, defined separately for each bundle and incremented by one for each TDMoP packet sent for that bundle. The initial value of the sequence number is random (unpredictable) for security purposes, and the value is incremented in wrap-around manner separately for each bundle. Used by the receiver to detect packet loss and restore packet sequence. The HDLC payload type machine supports three different modes for this field: always zero, incremented in wrap-around manner or incremented in wrap-around manner, but skips zero value. For OAM packets, it uniquely identifies the message. Its value is unrelated to the sequence number of the TDMoP data packets for the bundle in question. It is incremented in query messages, and replicated without change in replies.

### 10.6.1.9 RTP Header

Figure 10-20. RTP Header Format

Table 10-16. RTP Header Fields

Field	Description
V	RTP version. Must be set to 2.
P	Padding bit. Must be set to 0.
X	Extension bit. Must be set to 0.
CC	CSRC Count. Must be set to 0.
M	Marker bit. Must be set to 0.
PT	Payload Type. One PT value MUST be allocated from the range of dynamic values for each direction of the bundle. The same PT value MAY be reused for both directions of the bundle, and also reused between different bundles.
SN	Sequence number. Identical to the sequence number in the control word.
TS	Timestamp. The RTP header can be used in conjunction with the following modes of timestamp generation: Absolute mode: the chip sets timestamps using the clock from the incoming TDM circuit. As a consequence, the timestamps are closely correlated with the sequence numbers. The timestamp is incremented by one every 125 $\mu$ s. Differential (common clock) mode: The two chips at bundle edges have access to the same high-quality network clock, and this clock source is used for timestamp generation.

Field	Description
SSRC	Identifies the synchronization source. This identifier should be chosen randomly, with the intent that no two synchronization sources within the same RTP session have the same SSRC identifier.

#### 10.6.1.10 TDM-over-Packet Payload

This field can contain the following payload types:

- AAL1
- HDLC
- RAW (SAToP or CESoPSN formats)
- OAM (VCCV or UDP/IP-specific).

The AAL1, HDLC and RAW payload type details are provided in sections [10.6.6](#), [10.6.7](#) and [10.6.8](#), respectively. The formats of the OAM payload types are described below.

##### 10.6.1.10.1 VCCV OAM

When using inband performance monitoring, additional OAM packets are sent using the same bundle identifier as the TDM data packets. The OAM packets are identified by having their first nibble (after the PSN specific layers) equal to 0001 and must be separated from TDM data packets before further processing of the control word. The PSN-specific layers are identical to those used to carry the TDM data.

Figure 10-21. VCCV OAM Packet Format

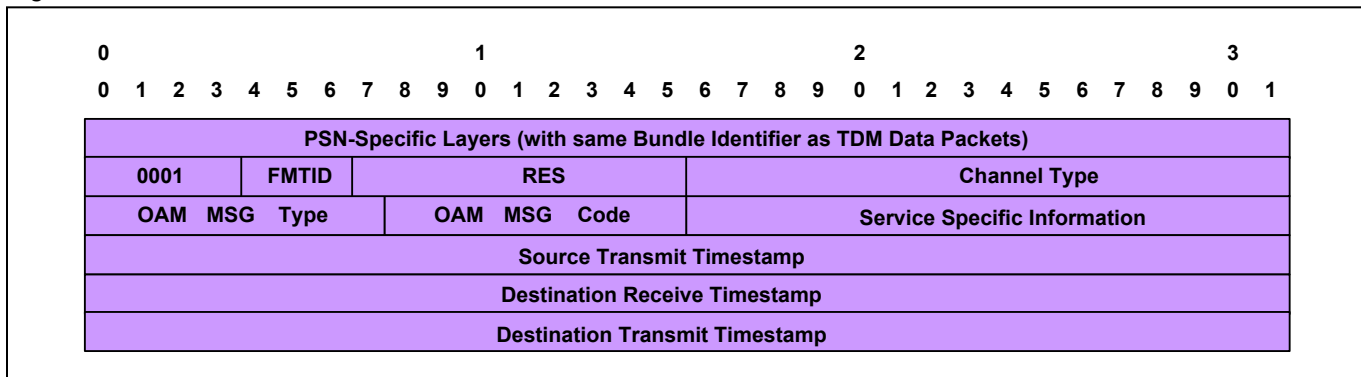

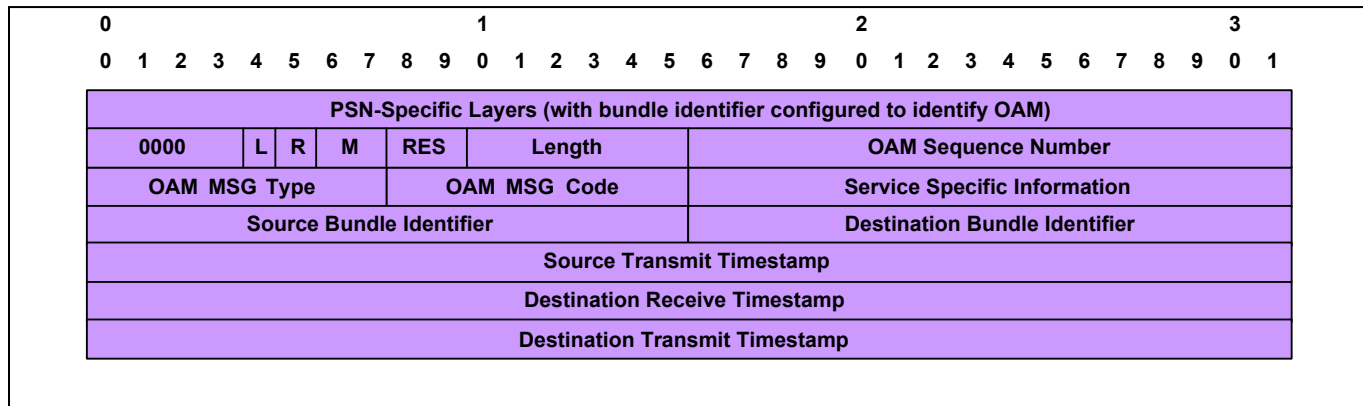

Table 10-17. VCCV OAM Payload Fields

Field	Description
FMTID	Must be set to zero
RES	Reserved and must be set to zero
Channel Type	Must be set to the value allocated by IANA for TDM-over-Packet VCCV OAM
OAM Msg Type	
OAM Msg Code	
Source Transmit Timestamp	See <a href="#">Table 10-18</a> .
Destination Receive Timestamp	
Destination Transmit Timestamp	

##### 10.6.1.10.2 UDP/IP-Specific OAM

When using a UDP/IP-Specific OAM, all OAM packet MUST use one of the bundle identifiers preconfigured to indicate OAM (using OAM ID Table). The PSN-specific layers are identical for OAM packets (except for the bundle identifier) to those used to carry the TDM data.

Figure 10-22. UDP/IP-Specific OAM Packet Format

**Table 10-18. UDP/IP-Specific OAM Payload Fields**

Field	Description
L, R, M	Identical to those of the bundle being tested
Length	OAM message packet length (in bytes)
OAM Sequence Number	Uniquely identifies the message. Its value is unrelated to the sequence number of the TDM data packets for the bundle in question. It is incremented in query messages, and replicated without change in replies.
OAM Msg Type	Indicates the function of the message. At present, the following are defined: 0: one way connectivity query message 8: one way connectivity reply message
OAM Msg Code	Information related to the message; its interpretation depends on the message type.  For OAM Msg Type=0 (connectivity query) messages, the following codes are defined: 0: Validate connection 1: Do not validate connection  For OAM Msg Type=8 (connectivity reply) messages, the available codes are: 0: Acknowledge valid query 1: Invalid query (configuration mismatch)
Service Specific Information	Can be used to exchange configuration information between gateways. If not used, it must contain zero. Its interpretation depends on the payload type. At present, the following is defined for AAL1 payloads: Bits 16–23: Number of timeslots being transported, e.g. 24 for full T1 Bits 24–31: Number of 48-byte AAL1 PDUs per packet, e.g. 8 when packing 8 AAL1 AAL1 SAR PDUs per packet
Source Bundle Identifier	The bundle identifier used for TDM-over-Packet traffic from the source to the destination.
Destination Bundle Identifier	The bundle identifier used for TDM-over-Packet traffic from the destination to source.
Source Transmit Timestamp	The time the PSN-bound gateway transmitted the query message. This field and the following fields only appear if delay is being measured. The resolution is configurable to 100 $\mu$ s or 1 $\mu$ s.
Destination Receive Timestamp	The time the destination gateway received the query message.
Destination Transmit Timestamp	The time the destination gateway transmitted the reply message.

For more details about OAM Signaling, see Section [10.6.17](#).

### 10.6.2 Typical Application

In the application below (Figure 10-23), the device is embedded in a TDMoIP gateway to achieve TDM connectivity over a PSN. The TDM-over-Packet packet formats for both IP and MPLS are shown in Figure 10-24 and Figure 10-25, respectively.

Figure 10-23. TDM Connectivity over a PSN

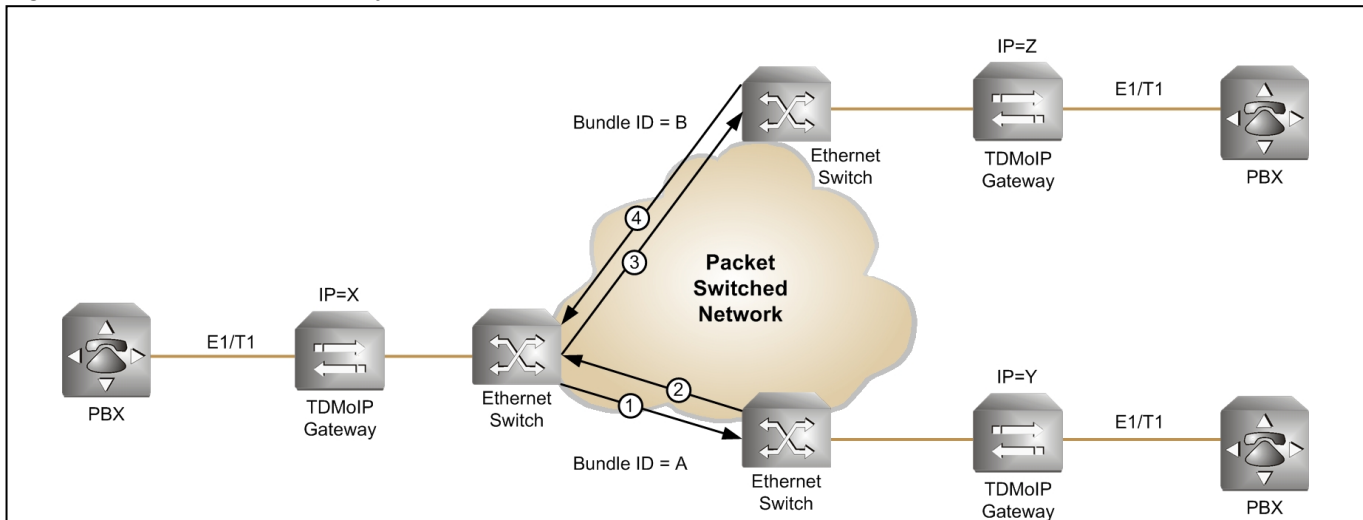

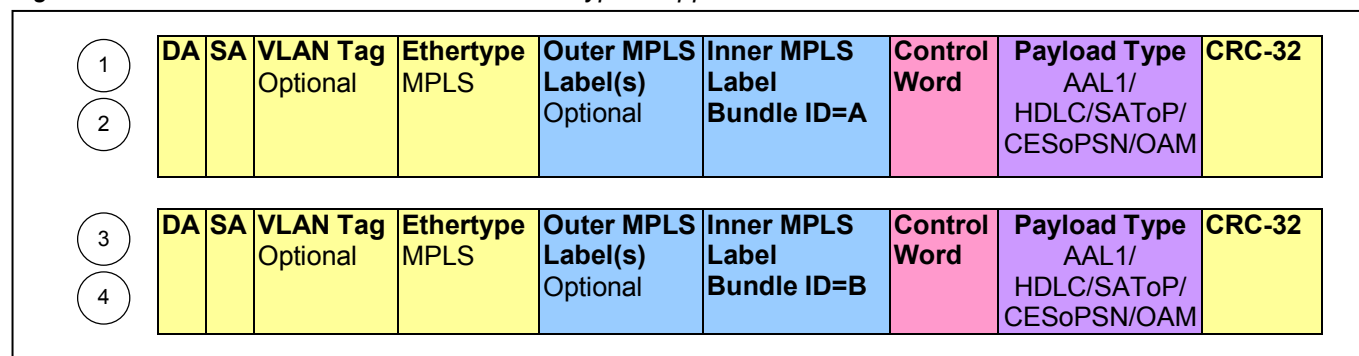

Figure 10-24. TDMoP Packet Format in a Typical Application

### 10.6.3 Clock Recovery

The TDM-over-Packet block's innovative clock recovery process is divided into two successive phases. In the acquisition phase, rapid frequency lock is attained. In the tracking phase, frequency lock is sustained and phase is also tracked. During the tracking phase, jitter is attenuated to comply with the relevant telecom standards even for packet-switched networks with relatively large packet delay variation. Packet loss immunity is also significantly improved.

During the acquisition phase, a direct estimation of the frequency discrepancy between the far-end and near-end service clocks continuously drives an internal frequency synthesis device through a band-limited control loop. As a result, frequency acquisition is achieved rapidly (typically less than 10 seconds). The clock recovery capture range is  $\pm 90$  ppm around the nominal service clock for any supported clock rate.

Once the frequency-monitoring unit has detected a steady frequency lock, the system switches to its tracking phase. During the tracking phase the fill level of the received-packet jitter buffer drives the internal frequency synthesizer through a similar band-limited control loop.

While in the tracking phase, two tasks are performed. First, the far-end service clock frequency is slowly and accurately tracked, while compelling the regenerated near-end service clock to have jitter and wander levels that conform to ITU-T G.823/G.824 requirements, even for networks that introduce high packet delay variation and packet loss. This performance can be attained due to a very efficient jitter attenuation mechanism, combined with a high resolution internal digital PLL ( $\Delta f = 0.4$  ppb). Second, the received-packet jitter buffer is maintained at its fill level, regardless of the initial frequency discrepancy between the clocks. As a result, the latency added by the mechanism is minimized, while immunity against overflow/underflow events (caused by extreme packet delay variation events) is substantially enhanced.

The TDM-over-Packet block supports two clock recovery modes: common clock (differential) mode and adaptive mode.

The common clock mode is used for applications where the TDMoP gateways at both ends of the PSN path have access to the same high-quality reference clock. This mode makes use of RTP differential mode time-stamps and therefore the RTP header must be present in TDMoP packets when this mode is used. The common reference clock is provided to the chip on the **CLK\_CMN** input pin. The device is configured for common clock mode when **Clock\_recovery\_en=1** in **General\_cfg\_reg0** and **RTP\_timestamp\_generation\_mode=1** in **General\_cfg\_reg1**.

The adaptive clock mode is based solely on packet inter-arrival time and therefore can be used for applications where a common reference clock is *not* available to both TDMoP gateways. This mode does not make use of time-stamps and therefore the RTP header is not needed in the TDMoP packets when this mode is used. The device is configured for adaptive clock mode when **Clock\_recovery\_en=1** in **General\_cfg\_reg0** and **RTP\_timestamp\_generation\_mode=0** in **General\_cfg\_reg1**.

In adaptive mode, for low-speed interfaces (up to 4.6 MHz), an on-chip digital PLL, clocked by a 38.88MHz clock derived from the **CLK\_HIGH** pin, synthesizes the recovered clock frequency. The frequency stability characteristics

of the [CLK\\_HIGH](#) signal depend on the wander requirements of the recovered TDM clock. For applications where the recovered TDM clock must comply with G.823/G.824 requirements for traffic interfaces, typically a TCXO can be used as the source for the [CLK\\_HIGH](#) signal. For applications where the recovered clock must comply with G.823/G.824 requirements for synchronization interfaces, the [CLK\\_HIGH](#) signal typically must come from an OCXO.

In addition to performing clock recovery for up to eight low-speed (typically E1/T1) signals, the device can also be configured in a high-speed mode in which it supports one E3, T3 or STS-1 signal in and out of port 1. In high-speed mode, the on-chip digital PLL synthesizes the recovered clock frequency divided by 10 (for STS-1) or 12 (for E3 or T3). This clock is available on the [TDM1\\_ACLK](#) output pin and can be multiplied by an external PLL to get the recovered clock of the high-speed signal (see section 15.3). High-speed mode is enabled when `High_speed=1` in [General\\_cfg\\_reg0](#).

For applications where the chip is used only for clock recovery purposes (i.e. data is not forwarded through the chip) the external SDRAM is not needed.

### **10.6.4 Timeslot Assigner (TSA)**

The TDM-over-Packet block contains one Timeslot Assigner for each TDM port (framed or multiframed). The TSA is bypassed in high-speed mode (i.e. when `High_speed=1` in [General\\_cfg\\_reg0](#).) The TSA tables are described in section 11.4.5.

The TSA assigns 2-, 7- or 8-bit wide timeslots to a specific bundle and a specific receive queue. 2-bit timeslots are used for delivering 16K HDLC channels. The 2 bits are located at the first 2 bits (PCM MSbits, HDLC LSbits) of the timeslot. The next 6 bits of the timeslot cannot be assigned. 7-bit timeslots are used for delivering 56kbps HDLC channels. The 7 bits are located at the first 7 bits (PCM MSbits, HDLC LSbits) of the timeslot. The last bit of the timeslot cannot be assigned. The 2-bit and 7-bit timeslots may be assigned only to the HDLC payload type machine. The AAL1 and RAW payload type machines support only 8-bit timeslots. For unframed/Nx64 interfaces all entries must be configured as 8-bit timeslots.

Each port has two TSA tables (banks): one active and the other one shadow. The [TSA\\_int\\_act\\_blk](#) status bit in [Port\[n\]\\_stat\\_reg1](#) indicates which bank is currently active. The CPU can only write to the shadow table. After TSA entries are changed in the shadow table the TSA tables should be swapped by changing the [TSA\\_act\\_blk](#) bit in [Port\[n\]\\_cfg\\_reg](#) so that the active table becomes the shadow table and the shadow table becomes the active table. Changes take effect at the next frame sync signal. For an unframed interface the changes take effect up to 256 TDM clock cycles after the [TSA\\_act\\_blk](#) is changed. After the change occurs, the [TSA\\_int\\_act\\_blk](#) bit is updated by the device.

Each table consists of 32 entries, one entry per timeslot. The first entry refers to the first timeslot, i.e. the first 8 bits of the frame (where the frame sync signal indicates start-of-frame). The second entry refers to the second timeslot, i.e. the 8 bits after the first 8 bits, and so on.

The format of a table entry is shown in section 11.4.5. If a port is configured for an unframed signal format, all 32 entries for that port must have the same settings for all fields.

A bundle can only be composed of timeslots from a single TDM port, but timeslots from a TDM port can be assigned to multiple bundles.

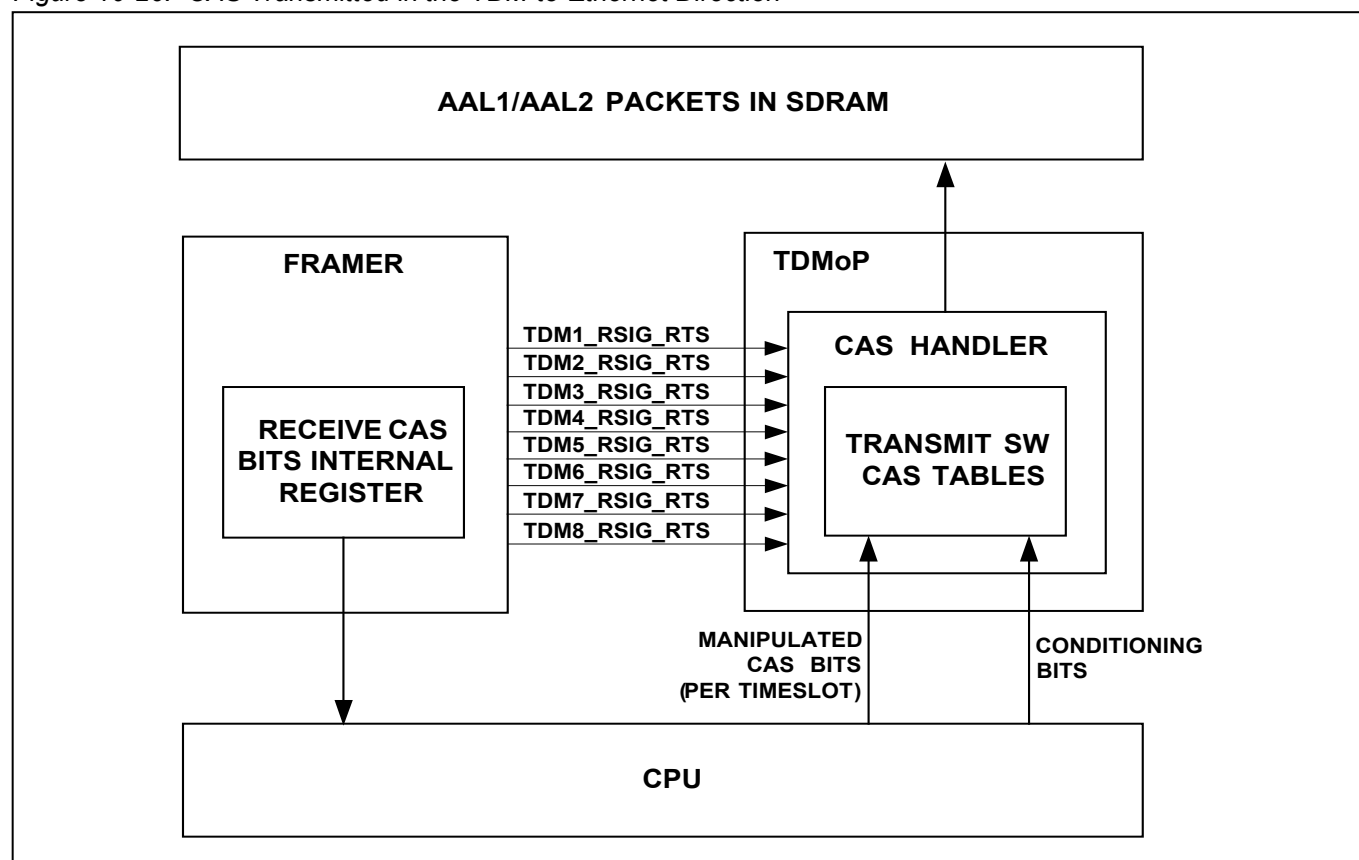

## 10.6.5 CAS Handler

### 10.6.5.1 CAS Handler, TDM-to-Ethernet Direction

In the TDM-to-Ethernet direction, the CAS handler receives the CAS bits (for structured-with-CAS AAL1/CESoPSN bundles) on the TDMn\_RSIG\_RTS signal. Depending on the value of the per-bundle [Tx\\_CAS\\_source](#) configuration bit in the [Bundle Configuration Tables](#), the CAS handler inserts either the CAS bits from the corresponding TDMn\_RSIG\_RTS signal or the values from the transmit SW CAS tables (section 11.4.9) into the AAL1/CESoPSN packets, in order to deliver the signaling as part of the AAL1/CESoPSN payload packets. See [Figure 10-26](#).

The transmit SW CAS tables may contain conditioning bits set by CPU software during configuration (per timeslot). If CAS bits received on the TDMn\_RSIG\_RTS signal change, a per-timeslot maskable interrupt is asserted. The [Tx\\_CAS\\_change](#) registers in the [Interrupt Controller](#) indicate which timeslots have changed CAS bits. The [Tx\\_CAS\\_change\\_mask](#) registers are available to selectively mask these interrupts. Upon notification that CAS bits have changed, the CPU can read the CAS bits directly from the receive signaling registers of the neighboring E1/T1 framer component, alter them if needed, and write them into the TDMoP block's transmit SW CAS tables.

Figure 10-26. CAS Transmitted in the TDM-to-Ethernet Direction

There is a transmit SW CAS table for each TDM port. Each table consists of 4 rows, and each row contains the CAS bits of eight timeslots. For ports configured for E1, timeslots 1–15 and 17–31 are used and timeslots 0 and 16 are meaningless. For ports configured for T1, timeslots 0–23 are used and timeslots 24–31 are meaningless. Ports configured for T1 SF have two copies of A and B CAS bits arranged A, B, A, B. Other port types have one copy of bits A, B, C and D. These cases are illustrated in [Figure 10-27](#) and [Figure 10-28](#).

Figure 10-27. Transmit SW CAS Table Format for E1 and T1-ESF Interfaces

31							0
ABCD (TS7)	ABCD (TS6)	ABCD (TS5)	ABCD (TS4)	ABCD (TS3)	ABCD (TS2)	ABCD (TS1)	ABCD (TS0)
ABCD (TS15)	..	..	..	..	..	..	ABCD (TS8)
ABCD (TS23)	..	..	..	..	..	..	ABCD (TS16)
ABCD (TS31)	..	..	..	..	..	..	ABCD (TS24)

Figure 10-28. Transmit SW CAS Table Format for T1-SF Interfaces

ABAB (TS7)	ABAB (TS6)	ABAB (TS5)	ABAB (TS4)	ABAB (TS3)	ABAB (TS2)	ABAB (TS1)	ABAB (TS0)
ABAB (TS15)	..	..	..	..	..	..	ABAB (TS8)
ABAB (TS23)	..	..	..	..	..	..	ABAB (TS16)

**Table 10-19. CAS – Supported Interface Connections for AAL1 and CESoPSN**

TDM-to-Packet Interface Format	Packet-to-TDM Interface Format	Transmitted Bits
E1 MF	E1 MF	CAS bits are transferred as-is.
T1 SF	T1 SF	
T1 ESF	T1 ESF	
T1 ESF	T1 SF	Only A and B bits transferred.
T1 SF	T1 ESF	A and B bits transferred. C and D bits sourced from the <a href="#">SF_to_ESF_low_CAS_bits</a> field in <a href="#">Port[n].cfg_reg</a> .

For structured-with-CAS bundles connecting two T1 SF/ESF interfaces, the per-bundle [Tx\\_dest\\_framing](#) bit in the [Bundle Configuration Tables](#) indicates the destination interface framing type (SF or ESF).

The figures below shows the location of the CAS bits in the TDMn\_RSIG\_RTS data stream for each framing mode.

Figure 10-29. E1 MF Interface RSIG Timing Diagram (two\_clocks=1)

**Figure 10-30. T1 ESF Interface RSIG Timing Diagram (two\_clocks=0)**

**Figure 10-31. T1 SF Interface RSIG (two\_clocks=0) – Timing Diagram**

TDMn\_RX\_SYNC can be left unconnected or connected to ground if the neighboring E1/T1 framer IC cannot drive it. The TDMoP block has an internal free running counter that generates this signal internally when not driven by an external source. This internally generated multiframe sync signal is synchronized to the TDMn\_RX\_SYNC input pulse when present.

#### **10.6.5.2 CAS Handler, Ethernet-to-TDM Direction**

In the Ethernet-to-TDM direction, the CAS is received from the incoming packets.

The AAL1/RAW payload type machine extracts the CAS bits from the TDM-over-packet payload and writes them into the CAS jitter buffers in the SDRAM (for structured-with-CAS AAL1/CESoPSN bundles only). The CAS jitter buffers store the CAS information of up to 128 timeslots of the eight ports.

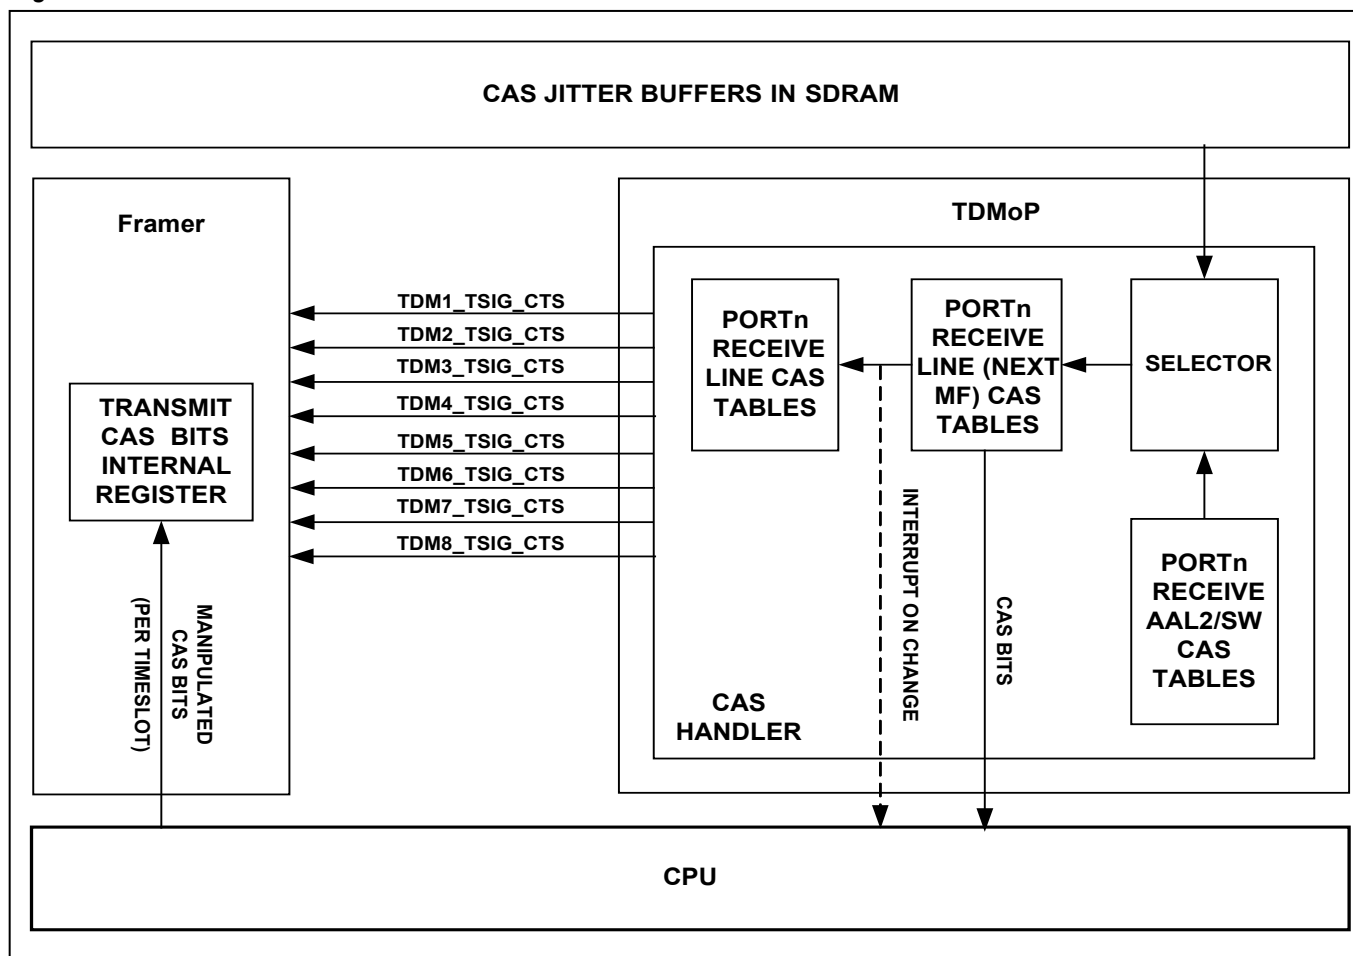

Selectors in the CAS handler send the CAS bits either from the CAS jitter buffers or from the [Receive SW CAS tables](#) to the line (next MF) CAS tables (see [Figure 10-32](#)). The selectors' decision logic is shown in [Table 10-20](#).

**Table 10-20. CAS Handler Selector Decision Logic**

Condition	Source of CAS bits Driven on TDMn_TSIG_CTS for this Timeslot
Timeslot not assigned or assigned to a bundle which is not an AAL1/CESoPSN structured bundle ( <a href="#">Rx_assigned</a> =0 or <a href="#">Structured_type</a> =0 for its TSA entry)	<a href="#">Receive SW CAS tables</a>
AAL1 bundle jitter buffer is in underrun state and <a href="#">Rx_CAS_src</a> =1	
Timeslot assigned to an AAL1/CESoPSN structured bundle ( <a href="#">Rx_assigned</a> =1 and <a href="#">Structured_type</a> =1 for its TSA entry)	Corresponding CAS jitter buffer in SDRAM (CAS value is the latest received)
AAL1/CESoPSN bundle jitter buffer is in underrun state and <a href="#">Rx_CAS_src</a> =0	

Figure 10-32. CAS Transmitted in the Ethernet-to-TDM Direction

The [Receive SW CAS](#) tables contains CAS bits written by CPU software.

Each port's [Receive Line CAS](#) table (section 11.4.10) is updated with the CAS bits stored in the Receive Line (Next MF) CAS table when the TDMn\_TX\_MF\_CD signal is asserted to indicate the multiframe boundary. For E1 ports, CAS bits are updated every 2 milliseconds. For T1 SF ports, CAS bits are updated every 1.5 milliseconds. For T1 ESF ports, CAS bits are updated every 3 milliseconds.

There is a [Receive Line CAS](#) table for each TDM port. These tables hold the CAS information extracted from received packets and subsequently transmitted on TDMn\_TSIG signals. Each table contains 32 rows, and each row holds the CAS bits of one timeslot. Only the first 24 rows are used for T1 interfaces. For E1 and T1 ESF interfaces, each row holds the A, B, C and D bits. For T1 SF interface where only the A and B bits exist, each row holds the A and B bits duplicated i.e. A, B, A, B.

If CAS bits change in the [Receive Line CAS](#) table, a per-timeslot interrupt is asserted. The [Rx\\_CAS\\_change](#) registers in the [Interrupt Controller](#) indicate which timeslots have changed CAS bits. Upon notification that CAS bits have changed, CPU software can read the CAS bits from the Receive Line (Next MF) CAS table, manipulate them and then write them directly into the transmit signaling registers of the neighboring E1/T1 framer IC. In this case, the framer should be configured to use the CAS information from its CAS registers and not from its signaling input pin.

The bits in each [Receive Line CAS](#) table are transmitted on the TDMn\_TSIG signal, as shown in the figures below.

**Figure 10-33. E1 MF Interface TSIG Timing Diagram**

**Figure 10-34. T1 ESF Interface TSIG Timing Diagram**

**Figure 10-35. T1 SF Interface TSIG Timing Diagram**

TDMn\_TX\_MF\_CD can be left unconnected or connected to ground if the framer cannot drive it. The TDMoP block has an internal free running counter that generates this signal internally when not driven by external source. This internally generated multiframe sync signal is synchronized to the TDMn\_TX\_SYNC input pulse when present.

### 10.6.6 AAL1 Payload Type Machine

For the prevalent case for which the timeslot allocation is static and no activity detection is performed, the payload can be efficiently encoded using constant bit rate AAL1 adaptation.

The AAL1 payload type machine converts E1, T1, E3, T3, STS-1 or serial data flows into IP, MPLS or Ethernet packets, and vice versa, according to ITU-T Y.1413, Y.1453, MEF 8, MFA 4.1 and IETF RFC 5087 TDMoIP. In this mapping method, data is actually mapped into 48-byte AAL1 SAR PDUs as described in I.361.1 section 2.4.2.

#### 10.6.6.1 TDM-to-Ethernet Direction

In the TDM-to-Ethernet direction, the AAL1 payload type machine concatenates the bundle's timeslots into structures and then slices and maps the structures into 46- or 47-octet AAL1 SAR PDU payloads. After adding the AAL1 SAR PDU header and pointer as needed, the AAL1 SAR PDUs are concatenated and inserted into the payload of the layer 2/layer 3 packet.

Figure 10-36. AAL1 Mapping, General

The structure of the AAL1 header is shown in [Table 10-21](#) below.

**Table 10-21. AAL1 Header Fields**

Field	Length (bits)	Description
C	1	Indicates if there is a pointer in the second octet of the AAL1 SAR PDU. When set, a pointer exists.
SN	3	AAL1 SAR PDU sequence number
CRC	3	Cyclic redundancy code on C and SN
P	1	Even parity bit on C, SN and CRC or the even byte parity LSB for the sequence number octet (P format AAL1 SAR PDUs only)
E	1	(P format AAL1 SAR PDUs only) Even byte parity MSB for pointer octet
Pointer	7	(P format AAL1 SAR PDUs only) Indicates the next structure boundary. It is always located at the first possible position in the sequence number cycle in which a structure boundary occurs. The pointer indicates one of 93 octets (46 octets of the current AAL1 SAR PDU + 47 octets of the next AAL1 SAR PDU). P=0 indicates that the first octet of the current AAL1 SAR PDU's payload is the first octet of the structure. P=93 indicates that the last octet of the next AAL1 SAR PDU is the final octet of the structure.

The AAL1 block supports the following bundle types:

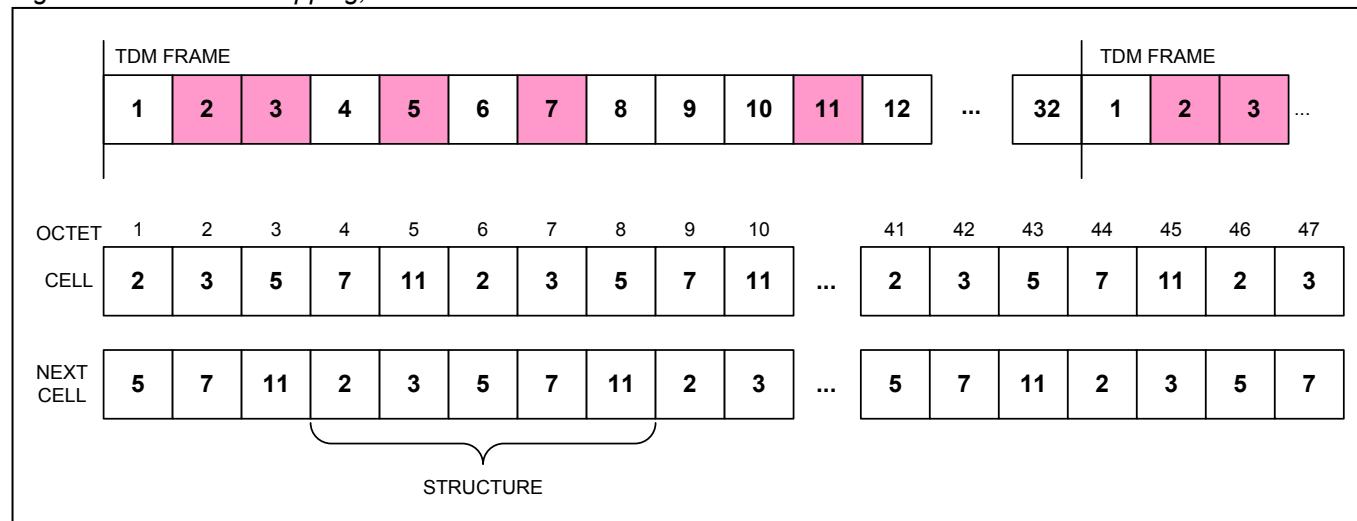

- Unstructured
- Structured
- Structured-with-CAS.

**Unstructured bundles**, for E1/T1 interfaces, support rates of  $N \times 64$  kbps, where N is the number of timeslots configured to be assigned to a bundle. Unstructured bundles may also carry traffic of the whole low-speed interface (up to 4.6 Mbps), E1/T1 interface (2.048Mbps/1.544 Mbps) and high-speed interface (up to 51.84 Mbps). The AAL1

SAR PDU payload contains 47 octets (376 bits) of TDM data without regard to frame alignment or timeslot byte alignment. All AAL1 SAR PDUs are non-P format for unstructured bundles.

**Structured bundles**, for E1/T1 interfaces, support rates of  $N \times 64$  kbps, where N is the number of timeslots configured to be assigned to a bundle. For this format, the N timeslots from one E1/T1 frame are sequentially mapped into an N-octet structure. This N-octet structure is then mapped into the AAL1 SAR PDU payload, octet-aligned. This process is repeated until all octets of the AAL1 SAR PDU payload are filled. The last octet of the payload may contain a timeslot other than the last timeslot of the structure. The remaining timeslots of the structure are mapped into the next AAL1 SAR PDU payload in the same manner and the process continues. This is illustrated in Figure 10-37.

Figure 10-37. AAL1 Mapping, Structured-Without-CAS Bundles

With this mapping each AAL1 SAR PDU can start with a different timeslot. To enable the far end TDMoP function to identify the start of a structure, a pointer to it is sent periodically in one of the even-numbered AAL1 SAR PDUs of every SN cycle. When this pointer is sent, a P-format AAL1 SAR PDU is used. In a P-format AAL1 SAR PDU the first byte of the payload contains the pointer while the last 46 bytes contain payload.

**Structured-with-CAS bundles**, for E1/T1 interfaces, support rates of  $N \times 64$  kbps, where N is the number of timeslots configured to be assigned to a bundle. This mapping is similar to the structured-without-CAS mapping described above except that the structure is an entire E1/T1 multiframe of the N timeslots assigned to the bundle, and a CAS signaling substructure is appended to the end of the structure. The addition of CAS only affects the structure arrangement and contents. CAS data of one timeslot is 4 bits long, meaning one octet can contain CAS data of 2 timeslots. Bundles containing an odd number of timeslots need a padding of 4 zeroes in the last CAS octet. For example, a 3-timeslot bundle of an E1 frame with CAS yields the following structure octet sequence: TS1, TS2, TS3 repeated 16 times (a whole E1 multiframe) and then CAS1+CAS2, CAS3+padding.

### 10.6.6.2 Ethernet-to-TDM Direction

In the Ethernet-to-TDM direction, AAL1 SAR PDUs of a bundle are being received only after the synchronization process. The synchronization process includes packet SN synchronization, AAL1 SAR PDU SN synchronization, and pointer synchronization. AAL1 SAR PDUs with CRC or parity errors in their header are discarded. Pointer mismatch imposes jitter buffer under-run and bundle resynchronization. AAL1 SAR PDU header errors or pointer errors may be ignored depending on per-bundle configuration. Missing AAL1 SAR PDUs are detected and restored in the jitter buffer.

### 10.6.7 HDLC Payload Type Machine

Handling HDLC in TDM-over-Packet ensures efficient transport of CCS (common channel signaling, such as SS7), embedded in the TDM stream or other HDLC-based traffic, such as Frame Relay, according to IETF RFC 4618 (excluding clause 5.3 – PPP) and RFC 5087 (TDMoIP).

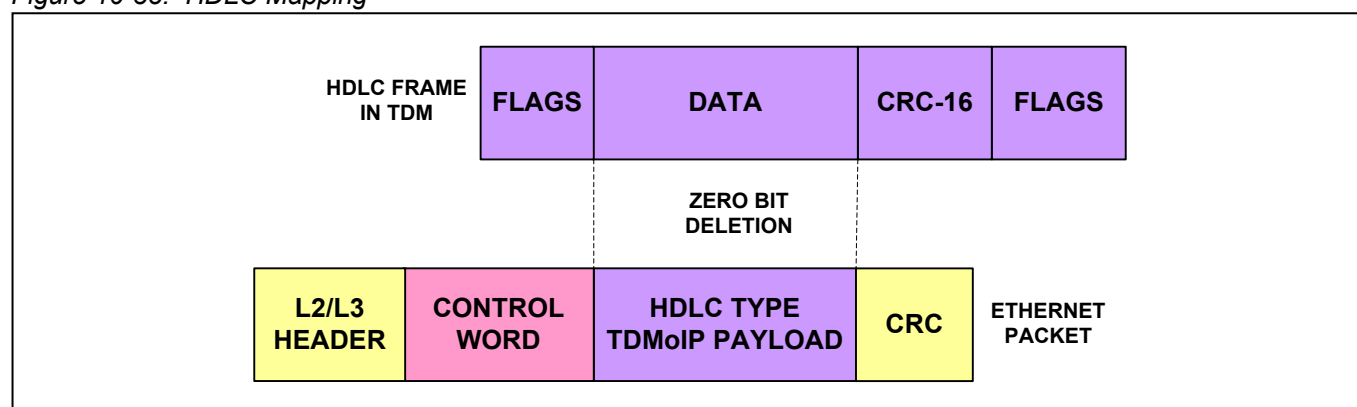

For an E1 interface, each bundle supports the rates of 16 kbps or  $N \times 64$  kbps, where  $N$  is the number of timeslots configured to be assigned to a bundle (between 1 to 32). For an T1 interface, each bundle supports the rates of 16 kbps, 56 kbps (not supported for T1 SF interface), full T1 (1.544 Mbps) or  $N \times 64$  kbps, where  $N$  varies from 1 to 24.

In the TDM-to-Ethernet direction, the HDLC block monitors flags until a frame is detected. It removes bit stuffing, collects the contents of the frame and checks the correctness of the CRC, alignment and frame length. Valid frame length is anything greater than 2 bytes and less than `Tx_max_frame_size` in `HDLC_Bundle[n]_cfg[95:64]`.

Erroneous frames are discarded. Good frames are mapped as-is into the payload of the configured layer 2/3 packet type (without the CRC, flags or transparency zero-insertions).

In the Ethernet-to-TDM direction, when a packet is received, its CRC is calculated, and the original HDLC frame reconstituted (flags are added, bit stuffing is performed, and CRC is added).

Figure 10-38. HDLC Mapping

### 10.6.8 RAW Payload Type Machine

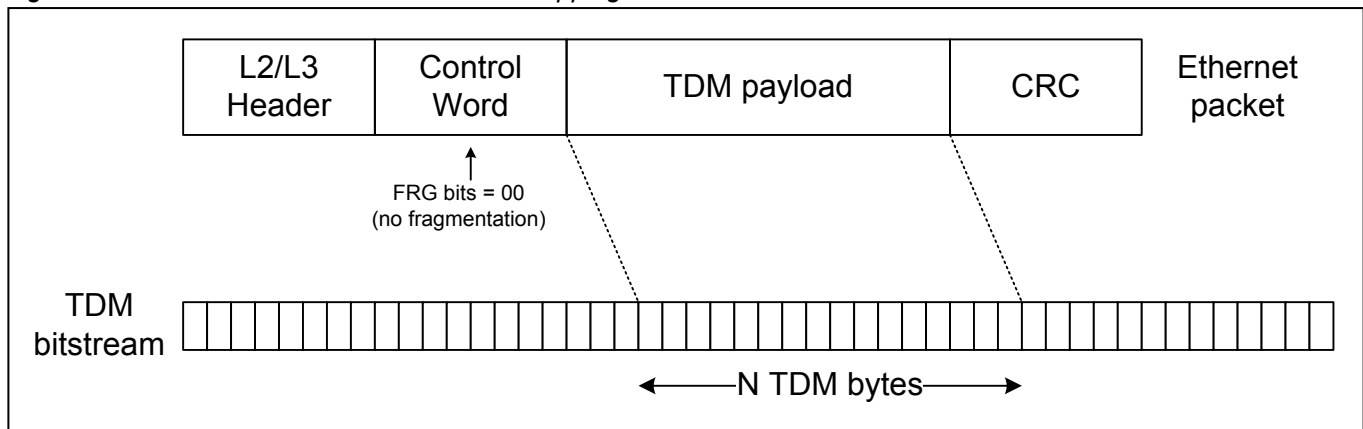

The RAW payload type machine support the following bundle types:

- **Unstructured**  
According to ITU-T Y.1413, Y.1453, MEF 8, MFA 8.0.0 and IETF RFC 4553 (SAToP).
- **Structured without CAS**  
According to ITU-T Y.1413, Y.1453, MEF 8, MFA 8.0.0 and IETF RFC 5086 (CESoPSN).
- **Structured with CAS**  
According to ITU-T Y.1413, Y.1453, MEF 8, MFA 8.0.0 and IETF RFC 5086 (CESoPSN).

#### 10.6.8.1 Unstructured

Unstructured bundles usually carry the data of a whole TDM port. This port may be low-speed such as an E1, T1 or Nx64k bit stream or high-speed such as an E3, T3 or STS1 signal. In an unstructured bundle, the packet payload is comprised of N bytes of the TDM stream without regard for byte or frame alignment. In the receiving device, the TDM data is extracted from the packet payload and inserted as a bit stream into the jitter buffer, from which it is then extracted and sent to the TDM port.

Figure 10-39. SAToP Unstructured Packet Mapping

The packetization delay of an unstructured (SAToP) bundle is:  $T = N \times 8 \times \text{the bit time of the TDM interface}$ .

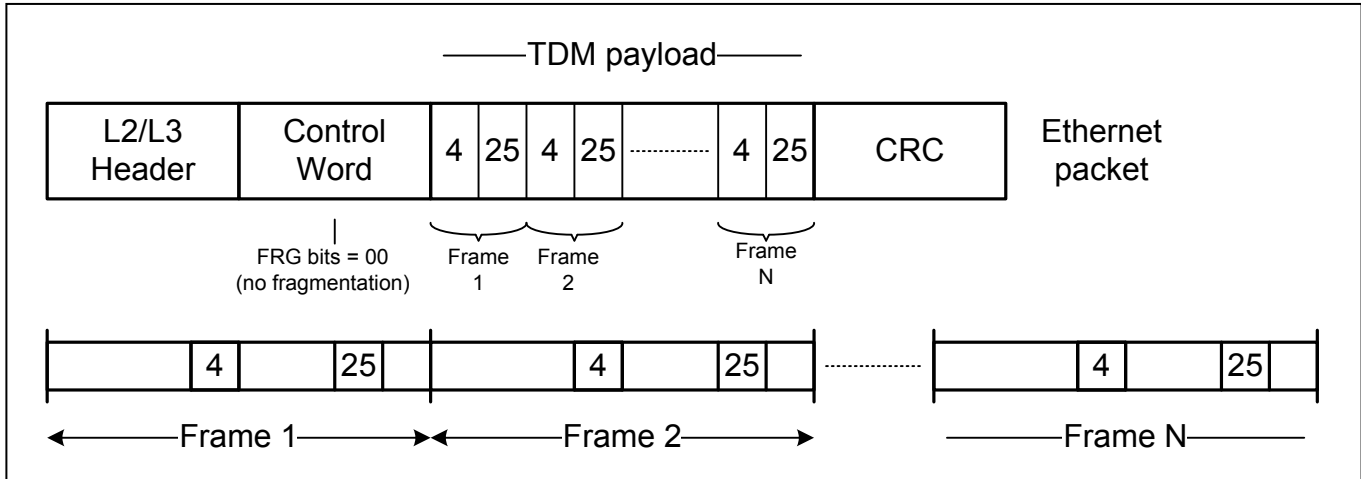

The minimum packetization time of an Ethernet packet for an unstructured (SAToP) bundle is as follows:

- 60  $\mu\text{s}$  for high speed mode
- 125  $\mu\text{s}$  for low speed mode

#### 10.6.8.2 Structured without CAS

In a structured-without-CAS bundle, the packet payload is comprised of the assigned timeslots from N TDM frames as illustrated in [Figure 10-40](#).

Figure 10-40. CESoPSN Structured-Without-CAS Mapping

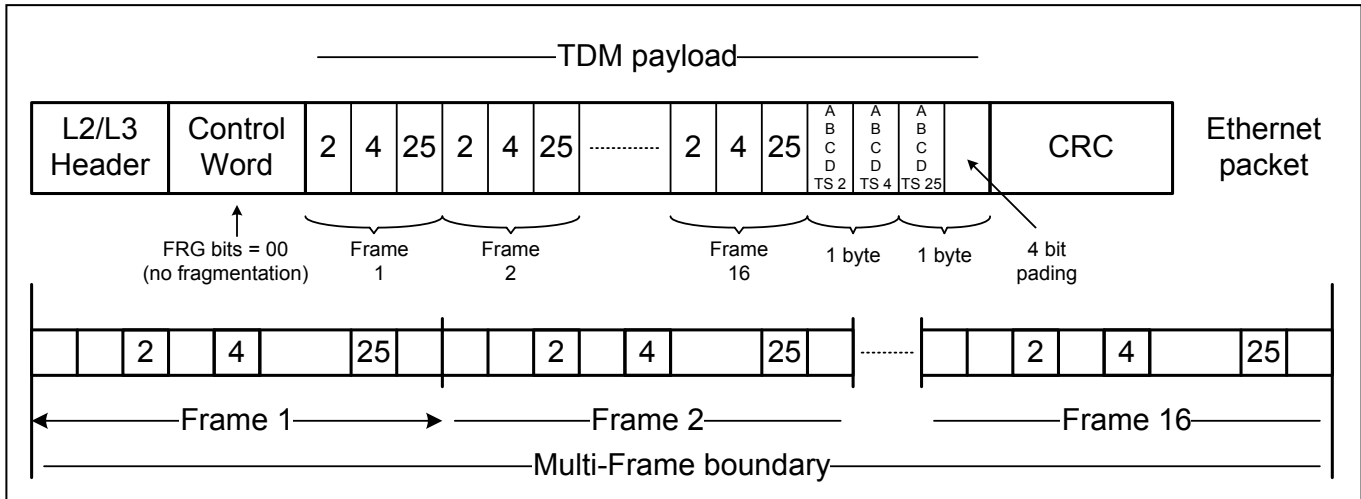

The packetization delay of a CESoPSN structured-without-CAS bundle is:  $T = N \times 125 \mu s$  (i.e.  $N \times$  the frame rate)

The minimum packetization time of an Ethernet packet for a structured (with or without CAS) bundle is 125  $\mu s$ .

### 10.6.8.3 Structured with CAS (without Fragmentation)

In a structured-with-CAS bundle, the packet payload is comprised of the assigned timeslots from all the TDM frames in a multiframe (e.g. 16 frames for E1) followed by the CAS signaling substructure, which contains the CAS info for the assigned timeslots.

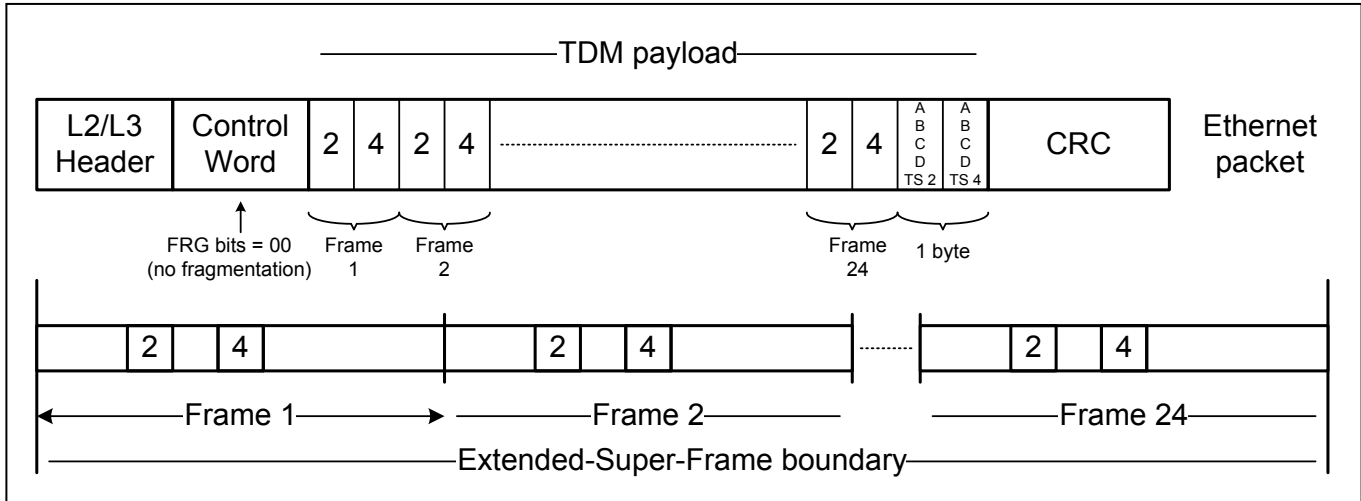

Figure 10-41. CESoPSN Structured-With-CAS Mapping (No Frag, E1 Example)

The minimum packetization time of an Ethernet packet for a structured (with or without CAS) bundle is 125  $\mu s$ .

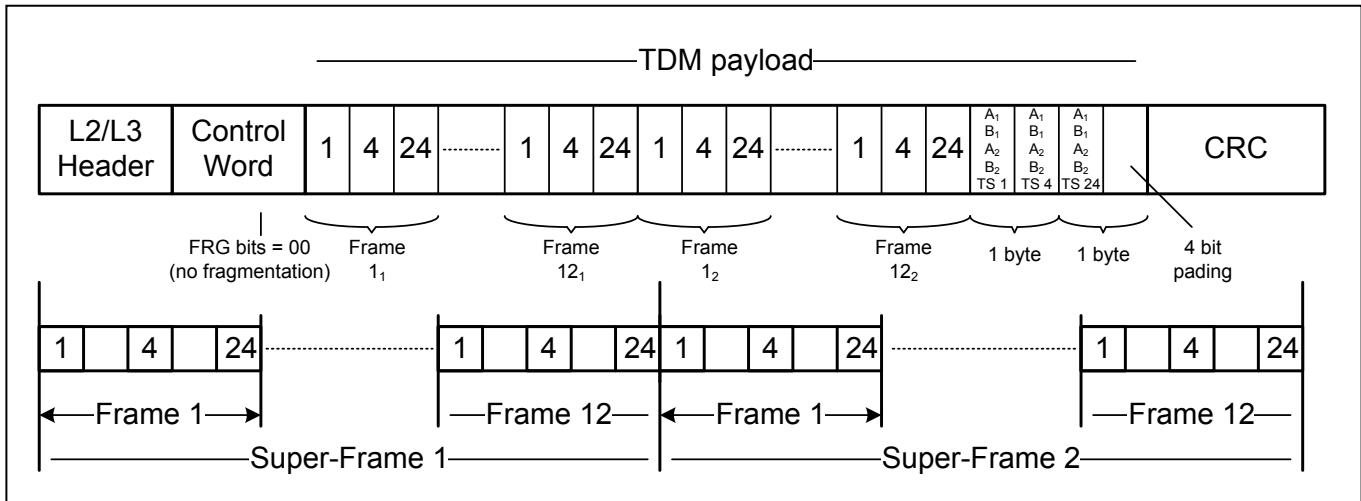

The minimum TDM payload of an Ethernet packet for a structured (with or without CAS) bundle is 8 bytes.

Figure 10-42. CESoPSN Structured-With-CAS Mapping (No Frag, T1-ESF Example)

In T1 SF, the multiframe structure is composed of 2 superframes resulting total of 24 TDM frames. The CAS info at the end of the structure contains the CAS info of the 2 corresponding superframes as well.

Figure 10-43. CESoPSN Structured-With-CAS Mapping (No Frag, T1-SF Example)

The packetization delay of a CESoPSN structured-with-CAS bundle (not fragmented) is as follows:

- Multiframe E1:  $T = 2 \text{ ms}$
- T1 SF, ESF:  $T = 3 \text{ ms}$

#### 10.6.8.4 Structured-with-CAS (with Fragmentation)

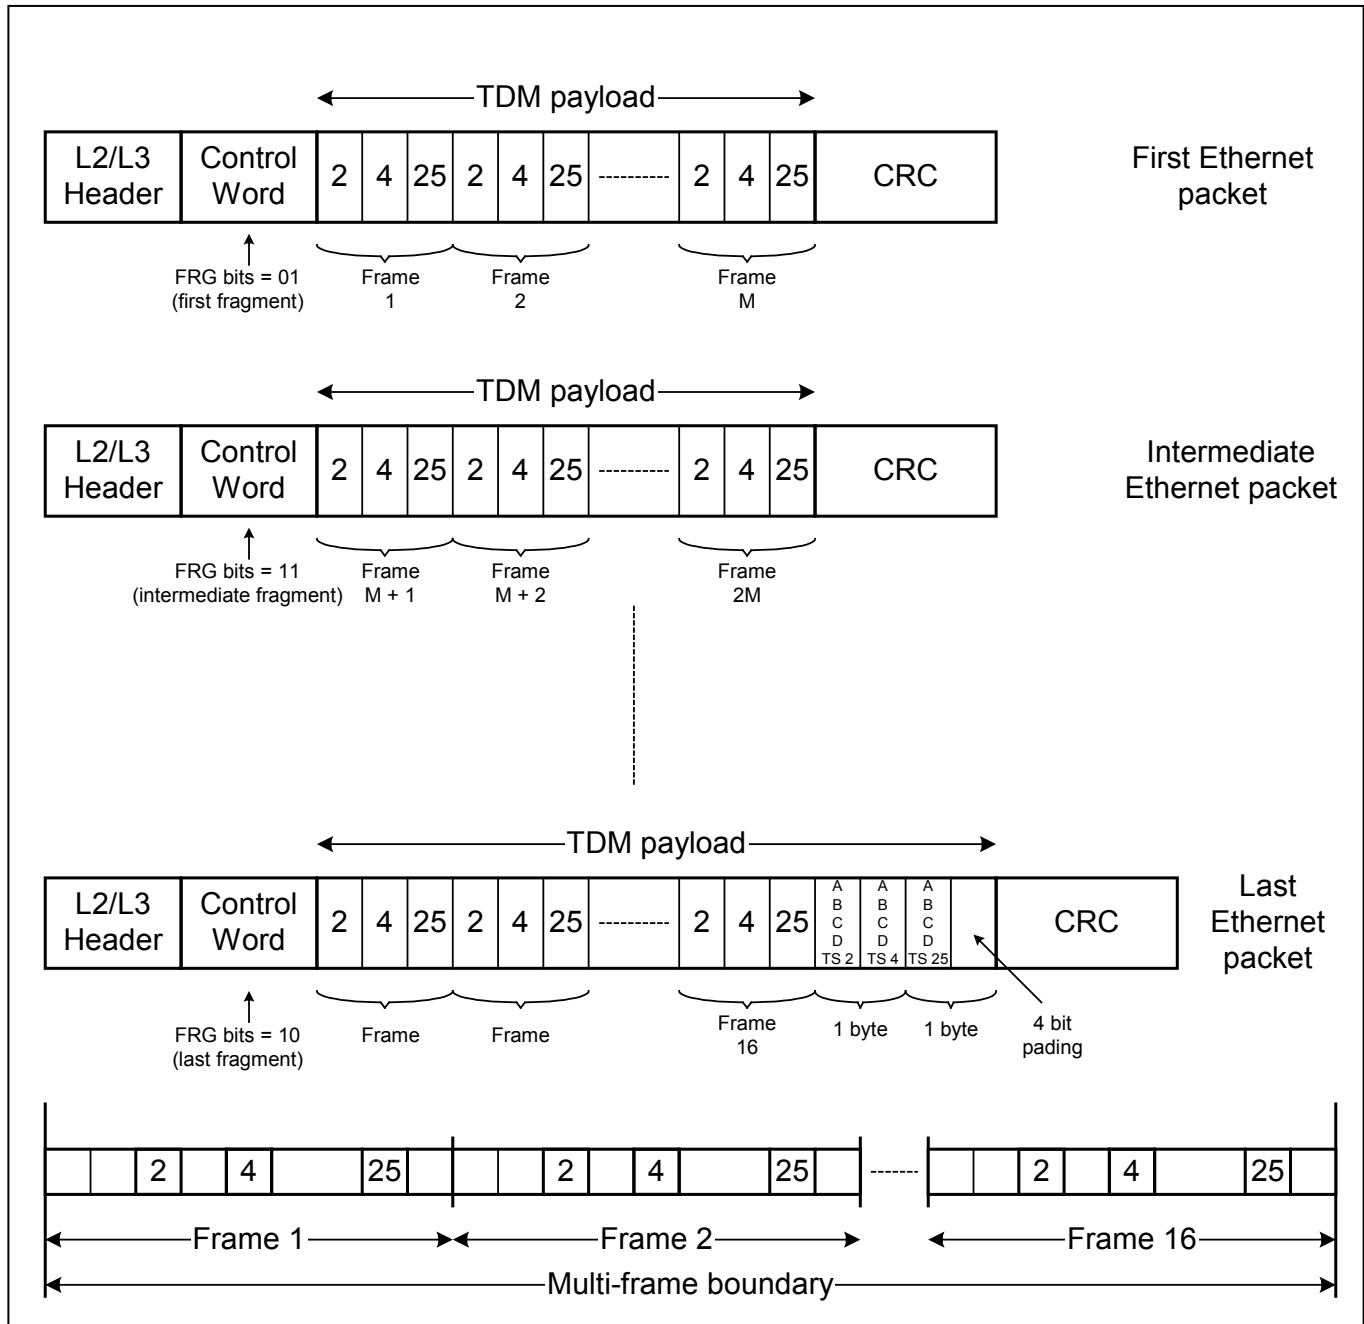

In order to reduce the packetization delay of structured-with-CAS bundle, the CESoPSN standard supports the option of fragmentation. In this mode, the multiframe data structure is fragmented among several packets. Each packet contains M TDM frames of the assigned timeslots. The last packet also contains the entire multiframe CAS substructure. Because of that, there is limited number of allowed “M” values:

- For multiframe E1:  $M = 1, 2, 4, 8, 16$  (16 means single packet with no fragmentation)
- For T1 SF:  $M = 1, 2, 3, 4, 6, 8, 12, 24$  (24 means single packet with no fragmentation)
- For T1 ESF:  $M = 1, 2, 3, 4, 6, 8, 12, 24$  (24 means single packet with no fragmentation)

The packetization delay of a CESoPSN structured-with-CAS bundle (with fragmentation) is:  $T = M \times 125 \mu\text{s}$ .

Figure 10-44. CESoPSN Structured-With-CAS Mapping (Frag, E1 Example)

### 10.6.9 SDRAM and SDRAM Controller

The device requires an external SDRAM for its operation. The following describes how the TDMoP block and the CPU use the SDRAM:

The TDMoP block accesses these sections of the SDRAM:

- **Transmit buffers section**  
This area stores outgoing packets created by the payload-type machines. It is a 1-Mbyte area with base address specified by the `Tx_buf_base_add` field in [General\\_cfg\\_reg1](#). The actual amount of SDRAM used in the transmit buffers section depends on the number of open bundles and the number of buffers assigned to each bundle.
- **Jitter buffer data section**  
This area stores incoming TDM data after it has been extracted from received packets by the payload-type machines. It is a 2-Mbyte area with base address specified by the `JBC_data_base_add` field in [General\\_cfg\\_reg1](#). The actual amount of the SDRAM used in the jitter buffer data section depends on the configuration (most applications allocate only 0.5 Mbyte).
- **Jitter buffer signaling section:**  
This area stores incoming TDM signaling information after it has been extracted from received packets by the payload-type machines. It is a 32-kbyte area, with base address specified by the `JBC_sig_base_add` field in [General\\_cfg\\_reg1](#). This section is used only when structured-with-CAS bundles have been opened.

The CPU uses the SDRAM as follows:

- The CPU may utilize the sections of SDRAM not used by the TDMoP block in order to send/receive packets through the CPU queues/pools.
- The CPU accesses the transmit buffers section in order to initialize the buffer headers before opening a bundle.

The built-in SDRAM controller allows glueless connection to an external SDRAM (the TDMoP block supplies the SDRAM clock). Supported SDRAM devices are listed in section [15.6](#).

The TDMoP block typically uses from 1.5 to 3 MB of SDRAM space, depending on configuration. The CPU may use the rest of the memory.

The supported resolutions of CPU access to the SDRAM are shown below.

**Table 10-22. SDRAM Access Resolution**

Data Bus Width	Access to SDRAM
32 bits	8, 16, 32 bit
16 bits	8, 16 bit

Prior to operation, the SDRAM controller configuration bits (see the [General\\_cfg\\_reg0](#) register) must be configured. First, the CPU must set the configuration bits while maintaining the `Rst_SDRAM_n` bit low (0). Then, it should deassert the `Rst_SDRAM_n` bit. The `Rst_SDRAM_n` bit must not be changed during operation.

The SDRAM Controller operates at either 50 or 75 MHz with the following CAS latency options:

**Table 10-23. SDRAM CAS Latency vs. Frequency**

Frequency [MHz]	CAS Latency [clock cycles]
50	2
75	2 or 3

During operation, the controller's arbiter receives access requests from various internal hardware blocks and the CPU and grants access permissions based on predefined priorities. The controller automatically refreshes the external SDRAM approximately once every 15  $\mu$ s.

Figure 10-45. SDRAM Access through the SDRAM Controller

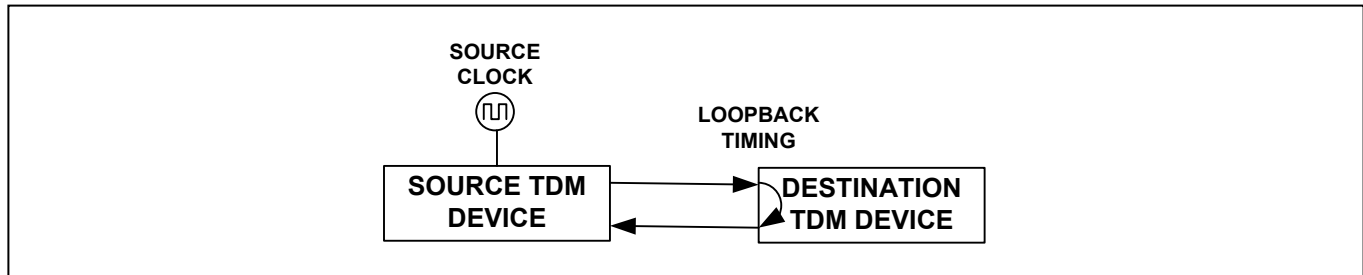

### 10.6.10 Jitter Buffer Control (JBC)

#### 10.6.10.1 Jitter Buffer Application

Routinely in TDM networks, destination TDM devices derive a clock from the incoming TDM signal and use it for transmitting data as depicted in Figure 10-46. This is called loopback timing.

Figure 10-46. Loop Timing in TDM Networks

When replacing the physical TDM connection with an IP/MPLS network and two TDM-over-Packet devices as shown in Figure 10-47 below, the receiving TDM-over-Packet device (slave) receives packets with variable delays (packet delay variation). After processing, the slave TDMoP device should send TDM data to the destination TDM device at the same clock rate at which the TDM data was originally sent by the source TDM device. To achieve this, the device works in clock recovery mode to reconstruct the source TDM clock to allow the destination TDM device to still work in loopback timing mode.

Figure 10-47. Timing in TDM-over-Packet

The jitter buffer, located in the SDRAM, has two main roles:

- Compensate for packet delay variation
- Provide fill level information as the independent variable used by the clock recovery machines to reconstruct the TDM clock on a slave TDMoP device.

The data enters the buffer at a variable rate determined by packet arrival times and leaves it at a constant TDM rate. In clock recovery mode, the amount of data in the jitter buffer (the “fill level”) steers the clock recovery mechanism.

#### 10.6.10.2 Jitter Buffer Configuration

Separate areas are allocated in the external SDRAM for TDM data and for signaling, as described in section 10.6.9.

In low-speed mode ([High\\_speed=0](#) in [General\\_cfg\\_reg0](#)) both data and signaling areas are divided into eight identical sections, one for each E1/T1/Nx64 interface. These section are further divided as follows:

- In E1/T1 structured mode, each per-port data section contains the data of 32 timeslots for E1 or 24 timeslots for T1 (a total of 32\*8=256 timeslots for all eight interfaces). Each E1/T1 timeslot is allocated a maximum of 4 kB of space (128kB per interface and a total of 1024 kB for all eight interfaces).
- Each signaling section is divided into multiframe sectors, with each sector containing the signaling nibbles of up to 32 timeslots (total of 64 kB for all 8 interfaces).
- In serial interface mode or E1/T1 unstructured mode, there is no per-timeslot allocation. The jitter buffer is divided into eight identical sections, one for each interface (each section is 512 kB for HDLC bundles or 128 kB for other bundle types).

In high-speed mode (E3, T3, STS-1), the jitter buffer is arranged as one large buffer without division into sections (total of 512 kB).

The Jitter Buffer maximum depth in time units (seconds) is calculated according to the following formula:

$$\frac{1}{2} \times \text{Buffer area per interface} \times \frac{8}{\text{Rate}}$$

where:

$\frac{1}{2}$	=	Two halves of the buffer
Buffer area per interface	=	512 kB for a single high-speed interface or 128 kB for a low-speed interface
8	=	Number of bits per byte
Rate	=	Transmission rate (e.g., 2.048 Mbps)

For T1 structured-with-CAS, multiply the above formula by 0.75.

The jitter buffer depth is defined by the [Rx\\_max\\_buff\\_size](#) parameter found in the [Bundle Configuration Tables](#). When the jitter buffer level reaches the value of [Rx\\_max\\_buff\\_size](#), an overrun situation is declared.

The [Rx\\_PDVT](#) parameter (also found in the [Bundle Configuration Tables](#)) defines the amount of data to be stored in the jitter buffer to compensate for network delay variation. This parameter has two implications:

- [Rx\\_PDVT](#) defines the chip's immunity to the Ethernet network delay variation.
- The data arriving from the network is delayed by [Rx\\_PDVT](#) before it is read out of the jitter buffer and transmitted on the TDM pins.

[Rx\\_PDVT](#) must be smaller than [Rx\\_max\\_buff\\_size](#). Also, the difference between [Rx\\_max\\_buff\\_size](#) and [Rx\\_PDVT](#) must be larger than the time that it takes to create a packet (otherwise an overrun may occur when the packet arrives). Typically, the recommended value for [Rx\\_max\\_buff\\_size](#) is  $2 * \text{Rx\_PDVT} + \text{PCT}$  (packet creation time). This provides equal immunity for both delayed and bursty packets.

Configuring the jitter buffer parameters correctly avoids underrun and overrun situations. Underrun occurs when the jitter buffer becomes empty (the rate data is entering the buffer is slower than the rate data is leaving). When an underrun occurs the TDMoP block transmits conditioning data instead of actual data towards the TDM interface. The conditioning data is specified by the [Receive SW Conditioning Octet Select](#) table for TDM data and the location specified by [Rx\\_CAS\\_src](#) (SDRAM or [Receive SW CAS](#)) for signaling. Overrun occurs when the jitter buffer is full and there is no room for new data to enter (the rate data is leaving the buffer is slower than the rate data is entering). Underrun and overrun require special treatment from the TDMoP hardware, depending on the bundle type.

Figure 10-48. Jitter Buffer Parameters

The JBC uses a 64 by 32 bit [Bundle Timeslot Table](#) to identify the assigned timeslots of each active bundle. The index to the table is the bundle number. The CPU must configure each active bundle entry (setting a bit means that the corresponding timeslot is assigned to this bundle). For unstructured bundles, the whole bundle entry (all 32 bits) must be set.

Jitter buffer statistics are stored in a 256-entry table called the [Jitter Buffer Status Table](#). Each TDM port has 32 dedicated entries, one per timeslot. This table stores the statistics of the active jitter buffer for each active bundle. A configurable parameter called [Jitter\\_buffer\\_index](#) located in the timeslot assignment tables (section 11.4.5) points to the entry in the [Jitter Buffer Status Table](#) where the associated jitter buffer statistics are stored. The value of the [Jitter\\_buffer\\_index](#) should be set as follows:

- For AAL1/HDLC/RAW structured bundles: the [Jitter\\_buffer\\_index](#) value is the number of the lowest timeslot in the bundle. For example, if the bundle consists of timeslots 2, 4, 17 on port 3, [Jitter\\_buffer\\_index](#)=0x2.
- For unstructured bundles the [Jitter\\_buffer\\_index](#) value is 0x0.

#### **10.6.10.3 Jitter Buffer Status and Statistics**

The CPU accesses the [Jitter Buffer Status Table](#) using the [Jitter\\_buffer\\_index](#) as described above. The status table contains the current jitter buffer status (such as, the current jitter buffer level and its current state (OK, underrun or overrun).

The status table also contains two variables, [Minimal\\_level](#) and [Maximal\\_level](#), which report the minimum and maximum fill levels of the jitter buffer since the last time the two fields were read (available for AAL1/RAW bundles only). These variables provide information about network packet delay variation. For example, using these values, the CPU can calculate the margins from the top ([Rx\\_max\\_buff\\_size](#)) and the bottom of the jitter buffer. If there is margin, CPU software may want to reduce [Rx\\_PDVT](#) to reduce the latency added by the jitter buffer to the incoming TDM data.

#### **10.6.10.4 Jitter Buffer Response to Packet Loss and Misordering**

The payload-type machines detect that a packet was lost by sequence number error in AAL1/RAW. If a packet is lost, conditioning data (specified by the receive software conditioning registers in section [11.4.12](#)) is inserted into the jitter buffer in place of the lost data to maintain bit integrity (i.e. the number of bits that are inserted into the jitter buffer must equal the number of bits that were transmitted by the far end).

If a packet is misordered in a RAW bundle (for example, the packet with the sequence number N arrives after the packet with sequence number N+1) it is reordered by the RAW payload-type machine, and its data is inserted into the appropriate location in the jitter buffer, assuming that the data in this location has not been transmitted to the TDM port yet.

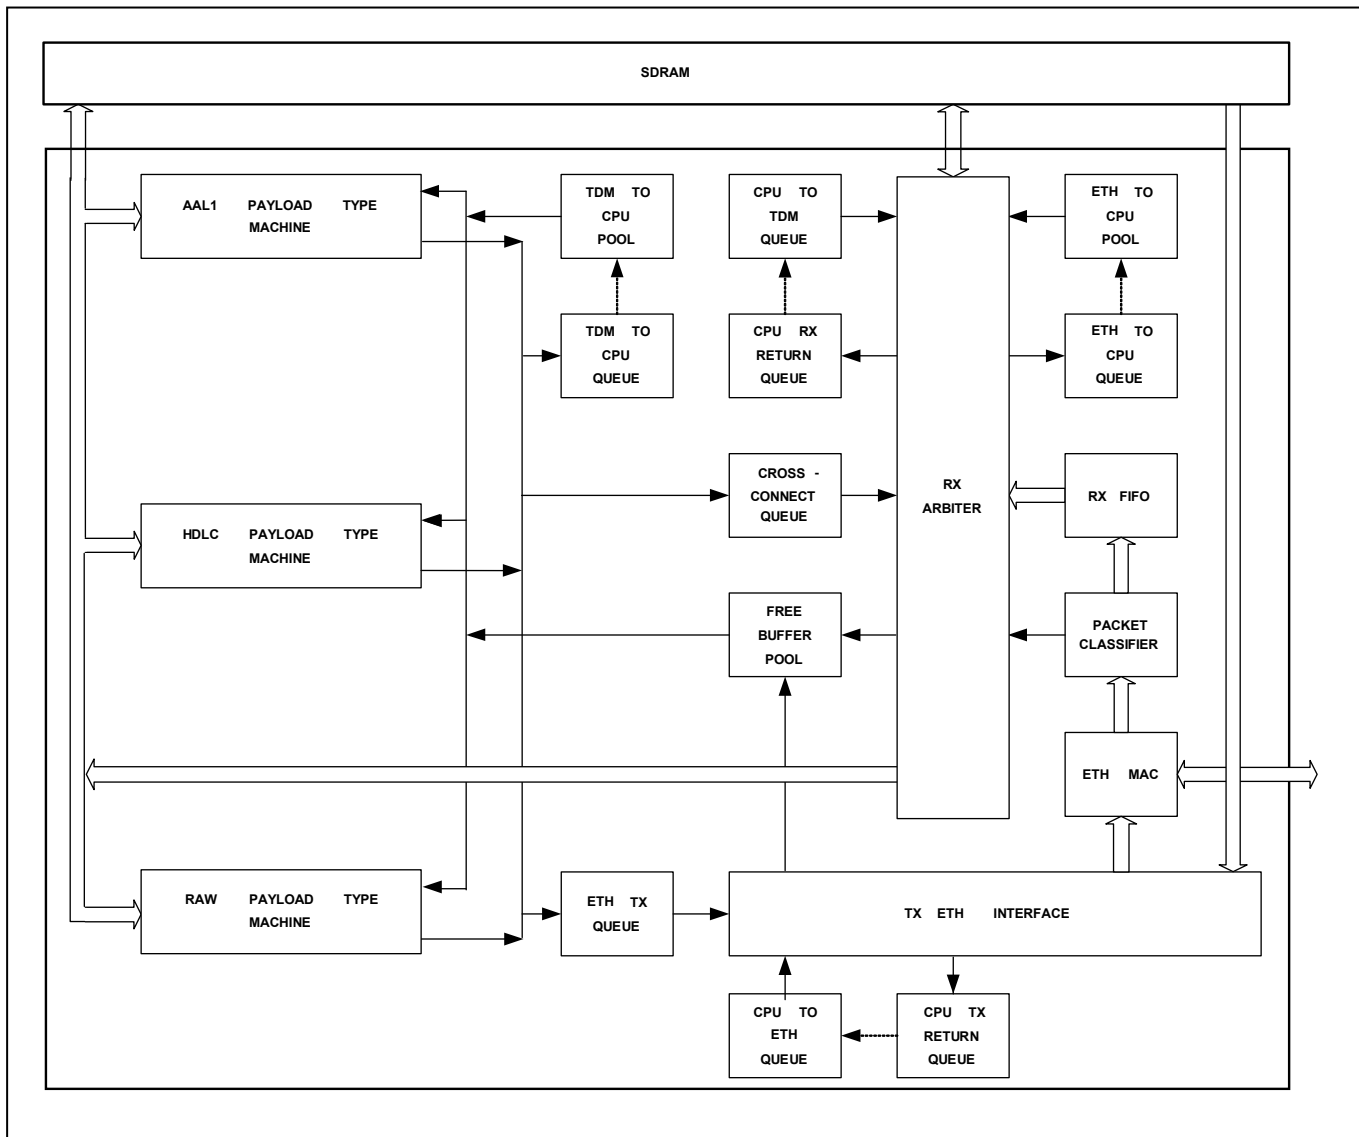

#### **10.6.11 Queue Manager**

Data flows through the TDMoP block in the following directions:

- [TDM to Ethernet](#) (implemented in HW)
- [Ethernet to TDM](#) (implemented in HW)
- [TDM to TDM](#) (cross-connect, implemented in HW)
- [TDM to CPU](#)
- [CPU to TDM](#)
- [CPU to Ethernet](#)
- [Ethernet to CPU](#).

These data flows are illustrated in [Figure 10-49](#). Each data flow is described in a subsection below.

Figure 10-49. TDM-over-Packet Data Flow Diagram

#### 10.6.11.1 Buffer Descriptor

Data is transferred between the Ethernet MAC, internal payload-type machines and the external CPU by means of buffers in the SDRAM. Payload data is stored in 2 kB SDRAM buffers along with a buffer descriptor located in the buffer's first dwords. The buffer pointers are managed inside the TDMoP block and are stored in queues, pools, and other internal blocks. Queues store pointers to SDRAM buffers containing packet data to be processed, while pools store pointers to empty buffers. The pointers are passed from one block to another. Only the block owning the pointer can access the associated buffer.

The size of the buffer descriptor size depends on the internal path it is used for:

TDM → TDM, TDM → CPU and CPU → TDM: One dword  
 TDM → ETH, CPU → ETH and ETH → TDM: Two dwords  
 ETH → CPU: Three dwords

The fields of the buffer descriptor dwords are described in the sections below.

**10.6.11.2 Buffer Descriptor First Dword**

Used for all paths. Located at offset 0x0 from the start of the buffer.

**Table 10-24. Buffer Descriptor First Dword Fields (Used for all Paths)**

Bits	Data Element	Description
[31]	MPLS/MEF/L2TPV3 or UDP/IP-specific OAM	For ETH → TDM and for CPU → TDM indicates that the buffer holds a packet with MPLS / MEF / L2TPv3 Ethertype. For ETH → CPU indicates that the buffer holds a UDP/IP-specific OAM packet.
[30]	RST	RX Reset command (the bundle is in reset process). For ETH→TDM and for CPU→TDM: used by the Packet Classifier or by the CPU to inform the next blocks in flow that the bundle was reset. The buffer contains no real data.
[29:27]	Buffer contents	000: Backwards-compatible (experimental) format packet going to the AAL1 payload-type machine 001: Standard format packet going to the AAL1 payload-type machine 010: Reserved 011: Non-TDMoP/MPLS packet (this buffer isn't assigned to any bundle) 100: Standard format packet going to the HDLC payload-type machine 101: Reserved 110: Standard format packet going to the RAW payload-type machine 111: Backwards-compatible (experimental) format packet going to the HDLC payload-type machine
[26:16]	Length/Rst_Ts	Packet Length or Payload Length For TDM→CPU, TDM→TDM, CPU→TDM and ETH→TDM: payload length in bytes (received bytes + control word if present + RTP header bytes in case of MPLS/MEF packet using RTP and control word) For TDM→ETH, ETH→CPU and CPU→ETH: packet length in bytes, without CRC For Buffer Contents =101: total length of packets concatenated in the buffer, in bytes For RST packets: the reset timeslot number  <i>Note: Length must be less than 1951 bytes.</i> <i>Note: Offset and Length sum must be less than 2000 bytes.</i>
[15]	Reserved	Must be set to zero.
[14:8]	Offset	For ETH→CPU, TDM→ETH and CPU→ETH: offset in bytes from start of buffer to start of packet For ETH→TDM, TDM→CPU, CPU→TDM: offset in bytes from start of buffer to start of payload or to the control word if present For TDM→TDM: bits 13-8 hold the internal bundle number from which the buffer has been transmitted  For CPU→ETH, when Buffer Content (above) is different than 011, must be calculated as follows: tx_payload_offset – header_length  <i>Note: Offset and Length sum must be less than 2000 bytes.</i> <i>Note: header_length is the number of bytes from start of packet to the control word (or to start of the payload if control word is not used).</i>
[7]	HW/SW Type	The pool the buffer has been extracted from and should be returned to. 0: HW buffers pool 1: SW buffers pool For packets coming from Ethernet: 0: destination = payload-type machines 1: destination = CPU
[6]	RTP	For ETH→TDM, ETH→CPU, TDM→TDM and CPU→ TDM indicates whether the packet includes an RTP header.
[5:0]	Bundle number	For TDM→ TDM: destination internal bundle number. For any other bundle: packet internal bundle number

**10.6.11.3 Buffer Descriptor Second Dword**

Located at offset 0x4 from the start of the buffer.

**10.6.11.3.1 TDM → ETH and CPU → ETH Packets****Table 10-25. Buffer Descriptor Second Dword Fields (TDM → ETH and CPU → ETH)**

Bits	Data Element	Description
31:15	Reserved	Must be set to zero.
14	Stamp	Indicates whether the packet should be time-stamped. Valid only for OAM and for non-TDMoP packets. Otherwise ignored.
13:7	Ts_offset	Indicates the number of dwords from start of buffer to timestamp location. Valid only for OAM and for non-TDMoP packets where Stamp bit is set above.
6:0	Hdr2_length	The second header length in bytes not including control word or RTP header (The offset to the second header from start of the buffer is 0x782). Limited to 122 bytes and valid only for AAL1, CESoPSN and SAToP bundles where the <a href="#">Protection_mode</a> setting of the bundle equals to “11” or “10”.

**10.6.11.3.2 ETH → CPU Packets****Table 10-26. Buffer Descriptor Second Dword Fields (ETH → CPU)**

Bits	Data Element	Description
31:30	Reserved	Must be set to zero.
29	Ipv6	IP packet with IP VER = 6
28	Ipv4	IP packet with IP VER = 4
27	MEF_OAM	MEF OAM packet, i.e. Ethertype equal to <a href="#">Mef_oam_ether_type</a> setting
26	VCCV_OAM	VCCV OAM packet
25:24	No. of MPLS labels	Number of MPLS labels. Equal to “11” for packet with more than 3 labels.
23	802.3	802.3 packet
22	Ethernet	Ethernet packet
21	Reserved	Must be set to zero.
20	L2TPv3/IP	L2TPv3/IP packet
19	Two_VLAN tag	Packet with two VLAN tags
18	VLAN tag	Packet with one/two VLAN tags
17	UDP/IP	UDP/IP packet
16	IP	IP packet (with any IP VER)
15	MEF	MEF packet, i.e. Ethertype equal to <a href="#">Mef_ether_type</a> setting
14	MPLS	MPLS packet, i.e. packet's Ethertype equal to 0x8847 or 0x8848
13:11	Reserved	
10	Mpls_over_3_ibls	MPLS packet with more than 3 labels
9	Unicast_not_mine	Unicast packet with destination address different than MAC addresses
8	cpu_dst_ether_type	Packet with Ethertype equal to <a href="#">CPU_dest_ether_type</a> setting
7	OAM	OAM packet
6	bndl_num_not_exist	A TDM-over-Packet/MPLS/MEF packet destined to the chip but with a bundle identifier that does not match any of one of the chip's OAM bundle numbers or one of the bundle identifiers assigned to the chip's internal bundles.
5	not_tdmop	UDP/IP packet with destination/source UDP port number different than <a href="#">TDMoIP_port_num1</a> and <a href="#">TDMoIP_port_num2</a>
4	ip_not_udp_l2tpv3	IP packet with protocol different than UDP or L2TPv3
3	arp_chip_ip	ARP packet with destination IP address equal to one of the chip's IPv4 addresses
2	unknown_ether_type	A packet with Ethertype different than IP, MPLS, ARP, MEF, MEF OAM or CPU Ethernets.
1	not_chip_ip	IP packet with destination IP address different than the chip's IP addresses
0	arp_not_chip_ip	ARP packet with destination IP address different than the chip's IP addresses

**10.6.11.4 Buffer Descriptor Third Dword**

Used for ETH → CPU packets. Located at offset 0x8 from start of the buffer.

**Table 10-27. Buffer Descriptor Third Dword Fields (ETH → CPU)**

Bits	Data Element	Description
31:0	Timestamp	32 bits timestamp latched by the packet classifier upon packet reception. Timestamp resolution is 100 $\mu$ s or 1 $\mu$ s as specified by the <a href="#">OAM_timestamp_resolution</a> field in <a href="#">General_cfg_reg0</a> .

**10.6.11.5 RX Arbiter**

The RX arbiter constantly checks for available packets in the Rx FIFO, the CPU-to-TDM queue and the cross-connect queue. It can do one of the following:

- Pass a packet from the Rx FIFO to the payload-type machines
- Pass a packet from the Rx FIFO to the external SDRAM and insert its pointer into the ETH-to-CPU queue
- Extract a pointer from the cross-connect queue and pass a packet from the external SDRAM into the payload-type machines
- Extract a pointer from the CPU-to-TDM queue and pass a packet from the external SDRAM into the payload-type machines.

In general, the Rx arbiter handles packets according to the following priorities:

1. Cross-connect queue
2. Rx FIFO (i.e., packets that arrive from the Ethernet port)
3. CPU-to-TDM queue.

The [Rx\\_fifo\\_priority\\_lvl](#) field in [General\\_cfg\\_reg0](#) specifies a priority level for the Rx FIFO. Whenever the fill level of the Rx FIFO is above this threshold, the Rx FIFO becomes the highest priority for the Rx arbiter rather than the Cross-connect queue until the fill level of the Rx FIFO drops below the threshold.

**10.6.11.6 TX Ethernet Interface**

The TX Ethernet interface first checks the Ethernet TX queue. If the queue is not empty, it extracts a pointer, passes the buffer data from the SDRAM to the Ethernet MAC, and returns the pointer to the free buffer pool. If the TX Ethernet queue is empty, the TX Ethernet Interface checks the status of the CPU-to-Ethernet queue. If the queue is not empty, it extracts a pointer, transfers buffer data to the Ethernet MAC, and returns the buffer to the CPU TX Return queue.

**10.6.11.7 Free Buffer Pool**

The free buffer pool mechanism explained below is used for the TDM-to-Ethernet and TDM-to-TDM flows.

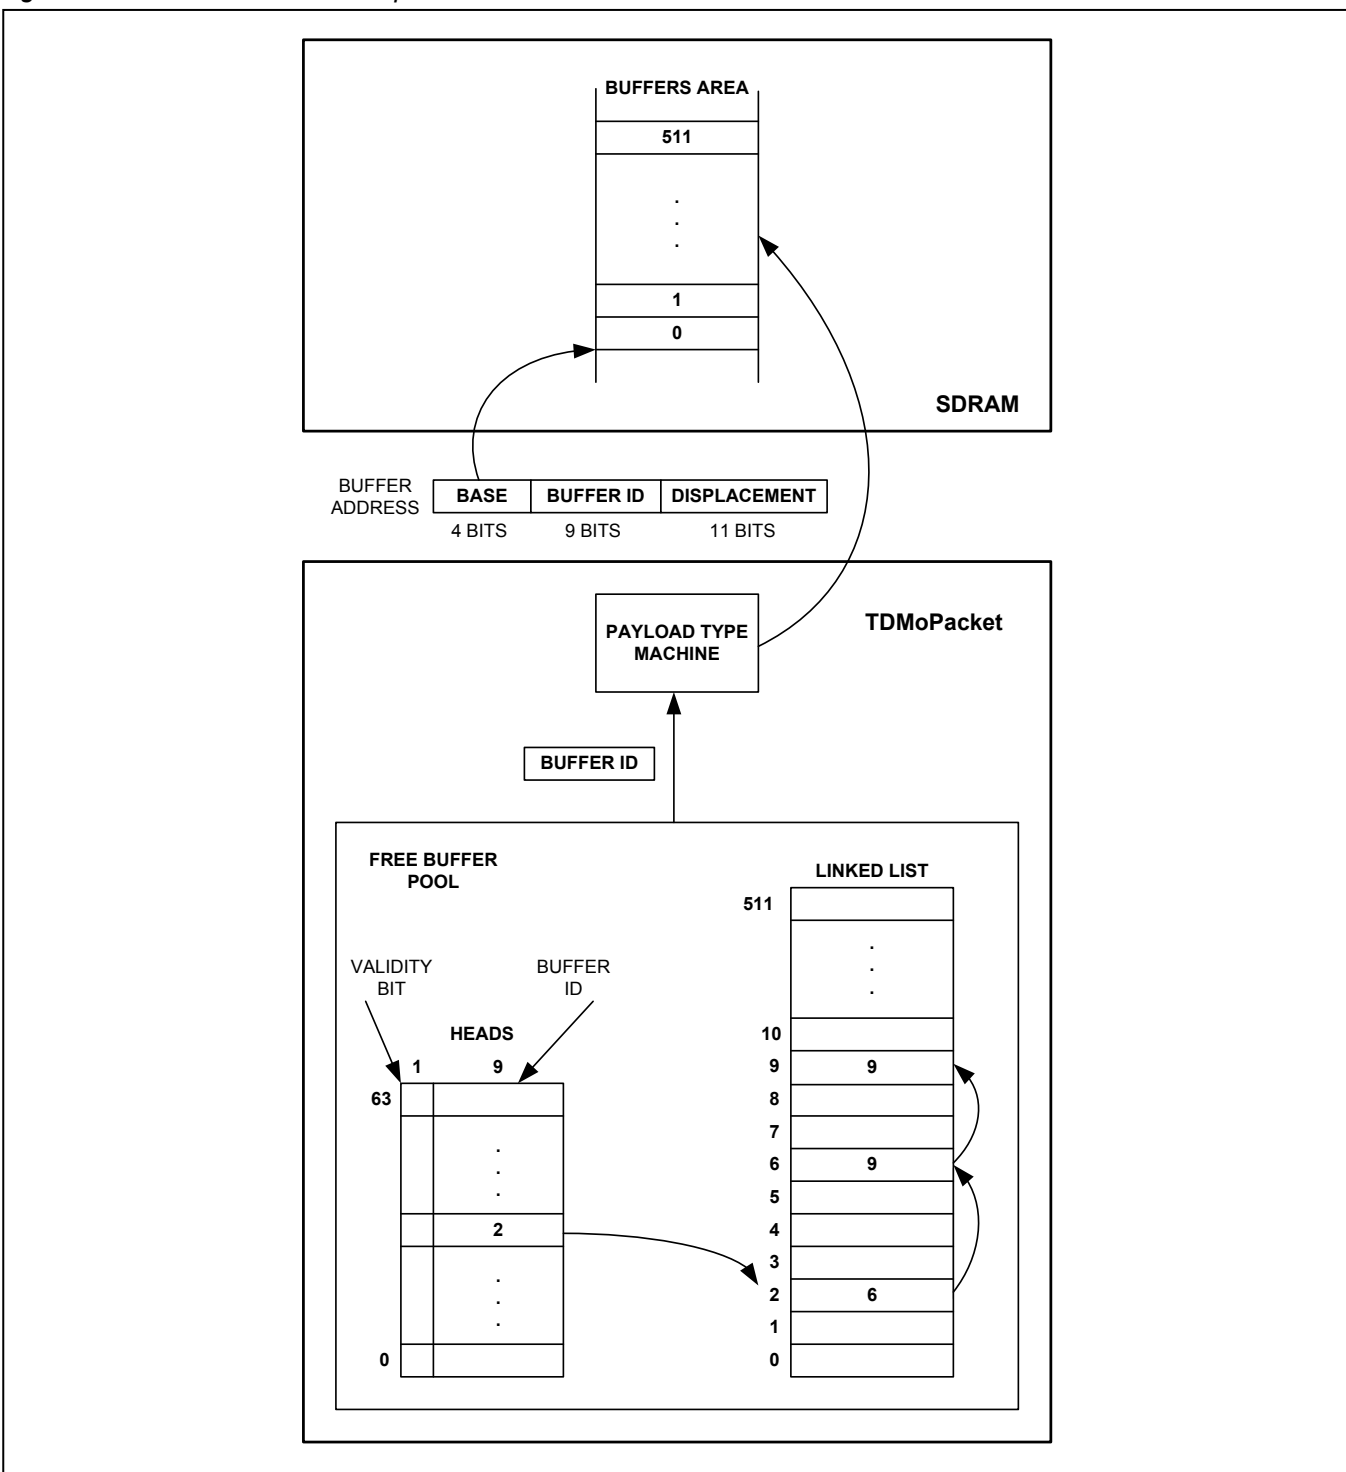

Before the payload-type machines can process any data, the CPU must initialize the free buffer pool. The free buffer pool contains pointers to SDRAM buffers that are used by the payload-type machines to store packets. There are a total of 512 SDRAM buffers. The CPU needs to pre-assign (statically) these SDRAM buffers to each bundle. The number of buffers allocated per specific bundle depends on the number of timeslots in the bundle. It is recommended to assign 4 buffers per timeslot.

The buffers are located in a continuous area in the SDRAM. The buffer address consists of the base address, the buffer number and the displacement within the buffer. The base address is specified by the [Tx\\_buf\\_base\\_add](#) field in [General\\_cfg\\_reg1](#). Free buffer numbers are contained in linked lists, with a head pointing to the first buffer, each buffer pointing to the next buffer and the last buffer pointing to itself. There are 64 heads (one per bundle), each one containing a validity indication bit (MSB) and another 9 bits pointing to the first free buffer in the linked list. The register descriptions for the [Per-Bundle Head Pointers](#) and [Per-Buffer Next-Buffer Pointers](#) are in section 11.4.7.

The CPU must define the number of buffers for each bundle by initializing the linked list for the bundle. Software prepares these buffers by writing the Ethernet, IP/MPLS/L2TPv3/MEF headers in advance, so that the payload-type machines need only to write the packet payload. Since the headers contain bundle-specific data (e.g., destination address), the same buffers are used for the same bundle until the bundle is closed by CPU software.

When closing a bundle, the CPU should check that all buffers have been returned, by following the linked list from the head to the last buffer. The buffers of a closed bundle may be used for a different new bundle. The linked list operation is depicted below.

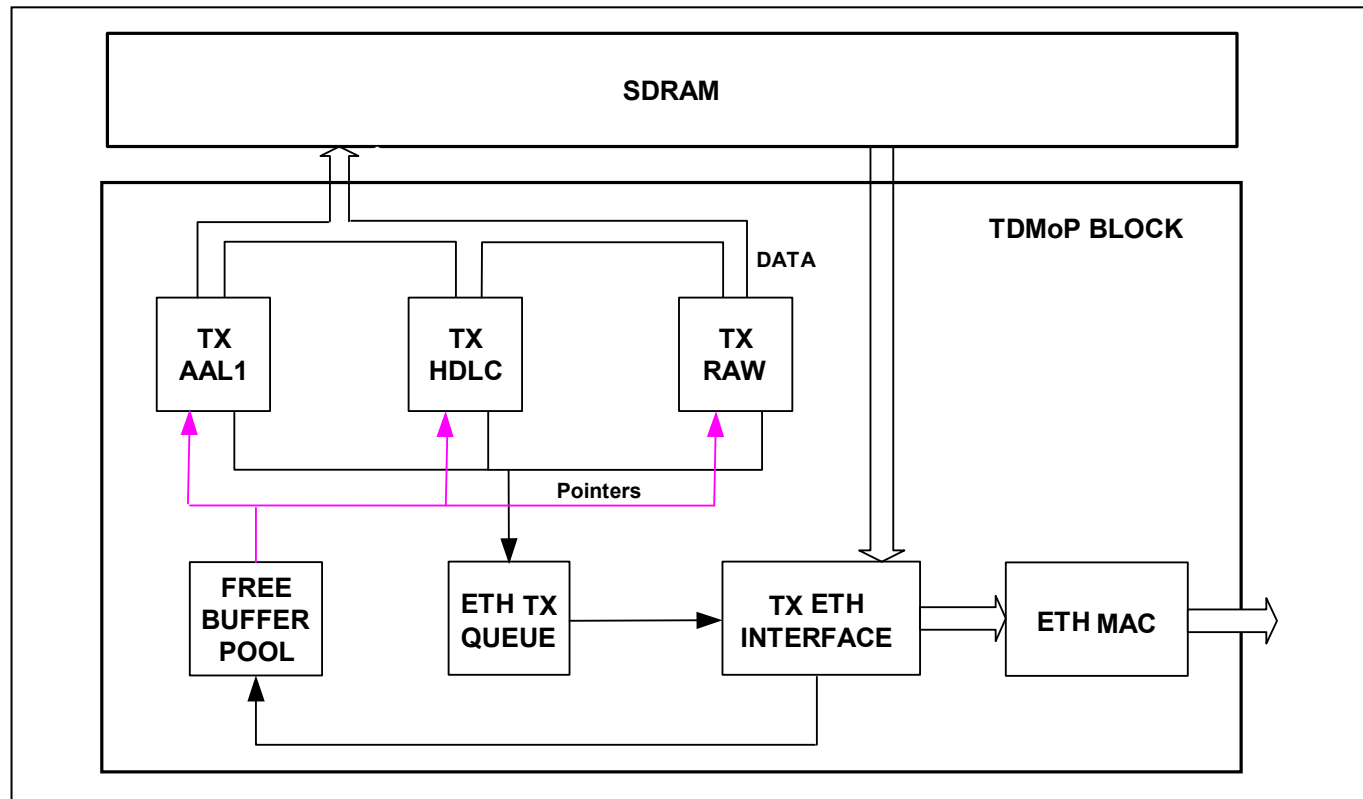

*Figure 10-50. Free Buffer Pool Operation*

### 10.6.11.8 TDM to Ethernet Flow

Each payload-type machine receives the data of specific bundle timeslots and maps it into packets. To store a new packet in preparation, the machine extracts a pointer from the free buffer pool (section 10.6.11.7) and fills the associated buffer with TDM timeslot data, one by one. When a packet is completed in a buffer, the payload-type machine places the buffer pointer in the Ethernet Tx queue. The Tx Ethernet interface polls the queue, extracts the pointer, and transfers the packets from the buffer to the Ethernet MAC block, to be sent over the Ethernet network. Then, it returns the pointer to the free buffer pool. The buffer can then be used again by the payload-type machine to store subsequent TDM data for the bundle.

Figure 10-51. TDM-to-Ethernet Flow

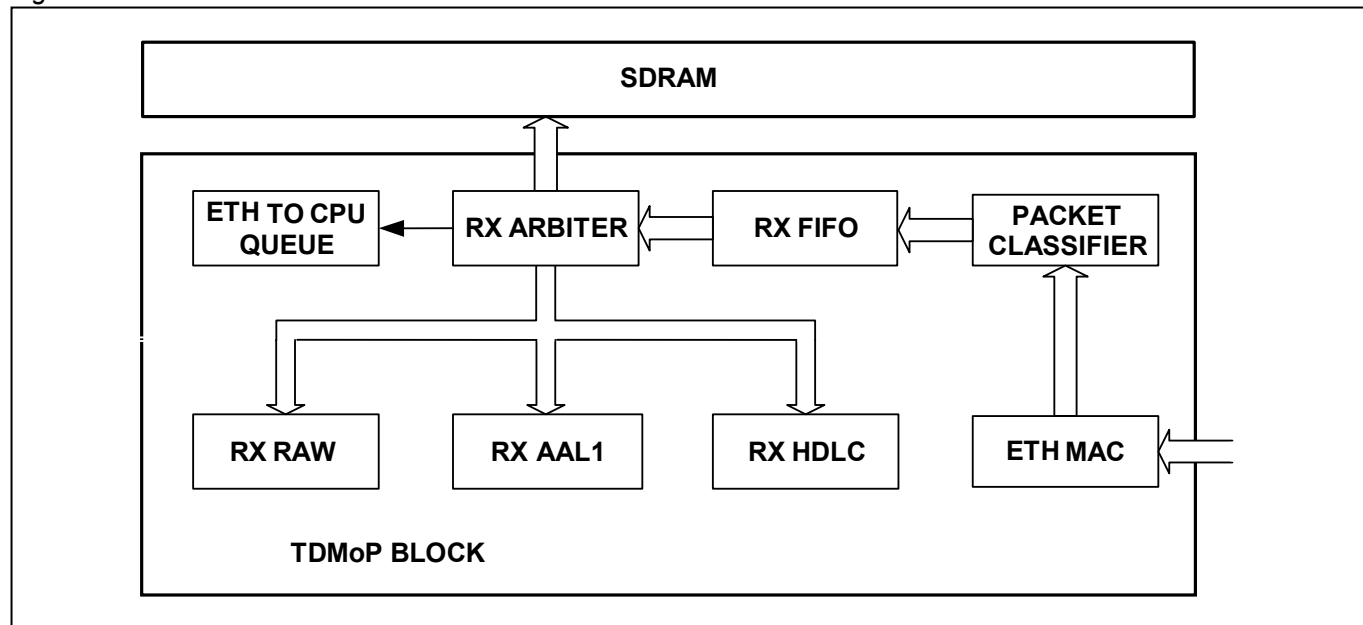

### 10.6.11.9 Ethernet to TDM Flow

A packet arriving from the Ethernet port passes through the Ethernet MAC block. The MAC block does not store the packet, but it does calculate the CRC to verify packet data integrity. If the packet is bad, the MAC signals this to the packet classifier on the last word of the packet, and the packet classifier discards it.

The packet classifier examines the packet header and decides to either discard the packet or transfer it into the chip based on the settings of the packet classifier configuration registers (see [Table 11-4](#)). The packet classifier tags the buffer descriptor for one of the following destinations: ETH-to-CPU queue or payload-type machines. The packet classifier stores the packet payload preceded by the buffer descriptor in the Rx FIFO and notifies the Rx arbiter. The Rx arbiter then passes it to one of the payload-type machines. The payload-type machine extracts the TDM data and inserts it into the jitter buffer in the SDRAM. From there, the data is transmitted serially out the TDM port.

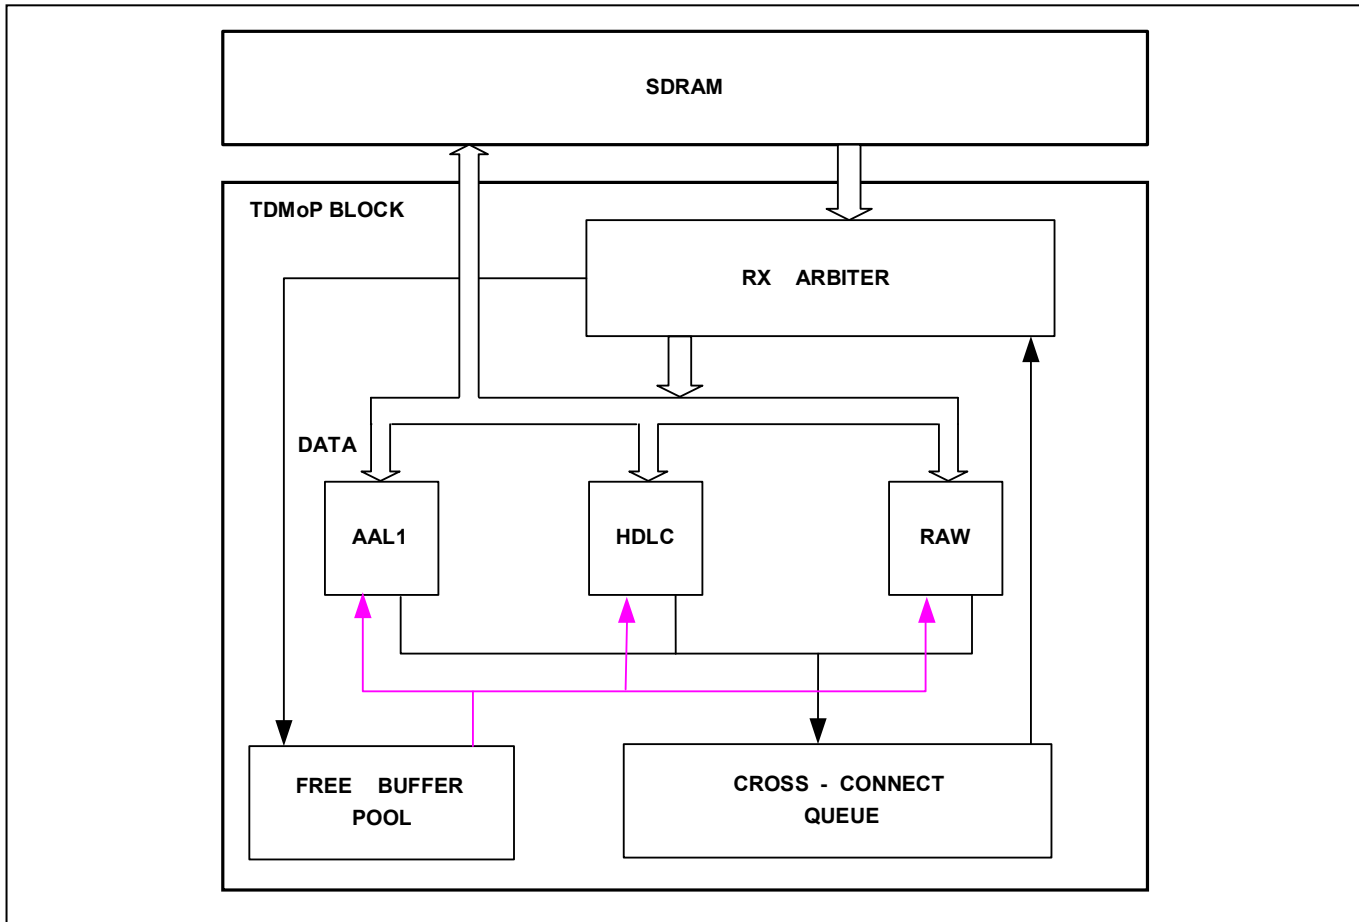

Figure 10-52. Ethernet-to-TDM Flow

**10.6.11.10 TDM to TDM (Cross-Connect) Flow**

Each payload-type machine receives the data of bundle-specific TDM timeslots and maps the data into Ethernet packets. To store a packet, the payload-type machine needs an SDRAM buffer which it gets by extracting a buffer pointer from the free buffer pool. It then fills the buffer as it processes the TDM timeslots. When a packet is completed in a buffer, the machine places the buffer pointer in the cross-connect queue. The RX arbiter polls the cross-connect queue, extracts the pointer, transfers the buffer data to the appropriate payload-type machine, and then returns the pointer to the free buffer pool. The payload-type machine then extracts the TDM data and inserts it into the jitter buffer in the SDRAM. From there, the data is transmitted serially out the TDM port.

Figure 10-53. TDM-to-TDM Flow

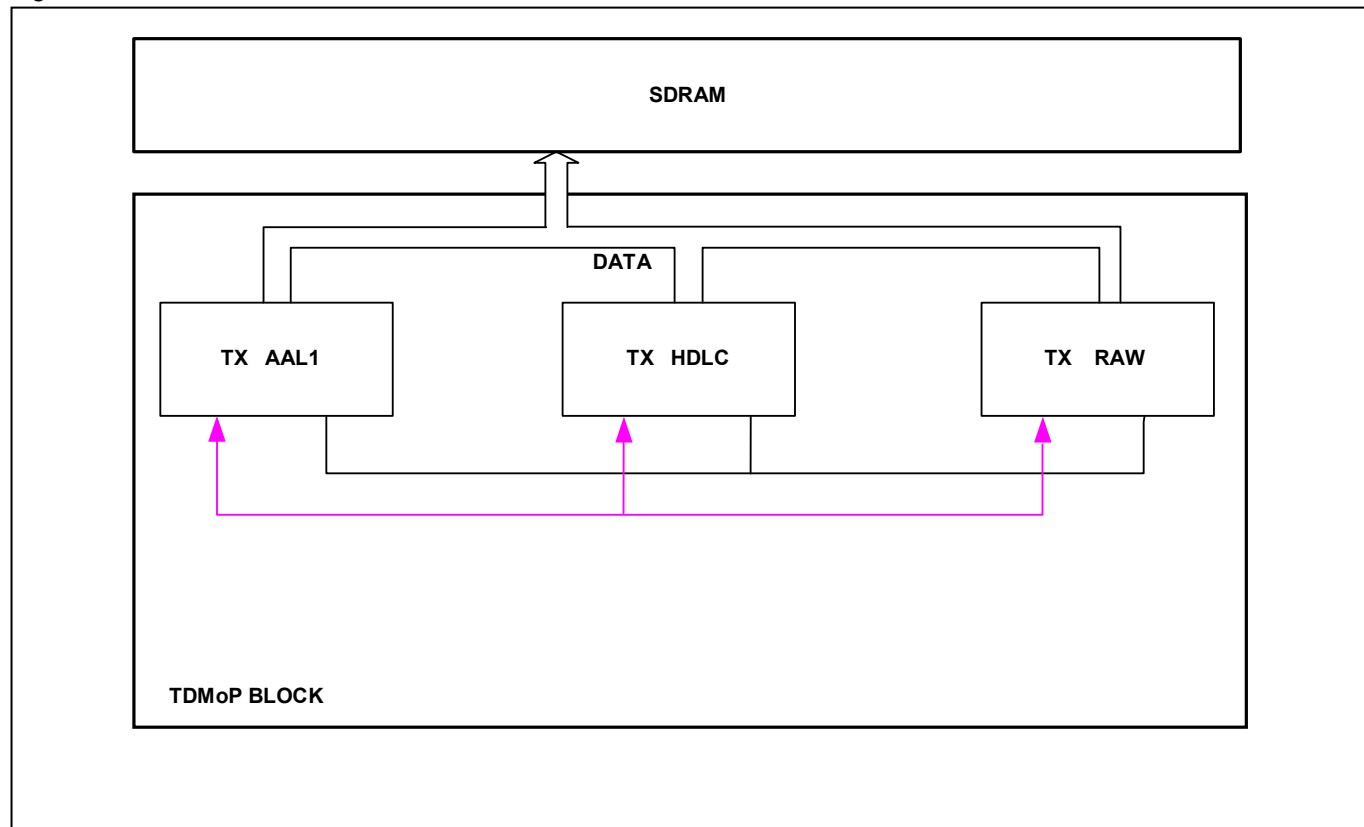

#### 10.6.11.11 TDM to CPU Flow

The payload-type machines identify the destination of their packets according to the per-bundle configuration. Upon getting the first byte of a packet in a bundle destined to the CPU, the machine needs a buffer to store the packet. It therefore checks whether a buffer is available in the TDM-to-CPU pool. If the pool is empty, the machine discards the current data. If a buffer is available, the machine stores the packet payload in the buffer and then adds the buffer pointer to the TDM-to-CPU queue. The CPU polls this queue to look for packets that need to be processed, gets the buffer pointer, and reads the packet from the SDRAM. After processing the packet, the CPU closes the loop by returning the pointer to the TDM-to-CPU pool.

The TDM-to-CPU pool and queue can contain up to 128 pointers each. Section 11.4.6 describes the pool and queue registers.

Figure 10-54. TDM-to-CPU Flow

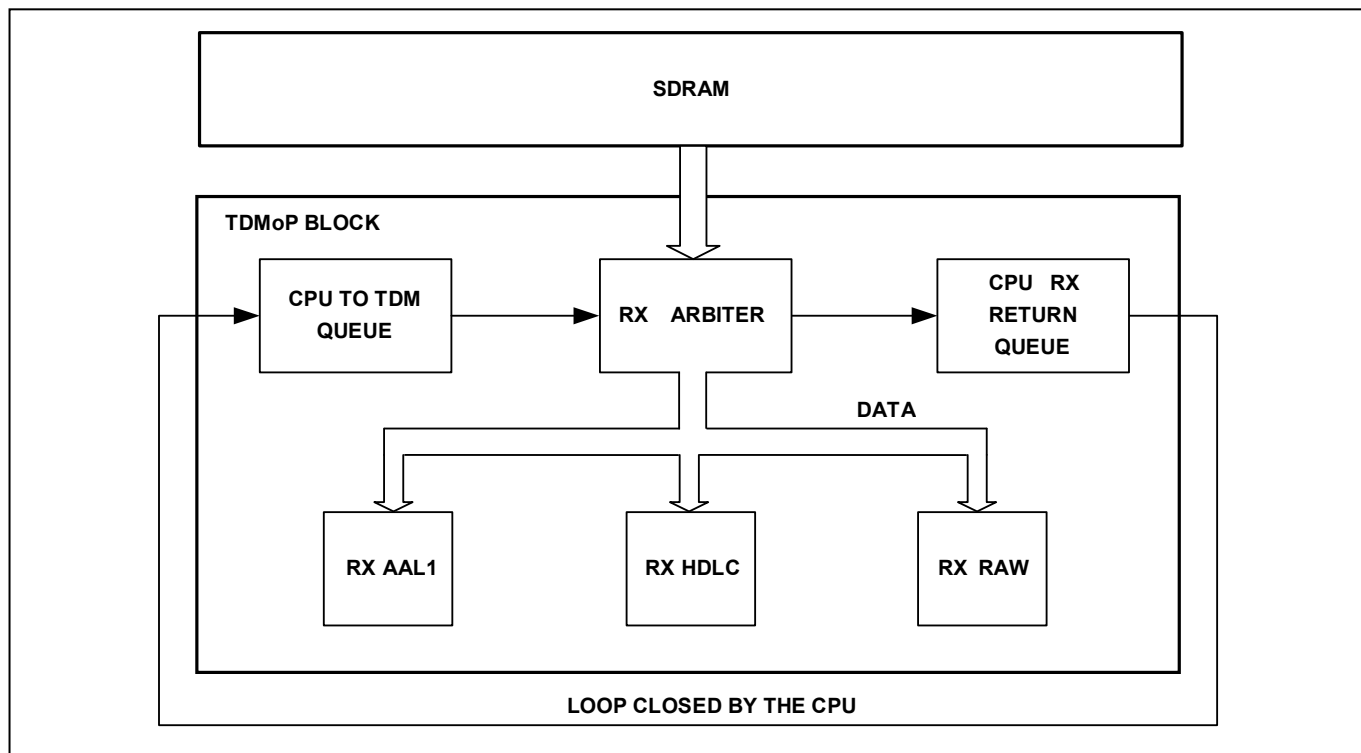

**10.6.11.12 CPU to TDM Flow**

The Rx arbiter polls the CPU-to-TDM queue for new packets waiting in the SDRAM to be processed. If the queue level is greater than zero and there are no buffers pending in the Rx FIFO or the cross-connect queue, the Rx arbiter extracts the pointer and copies the relevant data from the SDRAM buffer to the appropriate payload-type machine. The arbiter then checks whether the CPU Rx return queue is not full to return the pointer. If the return queue is full, the arbiter keeps the pointer and does not poll the CPU-to-TDM queue until it succeeds in returning the pointer. After returning the pointer to the CPU Rx return queue for reuse, the arbiter is ready to take another pointer from the CPU-to-TDM queue.

The CPU-to-TDM queue and the CPU Rx return queue can contain up to 32 pointers each. Section [11.4.6](#) describes the pool and queue registers.

Figure 10-55. CPU-to-TDM Flow

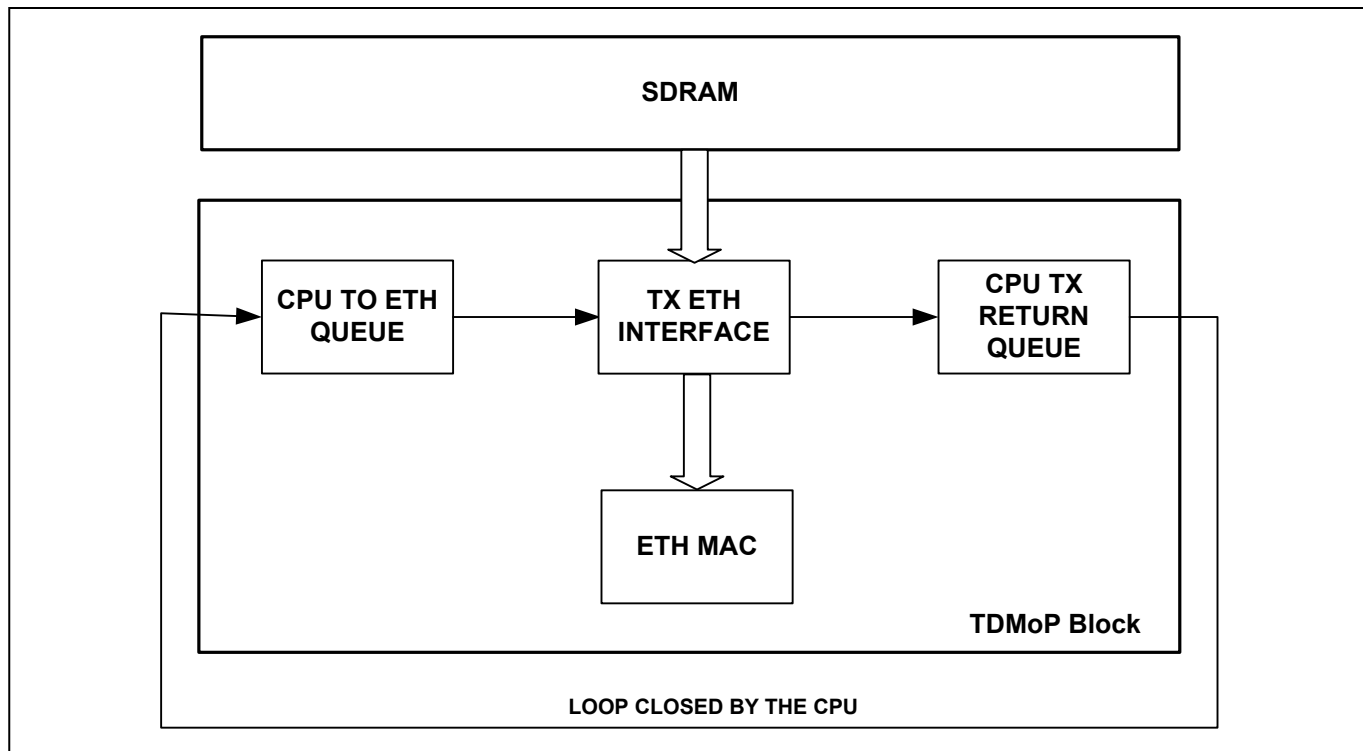

**10.6.11.13 CPU to Ethernet Flow**

The Tx Ethernet interface polls the CPU-to-Ethernet queue for new packets waiting in the SDRAM to be processed. If the queue level is greater than zero and no buffers from the payload-type machines are waiting in the Ethernet Tx queue, the Tx Ethernet interface extracts the pointer and copies the relevant data from the SDRAM buffer to the Ethernet MAC block. It then checks whether the CPU TX return queue is not full to return the pointer. If the return queue is full, it keeps the pointer and does not poll the CPU-to-ETH queue until it succeeds in returning the pointer. After returning the pointer to the CPU TX return queue for reuse, the Tx Ethernet interface is ready to take another pointer from the CPU-to-ETH queue.

The CPU-to-Ethernet queue and the CPU Tx return queue can contain up to 32 pointers each. Section [11.4.6](#) describes the pool and queue registers.

Figure 10-56. CPU-to-Ethernet Flow

#### 10.6.11.14 Ethernet to CPU Flow

Ethernet packets enter the chip via the Ethernet MAC block and the packet classifier into the Rx arbiter. When the Rx arbiter identifies that a packet is destined to the CPU, it extracts a pointer from the Ethernet-to-CPU pool (if the pool is empty, the Rx arbiter discards the packet) and stores the packet data into the SDRAM in the buffer indicated by the pointer. Then, it sends the pointer to the Ethernet-to-CPU queue (processed by the CPU). If the queue is full, the Rx arbiter keeps the pointer for itself for future use. The Ethernet-to-CPU queue and pool contain up to 128 pointers each. Section 11.4.6 describes the pool and queue registers.

Figure 10-57. Ethernet-to-CPU Flow

#### 10.6.12 Ethernet MAC

##### 10.6.12.1 Introduction

The Ethernet MAC can operate at 10 or 100 Mbps. It supports MII, RMI (Reduced pin-count MII), and SSMII (source-synchronous serial MII). The MAC interface to the physical layer must be configured by the CPU.

The UNH-tested Ethernet MAC complies with IEEE 802.3. Its counters enable the software to generate network management statistics compatible with IEEE 802.3 Clause 5.

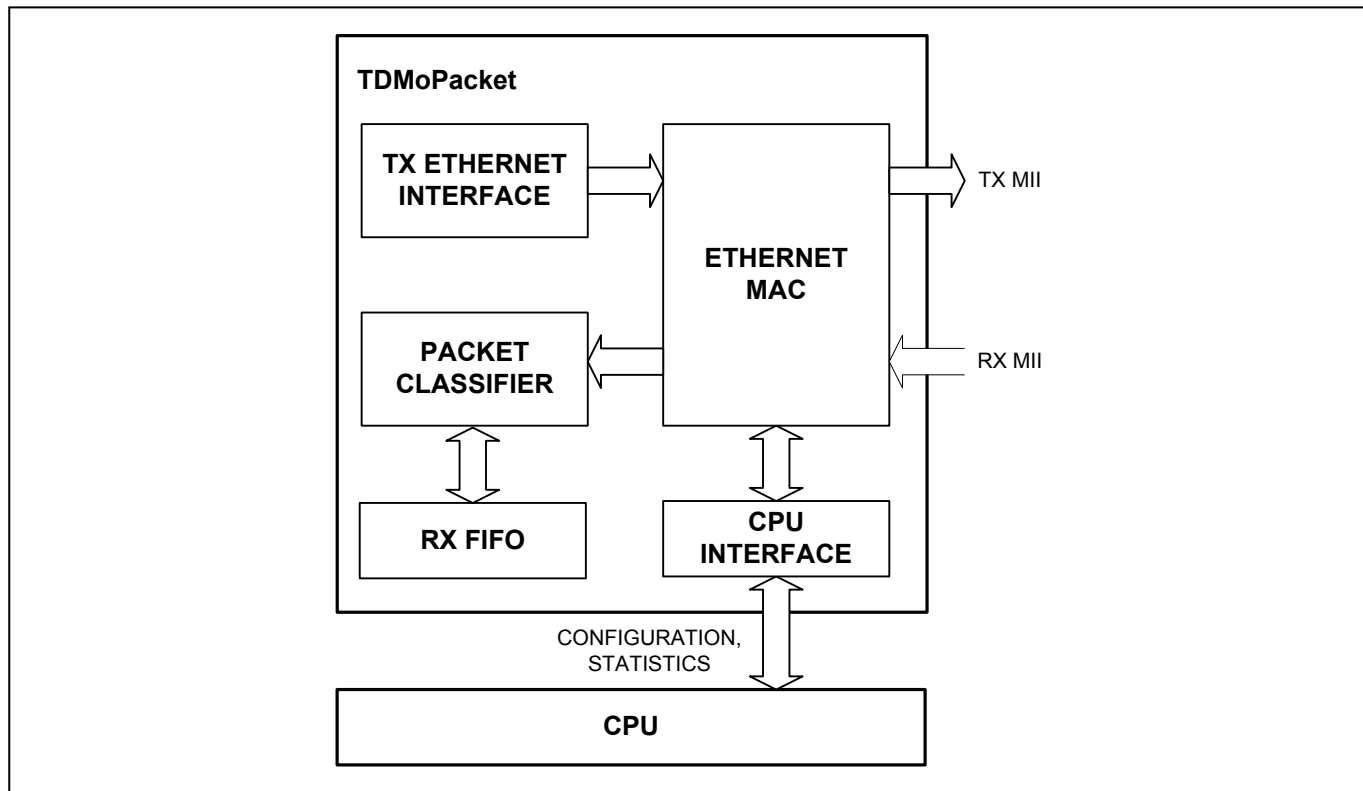

The Ethernet MAC supports physical layer management through an MDIO interface. The control registers drive the MDIO interface and select modes of operation, such as full or half duplex. Half-duplex flow control is achieved by forcing collisions on incoming packets. Full-duplex flow control supports recognition of incoming pause packets.

In the receive path, the MAC checks the incoming packets for valid preamble, FCS, alignment and length, and presents received packets to the packet classifier. Although packets with physical errors are discarded by default, the MAC can be configured to ignore errors and keep such packets.

In the transmit path, the MAC takes data from the Tx Ethernet interface, adds preamble and, if necessary, pad and FCS, then transmits data according to the CSMA/CD (carrier sense multiple access with collision detect) protocol.

In half-duplex mode the start of transmission is deferred if **MII\_CRS** (carrier sense) is active. If **MII\_COL** (collision) becomes active during transmission, a jam sequence is asserted and the transmission is retried after a random back off. **MII\_CRS** and **MII\_COL** have no effect in full-duplex mode.

Figure 10-58. Ethernet MAC

### 10.6.12.2 Pause Packet Support

Ethernet transmission pause in response to a received pause packet is enabled when [Pause\\_enable=1](#) in the [MAC\\_network\\_configuration](#) register.

When a valid pause packet is received, the [MAC\\_pause\\_time](#) register is updated with the packet's pause time regardless of its current contents and regardless of the state of [Pause\\_enable](#) bit. In addition, the [Pause\\_packet\\_Rxd](#) interrupt in the [MAC\\_interrupt\\_status](#) is triggered if it is enabled in the [MAC\\_interrupt\\_mask](#) register.

If [Pause\\_enable=1](#) and the value of the [MAC\\_pause\\_time](#) register is non-zero, no new packet is transmitted.

A valid pause packet is defined as having a destination address that matches 0x0180C2000001, an Ethertype of 0x8808, and the pause opcode of 0x0001 as shown in [Table 10-28](#).

**Table 10-28. Start of an 802.3 Pause Packet**

Destination Address	Source Address	Ethertype (MAC Control Frame)	Pause opcode	Pause Time
0x0180C2000001	6 bytes	0x8808	0x0001	2 bytes

Pause packets that have FCS or other errors are treated as invalid and discarded. Valid received pause packets increment the [Pause\\_packets\\_Rxd\\_OK](#) counter.

The [MAC\\_pause\\_time](#) register decrements every 512 bit times after transmission has stopped. For test purposes, the register decrements every MII receive clock cycle instead if [Retry\\_test=1](#) in the [MAC\\_network\\_configuration](#) register. If the [Pause\\_enable](#) bit is not set, the decrementing happens regardless of whether transmission has stopped or not.

The [Pause\\_time\\_zero](#) interrupt in the [MAC\\_interrupt\\_status](#) register is asserted whenever the [MAC\\_pause\\_time](#) register decrements to zero (assuming it is enabled in the [MAC\\_interrupt\\_mask](#)).

Automatic transmission of pause packets is supported through the transmit pause packet bits of the [MAC\\_network\\_control](#) register. If either [Transmit\\_pause\\_packet](#) or [Transmit\\_zero\\_quantum\\_pause\\_packet](#) is set, a pause packet is transmitted only if [Full\\_duplex=1](#) in the [MAC\\_network\\_configuration](#) register and [Transmit\\_enable=1](#) in the [MAC\\_network\\_control](#) register. Pause packet transmission takes place immediately if transmit is inactive or if transmit is active between the current packet and the next packet due to be transmitted. The transmitted pause packet comprises the items in the following list:

- Destination address of 01-80-C2-00-00-01
- Source address taken from the [MAC\\_specific\\_address](#) registers
- Ethertype of 0x8808 (MAC control frame)
- Pause opcode of 0x0001
- Pause quantum
- Fill of 0x00 to take the frame to minimum frame length
- Valid FCS.

The pause quantum used in the generated packet depends on the trigger source for the packet as follows:

- If [Transmit\\_pause\\_packet=1](#), the pause quantum comes from the [MAC\\_transmit\\_pause\\_quantum](#) register. The Transmit Pause Quantum register resets to a value of 0xFFFF giving a maximum pause quantum as a default.
- If [Transmit\\_zero\\_quantum\\_pause\\_packet=1](#), the pause quantum is zero.

After transmission, no interrupts are generated and the only counter incremented is the [Transmitted\\_pause\\_packets](#).

Pause packets can also be transmitted by the MAC using normal packet transmission methods. It is possible to transmit a pause packet while the transmitter is paused by resetting the [Pause\\_enable](#) bit.

### 10.6.13 Packet Classifier

The Packet Classifier is part of the receive path, immediately following the Ethernet MAC block. It analyzes the header of each incoming packet, by comparing the header fields to the chip's configured parameters, and then decides whether to discard the packet or add a buffer descriptor and forward the packet to the CPU or one of the payload-type machines. Section 11.4.1 has register descriptions for the packet classifier configuration registers.

#### IP version:

- Packets with IP version different than 4 or 6 are always discarded.
- The chip has three IPv4 addresses and two IPv6 addresses (all software configurable)
- The chip works in one of four modes defined by two bits in [General\\_cfg\\_reg1](#), as described in [Table 10-29](#).

**Table 10-29. Handling IPv4 and IPv6 Packets**

IP_version	Dual_stack	Transmitted Packets IP Version	Received Packets IP Version
0	0	IPv4	Receive only IPv4 packets (other IP versions are discarded)
1	0	IPv6	Receive only IPv6 packets (other IP versions are discarded)
0	1	IPv4	Receive both IPv4 and IPv6 packets (dual stack mode)
1	1	IPv6	Receive both IPv4 and IPv6 packets (dual stack mode)

Although the chip has more than one IP address, in most cases all three IPv4 addresses should have the same value and both IPv6 addresses should have the same value. The chip also has two configurable MAC addresses.

Packets with CRC errors are discarded regardless to their contents, unless the Ethernet MAC has been configured to ignore them (in which case they are treated as correct packets).

IP Packets with IP checksum error are discarded, unless the [Discard\\_ip\\_checksum\\_err](#) configuration bit is cleared in [General\\_cfg\\_reg0](#).

Packets other than TDM-over-IP or TDM-over-MPLS or TDM-over-MEF packets destined to the chip are not transferred to the payload-type machines. Instead, they are either discarded or transferred to the CPU according to the nine [Discard\\_switch](#) configuration bits in [Packet\\_classifier\\_cfg\\_reg3](#):

- Discard\_Switch\_0: An ARP packet whose Ipv4 destination address is not identical to any of the chip's Ipv4 addresses is discarded if Discard\_Switch\_0 is set. Otherwise it is transferred to the CPU.
- Discard\_Switch\_1: An IP (both Ipv4 or Ipv6) packet whose IP destination address is not identical to any of the chip's IP addresses is discarded if Discard\_Switch\_1 is set. Otherwise it is transferred to the CPU.
- Discard\_Switch\_2: A packet whose Ethertype is not known by the block is discarded if Discard\_Switch\_2 is set. Otherwise it is transferred to the CPU.
- Discard\_Switch\_3: An ARP packet whose Ipv4 destination address is identical to one of the chip's Ipv4 addresses is discarded if Discard\_Switch\_3 is set. Otherwise it is transferred to the CPU.
- Discard\_Switch\_4: An IP packet destined to the chip whose protocol is different than UDP and L2TPv3 is discarded if Discard\_Switch\_4 is set. Otherwise it is transferred to the CPU.
- Discard\_Switch\_5: An IP/UDP packet destined to the chip whose UDP destination/source port number is not identical to one of the chip's TDM-over-Packet port numbers (according to [TDMoIP\\_port\\_num\\_loc](#) in [Packet\\_classifier\\_cfg\\_reg3](#)) is discarded if Discard\_Switch\_5 is set. Otherwise it is transferred to the CPU.
- Discard\_Switch\_6: A TDMoP/MPLS/MEF packet destined to the chip whose bundle identifier is not identical to one of the chip's OAM Bundle Numbers or one of the bundle identifiers

assigned to the chip's internal bundles, is discarded if Discard\_Switch\_6 is set. Otherwise it is transferred to the CPU.

Discard\_Switch\_7: A packet recognized as OAM packet (see section 10.6.13.3) is discarded if Discard\_Switch\_7 is set. Otherwise it is transferred to the CPU.

Discard\_Switch\_8: A packet with Ethertype equal to CPU\_dest\_ether\_type configuration is discarded when Discard\_Switch\_8 is set. Otherwise it is transferred to the CPU.

A packet is identified as a TDM-over-Packet packet destined to the chip if it meets the following conditions:

- It is unicast with its destination address identical to the chip's MAC addresses, multicast or broadcast
- It has either no VLAN tags, one VLAN tag or two VLAN tags (supports VLAN stacking). See section 10.6.13.4.
- Its protocol is UDP/IP or L2TPv3
- Its IP address is identical to one of the IP addresses of the chip
- Its UDP destination port number is identical to one of the chip's TDM-over-Packet port numbers (optional). See section 10.6.13.1.
- Its bundle identifier is identical to one of the bundle identifiers assigned to the chip's internal bundles or the packet is identified as an OAM packet. See section 10.6.13.2.

A packet is identified as a TDMoMPLS or TDMoMEF packet destined to the chip if it meets the following conditions:

- It is unicast with its destination address identical to the chip's MAC addresses, multicast or broadcast
- It has either no VLAN tags, one VLAN tag or two VLAN tags (VLAN stacking)
- Its Ethertype is MPLS unicast, MPLS multicast, or MEF (see section 10.6.13.5)
- The bundle identifier located at the inner label is identical to one of the bundle identifiers assigned to the chip's internal bundles or the packet is identified as an OAM packet.

The structure of packets identified as TDM-over-Packet packets destined to a specific bundle of the chip or as OAM packets destined to the chip is shown below.

*Figure 10-59. Format of TDMoIP Packet with VLAN Tag*

*Figure 10-60. Format of TDMoMPLS Packet with VLAN Tag*

*Figure 10-61. Format of TDMoMEF Packet with VLAN Tag*

Packets that pass the classification process are temporarily stored in the Rx FIFO. This FIFO is used to buffer momentary bursts from the network if the internal hardware is busy. The Rx arbiter transfers the packets from the Rx FIFO to the payload-types machines or to external SDRAM.

### 10.6.13.1 TDMoIP Port Number

The [TDMoIP\\_port\\_num1](#) and [TDMoIP\\_port\\_num2](#) configuration fields are used by the block to identify UDP/IP TDMoIP packets. Although the chip has two of these fields, in most cases both fields should have the default value (0x085E) as assigned by IANA for TDM-over-Packet. The UDP source

Both values are compared against the UDP\_SRC\_PORT\_NUM or the UDP\_DST\_PORT\_NUM of incoming packets as specified by the [TDMoIP\\_port\\_num\\_loc](#) field in [Packet\\_classifier\\_cfg\\_reg3](#) (see [Table 10-30](#)).

**Table 10-30. TDMoIP Port Number Comparison for TDMoIP Packet Classification**

<a href="#">TDMoIP_port_num_loc</a> Value	Comparison
00	TDMoIP_port_num1/2 are ignored (no checking is performed)
01	TDMoIP_port_num1/2 are compared to source UDP port # of incoming packets
10	TDMoIP_port_num1/2 are compared to destination UDP port # of incoming packets
11	Reserved

### 10.6.13.2 Bundle Identifier Location and Width

The block determines the packet bundle identifier and its width after determining the packet type.

**Table 10-31. Bundle Identifier Location and Width**

Packet Type	Bundle Identifier Location	Bundle Identifier Width
MPLS	Inner label	20 bits
MEF	Inner label	20 bits
L2TPv3/IP	Session ID	32 bits
UDP/IP	Source UDP port number or destination UDP port number, as specified by <a href="#">lp_udp_bn_loc</a> in <a href="#">Packet_classifier_cfg_reg3</a>	1-16 bits as specified by <a href="#">lp_udp_bn_mask_n</a> in <a href="#">Packet_classifier_cfg_reg6</a> .

### 10.6.13.3 OAM Packet Identification

The block identifies OAM packets according to *one* of the following criteria:

- UDP/IP-specific OAM packets: Match between the packet's bundle identifier and one of the values (up to 8 different) configured in the [OAM\\_Identification](#) registers.
- VCCV OAM packets: Match between the packet's control word bits 31:16 and a 1 to 16 bit value specified by the combination of [VCCV\\_oam\\_mask\\_n](#) and [VCCV\\_oam\\_value](#) fields in [Packet\\_classifier\\_cfg\\_reg18](#). Such a match is taken into account only when [OAM\\_ID\\_in\\_CW](#)=1 in the [Bundle Configuration Tables](#).
- MEF OAM packets: Match between packet Ethertype and [Mef\\_oam\\_ether\\_type](#) in register [Packet\\_classifier\\_cfg\\_reg9](#).

### 10.6.13.4 VLAN Tag Identification

A VLAN tag is identified according to one of the following criteria:

- Tag protocol identifier = 0x8100
- Tag protocol identifier = [vlan\\_2nd\\_tag\\_identifier](#) in [Packet\\_classifier\\_cfg\\_reg7](#) (Created to support 0x9100 as a tag identifier)

### 10.6.13.5 Known Ethertypes

The block considers the following Ethertypes as known Ethertypes:

- IPv4 (0x800)
- IPv6 (0x86DD)
- MPLS unicast (0x8847)
- MPLS multicast (0x8848)
- ARP (0x806)
- MEF Ethertype as configured in [Mef\\_ether\\_type](#) in [Packet\\_classifier\\_cfg\\_reg9](#)
- MEF OAM Ethertype as configured in [Mef\\_oam\\_ether\\_type](#) in [Packet\\_classifier\\_cfg\\_reg9](#)
- Specific Ethertype as configured in [CPU\\_dest\\_ether\\_type](#) in [Packet\\_classifier\\_cfg\\_reg7](#)

### 10.6.13.6 Received OAM Time-Stamping

For any received packet forwarded to the CPU (ETH → CPU path) the third dword of the buffer descriptor holds the timestamp as latched by the block as the packet was received. This timestamp can be used by the CPU for network delays measurements. The timestamp is 1  $\mu$ s or 100  $\mu$ s as specified by the [OAM\\_timestamp\\_resolution](#) field in [General\\_cfg\\_reg0](#).

### 10.6.13.7 Neighbor Discovery (RFC 2461)

Where IPv4 has ARP, IPv6 has NDP, the neighbor discovery protocol. For the purposes of this discussion, NDP and ARP are very similar: one node sends out a request packet (called a *neighbor solicitation* in NDP), and the node it was looking for sends back a reply (*neighbor advertisement*) giving its link-layer address. NDP is part of ICMPv6, unlike ARP, which doesn't run over IP. NDP also uses multicast rather than broadcast packets.

For NDP (ICMPv6) packets to be forwarded to the CPU, [Discard\\_switch\\_4](#) must be cleared.

### 10.6.13.8 Packet Payload Length Sanity Check

The packet classifier performs a sanity check between the payload length of the received packet and the AAL1/SAToP/CESoPSN bundle's configuration. Discarding packets that fail the sanity check can be disabled per bundle by setting [Rx\\_discard\\_sanity\\_fail](#)=1 in the [Bundle Configuration Tables](#).

### 10.6.14 Packet Trailer Support

There are Ethernet switch chips that in some of their modes transmit packets with a trailer and expect the incoming packets to have a trailer. A trailer is an addition of several bytes at the end of the packet that helps the switch to decide about the incoming packet destination and to tag out-going packets.

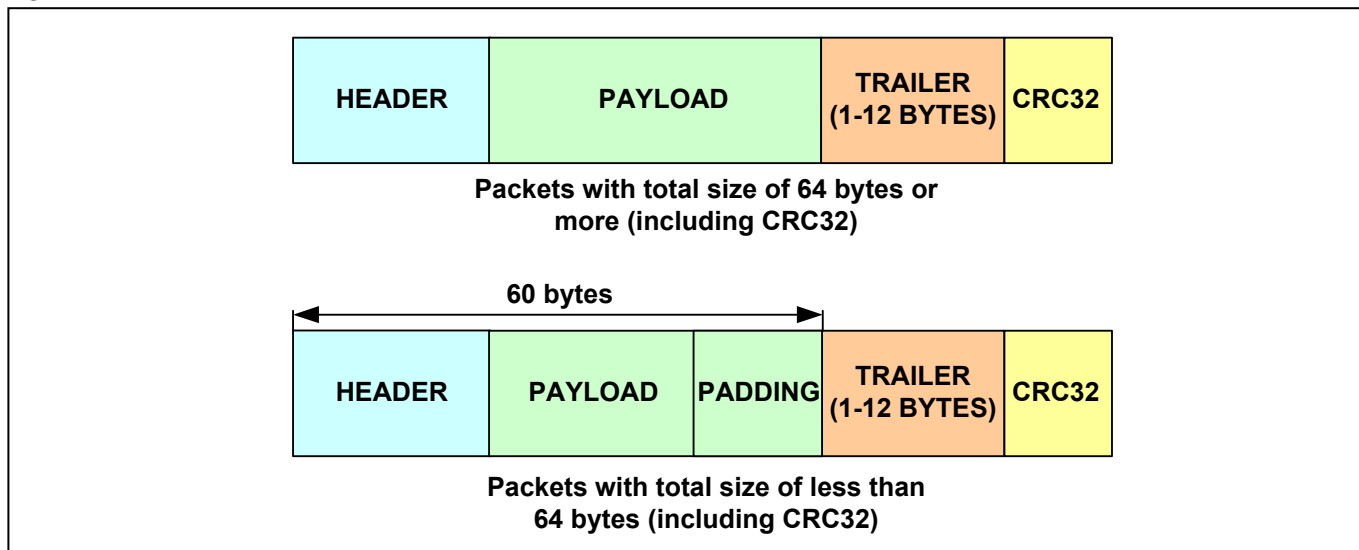

When the device operates opposite such a switch, the trailer is supported in the following manner:

- Transmitted packets: A 1 to 12 byte trailer is added to all transmitted packets. The trailer contents that are stored in the packet buffer (immediately after the buffer descriptor starting from offset 0x8) may be varied per packet.
- Received packets: The trailer content is ignored. It is removed from packets destined to the payload-type machines and not transferred with packets destined to CPU.
- Trailer size is set for all transmitted/received packets in the [Packet\\_trailer\\_length](#) field in [General\\_cfg\\_reg0](#).

The structure of packets with trailer is illustrated in [Figure 10-62](#).

Figure 10-62. Structure of Packets with Trailer

The CRC is calculated over all packet bytes including over the trailer bytes. The transmitted bytes counter and the received bytes counter (section 11.4.3.3) do not count the trailer bytes.

#### 10.6.15 Counters and Status Registers

For information about counters and registers in the TDMoP block, see section 11.4.

#### 10.6.16 Connection Level Redundancy

The TDMoP block provides optional connection level redundancy for AAL1, SAToP and CESoPSN bundles. In the TDM-to-Ethernet direction, on a bundle basis, each packet may be transmitted once with certain headers, or twice, each time with different headers. When transmitted twice, the packets have the same payload, same control word and same RTP header (if used) but may have different packet headers (including layer 2, 3 and 4 headers).

For example, the chip can duplicate a bundle's packets on transmission where the only difference between the duplicated packets is their bundle number or their VLAN ID.

On the receive side, when two redundant streams use different bundle numbers, the chip can be configured to receive only the packets with the first bundle number or the packets with the second bundle number.

To enable this feature, CPU software must initialize the transmit buffers of a bundle with both headers. The second header must be located at offset 0x782 from start of the buffer and its length (in bytes) is indicated by the buffer descriptor [Hdr2\\_length](#) field (not including the RTP header length neither the control word length). By changing the [Protection\\_mode](#) configuration field of the bundle, the user can choose (per bundle) whether to transmit each of the packets once with the first or the second header, or twice, each time with a different header.

On the receive side, only the packets with their bundle number configured in the [Rx\\_bundle\\_identifier](#) field of a specific bundle, are forwarded. The CPU may change this value dynamically, in order to switch to the redundant connection at any time.

On the receive side, when both streams use the same bundle number, switching from one stream to another is almost seamless. No software intervention is needed as the payload-type machine discards the duplicated packets. During this process the end-to-end delay may change because of different route delays and 1–2 packet of packet loss may occur.

The destination MAC/IP (and/or VLAN) of the duplicated packets can be different as the chip supports more than one MAC/IP address in the packet classifier.

### **10.6.17 OAM Signaling**

TDMoP bundles require a signaling mechanism to provide feedback regarding problems in the communications environment. In addition, such signaling can be used to collect statistics related to the performance of the underlying PSN. The OAM procedures detailed below are ICMP-like.

#### **10.6.17.1 Connectivity Check Messages**

In most conventional IP applications, a server sends some finite amount of information over the network after an explicit request from a client. With TDM-over-Packet, the source sends a continuous stream of packets towards the destination, without knowing whether the destination device is ready to accept them, leading to flooding of the PSN. The problem may occur when a TDM-over-Packet gateway fails or is disconnected from the PSN, or the bundle is broken. After an aging time, the destination gateway disappears from the routing tables, and intermediate routers may flood the network with the TDM-over-Packet traffic in an attempt to find a new path.

The solution to this problem is to significantly reduce the number of TDM-over-Packet packets transmitted per second when bundle failure is detected, and to return to full rate only when the bundle is restored. The detection of failure and restoration is made possible by the periodic exchange of one-way connectivity check messages. Connectivity is tested by periodically sending OAM messages from the source gateway to the destination gateway, and having the destination reply to each message.

The connectivity check mechanism can also be useful during setup and configuration. Without OAM signaling, one must ensure that the destination gateway is ready to receive packets before starting to send them. Since TDM-over-Packet gateways operate full duplex, both must be set up and properly configured simultaneously to avoid flooding. By using the connectivity mechanism, a configured gateway waits until it can detect its destination before transmitting at full rate. In addition, errors in configuration can be readily discovered by using the service-specific field.

#### **10.6.17.2 Performance Measurements**

In addition to one-way connectivity, the OAM signaling mechanism can be used to request and report on various PSN metrics, such as one-way delay, round trip delay, packet delay variation, etc. It can also be used for remote diagnostics, and for unsolicited reporting of potential problems (e.g. dying gasp messages).

#### **10.6.17.3 Processing OAM Packets**

In the Ethernet-to-CPU direction, the device identifies OAM packets as described in section [10.6.13.3](#).

In the CPU-to-Ethernet direction the chip timestamps packets when the [Stamp](#) field of the buffer descriptor field is set. The timestamp location in the packet is specified by the [Ts\\_offset](#) buffer descriptor field. When the CPU transmits an OAM packet, the buffer descriptor must identify the packet as a non-TDMoP/MPLS packet (i.e. is not assigned to any bundle), as other packet types are not time-stamped in any case.

## 10.7 Global Resources

See the top-level block diagram in [Figure 6-1](#). Global resources in the device include CLAD1, CLAD2 and the CPU Interface block. These resources are configured in the global registers described in [section 11.3](#). These registers also handle device identification, top-level mode configuration, I/O pin configuration, global resets, and top-level interrupts.

## 10.8 Per-Port Resources

See the top-level block diagram in [Figure 6-1](#). Each port is independently configured in the [Port\[n\]\\_cfg\\_reg](#) register. In addition to E1 and T1 modes, a port can also be configured as a serial data port that can connect to a serial interface transceiver for V.35 or RS-530 support. This would usually be in a DCE application of some kind. The port can be configured for this mode by setting [Port\[n\]\\_cfg\\_reg:Int\\_type=00](#).

The device also features one 10/100 Ethernet port that can be configured to have an MII, RMII or SSMII interface. The Ethernet port can work in half or full duplex mode and supports VLAN tagging and priority labeling according to 802.1p 802.1Q, including VLAN stacking. [Section 11.4.16](#) describes the Ethernet port.

## 10.9 Device Interrupts

The [H\\_INT](#) pin indicates interrupt requests. The only source for interrupts in the DS34S10x devices is the TDMoP block (which includes the MAC). The TDMoPIM bit in [GTIMR](#) must be set to 1 enable interrupts from the TDMoP block. The [Intpend](#) register indicates the source(s) of interrupt(s) from the TDMoP block. If one of the [Intpend](#) bits is set, it can be cleared only by writing 1 to it. At reset, all [Intpend](#) interrupts are disabled due to the [Intmask](#) register default values. Writing 0 to an [Intmask](#) bit enables the corresponding [Intpend](#) interrupt.

The TDMoP interrupts indicated in the [Intpend](#) register are of two types. The first type consists of interrupts generated by a single source. The second type consists of interrupts that can originate from any of several possible interrupt sources including the [ETH\\_MAC](#), [CW\\_bits\\_change](#), [Rx\\_CAS\\_change](#), [Tx\\_CAS\\_Change](#), and [JB\\_underrun](#) interrupts.

The [JBC\\_underrun](#) interrupts can be masked per timeslot by setting the appropriate bits in the [JBC\\_underrun\\_mask](#) registers.

The [Tx\\_CAS\\_change](#) interrupts can be masked per timeslot by setting the appropriate bits in the [Tx\\_CAS\\_change\\_mask](#) registers.

The [CW\\_bits\\_change](#) interrupts can be masked per bundle by setting the appropriate bits in the [CW\\_bits\\_mask](#) registers. In addition, the fields of the control word that cause an interrupt when changed (L, R, M, FRG) can be configured in the [CW\\_bits\\_change\\_mask](#) register.

When an interrupt is indicated on [H\\_INT](#), the CPU should read the [Intpend](#) register to identify the interrupt source and then proceed as follows:

Interrupt Type	Interrupt Procedure
Single-source Interrupts	<ol style="list-style-type: none"> <li>1. Clear the pending interrupt(s) by writing 1 to the corresponding <a href="#">Intpend</a> bit(s).</li> <li>2. Service the source of the interrupt.</li> </ol>
<a href="#">Rx_CAS_change</a>	<ol style="list-style-type: none"> <li>1. Read the <a href="#">Rx_CAS_change</a> bits in the <a href="#">Intpend</a> register to determine which port(s) are indicating Rx CAS change.</li> <li>2. Clear the set <a href="#">Rx_CAS_change</a> bits in the <a href="#">Intpend</a> register by writing 1 to them.</li> <li>3. Read the corresponding <a href="#">Rx_CAS_change</a> register(s) to determine which timeslot(s) have been changed.</li> <li>4. Clear the set bits in the <a href="#">Rx_CAS_change</a> register(s) by writing 1 to</li> </ol>

Interrupt Type	Interrupt Procedure
	them.
	5. Read the corresponding Rx CAS information from the Rx Line CAS registers (section 11.4.10).
Tx_CAS_change	<ol style="list-style-type: none"> <li>1. Read the Tx_CAS_change bits in the <a href="#">Intpend</a> register to determine which port(s) are indicating Tx CAS change.</li> <li>2. Clear the set Tx_CAS_change bits in the <a href="#">Intpend</a> register by writing 1 to them.</li> <li>3. Read the corresponding <a href="#">Tx_CAS_change</a> register(s) to determine which timeslot(s) have been changed.</li> <li>4. Clear the set bits in the <a href="#">Tx_CAS_change</a> register(s) by writing 1 to them.</li> <li>5. Read the appropriate Tx CAS information from neighboring framer IC(s).</li> </ol>
CW_bits_change	<ol style="list-style-type: none"> <li>1. Clear the CW_bits_change bit in the <a href="#">Intpend</a> register by writing 1 to it.</li> <li>2. Read the <a href="#">CW_bits_change_low_bundles</a> and <a href="#">CW_bits_change_high_bundles</a> registers to determine which bundles(s) have control bits that have changed.</li> <li>3. Clear the set bits in the <a href="#">CW_bits_change_low_bundles</a> and <a href="#">CW_bits_change_high_bundles</a> registers by writing 1 to them.</li> <li>4. Read the state of the control word fields from the <a href="#">Packet Classifier Status</a> register in the per-bundle status tables (section 11.4.4.1).</li> </ol>
JB_underrun_Pn	<ol style="list-style-type: none"> <li>1. Read the JBC_underrun bits in the <a href="#">Intpend</a> register to determine which port(s) are indicating jitter buffer underrun.</li> <li>2. Clear the set JBC_underrun bits in the <a href="#">Intpend</a> register by writing 1 to them.</li> <li>3. Read the corresponding <a href="#">JBC_underrun</a> register(s) to determine which buffers had underruns.</li> <li>4. Clear the set bits in the <a href="#">JBC_underrun</a> register(s) by writing 1 to them.</li> <li>5. Service the underrun(s) as needed.</li> </ol>
ETH_MAC	<ol style="list-style-type: none"> <li>1. Clear the ETH_MAC bit in the <a href="#">Intpend</a> register by writing 1 to it.</li> <li>2. Read the <a href="#">MAC_interrupt_status</a> register to determine the source(s) of interrupts in the MAC (all bits are reset to 0 upon read).</li> <li>3. Service the source(s) of the interrupt(s).</li> </ol>

If a bit in the [Intpend](#) register is set and that interrupt is then masked, the device generates an interrupt immediately after the CPU clears the corresponding mask bit. To avoid this behavior, the CPU should clear the interrupt from the [Intpend](#) register before clearing the mask bit.

## 11. Device Registers

### 11.1 Addressing

Device registers and memory can be accessed either 2 or 4 bytes at a time, as specified by configuration pin [DAT\\_32\\_16\\_N](#). In the 16-bit addressing mode, addresses are multiples of 2, while in 32-bit addressing, addresses are multiples of 4.

The prefix “0x” indicates hexadecimal (base 16) numbering, as does the suffix “h” (Example: 2FFh). Addresses are always indicated in hexadecimal format.

The byte order for both addressing modes is “big-endian” meaning the most significant byte has the lowest address. See byte order numbers in grey in [Figure 11-1](#) and [Figure 11-2](#).

Figure 11-1. 16-Bit Addressing

ADD	15	H_WR_BE1_N				8	7	H_WR_BE0_N				0
6				6							7	
4				4							5	
2				2							3	
0				0							1	

Figure 11-2. 32-Bit Addressing

ADD	31	H_WR_BE3_N				24	23	H_WR_BE2_N				16	15	H_WR_BE1_N				8	7	H_WR_BE0_N				0
C																								
8																								
4				4							5					6						7		
0				0							1					2						3		

Partial data elements (shorter than 16 or 32 bits) are always positioned from LSb to MSb with the rest of the bits left unused. Thus, the bit numbers of data elements shorter than 16 bits are identical for both addressing modes (see bits [12:0] in [Figure 11-3](#)) and the CPU can access all bits by a single read/write.

Figure 11-3. Partial Data Elements (shorter than 16 bits)

																ADD	15					8	7									0														
																2	15							8	7							0														
																0	31							24	23							16														
																ADD	31					24	23					16	15					8	7									0		
																0																														

Data elements 17 to 32 bits long need one read/write access in 32-bit addressing and two in 16-bit addressing. In [Figure 11-4](#), the 20-bit data element needs one 32-bit CPU access (bits [19:0]) and two 16-bit accesses (bits [15:0] and then [3:0]).

Figure 11-4. Partial Data Elements (16 to 32 bits long)

SPI interface mode ([H\\_CPU\\_SPI\\_N=0](#)) always uses 32-bit addressing. See section [10.3](#).

**11.2 Top-Level Memory Map**

Table 11-1. Top-Level Memory Map

Address Range	Contents	Page
0 – 7F,FFF	<a href="#">TDM-over-Packet Registers</a>	<a href="#">93</a>
80,000 – 107,FFF	Reserved	---
108,000 – 108,FFF	<a href="#">Global Registers</a>	<a href="#">91</a>
109,000 – FFF,FFF	Reserved	---
1,000,000 – 1,FFF,FFF	External SDRAM	---

### 11.3 Global Registers

Functions contained in the global registers include device ID, CLAD configuration and top-level interrupt masking. The global register base address is 0x108,000.

**Table 11-2. Global Registers**

Addr Offset	Register Name	R/W	Description	Page
0x00	<a href="#">GCR1</a>	R/W	Global Control Register 1	<a href="#">91</a>
08	<a href="#">GTRR</a>	R/W	Global Transceiver Reset Register	<a href="#">91</a>
0C	<a href="#">IDR</a>	RO	Identification Device Register	<a href="#">92</a>
10	<a href="#">GTISR</a>	RO	Global Transceiver Interrupt Status Register	<a href="#">92</a>
14	<a href="#">GTIMR</a>	R/W	Global Transceiver Interrupt Mask Register	<a href="#">92</a>

#### GCR1 (Global Control Register) 0x00

Bits	Data Element Name	R/W	Default	Description
[31:15]	Not Used	-	0	Must be set to zero.
[14]	SYSCLKS	R/W	0	TDMoP System Clock Frequency Select When a 25MHz clock is applied to the <a href="#">CLK_SYS</a> pin (i.e. when the <a href="#">CLK_SYS_S</a> pin is high), this bit configures the CLAD2 block to provide either a 50MHz clock or a 75MHz clock to the TDMoP block. When <a href="#">CLK_SYS_S</a> =0 this bit is a don't care. See section <a href="#">10.4</a> . 0 = 50MHz 1 = 75MHz
[13:12]	FREQSEL	R/W	00	Frequency Select Specifies the frequency of the signal applied to the <a href="#">CLK_HIGH</a> pin. 00 = 38.88MHz (CLAD bypass; 38.88MHz in and out). 01 = 19.44MHz 10 = 10.000MHz 11 = 77.76MHz
[11:9]	Not Used	-	0	Must be set to zero.
[8]	CLK_HIGHD	R/W	0	CLK_HIGH Disable Disables the 38.88MHz master clock to the clock recovery machines of the TDMoP block to save power. This bit should be set only when not using any of the <a href="#">TDMn_ACLK</a> signals. See section <a href="#">10.4</a> . 0 = Enabled 1 = Disabled
[7:0]	Not Used	-	0	Must be set to zero.

#### GTRR (Global Transceiver Reset Register) 0x08

Bits	Data Element Name	R/W	Default	Description
[31:19]	Not Used	-	0	Must be set to zero.
[18]	TOPRST	R/W	0	TDMoP Core Software Reset When set, this bit resets all of the TDMoP configuration registers to their default value. 0 = Normal operation 1 = Reset the TDMoP core
[17:0]	Not Used	-	0	Must be set to zero.

**IDR (Identification Device Register) 0x0C**

Bits	Data Element Name	R/W	Default	Description
[31:16]	ID[31:16]	RO	0	These bits are always zero.
[15:4]	ID[15:4]	RO	See JTAG ID.	Device ID These bits have the same information as the lower 12 bits of the Device ID portion of the JTAG ID register. See <a href="#">Table 12-2</a> .
[3:0]	ID[3:0]	RO	See JTAG ID.	Device Revision These bits have the same information as the four REV bits of the JTAG ID register. See <a href="#">Table 12-2</a> .

**GTISR (Global Transceiver Interrupt Status Register) 0x10**

Bits	Data Element Name	R/W	Default	Description
[31:25]	Not used.	-	0	Must be set to zero.
[24]	TDMoPIS	RO	0	TDM-over-Packet Interrupt Status This status bit indicates when the TDM-over-Packet block is signaling an interrupt request. Interrupt mask is <a href="#">GTIMR</a> .TDMoPIM. 0 = TDM-over-Packet has not issued an interrupt. 1 = TDM-over-Packet has issued an interrupt.
[23:0]	Not Used	-	0	Must be set to zero.

**GTIMR (Global Transceiver Interrupt Mask Register) 0x14**

Bits	Data Element Name	R/W	Default	Description
[31:25]	Not used.	-	0	Must be set to zero.
[24]	TDMoPIM	R/W	0	TDM-over-Packet Interrupt Mask This bit is the interrupt mask for <a href="#">GTISR</a> .TDMoPIS. 0 = Interrupt masked. 1 = Interrupt enabled.
[23:0]	Not Used	-	0	Must be set to zero.

## **11.4 TDM-over-Packet Registers**

The base address for the TDMoP registers is **0x0**.

**Table 11-3. TDMoP Memory Map**

<b>Address Offset</b>	<b>Contents</b>	<b>Page</b>
0x0,000	<a href="#">Configuration and Status Registers</a>	<a href="#">94</a>

#### 11.4.1.1 TDMoP Configuration Registers

##### General\_cfg\_reg0 0x00

Bits	Data Element Name	R/W	Reset Value	Description
[31]	Discard_ip_checksum_err	R/W	0x0	Indicates to discard packets received with a wrong IP checksum. See section <a href="#">10.6.13</a> .
[30:27]	Packet_trailer_length	R/W	0x0	The length of the trailer attached to all received and transmitted packets. Allowed values: 0–12 (decimal). When set to zero no trailer is attached. See section <a href="#">10.6.14</a> .
[26]	Clock_recovery_en	R/W	0x0	0 = Clock recovery block is disabled (power saving mode) 1 = Normal operation Should be cleared to reduce the chip power consumption when adaptive clock recovery is not used. When cleared, the clock recovery registers (offset 0x48,000) must not be accessed by the CPU because the clock recovery block does not assert <a href="#">H_READY_N</a> . See section <a href="#">10.4</a> .
[25:16]	Rx_fifo_priority_lvl	R/W	0x100	Rx FIFO threshold level in dwords. If the Rx FIFO level is higher than this threshold, then the Rx_fifo receives the higher priority instead of the cross-connect queue. This parameter is relevant only when there are bundles configured as cross-connect. The recommended value is 0x3FF (maximal value). See section <a href="#">10.6.11.5</a> .
[15:14]	MII_mode_select	R/W	0x0	00 = MII 01 = RMII 10 = Reserved 11 = Source sync SMII (SSMII)
[13:12]	Reserved	R/W	0x0	Must be set to zero
[11]	High_speed	R/W	0x0	0 = All ports active in E1/T1/J1 mode 1 = Port1 enabled in high-speed E3/T3/STS-1 mode, all other ports disabled
[10]	OAM_timestamp_resolution	R/W	0x1	0 = OAM timestamp is incremented every 1μs 1 = OAM timestamp is incremented every 100μs See section <a href="#">10.6.13.6</a> .
[9:8]	Reserved	R/W	0x0	Must be set to zero
[7]	Mem_size	R/W	0x0	SDRAM size: 0 = 64 Mb 1 = 128 Mb

**General\_cfg\_reg0 0x00**

Bits	Data Element Name	R/W	Reset Value	Description
[6:5]	Fq	R/W	0x0	SDRAM clock: 00 = 50 MHz 01 = 75 MHz 10 = Reserved 11 = Reserved for 100 MHz
[4:3]	Col_width	R/W	0x0	SDRAM columns and rows 00 = 8 bit (256 columns) 01 = 9 bit (512 columns) 10 = 10 bit (1K columns) 11 = 11 bit (2K columns)
[2:1]	CAS_latency	R/W	0x2	SDRAM CAS latency: 00 = {reserve value} 01 = 1 10 = 2 11 = 3
[0]	Rst_SDRAM_n	R/W	0x0	Resets SDRAM controller. Active low. After all configuration bits of the SDRAM controller have been written, the SDRAM controller must be reset by taking this bit low then high.

**General\_cfg\_reg1 0x04**

Bits	Data Element Name	R/W	Reset Value	Description
[31]	RTP_timestamp_generation_mode	R/W	0x0	Indicates the RTP timestamp generation mode: 0 = Absolute mode 1 = Differential (common clock) mode See the description of the TS field in <a href="#">Table 10-16</a> for more details.
[30:24]	Sw_packet_offset	R/W	0x04	The offset from the first byte of the packet to the start of the CPU buffer. For the Ethernet-to-CPU packets, 8 bytes are added automatically to each configured value. For example, if you intend to set the offset to 20 bytes, configure this value to 12 bytes. Allowed values are in the range of 4–127 (decimal) bytes.
[23:19]	Tx_payload_offset	R/W	0x00	Number of 32-bit words between the start of transmit buffer to the control word or to start of the TDM payload if the control word does not exist
[18]	Reserved	R/W	0x0	Must be set to zero
[17:10]	JBC_sig_base_add	R/W	0x060	Base address (8 MSbits) of Rx jitter buffer signaling section in SDRAM
[9:6]	Tx_buf_base_add	R/W	0x2	Base address (4 MSbits) of transmit buffers in SDRAM
[5]	IP_version	R/W	0x0	The IP version of transmitted TDMoP packets. See section <a href="#">10.6.13</a> . 0 = Ipv4 1 = Ipv6
[4]	Dual_stack	R/W	0x0	The IP version of received TDMoP packets. See section <a href="#">10.6.13</a> . 0 = Ipv4/Ipv6, according to IP_version field above 1 = Both Ipv4 and Ipv6 packets
[3]	Frames_count_check_en	R/W	0x1	Specifies whether to check received packets that are CESoPSN structured with CAS bundles and discard those that contain the wrong number of TDM frames 0 = Do not check 1 = Check
[2]	Reserved	R/W	0x0	Must be set to zero
[1:0]	JBC_data_base_add	R/W	0x0	Base address (2 MSbits) of Rx jitter buffer data section in SDRAM

**General\_cfg\_reg2 0x08**

Bits	Data Element Name	R/W	Reset Value	Description
[31:29]	Rx_HDLC_min_flags	R/W	0x0	Minimum number flags between 2 adjacent HDLC frames transmitted on the TDM pins. The number of flags is equal to Rx_hdlc_min_flags + 1. Range: 1 – 8.
[28:24]	Reserved	R/W	0x0	Must be set to zero
[23:20]	Rx_SAToP/CESoPSN_discard_mask	R/W	0x0	Each bit of this field determines whether a specific type of discarded packet is to be counted by the 'SAToP/CESoPSN_discarded_packets' counter. 0 = don't count 1 = count bit 23: count packets that were discarded because of jump operation that caused overflow in jitter buffer. bit 22: count packets that were discarded due to incorrect sequence number. bit 21: count packets that were discarded due to over-run state in jitter buffer. bit 20: count packets that were discarded because they were considered duplicated, or because they were received too late to be inserted into the jitter buffer.
[19:0]	Reserved	R/W	0x0	Must be set to zero

In the [Port\[n\]\\_cfg\\_reg](#) description below, the index **n** indicates port number: 1-8 for DS34S108, 1-4 for DS34S104, 1-2 for DS34S102, 1 only for DS34S101.

**Port[n]\_cfg\_reg 0x08+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:30]	Reserved	R/W	0x0	Must be set to zero.
[29:24]	Unframed_int_rate	R/W	0x0	The bit rate of an unframed interface type (Used only for absolute mode RTP timestamping). 1 = 64 kbps 2 = 128 kbps . . . 32 = 2.048 Mbps 33 = 1.544 Mbps 34 = 34 Mbps (E3 rate) 45 = 45 Mbps (T3 rate) 52 = 51.84 Mbps (STS-1 rate) <b>Note:</b> E3, T3 and STS-1 configurations are available for Port 1 only in high-speed mode, i.e. when <a href="#">General_cfg_reg0.High_speed=1</a> .
[23]	PCM_rate	R/W	0x0	Indicates the PCM frequency, i.e. the TDM rate in and out of the TDMoP port. Only applies when int_frame_type (bits 3:2 below) is set for frame, multiframe or ESF and int_type (bits 1:0 below) is set for E1 or T1. 0 = 1.544 MHz 1 = 2.048 MHz This bit is for enabling T1 data over an E1-rate port. The combination of Int_type=E1 and PCM_rate=1.544 MHz is not allowed.

**Port[n]\_cfg\_reg 0x08+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[22:21]	Tx_defect_modifier	R/W	0x0	Used in the control word M field for packets in all bundles associated with TDMoP port n.
[20]	Port_Rx_enable (Rx means from Ethernet MII)	R/W	0x0	0 = Outgoing TDM traffic from Port n of the TDMoP block is discarded (TDMn_TX and TDMn_TSIG are held high) 1 = Outgoing TDM traffic from Port n of the TDMoP block is enabled. <b>Note:</b> (Port 1 only) This bit also applies in high-speed mode, i.e. when <a href="#">General_cfg_reg0.High_speed=1</a> .
[19]	CTS	R/W	0x1	When the Int_type field (below) specifies a serial interface, the value of the <a href="#">TDMn_TSIG_CTS pin</a> —which behaves as CTS (Clear To Send)—comes from this field.
[18]	CD_en	R/W	0x0	When the Int_type field (below) specifies a serial interface, this field is the output enable control for the CD (Carrier Detect) function of the <a href="#">TDMn_TX_MF_CD pin</a> . When this pin is active, the output state of the <a href="#">TDMn_TX_MF_CD pin</a> comes from the CD field (below).
[17]	CD	R/W	0x1	When the Int_type field (below) specifies a serial interface, the value of the <a href="#">TDMn_TX_MF_CD pin</a> —which behaves as CD (Carrier Detect)—comes from this field when the CD_en bit (above) is high.
[16]	Loss	R/W	0x0	Loss of sync on TDM port n. Causes the L bit in the control word to be set for packets in all bundles associated with TDMoP port n.
[15:11]	Adapt_JBC_indx	R/W	0x00	Index of the jitter buffer used by the clock recovery block to generate the clock for TDMoP port n.
[10:9]	SF_to_ESF_low_CAS_bits	R/W	0x0	In the case where a SF (superframe) formatted T1 is connected by a structured-with-CAS bundle to an ESF interface, this field is the source of the C and D CAS bits for the ESF interface (in the Ethernet-to-TDM direction). See section <a href="#">10.6.5</a> .
[8]	TSA_act_blk	R/W	0x0	0 = TSA bank1 is the active bank for Port n. 1 = TSA bank2 is the active bank for Port n. Swapping banks takes effect at the next sync input assertion
[7]	Port_Tx_enable (Tx mean toward Ethernet MII)	R/W	0x0	0 = Incoming TDM traffic to Port n of the TDMoP block is discarded 1 = Incoming TDM traffic to Port n of the TDMoP block is enabled <b>Note:</b> (Port 1 only) This bit also applies in high-speed mode, i.e. when <a href="#">General_cfg_reg0.High_speed=1</a> .
[6]	Rx_sample	R/W	0x1	In one-clock mode (Two_clocks field below is 0) this field is ignored. In two-clock mode (Two_clocks=1) this field specifies the <a href="#">TDMn_RCLK</a> edge on which <a href="#">TDMn_RX</a> , <a href="#">TDMn_RX_SYNC</a> and <a href="#">TDMn_RSIG_RTS</a> are sampled. 0 = falling edge 1 = rising edge See the timing diagrams in <a href="#">Figure 14-10</a> through <a href="#">Figure 14-13</a> .
[5]	Tx_sample	R/W	0x0	In one-clock mode (Two_clocks field below is 0) this field specifies the <a href="#">TDMn_TCLK</a> edge on which <a href="#">TDMn_TX_SYNC</a> , <a href="#">TDMn_TX_MF_CD</a> , <a href="#">TDMn_RX</a> , <a href="#">TDMn_RX_SYNC</a> and <a href="#">TDMn_RSIG_RTS</a> are sampled and the edge on which <a href="#">TDMn_TX</a> and <a href="#">TDMn_TSIG_CTS</a> are updated. 0 = Inputs sampled on the falling edge, outputs updated on the rising edge 1 = Inputs sampled on the rising edge, outputs updated on the falling edge

**Port[n]\_cfg\_reg 0x08+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
				<p>In two-clock mode (Two-clocks=1) this field specifies the <a href="#">TDMn_TCLK</a> edge on which <a href="#">TDMn_TX_SYNC</a>, <a href="#">TDMn_TX_MF_CD</a> are sampled and the edge on which <a href="#">TDMn_TX</a> and <a href="#">TDMn_TSIG_CTS</a> are updated. The <a href="#">Rx_sample</a> field (above) specifies the <a href="#">TDMn_RCLK</a> edge for the Rx-side signals.</p> <p>0 = Inputs sampled on the falling edge, outputs updated on the rising edge</p> <p>1 = Inputs sampled on the rising edge, outputs updated on the falling edge</p> <p>See the timing diagrams in <a href="#">Figure 14-8</a> through <a href="#">Figure 14-13</a>.</p>
[4]	Two_clocks	R/W	0x1	<p>One-clock or two-clock mode.</p> <p>0 = one-clock mode: <a href="#">TDMn_TCLK</a> is used for both Rx and transmit interfaces</p> <p>1 = two-clock mode: <a href="#">TDMn_RCLK</a> is used for the Rx interface and <a href="#">TDMn_TCLK</a> is used for the transmit interface.</p> <p><b>Note:</b> (Port 1 only) This bit must be set in high-speed mode (i.e. when <a href="#">General_cfg_reg0.High_speed</a>=1).</p>
[3:2]	Int_framed_type	R/W	0x0	<p>Interface Framing Type</p> <p>00 = Unframed (no frame sync, no multiframe sync)</p> <p>01 = Frame (frame sync only, no multiframe sync)</p> <p>10 = Multiframe (E1), SF (T1) (sync and mf sync)</p> <p>11 = ESF(T1) (frame sync and multiframe sync)</p> <p>Changing value from 10 or 11 to 00 or 01 must be performed only after asserting the <a href="#">RST_SYS_N</a> pin.</p>
[1:0]	Int_type	R/W	0x1	<p>Interface Type</p> <p>00 = Serial</p> <p>01 = E1</p> <p>10 = T1</p> <p>11 = Reserved</p>

**Rst\_reg 0x2C**

Bits	Data Element Name	R/W	Reset Value	Description
[31:28]	Reserved	-	0x0	Must be set to zero
[27:24]	Rst_tx_port_num	R/W	0x0	Port number associated with <a href="#">Rst_tx</a> field (below). 0000 = Port 1 0001 = Port 2 0010 = Port 3 0011 = Port 4 0100 = Port 5 0101 = Port 6 0110 = Port 7 0111 = Port 8
[23:18]	Rst_tx_internal_bundle_num	R/W	0x00	Bundle number associated with <a href="#">Rst_tx</a> field (below)
[17]	Rst_tx_open/close	R/W	0x0	Valid when <a href="#">Rst_tx</a> is set 0 = When Rst_tx is done during bundle close procedure 1 = When Rst_tx is done during bundle open procedure This bit is also used in high-speed mode.
[16]	Rst_tx	R/W	0x0	If set, the relevant transmit payload type machine resets its variables (should be given with bundle number and a proper value of the RST_tx_open/close bit). The CPU should poll this bit until it is 0 meaning, "reset acknowledged". This bit is also used in high-speed mode.
[15:7]	Reserved	R/W	0x0	Must be set to zero
[6:1]	Rst_rx_internal_bundle_num	R/W	0x00	Bundle number associated with <a href="#">Rst_rx</a>
[0]	Rst_rx	R/ set	0x0	1 = Packet classifier generates a reset frame ( <a href="#">Rst_rx_internal_bundle_num</a> is valid). The CPU should poll this bit until it finds 0; this means "reset acknowledged".

The [TDM\\_cond\\_data\\_reg](#) register below holds four octets to be transmitted as conditioning data in the TDM direction during jitter buffer underrun. This data applies to all bundle types.

**TDM\_cond\_data\_reg 0x30**

Bits	Data Element Name	R/W	Reset Value	Description
[31:24]	TDM_cond_octet_a	R/W	0x00	TDM Conditioning Octet A Must be set to 0x7E for HDLC bundles Also used in high-speed mode
[23:16]	TDM_cond_octet_b	R/W	0x00	TDM Conditioning Octet B Must be set to 0x7E for HDLC bundles
[15:8]	TDM_cond_octet_c	R/W	0x00	TDM Conditioning Octet C Must be set to 0x7E for HDLC bundles
[7:0]	TDM_cond_octet_d	R/W	0x00	TDM Conditioning Octet D Must be set to 0x7E for HDLC bundles

The [ETH\\_cond\\_data\\_reg](#) register below holds four octets to be transmitted as conditioning data towards the packet network (i.e. toward the Ethernet MAC) when no valid data is available from the TDM port. This applies only to AAL1 or SAToP/CESoPSN bundles. [Tx\\_cond\\_octet\\_type](#) in the [Bundle Configuration Tables](#) specifies which of these octets is used on a per-bundle basis.

**ETH\_cond\_data\_reg 0x34**

Bits	Data Element Name	R/W	Reset Value	Description
[31:24]	ETH_cond_octet_d	R/W	0x00	Ethernet Conditioning octet D
[23:16]	ETH_cond_octet_c	R/W	0x00	Ethernet Conditioning octet C
[15:8]	ETH_cond_octet_b	R/W	0x00	Ethernet Conditioning octet B
[7:0]	ETH_cond_octet_a	R/W	0x00	Ethernet Conditioning octet A

**Packet\_classifier\_cfg\_reg0 0x38**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Ipv4_add1	R/W	0x0	This field holds the first of three IPv4 addresses for the device. The other addresses are held in register <a href="#">Packet_classifier_cfg_reg1</a> and <a href="#">Packet_classifier_cfg_reg8</a> . Relevant only for packets received from the Ethernet port.

**Packet\_classifier\_cfg\_reg1 0x3C**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Ipv4_add2	R/W	0x0	This field holds the second of three IPv4 addresses for the device. The other addresses are held in register <a href="#">Packet_classifier_cfg_reg0</a> and <a href="#">Packet_classifier_cfg_reg8</a> . Relevant only for packets received from the Ethernet port.

**Packet\_classifier\_cfg\_reg2 0x40**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	MAC_add1	R/W	0x0	This field holds bits 31:0 of the first of two MAC addresses for the device. The upper bits of this MAC address are in <a href="#">Packet_classifier_cfg_reg3</a> . The other MAC address is in <a href="#">Packet_classifier_cfg_reg5</a> and

**Packet\_classifier\_cfg\_reg2 0x40**

Bits	Data Element Name	R/W	Reset Value	Description
				<a href="#">Packet_classifier_cfg_reg6</a> . Relevant only for packets received from Ethernet port.

**Packet\_classifier\_cfg\_reg3 0x44**

Bits	Data Element Name	R/W	Reset Value	Description
[31:29]	Reserved	-	0x0	Must be set to zero
[28]	Discard_packet_length_mismatch	R/W	0x0	Must be set to zero
[27]	Ip_udp_bn_loc	R/W	0x0	0 = Bundle identifier is located in the source UDP port number field in IP/UDP packets 1 = Bundle identifier located in the destination UDP port number field in IP/UDP packets See section <a href="#">10.6.13.2</a> .
[26:25]	TDMoIP_port_num_loc	R/W	0x0	Used for UDP only: 00 = <a href="#">Packet_classifier_cfg_reg4</a> .TDMoIP_port_num1/2 is ignored (no checking is performed) 01 = TDMoIP_port_num1/2 should be compared to the source UDP port number field in IP/UDP packets 10 = TDMoIP_port_num1/2 should be compared to the destination UDP port number field in IP/UDP packets 11 = Reserved See section <a href="#">10.6.13.1</a> .
[24]	Discard_switch_8	R/W	0x0	Packets with Ethertype = <a href="#">CPU_dest_ether_type</a> . See section <a href="#">10.6.13</a> . 0 = Forward to CPU 1 = Discard
[23]	Discard_switch_7	R/W	0x0	TDMoP OAM packets. See section <a href="#">10.6.13</a> . 0 = Forward to CPU 1 = Discard
[22]	Discard_switch_6	R/W	0x0	TDMoP packets whose Rx_Bundle_Identifier doesn't match any of the chip's assigned bundle numbers or OAM bundle numbers. See section <a href="#">10.6.13</a> . 0 = Forward to CPU 1 = Discard
[21]	Discard_switch_5	R/W	0x0	IP/UDP packets whose UDP destination/source port number is different from <a href="#">Packet_classifier_cfg_reg4</a> .TDMoIP_Port_Num1 or 2. See section <a href="#">10.6.13</a> . 0 = Forward to CPU 1 = Discard See <a href="#">TDMoIP_port_num_loc</a> above.
[20]	Discard_switch_4	R/W	0x0	IP packets whose IP protocol field is different from UDP or L2TPv3. See section <a href="#">10.6.13</a> . 0 = Forward to CPU 1 = Discard
[19]	Discard_switch_3	R/W	0x0	ARP packets whose IP destination address matches one of the chip's IPv4 addresses. See section <a href="#">10.6.13</a> . 0 = Forward to CPU 1 = Discard
[18]	Discard_switch_2	R/W	0x0	Packets with Ethertype different from IP, MPLS or ARP. See section <a href="#">10.6.13</a> . 0 = Forward to CPU 1 = Discard
[17]	Discard_switch_1	R/W	0x0	IP packets whose IP destination address does not match chip's IP addresses. See section <a href="#">10.6.13</a> . 0 = Forward to CPU 1 = Discard

**Packet\_classifier\_cfg\_reg3 0x44**

Bits	Data Element Name	R/W	Reset Value	Description
[16]	Discard_switch_0	R/W	0x0	ARP packets whose IP destination address does not match chip's addresses. See section <a href="#">10.6.13</a> . 0 = Forward to CPU 1 = Discard
[15:0]	MAC_add1	R/W	0x0000	This field holds bits 47:32 of the first of two MAC addresses for the device. The lower bits of this MAC address are in <a href="#">Packet_classifier_cfg_reg2</a> . The other MAC address is in <a href="#">Packet_classifier_cfg_reg5</a> and <a href="#">Packet_classifier_cfg_reg6</a> . Relevant only for packets received from Ethernet port.

**Packet\_classifier\_cfg\_reg4 0x48**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	TDMoIP_port_num2	R/W	0x085E	Packets with UDP destination port number equal to this field are recognized as TDMoIP packets. See section <a href="#">10.6.13.1</a> .
[15:0]	TDMoIP_port_num1	R/W	0x085E	Packets with UDP destination port number equal to this field are recognized as TDMoIP packets. See section <a href="#">10.6.13.1</a> .

**Packet\_classifier\_cfg\_reg5 0x4C**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	MAC_add2	R/W	0x0	This field holds bits 31:0 of the second of two MAC addresses for the device. The upper bits of this MAC address are in <a href="#">Packet_classifier_cfg_reg6</a> . The other MAC address is in <a href="#">Packet_classifier_cfg_reg2</a> and <a href="#">Packet_classifier_cfg_reg3</a> . Relevant only for packets received from Ethernet port.

**Packet\_classifier\_cfg\_reg6 0x50**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Ip_udp_bn_mask_n	R/W	0x0000	This mask Indicates the width of the bundle identifier. For example, if the desired width is 8 bits, the following should be written to this field: 000000001111111b. See section <a href="#">10.6.13.2</a> .
[15:0]	MAC_add2	R/W	0x0000	This field holds bits 47:32 of the second of two MAC addresses for the device. The lower bits of this MAC address are in <a href="#">Packet_classifier_cfg_reg5</a> . The other MAC address is in <a href="#">Packet_classifier_cfg_reg2</a> and <a href="#">Packet_classifier_cfg_reg3</a> . Relevant only for packets received from Ethernet port.

**Packet\_classifier\_cfg\_reg7 0x54**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	CPU_dest_ether_type	R/W	0x0800	Ethertype which identifies packets destined for the CPU. Such packets are sent to CPU or discarded as specified by <a href="#">Packet_classifier_cfg_reg3</a> .Discard_switch_[8:0]. This field must be set to a value greater than 0x5DC. See

**Packet\_classifier\_cfg\_reg7 0x54**

Bits	Data Element Name	R/W	Reset Value	Description
				section <a href="#">10.6.13.5</a> .
[15:0]	vlan_2nd_tag_identifier	R/W	0x8100	Second VLAN tag protocol identifier (the first is 0x8100). See section <a href="#">10.6.13.4</a> .

**Packet\_classifier\_cfg\_reg8 0x58**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	ipv4_add3	R/W	0x0	This field holds the third of three IPv4 addresses for the device. The other addresses are held in register <a href="#">Packet_classifier_cfg_reg0</a> and <a href="#">Packet_classifier_cfg_reg1</a> . Relevant only for packets received from the Ethernet port. If a third IPv4 address is not needed, this field must be configured to the same value as <a href="#">Ipv4_add1</a> .

**Packet\_classifier\_cfg\_reg9 0x5C**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Mef_ether_type	R/W	0x88d8	Ethertype for MEF packets. Must be set to a value greater than 0x5DC. See section <a href="#">10.6.13.5</a> .
[15:0]	Mef_oam_ether_type	R/W	0x0800	Ethertype for MEF OAM packets. Must be set to a value greater than 0x5DC. See section <a href="#">10.6.13.3</a> .

**Packet\_classifier\_cfg\_reg10 0x60**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	ipv6_add1[127:96]	R/W	0x0	This field holds bits 127:96 of the first of two IPv6 addresses for the device. The other address is held in registers starting with <a href="#">Packet_classifier_cfg_reg14</a> . Relevant only for packets received from the Ethernet port.

**Packet\_classifier\_cfg\_reg11 0x64**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	ipv6_add1[95:64]	R/W	0x0	This field holds bits 95:64 of the first of two IPv6 addresses for the device. The other address is held in registers starting with <a href="#">Packet_classifier_cfg_reg14</a> . Relevant only for packets received from the Ethernet port.

**Packet\_classifier\_cfg\_reg12 0x68**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	ipv6_add1[63:32]	R/W	0x0	This field holds bits 63:32 of the first of two IPv6 addresses for the device. The other address is held in registers starting with <a href="#">Packet_classifier_cfg_reg14</a> . Relevant only for packets received from the Ethernet port.

**Packet\_classifier\_cfg\_reg13 0x6C**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Ipv6_add1[31:0]	R/W	0x0	This field holds bits 31:0 of the first of two IPv6 addresses for the device. The other address is held in registers starting with <a href="#">Packet_classifier_cfg_reg14</a> . Relevant only for packets received from the Ethernet port.

**Packet\_classifier\_cfg\_reg14 0x70**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Ipv6_add2[127:96]	R/W	0x0	This field holds bits 127:96 of the second of two IPv6 addresses for the device. The other address is held in registers starting with <a href="#">Packet_classifier_cfg_reg10</a> . Relevant only for packets received from the Ethernet port. If a second IPv6 address is not needed, this field must be configured to the same value as Ipv6_add1.

**Packet\_classifier\_cfg\_reg15 0x74**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Ipv6_add2[95:64]	R/W	0x0	This field holds bits 95:64 of the second of two IPv6 addresses for the device. The other address is held in registers starting with <a href="#">Packet_classifier_cfg_reg10</a> . Relevant only for packets received from the Ethernet port. If a second IPv6 address is not needed, this field must be configured to the same value as Ipv6_add1.

**Packet\_classifier\_cfg\_reg16 0x78**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Ipv6_add2[63:32]	R/W	0x0	This field holds bits 63:32 of the second of two IPv6 addresses for the device. The other address is held in registers starting with <a href="#">Packet_classifier_cfg_reg10</a> . Relevant only for packets received from the Ethernet port. If a second IPv6 address is not needed, this field must be configured to the same value as Ipv6_add1.

**Packet\_classifier\_cfg\_reg17 0x7C**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Ipv6_add2[31:0]	R/W	0x0	This field holds bits 31:0 of the second of two IPv6 addresses for the device. The other address is held in registers starting with <a href="#">Packet_classifier_cfg_reg10</a> . Relevant only for packets received from the Ethernet port. If a second IPv6 address is not needed, this field must be configured to the same value as Ipv6_add1.

**Packet\_classifier\_cfg\_reg18 0x80**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	VCCV_oam_mask_n	R/W	0x0000	Indicates which of the 16 most significant bits of the control word should be compared to identify VCCV OAM packets. The values of the bits to be compared are stored

**Packet\_classifier\_cfg\_reg18 0x80**

Bits	Data Element Name	R/W	Reset Value	Description
				in the VCCV_oam_value field below. See section <a href="#">10.6.13.3</a> .
[15:0]	VCCV_oam_value	R/W	0x0000	Indicates the value of the 16 most significant bits of the control word for identifying VCCV OAM packets. The combination of this field and VCCV_oam_mask_n above specifies how the device does VCCV OAM identification. For example, to identify VCCV OAM packets when the 4 most significant bits of the control word are equal to 0x1, then set this field to 0x1000 and set VCCV_oam_mask_n to 0xF000. See section <a href="#">10.6.13.3</a> .

**CPU\_rx\_arb\_max\_fifo\_level\_reg 0xD4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:25]	Tx_arb_max_fifo_level	R/W	0x00	Indicates the maximum level, which the TX_FIFO has reached (given in dwords) since the last time this register was read (or since reset). The value of the field is automatically reset when this register is read by the CPU.
[24:10]	Reserved	-	0x0000	Must be set to zero
[9:0]	Rx_arb_max_fifo_level	R/W	0x000	Indicates the maximum level, which the RX_FIFO has reached (given in dwords) since the last time this register was read (or since reset). The value of the field is automatically reset when this register is read by the CPU.

### 11.4.1.2 TDMoP Status Registers

The [General\\_stat\\_reg](#) register has latched status registers that indicate hardware events. For each bit, the value 1 indicates that the event occurred. Writing 1 to a bit clears it to 0. Writing 0 to a bit does not change its value.

#### General\_stat\_reg 0xE0

Bits	Data Element Name	R/W	Reset Value	Description
[31:10]	Reserved	-	0x0	Must be set to zero
[9]	MAC_Rx_fifo_overflow	R/W	0x0	MAC Rx FIFO overflowed
[8]	Ipver_err_status	R/W	0x0	Indicates that a packet was discarded due to IP version error
[7]	Rx_fifo_sof_err	R/W	0x0	Rx FIFO was flushed due to bundle configuration error
[6]	TDM_CPU_buff_err	R/W	0x0	Frames received from TDM discarded due to lack of buffers at TDM TO CPU pool
[5]	Rx_fifo_full	R/W	0x0	Packet received from Ethernet discarded because Rx FIFO is full
[4]	MPLS_err	R/W	0x0	Received MPLS packet with more than three labels
[3]	OAM_ETH_to_CPU_q_full	R/W	0x0	OAM packet received from Ethernet and destined to CPU discarded because ETH TO CPU queue is full.
[2]	OAM_SW_buff_err	R/W	0x0	OAM packet received from Ethernet and destined to CPU discarded due to lack of SW buffers
[1]	Non_OAM_ETH_to_CPU_q_full	R/W	0x0	Non-OAM packet received from Ethernet and destined to CPU discarded because ETH TO CPU queue is full.
[0]	Non_OAM_SW_buff_err	R/W	0x0	Non-OAM packet received from Ethernet and destined to CPU discarded due to lack of SW buffers.

#### Version\_reg 0xE4

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Chip_version_reg	R/O	0xABCD EF01	Contains the chip version for the TDMoP block

The [Port\[n\]\\_sticky\\_reg1](#) register has latched status bits that indicate port hardware events. For each bit, the value 1 indicates that the event occurred. Writing 1 to a bit clears it to 0. Writing 0 to a bit does not change its value. The index *n* indicates port number: 1-8 for DS34S108, 1-4 for DS34S104, 1-2 for DS34S102, 1 only for DS34S101.

#### Port[n]\_sticky\_reg1 0xE4+n\*4

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7]	Dpll_overflow	R/W	0x0	Port clock recovery DPLL overflowed
[6]	Cdc_detected	R/W	0x0	Port clock recovery detected constant delay change in the network
[5]	Smart_self_test_failed	R/W	0x0	Provided for debug purposes
[4]	Smart_timeout_expired	R/W	0x0	Provided for debug purposes
[3]	Sticky_filter_overflow	R/W	0x0	Port clock recovery loop filter overflowed
[2]	Virtual_jitter_buffer_or_ur	R/W	0x0	Port clock recovery virtual jitter buffer reached overrun/underrun state
[1]	Reacquisition_alarm	R/W	0x0	Provided for debug purposes
[0]	Adapt_freeze_state	R/W	0x0	Port clock recovery mechanism is in freeze state

The [Port\[n\]\\_stat\\_reg1](#) register has real-time (not latched) status fields. The index **n** indicates port number: 1-8 for DS34S108, 1-4 for DS34S104, 1-2 for DS34S102, 1 only for DS34S101.

**Port[n]\_stat\_reg1 0x100+n\*8**

Bits	Data Element Name	R/W	Reset Value	Description
[31:25]	Reserved	-	0x0	Must be set to zero
[24]	Smart_disabled	RO	0x0	not documented
[23:5]	DPLL_level	RO	0x0	not documented
[4:2]	Adapt_current_state	RO	0x0	Port n clock recovery current state: 0 = Idle 2 = Acquisition 3 = Tracking1 4 = Tracking2 5 = Recover from Underrun/Overrun
[1]	RTS	RO	0x0	When the <a href="#">Port[n]_cfg_reg.Int_type</a> field specifies a serial interface, the value of the <a href="#">TDMn_RSIG_RTS</a> pin—which behaves as RTS (Request To Send)—can be read from this bit.
[0]	TSA_int_act_blk	RO	0x0	Indicates which bank is active: 0 = Port n TSA bank1 is active 1 = Port n TSA bank2 is active

The [Port\[n\]\\_stat\\_reg2](#) register has real-time (not latched) status fields. The index **n** indicates port number: 1-8 for DS34S108, 1-4 for DS34S104, 1-2 for DS34S102, 1 only for DS34S101.

**11.4.2 Bundle Configuration Tables**

The base address for the TDMoP bundle configuration tables is **0x8,000**. Bundle configurations are 160 bits long and therefore span five 32-bit words. The least-significant 32-bit word of a bundle configuration is located at address offset 0x000 + BundleNumber x 4. The most-significant 32-bit word is located at address offset 0x400 + BundleNumber x 4. There are 64 bundles numbered 0 to 63. In the register descriptions in this section the index **n** indicates bundle number: 0 to 63.

Each bundle can be one of three different types: [AAL1](#), [HDLC](#) or [SAToP/CESoPSN](#). Subsections [11.4.2.1](#) through [11.4.2.3](#) describe the bundle configuration fields for each of the four types. Some fields are common to two or more of the bundle types. The payload type is specified in the Payload\_type\_machine field, bits 21:20 of xxxx\_Bundle[n]\_cfg[63:32].

**11.4.2.1 AAL1 Bundle Configuration**

In the register descriptions below, the index **n** indicates the bundle number: 0 to 63.

**AAL1\_Bundle[n]\_cfg[31:0] 0x000+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Rx_bundle_identifier	R/W	None	Holds the Rx bundle number

**AAL1\_Bundle[n]\_cfg[63:32] 0x100+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:22]	Rx_max_buff_size	R/W	None	The size of the jitter buffer. See section 10.6.10. Also the maximum time interval for which data is stored. The resolution is determined by the interface type as follows: For framed E1/T1: 0.5 ms. For unframed E1/T1 or serial bundles: 1024 bit periods For high-speed interface: 4096 bit periods. Allowed values: For T1-SF: Rx_max_buff_size ≤ 0x2FC For T1-ESF: Rx_max_buff_size ≤ 0x2F9 For E1-MF: Rx_max_buff_size ≤ 0x3FB For all interface types, the Rx_max_buff_size must be greater than Rx_PDVT + PCT (Packet Creation Time). <b>Note:</b> For unframed, the Rx_max_buff_size resolution is different than PDVT resolution.
[21:20]	Payload_type_machine	R/W	None	00 = HDLC 01 = AAL1 10 = Reserved 11 = SAToP/CESoPSN
[19]	Tx_RTP (Tx is toward Ethernet MAC)	R/W	None	0 = RTP header does not exist in transmitted packets 1 = RTP header exists in transmitted packets
[18]	Control_Word_exists	R/W	None	0 = Control word does not exist 1 = Control word exists (default, standard mode)
[17:16]	Tx_dest	R/W	None	Destination of packets: 00 = Reserved 01 = Ethernet 10 = CPU 11 = TDM (Cross-connect). See section 10.6.11.10.
[15:9]	Rx_max_lost_packets	R/W	None	The maximum number of Rx packets inserted upon detection of lost packets
[8:4]	Number_of_ts	R/W	None	One less than number of assigned timeslots per bundle. When Rx_AAL1_bundle_type='00' (unstructured) then Number_of_ts=31; this applies also to high speed mode.
[3]	Rx_discard_sanity_fail	R/W	None	0 = Discard AAL1 packets which fail the sanity check 1 = Don't discard the above packets See section 10.6.13.8.
[2:1]	Header_type	R/W	None	00 = MPLS 01 = UDP over IP 10 = L2TPv3 over IP 11 = MEF
[0]	Tx_R_bit	R/W	None	0 = Don't set R bit in header of transmitted packets 1 = Set R bit

**AAL1\_Bundle[n]\_cfg[95:64] 0x200+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31]	Reserved	R/W	None	Must be set to zero
[30]	Tx_cond_data	R/W	None	0 = Regular operation 1 = Use conditioning octet specified by Tx_cond_octet_type for transmitted packets
[29]	Tx_dest_framing	R/W	None	Only applies to T1 framed traffic. See section 10.6.5. 0 = Destination framer operates in SF framing 1 = Destination framer operates in ESF framing
[28]	Tx_CAS_source	R/W	None	Source of transmit CAS bits: 0 = TDMoP block's RSIG input 1 = Tx software CAS table (section 11.4.9)
[27:13]	Reserved	-	None	Must be set to zero
[12:11]	Tx_AAL1_bundle_type	R/W	None	Bundle type of transmitted payload:

**AAL1\_Bundle[n]\_cfg[95:64] 0x200+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
				00 = Unstructured 01 = Structured 10 = Structured with CAS 11 = Reserved
[10:6]	Reserved	R/W	None	Must be set to zero
[5:4]	Tx_cond_octet_type	R/W	None	Selects the ETH_cond_octet from <a href="#">ETH_cond_data_reg</a> to be transmitted towards packet network: 00 = ETH_cond_octet_a 01 = ETH_cond_octet_b 10 = ETH_cond_octet_c 11 = ETH_cond_octet_d
[3:2]	Rx_AAL1_bundle_type	R/W	None	Bundle type of received packets: 00 = Unstructured 01 = Structured 10 = Structured with CAS 11 = Reserved
[1:0]	Protection_mode	R/W	None	00 = Stop sending packets 01 = Send each packet once with the first header 10 = Send each packet once with the second header 11 = Send each packet twice: once with the first header and once with the second header See section <a href="#">10.6.16</a> .

**AAL1\_Bundle[n]\_cfg[127:96] 0x300+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31]	Reserved	R/W	None	Must be set to zero
[30:16]	Rx_PDVT	R/W	None	Packet delay variation time value for AAL1 bundles. See section <a href="#">10.6.10</a> . Bits [30:26] are used only when unframed. The resolution is determined by the interface type as follows: For framed E1/T1: 0.5 ms For unframed E1/T1 or serial bundles: 32 bit periods For high speed interface: 128 bit periods Allowed values: Minimum allowed value: 3 (for all interfaces types) For T1 SF, ESF: Rx_PDVT < 0x300
[15]	Rx_CAS_src	R/W	None	Source of signaling conditioning towards TDM: 0 = SDRAM signaling jitter buffer 1 = Rx SW CAS table (section <a href="#">11.4.13</a> )
[14]	Rx_cell_chk_ignore	R/W	None	0 = Discard AAL1 SAR PDUs with header parity/CRC errors 1 = Ignore AAL1 SAR PDU header (CRC /parity) checks Including AAL1 pointer parity error
[13]	Reserved	R/W	None	Must be set to zero
[12]	OAM_ID_in_CW	R/W	None	0 = Ignore the OAM packet indication in the control word 1 = Check the OAM packet indication in the control word See section <a href="#">10.6.13.3</a> .
[11]	Rx_discard	R/W	None	0 = Pass through all incoming packets 1 = Discard all incoming packets
[10]	Rx_dest	R/W	None	0 = TDM 1 = CPU
[9:8]	Tx_MPLS_labels_l2tpv3_cookies	R/W	None	For MPLS: 00 = Reserved 01 = One label in the TX MPLS stack 10 = Two labels in the TX MPLS stack 11 = Three labels in the TX MPLS stack For L2TPv3:

**AAL1\_Bundle[n]\_cfg[127:96] 0x300+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
				00 = No cookies in the TX L2TPv3 header 01 = One cookie in the TX L2TPv3 header 10 = Two cookies in the TX L2TPv3 header 11 = Reserved
[7:4]	Port_num	R/W	None	The port number which the bundle is assigned to: 0000 = Port 1, 0111=Port 8
[3:2]	Tx_VLAN_stack	R/W	None	00 = No VLAN tag in header 01 = One VLAN tag exists in header 10 = Two VLAN tags exist in header 11 = Reserved Not valid for Rx. Not used by Tx AAL1 but by Ethernet transmitter block
[1]	Rx_bundle_identifier_valid	R/W	None	0 = <a href="#">Rx_bundle_identifier</a> entry isn't valid: If the incoming frame bundle identifier isn't found in the whole packet classifier table, the incoming frame is handled according to packet classifier discard switches in <a href="#">Packet_classifier_cfg_reg3</a> . 1 = Rx_Bundle_Identifier entry is valid
[0]	Reserved	R/W	None	Must be set to zero

**AAL1\_Bundle[n]\_cfg[159:128] 0x400+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:23]	Reserved	R/W	None	Must be set to zero
[22]	Rx_RTP	R/W	None	0 = RTP header does not exist in received packets 1 = RTP header exists in received packets
[21:20]	Rx_L2TPV3_cookies	R/W	None	For MPLS: 00 = Reserved 01 = One label in the received MPLS stack 10 = Two label in the received MPLS stack 11 = Three label in the received MPLS stack For L2TPv3: 00 = No cookies in the received L2TPv3 header 01 = One cookie in the received L2TPv3 header 10 = Two cookies in the received L2TPv3 header 11 = Reserved
[19:15]	Reserved	R/W	None	Must be set to zero.
[14:10]	Packet_size_in_cells	R/W	None	AAL1 SAR PDUs per frame: 1 - 30
[9:5]	Tx_bundle_identifier	R/W	None	Tx bundle Identifier upper bits Used only for TX_AAL1 old format
[4:0]	Reserved	R/W	None	Must be set to zero

**11.4.2.2 HDLC Bundle Configuration**

In the register descriptions below, the index **n** indicates the bundle number: 0 to 63.

**HDLC\_Bundle[n]\_cfg[31:0] 0x000+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Rx_bundle_identifier	R/W	None	Holds the Rx bundle number

**HDLC\_Bundle[n]\_cfg[63:32] 0x100+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:22]	Reserved	R/W	None	Must be set to zero

**HDLC\_Bundle[n]\_cfg[63:32] 0x100+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[21:20]	Payload_type_machine	R/W	None	00 = HDLC 01 = AAL1 10 = Reserved 11 = SAToP/CESoPSN
[19]	Tx_RTP	R/W	None	0 = RTP header does not exist in transmitted packets 1 = RTP header exists in transmitted packets
[18]	Control_Word_exists	R/W	None	0 = Control word does not exist 1 = Control word exists (default, standard mode)
[17:16]	Tx_dest	R/W	None	Destination of packets: 00 = Reserved 01 = Ethernet 10 = CPU 11 = Reserved
[15:11]	Reserved	R/W	None	Must be set to zero.
[10:9]	Packet_SN_mode	R/W	None	Transmitted and expected sequence number is: 00 = Always 0 01 = Incremented normally in wrap-around manner 10 = Reserved 11 = Incremented in wrap-around manner but skips 0
[8:3]	Reserved	R/W	None	Must be set to zero.
[2:1]	Header_type	R/W	None	00 = MPLS 01 = UDP over IP 10 = L2TPv3 over IP 11 = MEF
[0]	Tx_R_bit	R/W	None	0 = Don't set R bit in header of transmitted packets 1 = Set R bit

**HDLC\_Bundle[n]\_cfg[95:64] 0x200+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Reserved	R/W	None	Must be set to zero
[15:13]	Reserved	R/W	None	Must be set to zero
[12:2]	Tx_max_frame_size	R/W	None	Tx HDLC maximum transmitted packet size in bytes. This does not include FCS.
[1:0]	Reserved	R/W	None	Must be set to zero

**HDLC\_Bundle[n]\_cfg[127:96] 0x300+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:28]	Reserved	R/W	None	Must be set to zero
[27]	Tx_stop	R/W	None	0 = Send one packet with the 1st header 1 = Stop transmission
[26:13]	Reserved		None	Must be set to zero
[12]	OAM_ID_in_CW	R/W	None	0 = Ignore the OAM packet indication in the control word 1 = Check the OAM packet indication in the control word
[11]	Rx_discard	R/W	None	0 = Pass through all incoming packets 1 = Discard all incoming packets
[10]	Rx_dest	R/W	None	0 = TDM 1 = CPU
[9:8]	Tx_MPLS_labels_l2tpv3_cookies	R/W	None	For MPLS: 00 = Reserved 01 = One label in the TX MPLS stack 10 = Two labels in the TX MPLS stack 11 = Three labels in the TX MPLS stack For L2TPv3:

**HDLC\_Bundle[n]\_cfg[127:96] 0x300+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
				00 = No cookies in the TX L2TPv3 header 01 = One cookie in the TX L2TPv3 header 10 = Two cookies in the TX L2TPv3 header 11 = Reserved
[7:4]	Port_num	R/W	None	The port number which the bundle is assigned to: 0000 = Port 1, 0111=Port 8
[3:2]	Tx_VLAN_stack	R/W	None	00 = No VLAN tag in header 01 = One VLAN tag exists in header 10 = Two VLAN tags exist in header 11 = Reserved Not valid for Rx. Not used by Tx AAL1 but by Ethernet MAC transmit block
[1]	Rx_Bundle_Identifier_valid	R/W	None	0 = <a href="#">Rx_bundle_identifier</a> entry isn't valid: If the incoming frame bundle identifier isn't found in the whole packet classifier table, the incoming frame is handled according to discard switches in ( <a href="#">Packet_classifier_cfg_reg3</a> ) 1 = Rx_Bundle_Identifier entry is valid
[0]	Reserved	R/W	None	Must be set to zero

**HDLC\_Bundle[n]\_cfg[159:128] 0x400+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:22]	Reserved		0x000	Must be set to zero
[21:20]	Rx_L2TPV3_cookies	R/W	None	For MPLS: 00 = Reserved 01 = One label in the received MPLS stack 10 = Two label in the received MPLS stack 11 = Three label in the received MPLS stack For L2TPv3: 00 = No cookies in the received L2TPv3 header 01 = One cookie in the received L2TPv3 header 10 = Two cookies in the received L2TPv3 header 11 = Reserved
[19:16]	Reserved	R/W	None	
[15:0]	Tx_IP_checksum	R/W	None	IP header checksum for IP total length equal to zero Explain more. Also, why isn't this in AAL1?

**11.4.2.3 SAToP/CESoPSN Bundle Configuration**

In the register descriptions below, the index **n** indicates bundle number: 0 to 63.

**SAToP/CESoPSN\_Bundle[n]\_cfg[31:0] 0x000+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Rx_bundle_identifier	R/W	None	Holds the Rx bundle number

**SAToP/CESoPSN\_Bundle[n]\_cfg[63:32] 0x100+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:22]	Rx_max_buff_size	R/W	None	The size of the jitter buffer. See section <a href="#">10.6.10</a> . Also the maximum time interval for which data is stored. The resolution is determined by the interface type as follows: For framed E1/T1: 0.5 ms.

**SAToP/CESoPSN\_Bundle[n]\_cfg[63:32] 0x100+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
				For unframed E1/T1 or serial bundles: 1024 bit periods For high speed interface: 4096 bit periods. Allowed values: For T1-SF: $RX\_max\_buff\_size \leq 2FChex$ For T1-ESF: $RX\_max\_buff\_size \leq 0x2F9$ For E1-MF: $RX\_max\_buff\_size \leq 0x3FB$ For all interface types the $RX\_max\_buff\_size$ must be greater than $Rx\_PDVT + PCT$ (Packet Creation Time). Note: For unframed, the $RX\_max\_buff\_size$ resolution is different than the $Rx\_PDVT$ resolution.
[21:20]	Payload_type_machine	R/W	None	00 = HDLC 01 = AAL1 10 = Reserved 11 = SAToP/CESoPSN
[19]	Tx_RTP	R/W	None	0 = RTP header does not exist in transmitted packets 1 = RTP header exists in transmitted packets
[18]	Control_Word_exists	R/W	None	0 = Control word does not exist 1 = Control word exists (default, standard mode)
[17:16]	Tx_dest	R/W	None	Destination of packets: 01 = Ethernet 10 = CPU 11 = TDM-Rx (cross-connect) 00 = Reserved
[15:9]	Rx_max_lost_packets	R/W	None	The maximum number of Rx packets inserted upon detection of lost packets
[8:4]	Number_of_ts	R/W	None	One less than number of assigned timeslots per bundle. Not relevant for unstructured bundles, or when working in high speed mode.
[3]	Rx_discard_sanity_fail	R/W	None	0 = Don't discard the above packets 1 = Discard SAToP/CESoPSN packets which fail the sanity check See section <a href="#">10.6.13.8</a> .
[2:1]	Header_type	R/W	None	00 = MPLS 01 = UDP over IP 10 = L2TPv3 over IP 11 = MEF
[0]	Tx_R_bit	R/W	None	0 = Don't set R bit in header of transmitted packets 1 = Set R bit

**SAToP/CESoPSN\_Bundle[n]\_cfg[95:64] 0x200+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31]	Reserved	R/W	None	Must be set to zero
[30]	Tx_cond_data	R/W	None	0 = Regular operation 1 = Use conditioning octet specified by <a href="#">Tx_cond_octet_type</a> for transmitted packets
[29]	Tx_dest_framing	R/W	None	Only applies to T1 framed traffic 0 = Destination framer operates in SF framing 1 = Destination framer operates in ESF framing
[28]	Tx_CAS_source	R/W	None	Source of transmit CAS bits: 0 = TDMoP block's RSIG input 1 = Tx software CAS table See sections <a href="#">10.6.5</a> and <a href="#">11.4.9</a> .
[27]	Reserved	R/W	None	Must be set to zero
[26:16]	TDM_frames_in_packet or TDM_bytes_in_packet	R/W	None	For structured and structured with CAS CESoPSN bundles: number of TDM frames included in each packet. For SAToP bundles: number of TDM bytes included in each packet.

**SAToP/CESoPSN\_Bundle[n]\_cfg[95:64] 0x200+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
				Note: For Structured with CAS bundles the allowed values are: E1 MF: 16, 8, 4, 2, 1 T1 SF/ESF: 24, 12, 8, 6, 4, 3, 2, 1
[15:13]	Reserved	R/W	None	Must be set to zero
[12:11]	Tx_SATOP_bundle_type	R/W	None	Bundle type of transmitted payload: 00 = Unstructured 01 = Structured 10 = Structured with CAS 11 = Reserved
[10:6]	Reserved	R/W	None	Must be set to zero.
[5:4]	Tx_cond_octet_type	R/W	None	Selects the ETH_cond_octet from <a href="#">ETH_cond_data_reg</a> to be transmitted towards packet network: 00 = ETH_cond_octet_a 01 = ETH_cond_octet_b 10 = ETH_cond_octet_c 11 = ETH_cond_octet_d
[3:2]	Rx_SAToP/CESoPSN_bundle_type	R/W	None	Bundle type of received packets: 00 = Unstructured 01 = Structured 10 = Structured with CAS 11 = Reserved
[1:0]	Protection_mode	R/W	None	00 = Stop sending packets 01 = Send each packet once with the first header 10 = Send each packet once with the second header 11 = Send each packet twice: one with the first header and one with the second header

**SAToP/CESoPSN\_Bundle[n]\_cfg[127:96] 0x300+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31]	Reserved	R/W	None	Must be set to zero.
[30:16]	Rx_PDVT	R/W	None	Packet delay variation time value for SAToP/CESoPSN bundles. See section <a href="#">10.6.10</a> . Bits[30:26] are used only when unframed. The resolution is determined by the interface type as follows: For framed E1/T1: 0.5 ms For unframed E1/T1 or serial bundles: 32 bit periods For high speed interface: 128 bit periods Allowed values: Minimum allowed value: 3 (for all interface types) For T1 SF, ESF: Rx_PDVT < 0x300
[15]	Rx_CAS_src	R/W	None	Source of signaling towards TDM: 0 = SDRAM signaling jitter buffer 1 = Rx SW CAS tables (section <a href="#">11.4.13</a> )
[14]	Rx_enable_reorder	R/W	None	0 = Disable reorder 1 = Enable reorder
[13]	Reserved	R/W	None	Must be set to zero

[11]	Rx_discard	R/W	None	0 = Pass through all incoming packets 1 = Discard all incoming packets
[10]	Rx_dest	R/W	None	0 = TDM 1 = CPU
[9:8]	Tx_MPLS_labels_l2tpv3_cookies	R/W	None	For MPLS: 00 = Reserved 01 = One label in the TX MPLS stack 10 = Two labels in the TX MPLS stack

**SAToP/CESoPSN\_Bundle[n]\_cfg[127:96] 0x300+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
				11 = Three labels in the TX MPLS stack For L2TPv3: 00 = No cookies in the TX L2TPv3 header 01 = One cookie in the TX L2TPv3 header 10 = Two cookies in the TX L2TPv3 header 11 = Reserved
[7:4]	Port_num	R/W	None	The port number which the bundle is assigned to: 0000 = Port 1, 0111=Port 8
[3:2]	Tx_VLAN_stack			00 = No VLAN tag in header 01 = One VLAN tag exists in header 10 = Two VLAN tags exist in header 11 = Reserved Not valid for Rx. Not used by Tx AAL1 but by Ethernet MAC transmitter block
[1]	Rx_Bundle_Identifier_valid	R/W	None	0 = <a href="#">Rx_bundle_identifier</a> entry isn't valid: If the incoming frame bundle identifier isn't found in the whole packet classifier table, the incoming frame is handled according to packet classifier discard switches in <a href="#">Packet_classifier_cfg_reg3</a> 1 = Rx_Bundle_Identifier entry is valid
[0]	Reserved	R/W	None	Must be set to zero

**SAToP/CESoPSN\_Bundle[n]\_cfg[159:128] 0x400+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:24]	Reserved		0x00	Must be set to zero
[23]	Last_value_insertion	R/W	None	Enables the insertion of the last received timeslot value in case packet loss was detected. This insertion is only performed if 3 frames or less of data per timeslot is lost. If more than 3 frames of data are lost, the insertion is not performed and, instead, conditioning is inserted as usual). 0 = last value insertion disabled 1 = last value insertion enabled
[22]	Rx_RTP	R/W	None	0 = RTP header doesn't exist in received packets 1 = RTP header exists in received packets
[21:20]	Rx_L2TPV3_cookies	R/W	None	For MPLS: 00 = Reserved 01 = One label in the received MPLS stack 10 = Two label in the received MPLS stack 11 = Three label in the received MPLS stack For L2TPv3: 00 = No cookies in the received L2TPv3 header 01 = One cookie in the received L2TPv3 header 10 = Two cookies in the received L2TPv3 header 11 = Reserved
[19:16]	Reserved	R/W	None	Must be set to zero
[15:0]	Tx_IP_checksum	R/W	None	IP header checksum for IP total length equal to zero

### 11.4.3 Counters

Each counter can be read from two different addresses. Reading from the first address—**0x10,000** + offset—does not affect the counter value. Reading from the second address—**0x11,000** + offset—causes the counter to be cleared after it is read.

**Table 11-6. Counters Types**

Address	Counter Type	Read/Write	Reset Value
10,000	Counters – no clear on read	Read Only	None
11,000	Counters – clear on read	Read Only-Clear on Read	None

When reading from counters wider than 16 bits in 16-bit mode, use the following procedure:

1. Read from address 2, i.e. [H\\_AD\[1\]=1](#). All 32 bits are internally latched and bits 15:0 are output on [H\\_D\[15:0\]](#).
2. Read from address 0, i.e. [H\\_AD \[1\]=0](#). Bits 31:16 are output on [H\\_D\[15:0\]](#).

#### 11.4.3.1 Per Bundle Counters

In the register descriptions in this section, the index **n** indicates the bundle number: 0 to 63.

##### Ethernet Rx Good Packets Counter 0x000+n\*4

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Good_packets_received	R	None	Good packets received from Ethernet. Counter wraps around to 0 from its maximum value.

##### Ethernet Tx Good Packets Counter 0x200+n\*4

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Good_packets_transmitted	R	None	Good packets transmitted to Ethernet. Counter wraps around to 0 from its maximum value.

##### Ethernet Rx Lost/Jump Event Packets Counter 0x300+n\*4

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Reserved	-	None	Must be set to zero
[15:0]	Lost_AAL1_packets_Rxd / Lost_HDLC_packets_Rxd / Jumped_SAToP/CESoPSN_packets_Rxd	R	None	<p>Number of lost/jumped packets encountered by RX_AAL1, RX_HDLC or RX_SATOP payload machine:</p> <p>AAL1 and SAToP/CESoPSN – The counter is increased by the gap between the received packet sequence number and the expected packet sequence number (except when this gap is higher than the configured <a href="#">Rx_max_lost_packets</a> value).</p> <p>HDLC – The counter is increased by the difference between the received packet sequence number and the expected packet sequence number only when this difference is smaller than 32768.</p> <p>SAToP/CESoPSN – the CPU can calculate the number of lost packets using the following equation: lost packets = (jumped packets – <a href="#">Rxd reordered packets</a>)</p>

**Ethernet Rx AAL1 Lost Cells / Rx SAToP/CESoPSN Discarded Packets Counter 0x400+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Reserved	-	None	Must be set to zero
[15:0]	Lost_AAL1_Rxd_cells /  Discarded_SAToP/CESoPSN_Rxd_packets	R	None	AAL1 – Number of lost AAL1 SAR PDUs  SAToP/CESoPSN – Number of received packets that were discarded by SAToP/CESoPSN hardware machine.

**TDM Tx HDLC Frames with Error Counter 0x500+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Reserved	-	None	Must be set to zero
[15:0]	TDM_HDLC_err_frames	R	None	Number of HDLC frames from TDM with any error, including CRC/alignment/abort/short/long. Counter sticks at its maximum value and does not roll over to 0.

**TDM Tx HDLC Good Frames Counter 0x600+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Reserved	-	None	Must be set to zero
[31:0]	TDM_HDLC_good_frames	R	None	HDLC good frames received from TDM (passed CRC). Counter wraps around to 0 from its maximum value.

**TDM Rx SAToP/CESoPSN Reordered Packets / HDLC/AAL1 Packet SN Error Outside Window Counter 0x100+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	SAToP/CESoPSN_Rxd_re_order ed_packets /  HDLC_packet_sn_oo_window /  AAL1_packet_sn_oo_window	R	None	SAToP/CESoPSN – Number of received misordered packets that were successfully reordered by SAToP/CESoPSN hardware machine. The counter is incremented each time a miss-ordered packet is received and saved in the SDRAM.  HDLC – Counter incremented by 1 when SN error outside window is detected (window of 32,768).  AAL1 – Counter incremented by 1 when SN error outside window is detected (window configured by <a href="#">Rx_max_lost_packets</a> ).  Counter sticks at its maximum value and does not roll over to 0.

### 11.4.3.2 Per Jitter Buffer Index Counters

In the register description in this section, the index **n** indicates the jitter buffer number: 0 to 255.

#### Jitter Buffer Underrun/Overflow Events Counter 0x800+n\*4

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	None	Must be set to zero
[7:0]	JBC_events	R	None	Number of jitter buffer underrun/overflow events.  AAL1/SAToP/CESoPSN bundles – count of underrun events. AAL1 counter does not include underruns caused by pointer mismatches.  HDLC bundles – count of overflow events.  Counter sticks at its maximum value and does not roll over to 0.

### 11.4.3.3 General Counters

#### Received Ethernet Bytes Counter 0xE00

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	ETH_bytes_received	R	0x0000 0000	Total bytes received from Ethernet (good packets which passed CRC check only). CRC bytes are not counted. Counter wraps around to 0 from its maximum value.

#### Transmitted Ethernet Bytes Counter 0xE04

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	ETH_bytes_transmitted	R	0x0000 0000	Total bytes transmitted to Ethernet (good packets which passed CRC check only). CRC bytes are not counted. Counter wraps around to 0 from its maximum value.

#### Classified Packets Counter 0xE08

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Classified_packets	R	0x0000 0000	Counts all packets that pass the packet classifier towards TDM or CPU and are not discarded. Counter wraps around to 0 from its maximum value.

#### Received IP Checksum Errors Counter 0xE0C

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Reserved	-	0x0000	Must be set to zero
[15:0]	IP_checksum_err_packets	R	0x0000	Counts packets, detected by the packet classifier, as packets with IP checksum errors. Counter sticks at its maximum value and does not roll over to 0.

### 11.4.4 Status Tables

The TDMoP status tables hold indications of hardware events. Except where noted, these are latched status bits. For each bit, the value 1 indicates that the event occurred. A bit set to 1 maintains its value unless the host CPU changes it. Writing 1 to a bit clears it to 0. Writing 0 to a bit does not change its value. The base address for the TDMoP status tables is **0x12,000**.

#### 11.4.4.1 Per Bundle Status Tables

In the register descriptions in this section, the index **n** indicates the bundle number: 0 to 63.

##### Rx Payload Type Machine Status 0x000+n\*4

Bits	Data Element Name	R/W	Reset Value	Description
[31:5]	Reserved	-	None	Must be set to zero
[4]	Rx_SAToP/CESoPSN_frame_count_err			SAToP/CESoPSN – packets that belong to structured-with-CAS bundles were received with incorrect number of frames.
[3]	Rx_AAL1_cell_hdr_err / Rx_SAToP/CESoPSN_jump_overflow_err /	R/W	None	AAL1 – AAL1 SAR PDUs received with incorrect SN (sequence number), protection fields (CRC/parity), corrected and not corrected AAL1 SAR PDU header.  SAToP/CESoPSN – Packets received with incorrect sequence number (higher than the expected sequence number and within the window allowed by the configured Rx_max_lost_packets value) and could not be inserted into the jitter buffer due to insufficient space.
[2]	Rx_AAL1_packet_sn_oo_window / Rx_HDLC_packet_sn_oo_window / Rx_SAToP/CESoPSN_packet_sn_oo_window	R/W	None	HDLC – Packet SN (Sequence Number) error outside window (window of 32768)  SAToP/CESoPSN/AAL1 – Packets discarded due to incorrect Sequence Number (SN equal to the former or gap between them exceeds limit determined by <a href="#">Rx_max_lost_packets</a> parameter).
[1]	Rx_AAL1_packet_sn_in_window / Rx_HDLC_packet_sn_in_window / Rx_SAToP/CESoPSN_overrun_discard	R/W	None	AAL1 – Packet sequence number error within window (determined by <a href="#">Rx_max_lost_packets</a> parameter)  HDLC – Packet sequence number error within window (window of 32768)  SAToP/CESoPSN – Packets discarded because the Jitter Buffer reached or was in the over-run state.
[0]	Rx_AAL1_ptr_mismatch / Rx_SAToP/CESoPSN_miss_ordered_discard	R/W	None	AAL1 – SAR PDUs received with pointer mismatch  SAToP/CESoPSN – Packets discarded because they were considered duplicated, or because they were received too late to be inserted into the Jitter Buffer.

##### Tx Payload Type Machine Status 0x200+n\*4

Bits	Data Element Name	R/W	Reset Value	Description
[31:5]	Reserved	-	None	Must be set to zero
[4]	Tx_HDLC_abort	R/W	None	HDLC – received frame from TDM with abort indication
[3]	Tx_HDLC_short	R/W	None	HDLC – received frame from TDM shorter than 4 bytes (including CRC bytes)
[2]	Tx_HDLC_long	R/W	None	HDLC – received frame from TDM longer than maximum allowed length ( <a href="#">Tx_max_frame_size</a> )

**Tx Payload Type Machine Status 0x200+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[1]	Tx_HDLC_align_err	R/W	None	HDLC – received frame from TDM with alignment error
[0]	Tx_AAL1_framing_mismatch / Tx_HDLC_CRC_err / Tx_SAToP/CESoPSN_framing_mismatch	R/W	None	AAL1 – Start of TDM frame or start of TDM multiframe mismatch HDLC – received frame from TDM with CRC error SAToP/CESoPSN – Start of TDM frame or start of TDM multiframe mismatch

**Tx Buffers Status 0x400+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:1]	Reserved	-	None	Must be set to zero
[0]	TDM_to_ETH_buff_err	R/W	None	Frames received from TDM were discarded due to lack of Tx buffers

**Packet Classifier Status 0x600+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	None	Must be set to zero
[7]	Packet_length_error	R/W	None	Packet discarded due to mismatch between IP_length/Control_word_length (for MPLS/MEF) and the actual length according to the following rules: IP packets – If IP_length > (actual payload + ip_hdr + CW + RTP) MPLS/MEF packets – If Control_word_length > actual payload length + CW + RTP
[6]	Rx_sync_loss	RO	None	received packet with “L” indication
[5]	Rx_remote_fail	RO	None	received packet with “R” indication
[4:3]	Rx_Lbit_modifier	RO	None	received packet with “M” indication
[2:1]	Fragmentation_bits	RO	None	Relevant for SAToP/CESoPSN payload type machine: 00 = Entire (unfragmented) multi-frame structure is carried in a single packet 01 = Packet carrying the first fragment 10 = Packet carrying the last fragment 11 = Packet carrying an intermediate fragment
[0]	Rx_length_mismatch_discard	R/W	None	Packet discarded due to mismatch between the packet length and the configuration (for AAL1 and SAToP/CESoPSN bundles only)

**11.4.4.2 Per JBC Index Tables**

In the register descriptions in this section, the index **n** indicates the jitter buffer number: 0 to 255.

**Rx JBC Status 0xC00+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:1]	Reserved	-	None	Must be set to zero
[0]	JBC_overrun	R/W	None	AAL1 – overrun has occurred HDLC – overrun has occurred SAToP/CESoPSN – overrun has occurred

### **11.4.5 Timeslot Assignment Tables**

Each port has two banks of timeslot assignment (TSA) tables, bank 1 and bank 2. While one bank is actively used by the TDMoP block, the other bank can be written by the CPU. The active bank for the port is specified by the [TSA\\_act\\_blk](#) field in the [Port\[n\]\\_cfg\\_reg](#) register.

The base address for the TDMoP status tables is **0x18,000**. From this base address:

- Bank 1 TSA tables are located at offset **0x000** for ports 1 to 4 and **0x400** for ports 5 to 8.
- Bank 2 TSA tables are located at offset **0x200** for ports 1 to 4 and **0x600** for ports 5 to 8.

In the register descriptions in this section, the index **port** indicates the port number: 1-8 for DS34S108, 1-4 for DS34S104, 1-2 for DS34S102, 1 only for DS34S101. The index **ts** is the timeslot number: 0 to 31.

**Bank1 Timeslot Assignment Registers**
**Ports 1 to 4: 0x000+(port-1)\*0x80+ts\*4**
**Ports 5 to 8: 0x400+(port-5)\*0x80+ts\*4**
**Bank2 Timeslot Assignment Registers**
**Ports 1 to 4: 0x200+(port-1)\*0x80+ts\*4**
**Ports 5 to 8: 0x600+(port-5)\*0x80+ts\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:21]	Reserved	-	None	Must be set to zero
[20]	Remote_loop	R/W	None	When set, establishes a loop (per timeslot) between the data received from the Ethernet port and the data transmitted towards the Ethernet port.  Notes: <i>Usually the remote loop is activated on all timeslots assigned to a bundle.</i> <i>Only the TDM data is looped back. CAS information is not looped back.</i> <i>Available only when interface is configured to single clock mode (<a href="#">Port[n]_cfg_reg.Two_clocks=0</a>).</i>
[19]	Local_loop	R/W	None	When set, establishes a loop (per timeslot) between the data received from the TDM port and the data transmitted towards the TDM port. The data transmitted towards the TDM port is delayed by one TDM frame vs. the received data.  Notes: <i>Usually the local loop is activated on all timeslots assigned to a bundle.</i> <i>Only the TDM data is looped back. CAS information is not looped back.</i> <i>Available only when interface is configured to single clock mode (<a href="#">Port[n]_cfg_reg.Two_clocks=0</a>).</i>
[18]	Structured_type	R/W		Must be set for timeslots that are part of AAL1/CESoPSN bundles whose type is structured or structured-with-CAS.
[17:16]	Timeslot_width	R/W	None	00 = Reserved 01 = 2 bits (only for HDLC bundles) 10 = 7 bits (only for HDLC bundles) 11 = 8 bits See section <a href="#">10.6.4</a> for additional details.
[15]	First_in_bundle	R/W	None	Must be set for the first timeslot of an AAL1 or CESoPSN bundle. Must be cleared for HDLC bundles.
[14]	Rx_assigned	R/W	None	0 = timeslot is not assigned for the Rx path 1 = timeslot is assigned for the Rx path
[13]	Transmit_assigned	R/W	None	0 = timeslot is not assigned for the transmit path 1 = timeslot is assigned for the transmit path
[12:7]	Bundle_number	R/W	None	Number of the bundle that the timeslot is assigned to.
[6:5]	Reserved	R/W	None	Must be set to zero
[4:0]	Jitter_buffer_index	R/W	None	Jitter buffer index. This field indicates which jitter buffer is being used for the timeslot or bundle. It is also the index into the <a href="#">Jitter Buffer Status Table</a> (section <a href="#">11.4.8</a> ). If a timeslot is assigned to a bundle, the jitter buffer index must be configured to the number of the first timeslot assigned to the bundle. Otherwise, it must be configured to the timeslot number. See section <a href="#">10.6.10</a> .

### 11.4.6 CPU Queues

The pools and queue referred to in this section are shown in the block diagram in [Figure 10-49](#). Whenever a queue or pool level exceeds the associated threshold register, a latched status bit is set in the [CPU\\_Queues\\_change](#) register which generates an interrupt unless masked by the associated mask bit in the [CPU\\_Queues\\_mask](#) register.

In this section the address offsets in parentheses apply when the CPU data bus is 16 bits wide (pin [DAT\\_32\\_16\\_N](#)=0). The base address for the TDMoP CPU queues is **0x20,000**.

**Table 11-7. CPU Queues**

Addr Offset	Register Name	Description	Page
0x00 (0x02)	<a href="#">TDM_to_CPU_pool_insert</a>	Write to insert a buffer ID into the TDM-to-CPU Pool	124
0x04 (0x06)	<a href="#">TDM_to_CPU_pool_level</a>	Number of buffers stored in the TDM-to-CPU Pool	125
0x08 (0x0A)	<a href="#">TDM_to_CPU_pool_thresh</a>	TDM-to-CPU Pool interrupt threshold	125
0x0C (0x0E)	<a href="#">TDM_to_CPU_q_read</a>	Read to get a buffer ID from the TDM-to-CPU Queue	125
0x10 (0x12)	<a href="#">TDM_to_CPU_q_level</a>	Number of buffers in the TDM-to-CPU Queue	125
0x14 (0x16)	<a href="#">TDM_to_CPU_q_thresh</a>	TDM-to-CPU Queue interrupt threshold	125
0x18 (0x1A)	<a href="#">CPU_to_ETH_q_insert</a>	Write to insert a buffer ID into the CPU-to-ETH Queue	125
0x1C (0x1E)	<a href="#">CPU_to_ETH_q_level</a>	Number of buffers in the CPU-to-ETH Queue	126
0x20 (0x22)	<a href="#">CPU_to_ETH_q_thresh</a>	CPU-to-ETH Queue interrupt threshold	126
0x24 (0x26)	<a href="#">ETH_to_CPU_pool_insert</a>	Write to insert a buffer ID into the ETH-to-CPU Pool	126
0x28 (0x2A)	<a href="#">ETH_to_CPU_pool_level</a>	Number of buffers stored in the ETH-to-CPU Pool	126
0x2C (0x2E)	<a href="#">ETH_to_CPU_pool_thresh</a>	ETH-to-CPU Queue interrupt threshold.	126
0x30 (0x32)	<a href="#">ETH_to_CPU_q_read</a>	Read to get a buffer ID from the ETH-to-CPU Queue	127
0x34 (0x36)	<a href="#">ETH_to_CPU_q_level</a>	Number of buffers in the ETH-to-CPU Queue.	127
0x38 (0x3A)	<a href="#">ETH_to_CPU_q_thresh</a>	ETH-to-CPU Queue interrupt threshold	127
0x54 (0x56)	<a href="#">CPU_to_TDM_q_insert</a>	Write to insert a buffer ID into the CPU-to-TDM Queue	127
0x58 (0x5A)	<a href="#">CPU_to_TDM_q_level</a>	Number of buffers stored in the CPU-to-TDM Queue	127
0x5C (0x5E)	<a href="#">CPU_to_TDM_q_thresh</a>	CPU-to-TDM Queue interrupt threshold	127
0x60 (0x62)	<a href="#">Tx_return_q_read</a>	Read to get a buffer ID from the CPU-tx-return Queue	128
0x64 (0x66)	<a href="#">Tx_return_q_level</a>	Number of buffers stored in the CPU-tx-return Queue	128
0x68 (0x6A)	<a href="#">Tx_return_q_thresh</a>	CPU-tx-return Queue interrupt threshold	128
0x6C (0x6E)	<a href="#">Rx_return_q_read</a>	Read to get a buffer ID from the CPU-rx-return Queue	128
0x70 (0x72)	<a href="#">Rx_return_q_level</a>	Number of buffers stored in the CPU-rx-return Queue	129
0x74 (0x76)	<a href="#">Rx_return_q_thresh</a>	CPU-rx-return Queue interrupt threshold	129

#### 11.4.6.1 TDM-to-CPU Pool

##### TDM\_to\_CPU\_pool\_insert 0x00 (0x02)

Bits	Data Element Name	R/W	Reset Value	Description
[31:13]	Reserved	-	0x0	Must be set to zero
[12:0]	Buffer ID	WO	None	Writing to this address causes a single 13-bit buffer ID to be inserted to the TDM-to-CPU pool. Only bits [12:0] are written. The buffer ID serves as the 13 MSBs of the buffer address in the SDRAM (i.e. corresponds to <a href="#">H_AD</a> [23:11] out of the 24 SDRAM address bits).

**TDM\_to\_CPU\_pool\_level 0x04 (0x06)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Level	RO	0x0	Number of buffers currently stored in the pool. These are the buffers that are still available to the Tx payload type machines. Range: 0 to 128.

**TDM\_to\_CPU\_pool\_thresh 0x08 (0x0A)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Threshold	RO	0x0	If the number of buffers in the pool is $\leq$ this threshold, an interrupt is generated. Range: 0 to 128.

**11.4.6.2 TDM-to-CPU Queue****TDM\_to\_CPU\_q\_read 0x0C (0x0E)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:13]	Reserved	-	0x0	Must be set to zero
[12:0]	Buffer ID	RO	None	Reading from this address extracts the first buffer ID from the TDM-to-CPU queue (bits [12:0]). The buffer ID serves as the 13 MSBs of the buffer address in the SDRAM (i.e. corresponds to <a href="#">H_AD</a> [23:11] out of 24 SDRAM address bits).

**TDM\_to\_CPU\_q\_level 0x10 (0x12)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Level	RO	0x0	Number of buffers currently stored in the queue. These are the buffers still waiting to be handled by the CPU. Range: 0 to 128.

**TDM\_to\_CPU\_q\_thresh 0x14 (0x16)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Threshold	RO	0x0	If the number of buffers in the queue is $\geq$ this threshold, an interrupt is generated. Range: 0-128

**11.4.6.3 CPU-to-ETH Queue****CPU\_to\_ETH\_q\_insert 0x18 (0x1A)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:13]	Reserved	-	0x0	Must be set to zero
[12:0]	Buffer ID	WO	None	Writing to this address causes a single 13-bit buffer ID to be inserted to the CPU-to-ETH queue. Only bits [12:0] are written. The buffer ID serves as the 13 MSBs of the buffer address in the SDRAM (i.e. corresponds to <a href="#">H_AD</a> [23:11] out of the 24 SDRAM address bits).

**CPU\_to\_ETH\_q\_level 0x1C (0x1E)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:6]	Reserved	-	0x0	Must be set to zero
[5:0]	Level	RO	0x0	Number of buffers currently stored in the queue. Range: 0 to 32.

**CPU\_to\_ETH\_q\_thresh 0x20 (0x22)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:6]	Reserved	-	0x0	Must be set to zero
[5:0]	Threshold	RO	0x0	If the number of buffers in the queue is $\leq$ this threshold, an interrupt is generated. Range: 0 to 32.

**11.4.6.4 ETH-to-CPU Pool****ETH\_to\_CPU\_pool\_insert 0x24 (0x26)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:13]	Reserved	-	0x0	Must be set to zero
[12:0]	Buffer ID	WO	None	Writing to this address causes a single 13-bit buffer ID to be inserted to the ETH-to-CPU pool. Only bits [12:0] are written. The buffer ID serves as the 13 MSBs of the buffer address in the SDRAM (i.e. corresponds to <a href="#">H_AD[23:11]</a> out of the 24 SDRAM address bits).

**ETH\_to\_CPU\_pool\_level 0x28 (0x2A)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Level	RO	0x0	Number of buffers currently stored in the pool. These are the buffers that are still available to the Rx arbiter. Range: 0 to 128.

**ETH\_to\_CPU\_pool\_thresh 0x2C (0x2E)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Threshold	RO	0x0	If the number of buffers in the pool is $\leq$ this threshold, an interrupt is generated and only OAM packets are inserted in the ETH-to-CPU queue (non-OAM packets are discarded). Range: 0 to 128.

**11.4.6.5 ETH- to-CPU Queue**
**ETH\_to\_CPU\_q\_read 0x30 (0x32)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:13]	Reserved	-	0x0	Must be set to zero
[12:0]	Buffer ID	RO	None	Reading from this address extracts the first buffer ID from the ETH-to-CPU queue (bits [12:0]). The buffer ID serves as the 13 MSbs of the buffer address in the SDRAM (i.e. corresponds to <a href="#">H_AD</a> [23:11] out of 24 SDRAM address bits).

**ETH\_to\_CPU\_q\_level 0x34 (0x36)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Level	RO	0x0	Number of buffers currently stored in the queue. These are the buffers still waiting to be handled by the CPU. Range: 0 to 128.

**ETH\_to\_CPU\_q\_thresh 0x38 (0x3A)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Threshold	RO	0x0	If the number of buffers in the queue is $\geq$ this threshold, an interrupt is generated. Range: 0 to 128.

**11.4.6.6 CPU-to-TDM Queue**
**CPU\_to\_TDM\_q\_insert 0x54 (0x56)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:13]	Reserved	-	0x0	Must be set to zero
[12:0]	Buffer ID	WO	None	Writing to this address causes a single 13-bit buffer ID to be inserted to the CPU-to-TDM queue. Only bits [12:0] are written. The buffer ID serves as the 13 MSbs of the buffer address in the SDRAM (i.e. corresponds to <a href="#">H_AD</a> [23:11] out of the 24 SDRAM address bits).

**CPU\_to\_TDM\_q\_level 0x58 (0x5A)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:6]	Reserved	-	0x0	Must be set to zero
[5:0]	Level	RO	0x0	Number of buffers currently stored in the queue. Range: 0 to 32.

**CPU\_to\_TDM\_q\_thresh 0x5C (0x5E)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:6]	Reserved	-	0x0	Must be set to zero
[5:0]	Threshold	RO	0x0	If the number of buffers in the queue is $\geq$ this threshold,

**CPU\_to\_TDM\_q\_thresh 0x5C (0x5E)**

Bits	Data Element Name	R/W	Reset Value	Description
an interrupt is generated. Range: 0 to 32.				

**11.4.6.7 Tx Return Queue****Tx\_return\_q\_read 0x60 (0x62)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:13]	Reserved	-	0x0	Must be set to zero
[12:0]	Buffer ID	RO	None	Reading from this address extracts the first buffer ID from the CPU Tx return queue (bits [12:0]). The buffer ID serves as the 13 MSbs of the buffer address in the SDRAM (i.e. corresponds to <a href="#">H_AD</a> [23:11] out of 24 SDRAM address bits).

**Tx\_return\_q\_level 0x64 (0x62)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:6]	Reserved	-	0x0	Must be set to zero
[5:0]	Level	RO	0x0	Number of buffers currently stored in the queue. Range: 0 to 32.

**Tx\_return\_q\_thresh 0x68 (0x6A)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:6]	Reserved	-	0x0	Must be set to zero
[5:0]	Threshold	RO	0x0	If the number of buffers in the queue is $\geq$ this threshold, an interrupt is generated. Range: 0 to 32.

**11.4.6.8 Rx Return Queue****Rx\_return\_q\_read 0x6C (0x6E)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:13]	Reserved	-	0x0	Must be set to zero
[12:0]	Buffer ID	RO	None	Reading from this address extracts the first buffer ID from the CPU Rx return queue (bits [12:0]). The buffer ID serves as the 13 MSbs of the buffer address in the SDRAM (i.e. corresponds to <a href="#">H_AD</a> [23:11] out of 24 SDRAM address bits).

**Rx\_return\_q\_level 0x70 (0x72)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:6]	Reserved	-	0x0	Must be set to zero
[5:0]	Level	RO	0x0	Number of buffers currently stored in the queue. Range: 0 to 32.

**Rx\_return\_q\_thresh 0x74 (0x76)**

Bits	Data Element Name	R/W	Reset Value	Description
[31:6]	Reserved	-	0x0	Must be set to zero
[5:0]	Threshold	RO	0x0	If the number of buffers in the queue is $\geq$ this threshold, an interrupt is generated. Range: 0 to 32.

**11.4.7 Transmit Buffers Pool**

The base address for the TDMoP transmit buffers pool is **0x28,000**. See section [10.6.11.7](#) for details.

**11.4.7.1 Per-Bundle Head Pointers**

In the register descriptions in this section, the index **n** indicates the bundle number: 0 to 63.

The RAM should be initialized by CPU software to hold the heads of the linked lists for all open bundles. See section [10.6.11.7](#).

**Per-Bundle Head[n] 0x800+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:10]	Reserved		None	Must be set to zero
[9]	Buffer_valid	R/W	None	0 = The head contains non-valid information (i.e. the pool is empty). 1 = The head points to a valid free buffer.
[8:0]	Buffer_id	R/W	None	The full address of the buffer consists of the Tx buffer base address (specified in <a href="#">General_cfg_reg1</a> . <a href="#">Tx_buf_base_add</a> ) concatenated with the buffer ID and eleven 0s.

**11.4.7.2 Per-Buffer Next-Buffer Pointers**

A pointer to the next buffer in the linked list.

In the register descriptions in this section, the index **n** indicates the buffer number: 0 to 511.

The RAM should be initialized by CPU software to hold the linked lists for all the bundles. See section [10.6.11.7](#).

**Per Buffer Next Buffer[n] 0x000+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:9]	Reserved	-	None	Must be set to zero
[8:0]	Buffer_offset	R/W	None	The offset (ID) of the next buffer in the linked list in the SDRAM area dedicated to the Tx payload-type machines. The full address of the buffer consists of the Tx buffer base address (specified in <a href="#">General_cfg_reg1</a> . <a href="#">Tx_buf_base_add</a> ) concatenated with the buffer offset and eleven 0s.

### 11.4.8 Jitter Buffer Control

The base address for the TDMoP jitter buffer control is **0x30,000**.

In the register descriptions in this section, the index **port** indicates port number: 1-8 for DS34T108, 1-4 for DS34T104, 1-2 for DS34T102, 1 only for DS34T101. The index **ts** indicates timeslot number: 0 to 31. The index **n** indicates the bundle number: 0 to 63. See section 10.6.10 for more information.

**Table 11-8. Jitter Buffer Status Tables**

Addr Offset	Register Name	Description	Page
0x000	<a href="#">Status_and_level[1, 0]</a>	Jitter buffer port 1 timeslot 0 status and fill level	<a href="#">130</a>
0x004	<a href="#">Min_and_max_level[1, 0]</a>	Jitter buffer port 1 timeslot 0 min / max levels	<a href="#">131</a>
(port-1)*0x100+ts*8	<a href="#">Status_and_level[port, ts]</a>	Jitter buffer status and fill level	<a href="#">130</a>
(port-1)*0x100+ts*8+4	<a href="#">Min_and_max_level[port, ts]</a>	Jitter buffer min / max levels	<a href="#">131</a>
0x7F8	<a href="#">Status_and_level[8, 31]</a>	Jitter buffer port 8 timeslot 31 status and fill level	<a href="#">130</a>
0x7FC	<a href="#">Min_and_max_level[8, 31]</a>	Jitter buffer port 8 timeslot 31 min / max levels	<a href="#">131</a>

Note 1: In high speed mode, Hs\_status\_and\_level and Hs\_min\_and\_max\_level reside in [Status\\_and\\_level0](#) and [Min\\_and\\_max\\_level0](#) registers, respectively.

Note 2: The CPU should never try to read [Min\\_and\\_max\\_level](#) from an HDLC bundle. When the CPU performs an access to these registers, it causes some bits to be changed – bits that are used for other purposes in HDLC bundles and thus may cause severe problems.

**Table 11-9. Bundle Timeslot Tables**

Addr Offset	Register Name	Description	Page
0xF00	<a href="#">Bundle_ts0</a>	Assigned timeslots in bundle 0	<a href="#">130</a>
0xF00+n*4	<a href="#">Bundle_ts[n]</a>	Assigned timeslots in bundle n	<a href="#">130</a>
0xFFC	<a href="#">Bundle_ts63</a>	Assigned timeslots in bundle 63	<a href="#">130</a>

#### 11.4.8.1 Status\_and\_level Registers

The status\_and\_level registers have different fields depending on the bundle type: [HDLC](#), [Structured AAL1/CESoPSN](#), [Unstructured AAL1/SAToP](#) or [High Speed AAL1/SAToP](#). The subsections below describe the status\_and\_level register fields for each type. In the register descriptions in this section, the index **port** indicates port number: 1-8 for DS34T108, 1-4 for DS34T104, 1-2 for DS34T102, 1 only for DS34T101. The index **ts** indicates timeslot number: 0 to 31.

##### 11.4.8.1.1 HDLC

##### Status\_and\_level (port-1)\*0x100+ts\*8

Bits	Data Element Name	R/W	Reset Value	Description
[31:2]	Reserved	RO	0x0	Always zero
[1:0]	Status	RO	None	The status of the bundle's jitter buffer: 00 = jitter buffer is empty 01 = jitter buffer is OK 10 = jitter buffer is full 11 = Reserved

**11.4.8.1.2 Structured AAL1/CESoPSN**
**Status\_and\_level (port-1)\*0x100+ts\*8**

Bits	Data Element Name	R/W	Reset Value	Description
[31:26]	Reserved	RO	0x0	Always zero
[25:16]	Current_level	RO	None	The current jitter buffer level for the bundle. The resolution is 0.5ms.
[15:2]	Reserved	RO	0x0	Always zero
[1:0]	Status	RO	None	The status of the bundle's jitter buffer: 00 = jitter buffer is empty 01 = jitter buffer is OK 10 = jitter buffer is full 11 = Reserved

**11.4.8.1.3 Unstructured AAL1/SAToP**
**Status\_and\_level (port-1)\*0x100**

Bits	Data Element Name	R/W	Reset Value	Description
[31]	Reserved	RO	0x0	Always zero
[30:16]	Current_level	RO	None	The current jitter buffer level for the bundle. The resolution is 32 interface bit periods.
[15:2]	Reserved	RO	0x0	Always zero
[1:0]	Status	RO	None	The status of the bundle's jitter buffer: 00 = jitter buffer is empty 01 = jitter buffer is OK 10 = jitter buffer is full 11 = Reserved

**11.4.8.1.4 High Speed AAL1/SAToP**
**Status\_and\_level 0x000**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Current_level	RO	0x0000	The 16 MSbs of the current jitter buffer level (the level is 17 bits wide). The resolution is 64 interface bit periods.
[15:2]	Reserved	RO	0x0	Always zero
[1:0]	Status	RO	0x0	The status of the bundle's jitter buffer: 00 = jitter buffer is empty 01 = jitter buffer is OK 10 = jitter buffer is full 11 = Reserved

**11.4.8.2 Min\_and\_max\_level**

In the register descriptions in this section, the index **port** indicates port number: 1-8 for DS34T108, 1-4 for DS34T104, 1-2 for DS34T102, 1 only for DS34T101. The index **ts** indicates timeslot number: 0 to 31..

**11.4.8.2.1 Structured AAL1/CESoPSN**
**Min\_and\_max\_level (port-1)\*0x100+ts\*8+4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:26]	Reserved	RO	0x0	Always zero
[25:16]	Minimal_level	RO	None	The minimal level that the jitter buffer has reached since the last time this register was read. After this register is read the TDMoP block resets this field to all ones. When underrun is reached, the value of this field remains zero until it is read by the CPU. The resolution is 0.5 ms..

**Min\_and\_max\_level (port-1)\*0x100+ts\*8+4**

Bits	Data Element Name	R/W	Reset Value	Description
[15:10]	Reserved	RO	0x00	These bits are always zero
[9:0]	Maximal_level	RO	None	The maximal level that the jitter buffer has reached since the last time this register was read. After this register is read the TDMoP block resets this field to zero. When overrun is reached, the value remains equal to <a href="#">Rx_max_buff_size</a> until it is read by the CPU. The resolution is 0.5 ms.

**11.4.8.2.2 Unstructured AAL1/SAToP****Min\_and\_max\_level (port-1)\*0x100+4**

Bits	Data Element Name	R/W	Reset Value	Description
[31]	Reserved	RO	0x0	This bit is always zero
[30:16]	Minimal_level	RO	None	The minimal level that the jitter buffer has reached since the last time this register was read. After this register is read the TDMoP block resets this field to all ones. When underrun is reached, the value of this field remains zero until it is read by the CPU. The resolution is 32 interface bit periods.
[15]	Reserved	RO	0x0	This bit is always zero
[14:0]	Maximal_level	RO	None	The maximal level that the jitter buffer has reached since the last time this register was read. After this register is read the TDMoP block resets this field to zero. When overrun is reached, the value remains equal to <a href="#">Rx_max_buff_size</a> until it is read by the CPU. The resolution is 32 interface bit periods.

**11.4.8.2.3 High Speed AAL1/SAToP****Min\_and\_max\_level 0x004**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Minimal_level	RO	0xFFFF	The 16 MSbs of the minimal level that the jitter buffer has reached since the last time this register was read. After this register is read the TDMoP block resets this field to all ones. When underrun is reached, the value of this field remains zero until it is read by the CPU. The level is 17 bits wide. The resolution is 64 interface bit periods.
[15:0]	Maximal_level	RO	0x0000	The 16 MSbs of the maximal level that the jitter buffer has reached since the last time this register was read. After this register is read the TDMoP block resets this field to zero. When overrun is reached, the value remains equal to <a href="#">Rx_max_buff_size</a> until it is read by the CPU. The level is 17 bits wide. The resolution is 64 interface bit periods.

**11.4.8.3 Bundle Timeslot Registers**

In this section, the index **n** indicates the bundle number: 0 to 63.

**Bundle\_ts[n] 0xF00+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Ts_assigned	R/W	None	Assigned timeslots of the bundle. See section <a href="#">10.6.10</a> . 1 = Timeslot is assigned to the bundle 0 = Timeslot is not assigned to the bundle

**Bundle\_ts[n] 0xF00+n\*4**

Bits	Data Element Name	R/W	Reset Value	Description
				Note: When the interface type is Nx64k this field should be set to all 1s.

### 11.4.9 Transmit Software CAS

The base address for the TDMoP transmit software CAS register space is **0x38,000**. For the CAS information transmitted in packets in the TDM-to-Ethernet direction, the CAS signaling information stored in these registers can be used instead of CAS bits coming into the TDMoP block on the TDMn\_RSIG\_RTS signals. This is configured on a per-bundle basis using the [Tx\\_CAS\\_source](#) field in the [Bundle Configuration Tables](#). In the register descriptions in this section, the index **port** indicates port number: 1-8 for DS34S108, 1-4 for DS34S104, 1-2 for DS34S102, 1 only for DS34S101.

**Table 11-10. Transmit Software CAS Registers**

Addr Offset	Register Name	Description	Page
<b>Port 1</b>			
0x00	<a href="#">Tx_SW_CAS_TS7_TS0</a>	CAS signaling for TS7 to TS0 for Port 1	<a href="#">135</a>

[11:8]	TS26_CAS_nibble	R/W	None	CAS signaling (ABCD) for timeslot 26
[7:4]	TS25_CAS_nibble	R/W	None	CAS signaling (ABCD) for timeslot 25
[3:0]	TS24_CAS_nibble	R/W	None	CAS signaling (ABCD) for timeslot 24

### 11.4.10 Receive Line CAS

The base address for the TDMoP Rx line CAS register space is **0x40,000**. These read-only registers allow the CPU to examine the state of the CAS signaling recovered from received packets and transmitted out of the TDMoP block on the TDMn\_TSIG signals. See section 10.6.5.2 for more details. When Rx line CAS bits change, an interrupt is generated. The [Rx\\_CAS\\_change](#) registers in the [Interrupt Controller](#) indicate which timeslots have changed CAS bits.

In the register descriptions in this section, the index **port** indicates port number: 1-8 for DS34S108, 1-4 for DS34S104, 1-2 for DS34S102, 1 only for DS34S101. The index **ts** indicates timeslot number: 0 to 31.

**Table 11-11. Receive Line CAS Registers**

### 11.4.11 Clock Recovery

The base address for the TDMoP clock recovery register space is **0x48,000**. Most of the registers in this section of the TDMoP block are not documented. The HAL (Hardware Abstraction Layer) software manages these registers.

In the register descriptions in this section, the index **port** indicates port number: 1-8 for DS34S108, 1-4 for DS34S104, 1-2 for DS34S102, 1 only for DS34S101.

**Table 11-12. Clock Recovery Registers**

Addr Offset	Register Name	Description	Page
<b>Port 1</b>			
0x0000	<a href="#">Control_Word_P1</a>	Port1 clock recovery control bits	<a href="#">137</a>
0x0004-00A0	Clk_recovery_cfg_reg1-40	Port1 clock recovery configuration registers (not documented)	---
<b>Port 2</b>			
0x0400	<a href="#">Control_Word_P2</a>	Port2 clock recovery control bits	<a href="#">137</a>
0x0404-04A0	Clk_recovery_cfg_reg1-40	Port2 clock recovery configuration registers (not documented)	---
<b>Port 3</b>			
0x0800	<a href="#">Control_Word_P3</a>	Port3 clock recovery control bits	<a href="#">137</a>
0x0804-08A0	Clk_recovery_cfg_reg1-40	Port3 clock recovery configuration registers (not documented)	---
<b>Port 4</b>			
0x0C00	<a href="#">Control_Word_P4</a>	Port4 clock recovery control bits	<a href="#">137</a>

<b>Port 6</b>			
0x1400	<a href="#">Control_Word_P6</a>	Port6 clock recovery control bits	<a href="#">137</a>
0x1404-14A0	Clk_recovery_cfg_reg1-40	Port6 clock recovery configuration registers (not documented)	---
<b>Port 7</b>			
0x1800	<a href="#">Control_Word_P7</a>	Port7 clock recovery control bits	<a href="#">137</a>
0x1804-18A0	Clk_recovery_cfg_reg1-40	Port7 clock recovery configuration registers (not documented)	---
<b>Port 8</b>			
0x1C00	<a href="#">Control_Word_P8</a>	Port8 clock recovery control bits	<a href="#">137</a>
0x1C04-1CA0	Clk_recovery_cfg_reg1-40	Port8 clock recovery configuration registers (not documented)	---

When using the clock recovery mechanism of a certain port, its [Rx\\_PDVT](#) parameter in the bundle configuration must also be configured.

#### **Clk\_Recovery\_Control\_Word 0x000+(port-1)\*0x400**

Bits	Data Element Name	R/W	Reset Value	Description
[31:1]	Reserved	-	0x0	Set according to the HAL function
[0]	System_Reset	W/O	0x0	1 = Reset the clock recovery system

### 11.4.12 Receive SW Conditioning Octet Select

The base address for the TDMoP Rx software conditioning octet select register space is **0x50,000**. These registers specify which of four conditioning bytes ([TDM\\_cond\\_octet\\_a](#) through [TDM\\_cond\\_octet\\_d](#) in [TDM\\_cond\\_data\\_reg](#)) the TDMoP block transmits on the TDMn\_TX signals during an unassigned timeslot. The specified value is also the conditioning octet that is inserted into the jitter buffer for lost packet compensation.

In the register descriptions in this section, the index **port** indicates port number: 1-8 for DS34S108, 1-4 for DS34S104, 1-2 for DS34S102, 1 only for DS34S101. The index **ts** indicates timeslot number: 0 to 31.

**Table 11-13. Receive SW Conditioning Octet Select Registers**

#### Rx\_SW\_cond 0x000+(port-1)\*0x80+ts\*4

Bits	Data Element Name	R/W	Reset Value	Description
[31:2]	Reserved	-	0x0	Must be set to zero
[1:0]	Cond_octet_sel	R/W	None	00 = TDM_cond_octet_a 01 = TDM_cond_octet_b 10 = TDM_cond_octet_c 11 = TDM_cond_octet_d

### 11.4.13 Receive SW CAS

The base address for the TDMoP Rx software CAS register space is **0x58,000**. These registers specify the CAS signaling bits the TDMoP block transmits on the TDMn\_TSIG signals during unassigned timeslots and during timeslots where CAS is not assigned. See section 10.6.5.2 for more details.

In the register descriptions in this section, the index **port** indicates port number: 1-8 for DS34S108, 1-4 for DS34S104, 1-2 for DS34S102, 1 only for DS34S101. The index **ts** indicates timeslot number: 0 to 31.

**Table 11-14. Receive SW CAS Registers**

**Rx\_SW\_CAS 0x000+(port-1)\*0x80+ts\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:4]	Reserved	-	0x0	Must be set to zero
[3:0]	Rx_CAS	R/W	None	CAS signaling (ABCD) transmitted towards TDMn_TSIG when Rx_CAS_src=1 in <a href="#">Bundle Configuration Tables</a> . Must be different from 0000.

### 11.4.14 Interrupt Controller

The base address for the interrupt controller register space is **0x68,000**.

The [Intpend](#) register and the “change” registers listed below have latched status bits that indicate various TDMoP hardware events. For each bit, the value 1 indicates that the event occurred. Writing 1 to a bit clears it to 0. Writing 0 to a bit does not change its value.

The [Intmask](#) register and the other “mask” registers listed below have an interrupt mask bit corresponding to each bit in the associated “change” register. Each mask bit masks the interrupt when set to 1 and does not mask the interrupt when set to 0.

The [Intpend](#) register is the master interrupt status register. “Change” bits in [Intpend](#) indicate that one or more events of a specific type have occurred. More details about which ports or bundles had that type of event can be found by reading the change register(s) for that event type.

In the register descriptions in this section, the index **port** indicates port number: 1-8 for DS34S108, 1-4 for DS34S104, 1-2 for DS34S102, 1 only for DS34S101.

**Table 11-15. Interrupt Controller Registers**

[31:28]	Reserved	-	0x0	Must be set to zero
[27]	ETH_MAC	R/W	0x0	Ethernet MAC interrupt. Read the <a href="#">MAC_interrupt_status</a> register to determine the interrupt source(s).
[26]	CPU Queues	R/W	0x0	The fill level of one or more of the CPU queues and pools has gone beyond the configured threshold. Read the <a href="#">CPU_Queue_change</a> register to determine the interrupt source(s).
[25]	CW_bits_change	R/W	0x0	At least one of the L, R, M or FRG control Word fields has changed in one or more bundles. Read the <a href="#">CW_bits_change_low_bundles</a> and <a href="#">CW_bits_change_high_bundles</a> registers to determine the interrupt source(s). The <a href="#">CW_bits_change_mask</a> register indicates which of the four CW fields can cause an interrupt when changed.
[24]	RTS_changes	R/W	0x0	1 = The state of the RTS pin ( <a href="#">TDMn_RSIG_RTS</a> ) for one or more ports has changed. This only applies for port in asynchronous serial interface mode ( <a href="#">Port[n]_cfg_reg.Int_type=00</a> ). Read the <a href="#">RTS_change</a> register to determine the interrupt source(s).
[23]	Tx_CAS_change_P8	R/W	0x0	A change has occurred in the CAS signaling bits for Port8. Read the Port7 <a href="#">Tx_CAS_change</a> register to determine the interrupt source(s).
[22]	Tx_CAS_change_P7	R/W	0x0	A change has occurred in the CAS signaling bits for Port7. Read the Port7 <a href="#">Tx_CAS_change</a> register to determine the interrupt source(s).
[21]	Tx_CAS_change_P6	R/W	0x0	A change has occurred in the CAS signaling bits for Port6. Read the Port7 <a href="#">Tx_CAS_change</a> register to determine the interrupt source(s).
[20]	Tx_CAS_change_P5	R/W	0x0	A change has occurred in the CAS signaling bits for Port5. Read the Port7 <a href="#">Tx_CAS_change</a> register to determine the interrupt source(s).
[19]	Tx_CAS_change_P4	R/W	0x0	A change has occurred in the CAS signaling bits for Port4. Read the Port7 <a href="#">Tx_CAS_change</a> register to determine the interrupt source(s).
[18]	Tx_CAS_change_P3	R/W	0x0	A change has occurred in the CAS signaling bits for Port3. Read the Port7 <a href="#">Tx_CAS_change</a> register to determine the interrupt source(s).
[17]	Tx_CAS_change_P2	R/W	0x0	A change has occurred in the CAS signaling bits for Port2. Read the Port7 <a href="#">Tx_CAS_change</a> register to determine the interrupt source(s).
[16]	Tx_CAS_change_P1	R/W	0x0	A change has occurred in the CAS signaling bits for Port1.

[2]	Rx_CAS_change_P3	R/W	0x1	Mask Rx_CAS_change_P3 interrupt.
[1]	Rx_CAS_change_P2	R/W	0x1	Mask Rx_CAS_change_P2 interrupt.
[0]	Rx_CAS_change_P1	R/W	0x1	Mask Rx_CAS_change_P1 interrupt.

**Rx\_CAS\_change 0x40+(port-1)\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Rx_CAS_change	R/W	0x0000 0000	Bit 31 represents timeslot 31 and bit 0 represents timeslot 0 for the port. When a bit is set it indicates a change in received CAS (from the Ethernet port) in the corresponding timeslot. The current CAS bits can be read from the appropriate <a href="#">Rx_Line_CAS</a> register (section <a href="#">11.4.10</a> ). See section <a href="#">10.6.5.2</a>

**JBC\_underrun 0x80+(port-1)\*4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	JBC_underrun	R/W	0x0000 0000	Bit 31 represents timeslot 31 and bit 0 represents timeslot 0 for the port. When a bit is set it indicates a jitter buffer underrun for the corresponding timeslot.

**JBC\_underrun\_mask 0x84+(port-1)\*8**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	JBC_underrun_mask	R/W	0xFFFF FFFF	Each bit masks an interrupt caused by the corresponding bit in the <a href="#">JBC_underrun</a> register.

**Tx\_CAS\_change 0xC0+(port-1)\*8**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Tx_CAS_change	R/W	0x0000 0000	Bit 31 represents timeslot 31 and bit 0 represents timeslot 0 for the port. When a bit is set it indicates a change in transmit (toward the Ethernet port) CAS bits in the corresponding timeslot. The current CAS bits can be read from the signaling registers in the neighboring framer IC. See section <a href="#">10.6.5.1</a> .

**Tx\_CAS\_change\_mask 0xC4+(port-1)\*8**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Tx_CAS_change_maxk	R/W	0xFFFF FFFF	Each bit masks interrupts caused by the corresponding bit in the <a href="#">Tx_CAS_change</a> register. See section <a href="#">10.6.5.1</a> .

**RTS\_change 0x100**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7]	RTS8_change	R/W	0x0	TDM8_RTS input level changed.
[6]	RTS7_change	R/W	0x0	TDM7_RTS input level changed.
[5]	RTS6_change	R/W	0x0	TDM6_RTS input level changed.
[4]	RTS5_change	R/W	0x0	TDM5_RTS input level changed.
[3]	RTS4_change	R/W	0x0	TDM4_RTS input level changed.
[2]	RTS3_change	R/W	0x0	TDM3_RTS input level changed.
[1]	RTS2_change	R/W	0x0	TDM2_RTS input level changed.
[0]	RTS1_change	R/W	0x0	TDM1_RTS input level changed.

**RTS\_mask 0x104**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	RTS_mask	R/W	0xFF	Each bit masks interrupts caused by the corresponding bit in the <a href="#">RTS_change</a> register.

**CW\_bits\_change\_low\_bundles 0x140**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	CW_bits_change	R/W	0xFFFF FFFF	Bit 31 represents bundle 31 and bit 0 represents bundle 0. When a bit is set it indicates the corresponding bundle had a change in one of the bundle's control word fields: L, R, M or FRG. The <a href="#">CW_bits_change_mask</a> register specifies which of the four Control Word fields can cause an interrupt when changed. The current state of the four fields can be read from the <a href="#">Packet Classifier Status</a> register in the per-bundle status tables (section <a href="#">11.4.4.1</a> ).

**CW\_bits\_mask\_low\_bundles 0x144**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	CW_bits_mask	R/W	0xFFFF FFFF	Bit 31 represents bundle 31 and bit 0 represents bundle 0. Mask the interrupt from the corresponding bit in the

**CW\_bits\_mask\_low\_bundles 0x144**

Bits	Data Element Name	R/W	Reset Value	Description
<a href="#">CW_bits_change_low_bundles</a> register.				

**CW\_bits\_change\_high\_bundles 0x148**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	CW_bits_change	R/W	0xFFFF FFFF	Bit 31 represents bundle 63 and bit 0 represents bundle 32. When a bit is set it indicates the corresponding bundle had a change in one of the bundle's control word fields: L, R, M or FRG. The <a href="#">CW_bits_change_mask</a> register specifies which of the four Control Word fields can cause an interrupt when changed. The current state of the four fields can be read from the <a href="#">Packet Classifier Status</a> register in the per-bundle status tables (section 11.4.4.1).

**CW\_bits\_mask\_high\_bundles 0x14C**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	CW_bits_mask	R/W	0xFFFF FFFF	Bit 31 represents bundle 63; bit 0 represents bundle 32. Mask the interrupt from the corresponding bit in the <a href="#">CW_bits_change_high_bundles</a> register.

**CW\_bits\_change\_mask 0x180**

Bits	Data Element Name	R/W	Reset Value	Description
[31:6]	Reserved	-	0x0	Must be set to zero
[5]	Rx_sync_loss	R/W	None	Mask interrupts caused by L field changing in Control Word
[4]	Rx_remote_fail	R/W	None	Mask interrupts caused by R field changing in Control Word
[3:2]	Rx_Lbit_modifier	R/W	None	Mask interrupts caused by M field changing in Control Word
[1:0]	Fragmentation_bits	R/W	None	Mask interrupts caused by FRG field changing in Control Word

**CPU\_Queue\_change 0x1C0**

Bits	Data Element Name	R/W	Reset Value	Description
[31:10]	Reserved	-	0x0	Must be set to zero
[9]	TDM_to_CPU_pool_thresh	R/W	0x0	TDM to CPU pool level $\leq$ threshold.
[8]	TDM_to_CPU_q_thresh	R/W	0x0	TDM to CPU queue level $\geq$ threshold.
[7]	CPU_to_ETH_q_thresh	R/W	0x0	CPU to Ethernet queue level $\leq$ threshold.
[6]	ETH_to_CPU_pool_thresh	R/W	0x0	Ethernet to CPU pool level $\leq$ threshold.
[5]	ETH_to_CPU_q_thresh	R/W	0x0	Ethernet to CPU queue level $\geq$ threshold
[4:3]	Reserved	R/W	0x0	Must be set to zero
[2]	CPU_to_TDM_q_thresh	R/W	0x0	CPU to TDM queue level $\geq$ threshold.
[1]	Tx_return_q_thresh	R/W	0x0	CPU TX return queue level $\geq$ threshold.
[0]	Rx_return_q_thresh	R/W	0x0	CPU RX return queue level $\geq$ threshold.

**CPU\_Queue\_mask 0x1C4**

Bits	Data Element Name	R/W	Reset Value	Description
[31:10]	Reserved	-	0x0	Must be set to zero
[9]	TDM_to_CPU_pool_thresh	R/W	0x1	Mask TDM_to_CPU_pool_thresh interrupts
[8]	TDM_to_CPU_q_thresh	R/W	0x1	Mask TDM_to_CPU_q_thresh interrupts
[7]	CPU_to_ETH_q_thresh	R/W	0x1	Mask CPU_to_ETH_q_thresh interrupts
[6]	ETH_to_CPU_pool_thresh	R/W	0x1	Mask ETH_to_CPU_pool_thresh interrupts
[5]	ETH_to_CPU_q_thresh	R/W	0x1	Mask ETH_to_CPU_q_thresh interrupts
[4:3]	Reserved	R/W	0x1	Must be set to zero
[2]	CPU_to_TDM_q_thresh	R/W	0x1	Mask CPU_to_TDM_q_thresh interrupts
[1]	Tx_return_q_thresh	R/W	0x1	Mask Tx_return_q_thresh interrupts
[0]	Rx_return_q_thresh	R/W	0x1	Mask Rx_return_q_thresh interrupts

### 11.4.15 Packet Classifier

The base address for the packet classifier register space is **0x70,000**. In the register descriptions in this section the index **n** indicates register number: 1 to 8. These registers can store eight possible OAM bundle numbers.

**Table 11-16. Packet Classifier OAM Identification Registers**

Addr Offset	Register Name	Description	Page
0x000	<a href="#">OAM Identification1</a>	1st Identification for control packets	<a href="#">147</a>
0x004	<a href="#">OAM Identification2</a>	2nd Identification for control packets	<a href="#">147</a>
0x008	<a href="#">OAM Identification3</a>	3rd Identification for control packets	<a href="#">147</a>
0x00C	<a href="#">OAM Identification4</a>	4th Identification for control packets	<a href="#">147</a>
0x010	<a href="#">OAM Identification5</a>	5th Identification for control packets	<a href="#">147</a>
0x014	<a href="#">OAM Identification6</a>	6th Identification for control packets	<a href="#">147</a>
0x018	<a href="#">OAM Identification7</a>	7th Identification for control packets	<a href="#">147</a>
0x01C	<a href="#">OAM Identification8</a>	8th Identification for control packets	<a href="#">147</a>
0x080	<a href="#">OAM Identification Validity1</a>	1st Identification validity for control packets	<a href="#">147</a>
0x084	<a href="#">OAM Identification Validity2</a>	2nd Identification validity for control packets	<a href="#">147</a>
0x088	<a href="#">OAM Identification Validity3</a>	3rd Identification validity for control packets	<a href="#">147</a>
0x08C	<a href="#">OAM Identification Validity4</a>	4th Identification validity for control packets	<a href="#">147</a>
0x090	<a href="#">OAM Identification Validity5</a>	5th Identification validity for control packets	<a href="#">147</a>
0x094	<a href="#">OAM Identification Validity6</a>	6th Identification validity for control packets	<a href="#">147</a>
0x098	<a href="#">OAM Identification Validity7</a>	7th Identification validity for control packets	<a href="#">147</a>
0x09C	<a href="#">OAM Identification Validity8</a>	8th Identification validity for control packets	<a href="#">147</a>

#### OAM\_Identification[n] 0x000+(n-1)\*4

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	OAM Identification	R/W	None	OAM Identification <b>n</b> . If the corresponding validity bit (below) is set then the packet classifier compares the bundle identifier of received packets with the value stored in this register. If they match then the packet classifier considers the received packet to be an OAM packet. See section <a href="#">10.6.13.3</a> .

#### OAM\_Identification\_validity[n] 0x080+(n-1)\*4

Bits	Data Element Name	R/W	Reset Value	Description
[31:1]	Reserved	-	0x0	Must be set to zero
[0]	OAM Identification Validity	R/W	0x0	1 = OAM Identification <b>n</b> (above) has a valid value. See section <a href="#">10.6.13.3</a> .

### 11.4.16 Ethernet MAC

The base address for the Ethernet MAC register space is **0x72,000**.

Configuration and status registers are listed in subsection 11.4.16.1. Counters are listed in subsection 11.4.16.2.

#### 11.4.16.1 Ethernet MAC Configuration and Status Registers

**Table 11-17. Ethernet MAC Registers**

Addr Offset	Register Name	Description	Page
0x00	<a href="#">MAC_network_control</a>	MAC control register	148
0x04	<a href="#">MAC_network_configuration</a>	MAC configuration register	149
0x08	<a href="#">MAC_network_status</a>	MAC network status register	150
0x14	<a href="#">MAC_transmit_status</a>	MAC transmitter status register	150
0x24	<a href="#">MAC_interrupt_status</a>	MAC interrupt status register	150
0x28	<a href="#">MAC_interrupt_enable</a>	MAC interrupt enable register	150
0x2C	<a href="#">MAC_interrupt_disable</a>	MAC interrupt disable register	151
0x30	<a href="#">MAC_interrupt_mask</a>	MAC interrupt mask register	151
0x34	<a href="#">MAC_PHY_maintenance</a>	PHY maintenance register	152
0x38	<a href="#">MAC_pause_time</a>	MAC pause time register	152
0x98	<a href="#">MAC_specific_address_lower</a>	MAC specific address register (bits 31:0)	152
0x9C	<a href="#">MAC_specific_address_upper</a>	MAC specific address register (bits 47:32)	152
0xBC	<a href="#">MAC_transmit_pause_quantum</a>	MAC transmit pause quantum register	153
0xC0	<a href="#">PHY_SMI status</a>	PHY SMI status register	153

When reading from Ethernet MAC data elements wider than 16 bits in 16-bit mode, use the following procedure:

1. Read from address 2, i.e. [H\\_AD](#)[1]=1. All 32 bits are internally latched and bits 15:0 are output on [H\\_D](#)[15:0].
2. Read from address 0, i.e. [H\\_AD](#) [1]=0. Bits 31:16 are output on [H\\_D](#)[15:0].

When writing to Ethernet MAC data elements wider than 16 bits in 16-bit mode, use the following procedure:

1. Write to address 2, i.e. [H\\_AD](#)[1]=1. Bits 15:0 are internally latched but not written to the register yet.
2. Write to address 0, i.e. [H\\_AD](#) [1]=0. All 32 bits are written to the register. Bits 31:16 on [H\\_D](#)[15:0] are written to address 0. Bits 15:0 in the internal latch are written to address 2.

#### **MAC\_network\_control 0x000**

Bits	Data Element Name	R/W	Reset Value	Description
[31:13]	Reserved.	RO	0x0	Read as zero, ignored on write
[12]	Transmit_zero_quantum_pause_packet	WO	None	Writing a 1 to this bit transmits a pause packet with zero pause quantum at the next available transmitter idle time.
[11]	Transmit_pause_packet	WO	None	Writing 1 to this bit transmits a pause packet with the pause quantum in the <a href="#">MAC_transmit_pause_quantum</a> register — at the next available transmitter idle time.
[10:9]	Reserved		0x0	Must be set to zero
[8]	Back_pressure	R/W	0x0	When set in half duplex mode forces collisions on all received packets.
[7]	Write_enable_for_statistics_registers	R/W	0x0	Setting this bit to 1 makes the Ethernet MAC counter registers writable for functional test purposes.
[6]	Increment_statistics_reg	WO	0x0	Writing 1 increments all statistics registers by one for test purposes.
[5]	Clear_statistics_reg	WO	0x0	Writing 1 clears the statistics registers.
[4]	Management_port_enable	R/W	0x0	0 = Disable PHY management port (MDIO high impedance, MDC forced low.) 1 = Enable the PHY management port

**MAC\_network\_control 0x000**

Bits	Data Element Name	R/W	Reset Value	Description
[3]	Transmit_enable	R/W	0x0	0 = Stop transmission immediately, clear the transmit FIFO and control registers, and reset the transmit queue pointer register to point to the start of the transmit descriptor list. 1 = Enable the MAC transmitter to send data. This bit must be set during normal operation.
[2]	Rx_enable	R/W	0x0	0 = Stop packet reception immediately 1 = Enable the MAC receiver to Rx data
[1:0]	Reserved	-	0x0	Must be set to zero

**MAC\_network\_configuration 0x004**

Bits	Data Element Name	R/W	Reset Value	Description
[31:20]	Reserved	-	0x0	Read as zero, ignored on write
[19]	Ignore_Rx_FCS	R/W	0x0	When set, packets with FCS/CRC errors are not rejected and no FCS error statistics are counted. For normal operation, this bit must be set to 0.
[18]	Enable_half_duplex_Rx	R/W	0x0	Enable packets to be received in half-duplex mode while transmitting.
[17]	Reserved	-	0x0	Must be set to zero
[16]	Rx_length_field_checking_enable	R/W	0x0	When set, packets with measured lengths shorter than their length fields are discarded. Packets containing a type ID in bytes 13 and 14 (length/type field) not counted as length errors. $\geq$
[15:14]	Reserved	-	0x0	Must be set to zero
[13]	Pause_enable	R/W	0x0	When set, Ethernet packet transmission pauses when a valid pause packet is received.
[12]	Retry_test	R/W	0x0	Must be set to zero for normal operation. If set to one, the back-off between collisions is always one slot time. Setting this bit to one helps test the 'too many retries condition'. Also used in pause packet tests to reduce the pause counters decrement time from 512 bit times to every <a href="#">CLK_MII_RX</a> cycle.
[11:10]	MDC_frequency	R/W	0x2	Set according to <a href="#">CLK_SYS</a> speed. This field determines by what number <a href="#">CLK_SYS</a> is divided to generate MDC. For conformance with 802.3 MDC must not exceed 2.5 MHz. (MDC is only active during MDIO read and write operations). Must be set to 0x2.
[9]	Reserved	-	0x0	Must be set to zero
[8]	Rx_2000_byte_packets	R/W	0x0	Setting this bit means the MAC receives packets up to 2000 bytes in length. Normally the MAC rejects any packet above 1518 bytes
[7:5]	Reserved	-	0x0	Must be set to zero
[4]	Reserved	R/W	0x0	Must be set to 1
[3:2]	Reserved	-	0x0	Must be set to zero
[1]	Full_duplex	R/W	0x0	If set to 1 the transmit block ignores the state of collision and carrier sense and allows Rx while transmitting.
[0]	Speed	R/W	0x0	0 = 10 Mbit/s operation 1 = 100 Mbit/s operation Used only for RMII and SMII interfaces.

**MAC\_network\_status 0x008**

Bits	Data Element Name	R/W	Reset Value	Description
[31:3]	Reserved	-	0x0	Must be set to zero
[2]	PHY_access_has_completed	RO	0x1	1 = PHY management logic is idle.
[1:0]	Reserved	-	0x0	Must be set to zero

**MAC\_transmit\_status 0x014**

Bits	Data Element Name	R/W	Reset Value	Description
[31:7]	Reserved	-	0x0	Must be set to zero
[6]	Transmit_underrun	R/W	0x0	Set when the MAC transmit FIFO was read while was empty. If this happens the transmitter forces bad CRC and forces <a href="#">MII_TX_ERR</a> high. Write 1 to clear this bit.
[5:3]	Reserved	-	0x0	Must be set to zero
[2]	Retry_limit_exceeded	R/W	0x0	Set when the retry limit has been exceeded. Write 1 to clear this bit.
[1]	Collision_occurred	R/W	0x0	Set when a collision occurs. Write 1 to clear this bit.
[0]	Reserved	-	0x0	Must be set to zero

The MAC generates a single interrupt, the [ETH\\_MAC](#) bit in the [Intpend](#) register. The [MAC\\_interrupt\\_status](#) register below indicates the source of this interrupt. For test purposes each bit can be set or reset by directly writing to this register regardless of the state of the mask register. Otherwise the corresponding bit in the [MAC\\_interrupt\\_mask](#) register must be cleared for a bit to be set in the [MAC\\_interrupt\\_status](#) register. All bits are reset to zero on read. If any bit is set in the [MAC\\_interrupt\\_status](#) register, the [ETH\\_MAC](#) bit is asserted.

At reset all MAC interrupts are disabled. Writing a one to the relevant bit location in the [MAC\\_interrupt\\_enable](#) register below enables the associated interrupt. Writing a one to the relevant bit location in the [MAC\\_interrupt\\_disable](#) register below disables the associated interrupt. [MAC\\_interrupt\\_enable](#) and [MAC\\_interrupt\\_disable](#) are not registers but merely mechanisms for setting and clearing bits in the read-only [MAC\\_interrupt\\_mask](#) register.

**MAC\_interrupt\_status 0x024**

Bits	Data Element Name	R/W	Reset Value	Description
[31:14]	Reserved	RO	0x0	Read 0, ignored on write
[13]	Pause_time_zero	R/W	0x0	Set when the <a href="#">MAC_pause_time</a> register decrements to zero. Cleared when read.
[12]	Pause_packet_Rxd	R/W	0x0	Indicates a valid pause packet has been received. Cleared when read.
[11:6]	Reserved		0x0	Must be set to zero
[5]	Retry_limit_exceeded	R/W	0x0	Transmit error. Cleared when read.
[4]	Ethernet_transmit_underrun	R/W	0x0	Set when the MAC transmit FIFO was read while was empty. If this happens the transmitter forces bad CRC and forces <a href="#">MII_TX_ERR</a> high. Cleared when read.
[3:1]	Reserved		0x0	Must be set to zero
[0]	Management_packet_sent	R/W	0x0	The PHY maintenance register has completed its operation. Cleared when read.

**MAC\_interrupt\_enable 0x028**

Bits	Data Element Name	R/W	Reset Value	Description
[31:14]	Reserved	-	0x0	Must be set to zero
[13]	Pause_time_zero	WO	0x0	1 = Enable <a href="#">Pause_time_zero</a> interrupt
[12]	Pause_packet_Rxd	WO	0x0	1 = Enable <a href="#">Pause_packet_Rxd</a> interrupt
[11:6]	Reserved	-	0x0	Must be set to zero

**MAC\_interrupt\_enable 0x028**

Bits	Data Element Name	R/W	Reset Value	Description
[5]	Retry_limit_exceeded	WO	0x0	1 = Enable Retry_limit_exceeded interrupt
[4]	Ethernet_transmit_underrun	WO	0x0	1 = Enable Ethernet_transmit_underrun interrupt
[3:1]	Reserved	-	0x0	Must be set to zero
[0]	Management_packet_sent	WO	0x0	1 = Enable Management_packet_sent interrupt

**MAC\_interrupt\_disable 0x02C**

Bits	Data Element Name	R/W	Reset Value	Description
[31:14]	Reserved	-	0x0	Must be set to zero
[13]	Pause_time_zero	WO	0x0	1 = Disable Pause_time_zero interrupt
[12]	Pause_packet_Rxd	WO	0x0	1 = Disable Pause_packet_Rxd interrupt
[11:6]	Reserved	-	0x0	Must be set to zero
[5]	Retry_limit_exceeded	WO	0x0	1 = Disable Retry_limit_exceeded interrupt
[4]	Ethernet_transmit_underrun	WO	0x0	1 = Disable Ethernet_transmit_underrun interrupt
[3:1]	Reserved	-	0x0	Must be set to zero
[0]	Management_packet_sent	WO	0x0	1 = Disable Management_packet_sent interrupt

**MAC\_interrupt\_mask 0x030**

Bits	Data Element Name	R/W	Reset Value	Description
[31:14]	Reserved	-	0x0	Must be set to zero
[13]	Pause_time_zero	RO	0x1	1 = Mask Pause_time_zero interrupt
[12]	Pause_packet_Rxd	RO	0x1	1 = Mask Pause_packet_Rxd interrupt
[11:6]	Reserved	-	0x0	Must be set to zero
[5]	Retry_limit_exceeded	RO	0x1	1 = Mask Retry_limit_exceeded interrupt
[4]	Ethernet_transmit_underrun	RO	0x1	1 = Mask Ethernet_transmit_underrun interrupt
[3:1]	Reserved	-	0x0	Must be set to zero
[0]	Management_packet_sent	RO	0x1	1 = Mask Management_packet_sent interrupt

The [MAC\\_PHY\\_maintenance](#) register below enables the MAC to communicate with a PHY by means of the [MDIO](#) interface. It is used during auto negotiation to ensure that the MAC and the PHY are configured for the same speed and duplex configuration.

The PHY maintenance register is implemented as a shift register. Writing to the register starts a shift operation which is signaled as complete when the [PHY\\_access\\_has\\_completed](#) bit is set in the [MAC\\_network\\_status](#) register (about 2000 [CLK\\_SYS](#) cycles later). An interrupt is generated as this bit is set. During this time, the MSB of the register is output on the [MDIO](#) pin and the LSB is updated from the [MDIO](#) pin with each [MDC](#) cycle. In this way a PHY management packet is transmitted on MDIO. See Section 22.2.4.5 of the IEEE 802.3 standard. Reading during the shift operation (not recommended) returns the current contents of the shift register.

At the end of the shift operation, the bits have shifted back to their original locations. For a read operation, the data bits are updated with data read from the PHY. It is important to write the correct values to the register to ensure a valid PHY management packet is produced.

**MAC\_PHY\_maintenance 0x034**

Bits	Data Element Name	R/W	Reset Value	Description
[31:30]	Start_of_packet	R/W	0x0	Must be written 01 for a valid packet
[29:28]	Operation	R/W	0x0	00 = Reserved 01 = Write 10 = Read 11 = Reserved
[27:23]	PHY_address	R/W	0x0	Specifies the PHY to access
[22:18]	Register_address	R/W	0x0	Specifies the register in the PHY to access
[17:16]	Must_be_written_to_10	R/W	0x0	Read as written
[15:0]	PHY_data	R/W	0x0000	For a write operation this field is the data to be written to the PHY. After a read operation this field contains the data read from the PHY

**MAC\_pause\_time 0x038**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Reserved	RO	0x0000	Read 0, ignored on write
[15:0]	Pause time	RO	0x0000	Stores the current value of the pause time register, which is decremented every 512 bit times.

**MAC\_specific\_address\_lower 0x098**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	MAC Specific Address [31:0]	R/W	0x0	Least significant bits of the MAC specific address, i.e. bits 31:0. This field is used for transmission of pause packets as described in section <a href="#">10.6.12.2</a> .

**MAC\_specific\_address\_upper 0x09C**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Reserved	RO	0x0000	Read 0, ignored on write
[15:0]	MAC Specific Address [47:32]	R/W	0x0000	Most significant bits of the MAC specific address, i.e. bits 47:32. See <a href="#">MAC_specific_address_lower</a> for details.

**MAC\_transmit\_pause\_quantum 0x0BC**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Reserved	-	0x0000	Must be set to zero
[15:0]	Pause_time	R/W	0xFFFF	Transmit pause quantum. Used in hardware generation of transmitted pause packets as value for pause quantum.

**PHY\_SMII\_status 0x0C0**

Bits	Data Element Name	R/W	Reset Value	Description
[31:21]	Reserved	RO	0x0000	Must be set to zero
[20]	SMII_speed	RO	None	Speed recovered from receive SMII 0=10Mbps, 1=100Mbps
[19]	SMII_Duplex	RO	None	Duplex recovered from receive SMII 0=Half Duplex, 1=Full Duplex
[18]	SMII_Link	RO	None	Link recovered from receive SMII 0=Link is Down, 1=Link is Up
[17]	SMII_Jabber	RO	None	Jabber recovered from receive SMII 0=OK, 1=Error
[16]	SMII_False_Carrier	RO	None	False carrier recovered from receive SMII 0=OK, 1=False carrier detected
[15:0]	Reserved	RO	0x0000	Must be set to zero

**11.4.16.2 Ethernet MAC Counters**
**Table 11-18. Ethernet MAC Counters**

Addr Offset	Register Name	Description	Page
0x3C	<a href="#">Pause_packets_Rxd_OK</a>	Pause packets received OK counter	<a href="#">154</a>
0x40	<a href="#">Packets_transmitted_OK</a>	Packets transmitted OK counter	<a href="#">154</a>
0x44	<a href="#">Single_collision_packets</a>	Single collision packets counter	<a href="#">154</a>
0x48	<a href="#">Multiple_collision_packets</a>	Multiple collision packets counter	<a href="#">154</a>
0x4C	<a href="#">Packets_Rxd_OK</a>	Packets received OK counter	<a href="#">154</a>
0x50	<a href="#">Packet_check_sequence_errors</a>	Packet check sequence errors counter	<a href="#">154</a>
0x54	<a href="#">Alignment_errors</a>	Alignment errors counter	<a href="#">155</a>
0x58	<a href="#">Deferred_transmission_packets</a>	Deferred transmission packets counter	<a href="#">155</a>
0x5C	<a href="#">Late_collisions</a>	Late collisions counter	<a href="#">155</a>
0x60	<a href="#">Excessive_collisions</a>	Excessive collisions counter	<a href="#">155</a>
0x64	<a href="#">Transmit_underrun_errors</a>	Transmit underrun errors counter	<a href="#">155</a>
0x68	<a href="#">Carrier_sense_errors</a>	Carrier sense errors counter	<a href="#">156</a>
0x74	<a href="#">Rx_symbol_errors</a>	Rx symbol errors counter	<a href="#">156</a>
0x78	<a href="#">Excessive_length_errors</a>	Excessive length errors counter	<a href="#">156</a>
0x7C	<a href="#">Rx_jabbers</a>	Rx jabbers counter	<a href="#">156</a>
0x80	<a href="#">Undersize_packets</a>	Undersize packets counter	<a href="#">156</a>
0x84	<a href="#">SQE_test_errors</a>	SQE test errors counter	<a href="#">157</a>
0x8C	<a href="#">Transmitted_pause_packets</a>	Transmitted pause packets counter	<a href="#">157</a>

These counters stick at their maximum value and do not roll over. They also reset to zero when read and therefore should be read frequently enough to prevent loss of data. The Rx counters are only incremented when the [Rx\\_enable](#) bit is set in the [MAC\\_network\\_control](#) register.

**Pause\_packets\_Rxd\_OK 0x03C**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Reserved	-	0x0	Must be set to zero
[15:0]	Pause_packets_Rxd_OK	R/W	0x0	A 16-bit register counting the number of good pause packets received. A good packet has a length of 64 to 1518 (2000 if <a href="#">Rx_2000_byte_packets</a> is set in the <a href="#">MAC_network_configuration</a> register) and has no FCS, alignment or Rx symbol errors.

**Packets\_transmitted\_OK 0x040**

Bits	Data Element Name	R/W	Reset Value	Description
[31:0]	Packets_transmitted_OK	R/W	0x0	A 32-bit register counting the number of packets successfully transmitted, i.e. no underrun and not too many retries.

**Single\_collision\_packets 0x044**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Reserved	-	0x0	Must be set to zero
[15:0]	Single_collision_packets	R/W	0x0	A 16-bit register counting the number of packets experiencing a single collision before being successfully transmitted, i.e. no underrun.

**Multiple\_collision\_packets 0x048**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Reserved	-	0x0	Must be set to zero
[15:0]	Multiple_collision_packets	R/W	0x0	A 16-bit register counting the number of packets experiencing between two and fifteen collisions prior to being successfully transmitted, i.e. no underrun and not too many retries.

**Packets\_Rxd\_OK 0x04C**

Bits	Data Element Name	R/W	Reset Value	Description
[31:24]	Reserved	-	0x0	Must be set to zero
[23:0]	Packets_Rxd_OK	R/W	0x0	A 24-bit register counting the number of good packets received, i.e. packet length is 64 to 1518 bytes (2000 if <a href="#">Rx_2000_byte_packets</a> is set in the <a href="#">MAC_network_configuration</a> register) and has no FCS, alignment or Rx symbol errors.

**Packet\_check\_sequence\_errors 0x050**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Packet_check_sequence_errors	R/W	0x0	An 8-bit register counting packets that are an integral number of bytes, have bad CRC and are between 64 and 1518 bytes in length (2000 if <a href="#">Rx_2000_byte_packets</a> is set in the <a href="#">MAC_network_configuration</a> register).

**Alignment\_errors 0x054**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Alignment_errors	R/W	0x0	An 8-bit register counting packets that are not an integral number of bytes long and have bad CRC when their length is truncated to an integral number of bytes and are between 64 and 1518 bytes in length (2000 if <a href="#">Rx_2000_byte_packets</a> is set in the <a href="#">MAC_network_configuration</a> register).

**Deferred\_transmission\_packets 0x058**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Reserved	-	0x0	Must be set to zero
[15:0]	Deferred_transmission_packets	R/W	0x0	A 16-bit register counting the number of packets experiencing deferral due to carrier sense being active on their first attempt at transmission. Packets involved in any collision are not counted nor are packets that experienced a transmit underrun.

**Late\_collisions 0x05C**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Late_collisions	R/W	0x0	An 8-bit register counting the number of packets that experience a collision after the slot time (512 bits) has expired. A late collision is counted twice i.e. both as a collision and a late collision.

**Excessive\_collisions 0x060**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Excessive_collisions	R/W	0x0	An 8-bit register counting the number of packets that failed to be transmitted because they experienced 16 collisions.

**Transmit\_underrun\_errors 0x064**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Transmit_underruns	R/W	0x0	An 8-bit register counting the number of packets not transmitted due to a transmit FIFO underrun. If this register is incremented, no other Ethernet MAC counter is incremented.

**Carrier\_sense\_errors 0x068**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Carrier_sense_errors	R/W	0x0	An 8-bit register counting the number of packets transmitted where carrier sense was not seen during transmission or where carrier sense was deasserted after being asserted in a transmit packet without collision (no underrun). Only incremented in half-duplex mode. The only effect of a carrier sense error is to increment this register. The behavior of the other Ethernet MAC counters is unaffected by the detection of a carrier sense error.

**Rx\_symbol\_errors 0x074**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Rx_symbol_errors	R/W	0x0	An 8-bit register counting the number of packets that had <a href="#">MII_RX_ERR</a> asserted during reception.

**Excessive\_length\_errors 0x078**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Excessive_length_packets	R/W	0x0	An 8-bit register counting the number of packets received exceeding 1518 bytes in length (2000 if <a href="#">Rx_2000_byte_packets</a> is set in the <a href="#">MAC_network_configuration</a> register) but do not have a CRC error, an alignment error nor a Rx symbol error.

**Rx\_jabbers 0x07C**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Rx_jabbers	R/W	0x00	An 8-bit register counting the number of packets received exceeding 1518 bytes in length (2000 if <a href="#">Rx_2000_byte_packets</a> is set in the <a href="#">MAC_network_configuration</a> register) and have either a CRC error, an alignment error or a Rx symbol error.

**Undersize\_packets 0x080**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	Undersize_packets	R/W	0x0	An 8-bit register counting the number of packets received less than 64 bytes in length, that do not have either a CRC error or an alignment error.

**SQE\_test\_errors 0x084**

Bits	Data Element Name	R/W	Reset Value	Description
[31:8]	Reserved	-	0x0	Must be set to zero
[7:0]	SQE_test_errors	R/W	0x0	An 8-bit register counting the number of packets where collision was not asserted within 96 bit times (an interpacket gap) of <a href="#">MII_TX_EN</a> being deasserted in half duplex mode.

**Transmitted\_pause\_packets 0x08C**

Bits	Data Element Name	R/W	Reset Value	Description
[31:16]	Reserved	-	0x0	Must be set to zero
[15:0]	Transmitted_pause_packets	R/W	0x0	A 16-bit register counting the number of pause packets transmitted.

## 12. JTAG Information

For the latest JTAG model, search under <http://www.maxim-ic.com/tools/bsdl/>.

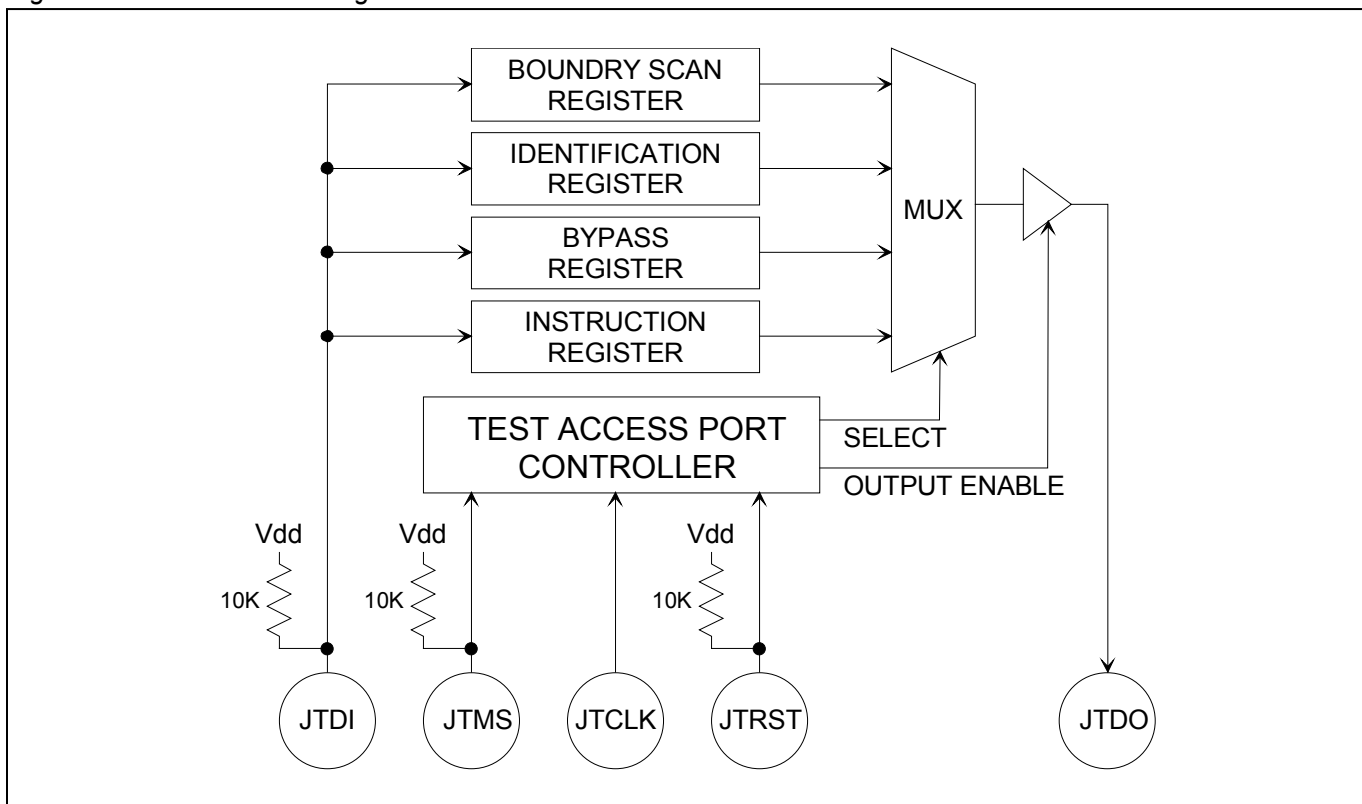

### JTAG Description

The device supports the standard instruction codes SAMPLE/PRELOAD, BYPASS, and EXTEST. Optional public instructions included are HIGHZ, CLAMP and IDCODE. See Figure 12-1 for a block diagram. The device contains the following items which meet the requirements set by the IEEE 1149.1 Standard Test Access Port and Boundary Scan Architecture:

Test Access Port (TAP)	TAP Controller
Instruction Register	Bypass Register
Boundary Scan Register	Device Identification Register

The Test Access Port has the necessary interface pins, namely JTCLK, JTRST\_N, JTDI, JTDO, and JTMS. Details on these pins can be found in Table 9-7. Details on the Boundary Scan Architecture and the Test Access Port can be found in IEEE 1149.1-1990, IEEE 1149.1a-1993, and IEEE 1149.1b-1994.

Figure 12-1. JTAG Block Diagram

### JTAG TAP Controller State Machine Description

This section covers the details on the operation of the Test Access Port (TAP) Controller State Machine. See Figure 12-2 for details on each of the states described below. The TAP controller is a finite state machine which responds to the logic level at JTMS on the rising edge of JTCLK.

Figure 12-2. JTAG TAP Controller State Machine

**Test-Logic-Reset.** Upon power-up of the device, the TAP controller starts in the Test-Logic-Reset state. The Instruction Register contains the IDCODE instruction. All system logic on the device operates normally.

**Run-Test-Idle.** Run-Test-Idle is used between scan operations or during specific tests. The Instruction Register and Test Register remain idle.

**Select-DR-Scan.** All test registers retain their previous state. With JTMS low, a rising edge of JTCLK moves the controller into the Capture-DR state and initiates a scan sequence. JTMS high moves the controller to the Select-IR-SCAN state.

**Capture-DR.** Data may be parallel loaded into the Test Data registers selected by the current instruction. If the instruction does not call for a parallel load or the selected register does not allow parallel loads, the Test Register remains at its current value. On the rising edge of JTCLK, the controller goes to the Shift-DR state if JTMS is low or it to the Exit1-DR state if JTMS is high.

**Shift-DR.** The Test Data Register selected by the current instruction is connected between JTDI and JTDO and shifts data one stage towards its serial output on each rising edge of JTCLK. If a Test Register selected by the current instruction is not placed in the serial path, it maintains its previous state.

**Exit1-DR.** While in this state, a rising edge on JTCLK with JTMS high puts the controller in the Update-DR state which terminates the scanning process. A rising edge on JTCLK with JTMS low puts the controller in the Pause-DR state.

**Pause-DR.** Shifting of the Test registers is halted while in this state. All Test registers selected by the current instruction retain their previous state. The controller remains in this state while JTMS is low. A rising edge on JTCLK with JTMS high puts the controller in the Exit2-DR state.

**Exit2-DR.** While in this state, a rising edge on JTCLK with JTMS high puts the controller in the Update-DR state and terminate the scanning process. A rising edge on JTCLK with JTMS low puts the controller in the Shift-DR state.

**Update-DR.** A falling edge on JTCLK while in the Update-DR state latches the data from the shift register path of the Test registers into the data output latches. This prevents changes at the parallel output due to changes in the shift register. A rising edge on JTCLK with JTMS low, puts the controller in the Run-Test-Idle state. With JTMS high, the controller enters the Select-DR-Scan state.

**Select-IR-Scan.** All Test registers retain their previous state. The Instruction register remains unchanged during this state. With JTMS low, a rising edge on JTCLK moves the controller into the Capture-IR state and initiates a scan sequence for the Instruction register. JTMS high during a rising edge on JTCLK puts the controller back into the Test-Logic-Reset state.

**Capture-IR.** The Capture-IR state is used to load the shift register in the Instruction register with a fixed value. This value is loaded on the rising edge of JTCLK. If JTMS is high on the rising edge of JTCLK, the controller enters the Exit1-IR state. If JTMS is low on the rising edge of JTCLK, the controller enters the Shift-IR state.

**Shift-IR.** In this state, the shift register in the Instruction register is connected between JTDI and JTDO and shifts data one stage for every rising edge of JTCLK towards the serial output. The parallel register, as well as all Test registers remain at their previous states. A rising edge on JTCLK with JTMS high moves the controller to the Exit1-IR state. A rising edge on JTCLK with JTMS low keeps the controller in the Shift-IR state while moving data one stage through the Instruction shift register.

**Exit1-IR.** A rising edge on JTCLK with JTMS low puts the controller in the Pause-IR state. If JTMS is high on the rising edge of JTCLK, the controller enters the Update-IR state and terminate the scanning process.

**Pause-IR.** Shifting of the Instruction register is halted temporarily. With JTMS high, a rising edge on JTCLK puts the controller in the Exit2-IR state. The controller remains in the Pause-IR state if JTMS is low during a rising edge on JTCLK.

**Exit2-IR.** A rising edge on JTCLK with JTMS high put the controller in the Update-IR state. The controller loops back to the Shift-IR state if JTMS is low during a rising edge of JTCLK in this state.

**Update-IR.** The instruction shifted into the Instruction shift register is latched into the parallel output on the falling edge of JTCLK as the controller enters this state. Once latched, this instruction becomes the current instruction. A rising edge on JTCLK with JTMS low, puts the controller in the Run-Test-Idle state. With JTMS high, the controller enters the Select-DR-Scan state.

### **JTAG Instruction Register and Instructions**

The Instruction register contains a shift register as well as a latched parallel output and is 3 bits in length. When the TAP controller enters the Shift-IR state, the instruction shift register is connected between JTDI and JTDO. While in the Shift-IR state, a rising edge on JTCLK with JTMS low shifts data one stage towards the serial output at JTDO. A rising edge on JTCLK in the Exit1-IR state or the Exit2-IR state with JTMS high moves the controller to the Update-IR state. The falling edge of that same JTCLK latches the data in the instruction shift register to the instruction parallel output. Instructions supported by the device and their respective operational binary codes are shown in [Table 12-1](#).

**Table 12-1. JTAG Instruction Codes**

Instructions	Selected Register	Instruction Codes
SAMPLE/PRELOAD	Boundary Scan	010
BYPASS	Bypass	111
EXTEST	Boundary Scan	000
CLAMP	Bypass	011
HIGHZ	Bypass	100
IDCODE	Device Identification	001

**SAMPLE/PRELOAD.** A mandatory instruction for the IEEE 1149.1 specification. This instruction supports two functions. The digital I/Os of the device can be sampled at the Boundary Scan register without interfering with the normal operation of the device by using the Capture-DR state. SAMPLE/PRELOAD also allows the device to shift data into the Boundary Scan register via JTDI using the Shift-DR state.

**EXTEST.** EXTEST allows testing of all interconnections to the device. When the EXTEST instruction is latched in the instruction register, the following actions occur. Once enabled via the Update-IR state, the parallel outputs of all digital output pins are driven. The Boundary Scan register is connected between JTDI and JTDO. The Capture-DR samples all digital inputs into the Boundary Scan register.

**BYPASS.** When the BYPASS instruction is latched into the parallel Instruction register, JTDI connects to JTDO through the one-bit Bypass Test register. This allows data to pass from JTDI to JTDO not affecting the device's normal operation.

**IDCODE.** When the IDCODE instruction is latched into the parallel Instruction register, the Identification Test register is selected. The device identification code is loaded into the Identification register on the rising edge of JTCLK following entry into the Capture-DR state. Shift-DR can be used to shift the identification code out serially via JTDO. During Test-Logic-Reset, the identification code is forced into the instruction register's parallel output. The device ID code always has a one in the LSB position. The device ID codes are listed in [Table 12-2](#).

**Table 12-2. JTAG ID Code**

Device	ID Code (hex)		
	Rev[31:28]	Device ID [27:12]	Manu[11:0]
DS34S101	0	0098	143
DS34S102	0	0099	143
DS34S104	0	009A	143
DS34S108	0	009B	143

**HIGHZ.** All digital outputs are placed into a high impedance state. The Bypass Register is connected between JTDI and JTDO.

**CLAMP.** All digital outputs pins output data from the boundary scan parallel output while connecting the Bypass Register between JTDI and JTDO. The outputs do not change during the CLAMP instruction.

## **JTAG Test Registers**

IEEE 1149.1 requires a minimum of two Test registers; the Bypass register and the Boundary Scan register. An optional Test register has been included in the device design. This Test register is the Identification register and is used in conjunction with the IDCODE instruction and the Test-Logic-Reset state of the TAP controller.

**Bypass Register.** This is a single one-bit shift register used in conjunction with the BYPASS, CLAMP, and HIGHZ instructions, which provides a short path between JTDI and JTDO.

**Identification Register.** The Identification register contains a 32-bit shift register and a 32-bit latched parallel output. This register is selected during the IDCODE instruction and when the TAP controller is in the Test-Logic-Reset state.

**Boundary Scan Register.** This register contains both a shift register path and a latched parallel output for all control cells and digital I/O cells and is 32 bits in length. The BSDL file found at <http://www.maxim-ic.com/tools/bsdl/> shows the entire cell bit locations and definitions.

### 13. DC Electrical Characteristics

#### ABSOLUTE MAXIMUM RATINGS

Voltage Range on Any Input, Bi-directional or Open Drain

Output Lead with Respect to DVSS .....	-0.5V to +5.5V
Supply Voltage (DVDDIO) with Respect to DVSS.....	-0.5V to +3.6V
Supply Voltage (DVDDC, ACVDD1, ACVDD2) with Respect to DVSS.....	-0.5V to +2.0V
Ambient Operating Temperature Range.....	-40°C to +85°C
Junction Operating Temperature Range.....	-40°C to +125°C
Storage Temperature Range.....	-55°C to +125°C
Soldering Temperature Range .....	See IPC/JEDEC J-STD-020 Specification

These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated in the operation sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods can affect reliability. Ambient Operating Temperature Range is assuming the device is mounted on a JEDEC standard test board in a convection cooled JEDEC test enclosure.

**Note:** The typical values listed below are not production tested.

**Table 13-1. Recommended DC Operating Conditions**

(T<sub>j</sub> = -40°C to +85°C.)

Parameter	Symbol	Conditions	Min	Typ	Max	Units
Output Logic 1	V <sub>IH</sub>		2.4		3.465	V
Output Logic 0	V <sub>IL</sub>		-0.3		+0.8	V
Power Supply Voltage	DVDDIO		3.135	3.300	3.465	V
Power Supply Voltage	DVDDC, ACVDD1, ACVDD2		1.71	1.8	1.89	V

**Table 13-2. DC Electrical Characteristics**

(T<sub>j</sub> = -40°C to +85°C.)

Parameter	Symbol	Conditions	Min	Typ	Max	Units
3.3V Supply Current (@ 3.465V)	I <sub>DDIO</sub>	Note 1		50	65	mA
DS34S108				50	65	
DS34S104				TBD	TBD	
DS34S102				TBD	TBD	
DS34S101						
1.8V Supply Current (@1.89V)	I <sub>DDC</sub>	Note 1		225	280	mA
Lead Capacitance	C <sub>IO</sub>			7		pF
Input Leakage	I <sub>IL</sub>		-10		+10	μA
Input Leakage, Internal Pull-Down	I <sub>ILP</sub>		-100		-10	μA
Output Leakage (when Hi-Z)	I <sub>LO</sub>		-10		+10	μA
Output Voltage (I <sub>OH</sub> = -4.0mA)	V <sub>OH</sub>	4 mA output	2.4			V
Output Voltage (I <sub>OL</sub> = +4.0mA)	V <sub>OL</sub>	4 mA output			0.4	V
Output Voltage (I <sub>OH</sub> = -8.0mA)	V <sub>OH</sub>	8 mA output	2.4			V
Output Voltage (I <sub>OL</sub> = -8.0mA)	V <sub>OL</sub>	8 mA output			0.4	V
Output Voltage (I <sub>OH</sub> = -12.0mA)	V <sub>OH</sub>	12 mA output	2.4			V
Output Voltage (I <sub>OL</sub> = +12.0mA)	V <sub>OL</sub>	12 mA output			0.4	V
Input Voltage Logic 1	V <sub>IH</sub>		2.0			V
Input Voltage Logic 0	V <sub>IL</sub>				0.8	V

**NOTES:**

1. All outputs loaded with rated capacitance; all inputs between DVDDIO and DVSS; inputs with pull-ups connected to DVDDIO.

## 14. AC Timing Characteristics

Table 14-1. Input Pin Transition Time Requirements

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
Rise Time	tr	10 to 90% of DVDDIO			6	ns
Fall Time	tf	90 to 10% of DVDDIO			6	ns

### 14.1 CPU Interface Timing

Table 14-2. CPU Interface AC characteristics

PARAMETER	SYMBOL	MIN	TYP	MAX	UNITS
RST_SYS_N Active Low Pulse Width	T5	50			μs
H_CS_N Deasserted or H_R_W_N Low to H_D[31:0] High-Z	T22			16.2	ns
H_READY_N Active Pull-Up Pulse Width	T26	2.9		6.8	ns
Latest of H_WR_BEx_N Asserted or H_CS_N Asserted to H_D[31:0] Valid	T31			0	ns
H_CS_N Deasserted to H_D[31:0] Not Valid	T32			0	ns
H_CS_N Asserted to H_AD[24:1] Valid	T33			0	ns
H_CS_N Deasserted to H_AD[24:1] Not Valid	T34			0	ns
H_CS_N Asserted to H_R_W_N Valid	T35			0	ns
H_CS_N Deasserted to H_R_W_N Not Valid	T36			0	ns
H_CS_N Deasserted to H_READY_N High	T37			12	ns
H_CS_N Deasserted to H_WR_BEx_N[3:0] Not Valid	T40			0	ns
Delay Between Two Successive Accesses	T43	1.5			Internal CLK_SYS cycles
H_D[31:0] Valid before H_READY_N Active Low	T44	1.5			ns

**NOTE:** The output timing specified assumes 50 pF load.

**Figure 14-7. SDRAM Interface Read Cycle Timing**

## 14.4 TDM-over-Packet TDM Interface Timing

**Table 14-5. TDMoP TDM Interface AC Characteristics**

PARAMETER	SYMBOL	MIN	TYP	MAX	UNITS
TDMn_TX_SYNC, TDMn_TX_MF_CD, TDMn_RX, TDMn_RX_SYNC, TDMn_RSIG_RTS Input Setup Prior to TDMn_TCLK for E1/T1/Serial Interface	T101	1.8			ns
TDMn_TX_SYNC, TDMn_TX_MF_CD, TDMn_RX, TDMn_RX_SYNC, TDMn_RSIG_RTS Input Hold After TDMn_TCLK for E1/T1/Serial Interface	T102	1.1			ns
TDMn_TCLK to TDMn_TX, TDMn_TSIG_CTS Output Hold for E1/T1/Serial Interface	T103	2.8			ns
TDMn_TCLK to TDMn_TX, TDMn_TSIG_CTS Output Valid for E1/T1/Serial Interface	T104			13.3	ns
TDM1_TCLK to TDM1_TX Output Hold for High Speed Interface	T103	4.5 (Note 1)			ns
TDM1_TCLK to TDM1_TX Output Valid for High Speed Interface	T104			12.5 (Note 1)	ns
TDMn_RX, TDMn_RX_SYNC, TDMn_RSIG_RTS Input Setup Prior to TDMn_RCLK for E1/T1/Serial Interface	T109	1.8			ns
TDMn_RX, TDMn_RX_SYNC, TDMn_RSIG_RTS Input Hold After TDMn_RCLK for E1/T1/Serial Interface	T110	0			ns
TDM1_RX Input Setup Prior to TDM1_RCLK for High Speed Interface	T109	1.8			ns
TDM1_RX Input Hold After TDM1_RCLK for High Speed Interface	T110	1.1			ns

**NOTES:**

1. The output timing specified for TDM1\_TX assumes 20 pF load.

**Table 14-6. TDMoP TDM Clock AC Characteristics**

PARAMETER	SYMBOL	MIN	TYP	MAX	UNITS
TDMn_TCLK Frequency for E1 Interface	T100		2.048		MHz
TDMn_TCLK Frequency for T1 Interface	T100		1.544		MHz
TDMn_RCLK, TDMn_TCLK Frequency for Serial Interface	T106	16k		4.65M	Hz
TDM1_RCLK, TDM1_TCLK Frequency for High Speed Interface	T106	16k		51.84M	Hz
TDMn_RCLK, TDMn_TCLK Duty Cycle for 1/T1 Serial Interface	T107	40		60	%
TDM1_RCLK, TDM1_TCLK Duty Cycle for High Speed Interface	T107	40		60	%

**NOTE:** The output timing specified for TDM interfaces assumes 30 pF load.

**Figure 14-8. TDMoP TDM Timing, One-Clock Mode (Two\_clocks=0, Tx\_sample=1)**

CLK_SSMII_TX Rising to MII_TXD[1:0] Output	T172	1.5		5	ns
MII_RXD[1:0] Input Setup Prior to CLK_MII_RX Rising	T175	1.5			ns
MII_RXD[1:0] Input Hold After CLK_MII_RX Rising	T176	1.3			ns

**Table 14-13. SSMII Clock Timing**

PARAMETER	SYMBOL	MIN	TYP	MAX	UNITS
CLK_SSMII_TX Frequency	T171		125		MHz
CLK_SSMII_TX Duty Cycle	T189	40		60	%
CLK_MII_RX Frequency	T171		125		MHz
CLK_MII_RX Duty Cycle	T189	40		60	%

**Figure 14-19. SSMII Interface Output Signal Timing**

**Figure 14-20. SSMII Interface Input Signal Timing**

**NOTES FOR SECTION 14.5:**

1. The output timing specified for MII/RMII/SSMII interfaces assumes 20pf load for MII\_TXD[3:0], MII\_TX\_EN, and MII\_TX\_ERR.
2. The output timing specified for MII/RMII/SSMII interfaces assumes 30pf load for MDC and MDIO.
3. The output timing specified for SSMII interface assumes 25pf load for CLK\_SSMII\_TX.

## 14.6 CLAD and System Clock Timing

**Table 14-14. CLAD1 and CLAD2 Input Clock Specifications**

PARAMETER	MIN	TYP	MAX	UNITS	ACCURACY
CLK_SYS Frequency		25 or 50		MHz	±50ppm
CLK_SYS Duty Cycle	40		60	%	
CLK_HIGH Frequency		10.00 19.44 38.88 77.76		MHz	Traceable to Stratum 3E or higher
CLK_HIGH Duty Cycle	40		60	%	
MCLK Frequency		1.544 2.048		MHz	±32ppm ±50ppm
MCLK Duty Cycle	40		60	%	
CLK_SYS Frequency		25 50 75		MHz	±50ppm
CLK_SYS Duty Cycle	40		60	%	

## 14.7 JTAG Interface Timing

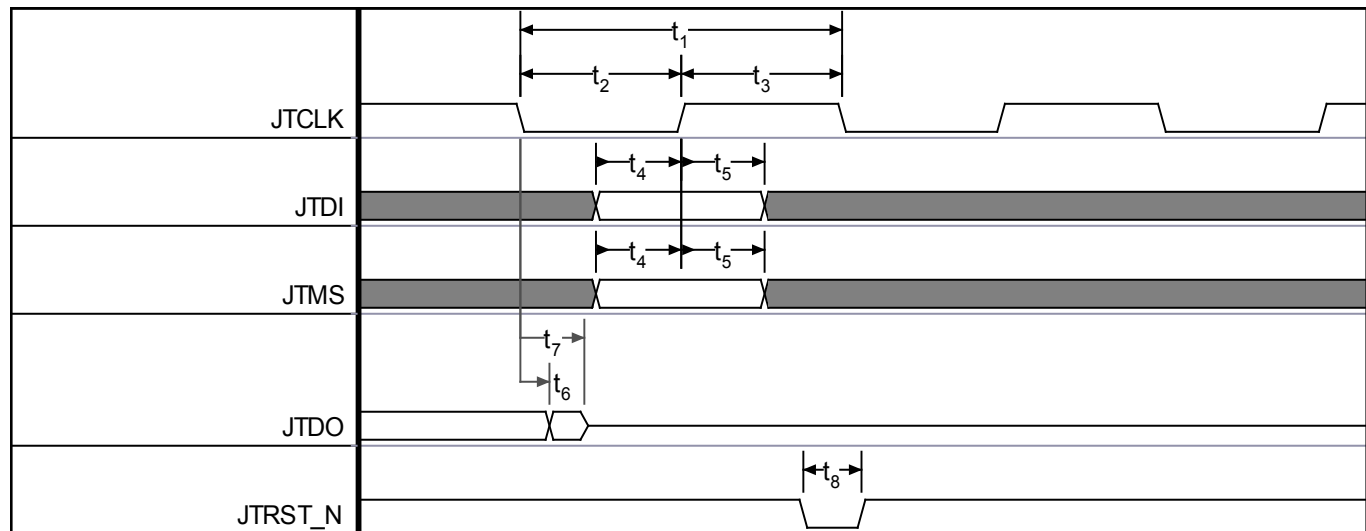

Table 14-15. JTAG Interface Timing

PARAMETER	SYMBOL	MIN	TYP	MAX	UNITS	NOTES
JTCLK Clock Period	$t_1$		1000		ns	
JTCLK Clock High / Low Time	$t_2 / t_3$	100	500		ns	1
JTCLK to JTDI, JTMS Setup Time	$t_4$	5			ns	
JTCLK to JTDI, JTMS Hold Time	$t_5$	2			ns	
JTCLK to JTDO Delay	$t_6$	2		50	ns	
JTCLK to JTDO Hi-Z Delay	$t_7$	2		50	ns	2
JTRST_N Width Low Time	$t_8$	100				

**NOTES:**

1. Clock can be stopped high or low.
2. Not tested during production test.

Figure 14-21. JTAG Interface Timing Diagram

## 15. Applications

### 15.1 Connecting a Serial Interface Transceiver

Figure 15-1 below shows the connection of one port of a DS34S10x chip to a serial interface transceiver such as V.35 or RS-530. The figure shows one port in a DCE (Data Communications Equipment) application. All other ports can be connected in the same way.

Each direction (Tx and Rx) has its own clock. However, TDM1\_RCLK is optional, as the DS34S10x chip may work in one clock mode ([GCR1.CLKMODE=0](#)) in which both directions are clocked by TDM1\_TCLK. The clock source of TDM1\_RCLK or TDM1\_TCLK can be:

- Internal (from the local oscillator)
- External
- Recovered from the packet network (provided by the chip on TDM1\_ACLK).

The control input signal [TDMn\\_RSIG\\_RTS](#) does not affect the data reception, but its value can be read by the CPU from register field [Port\[n\]\\_stat\\_reg1.RTS](#).

The [TDMn\\_TSIG\\_CTS](#) and [TDMn\\_TX\\_MF\\_CD](#) outputs can be controlled by software using registers fields CTS and CD in the [Port\[n\]\\_cfg\\_reg](#) register.

Figure 15-1. Connecting Port 1 to a Serial Transceiver

## 15.2 Connecting an Ethernet PHY or MAC

The figures below show the connection of the Ethernet port to a PHY or MAC device, in MII, RMII, and SSMII modes.

Figure 15-2. Connecting the Ethernet Port to a PHY in MII Mode

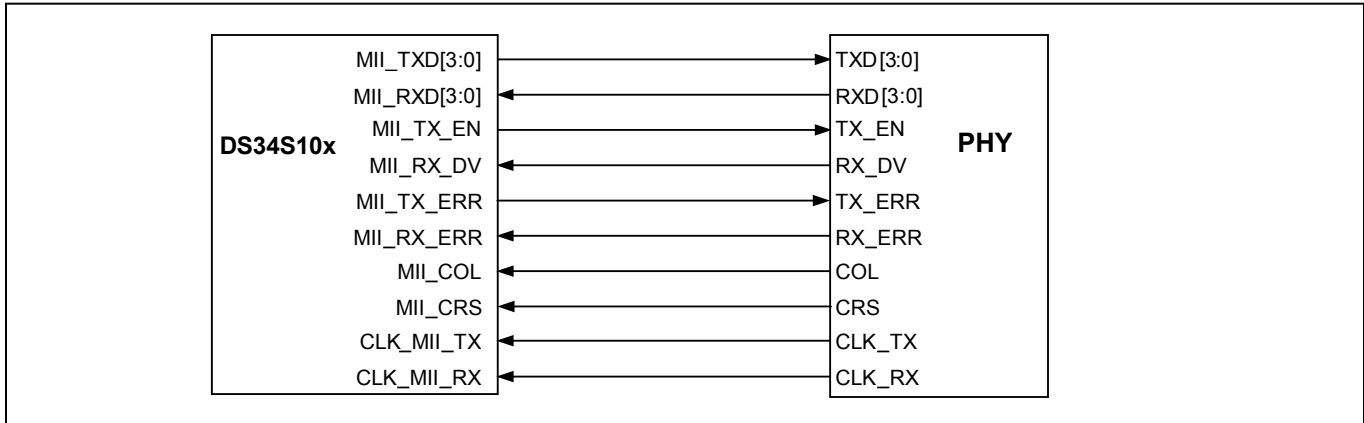

Figure 15-3. Connecting the Ethernet Port to a MAC in MII Mode

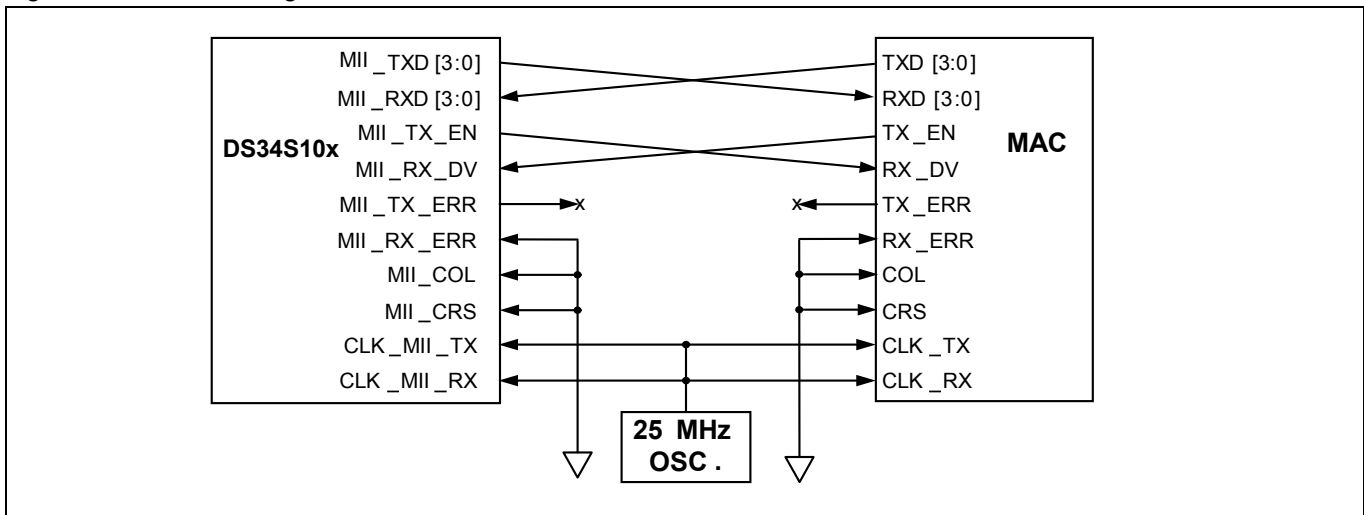

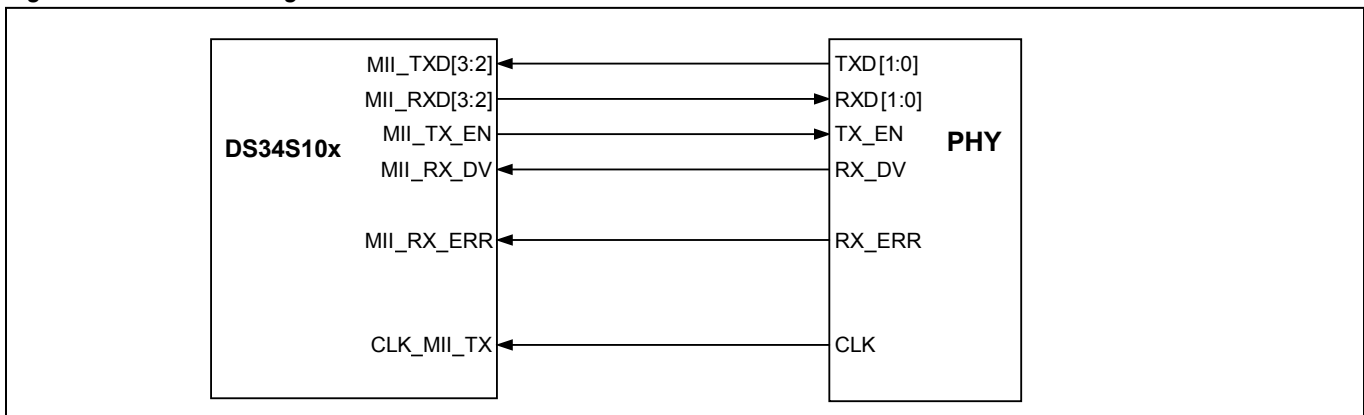

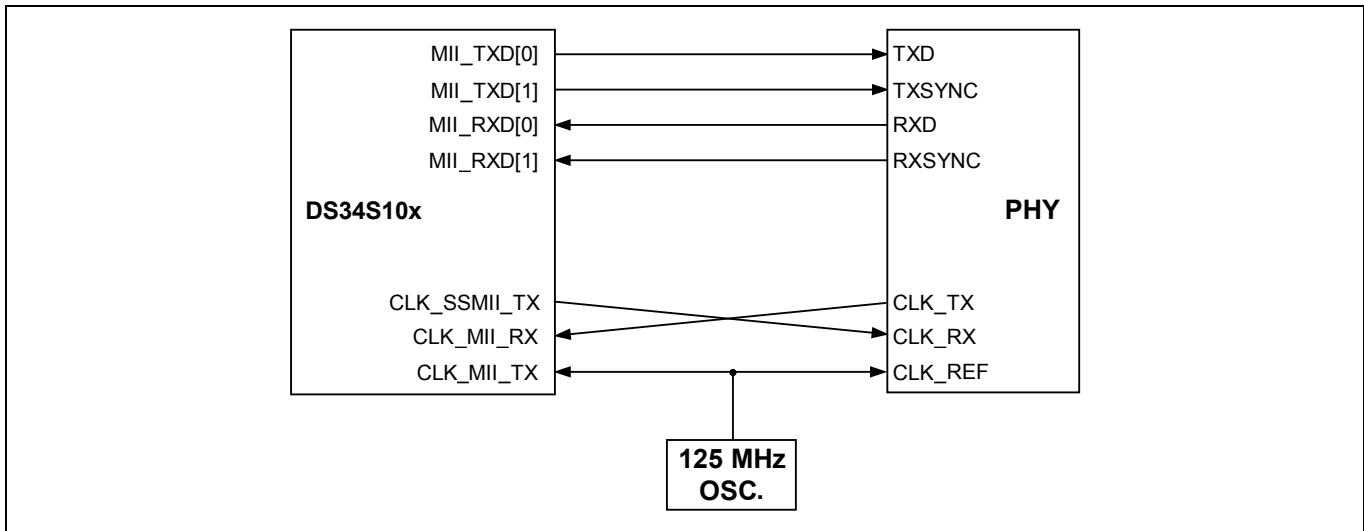

Figure 15-4. Connecting the Ethernet Port to a PHY in RMII Mode

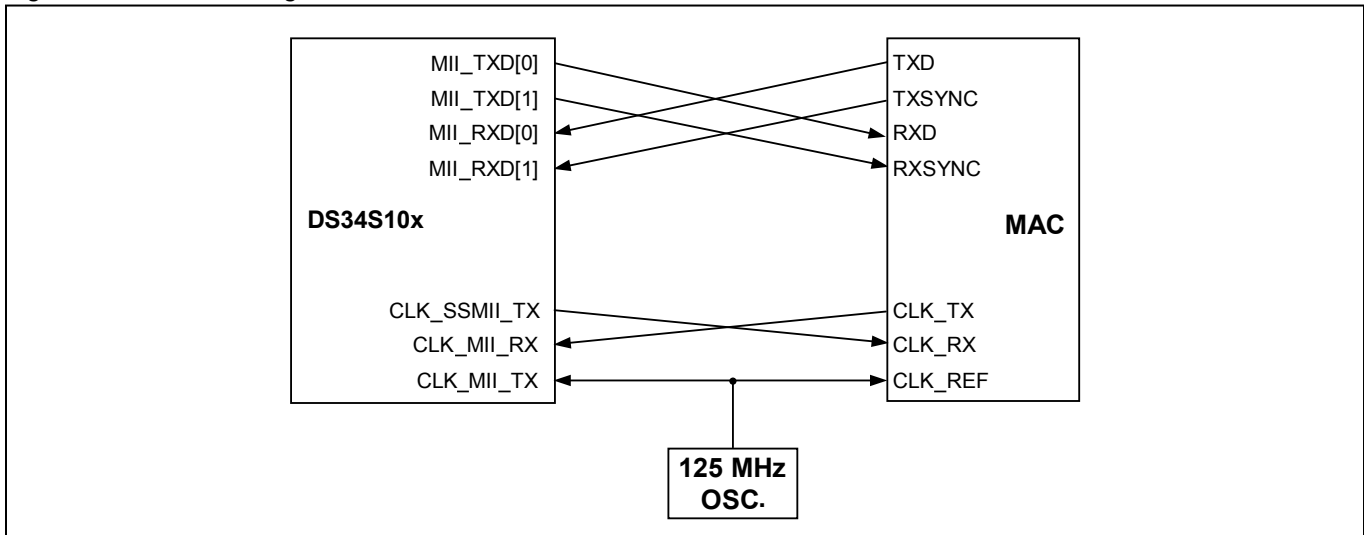

**Figure 15-5. Connecting the Ethernet Port to a MAC in RMII Mode**

**Figure 15-6. Connecting the Ethernet Port to a PHY in SSMII Mode**

**Figure 15-7. Connecting the Ethernet Port to a MAC in SSMII Mode**

For the applications above, apply the following layout considerations:

- Provide termination on all high-speed interface signals and clock lines.
- Provide impedance matching on long traces to prevent reflections.
- Keep the clock traces away from all other signals to minimize mutual interference.
- In RMII mode, a very low skew clock buffer/driver is recommended to maximize the timing budget. In this mode it is recommended to keep all traces as short as possible.
- In SSMII mode there are two clock signals, one for each direction (Rx and Tx), routed together with the sync and data signals. Since the delay between the clock and these signals is lower, the designer can apply a longer trace delay in this mode. Keep data/sync traces and clock traces at the same length to maximize the timing budget.

### **15.3 Implementing Clock Recovery in High Speed Applications**

For the high-speed interface (up to 51.84 MHz), an external clock multiplier and jitter attenuator are needed. Clock recovery in high-speed applications is depicted below:

*Figure 15-8. External Clock Multiplier for High Speed Applications*

The clock multiplier converts the low speed clock at ACLK to a clock at the frequency of the emulated high-speed circuit. The multiplication factor in the external clock multiplier must be 12 for an E3 or T3 interface and 10 for an STS-1 interface. The clock multiplier should be tuned to add minimal jitter. The jitter attenuator can be part of the LIU or an independent component.

### **15.4 Connecting a Motorola MPC860 Processor**

The device is easily connected to a Motorola MPC860 processor by means of the MPC860 GPCM (General Purpose Chip Select Machine) module.

#### **15.4.1 Connecting the Bus Signals**

Since the MPC860 address bus MSb is always 0 while the DS34S10x address bus LSb is always 0, the signal order can be reversed as shown in the following figures.

Figure 15-9. 32-Bit CPU Bus Connections

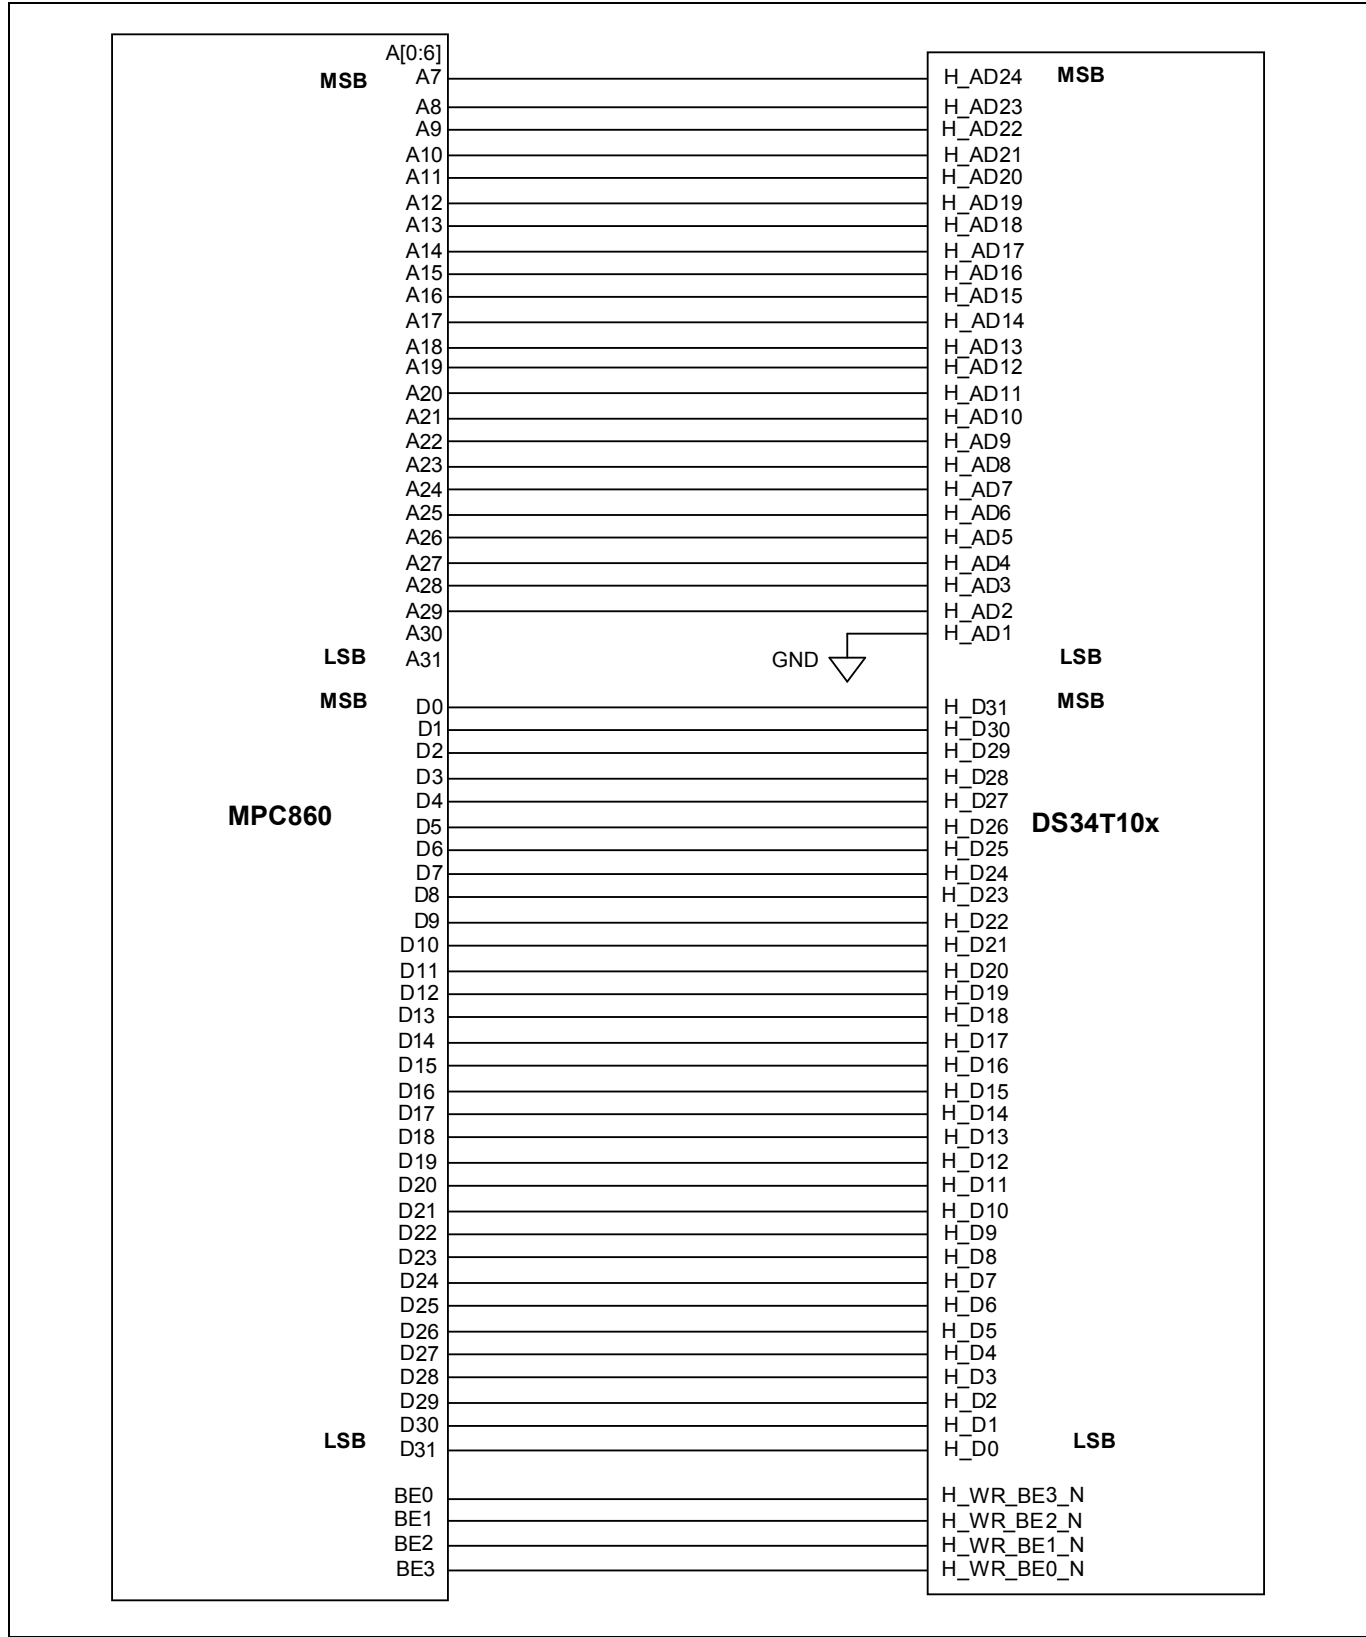

Figure 15-10. 16-Bit CPU Bus Connections

### 15.4.2 Connecting the H\_READY\_N Signal

The **H\_READY\_N** output should be connected to the MPC860 TA input. The CPU bus operates asynchronously. The TA of the MPC860 is a synchronous input (i.e., needs to meet set-up and hold times). The designer should synchronize **H\_READY\_N** to the MPC860 clock by means of a CPLD, which uses the MPC860 reference clock. The internal logic in the CPLD also uses the MPC860 CS (chip select) output. Both the **H\_READY\_N** output and the MPC860 TA input should have a 1k $\Omega$  pull-up resistor.

Figure 15-11. Connecting the H\_READY\_N Signal to the MPC860 TA Pin

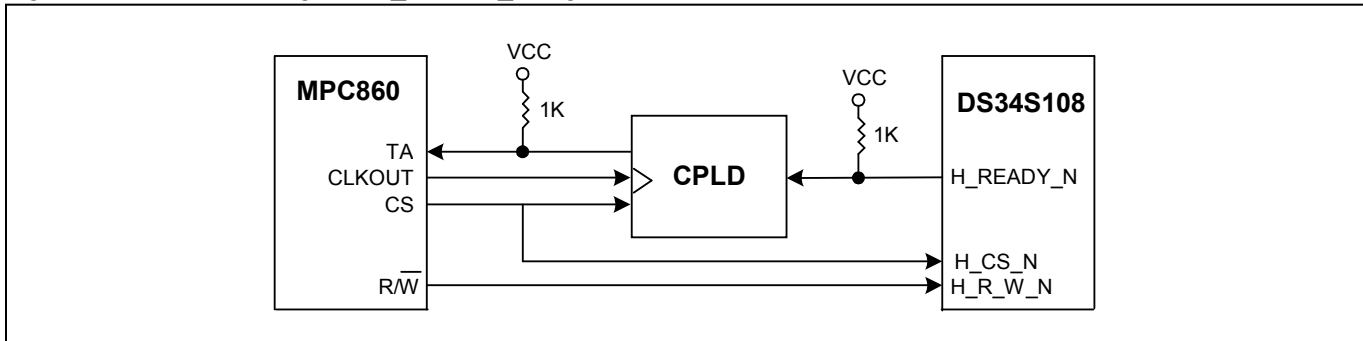

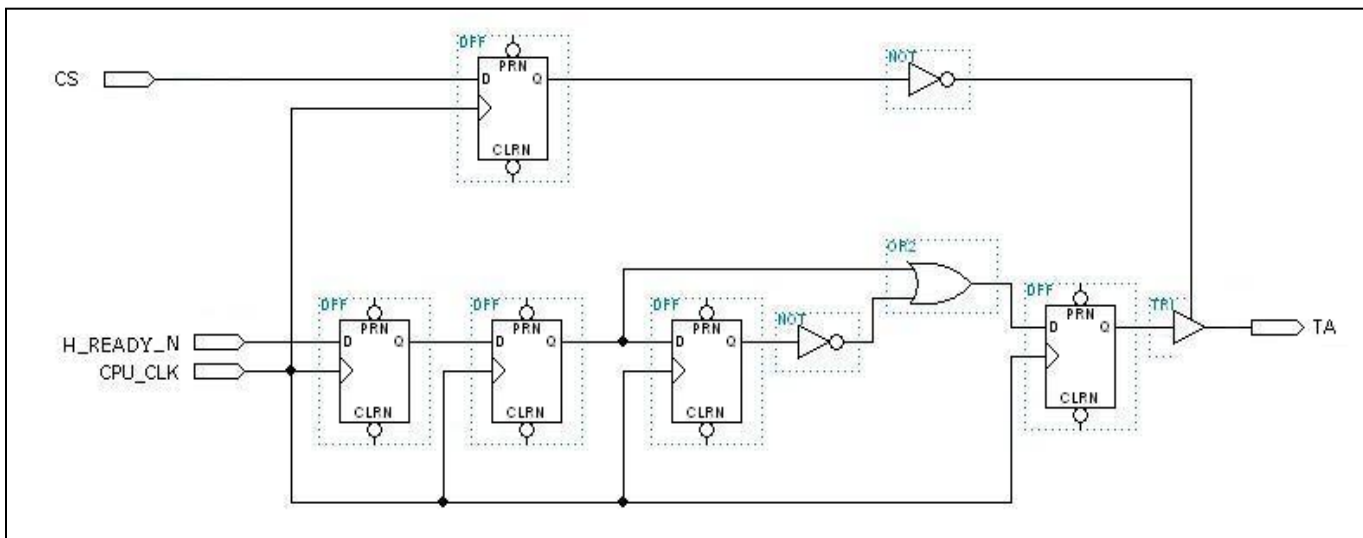

Figure 15-12. Internal CPLD Logic to Synchronize H\_READY\_N to the MPC860 Clock

Another alternative for connecting the **H\_READY\_N** signal is using the MPC860 UPM. In this option the **H\_READY\_N** output should be connected to the MPC860 UPWAIT (GPL4) signal, and no external timing adjustment is needed. The **H\_READY\_N** output should have a 1k $\Omega$  pull-up resistor. Refer to the MPC860 user manual for additional details.

## 15.5 Working in SPI Mode

The following table shows the I/O connections for operating in SPI mode.

**Table 15-1. SPI Mode I/O Connections**

Signal name	Connect to	Comments
<a href="#">H_CPU_SPI_N</a>	VSS (logic 0)	Selects SPI mode.
<a href="#">DAT_32_16_N</a>	DVDDIO or DVSS	Ignored in SPI mode.
<a href="#">H_CS_N</a>	DVDDIO or DVSS	Ignored in SPI mode.
<a href="#">H_AD[24:1]</a>	DVDDIO or DVSS	Ignored in SPI mode.
<a href="#">H_D[31:1]</a>	DVDDIO or DVSS	Ignored in SPI mode.
<a href="#">H_D[0] / SPI_MISO</a>	Master MISO	
<a href="#">H_WR_BE0_N / SPI_CLK</a>	Master SPI clock	
<a href="#">H_WR_BE1_N / SPI_MOSI</a>	Master MOSI	
<a href="#">H_WR_BE2_N / SPI_SEL_N</a>	Master SPI select	
<a href="#">H_WR_BE3_N / SPI_CI</a>	DVDDIO (logic 1) or DVSS (logic 0)	According to required SPI mode
<a href="#">H_R_W_N / SPI_CP</a>	DVDDIO (logic 1) or DVSS (logic 0)	According to required SPI mode

## 15.6 Connecting SDRAM Devices

The following table lists suggested SDRAM devices to use in conjunction with the DS34S10x devices.

**Table 15-2. List of Suggested SDRAM Devices**

Vendor	64 Mb Device	128 Mb Device
Micron	MT48LC2M32B2TG-6	MT48LC4M32B2TG-6
Samsung	K4S643232H-TC/L60	K4S283232E-TC/L60
Hynix	HY57V653220BTC-6 or HY57V643220CT-6	HY57V283220T-6
Elpida	N/A	EDS1232AATA-60
Winbond	W986432DH-6	N/A
ICSI	IC42S32200/L-6T or IC42S32200/L-6TI	N/A
ISSI	IS42S32200C1-6T	IS42S32400B-6T

When connecting the device to an external SDRAM, it is advised to connect [SD\\_CLK](#) through a serial termination resistor.

When connecting the device to a 64 Mb external SDRAM, it is advised to connect [SD\\_A\[11\]](#) through a serial resistor to the SDRAM “NC” pin that is used for address pin A11 for a 128 Mb SDRAM. In this way, the 64Mb SDRAM could be replaced by a 128 Mb SDRAM later, if needed.

## **16. PIN ASSIGNMENTS**

### **16.1 Board Design for Multiple DS34S101/2/4 Devices**

The DS34S101, DS34S102 and DS34S104 require the same footprint on the board. It is recommended that boards be design to support the use of higher port-count devices in a lower port-count socket. If this is done, unused inputs, input/outputs, and outputs must be biased appropriately. Generally, unused inputs are tied directly to the ground plane, unused outputs are not connected, and unused input/outputs are tied to ground through a 10kΩ resistor. Unused inputs with internal pull-ups or pull-downs are not connected. [Table 16-1](#) designates how each ball on the package should be connected to implement a common board design. Shading indicates balls for the unused inputs, input/outputs, and outputs of higher port-count devices.

If a common board design is not done, the balls for the unused inputs, input/outputs, and outputs need not be connected, and the stuffing of higher port-count devices into a lower port-count socket is not recommended.

Note: When a higher port-count device is used in a socket, the BSDL file of the higher port-count device must be used. BSDL files are available from the factory upon request.

**Table 16-1. Common Board Design Connections for DS34S101/2/4 (Sorted by Signal Name)**

## **17. Package Information**

For the latest package outline information and land patterns, go to [www.maxim-ic.com/packages](http://www.maxim-ic.com/packages).

DS34S101, DS34S102 and DS34S108 have a 256-lead thermally enhanced chip-scale ball grid array (TECSBGA) package. The TECSBGA package dimensions are shown in Maxim document [21-0353](#).

DS34S108 has a 484-lead thermally enhanced ball grid array (TEBGA) package. The TEBGA package dimensions are shown in Maxim document [21-0365](#).

## **18. Thermal Information**

<b>Parameter</b>	<b>TECSBGA-256 DS34S101 DS34S102 DS34S104</b>	<b>TEBGA-484 DS34S108</b>
Target Ambient Temperature Range	-40 to 85°C	-40 to 85°C
Die Junction Temperature Range	-40 to 125°C	-40 to 125°C
Theta Jc (junction to top of case)	3.7 °C/W	4.5 °C/W
Theta Jb (junction to bottom pins)	13.1 °C/W	7.1 °C/W
Theta Ja, Still Air (Note 1)	26.2 °C/W	15.0 °C/W

**Note 1:** These numbers are estimates using JEDEC standard PCB and enclosure dimensions.

**19. Data Sheet Revision History**

REVISION DATE	DESCRIPTION
071108	Initial release.
100108	<p>In the <i>Ordering Information</i> table on page 1, removed the asterisks and footnotes that indicated DS34S101, DS34S102 and DS34S104 were future products.</p> <p>In <a href="#">Table 11-11</a>, <a href="#">Table 11-13</a>, <a href="#">Table 11-14</a> and <a href="#">Table 11-15</a>, corrected the index variable in the Description column from n to ts to match the other columns.</p> <p>Updated <a href="#">Figure 6-1</a> to show all CPU interface pins including SPI bus pin names.</p> <p>In section <a href="#">11.4.8</a>, changed the index into the jitter buffer control registers from j = 0 to 255 to port = 1 to 8 and ts = 0 to 31 for additional clarity.</p>
101408	<p>Removed all references to AAL2 mode.</p> <p>Replaced the incorrect terms “cell” and “cells” with “AAL1 SAR PDU” throughout the document except in register names and register field names.</p> <p>Edited section <a href="#">10.6.6</a> for additional clarity about the AAL1 mapping methods.</p> <p>Corrected some spelling errors and other minor typos.</p> <p>In <a href="#">Table 9-1</a>, change note on <a href="#">TST_CLD</a> pin from “DS34S104 only” to “DS34S108 only”.</p> <p>Corrected <a href="#">Table 16-1</a>, which previously was missing a large section from the middle.</p> <p>Added future status for DS34S101 and DS34S102 to the <i>Ordering Information</i> table.</p>
032609	Removed future status for the DS34S101 and DS34S102 in the <i>Ordering Information</i> table.
