

Quad Channel Clock Translator

Features

- Four Independent OTN Desynchronizers
- Excellent Jitter Performance of 180 fs_{RMS} in 12 kHz to 20 MHz, Band Meets Jitter Requirements of 10G/40G and 100G PHYs
- Three Programmable Ultra-low Jitter Synthesizers Generate Frequencies from 1 Hz to 900 MHz.
- One Programmable General Purpose Synthesizer Generates Any Clock from 1 Hz to 180 MHz
- 6 Differential (CML) or 12 Single-ended (CMOS) Ultra-low Jitter Outputs plus Two General Purpose CMOS Outputs
- Accepts up to 10 LVPECL/LVDS/HCSL/LVCMOS Inputs
- Up to Four Programmable Digital PLLs/NCOs with Loop Bandwidth from 14 Hz to 470 Hz Synchronize to Any Clock Rate from 1 kHz to 900 MHz
- Automatic Hitless Reference Switching and Digital Holdover on Reference Fail with Initial Holdover Accuracy Better than 10 ppb

Applications

- OTN Transponders/Muxponders
- OTN Switches
- Test Equipment

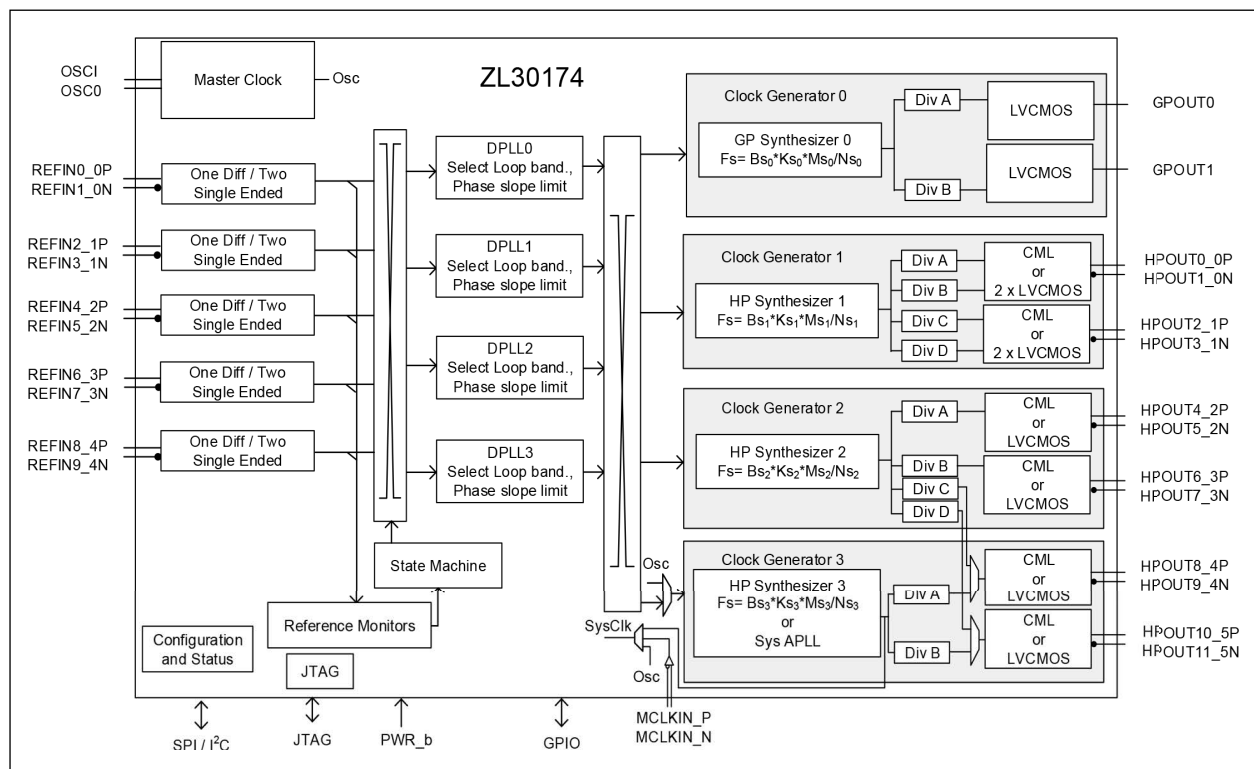

FIGURE 0-1: Functional Block Diagram.

TO OUR VALUED CUSTOMERS

It is our intention to provide our valued customers with the best documentation possible to ensure successful use of your Microchip products. To this end, we will continue to improve our publications to better suit your needs. Our publications will be refined and enhanced as new volumes and updates are introduced.

If you have any questions or comments regarding this publication, please contact the Marketing Communications Department via E-mail at docerrors@microchip.com. We welcome your feedback.

Most Current Data Sheet

To obtain the most up-to-date version of this data sheet, please register at our Worldwide Web site at:

<http://www.microchip.com>

You can determine the version of a data sheet by examining its literature number found on the bottom outside corner of any page. The last character of the literature number is the version number, (e.g., DS30000000A is version A of document DS30000000).

Errata

An errata sheet, describing minor operational differences from the data sheet and recommended workarounds, may exist for current devices. As device/documentation issues become known to us, we will publish an errata sheet. The errata will specify the revision of silicon and revision of document to which it applies.

To determine if an errata sheet exists for a particular device, please check with one of the following:

- Microchip's Worldwide Web site; <http://www.microchip.com>
- Your local Microchip sales office (see last page)

When contacting a sales office, please specify which device, revision of silicon and data sheet (include -literature number) you are using.

Customer Notification System

Register on our web site at www.microchip.com to receive the most current information on all of our products.

1.0 FEATURE LIST

1.1 General features

- Four independent clock channels
- Operates from a single crystal resonator or clock oscillator
 - Supports split XO mode for low-frequency stability TCXO/OCXO with ultra-low jitter clock outputs
- Configurable from SPI/I²C bus or from pre-configured flash memory

1.2 Electrical Clock Inputs

- Accepts up to 10 LVCMOS or 5 LVDS/HCSL/LVPECL/CML differential inputs
- Frequencies from 1 kHz to 180 MHz for LVCMOS
- Frequencies from 1 kHz to 900 MHz for LVDS/HCSL/LVPECL/CML
- Flexible input reference monitoring automatically disqualifies references based on frequency and phase irregularities.
 - Each input reference has its own set of monitors which can be independently programmed.
 - Loss of signal (LOS)
 - Single Cycle Monitor (Triggers on glitches or variation in duty cycle)
 - Coarse Frequency Monitor
 - Precise Frequency Monitor
- Programmable phase slope limiting down to 1 ns/s
- Locks to gapped clocks

1.3 Electrical Clock Engine

- Digital PLLs filter jitter from 14 Hz up to 470 Hz
- Multiple modes of operation
 - Freerun
 - Forced holdover
 - Forced reference
 - Automatic
 - NCO
- Internal state machine automatically controls state
 - Locked
 - Acquiring
 - Holdover
- Automatic hitless reference switching and digital holdover on reference fail
- Programmable bandwidth
- Programmable damping and phase gain (gain peaking)
- Programmable lock and fast lock options
- Support for fast lock with lock times in seconds
- Support for hitless reference switching with typical performance 0.6 ns
- Holdover better than 1 ppb with post holdover filter. Without the post holdover filter the initial holdover accuracy is better than 10 ppb.
- Full rate conversion between input and output clock frequencies

1.4 Electrical Clock Generation

- Four programmable synthesizers
- Precision Synthesizers
 - Each ultra-low jitter output can be independently set to be differential (CML) or two CMOS
 - Six CML outputs
 - Generate clock rates from 1 Hz to 900 MHz
 - Jitter performance of 180 fs_{RMS} (12 kHz–20 MHz)
 - Meets OC-192, STM-64, 1 GbE and 10 GbE interface jitter requirements
 - Twelve LVCMOS outputs
 - Generate clock rates from 1 Hz to 180 MHz
 - Jitter performance of 290 fs_{RMS} (12 kHz–20 MHz)
- General Synthesizer
 - Two LVCMOS outputs
 - Generate clock rates from 1 Hz to 180 MHz
 - Jitter performance of 17 ps_{RMS} (12 kHz–20 MHz)
- Programmable output advancement to accommodate trace delays or compensate for system routing paths
- Each output has its own power supply pin which can be hooked to 3.3V, 2.5V, or 1.8V supplies. Outputs may be disabled to save power

2.0 COMPANION DOCUMENTATION

2.1 Application Notes

- ZLAN-442 Crystals and Oscillators for Next Generation Timing Solutions
- ZLAN-620 Precision Input-Output Alignment Process
- ZLAN-599 Jitter Measurements
- ZLAN-600 Cycle-to-Cycle and Periodic Jitter (PCIe Applications)
- ZLAN-517 Power Supply Decoupling and Layout Guidelines
- ZLAN-527 Assembly and PCB Layout Guidelines for 100-lead dual row (DR) VQFN Package

2.2 Evaluation and Demonstration Board (SyncE and clock input-output focused)

- ZLE30174 EVB (with schematic)
- ZLE30174 GUI
 - Windows register configuration tool
 - Generates flash image configuration file
 - Generates raw register list configuration file
 - Includes useful power calculator for desired PLL configuration

3.0 APPLICATION EXAMPLES

ZL30174 is multifunctional device which can be used in many OTN applications. It provides three independent PLL channels which can synchronize to any input frequency from 1 KHz up to 900 MHz. ZL30174 can generate frequencies from 1 Hz up to 180 MHz for LVCMOS and up to 900 MHz for CML outputs. Each channel is comprised of a DPLL and a Synthesizer.

ZL30174 with its three ultra-low jitter channels can be used in OTN Transponder OTU-4 applications as shown in Figure 4-1. To simplify the block diagram ZL30174 is split into two blocks each containing one PLL. Each PLL here comprises of DPLL with sub 300 Hz loop bandwidth as required by OTN specs and a synthesizer used to generate required frequency with ultra-low jitter required by serializers. The third ultra-low jitter synthesizer is used to generate system clock.

Figure 3-1 shows one channel (PLL0) used as a de-synchronizer to filter gapped OTN line clock. The gapped clock is generated in demapper justification block by removing pulses from the extracted OTN line clock. The gapped clock needs to be cleaned from jitter before it can be used to drive 100G Ethernet CAUI serializers. The second PLL (PLL1) is used to drive OTN line. It can be set in a free run mode where the clock is synchronized to free run crystal oscillator used as ZL30174 master clock or the OTN line can be synchronized to 100G client by synchronizing PLL1 to the Ethernet clock as shown in Figure 3-1.

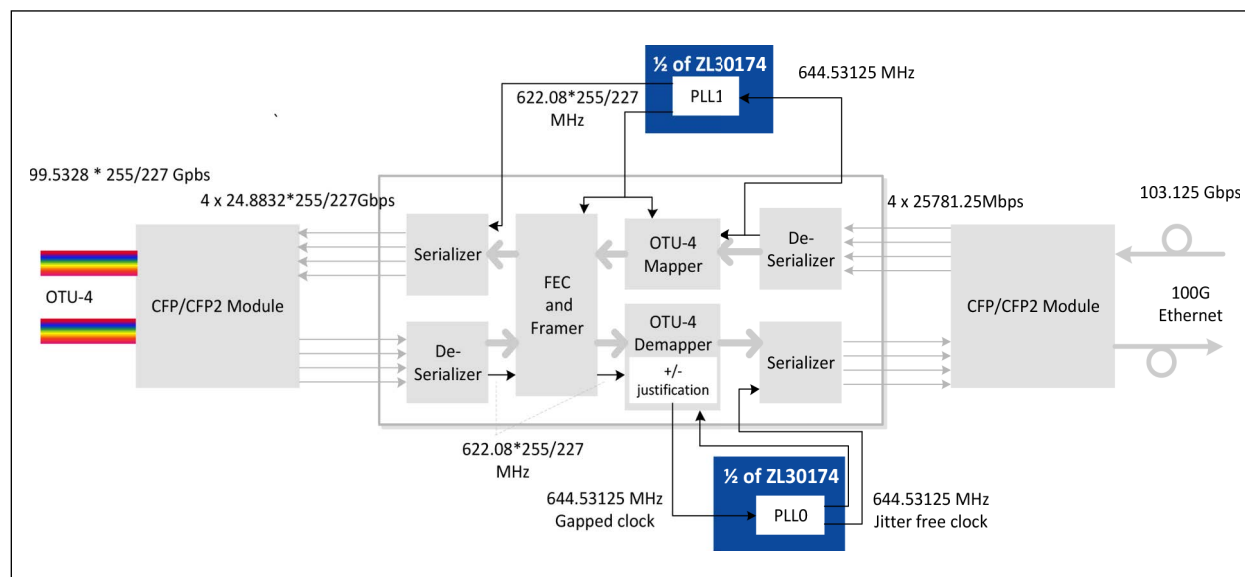

FIGURE 3-1: OTU-4 Transponder.

An example of phase noise at the output of one of ultra-low jitter synthesizers is shown in Figure 3-2.

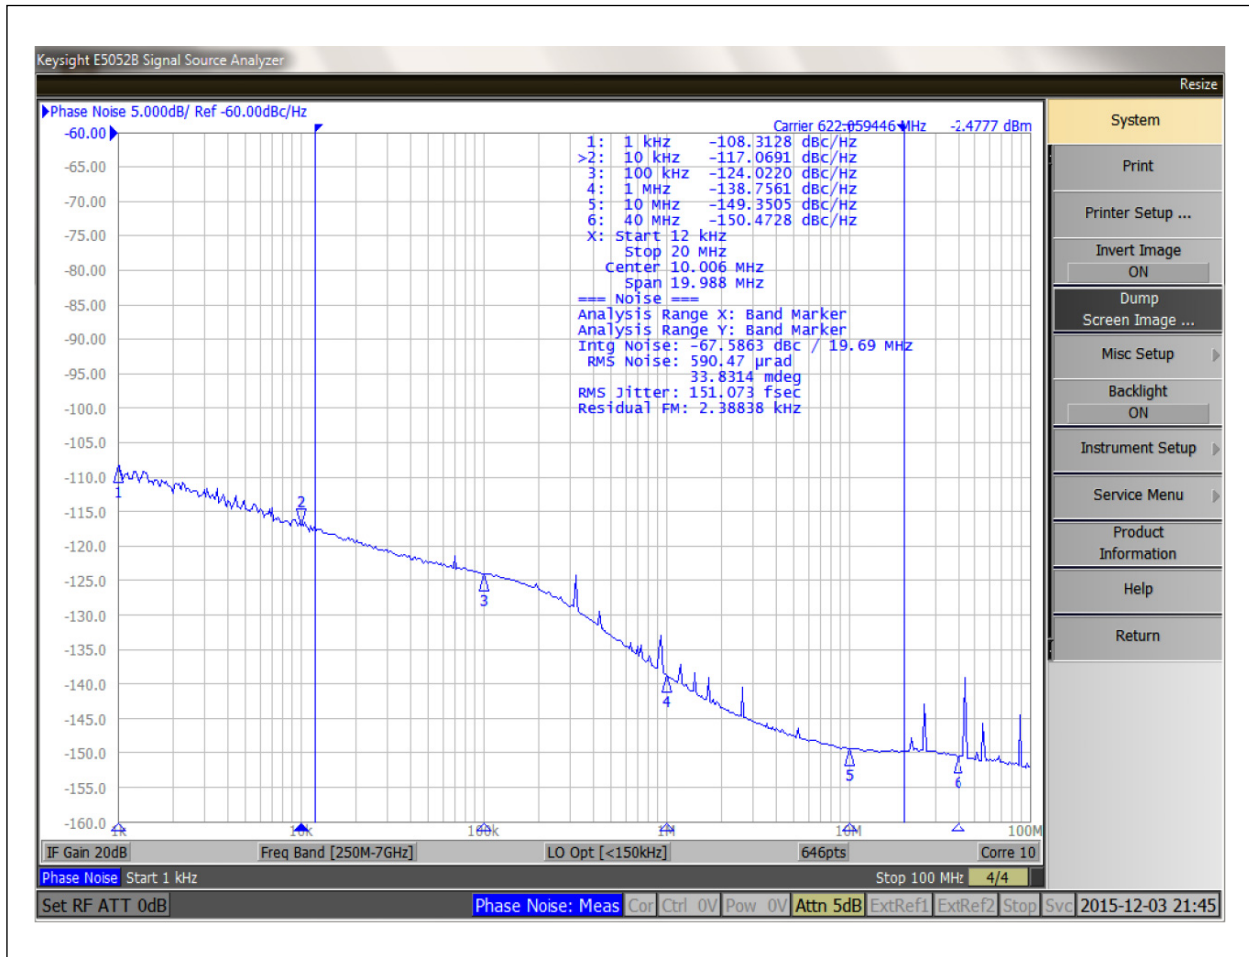

FIGURE 3-2: Phase Noise Plot for 622.08 MHz Output Clock with 200 MHz (151 fs jitter in 12 kHz to 20 MHz Band).

4.0 PIN DIAGRAM

The device is packaged in a 10 mm × 10 mm dual row (DR) 100-lead VQFN.

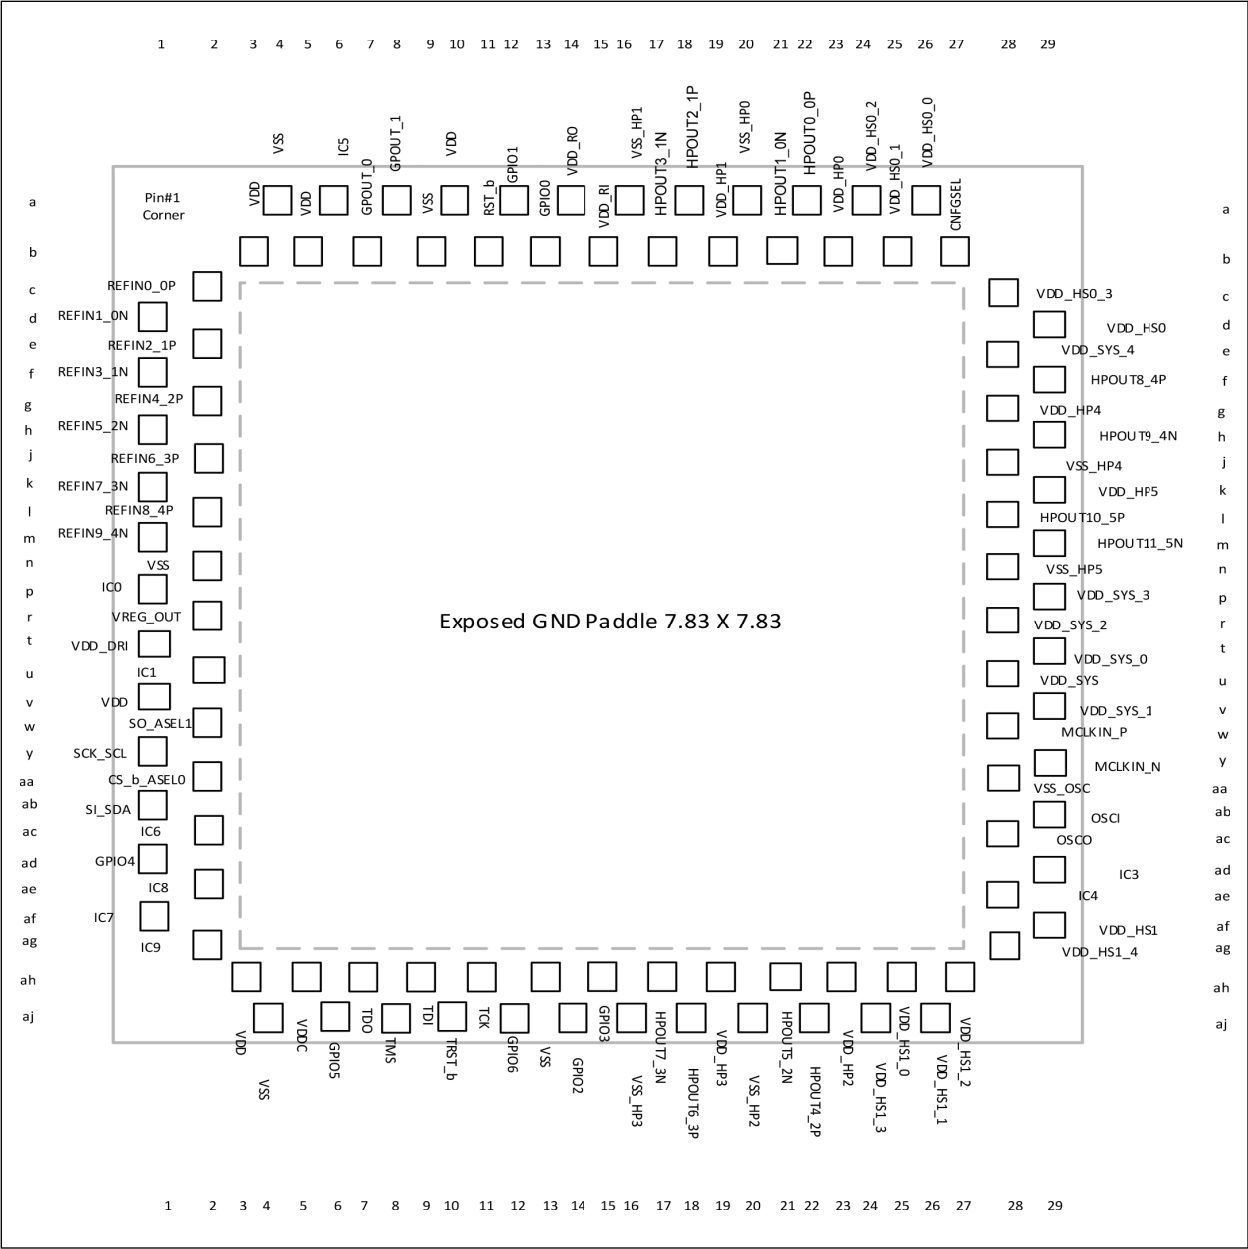

FIGURE 4-1: Pin Diagram.

5.0 PIN DESCRIPTIONS

All device inputs and outputs are LVCMOS unless described otherwise. The Type column uses the following symbols: I – input, I_{PU} – input with 50 kΩ internal pull-up resistor, O – output, A – analog, P – power supply pin. All GPIO and SPI/I²C interface pins have Schmitt-trigger inputs and have output drivers that can be disabled (high impedance).

TABLE 5-1: PIN DESCRIPTIONS

Pin Number	Pin Name	I/O	Description
Input Reference			
C2	REFIN0_0P	I	Input References 0 to 9 (LVCMOS, LVDS, LVPECL, CML, HCSL). These input references can accept up to ten single-ended or up to five differential input signal sources used for synchronization. Each input pair can be programmed to be a differential input or two single-ended inputs. Input frequency range for LVPECL, LVDS, HCSL, CML is from 1 kHz to 900 MHz. Input frequency range for LVCMOS is from 1 kHz to 180 MHz.
D1	REFIN1_0N		
E2	REFIN2_1P		
F1	REFIN3_1N		
G2	REFIN4_2P		
H1	REFIN5_2N		
J2	REFIN6_3P		
K1	REFIN7_3N		
L2	REFIN8_4P		
M1	REFIN9_4N		
Output Clocks			
A22	HPOUT0_0P	O	High Performance (Ultra Low Jitter) Outputs 0 to 11 (CML or LVCMOS). Each output pair can be configured to be CML differential output or two independent LVCMOS outputs. CML output frequency range is from 1 Hz to 900 MHz. LVCMOS output frequency range is from 1 Hz to 180 MHz

M29	HPOUT11_5N		
B7	GPOUT0		
A8	GPOUT1		
Control and Status			
B11	RST_b	I	Power-on Reset. A logic low at this input resets the device. To ensure proper operation, the device must be reset after power-up. The RST_b pin should be held low for 2 ms. This pin is internally pulled-up to VDD. User can access device registers either 500 ms after RST_b goes high, or after bit 7 in register at address 0x00 goes high, which can be determined by polling address 0x00.

TABLE 5-1: PIN DESCRIPTIONS (CONTINUED)

Pin Number	Pin Name	I/O	Description								
B13	GPIO0	I/O	General Purpose Input and Output pins. These are general purpose pins managed by the internal processor based on device configuration. Recommended usage of GPIO include: <ul style="list-style-type: none">• DPLL lock indicators• DPLL holdover indicators• Reference fail indicators• Reference select control or monitor• Differential output clock enable (per output or as a bank of 2 or 4 outputs)• High performance LVCMOS outputs enable• Host Interrupt Output: flags changes of device status prompting the processor to read the enabled interrupt service registers (ISR).• Pins 6:0 are internally pulled down to GND.• If not used, GPIO can be kept unconnected. After power on reset, device GPIO[5:0] configure some of device basic functions, GPIO[4] sets SPI (low) or I ² C (high) control mode, GPIO[3,0] and GPIO[5] set master clock rate selection. The GPIO[5:0] pins must be either pulled low or high with an external 1 K Ω resistor as needed for their assigned functions at reset; or they must be driven low or high for 500 ms after reset, and released and used for normal GPIO functions. Refer to Section 6.5.2 “Master Clock Frequency Selection” and Table 6-2 for how GPIO[5,3,2,1,0] is used to set the master oscillator frequency.								
A12	GPIO1										
AJ14	GPIO2										
AH15	GPIO3										
AD1	GPIO4										
AJ6	GPIO5										
AJ12	GPIO6										
B27	CNFGSEL	I	Configuration Select. This pin is three level input which selects one of three custom configurations on the power up. Custom configurations have to be pre-loaded by MSCC. If custom configurations are not loaded, this pin is ignored on the power up and the device registers are loaded with default values. <table><tr><th>Configuration</th><th>CNFGSEL</th></tr><tr><td>0</td><td>GND</td></tr><tr><td>1</td><td>V_{DD} (has to be pulled up with 4.7 kΩ resistor)</td></tr><tr><td>2</td><td>V_{DD} /2 or Open</td></tr></table>	Configuration	CNFGSEL	0	GND	1	V _{DD} (has to be pulled up with 4.7 k Ω resistor)	2	V _{DD} /2 or Open
Configuration	CNFGSEL										
0	GND										
1	V _{DD} (has to be pulled up with 4.7 k Ω resistor)										
2	V _{DD} /2 or Open										
Host Interface											
Y1	SCK_SCL	I/O	Clock for Serial Interface. Provides clock for serial micro-port interface. This pin is also the serial clock line (SCL) when the host interface is configured for I ² C mode. As an input this pin is internally pulled up to V _{DD} . In I ² C mode this pin should be externally pulled high by 1 K Ω to 5 K Ω resistor.								
AB1	SI_SDA	I/O	Serial Interface Input. Serial interface input stream. The serial data stream holds the access command, the address and the write data bits. This pin is also the serial data line (SDA) when host interface is configured for I ² C mode. This pin is internally pulled up to V _{DD} . In I ² C mode this pin should be externally pulled high by 1 K Ω to 5 K Ω resistor.								
W2	SO_ASEL1	I/O	Serial Interface Output. Serial interface output stream. As an output the serial stream holds the read data bits. This pin is also the I ² C address select when host interface is configured for I ² C mode.								
AA2	CS_b_ASEL0	I	Chip Select for Serial Interface. Serial interface chip select, this is an active low signal. This pin is also the I ² C address select when host interface is configured for I ² C mode. This pin is internally pulled up to V _{DD} .								

TABLE 5-1: PIN DESCRIPTIONS (CONTINUED)

Pin Number	Pin Name	I/O	Description
JTAG (IEEE 1149.1)			
AH7	TDO	O	Test Serial Data Out. JTAG serial data is output on this pin on the falling edge of TCK. This pin is held in high impedance state when JTAG scan is not enabled.
AH9	TDI	I	Test Serial Data In. JTAG serial test instructions and data are shifted in on this pin. This pin is internally pulled up to VDD. If this pin is not used then it should be left unconnected.
AJ10	TRST_b	I	Test Reset. Asynchronously initializes the JTAG TAP controller by putting it in the Test-Logic-Reset state. This pin should be held low, or pulsed low on power-up, to ensure that the device is in the normal functional state. This pin is internally pulled up to VDD. If this pin is not used then it should be connected to GND.
AH11	TCK	I	Test Clock. Provides the clock to the JTAG test logic. This pin is internally pulled up to VDD. This pin is internally pulled up to VDD. If this pin is not used then it should be connected to GND.
AJ8	TMS	I	Test Mode Select. JTAG signal that controls the state transitions of the TAP controller. This pin is internally pulled up to VDD. If this pin is not used, then it should be left unconnected.
Master Clock			
AC28	OSCO	A-O	Oscillator Master Clock. For crystal operation, a crystal is connected from this pin to OSCI. Not suitable for driving other devices. For clock oscillator operation, this pin is left unconnected. If OSCI is not used (MCLKIN is used) this pin is left unconnected.
AB29	OSCI	I	Oscillator Master Clock. For crystal operation, a crystal is connected from this pin to OSCO. For clock oscillator operation, this pin is connected to a clock source. Supported Crystal/Oscillator frequencies: 10 MHz, 20 MHz, 24.576 MHz, 25 MHz, 49.152 MHz, 50 MHz, 98.304 MHz, 100 MHz, 114.285 MHz,125 MHz. If 98.304 MHz, 100 MHz, 114.285 MHz or 125 MHz is available then the system PLL can be used as a third synthesizer. If OSCI is not used (MCLKIN is used), it should be pulled-up or pulled-down.
W28	MCLKIN_P	I	Differential Oscillator Master Clock. This input is connected to a differential clock oscillator. Supported oscillator frequencies: 98.304 MHz, 100 MHz, 114.285 MHz, 125 MHz, 200 MHz. If the differential master clock input is not used, MCLKIN_P and MCLK_N should be pulled low.
Y29	MCLKIN_N		
Miscellaneous			
P1	IC0	A-I/O	Internal Connection. Leave unconnected.
A6	IC5		
AC2	IC6		
AF1	IC7		
AG2	IC9		
AD29	IC3	I	Internal Connection. Connect to GND.
AE28	IC4		
U2	IC1	I	Internal Connection. Pull-down with 1 KΩ resistor or connect directly to ground.
AE2	IC8		

TABLE 5-1: PIN DESCRIPTIONS (CONTINUED)

Pin Number	Pin Name	I/O	Description
Power and Ground			
T1	VDD_DRI	P	Positive Supply Voltage. Connect to +1.8 V _{DC} . Associated with core operation (internal regulator block). Refer to Section 6.6.5 “VDD_DRI and VREG_OUT” for more details.
R2	VREG_OUT	P	Positive Supply Voltage. Connect to an external capacitor to ground. Connect to an external 340Ω resistor to ground. Connect to an external 150Ω resistor to VDD_DRI (pin T1). 340Ω and 150Ω resistors are required only for devices with chip_revision_id equal to 0 or 1. For devices with chip_revision_id equal to 2 these resistors are optional. Refer to Section 6.6.5 “VDD_DRI and VREG_OUT” for more details. Associated with core operation (internal regulator block).
AH5	VDDC	P	Positive Supply Voltage. Connect to VREG_OUT (pin R2). Associated with core operation.
V1	VDD	P	Positive Supply Voltage. Connect to +2.5 V _{DC} or +3.3 V _{DC} . Associated with Control and Status signals (GPIO[4:6]), Host Interface signals, JTAG signals, Input Reference signals, Output Clocks (GPOUT[0:1]) signals, and core operation.
AH3			
A10			
B5			
B3			
A26	VDD_HS0_0	P	Positive Supply Voltage. Connect to +1.8 V _{DC} . Associated with core operation of synthesizer 1.
A24	VDD_HS0_2		
B25	VDD_HS0_1	P	Positive Supply Voltage. Connect to +2.5 V _{DC} or +3.3 V _{DC} . Associated with core operation of synthesizer 1. The choice of +2.5 V _{DC} or +3.3 V _{DC} must be the same across all synthesizers.
C28	VDD_HS0_3		
D29	VDD_HS0	P	Positive Supply Voltage. Connect to +2.5 V _{DC} if the device is powered by +1.8 V _{DC} /+2.5 V _{DC} . Connect only to an external capacitor to ground if the device is powered by +1.8 V _{DC} /+3.3 V _{DC} . Associated with core operation of synthesizer 1.
AH25	VDD_HS1_0	P	Positive Supply Voltage. Connect to +1.8VDC. Associated with core operation of synthesizer 2.
AJ26	VDD_HS1_1		
AH27	VDD_HS1_2		
AJ24	VDD_HS1_3		
AG28	VDD_HS1_4	P	Positive Supply Voltage. Connect to +2.5 V _{DC} or +3.3 V _{DC} . Associated with core operation of synthesizer 2. The choice of +2.5 V _{DC} or +3.3 V _{DC} must be the same across all synthesizers.
AF29	VDD_HS1	P	Positive Supply Voltage. Connect to +2.5 VDC if the device is powered by 1.8VDC /+2.5 VDC. Connect only to an external capacitor to ground if the device is powered by 1.8VDC /+3.3 VDC. Associated with core operation of synthesizer 2.
T29	VDD_SYS_0	P	Positive Supply Voltage. Connect to +2.5 V _{DC} or +3.3 V _{DC} . Associated with core operation of synthesizer 3 (system PLL). The choice of +2.5 VDC or +3.3VDC must be the same across all synthesizers.
V29	VDD_SYS_1		
R28	VDD_SYS_2	P	Positive Supply Voltage. Connect to +1.8 V _{DC} . Associated with core operation of synthesizer 3 (system PLL).
P29	VDD_SYS_3		
E28	VDD_SYS_4		
U28	VDD_SYS	P	Positive Supply Voltage. Connect to +2.5 V _{DC} if the device is powered by +1.8 V _{DC} /+2.5 V _{DC} . Connect only to an external capacitor to ground if the device is powered by +1.8 V _{DC} /+3.3 V _{DC} . Associated with core operation of synthesizer 3 (system PLL).

6.0 HARDWARE FUNCTIONAL DESCRIPTION

6.1 Input References

6.1.1 INPUT SOURCES

The device has twelve input sources: ten input references (ten single-ended or five differentials) and two oscillator clock sources (one single-ended or one differential).

The device master clock frequency is configured on reset via external voltage levels on GPIO[5,3,2,1,0] pins as described in [Section 5.0 “Pin Descriptions”](#).

The device synchronizes (locks) to any input reference which is a 1 kHz multiple, or it synchronizes (locks) to any input reference which is an $M/N \times 1$ kHz multiple (FEC rate) where M and N are 16 bits wide. In some cases $M/N \times 1$ Hz, $M/N \times 10$ Hz, and $M/N \times 100$ Hz is supported.

The device input reference frequency is programmed during initialization. The input reference frequency can be changed when the input reference is not the active source for a DPLL.

The device accepts an input reference with a maximum frequency of 180 MHz through single-ended LVCMOS input or 900 MHz frequency through differential inputs.

If the frequency of an input reference exceeds 400 MHz, the reference must be internally divided by 2 before being fed to DPLL (refer to **ref_config** registers).

6.1.2 INPUT REFERENCE MONITORING

The input references are monitored by reference monitor indicators which are independent for each reference. They indicate abnormal behavior of the reference signal, for example; drift from its nominal frequency or excessive jitter.

6.1.2.1 Input Loss of Signal Monitor (LOS)

LOS is an external signal, fed to one of ZL30174 GPIO pins. LOS is typically generated by a PHY device whose recovered clock is fed to one of the reference inputs. The PHY device will generate a LOS signal when it cannot reliably extract the clock from the line. The user can set one of GPIO pins as a LOS input by programming corresponding GPIO register.

The GPIO inputs are read approximately every 10 ms, except with using system PLL bypass mode with 100 MHz oscillator where they are read approximately every 25 ms.

6.1.2.2 Input Coarse Frequency Monitor (CFM)

The CFM monitors the input reference frequency for 1.25 ms so that it can quickly detect large changes in frequency. CFM limit for each input reference can be selected in **ref_cfm** mailbox register with range from 0.1% to 50%. If the CFM limit is exceeded, then CFM failure is declared for corresponding reference.

For frequencies below 16 kHz, the CFM and SCM limits should be set to the same value for proper operation.

6.1.2.3 Input Precise Frequency Monitor (PFM)

The PFM block measures the frequency accuracy of the reference and updates the indicator bit. To prevent PFM from being false triggered by jitter/wander at the reference input, PFM averages frequency for more than 10 second period and indicate failure when the measured frequency exceeds limit specified in **ref_pfm_disqualify** register. To ensure an accurate frequency measurement, the PFM measurement interval is restarted if phase or frequency irregularities are detected by SCM or CFM. The PFM provides a level of hysteresis to prevent a failure indication from toggling between valid and invalid for input references that are on the edge of the acceptance range. PFM limit should be set as described in **ref_pfm_disqualify** and **ref_pfm_qualify** mailbox registers.

When determining the frequency accuracy of the reference input, the PFM uses the external master clock oscillator's frequency as its reference. As a result, the actual acceptance and rejection frequencies can be offset with respect to the external oscillator's output frequency. This is accounted for in the acceptance and rejection requirements as defined in AN4287A with recommended oscillators in AN3467.

An example of the acceptance and rejection ranges for Stratum 3 application (acceptance in the range of ± 9.2 ppm, rejection at ± 12 ppm) given a ± 4.6 ppm freerun frequency accuracy of a Stratum 3 reference oscillator is shown in [Figure 6-1](#).

FIGURE 6-1: Stratum 3/G.8262 Option I Frequency Acceptance and Rejection Ranges.

6.1.2.4 Input Single Cycle Monitor (SCM)

This detector measures the rising to rising edge and falling to falling edge periods of the input reference. If either exceeds the predefined SCM limit then a SCM failure is declared. The SCM limit for each input reference can be selected in the **ref_scm** mailbox registers with range from 0.1% to 50%. The limits are input frequency dependent. Please refer to the description in **ref_scm** mailbox register.

For frequencies below 16 kHz, the CFM and SCM limits should be set to the same value for proper operation.

For frequencies above 400 MHz, SCM (and the GST) should not be used.

6.1.2.5 Input Guard Soak Timer (GST)

When selected, the guard soak timer adds extra time to qualify and disqualify a reference. The default time to wait to qualify a reference is 50 ms after the CFM and SCM limits have been satisfied. When disqualifying a reference, the time starts after a CFM or SCM failure is detected and before the reference is disqualified. The default disqualification time is 4 times the qualification time. A PFM failure does not affect this timer.

When a reference is currently qualified and a failure occurs, the timer for disqualification is started. When the timer reaches the programmed threshold the reference is disqualified. If at any time between the starting of the timer and reaching the programmed threshold the input reference returns to a good state then the disqualification timer is reset.

When a reference is currently disqualified and the reference returns to good status, the timer for qualification is started. When the timer reaches the programmed threshold the reference is qualified. If at any time between the starting of the timer and reaching the programmed threshold the input reference returns to a failure state then the qualification timer is reset.

For frequencies above 400 MHz, the GST should not be used because the single cycle monitor (SCM) will never be valid.

It is possible to mask an individual reference monitor from triggering a reference failure by setting corresponding bits in **ref_mon_mask** register.

6.1.2.6 Input Reference Monitoring Interrupt Generation

Block diagram describing how reference monitoring block interact and how they generate an interrupt is shown in [Figure 6-2](#). As can be seen from the block diagram, the reference monitoring interrupt generation is separate from reference monitoring DPLL control, which is described in [Section 6.2 “Digital Phase Locked Loop \(DPLL\)”](#). The purpose of this is to allow user full flexibility during forced reference (manual) control.

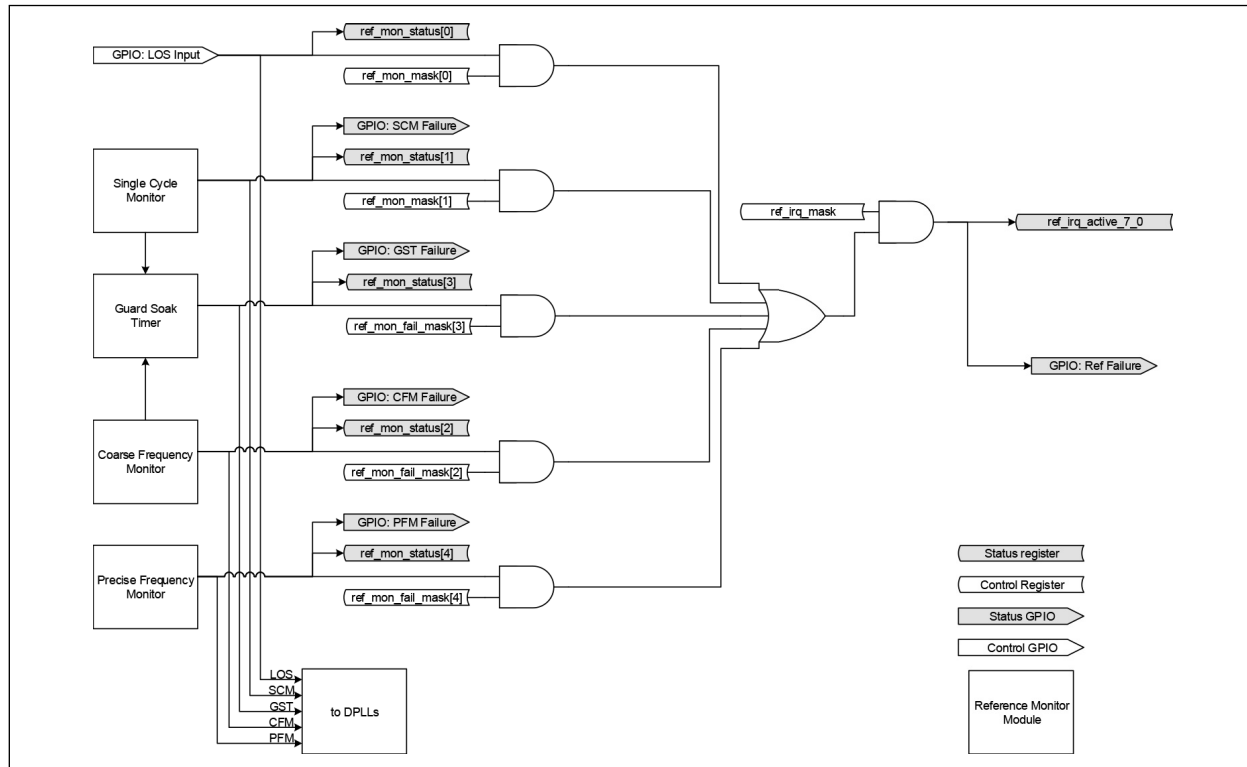

FIGURE 6-2: Reference Monitoring Interrupt Generation.

6.1.3 INPUT GAPPED CLOCKS

The device supports locking to input gapped clocks.

6.1.4 INPUT BUFFERS

The device has ten single-ended reference inputs REFIN[0:9] and each reference input pair REFIN[2n]/REFIN[2n+1] can be used as a differential input for the total of five differential inputs. By default all reference inputs are single-ended. This can be changed by programming **ref_config** register.

Each input pair REFIN[2n]/REFIN[2n+1] can terminate two LVCMOS inputs, one differential input or two LVDS/LVPECL/HCSL inputs where only the positive signal of differential pair is fed to the input pins as shown in [Figure 6-3](#).

[Figure 6-4](#) shows how each input pair can terminate two LVCMOS inputs where the supply voltage of LVCMOS drivers is the same as the VDD of MSCC device (3.3V or 2.5V).

[Figure 6-5](#) shows how to terminate two differential inputs by taking only the positive signal out of each differential pair. In this case the device's common mode voltage (VREF-PECL) is set at 55% of VDD so the common mode voltage will have to be created with external biasing resistors (10k in parallel with 12.7k) as in [Figure 6-5](#) which shows an example how to terminate CML signals—CML drivers require 50Ω pull-up resistors to VDD. For other differential formats 50Ω resistors should be replaced with appropriate termination resistor(s): LVPECL with 127Ω and 82Ω resistors connected in Thevenin termination, source terminated HCSL does not need any termination and LVDS with 100Ω resistor between p and n. It should be noted that common mode voltage is different for differential input ([Figure 6-9](#)) where it needs to be between 1.1V and 1.2V. If only one of the inputs in the P/N pair needs to be single-ended LVPECL and the other needs to be set as a standard LVCMOS than single-ended LVPECL should be connected to the N input and standard LVCMOS on the P input. If the second input is unused, then it should be left unconnected.

[Figure 6-6](#) shows how each input pair can terminate two LVCMOS inputs where the supply voltage of their drivers is lower than the VDD of MSCC device. This is very useful in applications where input references are sources from a device with low output voltages (1.2V, 1.5V, 1.8V, or 2.5V). The input pair needs to be set into single-ended LVPECL mode and the external Thevenin termination resistors (90Ω and 110Ω) need to provide biasing (55% of VDD) and 50Ω transmission line termination. The series termination resistors R_s should be inserted at the source and the sum of their resistance and internal resistance of the driver should match the characteristic impedance of the transmission line (50Ω). The table in [Figure 6-6](#) provides commonly used values for series termination resistors but the user should always use the recommended series termination for the particular driver.

The input frequency range for differential inputs (Figure 6-3, Figure 6-5, and Figure 6-6) is: 1 kHz to 900 MHz; for single LVCMOS ended inputs (Figure 6-4) is: 1 kHz to 180 MHz.

FIGURE 6-3: LVDS Example of Input Buffers and Termination.

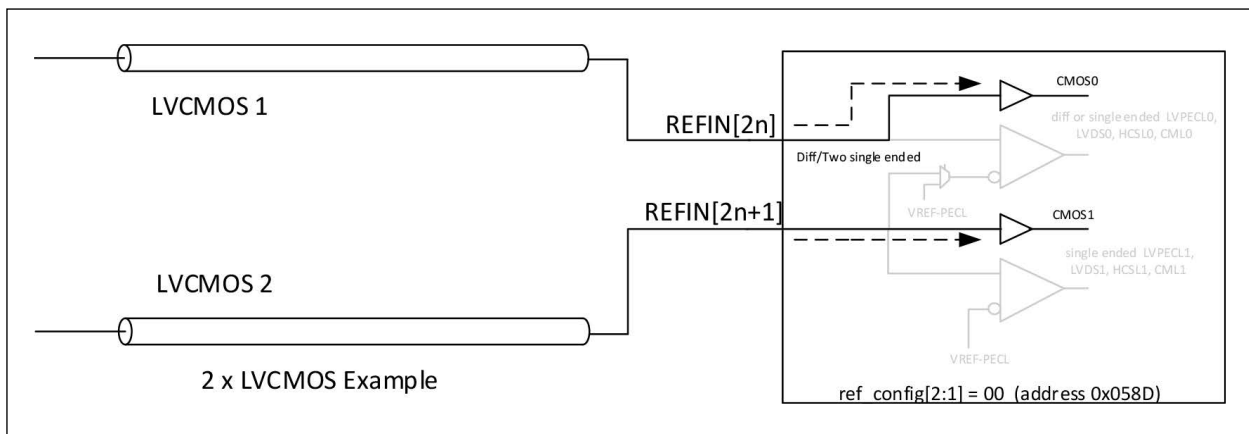

FIGURE 6-4: 2 x LVCMOS Example of Input Buffers and Termination.

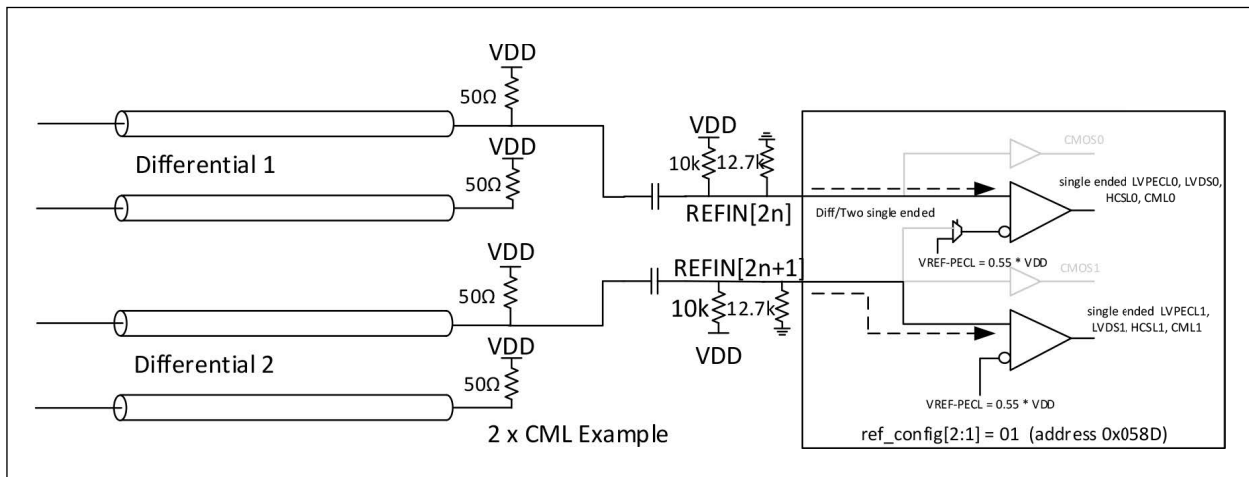

FIGURE 6-5: 2 x CML Example of Input Buffers and Termination.

The top diagram illustrates a driver configuration where the LVPECL driver has series resistors of 182 Ω and shunt resistors of 68 Ω to ground. The signal lines are 50 Ω transmission lines. The receiver (MSCC Device) also has series resistors of 182 Ω and shunt resistors of 68 Ω to ground. Power supply rails are 3.3V/2.5V.

The bottom diagram illustrates a driver configuration where the LVPECL driver has shunt resistors of 200 Ω to ground and 10 nF coupling capacitors. The signal lines are 50 Ω transmission lines. The receiver (MSCC Device) has series resistors of 127 Ω and shunt resistors of 82 Ω to ground. Power supply rails are 3.3V/2.5V.

FIGURE 6-7: *Differential DC and AC Coupled LVPECL Termination.*

Terminations for DC and AC coupled LVDS lines are shown in [Figure 6-8](#). Differential input biasing is provided by LVDS driver in case of DC coupling whereas for AC coupling biasing is generated by 12 k Ω and 8.2 k Ω resistors. In both cases, the line is terminated with 100 Ω resistor.

FIGURE 6-8: Differential DC and AC Coupled LVDS Termination.

Transmission line should be terminated at the source with 22 Ω resistor as shown in [Figure 6-9](#).

FIGURE 6-9: Single-ended LVCMOS Termination.

6.2 Digital Phase Locked Loop (DPLL)

The device supports four independent digital PLL modules. All available DPLLs are enabled by default. Each DPLL can be enabled/disabled through the host registers.

6.2.1 DPLL INPUT MONITORING MASKS

Each DPLL has its own reference switching (**dppl_ref_sw_mask**) and holdover (**dppl_ref_ho_mask**) mask mailbox registers which are used to prevent reference monitoring circuit from triggering DPLL to switch references or to go into the holdover state. Please note that the GST bit should not be unmasked (GST trigger enabled) without unmasking either the SCM or the CFM or both bits. The reference switching mask is used only in the automatic control mode. In forced reference mode this register is ignored. The holdover mask register is active in both: automatic and forced reference modes.

Refer to the **dppl_priority_1_0** through **dppl_priority_9_8** mailbox register,

6.2.2 DPLL INPUT REFERENCE PRIORITY

Every reference is assigned a local priority value (0 to 10) to allow system designers to specify the priority of each input references. The priorities are relative to each other, with lower value numbers being the higher priority. Value "1111" disables the ability to select the reference (i.e., don't use for synchronization).

If two or more inputs are given the same priority number, the input is selected based on the reference naming convention (i.e., ref0 is higher priority than ref1). The default reference selection priority is equal to its reference number (i.e., ref0 is highest priority and ref10 is the lowest priority).

When two references have the same priority, they will not revert to each other (as reference availability changes), but they will revert to a reference with a higher priority when it is available.

6.2.3 DPLL INPUT PULL-IN, HOLD-IN RANGE

Pull-in/hold-in range is programmable in the **dppl_range** mailbox register. When the input reference input exceeds the pull-in hold-in limit a notification may be generated. Refer to **flhit** parameter in the register map.

6.2.4 DPLL INPUT TOLERANCE CRITERIA

Input tolerance indicates that the device tolerates certain jitter, wander and phase transients at its input reference while maintaining outputs within an expected performance and without experiencing any alarms, reference switching or hold-over conditions. Input tolerance is associated with input reference source characteristics and the standards associated with input reference type.

6.2.5 DPLL INPUT ADVANCE AND DELAY

The DPLL phase may be advanced or delayed in units of nanoseconds using **dppl_tie_data_x**, **dppl_tie_ctrl_x**, **dppl_tie** and **dppl_tie_wr_thresh** mailbox registers. This phase adjustment feature acts as if the input signal was ahead or behind its true location by the programmed amount; therefore, any changes to the phase adjustment are filtered through the DPLL bandwidth. There is no lifetime limit to the range. The value applied will be retained for all inputs and all modes of operation of the DLL and is only cleared by the user.

6.2.6 DPLL INPUT PHASE SLOPE LIMITER

A sudden phase change at the input of the DPLL can occur due to reference rearrangement upstream the timing chain. While most modern devices (DPLL) can perform hitless switch between references, telecom standards (ITU-T G.8262 for example) provision for relatively large phase changes. For example ITU-T G.8262 Option 1, allows for up to 1000 ns phase change within 15 second window (Requirement 11.1 Short-term phase transient response). The response of DPLL to such phase transient will be governed by the DPLL loop bandwidth—the narrower the loop bandwidth, the slower the phase change at the output.

Some applications may be sensitive to fast phase transients and mitigating them with the DPLL loop bandwidth reduction may not be possible (the loop bandwidths are generally restricted to a specific range in compliance with a standard). In such cases MSCC device offers Phase Slope Limiter block which limits the slope of the phase change fed to the device.

The value of Phase Slope Limiter can be adjusted in **dp1l_psl** mailbox register from 1 ns/s to 65535 ns/s. These low PSL values may be very useful to slow incoming clock transients or to limit the frequency offset (compared with the master clock). Care must be taken when setting a low PSL value that the oscillator is sufficiently stable. Care must also be taken when wander transfer is important that the PSL does not impact any expected input-to-output wander transfer behavior.

When the input reference input exceeds the phase slope limit and the phase slope limit engages a notification may be generated. Refer to **pslhit** parameter in the register map.

6.2.7 DPLL CORE MODE

The DPLL in the device support five modes: freerun, forced holdover, automatic, forced reference lock and numerically controlled oscillator (NCO). To lock the DPLL to a reference, automatic or forced reference mode should be used. In each of the locked modes, there are three states: acquiring, locked and holdover. The acquiring state is temporary state between the availability of a reference and the completion of the locking process. In the automatic mode, the DPLL may transition between the states depending on the availability of the references. In forced reference mode, the device will go into holdover if the reference selected is unavailable even if other references are available. The availability of a reference is determined by the reference qualification process. In the holdover mode or holdover state, the device provides output clocks which are not locked to an external reference signal, but are based on an estimate of the frequency during the previous time in the locked state. To force the DPLL into the holdover state even with good references present, the forced holdover mode is used.

In addition, the DPLL can be put into the freerun mode. This is used when the synchronization to a reference is not required or is not possible. Typically, this is used immediately following system power-up. In the freerun mode, the device provides timing and synchronization signals which are based on the master clock frequency only, and are not synchronized to the reference input signals. The freerun accuracy of the output clock is equal to the accuracy of the master clock. So if a ± 20 ppm freerun output clock is required, the master clock must also be ± 20 ppm.

The freerun mode:

- The DPLL has to generate all its output clocks based only on the device master clock input.
- The DPLL will not lock or switch to a reference or go into holdover.
- The reference switch mask and the reference holdover mask are ignored.

The forced holdover mode:

- All references are ignored and the DPLL has to go to holdover (based on last selected reference)
- The reference switch mask and the reference holdover mask are ignored.

The forced reference lock mode:

- The DPLL will try to lock to the host-specified reference.
- The reference switch mask is ignored. No reference switching will be performed.
- If the holdover mask is set, then the device will switch to holdover if the selected reference fails.
- If the holdover mask is not set, then the device will attempt to lock to the selected reference, even if it is failing one of the reference monitors. The input frequency tracking will be limited by the pull-in/hold-in settings of the DPLL.

The automatic mode:

- Reference selection and holdover is automatically handled by the device, based on the holdover and reference switch masks, and the reference priority.
- If the reference switch mask is set, then reference will be selected based on availability and priority. If all enabled references are bad, then the device will enter holdover.
- If holdover mask is set (and ref. switch mask cleared), then device switches to holdover on ref failure.
- If neither the reference switch nor the holdover masks are set, then device will keep trying to lock to a failed reference. The input frequency tracking will be limited by the pull-in/hold-in settings of the DPLL.

The NCO mode:

- The DPLL is run in freerun mode. The output clock is the requested synthesizer frequency with an offset specified by the **dp1l_df_offset** register. This write-only register will change the output frequency of the DPLL.

6.2.8 DPLL STATUS INDICATORS

The DPLL provides lock and holdover indicators using the default lock indicator conditions. There are two major status indicators: LOL (Loss of Lock) and HO (Holdover) which may be used with the following truth table:

TABLE 6-1: DPLL STATUS INDICATORS

nLOL	HO	State
0	1	Holdover
0	0	Acquiring
1	0	Locked

6.2.9 DPLL BANDWIDTH (JITTER/WANDER TRANSFER)

The DPLL loop bandwidth is programmable from 14 Hz to 470 Hz. The DPLL bandwidth is typically programmed during initialization. When changing the bandwidth dynamically, it is recommended to put the DPLL to Holdover mode first and then change the bandwidth. After the bandwidth has been changed, the DPLL should be set to the Normal mode.

Loop bandwidth is set by programming the **dp1l_bw_fixed** mailbox register for one of five loop bandwidths: 14 Hz, 29 Hz, 61 Hz, 130 Hz, or 380 Hz. Additionally, there is support for 470 Hz.

The DPLL locks to an input reference and provides a stable low jitter output clock when the selected loop bandwidth is less than $1/30^{\text{th}}$ of the input reference frequency. As an example, a DPLL fed with a 19.44 MHz reference can have loop bandwidth up to the maximum (470 Hz). For 1 kHz input reference, the DPLL loop bandwidth can be up to 14 Hz. For 8 kHz input reference, the recommended maximum loop bandwidth is 61 Hz.

6.2.10 DPLL PROGRAMMABLE DAMPING AND PHASE GAIN

The device supports programmable damping and phase gain using the **dp1l_damping** mailbox register. A common value would be the default value of 0x5 for gain peaking < 0.1 dB.

6.2.11 DPLL LOCK TIME

The lock time is dependent on employed loop bandwidth. The device has a lock time of less than 2sec for loop bandwidths larger or equal than 14 Hz and the phase slope limit set to unlimited. For the other loop bandwidths and phase slope limits, please refer to [Table 11-12](#).

There is some configurability of the lock thresholds for phase stability and duration. Refer to **dp1l_lock_phase** and **dp1l_lock_period** mailbox registers for more details.

6.2.11.1 DPLL Fast Lock

It is recommended that the fast lock mode be enabled when phase slope limiting is used. It should be disabled with an unlimited PSL. This can be done in the **dp1l_fast_lock_ctrl** mailbox register.

6.2.12 DPLL HITLESS REFERENCE SWITCHING

The device is able to switch between input references with typical performance of 0.6 ns well below the ITU-T G.8262 specifications (see [Table 11-12](#)). Note that the device will transition through the holdover state when switching between input references. The switching between input references may be fully automated when an old input reference fails (is disqualified) and a new input reference is available (is qualified).

6.2.13 DPLL HOLDOVER CAPABILITY

6.2.13.1 Holdover Stability

The DPLL initial holdover accuracy is documented in [Table 11-12](#). The initial holdover accuracy depends on the core DPLL filter bandwidth as well as the additional holdover filter bandwidth and holdover storage delay.

- Initial accuracy of 2 ppb when the core DPLL filter bandwidth is higher (line card applications).

6.2.13.2 Hitless Entry and Exit from Holdover

Referring to [Table 11-12](#), the device has typical entry into holdover of 0.6 ns and typical exit from holdover of 0.6 ns, well below the ITU-T G.8262 specifications. The entry and exit into holdover may be fully automated when an old input reference fails (is disqualified) and a new input reference is available (is qualified).

6.2.13.3 Additional Post-DPLL Holdover Options

In addition to the holdover benefits gained through the DPLL filter bandwidth there is a separate holdover filter bandwidth and holdover storage delay controlled using **dpll_ho_filter** and **dpll_ho_delay** registers.

The post-DPLL holdover filter bandwidth may be set very narrow even when the core DPLL bandwidth is higher or the local oscillator is less stable. The post-DPLL holdover filter bandwidth may be set as low as 1.7 MHz, which provides great benefits for holdover because the minimum loop bandwidth of the DPLL is 14 Hz.

The post-DPLL holdover storage delay is a history of the previous post-DPLL holdover filter bandwidth values. When the DPLL enters holdover it may use the most recently computed holdover value, or may go back in history to an earlier value. If a transient has just occurred on an input reference, causing the entry to holdover, it would be beneficial to use a holdover value that was computed before the start of the transient. Therefore the holdover storage delay is generally set based on the expected types of transients on the input references. Care should be taken not to go excessively back in time using the holdover storage delay register as the local oscillator may have drifted from that location due to temperature or aging effects. The user may select a holdover storage value over one hour back in time.

6.2.13.4 Additional Post-DPLL Holdover Filter Details

If the input reference is noisy (have jitter and wander), the quality of holdover value will depend on jitter and wander and on loop bandwidth of the DPLL because the holdover value is taken from the DPLL low pass filter. Lower the loop bandwidth-better the attenuation of the noise and more accurate holdover value. As explained previously, narrower loop bandwidths require longer lock time and a more stable (and often more expensive) master clock. The holdover filter solves this problem because it is not part of the loop, as shown in the simplified block diagram in [Figure 6-10](#) so it can be freely adjusted without affecting any loop parameters.

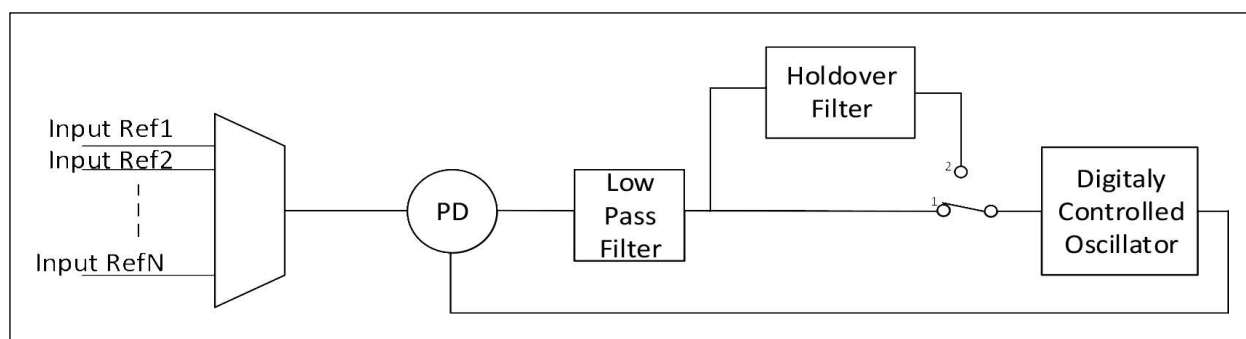

FIGURE 6-10: Simplified Block Diagram of the Holdover Filter.

The functionality of the holdover filter can be illustrated with the following example.

FIGURE 6-11: Benefits of Holdover Filter.

If the input reference is modulated by a sine wave jitter, the instantaneous frequency of the input clock will also change in the sine wave fashion. This is shown in the top plot of the Figure 6-11. If the loop bandwidth of the DPLL is set to 14 Hz and if the jitter happens to have same frequency, the output of the DPLL will pass the jitter with 3dB attenuation and the output frequency will deviate 3dB less than the input frequency (middle plot). If the DPLL goes into holdover state its output frequency will be equal to the nominal frequency only at zero crossing of the sine wave which is highly unlikely. Hence assuming the jitter frequency is constant, the holdover value will depend on the amplitude of the input jitter—higher the amplitude lower the initial holdover accuracy. Deviation of the frequency can be calculated as:

EQUATION 6-1:

$$Dfm = \pi \times fm \times ja \text{ [in Ulpp]}$$

Where fm is the frequency of the jitter and ja is the jitter amplitude in unit intervals.

Note that fm is 14 Hz in our example.

If we insert an additional filter (holdover filter) which is not part of the loop we will be able to filter jitter without affecting the loop performance. Now when DPLL goes into holdover it will take value from holdover filter which is much more accurate (closer to nominal) than the value from the loop filter.

When holdover filter is enabled the Digitally Controlled Oscillator will use value from holdover filter (position 2 of the switch). Holdover filter bandwidth can be set in **dp1l_ho_filter** mailbox register. If the value in this register is 0x00 the holdover filter is not used—holdover in this case is based on DPLL loop bandwidth.

6.2.13.5 User Holdover Compensation Support

The user may provide advanced holdover compensation schemes to reduce the effects of temperature variation or aging of the local oscillator while in the holdover state or holdover mode. To support this operation the DPLL has several support tools.

During locked operation the user may read the core DPLL frequency offset. With this information the user may learn the ageing characteristics of the local oscillator. Additional, when combined with a temperature sensor, the user may learn the temperature characteristics of the local oscillator. Refer to **dp1l_df_offset_x** and **dp1l_df_ctrl_x** registers for more details.

The user may control the frequency offset by switching the DPLL mode to NCO (seeded with the initial holdover frequency offset value) and writing frequency offsets to the device. Refer to **dp1l_df_offset_x** and **dp1l_df_ctrl_x** registers for more details.

6.2.14 DPLL SUPERVISION AND MANAGEMENT

6.2.14.1 DPLL Management Mode Comparisons

In unmanaged mode of operation, the DPLL state (locked, holdover, acquiring) and the selected reference is automatically set by the internal state machine of the device. It is based on availability of a valid reference and on the reference's selection priority.

In managed mode of operation, the DPLL state and the selected reference is manually set by the user.

The device allows for a smooth transition from in and out of the two modes of operation. Hence if the DPLL was in managed mode, for example locked to Ref2 reference and switched to unmanaged mode of operation, then the state machine continues managing the DPLL, locked to the Ref2 and it will not force reference switching to any other reference unless a change in the Ref2 input conditions occurs that necessitate a change to an alternate input reference.

Each DPLL has its own independent state control and reference selection state machine.

6.2.14.2 DPLL Unmanaged Mode

The unmanaged mode combines the functionality of the normal state with automatic holdover and automatic reference switching. In this mode, transitioning from one mode to the other is controlled by the device internal state machine.

The on-chip state machine monitors the DPLL status bits, and based on the status information the state machine makes a decision to force holdover or to perform reference switch.

The reference switching state machine is based on the internal clock monitoring of each of the available input references and their priorities.

The state machine selects a reference source based on its priority value defined in a control register and the current availability of the reference. If all the references are available, the reference with the highest priority is selected; if this reference fails, the next highest priority reference is selected, and so on.

In unmanaged mode, the state machine only reacts to reference failure indicators and performs reference switching any-time one of the following conditions takes place assuming they are not masked with their corresponding mask bits:

- LOS detected a failure and refswitch mask LOS is at logic "1"
- SCM detected a failure and refswitch mask SCM is at logic "1"
- CFM detected a failure and refswitch mask CFM is at logic "1"
- PFM detected a failure and refswitch mask PFM is at logic "1"
- GST is triggered and refswitch mask GST is at logic "1"

In unmanaged mode, the device automatically selects a valid reference input. If the current reference used for synchronization fails, the state machine switches to another available reference. If all the available references fail, then the device enters the holdover state under one of the following conditions if they are not masked with their corresponding mask bits:

- LOS detected a failure and holdover mask LOS is at logic "1"
- SCM detected a failure and holdover mask SCM is at logic "1"
- CFM detected a failure and holdover mask CFM is at logic "1"
- PFM detected a failure and holdover mask PFM is at logic "1"
- GST is triggered and holdover mask GST is at logic "1"

In unmanaged mode of operation, the state machine automatically recovers from holdover when the conditions to enter auto-holdover are not present.

The reference selection is based on reference priority. The current active reference for each DPLL can be read from DPLLx Reference Selection Status register.

If neither the reference switch nor the holdover masks are set, then device will keep trying to lock to a failed reference subject to the limits of the pull-in/hold-in range.

6.2.14.3 DPLL Managed (Manual) Mode

In managed mode, the device does not auto-select between different reference inputs. The user specifies which reference to use for synchronization and if it fails the DPLL enters the auto-holdover state without switching to another reference.

The user (external uP) monitors the device status bits. Based on the status information, the user makes a decision to force holdover or to perform reference switch. In managed mode the active reference input is selected based on reference selection control bits. If the user sets the device to lock to a failed reference, the device stays in auto-holdover and only locks to that reference if it becomes valid.

The state machine only reacts to failure indicators and goes into auto-holdover under one of the following conditions if they are not masked with their corresponding mask bits:

- LOS detected a failure and holdover mask LOS is at logic “1”
- SCM detected a failure and holdover mask SCM is at logic “1”
- CFM detected a failure and holdover mask CFM is at logic “1”
- PFM detected a failure and holdover mask PFM is at logic “1”
- GST is triggered and holdover mask GST is at logic “1”

The state machine automatically recovers from auto-holdover when the conditions to enter auto-holdover are not present.

Time critical transitions for entry into auto-holdover and exit from auto-holdover are managed by the internal state machine. A change of the reference select bits triggers an internal state transition into auto-holdover and then an exit into Normal state and locking to the new reference.

If neither the reference switch nor the holdover masks are set, then device will keep trying to lock to a failed reference subject to the limits of the pull-in/hold-in range.

6.2.15 DPLL JITTER/WANDER GENERATION

The wander generation is dominated by the high-pass filter characteristics of the local oscillator above the programmed DPLL filter bandwidth.

The jitter generation performance is provided in **Section 11.1 “Output Clocks Jitter Generation”**.

6.3 Input-Output Conversions

6.3.1 INPUT TO OUTPUT AND OUTPUT TO OUTPUT PHASE ALIGNMENT

6.3.1.1 Phase Alignment Control

When the output clock is locked to a jitter free and wander free input clock, input to output latency is expected to have a typical error of 0 nsec. This is accomplished within the device using advanced, automatic precision input-output alignment routines at initialization.

Additionally, there are user accessible phase adjustments that allow for input to output and output to output latency corrections to compensate for PCB load delay, as detailed in [Section 6.2.5 “DPLL Input Advance and Delay”](#) and [Section 6.4.3 “Output Skew Management”](#).

6.3.1.2 External Feedback

The PLL architecture allows for implementation of an external feedback (external output clock phase sense) of the PLL path that is fed through one of the available references. Such external feedback would allow for dynamic changes of PCB routing and external buffer delay caused by changes in temperature.

It is recommended that the DPLLs be fully configured before enabling external feedback. If a synthesizer or DPLL in the external feedback path need to be reconfigured, disable external feedback before changing the parameters and then enable external feedback.

Refer to **ext_fb_ctrl** and **ext_fb_sel** registers.

6.3.2 RATE CONVERSION FUNCTION AND FEC SUPPORT

The DPLL provides up scaling and down scaling functions. It has the ability to switch from normal rate (before FEC is negotiated) to FEC rate and vice versa.

The DPLL supports:

Simple rate conversion (i.e., take in 19.44 MHz and create 255/238 FEC SONET/SDH clock of 666.51 MHz),

Double rate conversion (i.e., take in 19.44 MHz, create FEC 10 GbE clock of 644.5313, which is 66/64 rate converted 625 MHz, or create 690.5692 which is $255/238 \times 66/64$ rate converted 625 MHz).

The following is just an example of the frequencies that can be supported at the input and output independently (many more frequencies can be supported):

GbE:

- 25 MHz
- 125 MHz

XAUI (chip to chip interface, which is a common chassis to chassis interface):

- 156.25 MHz or $\times 2$ or $\times 4$ version

OC-192/STM-64:

- 155.52 MHz or $\times 2$ or $\times 4$ version
- 155.52 MHz $\times 255/237$ (standard EFEC for long reach) or $\times 2$ or $\times 4$ version
- 155.52 MHz $\times 255/238$ (standard GFEC for long reach) or $\times 2$ or $\times 4$ version

10 GbE:

- 156.25 MHz which is 125 MHz $\times 10/8$ or $\times 2$ or $\times 4$ version
- 155.52 MHz $\times 66/64$ or $\times 2$ or $\times 4$ version

Long reach 10 GE might require the following frequencies with simple rate conversion: (156.25 MHz $\times 255/237$) and (156.25 MHz $\times 255/238$).

The following frequencies with double rate conversion: (155.52 MHz $\times 66/64 \times 255/237$) or (155.52 MHz $\times 66/64 \times 255/238$) and (156.25 MHz $\times 66/64 \times 255/238$) or (156.25 MHz $\times 66/64 \times 255/238$). Also, user can use $\times 2$ or $\times 4$ version of the listed frequencies.

6.4 Output Clocks

6.4.1 OUTPUT FREQUENCY SYNTHESIS ENGINE

The device frequency synthesizers can generate output clocks which meet the jitter generation requirements for various timing requirements detailed in **Section 11.1 “Output Clocks Jitter Generation”**.

The frequency synthesis engines can generate any clock frequency between:

- Synthesizer 0: 750 MHz to 950 MHz
- Synthesizer 1: 3.8 GHz to 4.56 GHz
- Synthesizer 2: 3.0 GHz to 3.75 GHz
- Synthesizer 3: 2.304 GHz to 3.0 GHz

The frequency for each synthesizer is programmed as $B \times K \times M/N$ Hz where B, M, and N are 16 bits wide registers, while K is a 24 bit wide register.

6.4.2 OUTPUT DIVIDERS (HIGH PERFORMANCE SYNTHESIZERS)

Differential CML outputs can generate any frequency from 1 Hz to 900 MHz for Synthesizers 1 and 2. The outputs connected to the Synthesizer 3 can also generate any frequency between 1 Hz to 900 MHz except for frequencies in the range between 750 MHz and 768 MHz, however the boundary frequencies (750 MHz and 768 MHz) can themselves be generated. single-ended LVCMOS outputs can generate clocks between 0.5 Hz and 180 MHz. When differential CML outputs are generated, only one out of two independent dividers is used, while the other is powered down. Both dividers can be used to generate two independent LVCMOS output clocks. Refer to [Figure 0-1](#) and [Section 6.5.3 “System PLL Bypass and Synthesizer 3”](#) for information on which synthesizers are assigned which dividers.

6.4.3 OUTPUT SKEW MANAGEMENT

Each output may be advanced (not delayed) using phase_step_ctrl, phase_step_data and phase_step_max registers. The resolution is 1.25 ns and will internally be rounded to the nearest VCO cycle. The range is 1 UI per update, and unlimited lifetime updates.

6.4.4 OUTPUT CLOCK POLARITY

The device supports programming per output clock polarity, refer to **synth_out_x_ctrl** register.

In the following scenario, the output clock polarity feature is not supported without additional configuration when

- The synthesizer output is configured with a post-divider value ≤ 24

To correctly enable the output clock polarity the user must first configure the output frequency and desired polarity with post divider value > 24 , and then second set the post divider to the proper value ≤ 24 .

In the following scenario, the output clock polarity feature is incorrectly enabled

- The device is not using custom configuration record option
- The device is in system PLL bypass mode (using high speed local master oscillator)
- The HPOUT[8:11] is configured with a post-divider value ≤ 24

To correctly enable the output clock polarity the user must first configure the output frequency and desired polarity with post divider value > 24 and then second set the post divider to the proper value ≤ 24 .

6.4.5 OUTPUT FRAME SYNC PULSE WIDTH

The default output clock duty cycle is 50/50. The user may program the output pulse width (duty cycle) using **synth_out_x_width** register. This may be useful for 1 PPS outputs when a duty cycle other than 50/50 is required, such as setting the pulse high time to 1 UI of a companion clock.

6.4.6 OUTPUT PRECISION ALIGNMENT

The device supports precise input-output alignment per output clock (typically 0). Additionally, output-output alignment is a natural result of the input-output alignment. When the precision alignment is enabled (default), the outputs will meet the input-output alignment performance listed in [Table 10-22](#), if the DPLL is appropriately configured with TIE clear enabled. A brief introduction is included in this section. Disabling the precision alignment is not recommended, even if the application does not require input-output alignment or the user operates with TIE clear disabled.

The alignment routine is triggered by a set of conditions and is then executed at the appropriate time. The alignment routine is triggered per output clock under the following conditions

- the output clock is changed from disabled to enabled
 - for example at power-up initialization
 - for example at power-up preconfiguration (pre-programming)
 - for example when the user manually toggles the output clock enable state
- the output clock configuration parameters are changed (e.g. frequency)
- the synthesizer is changed from disabled to enabled
- the synthesizer configuration parameters are changed (e.g. VCO frequency)
- the system clock configuration is changed (e.g. center frequency)

While the alignment routine is triggered, the output clock is not driven (not visible externally). It is expected that the alignment routine is only triggered at start-up once, as changing the above configuration capabilities is not typical during normal operation.

6.4.6.1 Precision Alignment Enabled with Freerun Mode

By default the device operates in Freerun mode. The user may poll to confirm the alignment routine is completed, as the process takes some time for each output (such as 80 ms for clock frequencies above 8 kHz). The alignment routine processes Synthesizer 0, 1, 2 and 3 in that order.

6.4.6.2 Precision Alignment Enabled with Pre-Configured Auto or Forced Reference Mode

In some instances the device may be pre-configured to start in Automatic or Forced Reference mode of operation (rather than the default Freerun mode). This may be typical when the device is used in unmanaged mode. At power-up reset, the DPLL by default will qualify the input references according to the PFM (default 10 seconds). During this qualification time the alignment routine will execute, while the DPLL is in the holdover state.

6.4.7 OUTPUT CLOCKS CONFIGURATION

Figure 6-12 shows relationship between synthesizers and output dividers. Each output can be configured to be one differential CML output or two independent LVCMOS outputs. When an output is configured as differential CML output only upper divider is used while lower divider is powered down. As an example differential output HPOUT0_0p/HPOUT1_0n is driven from the divider A, while divider B connected to the same synthesizer (Synthesizer 1) is powered down.

6.4.8 OUTPUT DRIVERS

The device has six high performance differential (CML) outputs. Each differential output can be programmed to be two independent single-ended LVCMOS outputs for the total of twelve LVCMOS outputs.

Functional block diagram of the output driver is shown in Figure 6-12.

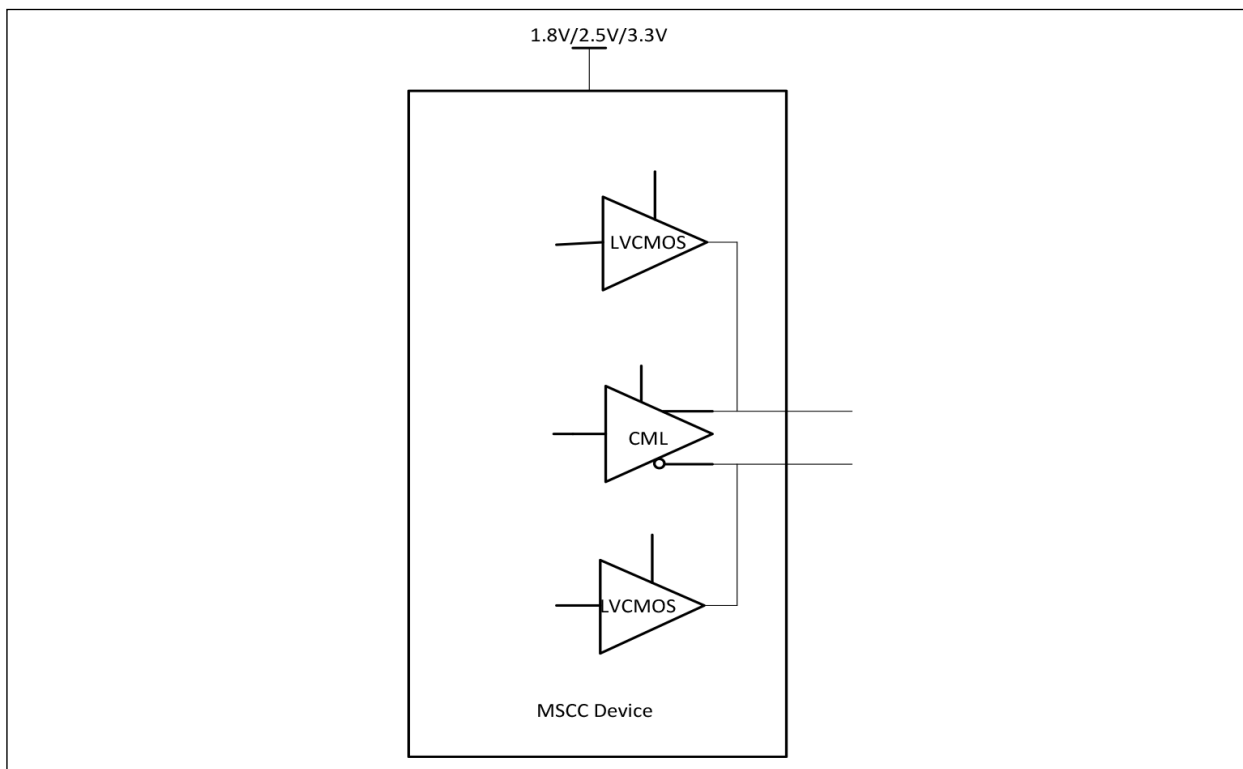

FIGURE 6-12: Functional Block Diagram of the Output Buffer.

When operating with 3.3V and 1.8V power supply mode, each output pair can be independently powered from 1.8V, 2.5V or 3.3V supply. When operating with 2.5V and 1.8V power supply mode, each output pair can be independently powered from 1.8V or 2.5V supply.

The high performance single-ended driver (LVCMOS) supports a maximum clock frequency of 180 MHz and the high performance differential driver (CML) supports a maximum clock frequency of 900 MHz, the jitter performance is detailed in **Section 11.0 “Performance Characteristics”**.

Following sections describe how to drive different differential receivers via DC and AC coupled transmission line. All resistors should have $\pm 1\%$ and capacitors $\pm 5\%$ tolerance. The coupling capacitance of AC coupled transmission lines should be adjusted (increased) for frequencies lower than 100 MHz to minimize voltage drop.

The CML outputs require external 50 Ω pull up resistors for biasing which should be placed as close as possible to the output pins. Figure 6-13 shows how to drive an external CML receiver via DC and AC coupled transmission line respectively. The line is terminated with 50 Ω resistors which should be placed as close as possible to the receiver pins.

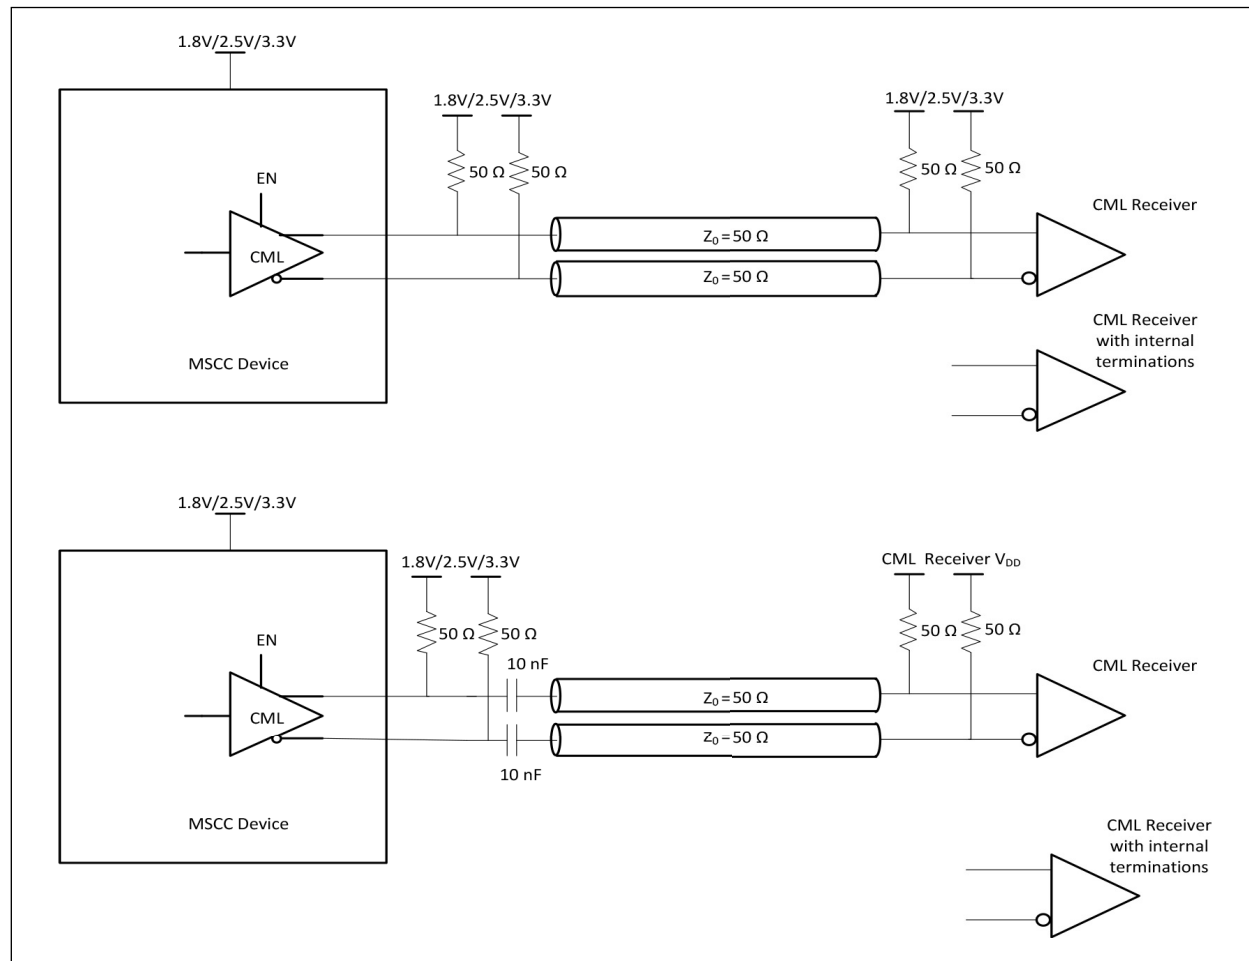

FIGURE 6-13: Driving CML Receiver.

Figure 6-14 shows how to terminate an LVPECL receiver. Terminating resistors 82Ω and 127Ω provide 50Ω equivalent Thevenin termination as well as biasing for the LVPECL receiver. Terminating resistors should be placed as close as possible to input pins of the LVPECL receiver. If the LVPECL receiver has internal biasing then AC coupling capacitors should be added.

FIGURE 6-14: Driving LVPECL Receiver.

Figure 6-15 shows how to terminate an LVDS receiver. Transmission line needs to be terminated only with $100\ \Omega$ resistors if LVDS receiver contains internal biasing circuit. If the internal biasing is not provided then appropriate Thevenin termination should be used instead.

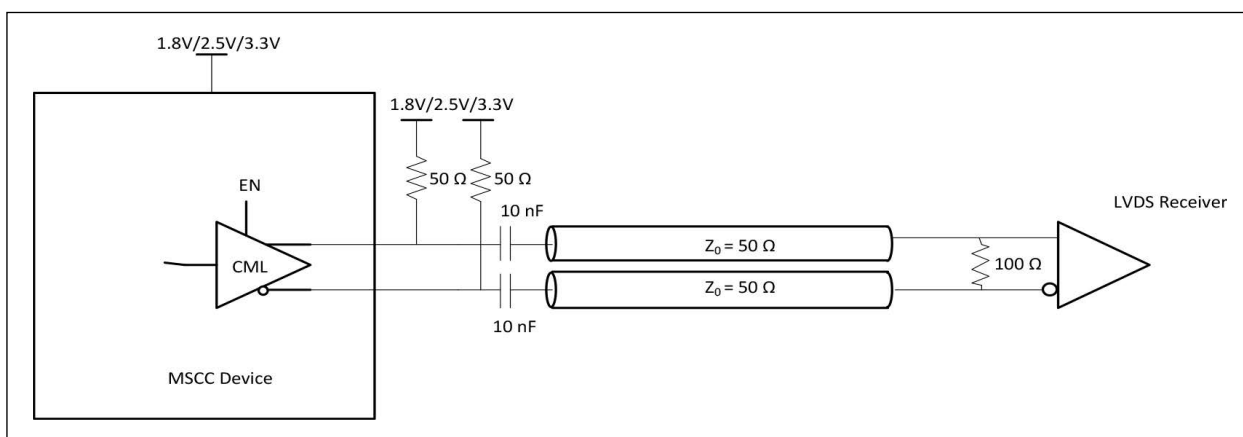

FIGURE 6-15: Driving LVDS Receiver.

High performance LVCMOS outputs should be terminated at the source with 22Ω resistors as shown in [Figure 6-16](#).

FIGURE 6-16: Driving LVCMOS Receiver.

6.5 System Clock

The device internal system clocks are generated off the device master clock input (oscillator or a crystal employing an on-chip buffer/driver). The device can accept master clock from an XO, Crystal Resonator or from an XO with differential output. Only one master source shall be used at the time. Unused inputs shall be pulled high or low. For a list of reference crystals and oscillators, refer to ZLAN-442.

6.5.1 MASTER CLOCK INTERFACE

When using a clock oscillator as the master timing source, connect the oscillator's output clock to the **OSCI** pin as shown in [Figure 6-17](#). The connection to OSCI should be direct and not AC coupled.

When using a crystal resonator as the master timing source, connect the crystal between **OSCI** and **OSCO** pins as shown in [Figure 6-17](#). The crystal should have bias resistor of $1\text{ M}\Omega$ and load capacitances C1 and C2. The values of the load capacitances are dependent on the crystal and should be per the crystal's data sheet. The crystal should be a fundamental mode type—not an overtone.

When using high frequency XO with LVEPCL differential outputs, connect the oscillator's output to **MCLKIN_P** and **MCLKIN_N**. Thevenin termination resistors 182Ω and 68Ω should be used for termination and biasing.

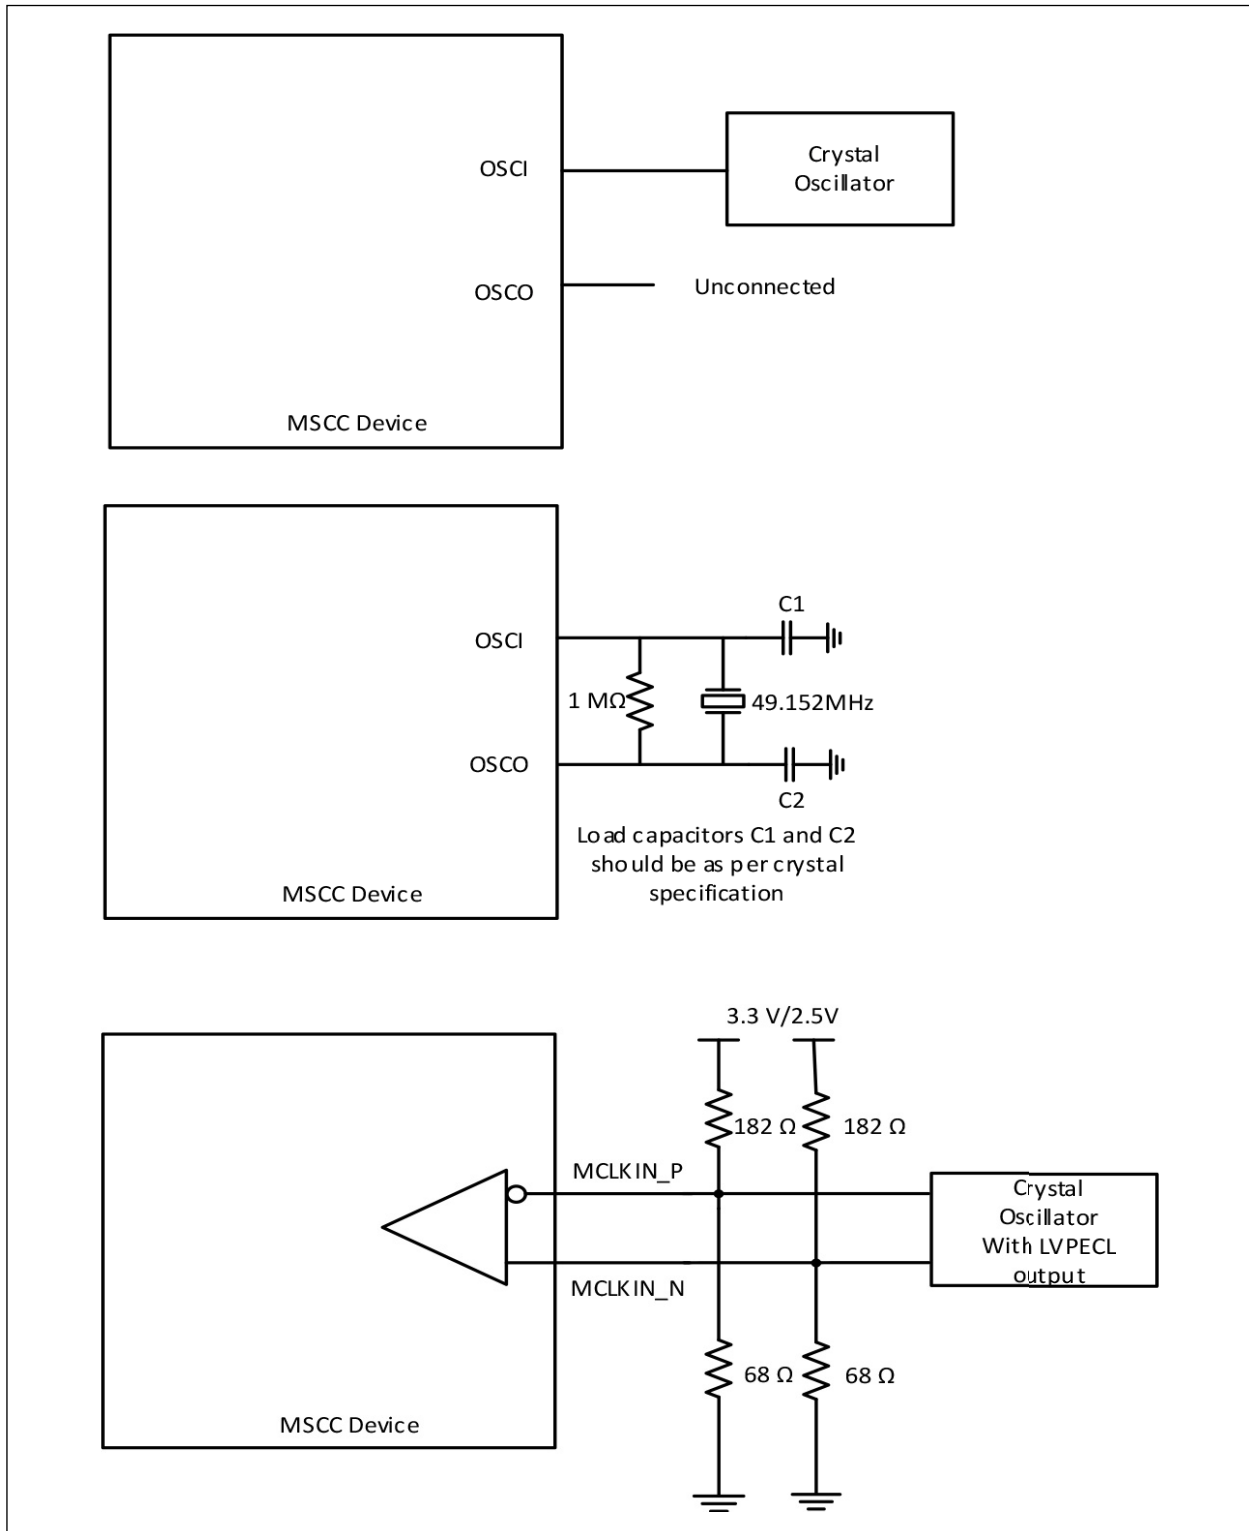

FIGURE 6-17: Master Clock Oscillator.

6.5.2 MASTER CLOCK FREQUENCY SELECTION

The master clock selection is done at start-up using the GPIO [5,3,2,1,0] pins, right after **RST_b** gets de-asserted. The GPIO [5,3,2,1,0] pins are required to be in desired configuration (high or low) for 500 ms after the de-assertion of **RST_b**, and then they can be released and used as regular GPIOs. Alternatively, these pins can be pulled high or low with 1 kΩ resistors.

TABLE 6-2: GPIO MASTER CLOCK SELECTION

GPIO[5,3,2,1,0]	Master Clock Frequency	Oscillator
10100	10 MHz	Single-ended (OSCI/O)
00010	20 MHz	Single-ended (OSCI/O)
00000	24.576 MHz, 25 MHz	Single-ended (OSCI/O)
00001	49.152 MHz, 50 MHz	Single-ended (OSCI/O)
11111	98.304 MHz, 100 MHz (System PLL Bypass)	Single-ended (OSCI/O)
01011	98.304 MHz, 100 MHz (System PLL Bypass)	Differential (MCLKIN_P/N)
11001	114.285 MHz, 125 MHz (System PLL Bypass)	Single-ended (OSCI/O)
01101	114.285 MHz, 125 MHz (System PLL Bypass)	Differential (MCLKIN_P/N)
01100	200 MHz (System PLL Bypass)	Differential (MCLKIN_P/N)

6.5.2.1 Nominal Master Clock Frequencies

The device supports XO nominal frequencies: 10 MHz, 20 MHz, 25 MHz, and 50 MHz. These nominal frequencies may have offsets down to -4%. This offset would then enable support for 24.576 MHz and 49.152 MHz, for example.

The device supports XO nominal frequencies: 100 MHz, 125 MHz, and 200 MHz. These nominal frequencies may have offsets down to -10%. This offset would then enable support for 98.3048 MHz and 114.285 MHz, for example.

6.5.2.2 Offset from Nominal Frequencies

Offset from nominal is programmed by writing **central_freq_offset** register. For example, when using 24.576 MHz or 49.152 MHz oscillators, the user should maintain the default value of the **central_freq_offset** register (0x046AAAAB).

For 114.285 MHz the value should be 0x180072B0.

For other oscillator values: 10 MHz, 20 MHz, 25 MHz, 50 MHz, 100 MHz, 125 MHz, and 200 MHz **central_freq_offset** register should be programmed to 0x00000000.

6.5.3 SYSTEM PLL BYPASS AND SYNTHESIZER 3

The signals HPOUT8_4P, HPOUT9_4N, HPOUT10_5P and HPOUT11_5N are driven by either the Synthesizer 2 (System PLL Bypass FALSE) or Synthesizer 3 (System PLL Bypass TRUE), depending on the utilization of “system PLL bypass” option as shown in [Figure 6-18](#),

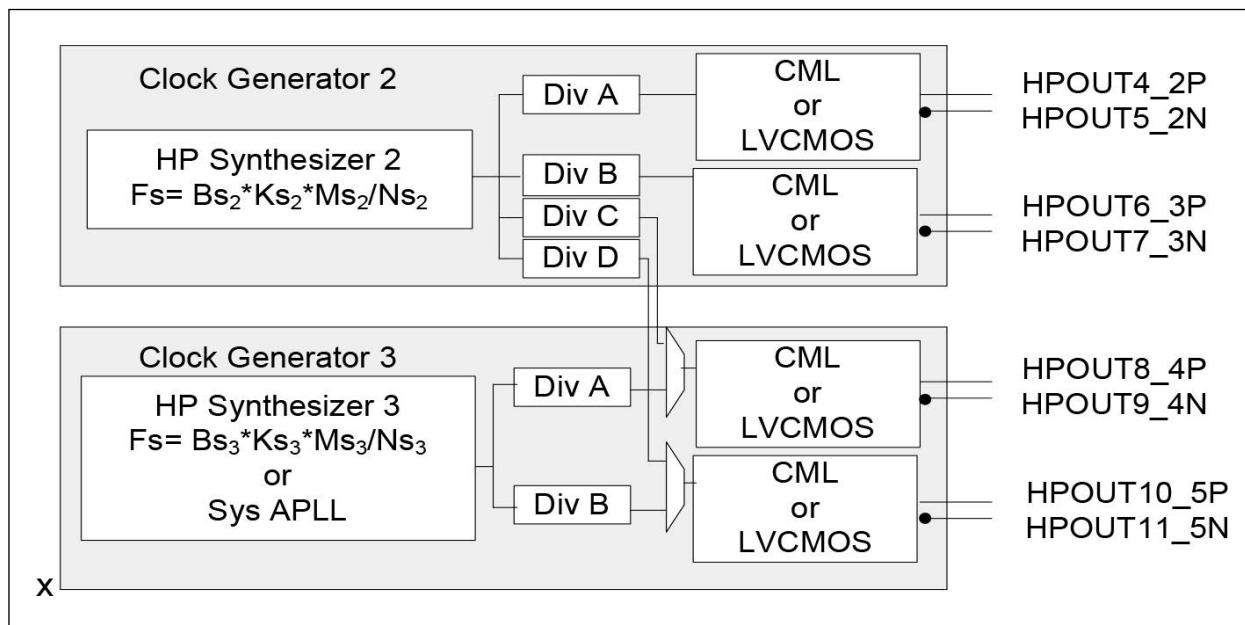

FIGURE 6-18: HPOUT[8:9] MUX.

When a low frequency master clock is used, nominal frequencies 10 MHz, 20 MHz, 25 MHz, and 50 MHz, the HPOUT[8:9] clocks are driven by synthesizer 2 as shown in [Figure 6-19](#).

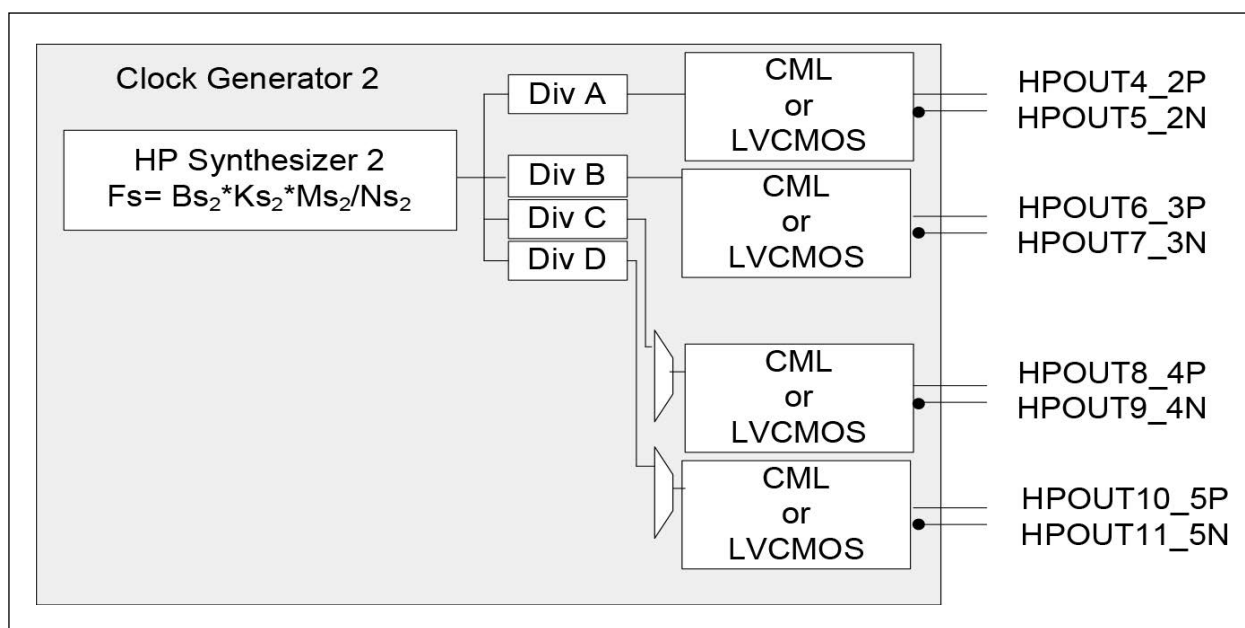

FIGURE 6-19: HPOUT[8:9] Driven by Synthesizer 2 (System PLL Bypass FALSE).

When a high frequency master clock is used (either nominal or offset from nominal), such as frequencies 98.304 MHz, 100 MHz, 114.285 MHz, 125 MHz, and 200 MHz, the HPOUT[8:9] clocks are driven by synthesizer 3, as shown in [Figure 6-20](#). This allows synthesizer 3 to create an independent frequency family from synthesizer 2 to drive HPOUT[8:9]. This may enable various LAN, WAN, and FEC clock possibilities across Synthesizer 1, 2, and 3.

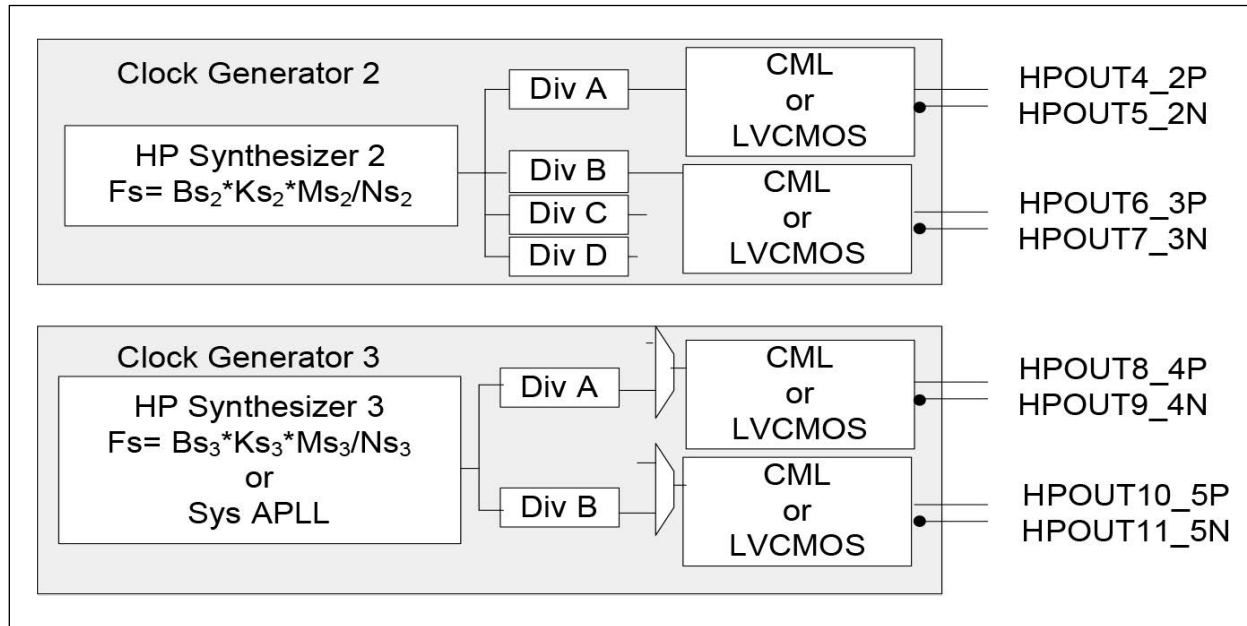

FIGURE 6-20: HPOUT[8:9] Driven by Synthesizer 3 (System PLL Bypass TRUE).

6.5.4 SPLIT XO MODE

6.5.4.1 Split XO Mode Introduction

The device offers a “Split-XO mode” where the Synthesizer 3 is available to the user. Split XO mode is intended for timing card application or for line card applications requiring good holdover. In timing card applications the DPLL loop bandwidth needs to be narrow (for example 0.1 Hz for G.8262 Option 2) to be able to filter jitter and wander. A DPLL behaves as a low pass filter for phase noise coming from its input reference, but at the same time it behaves as a high pass filter for noise coming from its master clock source (XO). Hence the timing card DPLL requires very stable XO such as TCXO or OCXO. The TCXO or OCXO needs to have very good jitter because DPLL’s output clock jitter is a function of jitter from the master clock.

The Split XO mode uses a high frequency low cost XO and a TCXO/OCXO of any frequency as shown in Figure 8-2. In this mode the device combines best of each component. It is called Split-XO because the device output jitter will be function of XO’s jitter and output stability will be based on TCXO/OCXO stability. So in this mode the device merges good features from XO (jitter) and TCXO/OCXO (stability).

Because only stability of TCXO/OCXO is important, the TCXO/OCXO does not have to be placed close to the device and it can be shared among multiple ZL30601/602/603/604 devices—TCXO/OCXO can also be located on a different card.

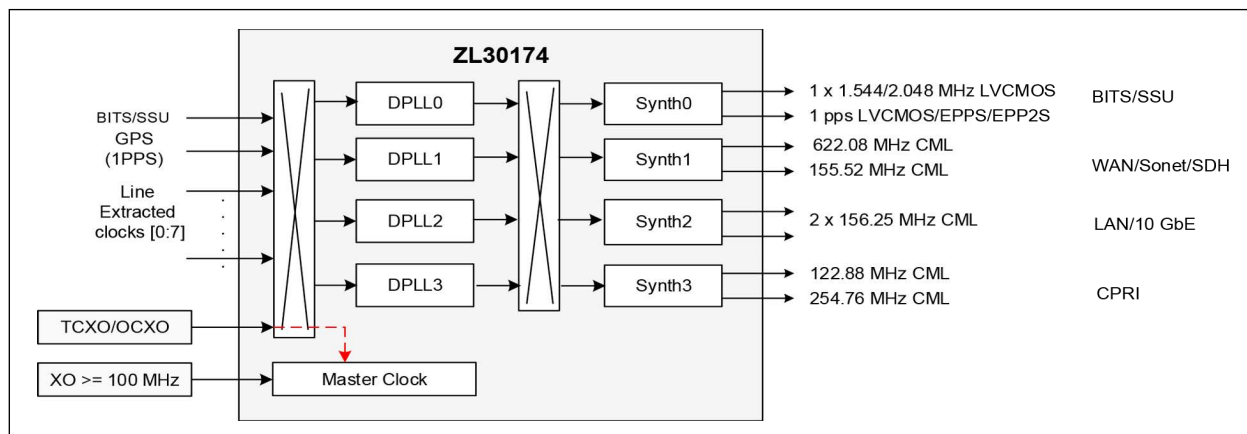

FIGURE 6-21: Split-XO Mode (System PLL Bypass TRUE).

The benefits of Split-XO mode are summarized below:

- Output jitter generation is not affected by TCXO/OCXO jitter.
- Any TCXO/OCXO frequency can be used (for example 10 MHz)
- Because frequency and jitter of TCXO/OCXO are not important, the user can source TCXO/OCXO from many crystal vendors as long as the stability of TCXO/OCXO meets relevant standard.
- The TCXO/OCXO does not have to be located on the same card. One TCXO/OCXO can drive multiple devices.
- The Synthesizer 3 is available for user application (with use of 100 MHz or higher nominal XO frequency).

6.6 Power Supply

The device power supply can be split into three distinct groups. All high performance outputs (differential or single-ended pairs) can be independently powered with 1.8V, 2.5V or 3.3V supply. All the other device inputs and outputs are powered from either 2.5 V or 3.3V supply (only one at the time). The device core is powered from 1.8V supply.

6.6.1 POWER UP/DOWN SEQUENCE

The I/O supply (3.3V or 2.5V) should be powered before or simultaneously with the 1.8V supply. The 1.8V supply must never be greater than the 3.3V/2.5V supply by more than 0.3V.

The power-down sequence is less critical; however, it should be performed in the reverse order to reduce transient currents that consume power.

6.6.2 POWER SUPPLY FILTERING

Jitter levels on the output clocks may increase if the device is exposed to excessive noise on its power pins. For optimal jitter performance, the device should be isolated from noise on power planes connected to its 3.3V and 1.8V supply pins. The device has additional internal voltage regulators for 3.3V power rail.

For recommended power supply decoupling, please refer to ZLAN-517.

For recommended assembly and PCB layout guidelines, please refer to ZLAN-527.

6.6.3 POWER CALCULATOR

The ZLE30174 EVB GUI includes a useful power calculator that estimates power utilization for a specific configuration or application of the ZL30611/612/614.

6.6.4 RESET AND CONFIGURATION CIRCUIT

To ensure proper operation, the device must be reset by holding the RST_b pin low for at least 2 ms after power-up when 3.3V/2.5V and 1.8V supplies are stable. Following reset, the device will operate under specified default settings.

The reset pin can be controlled with on-board system reset circuitry or by using a stand-alone power-up reset circuit. The RST_b input has a Schmidt trigger properties to prevent level bouncing.

Microchip recommends that the power-on reset (RST_b) signal be controlled by an on-board reset circuit or by a commercially available voltage supervisory device.

It may also be possible to use a standalone power-up RC reset circuit. It is important to note that this circuit works reasonably well for power-up as long as the power supply rise time is fast with respect to the RC time constant, which may not always be the case. It is the board designer's responsibility to ensure that the circuit is properly tuned to each power supply's specific situation. As an example, for the capacitor C of 1 μ F, the resistor should be 10 k Ω or higher.

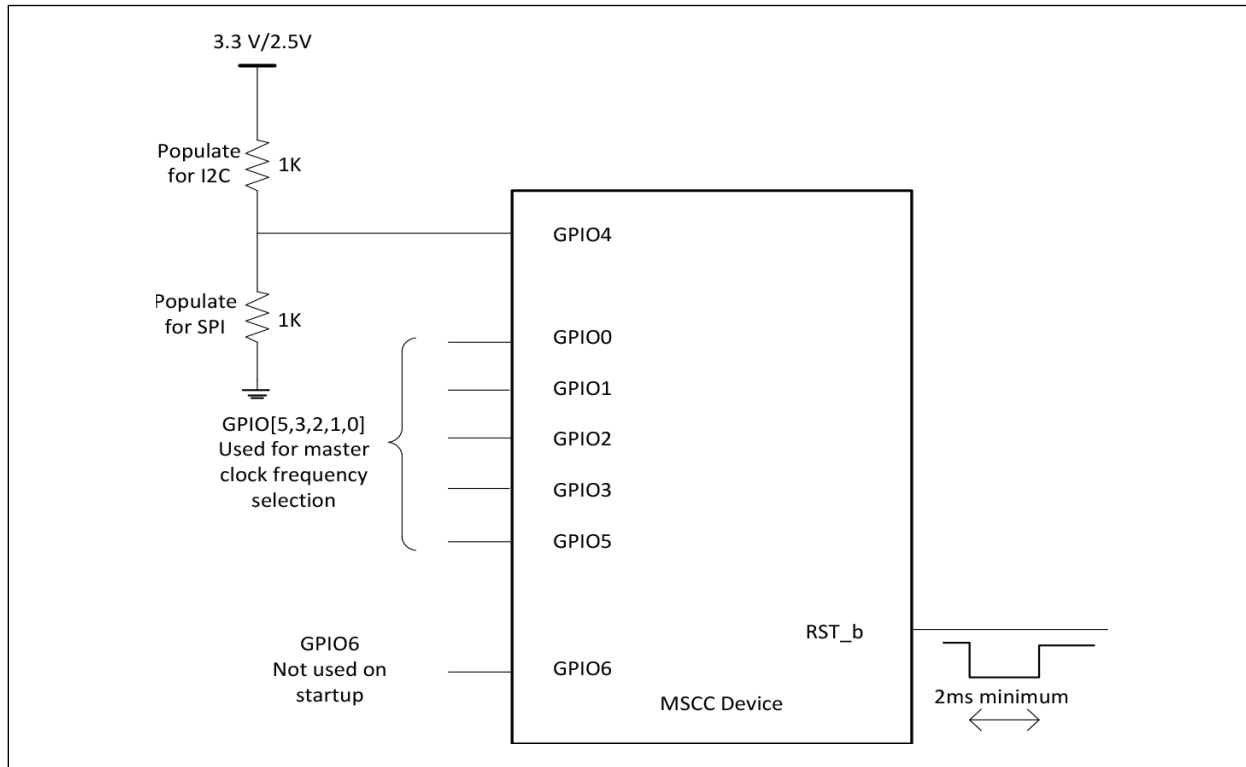

FIGURE 6-22: Typical Configuration and Power-up Reset Circuit.

General purpose pins gpio[5:0] are used to configure device on power up. They have to be pulled up/down with 1 kΩ resistors as shown in [Figure 6-21](#) or they can be held at the desired level for at least 500 ms after **RST_b** goes high and then they can be released and used as general purpose I/O as described in [Section 8.0 “Host Interface”](#).

By default, all outputs are disabled to allow programming of required frequencies for different outputs and enabling corresponding outputs.

6.6.5 VDD_DRI AND VREG_OUT

Refer to ZLAN-517 for full power supply decoupling scheme. [Figure 6-22](#) highlights the recommended circuitry for VDD_DRI and VREG_OUT. 150Ω and 340Ω resistors are required only for devices whose chip_revision_id in **revision** register at address 0x0003 is 0 or 1. When chip_revision_id ≥ 2, these resistors are optional.

FIGURE 6-23: External Connection of VDD_DRI and VREG_OUT.

7.0 CONFIGURATION AND CONTROL

The SPI/I2C host interface allows field programmability of the device’s configuration registers. As an example, the user might start the device at nominal SONET/SDH rate, and then switch to an OTN FEC rate once the link’s FEC rate is negotiated.

7.1 Pre-Configured Default Values on Power-Up

On the power up device registers will have values as described in **Section 9.0 “Register Map”**. If the device needs to come up with settings different from default it can be pre-configured (pre-programmed) by Microchip. The device can be pre-configured with up to three different custom configurations. The device will select one of three pre-configured values based on the voltage level of CNFGSEL pin (pin B27). CNFGSEL is a three-level input pin,f and its input should be set as shown in [Figure 6-23](#).

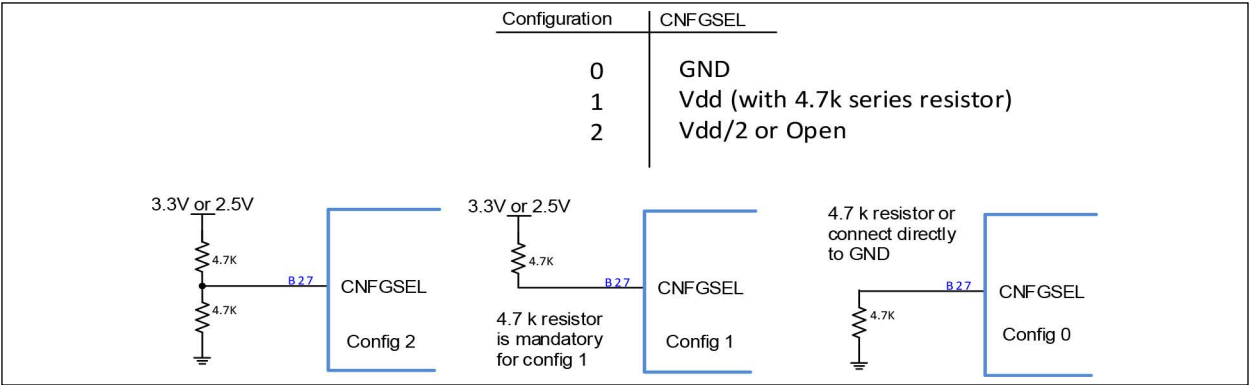

FIGURE 7-1: Selection of Pre-Configured Values.

It should be noted that 4.7 kΩ is required whenever this pin is connected to VDD (3.3V or 2.5V rails). This pin can be driven from a LVCMOS output with tristate options to allow the user to select one of the three configurations. It should be noted that in this case a series resistor of 4.7 kΩ is required as shown in [Figure 7-1](#).

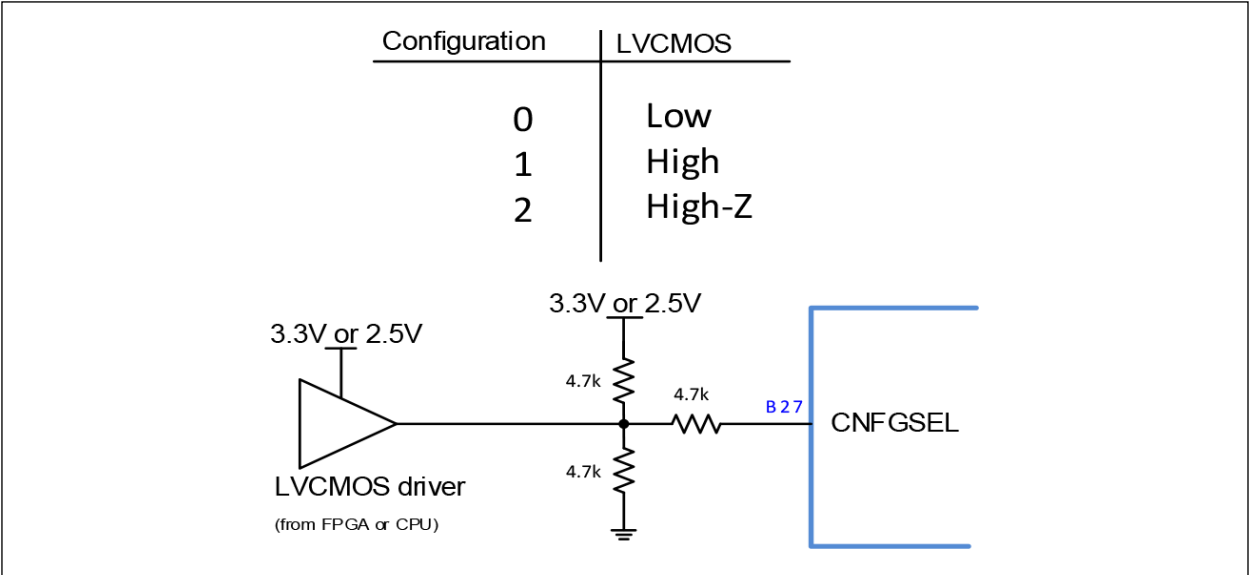

FIGURE 7-2: Selection of Pre-Configured Values with FPGA/CPU.

The level CNFGSEL pin is ignored if the device is not pre-configured.

7.2 Registers Configuration

This section refers to configuration registers that are set by the user to control operation of the device.

7.2.1 INPUT REFERENCE CONFIGURATION

The following parameters can be configured for the reference input:

- Input reference frequency
- Default input reference selection
- Reference selection priority
- Automatic or manual reference switching
- Glitch-less or hit-less reference switching
- Reference switch based on single cycle monitor, coarse frequency monitor, guard soak timer and precise frequency monitor

7.2.2 DPLL CONFIGURATION

The following parameters can be configured for each DPLL:

- Input reference
- Loop bandwidth
- Phase slope limiter
- Pull-in range

7.2.3 OUTPUT MULTIPLEXER CONFIGURATION

The following parameter can be configured:

- Select which DPLL drives which Synthesizer

7.2.4 SYNTHESIZER CONFIGURATION

The following parameters can be configured for each Synthesizer:

- Synthesizers can be configured to be locked to any DPLL or disabled
- Synthesizer frequency:
 - Synthesizer 0: 750 MHz to 950 MHz
 - Synthesizer 1: 3.8 GHz to 4.56 GHz
 - Synthesizer 2: 3.0 GHz to 3.75 GHz
 - Synthesizer 3: 2.304 GHz to 3.0 GHz

7.2.5 OUTPUT DIVIDERS AND OUTPUT PHASE OFFSET (SKEW) CONFIGURATION

The following parameters can be configured:

- Output divider enable/disable
- Divider ratio
- Output phase offset (fine and coarse)

7.2.6 OUTPUT DRIVERS CONFIGURATION

The following parameters can be configured:

- Output enable/disable
- Output driver type (CML, LVCMOS)

7.3 GPIO Configuration

The device GPIO is configured using the SPI/I2C. Each GPIO pin can be programmed independently to be:

General Input: In this mode the user can read the logic level of the corresponding pin (either high or low). For example the logic level of GPIO0 is reflected in the register **gpio_in_status_6_0**, bit 0 at address 0x100.

General Output: In this mode the user can program GPIO pin to drive either high or low. For example GPIO0 would drive the value specified in register **gpio_out_6_0**, bit 0, at address 0x0AE.

Control Inputs: In this mode the user can control the device function via GPIOs. For example, the function controlled by GPIO0 is selected by configuring **gpio_select_0** at address 0x0B6:0x0B7. Nearly any device function that is controllable through the host register may be controlled via GPIO. Small subset of control functions is shown below:

- Select DPLL reference
- External Loss Of Signal (LOS) indications
- Enable/disable differential and single-ended outputs
- Enable/disable TIE Clear
- Stop/start output clocks

Status Outputs: In this mode the user can feed a status message from any of status registers to the corresponding GPIO pin. For example, GPIO0 will mirror a bit from the status register specified in register **gpio_select_0** at address 0x0B6:0x0B7. A subset of status messages is listed below:

- DPLL loss of lock indicators
- DPLL holdover indicators
- Reference 0 to 9 fail indicators

Loss of Signal (LOS) input: This function can be used to indicate to the device that one of input references have failed. When the active input is forced to indicate failure the DPLL may be programmed to automatically enter the holdover state or some alternate action. For example GPIO0 can be used to indicate a reference failure by programming **gpio_select_0** at address 0x0B6:0x0B7.

The GPIO outputs are updated, and the GPIO inputs are read, approximately every 10 ms, except with using system bypass mode with 100 MHz oscillator where they are read approximately every 25 ms.

Note: If a GPIO is programmed as a Control Input, the corresponding **gpio_select** register must always point to a valid control register bit. Therefore, when switching GPIO from a Control Input to another mode, the user should first switch the mode via the **gpio_config** register and then switch the **gpio_select** register if necessary. Conversely, when switching a GPIO to a Control Input from another mode, the user should specify the desired control register bit in the **gpio_select** register first, then switch to the control input mode via the **gpio_config** register.

7.4 Ready Status

The user may start to configure the device registers when the ready bit in register info is asserted. This is typically 500 ms after power-up/reset.

8.0 HOST INTERFACE

A host processor controls and receives status from the Microchip device using either an SPI or I²C interface.

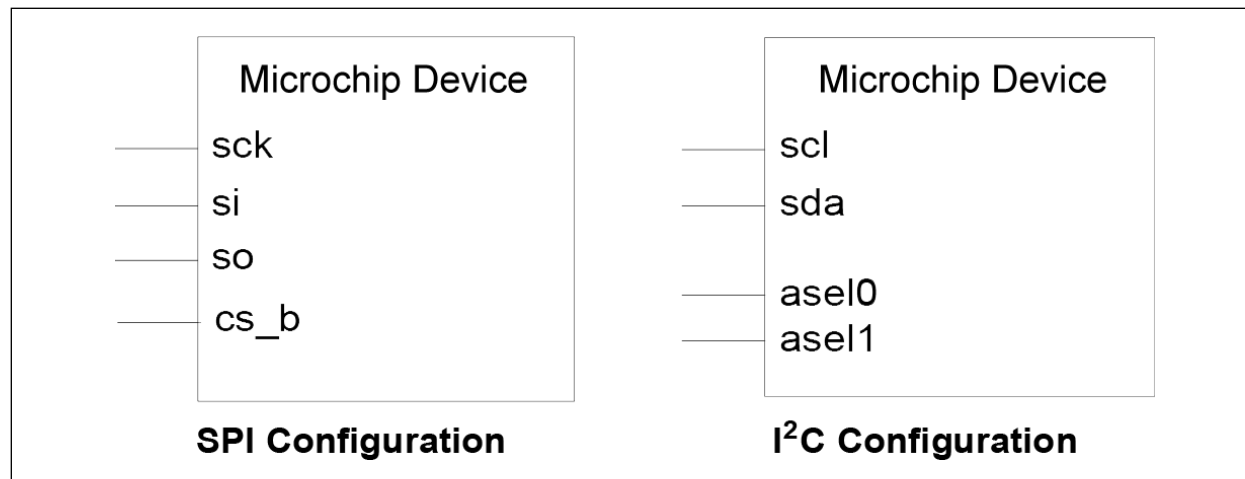

FIGURE 8-1: Serial Interface Configuration.

The selection between I²C and SPI interfaces is performed at start-up using GPIO[4] pin, as RST_b gets deasserted. The GPIO[4] pin needs to be held at required level for 500 ms after the deassertion of RST_b, after which time they can be released and used as regular GPIO.

TABLE 8-1: SERIAL INTERFACE SELECTION

GPIO[4]	Serial Interface
0	SPI
1	I ² C

Both interfaces use seven bit address field and the device has eight bit address space. Hence, the device register space is divided in fourteen pages of 127 registers each. Page 0 has addresses 0x000 to 0x07E; page 1 has addresses 0x080 to 0x0FF; and so on until page 13, which has addresses 0x680 to 0x6FF. The host selects between the pages by writing to the Page Select register (address 0x7F on each page). For example, writing a 0x03 to the page select register makes registers 0x180 to 0x1FF available through the host interface.

The device registers are divided into direct access and indirect (mailbox) access registers. The direct access registers (pages 0 to 10) are accessed simply by reading or writing specific memory location. For example, to set DPLL0 to freerun mode, the user needs to write to **dppll_ctrl_0** register at address 0x021F. The mailbox access registers (pages 11 to 13) have shared address space. For example, page 11 is shared among all input references. To initialize one of the input references the user needs to specify which input reference needs to be updated (**ref_ctrl** register at address 0x0582:0x0583), to program all the other registers that need to be modified and finally to issue the write command by writing to **ref_semaphore** register at the address 0x0584. The device will read the mailbox and clear the write bit in the **ref_semaphore** register.

8.1 Serial Peripheral Interface

The serial peripheral interface (SPI) allows read/write access to the device internal registers that are used to configure, read status, and allow manual control of the device.

The serial peripheral interface supports half-duplex processor mode which means that during a write cycle to the device, output data from the so_asel1 pin must be ignored. Similarly, the input data on the si_sda pin is ignored by the device during a read cycle.

The SPI interface supports two modes of access: Most Significant bit (MSb) first transmission or Least Significant bit (LSb) first transmission. The mode is automatically selected based on the state of sck_scl pin when the cs_b_asel0 pin is active. If the sck_scl pin is low during cs_b_asel0 activation, then MSb first timing is selected. If the sck_scl pin is high during cs_b_asel0 activation, then LSb first timing is assumed.

The SPI port expects 1-bit to differentiate between read and write operation followed by 7-bit addressing and 8-bit data transmission. During SPI access, the cs_b_ase10 pin must be held low until the operation is complete. Burst read/write mode is also supported by leaving the chip select signal cs_b_ase10 is low after a read or a write. The address will be automatically incremented after each data byte is read or written.

Functional waveforms for the LSb and MSb first mode, and burst mode are shown in [Figure 8-1](#), [Figure 8-2](#), and [Figure 8-3](#). Timing characteristics are shown in [Table 9-4](#), [Figure 8-6](#), and [Figure 8-7](#).

8.1.1 LEAST SIGNIFICANT BIT (LSB) FIRST TRANSMISSION MODE

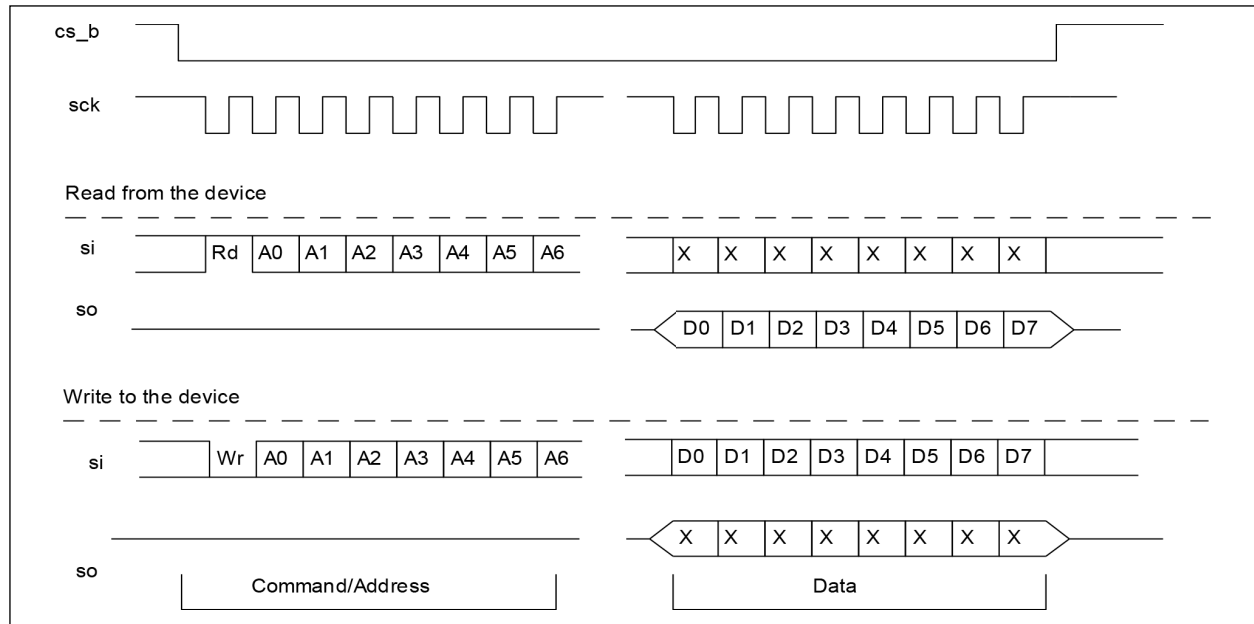

FIGURE 8-2: Serial Peripheral Interface Functional Waveform — LSb First Mode.

8.1.2 MOST SIGNIFICANT BIT (MSB) FIRST TRANSMISSION MODE

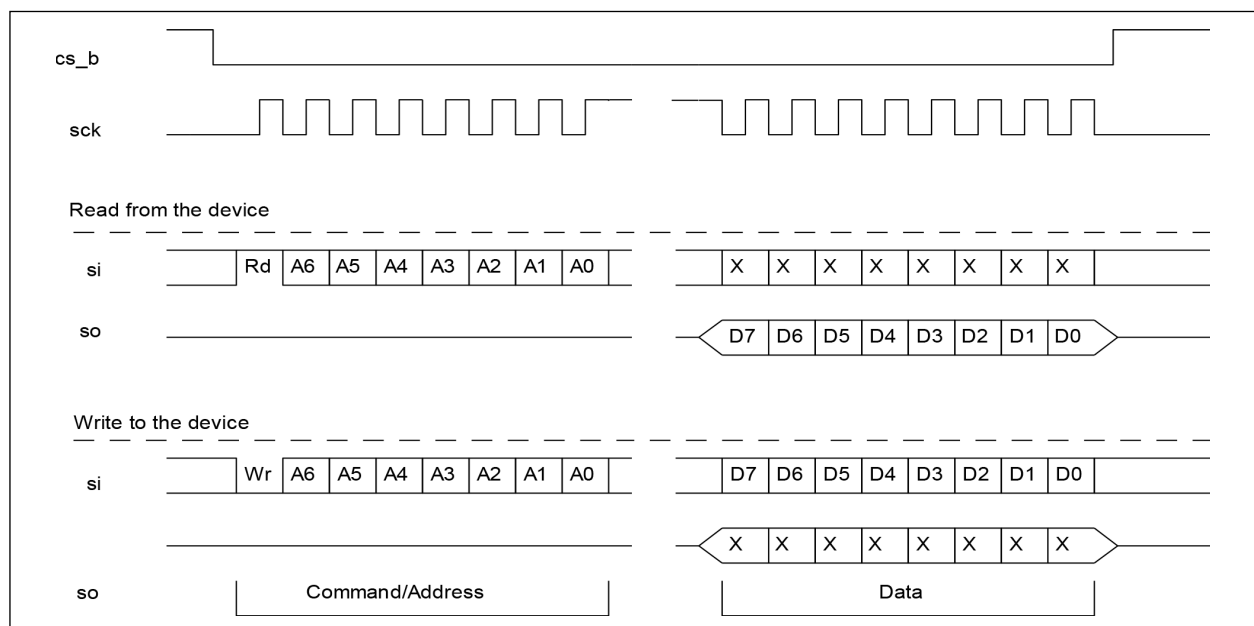

FIGURE 8-3: Serial Peripheral Interface Functional Waveform — MSb First Mode.

8.1.3 SPI BURST MODE OPERATION

FIGURE 8-4: Example of the Burst Mode Operation.

8.2 I²C Interface

The I²C controller supports version 2.1 (January 2000) of the Philips I²C bus specification. The port operates in client mode with 7-bit addressing, and can operate in Standard (100 kbits/s) and Fast (400 kbits/s) mode. Burst mode is supported in both standard and fast modes.

Data is transferred MSb first and occurs in 1-byte blocks. As shown in Figure 8-3 a write command consists of a 7-bit device (client) address, a R/W indicator bit, a 7-bit register address (0x00 - 0x7F), and 8 bits of data.

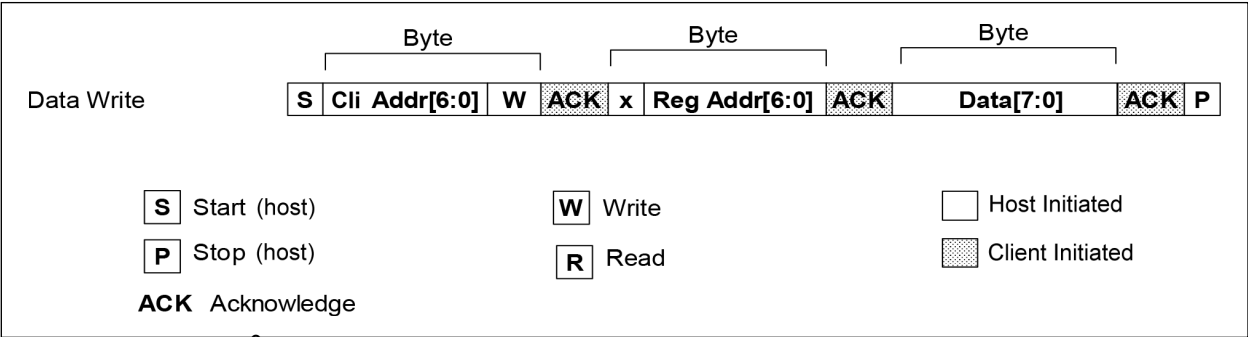

FIGURE 8-5: I²C Data Write Protocol.

A read is performed in two stages. A data write is used to set the register address, then a data read is performed to retrieve the data from the set address. This is shown in Figure 8-6.

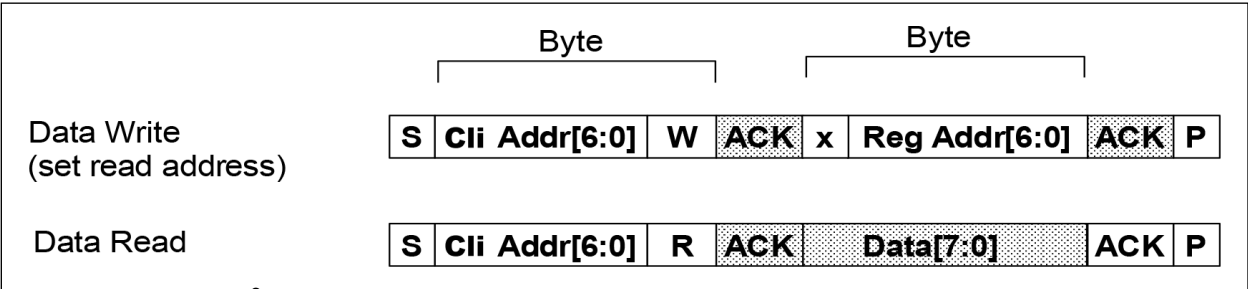

FIGURE 8-6: I²C Data Read Protocol.

The 7-bit device (client) address contains a 5-bit fixed address plus variable bits which are set with the `asel0`, and `asel1` pins. This allows multiple devices to share the same I²C bus. The address configuration is shown in Figure 8-7.

FIGURE 8-7: I²C 7-bit Client Address.

The device also supports burst mode which allows multiple data write or read operations with a single specified address. This is shown in [Figure 8-4](#) (write) and [Figure 8-5](#) (read). The first data byte is written/read to/from the specified address, and subsequent data bytes are written/read using an automatically increment address. The maximum auto increment address of a burst operation is 0x7F and operations beyond this limit will be ignored. In other words, the auto increment address does not wrap around to 0x00 after reaching 0x7F.

FIGURE 8-8: I2C Data Write Burst Mode.

9.0 REGISTER MAP

The device is controlled by accessing registers through the serial interface (SPI or I²C). The device can be configured to operate in unmanaged (automatic) mode, which minimizes its interaction with the system's processor, or it can operate in a managed (manual) mode where the system processor controls operation of the device.

The register map is big-endian format.

A simple way to generate configuration for the device is to use the ZLE30174 evaluation board GUI, which can operate standalone (without the evaluation board). Through the GUI, the user can quickly set all required parameters and save the configuration to a text file, which can then be used by the system processor to load and configure the device.

9.1 Multi-byte Register Values

The device register map is based on 8-bit register access, so register values that require more than 8 bits are spread out over multiple registers and accessed in 8-bit segments. When accessing multi-byte register values, it is important that the registers are accessed in the proper order. The 8-bit register containing the most significant byte (MSB) must be accessed first, and the register containing the least significant byte (LSB) must be accessed last. An example of a multi-byte register is shown in [Figure 8-8](#). When writing a multi-byte value, the value is latched when the LSB is written.

In this example, the **central_freq_offset** register is written with the default value of 0x046AAAAB, a 32-bit value spread over four 8-bit registers. The MSB is contained in address 0x000B and the LSB in 0x000E. When reading or writing this multi-byte value, the MSB must be accessed first, then the middle bytes, and the LSB last.

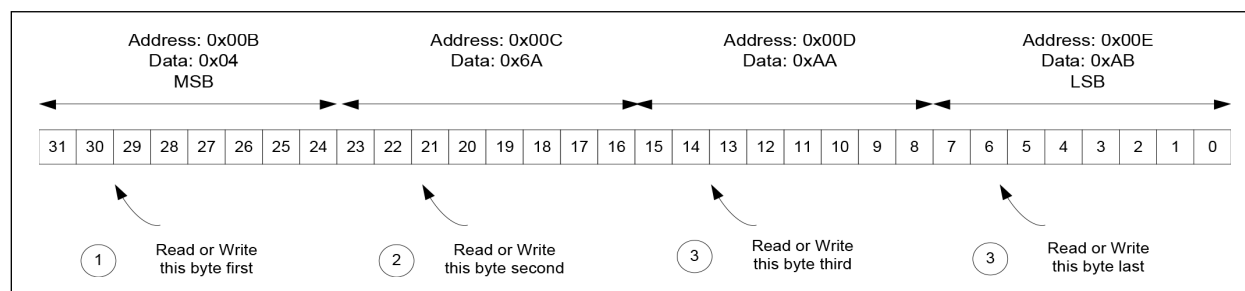

FIGURE 9-1: Accessing Multi-byte Register Values.

9.1.1 TIME BETWEEN TWO WRITE ACCESSES TO THE SAME REGISTER

The user should not write to the same register faster than 25 ms. Some registers that control state machine or system clock operation will require larger delays after writing in order for the state and configurations to be updated. One example is the register **central_freq_offset** requires much larger time, but this register should not be changed dynamically. Other examples include those related to precise input-output alignment (refer to [Section 6.4.6 "Output Precision Alignment"](#)).

The **dpil_df_offset_n** registers can be written with a minimum wait time of 600 μ s between write accesses to the same register.

For the page selection register (at addresses 0x007F, 0x00FF, 0x017F, ..., 0x06FF), there is no waiting time required between write accesses.

9.1.2 TIME AFTER CHANGE TO STATE MACHINE OR SYSTEM-CLOCK RELATED CONFIGURATION

The user should wait for appropriate time after configuration of state machine or system clock related configuration prior to updating other registers. One example is the register **central_freq_offset**. Other examples include those related to precise input-output alignment (refer to [Section 6.4.6 "Output Precision Alignment"](#)).

9.2 Basic Procedure for Refreshing Latest Device Status from Sticky Read (StickyR) Registers without Interrupt Handler

Access to some status registers is defined as Sticky Read (StickyR). Procedure for accessing these registers is:

- write 0x01 to Sticky Lock Register at address 0x0180
- clear status register(s) by writing 0x00 to it
- write 0x00 to StickyR Lock Register at address 0x0180
- wait for 25 ms
- read the status register(s)

9.3 Register Map List Summary

The following tables provide summaries of the registers available for status and configuration of the device.

TABLE 9-1: REGISTER MAP (PAGE 0)

Address	Name	Default	Type

9.4 Register List

9.4.1 REGISTER LIST (PAGE 0)

Address:	0x0000	
Name:	info	
Default:	0x1E	
Type:	R	
Bit Field	Function Name	Description
7	ready	Status bit indicating when the device has performed initialization, and it is ready to be programmed. Typically 500 ms from power-up.
6:0	reserved	—

Address:	0x0001:0x0002	
Name:	id	
Default:	0x1C66	
Type:	R	
Bit Field	Function Name	Description
15:0	chip_id	Chip identification number (the unsigned binary value of these bits represent the chip identification number)

Address:	0x0003	
Name:	revision	
Default:	0x04	
Type:	R	
Bit Field	Function Name	Description
7:0	chip_revision_id	<p>Chip revision number: Unsigned binary value of these bits represent chip revision number. Refer to Section 6.6.5, VDD_DRI and VREG_OUT.</p> <p>Note: Following the warm start initiated by enabling split XO mode (see register 0x021D), this register will be reset to 0x00. To determine the correct revision of the device, this register should be read before split XO mode is enabled. If the device uses a custom configuration, the revision register will be correct after the device is automatically configured, even if split XO mode is enabled by the custom configuration).</p>

Address:	0x0007:0x000A	
Name:	custom_config_ver	
Default:	0xFFFFFFFF	
Type:	R/W	
Bit Field	Function Name	Description
31:0	—	This register is intended (but not limited) to be used as configuration version number. Up to 3 custom register configurations can be programmed into the device.

Address:	0x000B:0x000E	
Name:	central_freq_offset	
Default:	0x046AAAAB	
Type:	R/W	
Bit Field	Function Name	Description
31:0	—	<p>2's complement binary value of these bits represent central frequency offset for the device. This value should be used to compensate for oscillator inaccuracy, or make the device look like Numerically Controlled Oscillator (NCO). This register controls central frequency of all 4 synthesizers. Expressed in steps of $\pm 2^{-32}$ of nominal setting.</p> <p>When oscillator inaccuracy is known, $\text{inacc_osc} = (f_{\text{osc}} - f_{\text{nom}})/f_{\text{nom}}$ (usually specified in ppm), the value to be programmed in this register is calculated with the following formula:</p> <p style="padding-left: 40px;">When $f_{\text{osc}} < f_{\text{nom}}$, then $X = (1/(1 + \text{inacc_osc}) - 1) \times 2^{32}$ When $f_{\text{osc}} > f_{\text{nom}}$, then $X = (1/(1 - \text{inacc_osc}) - 1) \times 2^{32}$</p> <p>Where:</p> <ul style="list-style-type: none"> • inacc_osc represents oscillator frequency inaccuracy, • f_osc represents oscillator frequency, and • f_nom represents oscillator nominal frequency (i.e. 25 MHz, 20 MHz, or 50 MHz) <p>When the oscillator frequency is lower than the nominal, frequency offset has to be programmed to compensate for it in the opposite direction, i.e. frequency offset has to be positive and vice versa.</p> <p>For example, if oscillator inaccuracy is -2% $(f_{\text{osc}} = 24.5 \text{ MHz}; \text{inacc_osc} = [f_{\text{osc}} - 25 \text{ MHz}]/25 \text{ MHz} = -0.02)$, then $X = (1/(1 + (-0.02)) - 1) \times 2^{32} = (1/0.98 - 1) \times 2^{32} = 87652394 = 0x0539782A$.</p> <p>When NCO behavior is desired, the output frequency should be calculated as per this formula:</p> $f_{\text{out}} = (1 + X/2^{32}) \times f_{\text{init}}$ <p>Where:</p> <ul style="list-style-type: none"> • X represents 2's complement number specified in this register • finit refers to initial frequency set by Bs, Ks, Ms, Ns, and postdivider number for particular VCO • fout represents output frequency <p>Note 1: CFN offset should not be programmed to exceed +0% to -4% or -10% (depending on master clock frequency)</p> <p>2: This register cannot be accessed more than once per 25 ms.</p>

Address:	0x007E	
Name:	uport	
Default:	0x00	
Type:	R/W	
Bit Field	Function Name	Description
7:0	lockout	When set, this field causes all other uport registers to be read-only. When zero, all registers are open for writing.
6:1	reserved	—
0	status	This field indicates if microport attempted access had not been successful. The register content will be 0x00 if the access had been successful.

Address:	0x007F	
Name:	page_sel	
Default:	0x00	
Type:	R/W	
Bit Field	Function Name	Description
7:0	—	Unsigned binary value of these bits represents selected page for SPI access: <ul style="list-style-type: none">• 0x00: page 0 (first 128 bytes)• 0x01: page 1 (second 128 bytes)• 0x02: page 2 (third 128 bytes)• 0x03: page 3 (fourth 128 bytes)• 0x04: page 4 (fifth 128 bytes)• 0x05: page 5 (sixth 128 bytes)• 0x06: page 6 (seventh 128 bytes)• 0x07: reserved• 0x08: page 8 (ninth 128 bytes)• 0x09: reserved• 0x0A: page 10 (eleventh 128 bytes)• 0x0B: page 11 (twelfth 128 bytes)• 0x0C: page 12 (thirteenth 128 bytes)• 0x0D: page 13 (fourteenth 128 bytes)• 0x0E-0xFF: reserved

9.4.2 REGISTER LIST (PAGE 1)

Address:	0x0080	
Name:	ref_irq_mask_7_0

1:0	reserved	—

Address:	0x017E	
Name:	uport	
Default:	0x00	
Type:	R/W	
Bit Field	Function Name	Description
7:0	lockout	When set, this field causes all other uport registers to be host read-only. When zero, all registers are open for writing.
6:1	reserved	—
0	status	This field indicates if microport attempted access had not been successful. The register content will be 0x00 if the access had been successful.

Address:	0x017F	
Name:	page_sel	
Default:	0x00	
Type:	R/W	
Bit Field	Function Name	Description
7:0	—	Unsigned binary value of these bits represents selected page for SPI access: 0x00: page 0 (first 128 bytes) 0x01: page 1 (second 128 bytes) 0x02: page 2 (third 128 bytes) 0x03: page 3 (fourth 128 bytes) 0x04: page 4 (fifth 128 bytes) 0x05: page 5 (sixth 128 bytes) 0x06: page 6 (seventh 128 bytes) 0x07: reserved 0x08: page 8 (ninth 128 bytes) 0x09: reserved 0x0A: page 10 (eleventh 128 bytes) 0x0B: page 11 (twelfth 128 bytes) 0x0C: page 12 (thirteenth 128 bytes) 0x0D: page 13 (fourteenth 128 bytes) 0x0E-0xFF: reserved

9.4.4 REGISTER LIST (PAGE 3)

Address:	0x0180	
Name:	sticky_lock	
Default:	0x00	
Type:	R/W	
Bit Field	Function Name	Description
7:0	—	<p>This register needs to be set to a non-zero value prior to clearing sticky bits, to avoid race condition that can happen when the internal processor updates the register while the host clears the bit. Having non-zero value in this register will prevent the internal processor from updating the sticky bit registers.</p> <p>For proper sticky bit monitoring, the following procedure is recommended:</p> <ol style="list-style-type: none"> 1. Write non-zero value into this register 2. Clear sticky bits in other registers 3. Write 0 into this register 4. Read sticky bits status registers

Address:	0x0182

Default:	0x04	
Type:	R/W	
Bit Field	Function Name	Description
7:3	reserved	—
2:0	num	0: All DPLLs disabled. n: DPLL0 to DPLL(n-1) enabled. If n is greater than the highest numbered DPLL, all DPLLs will be enabled.

Address:	0x021E	
Name:	split_xo_mode_control	
Default:	0x00	
Type:	R/W	
Bit Field	Function Name	Description
7:4	ref	Sets the reference to use as the TCXO/OCXO input source. An invalid reference number will set the source to ref0.
3:1	reserved	—
0	en	<p>0: Split-XO mode disabled. 1: Split-XO mode enabled.</p> <p>Note 1: Changing this bit will cause the device to perform a warm start.</p> <p>2: Following the warm start the revision register (0x003) will be set to 0x00. To determine the correct revision of the device, the revision register (0x003) should be read before split_xo mode is enabled.</p>

Address:	0x021E	
Name:	dpll_mode_refsel_0	
Default:	0x00	
Type:	R/W	
Bit Field	Function Name	Description
7:4	ref	Specifies which reference the DPLL0 is forced to select, when the mode bitfield is set to '010' (forced reference lock mode). When this forced reference fails, DPLL0 will go to holdover state. An invalid reference number will select ref0. When DPLL0 is not in forced reference lock mode, this bitfield is ignored.
3	reserved	—
2:0	mode	<p>000: Freerun mode 001: Forced holdover mode 010: Forced reference lock mode 011: Automatic mode 100: NCO mode 101-111: Invalid (automatic mode)</p>

Address:	0x021F	
Name:	dpll_ctrl_0	
Default:	0x08	
Type:	R/W	
Bit Field	Function Name	Description
7:5	reserved	—
4	nco_auto_read	0: DPLL0 automatic NCO read is disabled. 1: DPLL0 automatic NCO read is enabled. When switching to forced holdover or NCO modes, an NCO read operation is automatically performed, the device will write DPLL0's frequency offset to register 0x300-0x304 (dpll_df_offset_0).
3:2	reserved	—
1	tie_clear	0: DPLL0 will not align its output to the reset position. This represents "hitless" reference switching mode. 1: DPLL0 will align its outputs to the reset position (specified by appropriate phase shift selection). This bit should be set when initial output to input alignment is desired after numerous reference rearrangements.

Address:	0x0306:0x0309	
Name:	dpll_tie_data_0	
Default:	0x00000000	
Type:	R/W	
Bit Field	Function Name	Description
31:0	—	<p>This register contains the argument or results of a DPLL0 time interval error (TIE) control operation. LSB = 1ns.</p> <p>See register 0x30A (dpll_tie_ctrl_0) for details on TIE control operations. This register should only be read or written when register 0x30A bits 1:0 (dpll_tie_ctrl_0::op) == 00.</p>

Address:	0x030A	
Name:	dpll_tie_ctrl_0	
Default:	0x00	
Type:	R/W	
Bit Field	Function Name	Description
7:2	reserved	—
1:0	op	<p>This field selects a time interval error (TIE) related operation to perform. When the operation request has been latched by the device, this bitfield reads 00. To prevent race conditions, the host only writes non-zero values to this register, while the device only writes zero. The host controller should read this register prior to writing, and should only write to this bitfield when it contains value 00.</p> <p>All operations provided by this register are only valid when DPLL0 is in forced reference or automatic or mode (see register 0x21E) with a valid, qualified reference. If an operation is requested on DPLL0 in another mode of operation (e.g., NCO mode), then the operation will be delayed until DPLL0 is configured to forced reference or automatic mode with a qualified reference. Available operations are:</p> <p>00: Previous operation complete / new operation can be requested 01: Request a Snap MTIE operation 10: Request to read TIE 11: Request to write TIE</p> <p>Snap MTIE: When the input reference is 1 Hz, the DPLL0 bandwidth must be ≤ 30 mHz. With such a low bandwidth and a low edge rate it would take very long time to do zero phase alignment between the input and output. This operation allows the user to perform an instantaneous I/O alignment. This alignment zeros out hitless reference switch TIE and Write TIE offsets, but excludes post-divider phase steps. The instantaneous alignment is completed when this bitfield reads 00.</p> <p>Read TIE: Reads the TIE between the input reference and output, not including post-divider phase steps. The results are returned in registers 0x306-0x309 (dpll_tie_data_0). The results are valid when this bitfield reads 00. The return value "wraps around" such that the range is -1s to 1s. When mailbox register 0x608, bit 3 (dpll_ctrl::low_freq_mode) is set to 1, the return range is -2s to 2s.</p> <p>Write TIE: Write the TIE between the input reference and output. The desired TIE value is written to registers 0x306-0x309 (dpll_tie_data_0) prior to writing this bitfield. The allowed range is -1s to 1s. When mailbox register 0x608, bit 3 (dpll_ctrl::low_freq_mode) is set to 1, the allowed range is -2s to 2s. Another write TIE request can be made only after this bitfield reads 00. Register 0x1AA (dpll_tie_wr_sticky) can be used to determine when the requested TIE has been fully applied to the output. Write TIE operations are cumulative; subsequent write TIEs are added to the previous TIE.</p>

9.4.8 REGISTER LIST (PAGE 10)

Address:	0x0501	
Name:	phase_step_ctrl	
Default:	0x00	
Type:	R/W	
Bit Field	Function Name	Description
7	reserved	—
6:4	dpll	Selects the DPLL that is the target of the requested phase step operation. This bitfield should be set during the same write that changes the op bitfield to a non-zero value. If this value is invalid, no phase step operation will execute.
3:2	reserved	—
1:0	op	<p>This field selects a Phase-Step-related operation to perform. When the device has grabbed the information in phase_step_data and phase_step_max registers (see registers 0x0502-0x0506), this field is cleared to 0x00. To prevent race conditions, the host only writes non-zero values to this field, while the device only writes zero. The host controller should read this field prior to writing, and should only write to this field when it contains a 0x00 value. Available operations are:</p> <p>00 = Previous operation complete / New operation can be requested 01 = Request a Phase Step Reset 10 = Request a Phase Step Read 11 = Request a Phase Step Write</p> <p>Below is a summary of each of the operations.</p> <p>Phase Step Write: Write and apply a new Phase Step Offset to the specified synthesizer (see Synthesizer Selection). The desired phase step value should be written to the phase_step_data register prior to writing this field. Phase step operations are cumulative -- subsequent phase steps are added to the previous accumulated phase step offset.</p> <p>Phase Step Read: Read the current Phase Step Offset for the specified synthesizer (see Synthesizer Selection). The result of this operation is found in the phase_step_data register once the control field has returned to 0x00. Note that bits 7:4 are used to select which output is read, and that only one output should be selected for read operations.</p> <p>Phase Step Reset: Clears all previously applied phase steps.</p>

Address:	0x0502:0x0505	
Name:	phase_step_data	
Default:	0x00000000	
Type:	R/W	
Bit Field	Function Name	Description
31:0	—	<p>This register contains the argument or results of a Phase Step control operation. For details, see the phase_step_ctrl register. This register should not be read or written while a Phase Step control operation is ongoing. The register should only be read or written when the phase_step_ctrl::op bitfield is zero.</p> <p>The phase step contained in this register is a 32-bit signed word with the MSB at the lowest address. The signed representation is in 2's complement form. A positive phase step implies phase advancement and a negative step implies phase delay. The step size of the phase step data is 1.25 ns.</p>

Address:	0x0506	
Name:	phase_step_max	
Default:	0x00	
Type:	R/W	
Bit Field	Function Name	Description
7:0	—	This register contains a numerical value which specifies the maximum phase step to be applied to an output clock/frame pulse. This value is specified as a percentage of the output clock/frame pulse period. This value must be between 1 and 49.

Address:	0x0510	
Name:	synth_step_div_mask_1_0

Address:	0x0592	
Name:	ref_pfm_ctrl	
Default:	0x00	
Type:	R/W	
Bit Field	Function Name	Description
7:1	reserved	—
0	resolution	Sets the resolution and range of ref_pfm_disqualify (0x593–0x594) and ref_pfm_qualify (0x595–0x596). 0: Resolution is 0.01 ppm, range is ± 0.01 ppm to 655.35 ppm. 1: Resolution is 0.1 ppm, range is ± 0.1 ppm to 6553.5 ppm.

Address:	0x0593:0x0594	
Name:	ref_pfm_disqualify	
Default:	0x32B4	
Type:	R/W	
Bit Field	Function Name	Description
15:0	—	Sets the Precise Frequency Monitor (PFM) disqualify frequency offset. If a reference exceeds this offset, the pfm bit in the associated ref_mon_status_n register will go high. The default value is 130 ppm.

Address:	0x0595:0x0596	
Name:	ref_pfm_qualify	
Default:	0x2724	
Type:	R/W	
Bit Field	Function Name	Description
15:0	—	Sets the PFM qualify frequency offset. If a reference is below this offset, the pfm bit in the associated ref_mon_status_n register will go low. The default value is 100 ppm. Note: When the reference offset is between the qualify and disqualify limits (hysteresis), the state of the pfm bit in the ref_mon_status_n register will not be changed.

Address:	0x0597:0x0598	
Name:	ref_pfm_period	
Default:	0x0000	
Type:	R/W	
Bit Field	Function Name	Description
15:0	—	Range 1 to 2048s with 1s resolution. Default value is 0. Setting value of 0 is recommended. Setting value of 0 disables this use register override, and uses the recommended defaults which are suitable for standard compliant behavior (e.g., 10 second observation interval).

Address:	0x0599	
Name:	ref_pfm_filter_limit	
Default:	0x28	
Type:	R/W	
Bit Field	Function Name	Description
7:0	—	<p>The PFM filter limit represents a threshold. When the threshold is a non-zero value, and the difference between the PFM average filter output and 10 second PFM average is larger than this threshold, the PFM average filter will be replaced by 10 second PFM average output. The purpose of this is to speed up the filter reaction.</p> <p>The default value corresponds to a 4 ppm filter limit. A value of 0 disables the filter limit check. Any other value is in units (or resolution) of 100 ppb. Thus the allowed range is 100 ppb to 25.5 ppm.</p> <p>It is recommended to be used for PFM filter average time being larger than 10 seconds. This threshold should be set to 0 (means disabled) when the average time is smaller than 10 seconds.</p>

Address:	0x059A	
Name:	ref_phase_mem	
Default:	0x1B	
Type:	R/W	
Bit Field	Function Name	Description
7:0	—	<p>These bits specify reference phase memory limit using the following E32 series formula:</p> <p>Value = $\text{round}(32 \times \log(\text{phase_mem_limit} / 10))$, where phase_mem_limit is given in us. e.g., 10 us (min) = 0x00, 1 ms = 0x40, 1 s (max) = 0xA0.</p> <p>This register should be programmed to have value that represents at least one reference period. Values 0xA1–0xFF will set the phase memory limit to 1s.</p>

Address:	0x05FE	
Name:	uport	
Default:	0x00	
Type:	R/W	
Bit Field	Function Name	Description
7:0	lockout	When set, this field causes all other uport registers to be read-only. When zero, all registers are open for writing.
6:1	reserved	—
0	status	This field indicates if microport attempted access had not been successful. The register content will be 0x00 if the access had been successful.

Address:	0x05FF	
Name:	page_sel	
Default:	0x00	
Type:	R/W	
Bit Field	Function Name	Description
7:0	—	<p>Unsigned binary value of these bits represents selected page for SPI access:</p> <ul style="list-style-type: none"> • 0x00: page 0 (first 128 bytes) • 0x01: page 1 (second 128 bytes) • 0x02: page 2 (third 128 bytes) • 0x03: page 3 (fourth 128 bytes) • 0x04: page 4 (fifth 128 bytes) • 0x05: page 5 (sixth 128 bytes) • 0x06: page 6 (seventh 128 bytes) • 0x07: reserved • 0x08: page 8 (ninth 128 bytes) • 0x09: reserved • 0x0A: page 10 (eleventh 128 bytes) • 0x0B: page 11 (twelfth 128 bytes) • 0x0C: page 12 (thirteenth 128 bytes) • 0x0D: page 13 (fourteenth 128 bytes) • 0x0E–0xFF: reserved

9.4.10 REGISTER LIST (PAGE 12)

Address:	0x0602:0x0603	
Name:	dpll_ctrl	
Default:	0x0001	
Type:	R/W	
Bit Field	Function Name	Description
15:7	reserved	—
6:0	mask	<p>For a write operation (see dpll_semaphore_wr bit), this field determines which DPLL's configuration is modified. Multiple bits can be set to affect multiple DPLLs in a single operation.</p> <p>For a read operation (see dpll_semaphore_rd bit), this field determines which DPLL configuration to read back from the device. One (and only one) bit should be set for a read operation.</p> <ul style="list-style-type: none"> • Bit 0 – DPLL0 • Bit 1 – DPLL1 • Bit 2 – DPLL2 • Bit 3 – DPLL3 • Bit 4 – unused • Bit 5 – unused • Bit 6 – unused

Address:	0x0604	
Name:	dpll_semaphore	
Default:	0x00

Default:	0x17	
Type:	R/W	
Bit Field	Function Name	Description
7:5	reserved	—
4	pfm	<p>When set to high, this bit will allow selected reference PFM failure to cause associated DPLL to go to holdover. When low, selected reference PFM failure will be masked and the associated DPLL will not go to holdover due to the PFM failure.</p> <p>A switch to holdover will only be attempted after all reference switching options have been exhausted, regardless of the state of the dpll_ref_ho_mask bits.</p>
3	gst	This bit acts as an enable mask for the GST holdover switch. See pfm bit description.
2	cfm	This bit acts as an enable mask for the CFM holdover switch. See pfm bit description.
1	scm	This bit acts as an enable mask for the SCM holdover switch. See pfm bit description.
0	los	This bit acts as an enable mask for the LOS holdover switch. See pfm bit description.

Address:	0x0613	
Name:	dpll_ho_filter	
Default:	0x00	
Type:	R/W	
Bit Field	Function Name	Description
7:4	reserved	—
3:0	bw	<p>This register specifies the holdover filter bandwidth. The default value of 0x00 means that the filter is bypassed. These are the possible settings:</p> $BW = 343/(2^{n \times 2\pi}) \text{ Hz}$ <p>Selection:</p> <ul style="list-style-type: none"> • 0x0: Bypass • 0x1: 27.3 Hz • 0x2: 13.6 Hz • 0x3: 6.8 Hz • 0x4: 3.4 Hz • 0x5: 1.7 Hz • 0x6: 883 mHz • 0x7: 426 mHz • 0x8: 213 mHz • 0x9: 107 mHz • 0xA: 53.3 mHz • 0xB: 26.6 mHz • 0xC: 13.3 mHz • 0xD: 6.7 mHz • 0xE: 3.3 mHz • 0xF: 1.7 mHz

Address:	0x0614	
Name:	dpll_ho_delay	
Default:	0x4C	
Type:	R/W	
Bit Field	Function Name	Description
—	—	<p>This register specifies the DPLL holdover storage delay using the following E32 series formula:</p> $\text{Value} = \text{round}(32 \times \log(\text{delay})), \text{ where delay is in ms}$ <p>Example: If desired delay is 1 ms, value to be written to this register is 0x00, for 1 second the value is 0x60, and for 2 hours the value is 0xDC. The default value of 0x4C corresponds to 237 ms.</p>

Address:	0x0615	
Name:	dpll_priority_1_0	
Default:	0x10	
Type:	R/W	
Bit Field	Function Name	Description
7:4	ref_1	<p>Priority of ref1. When the DPLL is in automatic mode of operation (see dpll_mode_refsel_x::mode bitfield), these bits set the priority of each reference for the DPLL. 0000 is highest priority and 1110 is lowest priority. Setting these bits to 1111 will disable the reference (the DPLL will never lock to it).</p> <p>When two references are programmed to have different priority numbers, the DPLL will perform revertive switching between them: the DPLL will always switch to the highest priority reference (lowest priority number) whenever that reference is qualified.</p> <p>When two references are programmed to have the same priority number, the DPLL will perform non-revertive switching between them: the DPLL will not switch to the reference with the same priority when that reference qualifies.</p> <p>Combinations of same and different priority numbers can be used, such that DPLL performs revertive switching between different priority references, but non-revertive switching among references with the same priority. Example: if ref0 has priority 0 (highest), ref1, ref2 and ref3 have priority 1. Whenever ref0 is qualified, the DPLL will switch to it. If ref0 is not qualified, the DPLL will not change the currently selected reference (e.g., ref3) even if ref2 or ref2 become available.</p>
3:0	ref_0	Priority of ref0

Address:	0x0616	
Name:	dpll_priority_3_2

10.0 ELECTRICAL CHARACTERISTICS

10.1 Absolute Maximum Ratings

TABLE 10-1: ABSOLUTE MAXIMUM RATINGS

Parameter	Symbol	Min.	Typ.	Max.	Units
Supply Voltage, 3.3V	V_{DD_R}	-0.5	—	4.0	V
Supply Voltage, 2.5V	V_{DD_R}	-0.5	—	4.0	V
Supply Voltage, 1.8V	V_{DD18_R}	-0.5	—	2.5	V
Output Supply Voltage	V_{DDO_R}	-0.5	—	4.0	V
CML Pull-up Voltage	V_{DDU_R}	-0.5	—	4.0	V
Voltage on any Digital Pin	V_{PIN}	-0.5	—	4.0	V
Voltage on any OSCI or OSCO Pin	V_{OSC}	-0.3	—	$V_{DD} + 0.3$	V
Storage Temperature	T_{ST}	-55	—	125	°C

- Note 1:** Exceeding these values may cause permanent damage.
2: Functional operation under these conditions is not implied.
3: Voltages are with respect to ground (GND) unless otherwise stated.
4: The device supports two power supply modes (3.3V and 1.8V; 2.5V and 1.8V).

10.2 Recommended Operating Conditions

TABLE 10-2: RECOMMENDED OPERATING CONDITIONS

Parameter	Symbol	Min.	Typ.	Max.	Units
Supply Voltage, 3.3V	V_{DD}	3.135	3.30	3.465	V
Supply Voltage, 2.5V	V_{DD}	2.375	2.50	2.625	V
Supply Voltage, 1.8V	V_{DD18}	1.71	1.80	1.89	V
Output Supply Voltage	V_{DDO}	1.71	1.8	1.89	V
		2.375	2.5	2.625	
		3.135	3.3	3.465	
CML Pull-up Voltage	V_{DDPU}	1.71	1.8	1.89	V
		2.375	2.5	2.625	
		3.135	3.3	3.465	
Operating Temperature	T_A	-40	25	85	°C
Input Voltage	V_{DD-IN}	$V_{DD} - 0.3$	—	$V_{DD} + 0.3$	V

- Note 1:** Voltages are with respect to ground (GND) unless otherwise stated.
2: The device supports two power supply modes (3.3V and 1.8V; 2.5V and 1.8V).

10.3 DC Electrical Characteristics

Note: All table values in Section 10.3 are over Recommended Operating Conditions.

TABLE 10-3: DC ELECTRICAL CHARACTERISTICS: CURRENT—CORE

Characteristics	Symbol	Min.	Typ.	Max.	Units	Notes
Current for Core	I_{CORE} (V_{DD} 3.3V)	—	150	160	mA	3.3V/1.8V sysAppl
		—	90	100	mA	3.3V/1.8V bypAppl
	I_{CORE} (V_{DD18} 1.8V)	—	280	300	mA	3.3V/1.8V sysAppl
		—	190	210	mA	3.3V/1.8V bypAppl
	I_{CORE} (V_{DD} 2.5V)	—	130	150	mA	2.5V/1.8V sysAppl
		—	70	80	mA	2.5V/1.8V bypAppl
	I_{CORE} (V_{DD18} 1.8V)	—	280	300	mA	2.5V/1.8V sysAppl
		—	200	210	mA	2.5V/1.8V bypAppl

- Note 1:** V_{DD0} is connected to V_{DD} and is included in the V_{DD} measured current value.
- 2:** sysAppl is “System APLL Mode” and is when osc input is 49.152 MHz and Syn[3] is used for internal clock generation.
- 3:** bypAppl is “Bypass APLL Mode” and is when osc input is 114.285 MHz and no synthesizers are used for internal clock generation.
- 4:** Current is measured with synthesizers, dividers and outputs disabled.

Note: All table values in Section 10.3 are over Recommended Operating Conditions.

TABLE 10-4: DC ELECTRICAL CHARACTERISTICS: CURRENT—CORE + SYNTHESIZERS 3:1

Characteristics	Symbol	Min.	Typ.	Max.	Units	Notes
Current for Core plus Syn1	$I_{C_SYN1}(V_{DD} 3.3V)$	—	310	340	mA	3.3V/1.8V sysAppl
		—	250	270	mA	3.3V/1.8V bypAppl
	$I_{C_SYN1}(V_{DD18} 1.8V)$	—	350	370	mA	3.3V/1.8V sysAppl
		—	260	280	mA	3.3V/1.8V bypAppl
	$I_{C_SYN1}(V_{DD} 2.5V)$	—	280	310	mA	2.5V/1.8V sysAppl
		—	220	250	mA	2.5V/1.8V bypAppl
	$I_{C_SYN1}(V_{DD18} 1.8V)$	—	350	370	mA	2.5V/1.8V sysAppl
		—	260	280	mA	2.5V/1.8V bypAppl
Current for Core plus Syn2	$I_{C_SYN2}(V_{DD} 3.3V)$	—	240	270	mA	3.3V/1.8V sysAppl
		—	180	200	mA	3.3V/1.8V bypAppl
	$I_{C_SYN2}(V_{DD18} 1.8V)$	—	400	430	mA	3.3V/1.8V sysAppl

	$I_{C_SYN2}(V_{DD} 2.5V)$	—	210	240	mA	2.5V/1.8V sysAppl
		—	150	180	mA	2.5V/1.8V bypAppl
	$I_{C_SYN2}(V_{DD18} 1.8V)$	—	400	430	mA	2.5V/1.8V sysAppl
		—	320	340	mA	2.5V/1.8V bypAppl
Current for Core plus Syn3	$I_{C_SYN3}(V_{DD} 3.3V)$	—	160	180	mA	3.3V/1.8V bypAppl
	$I_{C_SYN3}(V_{DD18} 1.8V)$	—	300	320	mA	
	$I_{C_SYN3}(V_{DD} 2.5V)$	—	140	160	mA	2.5V/1.8V bypAppl
	$I_{C_SYN3}(V_{DD18} 1.8V)$	—	300	320	mA	
Current for Core plus Syn1 + Syn2	$I_{C_SYN12}(V_{DD} 3.3V)$	—	400	450	mA	3.3V/1.8V sysAppl
		—	340	380	mA	3.3V/1.8V bypAppl
	$I_{C_SYN12}(V_{DD18} 1.8V)$	—	480	510	mA	3.3V/1.8V sysAppl
		—	390	410	mA	3.3V/1.8V bypAppl
	$I_{C_SYN12}(V_{DD} 2.5V)$	—	360	410	mA	2.5V/1.8V sysAppl
		—	300	340	mA	2.5V/1.8V bypAppl
	$I_{C_SYN12}(V_{DD18} 1.8V)$	—	480	510	mA	2.5V/1.8V sysAppl
		—	390	410	mA	2.5V/1.8V bypAppl
Current for Core plus Syn1 + Syn2 + Syn3	$I_{C_SYN3}(V_{DD} 3.3V)$	—	420	460	mA	3.3V/1.8V bypAppl
	$I_{C_SYN3}(V_{DD18} 1.8V)$	—	490	530	mA	
	$I_{C_SYN3}(V_{DD} 2.5V)$	—	380	420	mA	2.5V/1.8V bypAppl
	$I_{C_SYN3}(V_{DD18} 1.8V)$	—	490	530	mA	

Note 1: V_{DDO} is connected to V_{DD} and is included in the V_{DD} measured current value.

2: sysAppl is “System APLL Mode” and is when osc input is 49.152 MHz and Syn[3] is used for internal clock generation.

3: bypAppl is “Bypass APLL Mode” and is when osc input is 114.285 MHz and no synthesizers are used for internal clock generation.

4: VCOs are programmed to their highest rate; dividers and outputs are disabled.

5: Current is measured with synthesizer individually enabled/disabled and includes core current.

Note: All table values in Section 10.3 are over Recommended Operating Conditions.

TABLE 10-5: DC ELECTRICAL CHARACTERISTICS: CURRENT—CORE + SYNTHESIZER 1 + HPOUT_DIFF[1:0] OUTPUTS

Characteristics	Symbol	Min.	Typ.	Max.	Units	Notes
Current for Core plus: Syn1DivA + HPOUT_DIFF[0]	$I_{CS1_HPD}(V_{DD} 3.3V)$	—	330	370	mA	3.3V/1.8V sysApI
		—	270	300	mA	3.3V/1.8V bypApI
	$I_{CS1_HPD}(V_{DD18} 1.8V)$	—	350	370	mA	3.3V/1.8V sysApI

Current for Core plus: Syn1DivABCD + Syn2DivAB + Syn3DivAB + HPOUT[0:11]	$I_{CS2_HPO}(V_{DD} 3.3V)$	—	720	760	mA	3.3V/1.8V bypAppl
	$I_{CS2_HPO}(V_{DD18} 1.8V)$	—	550	610	mA	
	$I_{CS2_HPO}(V_{DD} 2.5V)$	—	620	660	mA	2.5V/1.8V bypAppl
	$I_{CS2_HPO}(V_{DD18} 1.8V)$	—	550	510	mA	
Current for Core plus: Syn1DivABCD + Syn2DivAB + Syn3DivAB + HPOUT[0:11] (Outputs are at 100 Hz)	$I_{CS2_HPO}(V_{DD} 3.3V)$	—	590	650	mA	3.3V/1.8V bypAppl
	$I_{CS2_HPO}(V_{DD18} 1.8V)$	—	520	580	mA	
	$I_{CS2_HPO}(V_{DD} 2.5V)$	—	520	570	mA	2.5V/1.8V bypAppl
	$I_{CS2_HPO}(V_{DD18} 1.8V)$	—	520	580	mA	

Note 1: V_{DDO} is connected to V_{DD} and is included in the V_{DD} measured current value.

2: sysAppl is “System APLL Mode” and is when osc input is 49.152 MHz and Syn[3] is used for internal clock generation.

3: bypAppl is “Bypass APLL Mode” and is when osc input is 114.285 MHz and no synthesizers are used for internal clock generation.

4: VCOs are programmed to their highest rate; outputs are at 125 MHz unless otherwise indicated.

5: Current is measured with synthesizer and outputs individually enabled/disabled and includes core current.

6: See [Figure 10-1](#).

Note: All table values in Section 10.3 are over Recommended Operating Conditions.

TABLE 10-13: DC ELECTRICAL CHARACTERISTICS: CURRENT—CORE + SYNTHESIZER 0 + GPOUT[1:0] OUTPUTS

	$I_{CS0123_HPOGP}(V_{DD18} 1.8V)$	—	520	580	mA	—

Note 1: V_{DDO} is connected to V_{DD} and is included in the V_{DD} measured current value.

2: sysAppl is “System APLL Mode” is when osc input is 49.152 MHz and Syn[3] is used for internal clock generation.

3: bypAppl is “Bypass APLL Mode” and is when osc input is 114.285 MHz and no synthesizers are used for internal clock generation.

4: VCOs are programmed to their highest rate; outputs are at 125 MHz unless otherwise indicated.

5: GPOUT output driv level is set to 4X.

6: Current is measured with synthesizer and outputs individually enabled/disabled and includes core current.

7: See [Figure 10-1](#).

Note: All table values in Section 10.3 are over Recommended Operating Conditions.

TABLE 10-15: DC ELECTRICAL CHARACTERISTICS: REFERENCE INPUTS ([Note 1](#))

Characteristics	Symbol	Min.	Typ.	Max.	Units	Notes
Single-ended CMOS high-level input voltage for ref[9:0]	$V_{IH-CMOS}$	$0.7 \times V_{DD}$	—	—	V	—
Single-ended CMOS low-level input voltage for ref[9:0]	$V_{IL-CMOS}$	—	—	$0.3 \times V_{DD}$	V	—
Single-ended CMOS input leakage current for ref[9:0]	$I_{IL-CMOS}$	–10	—	10	μA	Note 2 , Note 3
Single-ended PECL high-level input voltage for ref[9:0]	$V_{IH-PECL}$	$V_{REF-PECL} + 0.2$	—	—	V	$V_{DD} = 3.3V$ or 2.5V
Single-ended PECL low-level input voltage for ref[9:0]	$V_{IL-PECL}$	—	—	$V_{REF-PECL} - 0.2$	V	
Single-ended PECL input reference voltage for ref[9:0]	$V_{IL-PECL}$	—	$0.55 \times V_{DD}$	—	V	
Single-ended PECL input leakage current for ref[9:0]	$I_{IL-PECL}$	—	—	10	μA	$V_I = V_{DD}$ or 0.8V, Note 2
Differential input common mode voltage for ref[4:0]	V_{CM}	—	—	2.0	V	—
Differential input voltage difference for ref[4:0]	V_{ID}	—	—	1.0	V	—
Differential input leakage current for ref[4:0]	I_{IL}	—	—	10	μA	Note 2 , Note 3

Note 1: Values are over both power supply modes (3.3V and 1.8V, 2.5V and 1.8V).

2: Leakage current flowing out of the device pin referenced as positive.

3: $V_I = V_{DD}$ or 0V.

Note: All table values in Section 10.3 are over Recommended Operating Conditions.

TABLE 10-16: DC ELECTRICAL CHARACTERISTICS* - OTHER INPUTS AND I/O, BI-DIRECTIONAL

Characteristics	Symbol	Min.	Typ.	Max.	Units	Notes
High-level input voltage for osci[2:0]	V_{IH}	1.26	—	—	V	—
Low-level input voltage for osci[2:0]	V_{IL}	—	—	0.54	V	—
Input leakage current for osci[2:0]	I_{IL}	–10	—	10	μA	Note 1, Note 2
Differential input common mode voltage for mclki[p,n]	V_{CM}	—	—	2.0	V	—
Differential input voltage difference for mclki[p,n]	V_{ID}	—	—	1.0	V	—
Differential input leakage current for mclki[p,n]	I_{IL}	–20	—	10	μA	Note 1, Note 2
CMOS high-level input voltage for gpio[3:0], rst_b	$V_{IH-CMOS}$	—	—	—	V	—
CMOS low-level input voltage for gpio[3:0], rst_b	$V_{IL-CMOS}$	—	—	$0.3 \times V_{DD}$	V	—
CMOS input leakage current for gpio[3:0] (75 k Ω pulldown)	$I_{IL-CMOS}$	–80	—	10	μA	Note 1, Note 2
CMOS input leakage current for rst_b (75 k Ω pullup)	$I_{IL-CMOS}$	–10	—	80	μA	Note 1, Note 2
Schmitt high-level input voltage for tdi, tms, tck, trst_b, cs_b_ase10, m_so	$V_{IH-SCHM}$	2.0	—	—	V	—
Schmitt low-level input voltage for tdi, tms, tck, trst_b, cs_b_ase10, m_so	$V_{IL-SCHM}$	—	—	0.7	V	—
Schmitt input leakage current for tdi, tms, tck, trst_b, cs_b_ase10, m_so (33 k Ω pullup)	$I_{IL-SCHM}$	–10	—	160	μA	Note 1, Note 2
Bidirectional schmitt high-level input voltage for si_sda, sck_scl, so_ase11, gpio[6:4]	$V_{IH-BIDI}$	2.0	—	—	V	—
Bidirectional schmitt low-level input voltage for si_sda, sck_scl, so_ase11, gpio[6:4]	$V_{SIL-BIDI}$	—	—	0.7	V	—
Bidirectional schmitt input leakage current for si_sda, sck_scl (33 k Ω pullup)	$I_{IL-BIDI}$	–10	—	160	μA	Note 1, Note 2
Bidirectional schmitt input leakage current for so_ase11	$I_{IL-BIDI}$	–10	—	10	μA	Note 1, Note 2
Bidirectional schmitt input leakage current for gpio[6:4] (33 k Ω pulldown)	$I_{IL-BIDI}$	–160	—	15	μA	Note 1, Note 2
Tri-Level high-level input voltage for cnfgsel	V_{IH-TRI}	2.2	—	—	V	—
Tri-Level mid-level input voltage for cnfgsel	V_{IM-TRI}	1.1	—	1.8	V	—
Tri-Level low-level input voltage for cnfgsel	V_{IL-TRI}	—	—	0.8	V	—
Tri-Level input leakage current for cnfgsel (115 k Ω pullup, 125 k Ω pulldown)	I_{IL-TRI}	–10	—	50	μA	$V_I = V_{DD18}$ or 0V, Note 1

Note 1: Leakage current flowing out of the device pin referenced as positive.

2: $V_I = V_{DD}$ or 0V.

Note: All table values in Section 10.3 are over Recommended Operating Conditions.

TABLE 10-17: DC ELECTRICAL CHARACTERISTICS: HPOUT_DIFF OUTPUTS

Output Voltage Characteristics	Symbol	Min.	Typ.	Max.	Units	Notes
HPOUT_DIFF[0:1] high level	V_{OH-CML}	$V_{DDO} - 0.11$	$V_{DDO} - 0.02$	V_{DDO}	V	V_{DDO} 3.3V or 2.5V, Output Setting 0.7V (see Figure 10-2 and Figure 6-13)
HPOUT_DIFF[0:1] low level	V_{OL-CML}	$V_{DDO} - 0.92$	$V_{DDO} - 0.69$	$V_{DDO} - 0.48$	V	
HPOUT_DIFF[0:1] high to low	V_{OD-CML}	0.46	0.67	0.90	V	
HPOUT_DIFF[0:1] differential	$2 \times V_{OD-CML}$	0.92	1.34	1.80	V	
HPOUT_DIFF[2:3] high level	V_{OH-CML}	$V_{DDO} - 0.11$	$V_{DDO} - 0.02$	V_{DDO}	V	
HPOUT_DIFF[2:3] low level	V_{OL-CML}	$V_{DDO} - 0.96$	$V_{DDO} - 0.74$	$V_{DDO} - 0.54$	V	
HPOUT_DIFF[2:3] high to low	V_{OD-CML}	0.50	0.72	0.94	V	
HPOUT_DIFF[2:3] differential	$2 \times V_{OD-CML}$	1.0	1.44	1.88	V	
HPOUT_DIFF[4:5] high level	V_{OH-CML}	$V_{DDO} - 0.11$	$V_{DDO} - 0.02$	V_{DDO}	V	
HPOUT_DIFF[4:5] low level	V_{OL-CML}	$V_{DDO} - 0.84$	$V_{DDO} - 0.61$	$V_{DDO} - 0.43$	V	
HPOUT_DIFF[4:5] high to low	V_{OD-CML}	0.41	0.59	0.83	V	
HPOUT_DIFF[4:5] differential	$2 \times V_{OD-CML}$	0.82	1.18	1.66	V	
HPOUT_DIFF[0:1] high level	V_{OH-CML}	$V_{DDO} - 0.11$	$V_{DDO} - 0.02$	V_{DDO}	V	V_{DDO} 3.3V, 2.5V, or 1.8V, Output Setting 0.6V (see Figure 10-2 and Figure 6-13)
HPOUT_DIFF[0:1] low level	V_{OL-CML}	$V_{DDO} - 0.82$	$V_{DDO} - 0.61$	$V_{DDO} - 0.43$	V	
HPOUT_DIFF[0:1] high to low	V_{OD-CML}	0.41	0.60	0.81	V	
HPOUT_DIFF[0:1] differential	$2 \times V_{OD-CML}$	0.82	1.20	1.62	V	
HPOUT_DIFF[2:3] high level	V_{OH-CML}	$V_{DDO} - 0.11$	$V_{DDO} - 0.02$	V_{DDO}	V	
HPOUT_DIFF[2:3] low level	V_{OL-CML}	$V_{DDO} - 0.85$	$V_{DDO} - 0.66$	$V_{DDO} - 0.48$	V	
HPOUT_DIFF[2:3] high to low	V_{OD-CML}	0.46	0.65	0.84	V	
HPOUT_DIFF[2:3] differential	$2 \times V_{OD-CML}$	0.92	1.30	1.68	V	
HPOUT_DIFF[4:5] high level	V_{OH-CML}	$V_{DDO} - 0.11$	$V_{DDO} - 0.02$	V_{DDO}	V	
HPOUT_DIFF[4:5] low level	V_{OL-CML}	$V_{DDO} - 0.76$	$V_{DDO} - 0.55$	$V_{DDO} - 0.38$	V	
HPOUT_DIFF[4:5] high to low	V_{OD-CML}	0.36	0.53	0.74	V	
HPOUT_DIFF[4:5] differential	$2 \times V_{OD-CML}$	0.72	1.06	1.48	V	
HPOUT_DIFF[0:1] high level	V_{OH-CML}	$V_{DDO} - 0.11$	$V_{DDO} - 0.02$	V_{DDO}	V	V_{DDO} 3.3V, 2.5V, or 1.8V, Output Setting 0.4V (see Figure 10-2 and Figure 6-13)
HPOUT_DIFF[0:1] low level	V_{OL-CML}	$V_{DDO} - 0.55$	$V_{DDO} - 0.42$	$V_{DDO} - 0.28$	V	
HPOUT_DIFF[0:1] high to low	V_{OD-CML}	0.27	0.41	0.54	V	
HPOUT_DIFF[0:1] differential	$2 \times V_{OD-CML}$	0.54	0.82	1.08	V	
HPOUT_DIFF[2:3] high level	V_{OH-CML}	$V_{DDO} - 0.11$	$V_{DDO} - 0.02$	V_{DDO}	V	
HPOUT_DIFF[2:3] low level	V_{OL-CML}	$V_{DDO} - 0.58$	$V_{DDO} - 0.45$	$V_{DDO} - 0.31$	V	
HPOUT_DIFF[2:3] high to low	V_{OD-CML}	0.31	0.44	0.56	V	
HPOUT_DIFF[2:3] differential	$2 \times V_{OD-CML}$	0.62	0.88	1.12	V	
HPOUT_DIFF[4:5] high level	V_{OH-CML}	$V_{DDO} - 0.11$	$V_{DDO} - 0.02$	V_{DDO}	V	
HPOUT_DIFF[4:5] low level	V_{OL-CML}	$V_{DDO} - 0.53$	$V_{DDO} - 0.37$	$V_{DDO} - 0.25$	V	
HPOUT_DIFF[4:5] high to low	V_{OD-CML}	0.24	0.36	0.52	V	
HPOUT_DIFF[4:5] differential	$2 \times V_{OD-CML}$	0.48	0.72	1.04	V	

- Note 1:** V_{DD} may be 2.5V or 3.3V as specified in Recommended Operating Conditions.
Note 2: V_{DDO} may be 1.8V, 2.5V, or 3.3V as specified in Recommended Operating Conditions.
Note 3: HPOUT_DIFF for CML outputs.
Note 4: CML pull-up resistors are $R_{PU} = 50\Omega$ to V_{DDO} and far end termination is 50Ω to V_{DDO} .
Note 5: Output drive impedance is set to 25Ω .
Note 6: CML drive level can be set to 0.7V, 0.6V, or 0.4V when V_{DDO} is 3.3V.
Note 7: CML drive level can be set to 0.6V or 0.4V when V_{DDO} is 1.8V.

FIGURE 10-3: HPOUT_DIFF (CML) DC Output Level.

Note: All table values in Section 10.3 are over Recommended Operating Conditions.

TABLE 10-18: DC ELECTRICAL CHARACTERISTICS: HPOUT AND GPOUT OUTPUTS

Output Voltage Characteristics	Symbol	Min.	Typ.	Max.	Units	Notes
HPOUT[3:0] high level ($V_{DDO} = 1.8V$, $I_{OH} = 3\text{ mA}$)	$V_{OH-HPOUT}$	$0.8 \times V_{DDO}$	—	—	V	See Figure 10-1, Figure 10-3
HPOUT[3:0] low level ($V_{DDO} = 1.8V$, $I_{OL} = 3\text{ mA}$)	$V_{OL-HPOUT}$	—	—	$0.2 \times V_{DDO}$	V	
HPOUT[3:0] high level ($V_{DDO} = 2.5V$, $I_{OH} = 8\text{ mA}$)	$V_{OH-HPOUT}$	$0.8 \times V_{DDO}$	—	—	V	
HPOUT[3:0] low level ($V_{DDO} = 2.5V$, $I_{OL} = 8\text{ mA}$)	$V_{OL-HPOUT}$	—	—	$0.2 \times V_{DDO}$	V	
HPOUT[3:0] high level ($V_{DDO} = 3.3V$, $I_{OH} = 14\text{ mA}$)	$V_{OH-HPOUT}$	$0.8 \times V_{DDO}$	—	—	V	
HPOUT[3:0] low level ($V_{DDO} = 3.3V$, $I_{OL} = 14\text{ mA}$)	$V_{OL-HPOUT}$	—	—	$0.2 \times V_{DDO}$	V	
HPOUT[11:4] high level ($V_{DDO} = 1.8V$, $I_{OH} = 5\text{ mA}$)	$V_{OH-HPOUT}$	$0.8 \times V_{DDO}$	—	—	V	See Figure 10-1, Figure 10-3
HPOUT[11:4] low level ($V_{DDO} = 1.8V$, $I_{OL} = 5\text{ mA}$)	$V_{OL-HPOUT}$	—	—	$0.2 \times V_{DDO}$	V	
HPOUT[11:4] high level ($V_{DDO} = 2.5V$, $I_{OH} = 12\text{ mA}$)	$V_{OH-HPOUT}$	$0.8 \times V_{DDO}$	—	—	V	
HPOUT[11:4] low level ($V_{DDO} = 2.5V$, $I_{OL} = 12\text{ mA}$)	$V_{OL-HPOUT}$	—	—	$0.2 \times V_{DDO}$	V	
HPOUT[11:4] high level ($V_{DDO} = 3.3V$, $I_{OH} = 21\text{ mA}$)	$V_{OH-HPOUT}$	$0.8 \times V_{DDO}$	—	—	V	
HPOUT[11:4] low level ($V_{DDO} = 3.3V$, $I_{OL} = 21\text{ mA}$)	$V_{OL-HPOUT}$	—	—	$0.2 \times V_{DDO}$	V	
GPOUT high level ($I_{OH} = 1.5\text{ mA}$)	$V_{OH-GPOUT}$	$0.8 \times V_{DDO}$	—	—	V	Drive Setting = 1X, see Figure 10-1, Figure 10-3
GPOUT low level ($I_{OL} = 1.5\text{ mA}$)	$V_{OL-GPOUT}$	—	—	$0.2 \times V_{DDO}$	V	
GPOUT high level ($I_{OH} = 3\text{ mA}$)	$V_{OH-GPOUT}$	$0.8 \times V_{DDO}$	—	—	V	Drive Setting = 2X, see Figure 10-1, Figure 10-3
GPOUT low level ($I_{OL} = 3\text{ mA}$)	$V_{OL-GPOUT}$	—	—	$0.2 \times V_{DDO}$	V	
GPOUT high level ($I_{OH} = 4.5\text{ mA}$)	$V_{OH-GPOUT}$	$0.8 \times V_{DDO}$	—	—	V	Drive Setting = 3X, see Figure 10-1, Figure 10-3
GPOUT low level ($I_{OL} = 4.5\text{ mA}$)	$V_{OL-GPOUT}$	—	—	$0.2 \times V_{DDO}$	V	
GPOUT high level ($I_{OH} = 6\text{ mA}$)	$V_{OH-GPOUT}$	$0.8 \times V_{DDO}$	—	—	V	Drive Setting = 4X, see Figure 10-1, Figure 10-3
GPOUT low level ($I_{OL} = 6\text{ mA}$)	$V_{OL-GPOUT}$	—	—	$0.2 \times V_{DDO}$	V	

Note 1: Values are over both power supply modes (3.3V and 1.8V; 2.5V and 1.8V).

Note 2: V_{DD} may be 2.5V or 3.3V as specified in Recommended Operating Conditions.

Note 3: V_{DDO} may be 1.8V, 2.5V, or 3.3V as specified in Recommended Operating Conditions.

FIGURE 10-4: HPOUT and GPOUT (CMOS) Output Termination and DC Output Level.

Note: All table values in Section 10.3 are over Recommended Operating Conditions.

TABLE 10-19: DC ELECTRICAL CHARACTERISTICS: OTHER OUTPUTS AND IO (BI-DIRECTIONAL)

Output Voltage Characteristics	Symbol	Min.	Typ.	Max.	Units	Notes
CMOS high-level (m_si, m_cs_b, m_sck)	$V_{OH-CMOS}$	$0.8 \times V_{DDO}$	—	—	V	$I_{OH} = 6 \text{ mA}$
CMOS low-level (m_si, m_cs_b, m_sck)	$V_{OL-CMOS}$	—	—	$0.2 \times V_{DDO}$	V	$I_{OL} = 10 \text{ mA}$
CMOS high-level (tdo)	$V_{OH-CMOS}$	$0.8 \times V_{DDO}$	—	—	V	$I_{OH} = 3.5 \text{ mA}$
CMOS low-level (tdo)	$V_{OL-CMOS}$	—	—	$0.2 \times V_{DDO}$	V	$I_{OL} = 5 \text{ mA}$
Bidirectional high level (so_asel1, gpio[5])	$V_{OH-BIDI}$	$0.8 \times V_{DDO}$	—	—	V	$I_{OH} = 6 \text{ mA}$
Bidirectional low level (so_asel1, gpio[5])	$V_{OL-BIDI}$	—	—	$0.2 \times V_{DDO}$	V	$I_{OL} = 6 \text{ mA}$
Bidirectional low level (si_sda, sck_scl)	$V_{OL-BIDI}$	—	—	$0.2 \times V_{DDO}$	V	$I_{OL} = 2 \text{ mA}$
Bidirectional high level (gpio[6,4])	$V_{OH-BIDI}$	$0.8 \times V_{DDO}$	—	—	V	$I_{OH} = 2.5 \text{ mA}$
Bidirectional low level (gpio[6,4])	$V_{OL-BIDI}$	—	—	$0.2 \times V_{DDO}$	V	$I_{OL} = 2.5 \text{ mA}$
Bidirectional high level (gpio[3:0])	$V_{OH-BIDI}$	$0.8 \times V_{DDO}$	—	—	V	$I_{OH} = 6 \text{ mA}$
Bidirectional low level (gpio[3:0])	$V_{OL-BIDI}$	—	—	$0.2 \times V_{DDO}$	V	$I_{OL} = 6 \text{ mA}$

Note 1: Values are tested over both power supply modes (3.3V and 1.8V; 2.5V and 1.8V).

2: V_{DD} may be 2.5V or 3.3V as specified in Recommended Operating Conditions.

10.4 AC Electrical Characteristics

Note: All table values in Section 10.4 are over Recommended Operating Conditions.

TABLE 10-20: AC ELECTRICAL CHARACTERISTICS: OUTPUT TIMING PARAMETERS MEASUREMENT VOLTAGE LEVELS

Characteristics	Symbol	Units	Notes
HPOUT_DIFF (CML) threshold voltage	V_T	V	Threshold (V_T) is 50% of output swing.
HPOUT_DIFF (CML) rise/fall threshold voltage high	V_{HM}	V	
HPOUT_DIFF (CML) rise/fall threshold voltage low	V_{LM}	V	
HPOUT threshold voltage	V_T	V	Threshold high (V_{HM}) is 80% of output swing.
HPOUT rise/fall threshold voltage high	V_{HM}	V	
HPOUT rise/fall threshold voltage low	V_{LM}	V	
GPOUT threshold voltage	V_T	V	Threshold low (V_{LM}) is 20% of output swing.
GPOUT rise/fall threshold voltage high	V_{HM}	V	
GPOUT rise/fall threshold voltage low	V_{LM}	V	

Note 1: For the threshold voltage drawing, see [Figure 10-4](#).

FIGURE 10-5: Timing Parameter Measurement Voltage Levels.

Note: All table values in Section 10.4 are over Recommended Operating Conditions.

TABLE 10-21: AC ELECTRICAL CHARACTERISTICS: INPUT TIMING

Characteristics	Symbol	Min.	Typ.	Max.	Units	Notes
Single-ended CMOS input reference frequency for ref[9:0]	$1/T_{TREFP}$	—	—	180		See Figure 10-5 .
Single-ended CMOS input reference pulse width low or high for ref[9:0]	T_{TREFW}	2.7	—	—		
Single-ended PECL input reference frequency for ref[9:0]	$1/T_{TREFP}$	—	—	900		
Single-ended PECL input reference pulse width low or high for ref[9:0]	T_{TREFW}	0.55	—	—		
Differential input reference frequency for ref[4:0]	$1/T_{TREFP}$	—	—	900		
Differential input reference pulse width low or high for ref[4:0]	T_{TREFW}	0.55	—	—		
Duty cycle for osci		40	—	60		—
Duty cycle for mclki[p,n]		40	—	60		—

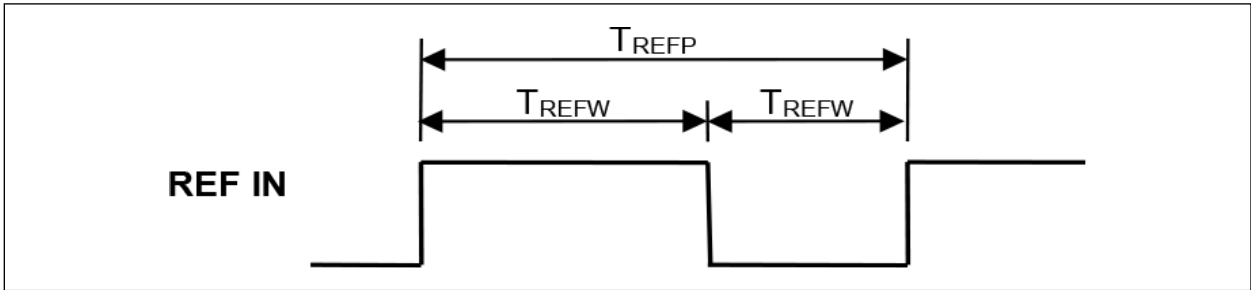

FIGURE 10-6: Reference Input Timing.

Note: All table values in Section 10.4 are over Recommended Operating Conditions.

TABLE 10-22: AC ELECTRICAL CHARACTERISTICS: REF INPUT TO HPOUT_DIFF, HPOUT AND GPOUT OUTPUT CLOCK TIMING

Characteristics	Symbol	Min.	Typ.	Max.	Units	Notes
Input reference (REF DIFF) to HPOUT_DIFF output delay	$T_{D-REF-HPOUT_DIFF}$	-2.0	0	+2.0	ns	See Figure 9-1 and Figure 10-6
Input reference (REF) to HPOUT output delay	$T_{D-REF-HPOUT}$	-2.0	0	+2.0	ns	See Figure 10-1 and Figure 10-6
Input reference (REF) to GPOUT output delay	$T_{D-REF-GPOUT}$	-2.5	0	+2.5	ns	

- Note 1:** Input and output are at the same frequency.
Note 2: HPOUT_DIFF output drive impedance is set to 25Ω and drive level is set to 0.7V.
Note 3: GPOUT output drive level is set to 4X.

FIGURE 10-7: Reference Input to Output Clock Timing.

FIGURE 10-8: Output to Output Clock Timing.

Note: All table values in Section 10.4 are over Recommended Operating Conditions.

TABLE 10-23: AC ELECTRICAL CHARACTERISTICS: HPOUT_DIFF OUTPUT TIMING

Characteristics	Symbol	Min.	Typ.	Max.	Units	Notes
Frequency for HPOUT_DIFF outputs	$F_{OUT-HPOUT_DIFF}$	—	—	900	MHz	—
Duty cycle for HPOUT_DIFF outputs (drive 0.7V)	T_{PWL}, T_{PWH}	45	50	55	%	Tested at 707.352 MHz and 900 MHz
Rise/fall time for HPOUT_DIFF outputs (drive 0.7V)	t_r / t_f	200	285	450	ps	3.3V and 1.8V supply mode with 3.3V V_{DDO}
		200	310	450	ps	2.5V and 1.8V supply mode with 2.5V V_{DDO}
Rise/fall time for HPOUT_DIFF outputs (drive 0.4V)	t_r / t_f	200	320	450	ps	2.5V and 1.8V supply mode with 1.8V V_{DDO}

- Note 1:** Output drive impedance is set to 25Ω.
2: See [Figure 10-4](#), [Figure 10-8](#), and [Figure 10-9](#).

FIGURE 10-9: HPOUT_DIFF Output t_r and t_f Measurement Setup.

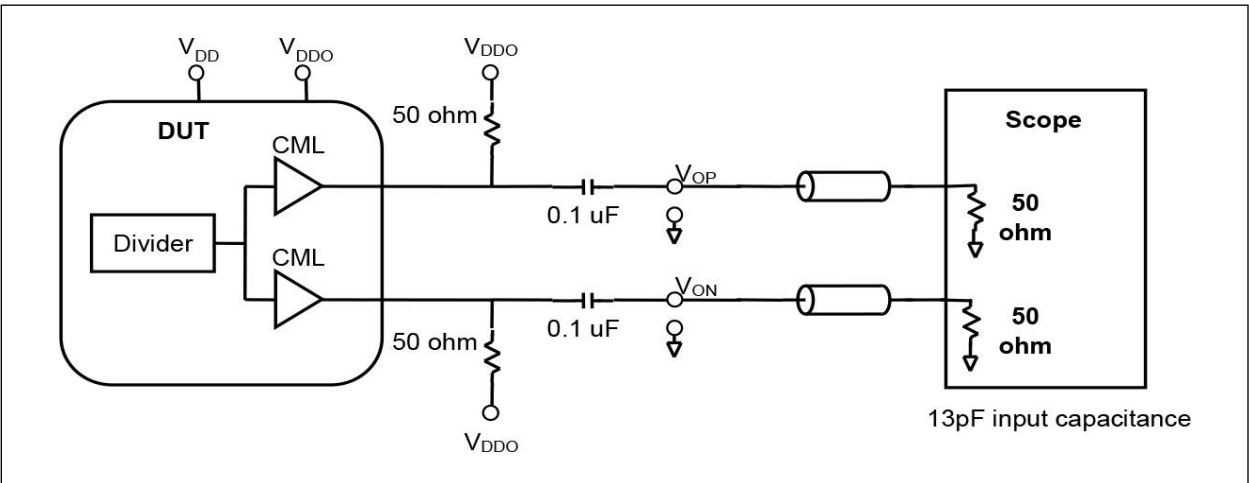

FIGURE 10-10: HPOUT_DIFF Output Duty Cycle Measurement Setup.

Note: All table values in Section 10.4 are over Recommended Operating Conditions.

TABLE 10-24: AC ELECTRICAL CHARACTERISTICS: HPOUT AND GPOUT OUTPUT TIMING

Characteristics	Symbol	Min.	Typ.	Max.	Units	Notes
Frequency for HPOUT outputs	$F_{OUT-HPOUT}$	—	—	180	MHz	—
Frequency for GPOUT outputs	$F_{OUT-GPOUT}$	—	—	180	MHz	—
Duty cycle for HPOUT outputs	T_{PWL}, T_{PWH}	45	50	55	%	Tested at 77.760 MHz, 125 MHz, 156.25 MHz and 180 MHz
Duty cycle for GPOUT outputs	T_{PWL}, T_{PWH}	40	50	60	%	Tested at 125 MHz and 180 MHz
Rise times for HPOUT outputs	t_r	450	700	950	ps	3.3V and 1.8V supply mode with 3.3V V_{DDO}
		750	1000	2100	ps	2.5V and 1.8V supply mode with 1.8V V_{DDO}
Fall times for HPOUT outputs	t_f	450	700	950	ps	3.3V and 1.8V supply mode with 3.3V V_{DDO}
		750	1000	2100	ps	2.5V and 1.8V supply mode with 1.8V V_{DDO}
Rise times for GPOUT outputs (drive 4X)	t_r	800	1500	2500	ps	3.3V and 1.8V supply mode
		1200	1900	3200	ps	2.5V and 1.8V supply mode
Fall times for GPOUT outputs (drive 4X)	t_f	500	700	1700	ps	3.3V and 1.8V supply mode
		600	900	2200	ps	2.5V and 1.8V supply mode

Note 1: See Figure 10-4 and Figure 10-10.

FIGURE 10-11: HPOUT and GPOUT Output t_r , t_f , and Duty Cycle Measurement Setup.

Note: All table values in Section 10.4 are over Recommended Operating Conditions.

TABLE 10-25: AC ELECTRICAL CHARACTERISTICS: SPI (SERIAL PERIPHERAL INTERFACE) TIMING

Characteristics	Symbol	Min.	Typ.	Max.	Units	Notes
sck period	tcyc	80	—	—	ns	See Figure 10-11 and Figure 10-12
sck pulse width low	tclkl	40	—	—	ns	
sck pulse width high	tclkh	40	—	—	ns	
si setup (write) from sck rising edge	trxs	8	—	—	ns	
si hold (write) from sck falling edge	trxh	8	—	—	ns	
so delay (read) from sck falling edge	txd	—	—	25	ns	
cs_b to output high impedance	tohz	—	—	60	ns	See Figure 10-11
cs_b setup from sck falling edge (LSB first)	tcssi	16	—	—	ns	
cs_b hold from sck rising edge (LSB first)	tcshi	8	—	—	ns	See Figure 10-12
cs_b setup from sck rising edge (MSB first)	tcssm	16	—	—	ns	
cs_b hold from sck falling edge (MSB first)	tcshm	8	—	—	ns	

Note 1: For LSB first mode timing diagram, refer to Figure 10-11.

2: For LSB first mode timing diagram, refer to Figure 10-12.

FIGURE 10-13: SPI (Serial Peripheral Interface) Timing, MSB First Mode.

Note: All table values in Section 10.4 are over Recommended Operating Conditions.

TABLE 10-26: AC ELECTRICAL CHARACTERISTICS: I²C SERIAL MICROPORT TIMING

Characteristics	Symbol	Min.	Typ.	Max.	Units	Notes
SCL clock frequency	f_{SCL}	0	—	400	kHz	—
Hold time START condition	$t_{HD:STA}$	0.6	—	—	us	—
Low period SCL	t_{LOW}	1.3	—	—	us	—
Better/high period SCL	t_{HIGH}	0.6	—	—	us	—
Setup time START condition	$t_{SU:STA}$	0.6	—	—	us	—
Data hold time	$t_{HD:DAT}$	0	—	0.9	us	—
Data setup time	$t_{SU:DAT}$	100	—	—	ns	—
Rise time	t_r	$20 + 0.1$	—	250	ns	—
Fall time	t_f	—	—	250	ns	—
Setup time STOP condition	$t_{SU:STO}$	0.6	—	—	ns	—
Bus free time between STOP/START	t_{BUF}	1.3	—	—	ns	—
Pulse width of spikes	t_{SP}	0	—	50	ns	Must be suppressed by the input filter
Max capacitance for each I/O pin	—	—	—	10	pF	—

Note 1: For I²C timing diagram, refer to Figure 10-13.

FIGURE 10-14: I²C Serial Microport Timing.

11.0 PERFORMANCE CHARACTERISTICS

11.1 Output Clocks Jitter Generation

Note: All table values in Section 11 (including all its subsections) are over Recommended Operating Conditions.

TABLE 11-1: OUTPUT CLOCKS JITTER GENERATION: HPOUT_DIFF[0:1] (CML) WITH 114.285 MHz XO

Outputs	Output Frequency	Jitter Measurement Filter	Typ.	Max.	Units
HPOUT_DIFF[0]	622.08 MHz	50 kHz–80 MHz	175	250	fs-rms
		12 kHz–20 MHz	185	260	fs-rms
	625 MHz	50 kHz–80 MHz	175	250	fs-rms
		12 kHz–20 MHz	180	260	fs-rms
	156.25 MHz	10 kHz–1 MHz	160	220	fs-rms
		50 kHz–8 MHz	185	270	fs-rms
		12 kHz–20 MHz	240	325	fs-rms
HPOUT_DIFF[1]	622.08 MHz	50 kHz–80 MHz	195	270	fs-rms
		12 kHz–20 MHz	190	270	fs-rms
	625 MHz	50 kHz–80 MHz	190	270	fs-rms
		12 kHz–20 MHz	190	280	fs-rms
	156.25 MHz	10 kHz–1 MHz	160	220	fs-rms
		50 kHz–8 MHz	190	275	fs-rms
		12 kHz–20 MHz	250	340	fs-rms

- Note 1:** Values are over both power supply modes (3.3V and 1.8V; 2.5V and 1.8V).
- 2:** Values are with $V_{DDO} = 3.3V$ for 3.3V/1.8V mode and with $V_{DDO} = 2.5V$ for 2.5V/1.8V mode.
- 3:** Output drive impedance is set to 25Ω.
- 4:** Output drive levels are set to 0.4V.
- 5:** The DPLL is in locked mode with 14 Hz bandwidth and reference input at 19.44 MHz.
- 6:** Oscillators: VCC1-9004-114M285000 or VC-820-9004-114M285000.
- 7:** The jitter test circuit is shown in [Figure 10-14](#).

Note: All table values in Section 11 (including all its subsections) are over Recommended Operating Conditions.

TABLE 11-2: OUTPUT CLOCKS JITTER GENERATION: HPOUT_DIFF[2:3] (CML) WITH 114.285 MHz XO

Outputs	Output Frequency	Jitter Measurement Filter	Typ.	Max.	Units
HPOUT_DIFF[2]	622.08 MHz	50 kHz–80 MHz	170	230	fs-rms
		12 kHz–20 MHz	185	250	fs-rms
	625 MHz	50 kHz–80 MHz	170	230	fs-rms
		12 kHz–20 MHz	185	250	fs-rms
	156.25 MHz	10 kHz–1 MHz	165	215	fs-rms
		50 kHz–8 MHz	175	235	fs-rms
		12 kHz–20 MHz	215	275	fs-rms
HPOUT_DIFF[3]	622.08 MHz	50 kHz–80 MHz	170	230	fs-rms
		12 kHz–20 MHz	185	250	fs-rms
	625 MHz	50 kHz–80 MHz	170	230	fs-rms
		12 kHz–20 MHz	185	250	fs-rms
	156.25 MHz	10 kHz–1 MHz	165	215	fs-rms
		50 kHz–8 MHz	180	240	fs-rms
		12 kHz–20 MHz	225	285	fs-rms

- Note 1:** Values are over both power supply modes (3.3V and 1.8V; 2.5V and 1.8V).
Note 2: Values are with $V_{DDO} = 3.3V$ for 3.3V/1.8V mode and with $V_{DDO} = 2.5V$ for 2.5V/1.8V mode.
Note 3: Output drive impedance is set to 25Ω.
Note 4: Output drive levels are set to 0.4V.
Note 5: The DPLL is in locked mode with 14 Hz bandwidth and reference input at 19.44 MHz.
Note 6: Oscillators: VCC1-9004-114M285000 or VC-820-9004-114M285000.
Note 7: The jitter test circuit is shown in [Figure 10-14](#).

Note: All table values in Section 11 (including all its subsections) are over Recommended Operating Conditions.

TABLE 11-3: OUTPUT CLOCKS JITTER GENERATION: HPOUT_DIFF[4:5] (CML) WITH 114.285 MHZ XO

Outputs	Output Frequency	Jitter Measurement Filter	Typ.	Max.	Units
HPOUT_DIFF[4]	622.08 MHz	50 kHz–80 MHz	200	310	fs-rms
		12 kHz–20 MHz	200	280	fs-rms
	625 MHz	50 kHz–80 MHz	195	290	fs-rms
		12 kHz–20 MHz	200	280	fs-rms
	156.25 MHz	10 kHz–1 MHz	165	215	fs-rms
		50 kHz–8 MHz	190	270	fs-rms
		12 kHz–20 MHz	250	340	fs-rms
HPOUT_DIFF[5]	622.08 MHz	50 kHz–80 MHz	195	280	fs-rms
		12 kHz–20 MHz	190	260	fs-rms
	625 MHz	50 kHz–80 MHz	190	280	fs-rms
		12 kHz–20 MHz	195	270	fs-rms
	156.25 MHz	10 kHz–1 MHz	165	210	fs-rms
		50 kHz–8 MHz	185	250	fs-rms
		12 kHz–20 MHz	245	320	fs-rms

- Note** 1: Values are over both power supply modes (3.3V and 1.8V; 2.5V and 1.8V).
2: Values are with $V_{DDO} = 3.3V$ for 3.3V/1.8V mode and with $V_{DDO} = 2.5V$ for 2.5V/1.8V mode.
3: Output drive impedance is set to 25Ω.
4: Output drive levels are set to 0.4V.
5: The DPLL is in locked mode with 14 Hz bandwidth and reference input at 19.44 MHz.
6: Oscillators: VCC1-9004-114M285000 or VC-820-9004-114M285000.
7: The jitter test circuit is shown in [Figure 10-14](#).

TABLE 11-4: OUTPUT CLOCKS JITTER GENERATION: HPOUT_DIFF[0:1] (CML) WITH 49.152 MHZ XO

Outputs	Output Frequency	Jitter Measurement Filter	Typ.	Max.	Units

		12 kHz–20 MHz	305	385	fs-rms

- Note** 1: Values are over both power supply modes (3.3V and 1.8V; 2.5V and 1.8V).
2: Values are with $V_{DDO} = 3.3V$ for 3.3V/1.8V mode and with $V_{DDO} = 2.5V$ for 2.5V/1.8V mode.
3: Output drive impedance is set to 25Ω.
4: Output drive levels are set to 0.4V.
5: The DPLL is in locked mode with 14 Hz bandwidth and reference input at 19.44 MHz.
6: Oscillator: VC-820-9013-24M5760000.
7: The jitter test circuit is shown in [Figure 10-14](#).

Note: All table values in Section 11 (including all its subsections) are over Recommended Operating Conditions.

TABLE 11-8: OUTPUT CLOCKS JITTER GENERATION: HPOUT_DIFF[2:3] (CML) WITH 24.576MHZ XO

Outputs	Output Frequency	Jitter Measurement Filter	Typ.	Max.	Units
HPOUT_DIFF[2]	622.08 MHz	50 kHz–80 MHz	220	270	fs-rms
		12 kHz–20 MHz	240	310	fs-rms
	625 MHz	50 kHz–80 MHz	220	270	fs-rms
		12 kHz–20 MHz	240	300	fs-rms
	156.25 MHz	10 kHz–1 MHz	220	280	fs-rms
		50 kHz–8 MHz	220	265	fs-rms
		12 kHz–20 MHz	260	320	fs-rms
HPOUT_DIFF[3]	622.08 MHz	50 kHz–80 MHz	225	270	fs-rms
		12 kHz–20 MHz	245	310	fs-rms
	625 MHz	50 kHz–80 MHz	225	270	fs-rms
		12 kHz–20 MHz	245	310	fs-rms
	156.25 MHz	10 kHz–1 MHz	225	280	fs-rms
		50 kHz–8 MHz	225	270	fs-rms
		12 kHz–20 MHz	270	325	fs-rms

- Note 1:** Values are over both power supply modes (3.3V and 1.8V; 2.5V and 1.8V).
Note 2: Values are with $V_{DDO} = 3.3V$ for 3.3V/1.8V mode and with $V_{DDO} = 2.5V$ for 2.5V/1.8V mode.
Note 3: Output drive impedance is set to 25Ω.
Note 4: Output drive levels are set to 0.4V.
Note 5: The DPLL is in locked mode with 14 Hz bandwidth and reference input at 19.44 MHz.
Note 6: Oscillator: VC-820-9013-24M5760000.
Note 7: The jitter test circuit is shown in [Figure 10-14](#).

Note: All table values in Section 11 (including all its subsections) are over Recommended Operating Conditions.

TABLE 11-9: OUTPUT CLOCKS JITTER GENERATION: HPOUT_DIFF[4:5] (CML) WITH 24.576 MHz XO

Outputs	Output Frequency	Jitter Measurement Filter	Typ.	Max.	Units
HPOUT_DIFF[4]	622.08 MHz	50 kHz–80 MHz	230	280	fs-rms
		12 kHz–20 MHz	250	310	fs-rms
	625 MHz	50 kHz–80 MHz	230	280	fs-rms
		12 kHz–20 MHz	250	310	fs-rms
	156.25 MHz	10 kHz–1 MHz	225	290	fs-rms
		50 kHz–8 MHz	235	285	fs-rms
		12 kHz–20 MHz	290	360	fs-rms
HPOUT_DIFF[5]	622.08 MHz	50 kHz–80 MHz	230	280	fs-rms
		12 kHz–20 MHz	250	310	fs-rms
	625 MHz	50 kHz–80 MHz	225	280	fs-rms
		12 kHz–20 MHz	245	310	fs-rms
	156.25 MHz	10 kHz–1 MHz	220	280	fs-rms
		50 kHz–8 MHz	230	280	fs-rms
12 kHz–20 MHz		285	350	fs-rms	

- Note 1:** Values are over both power supply modes (3.3V and 1.8V; 2.5V and 1.8V).
2: Values are with $V_{DDO} = 3.3V$ for 3.3V/1.8V mode and with $V_{DDO} = 2.5V$ for 2.5V/1.8V mode.
3: Output drive impedance is set to 25Ω.
4: Output drive levels are set to 0.4V.
5: The DPLL is in locked mode with 14 Hz bandwidth and reference input at 19.44 MHz.
6: Oscillator: VC-820-9013-24M5760000.
7: The jitter test circuit is shown in [Figure 10-14](#).

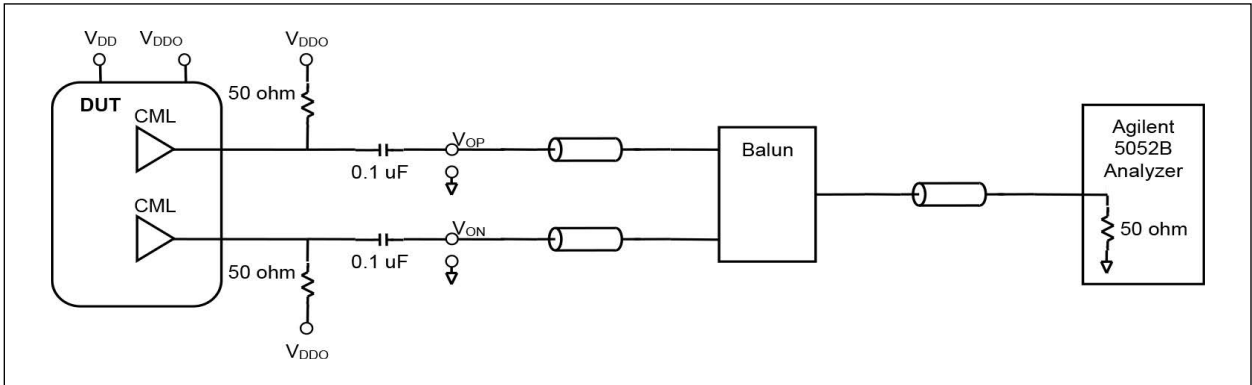

FIGURE 11-1: HPOUT_DIFF (CML) Output Jitter Test Circuit.

Note: All table values in Section 11 (including all its subsections) are over Recommended Operating Conditions.

TABLE 11-10: Output Clocks Jitter Generation: HPOUT (LVCMOS) Output Clock Timing

Output and Output Frequency	Jitter Measurement Filter	Typ.	Max.	Units	Notes
HPOUT[11:0] 125 MHz	12 kHz–20 MHz	0.29	0.55	ps-rms	osci = 49.152 MHz osci = 24.576 MHz osci = 114.285 MHz
HPOUT[11:0] 25 MHz	12 kHz–5 MHz	0.26	0.52	ps-rms	

- Note 1:** Maximum value shows worst case for all outputs.
2: Individual outputs can have significantly better maximum value.
3: Values are over both power supply modes (3.3V and 1.8V; 2.5V and 1.8V).
4: Values are with $V_{DDO} = 3.3V$ for 3.3V/1.8V mode and with $V_{DDO} = 2.5V$ for 2.5V/1.8V mode.
5: The DPLL is in locked mode with 14 Hz bandwidth and reference input at 19.44 MHz.
6: Oscillator type and part numbers is as follows: 24.576 MHz = VC-820-9013-24M5760000, 49.152 MHz = VC-820-9002-49M1520000, and 114.285 MHz = Vectron VCC1-9004-114M285000 or VC-820-9004-114M285000.
7: The jitter test circuit is shown in [Figure 11-1](#).

TABLE 11-11: Output Clocks Jitter Generation: GPOUT (LVCMOS) Output Clock Timing

Output Frequency	Jitter Measurement Filter	Typ.	Max.	Units	Notes
125 MHz	12 kHz–20 MHz	17	24	ps-rms	osci = 49.152 MHz
25 MHz	12 kHz–5 MHz	12	20	ps-rms	

- Note 1:** Maximum value shows worst case for all outputs.
2: Individual outputs can have significantly better maximum value.
3: Values are over both power supply modes (3.3V and 1.8V; 2.5V and 1.8V).
4: Values are with $V_{DDO} = 3.3V$ for 3.3V/1.8V mode and with $V_{DDO} = 2.5V$ for 2.5V/1.8V mode.
5: The DPLL is in locked mode with 14 Hz bandwidth and reference input at 19.44 MHz.
6: Oscillator: 49.152 MHz = VC-820-9002-49M1520000.
7: The jitter test circuit is shown in [Figure 11-1](#).

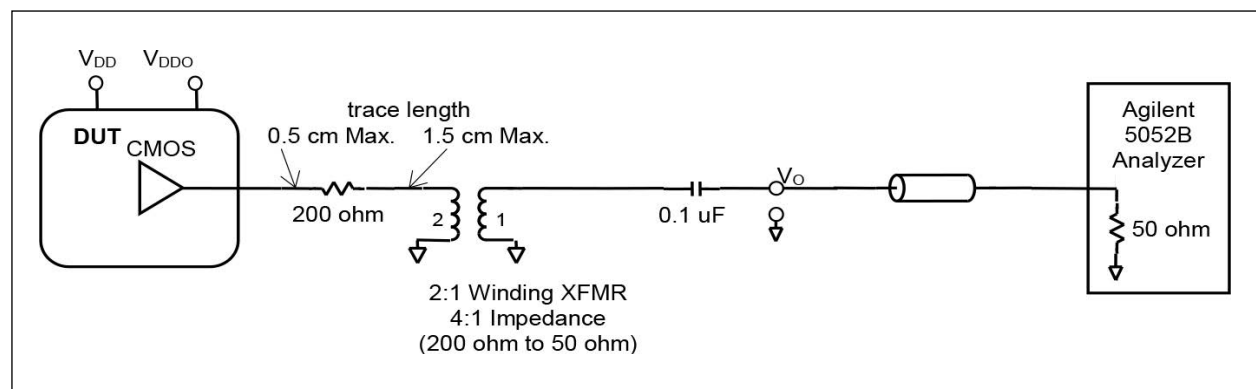

FIGURE 11-2: HPOUT (LVCMOS) and GPOUT (LVCMOS) Output Jitter Test Circuit.

11.2 DPLL Performance Characteristics

Note: All table values in Section 11 (including all its subsections) are over Recommended Operating Conditions.

TABLE 11-12: DPLL PERFORMANCE CHARACTERISTICS

Characteristics	Min.	Typ.	Max.	Units	Notes
Pull-in/hold-in range	0.1	12	2100	ppm	User programmable
Lock time (bandwidth > 14 Hz)	—	1.6	2	sec	Unlimited phase slope limit 10 us / 1s lock selection ±200 ppm pull-in/hold range
Reference switching MTIE	—	0.6	—	ns	Bandwidth = 14 Hz Jitter-free input (1 ps-rms)
Entry into holdover MTIE	—	0.6	—	ns	
Exit from holdover MTIE	—	0.6	—	ns	
Initial holdover accuracy (bandwidth = 14 Hz)	—	2	10	ppb	Input frequency = 19.44 MHz Jitter-free input (1 ps-rms)
Damping factor	1	5	50	—	User programmable
Phase gain in the pass band	—	0.08	0.1	dB	Damping factor set to 5

Note 1: Jitter free input implies less than 1ps rms jitter.

11.3 Package Thermal Information

Note: All table values in Section 11 (including all its subsections) are over Recommended Operating Conditions.

TABLE 11-13: PACKAGE THERMAL CHARACTERISTICS

Parameter	Symbol	Value	Units	Conditions
Maximum ambient temperature	T_A	85	°C	—
Maximum junction temperature	T_{JMAX}	125	°C	—
Junction-to-ambient thermal resistance (Note 1)	θ_{JA}	11.6	°C/W	Still air
		9.20	°C/W	1 m/s airflow
		8.50	°C/W	2 m/s airflow
Junction-to-board thermal resistance	θ_{JB}	2.56	°C/W	—
Junction-to-case thermal resistance	θ_{JC}	3.84	°C/W	—
Junction-to-top-center thermal characterization parameter	Ψ_{JT}	0.21	°C/W	Still air

Note 1: Theta-JA (θ_{JA}) is the thermal resistance from junction to ambient when the package is mounted on an 8-layer JEDEC standard test board and dissipating maximum power.

12.0 PACKAGE OUTLINE

12.1 Package Marking Information

Legend:	XX...X	Product code or customer-specific information
	Y	Year code (last digit of calendar year)
	YY	Year code (last 2 digits of calendar year)
	WW	Week code (week of January 1 is week '01')
	NNN	Alphanumeric traceability code
	(e3)	Pb-free JEDEC® designator for Matte Tin (Sn)
	*	This package is Pb-free. The Pb-free JEDEC designator ((e3) can be found on the outer packaging for this package.
	•, ▲, ▼	Pin one index is identified by a dot, delta up, or delta down (triangle mark).
Note:	In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line, thus limiting the number of available characters for customer-specific information. Package may or may not include the corporate logo.	
	Underbar (¯) and/or Overbar (¯) symbol may not be to scale.	

100-Lead 10 mm × 10 mm VQFN [LPC] Package Outline and Recommended Land Pattern

Note: For the most current package drawings, please see the Microchip Packaging Specification located at <http://www.microchip.com/packaging>

Microchip Technology Drawing C04-25388 Rev A Sheet 1 of 2

100-Lead 10 mm × 10 mm VQFN [LPC] Package Outline and Recommended Land Pattern

Note: For the most current package drawings, please see the Microchip Packaging Specification located at <http://www.microchip.com/packaging>

Dimension Limits	Units	MILLIMETERS		
		MIN	NOM	MAX
Number of Terminals	N	100		
Pitch	e	0.666 BSC		
Pitch	e1	4.442 BSC		
Overall Height	A	—	—	0.85
Standoff	A1	0.02	0.05	0.08
Substrate Thickness	A3	0.13 REF		
Overall Length	D	10.00 BSC		
Exposed Pad Length	D2	8.134	8.234	8.334
Overall Width	E	10.00 BSC		
Exposed Pad Width	E2	8.134	8.234	8.334
Terminal Width	b	0.20	0.25	0.30

Notes:

- Pin 1 visual index feature may vary, but must be located within the hatched area.
- Package is saw singulated
- Dimensioning and tolerancing per ASME Y14.5M
 BSC: Basic Dimension. Theoretically exact value shown without tolerances.
 REF: Reference Dimension, usually without tolerance, for information purposes only.

100-Lead 10 mm × 10 mm VQFN [LPC] Package Outline and Recommended Land Pattern

Note: For the most current package drawings, please see the Microchip Packaging Specification located at <http://www.microchip.com/packaging>

RECOMMENDED LAND PATTERN

Dimension Limits	Units	MILLIMETERS		
		MIN	NOM	MAX
Contact Pitch	E	0.666 BSC		
Optional Center Pad Width	X2			8.21
Optional Center Pad Length	Y2			8.21
Contact Pad Spacing	C1		9.55	
Contact Pad Spacing	C2		9.55	
Contact Pad Spacing	C3		8.884	
Contact Pad Spacing	C4		8.884	
Contact Pad Diameter	X			0.27
Contact Pad to Center Pad	G1	0.20		
Contact Pad to Contact Pad	G2	0.20		
Thermal Via Diameter	V		0.33	
Thermal Via Pitch	EV		1.20	

Notes:

- Dimensioning and tolerancing per ASME Y14.5M
BSC: Basic Dimension. Theoretically exact value shown without tolerances.
- For best soldering results, thermal vias, if used, should be filled or tented to avoid solder loss during reflow process

Microchip Technology Drawing C04-27388 Rev A

13.0 ACRONYMS AND ABBREVIATIONS

APLL	analog phase locked loop
CML	current mode logic
GbE	gigabit Ethernet
HCSL	high-speed current steering logic
I/O	input/output
LOS	loss of signal
LVDS	low-voltage differential signal
LVPECL	low-voltage positive emitter-coupled logic
MSCC	formerly Microsemi, now part of Microchip
PFD	phase/frequency detector
pk-pk	peak-to-peak
PLL	phase locked loop
ppb	parts per billion
ppm	parts per million
PRC	primary reference clock
PRS	primary reference source
RMS	root-mean-square
RO	read-only
R/W	read/write
SS or SSM	spread spectrum modulation
TCXO	temperature-compensated crystal oscillator
UI	unit interval
UI _{pp} or UI _{p-p}	unit interval, peak-to-peak
XO	crystal oscillator

APPENDIX A: DATA SHEET REVISION HISTORY

Revision	Section/Figure/Entry	Correction
DS20006854A (01-05-24)	—	Initial release of ZL30174 data sheet in Microchip format. $V_{OH-HPOUT}$ and $V_{OL-HPOUT}$ for HPOUT[3:0] is now specified at 3 mA, 8 mA, and 14 mA for a VDDO of 1.8V, 2.5V, and 3.3V, respectively. These were previously specified at 5 mA, 12 mA, and 21 mA. $V_{OH-HPOUT}$ and $V_{OL-HPOUT}$ for HPOUT[11:4] are unchanged.

PRODUCT IDENTIFICATION SYSTEM

To order or obtain information, e.g., on pricing or delivery, refer to the factory or the listed sales office.

<u>Device</u>	<u>X</u>	<u>X</u>	<u>X</u>	<u>X</u>	<u>X</u>
Part Number	Chip Carrier Type	Package	Media Type	Finish	Size
Device: ZL30174: Quad Channel Clock Translator Chip Carrier Type: L = Leadless Chip Carrier Package: D = VQFN Media Type: G = 260/Tray Finish: 1 = Pb-Free, Matte Tin (Sn) Finish Size: <blank> = 64-Lead 9 mm x 9 mm					
Examples: a) ZL30174LDG6: Quad Channel Clock Translator, Leadless Chip Carrier, VQFN, 260/Tray, Pb-Free Matte Tin (Sn) Finish, 100-Lead 10 mm x 10 mm Note 1: Tape and Reel identifier only appears in the catalog part number description. This identifier is used for ordering purposes and is not printed on the device package. Check with your Microchip Sales Office for package availability with the Tape and Reel option.					

NOTES:

Note the following details of the code protection feature on Microchip products:

- Microchip products meet the specifications contained in their particular Microchip Data Sheet.
 - Microchip believes that its family of products is secure when used in the intended manner, within operating specifications, and under normal conditions.
 - Microchip values and aggressively protects its intellectual property rights. Attempts to breach the code protection features of Microchip product is strictly prohibited and may violate the Digital Millennium Copyright Act.
 - Neither Microchip nor any other semiconductor manufacturer can guarantee the security of its code. Code protection does not mean that we are guaranteeing the product is "unbreakable" Code protection is constantly evolving. Microchip is committed to continuously improving the code protection features of our products.
-

This publication and the information herein may be used only with Microchip products, including to design, test, and integrate Microchip products with your application. Use of this information in any other manner violates these terms. Information regarding device applications is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. Contact your local Microchip sales office for additional support or, obtain additional support at <https://www.microchip.com/en-us/support/design-help/client-support-services>.
