

General Description

The MIC2010 is a dual channel USB power switch designed to support the power distribution requirements for USB Wakeup from the ACPI S3 state. The MIC2010 will directly switch its two outputs between a 5V main supply and a 5V auxiliary supply normally provided in ATX style power supplies.

The MIC2010 will adjust its current-limit threshold according to the ACPI state it is in. In the normal active ACPI S0 state the current-limit is set at 500mA minimum per channel satisfying the USB continuous output current specification. In the S3 state the current-limit can be reduced to a value determined by an external resistor to minimize the current that is supplied by the auxiliary supply, thereby ensuring that voltage regulation is maintained even during fault conditions.

The MIC2010 provides make-before-break switching to ensure glitch-free transitions between the S3 and S0 states. Each channel is also thermally isolated from the other so that a fault in one channel does not effect the other. FAULT status output signals are also provided indicating overcurrent and thermal shutdown conditions.

The MIC2070 option latches the output off upon detecting an overcurrent condition lasting for more than 5ms minimum. The output can be reset by either toggling the EN inputs of the MIC2070-1/-2 or by removing the load. Latching the output off provides a circuit breaker mode of operation which reduces power consumption during fault conditions.

Features

- Compliant to USB power distribution specifications
- Two completely independent switches
- Integrated switching matrix supports ACPI S0/S3 state transitions without external FET circuits
- Make-before-break switching ensures glitch-free transitions
- No back-feed of auxiliary supply onto main supply during standby mode
- Bi-level current-limit preserves auxiliary supply voltage regulation in standby mode
- Thermally isolated channels
- Thermal shutdown protection
- Fault status outputs with filter prevents false assertions during hot-plug events
- Circuit breaker options with auto-reset (MIC2070)
- Undervoltage lockout
- UL File #179633

Applications

- Desktop PCs
- Notebook PCs
- Notebook docking stations
- LAN Servers
- PC motherboard

Typical Application

Pin Configuration

Pin Description

Pin Number	Pin Name	Pin Function
1	FAULT1	Fault Status (Output): Channel 1, active-low; weak pull-up to AUX. FAULT1 is asserted LOW when channel 1 is in a thermal shutdown state or overcurrent condition for more than 5ms. MIC2070 latches this output in its asserted state upon overcurrent condition. Toggling EN1 or removing the load will reset the circuit breaker latch, and deassert FAULT1.
2	EN1	Enable (Input): Channel 1, active-high (–1) or active-low (–2). Toggling this input also resets the latched output of the MIC2070.
3	S3#	Control (Input): When this input is high, the MAIN inputs are connected to OUT1 and OUT2 via 100mΩ, 500mA MOSFET switches. When this input is LOW, the AUX inputs are connected to OUT1 and OUT2 via 500mΩ MOSFET switches with a current-limit threshold specified by external resistors, RSET1 and RSET2.
4	RSET1	Current-Limit Set Resistor (Input): Channel 1. A resistor connected to this input sets the current-limit threshold in AUX mode (S3# asserted). The current-limit threshold is determined by approximately $18/RSET1$.
5	AUX	Auxiliary 5V Supply (Input): Also used as power supply for internal circuitry.
6	NC	No Connection: This pin may be connected to other pins without restriction.
7	RSET2	Current-Limit Set Resistor (Input): Channel 2. A resistor connected to this input sets the current-limit threshold in AUX mode (S3# asserted). The current-limit threshold is determined by approximately $18/RSET2$.
8	GND	Ground
9, 10	OUT2	Channel 2 (Output): Both pins must be connected together externally.
11, 12	MAIN	5V Main Supply (Input): All MAIN inputs must be connected together externally.
13, 14	OUT1	Channel 1 (Output): Both pins must be connected together externally.
15	EN2	Enable (Input): Channel 2, active-high (–1) or active-low (–2). Toggling this input also resets the latched output for the MIC2070.
16	FAULT2	Fault Status (Output): Channel 2, active-low; weak pull-up to AUX. FAULT2 is asserted LOW when channel 2 is in a thermal shutdown state or overcurrent condition for more than 5ms. MIC2070 latches this output in its asserted state upon overcurrent condition. Toggling EN2 or removing load will reset the circuit breaker latch, and deassert FAULT2.

Notes:

1. Exceeding the absolute maximum rating may damage the device.
2. The device is not guaranteed to function outside its operating rating.
3. Devices are ESD sensitive. Handling precautions recommended. Human body model, 1.5k in series with 100pF.
4. All voltages are referenced to ground.
5. For MIC2070-1(P) OFF occurs when $V_{EN} < 0.8V$ and ON occurs when $V_{EN} > 2.4V$. For MIC2070-2(P) OFF occurs when $V_{EN} > 2.4V$ and ON occurs when $V_{EN} < 0.8V$.
6. Current-limit threshold is defined by the current-limit factor divided by R_{SET} .
7. Guaranteed by design. Not production tested.
8. Assumes only one channel in current-limit. Delay circuitry is shared among channels so it is possible for t_{DLY} to be 40ms max if one channel enters current-limit as the other is about to time-out.
9. Cross conduction time is the duration in which both MAIN and AUX internal switches are on subsequent to S3# transitioning.

Functional Diagram

Functional Description

The MIC2010/2070 are designed to support the power distribution requirements for USB wakeup from the ACPI S3 state. It integrates two independent channels under control of input S3#. When S3# is asserted LOW (ACPI S3 state) the MIC2010/2070 will switch a 500mΩ MOSFET switch from the AUX input to each of its two outputs. In addition the current-limit threshold will be set to a value specified by a resistor connected to the RSET inputs. Conversely when the S3# input is HIGH the MIC2010/2070 will switch a 100mΩ MOSFET switch from the MAIN inputs to each of its two outputs. The current-limit threshold is preset to 500mA in this state. The lower current limit during the ACPI S3 state helps to ensure that the standby supply maintains regulation even during fault conditions.

Thermal Shutdown

Thermal shutdown is employed to protect the device from damage should the die temperature exceed safe margins due mainly to short circuit faults. Thermal shutdown shuts off the output MOSFET and asserts the FAULT output if the die temperature reaches 140°C and the overheated channel is in current limit. The other channel is not affected. If however, the die temperature exceeds 160°C, both channels will be shut off even if neither channel is in current limit.

Power Dissipation

The device's junction temperature depends on several factors such as the load, PCB layout, ambient temperature and package type. The power dissipated in each channel is

$P_D = R_{DS(on)} \times I_{OUT}^2$ where $R_{DS(on)}$ is the on-resistance of the internal MOSFETs and I_{OUT} is the continuous output current.

Total power dissipation of the device will be the summation of P_D for both channels. To relate this to junction temperature, the following equation can be used:

$$T_J = P_D \times \theta_{JA} + T_A$$

where:

T_J = junction temperature

T_A = ambient temperature

θ_{JA} = is the thermal resistance of the package

Current Sensing and Limiting

The current-limit threshold of each channel is preset internally at 500mA when S3# is deasserted. When S3# is asserted the current-limit threshold is specified by a resistor connected to the RSET input. The value of the current-limit threshold is determined by the equation $18/R_{SET}$ ohms where R_{SET} is the resistance connected between the RSET pin and ground. The current-limit threshold should be set at 1.2X of the applications continuous output current requirement.

When an overcurrent condition lasts longer than t_{DLY} the MIC2070 will activate an internal circuit breaker that will latch the output off and assert FAULT. The output will remain off until either the load is removed or EN is toggled. When the MIC2070 enters a latched output condition a 1mA pull-up current source is activated. This provides a way to automatically reset the output once the load is removed without the need to toggle the enable input. Please refer to Figure 7 for timing details.

The MIC2010 will automatically reset its output when the die temperature cools down to 120°C. The MIC2010 output and FAULT signal will continue to cycle on and off until the device is disabled or the fault is removed. Figure 6 depicts typical timing. Depending on PCB layout, package, ambient temperature, etc., it may take several hundred milliseconds from the incidence of the fault to the output MOSFET being shut

off. This time duration will be shortest in the case of a dead short on the output.

Fault Status Output

The FAULT signal is an active-low output with a weak pull-up. FAULT is asserted when either an overcurrent or thermal shutdown condition occurs. In the case of an overcurrent condition, FAULT will be asserted only after the flag response delay time, t_{DLY} , has elapsed. This ensures that FAULT is asserted only upon valid overcurrent conditions and that erroneous error reporting is eliminated. The FAULT response delay time t_{DLY} is typically 10ms. Since the delay timer is shared between both channels it is possible for t_{DLY} to be

extended by an amount equal to the difference between the occurrence of the over-current event in both channels.

Undervoltage Lockout

Undervoltage lockout (UVLO) prevents the output MOSFET from turning on until the AUX input exceeds approximately 3.5V. UVLO ensures that the output MOSFETs remain off to prevent high transient inrush current due to stray or bulk load capacitance. This helps to ensure that the power supply voltage regulation is preserved and also prevents possible damage to sensitive components.
