DESCRIPTION

MP62550/MP62551 Power Distribution Switch is designed for precision current limiting and provides up to 1.5A continuous output current. It offers programmable current limit between 60mA and 1.7A (typ) with ±10% accuracy by an external resistor. The switch includes an 88mΩ N-channel Power MOSFET and operates from 2.5V to 5.5V input voltage.

The device has built-in protection for both over current and increased thermal stress. For over current, the device will limit the current by changing to a constant current mode. It will shutdown when its internal temperature reaches unsafe levels and recover once the device temperature reduces approx 10°C.

It provides built-in soft-start which controls the rise and fall times of the output voltage to limit the initial inrush current and voltage surges.

The reverse-voltage protection feature turns off the MOSFET to protect the device.

The FLAG output will report a fail mode (low level) when over current or over temperature is encountered. The FLAG will not change state when the input UVLO is triggered.

The MP62550/MP62551 is available in space saving 6-pin TQFN 2x2mm package and TSOT23-6 package.

FEATURES

- Up to 1.5A Continuous Output Current
- ±10% Current-Limit Accuracy
- Adjustable Current-Limit, 60mA -1700mA (typ)
- Fast Over-current Response 2μs (typ)
- 2.5V to 5.5V Supply Range
- 88mΩ MOSFET (TQFN Package)
- 1.5μA Maximum Standby Supply Current
- Reverse Input-Output Voltage Protection
- Built-in Soft-Start
- Thermal-Shutdown Protection
- Automatic-on after Fault Removed
- Under-Voltage Lockout
- Deglitched Fault Report
- FLAG won't Change State at Input UVLO Transition
- Bidirectional Fault Deglitch Time
- Active Low & Active High Options

APPLICATIONS

- Smart Phone and PDA
- Portable GPS Device
- Notebook PC
- Set-top-box
- Telecom and Network Systems
- PC Card Hot Swap
- USB Power Distribution

TYPICAL APPLICATION

(*EN active low for MP62550)

## PACKAGE REFERENCE

### ABSOLUTE MAXIMUM RATINGS (1)

- **IN** to **GND**: -0.3V to +6.5V
- **ILIM**, **EN**, **FLAG**, **OUT** to **GND**: -0.3V to +6.5V
- $R_{ILIM}$ Range (1%) \(\frac{12.4\,\text{kQ}}{210\,\text{kQ}}\)
- Continuous Power Dissipation \(\left(T_A = +25°C\right)\) \(1.56\,\text{W}\)
- TSOT23-6 \(0.57\,\text{W}\)
- Lead Temperature \(260°C\)
- Storage Temperature \(-65°C to +150°C\)
- Maximum Junction Temp. \(T_J\) \(+125°C\)

### Thermal Resistance (3)

- **TQFN6 (2x2mm)**: \(\theta_{JA} \approx 80\,\text{°C/W}\)
- **TSOT23-6**: \(\theta_{JC} \approx 220\,\text{°C/W}\)

**Notes:**

1. Exceeding these ratings may damage the device.
2. The maximum allowable power dissipation is a function of the maximum junction temperature $T_J$(MAX), the junction-toambient thermal resistance $\theta_{JA}$, and the ambient temperature $T_A$. The maximum allowable continuous power dissipation at any ambient temperature is calculated by $P_D$(MAX)\(\neq (T_J$(MAX)-$T_A)\)/$\theta_{JA}$. Exceeding the maximum allowable power dissipation will cause excessive die temperature, and the regulator will go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
3. Measured on JESD51-7, 4-layer PCB.

DETAILED DESCRIPTION

The MP62550/MP62551 is a precision current-limit power distribution switch which can provide up to 1.5A continuous output current. It allows the user to program the current-limit between 60mA and 1.7A (typ) with ±10% accuracy via an external resistor connected between ILIM and GND pins.

The switch includes an N-channel power MOSFET and an internal charge pump to generate the gate driver voltage which is higher than input. The charge pump can work from input as low as 2.5V.

The device has built-in protection for both over current and increased thermal stress. For over current, the device will limit the current by changing to a constant current mode. It will shutdown when its internal temperature reaches unsafe levels and recover once the device temperature reduces approx 10°C.

It provides built-in soft-start which controls the rise and fall times of the output voltage to limit the initial inrush current and voltage surges.

The reverse-voltage protection feature turns off the MOSFET to protect the device.

The FLAG output will report a fail mode (low level) when over current or over temperature is encountered. The FLAG will not change state when the input UVLO is triggered.

Over Current

MP62550/MP62551 switches into to a constant-current mode when responding to over-current conditions. It ramps the output current to current limit value $I_{OS}$ and reduces the output voltage accordingly. MP62550/MP62551 will be thermal cycles only if the over current condition stays long enough to trigger thermal protection.

Trigger over current protection for different overload conditions occurring in applications:

1) The output has been shorted or overloaded before the device is enabled or input applied. MP62550/MP62551 detects the short or overload and switches into constant-current mode immediately.

2) A short or an overload occurs after the device is enabled. The device responds to the over-current condition within time $T_{IOS}$. The current-sense amplifier is overdriven, so high current may flow during this period of time and the internal current-limit MOSFET is disabled momentarily before the current-limit circuit can react. Then the current-sense amplifier recovers switches into constant-current mode. Similar to the previous case, the MP62550/MP62551 will limit the current to $I_{OS}$ until the overload condition is removed or the device entering thermal cycle.

3) Output current has been gradually increased beyond the recommended operating current. The load current rises until the current-limit threshold is reached or until the thermal limit of the device is exceeded. The MP62550/MP62551 is capable of delivering current up to the current-limit without damaging the device.

Reverse-Voltage Protection

To prevent damage the device on the input side of MP62550/MP62551, the N-channel MOSFET will be turned off immediately whenever the output voltage exceeds the input voltage by 135mV (typ). There is an internal comparator which compares the voltage difference between drain and source of N-channel MOSFET. The reverse voltage protection circuit only activates when $R_{DS(on)} \times I_{Reverse}>135mV$, that means there must be a temporary large reverse current from output to input that can trigger the reverse-voltage protection. After the comparator is triggered, the internal driver circuit starts to discharge the gate voltage via a constant current. It needs several milliseconds to fully turn off the N-channel MOSFET.

This protection could prevent significant current sinking into the input side.

The MP62550/MP62551 exist the protection mode and enter to normal state once the reverse-voltage condition is removed. No need to recycle the input power or enable logic.

There is no reverse current flow through the switch at the condition of 0V input and 5.5V output whatever the enable is high or low.
Flag Response
The FLAG pin is an open drain configuration. When over current or over temperature is encountered, FLAG will report a fail mode (low level).
For over current, 7.5ms deglitch time-out is needed. This is used to ensure that no false fault signal is reported. This internal deglitch circuit eliminates the need for components.
For over temperature, the FLAG pin is not deglitched.
The FLAG will not change state when the input UVLO is triggered.

Under-voltage Lockout (UVLO)
This circuit is used to monitor the input voltage to ensure that the MP62550/MP62551 is operating correctly. This UVLO circuit also ensures that there is no operation until the input voltage reaches the minimum spec. Built-in 130mV hysteresis prevents unwanted on/off power cycling due to input voltage drop from large current surges.

Enable
The logic pin disables the chip to reduce the supply current. Enable high activate the MP62551 while enable low activate the MP62550.
The device will operate once the enable signal reaches the appropriate level. There is no hysteresis for enable pin. The input is compatible with both COMS and TTL.

Thermal Protection
The purpose of thermal protection is to prevent damage in the IC by allowing excessive current to flow and heat the junction. The die temperature is internally monitored by two independent thermal sensing circuits until the thermal limit is reached. The first thermal sensor turns off the power switch when the die temperature exceeds 135°C (min) and the part is in current limit. The second thermal sensor turns off the power-switch when the die temperature exceeds 155°C (min) regardless of whether the switch is in current limit. Both two thermal sensors have built-in hysteresis. It will turn on the switch once it is cooled down 10°C approximately. MP62550/MP62551 continues to cycle off and on until the fault is removed.
APPLICATION INFORMATION

Power-Supply Considerations

Over 10μF capacitor between IN and GND is recommended. This precaution reduces power-supply transients that may cause ringing on the input and improves the immunity of the device to short-circuit transients.

In order to achieve smaller output load transient ripple, placing a high-value electrolytic capacitor on the output pin is recommended when the load is heavy.

A 0.01μF to 0.1μF ceramic bypassing capacitor is recommended to improve the immunity of the device to transient conditions and noise.

Programming the Current-Limit

The current-limit is programmed via an external resistor from ILIM to GND. The recommended 1% resistor range of R_{ILIM} is 12.4kΩ ≤ R_{ILIM} ≤ 210kΩ. The ILIM pin can be connected to IN to set the current-limit at its minimum level of 60mA (typ).

Figure 5 can be used to calculate the current limit value for a given ILIM resistor and also can be used to select ILIM resistor for a certain current limit.

In theory, the result of current limit multiplied by R_{ILIM} is a constant. But the internal amplifier has offset, as a result the current limit vs 1/R_{ILIM} is not linear at small programming resistor range. The theoretical current limit calculation formula is given as following:

\[ I_{OS}(A) = \frac{18.818V}{R_{ILIM}^{0.9248}kΩ} \]

Where: 12.4kΩ ≤ R_{ILIM} ≤ 210kΩ.

For better accuracy current limit setting, Table 1 and Figure 5 are highly recommended. Those curve or data are provided basing on large amount experimental test results.

Table 1 shows the common R_{ILIM} vs. current limit data. 1% accuracy resistor is recommended for general applications. If a precision current limit is needed, it’s better to use more tightly tolerance resistors, e.g. 0.5% or 0.1%. Resistor accuracy tolerance is not included in Table 1.

</tbody>
</table>

Notes:
10) Above current limit vs. R_{ILIM} data is typical value only and NOT guaranteed by production. Refer to EC table for more accurate current limit setting.

While the maximum recommended value of R_{ILIM} is 210kΩ, there is one additional configuration that allows for a lower current limit. The ILIM pin may be connected directly to IN to provide a 60 mA (typ) current limit.
Figure 5: Current-Limit vs R_{LIM}
Auto-Retry Function

Figure 6 shows an auto-retry circuit implanted by an external resistor and capacitor.

When over-current happens the FLAG will report a low level, EN is pulled down immediately and thus the part is shutdown.

During the moment of EN shutdown, the FLAG changes to high impedance allowing $C_{RETRY}$ to begin charging. After a time delay determined by the RC constant, the EN voltage reaches its turn-on threshold and re-enables the part. The part will continue to cycle in this manner until the fault condition is removed.
