**Table 8. EMI emission testing specifications**

Parameter	Conditions	Clocks	Frequency Range	Level (Typ)	Unit
	VDD33 = 3.3V VDD = 1.25V Temp = 25°C				

**NOTE**

1. Measurements were made per IEC 61967-2 while the device was running typical application code.
2. The reported emission level is the value of the maximum measured emission, rounded up to the next whole number, from among the measured orientations in each frequency range.
3. IEC Level Maximums:  $M \leq 18$  dBmV,  $L \leq 24$  dBmV,  $K \leq 30$  dBmV

**4.6 Electrostatic discharge (ESD) characteristics**

Electrostatic discharges (a positive then a negative pulse separated by 1 second) are applied to the pins of each sample according to each pin combination. The sample size depends on the number of supply pins in the device (3 parts  $\times$  ( $n + 1$ ) supply pin). This test conforms to the AEC-Q100-002/-003/-011 standard.

**NOTE**

A device will be defined as a failure if after exposure to ESD pulses the device no longer meets the device specification requirements. Complete DC parametric and functional testing shall be performed per applicable device specification at room temperature followed by hot temperature, unless specified otherwise in the device specification.

**Table 9. ESD ratings**

No.	Symbol	Parameter	Conditions <sup>1</sup>	Class	Max value <sup>2</sup>	Unit

1. All ESD testing is in conformity with CDF-AEC-Q100 Stress Test Qualification for Automotive Grade Integrated Circuits.
2. Data based on characterization results, not tested in production.
3. 500v for non AFE pins, 400v for AFE pins. "AFE pins" here are not just pins labeled as such in the Muxing Ballmap spreadsheet attached to the Reference Manual but also includes the associated power and grounds for the AFE block. Pin A1 (VSS\_HV\_RAW) is considered an AFE pin and not a corner pin.

Symbol	Characteristic	Min	Typical	Max <sup>1</sup>	Units <sup>2</sup>
$t_{ai16kseq}$	Array Integrity time for sequential sequence on 16 KB block.	—	—	512 x $T_{period}$ x $N_{read}$	—
$t_{ai32kseq}$	Array Integrity time for sequential sequence on 32 KB block.	—	—	1024 x $T_{period}$ x $N_{read}$	—
$t_{ai64kseq}$	Array Integrity time for sequential sequence on 64 KB block.	—	—	2048 x $T_{period}$ x $N_{read}$	—
$t_{ai256kseq}$	Array Integrity time for sequential sequence on 256 KB block.	—	—	8192 x $T_{period}$ x $N_{read}$	—
$t_{mr16kseq}$	Margin Read time for sequential sequence on 16 KB block.	73.81	—	110.7	$\mu s$
$t_{mr32kseq}$	Margin Read time for sequential sequence on 32 KB block.	128.43	—	192.6	$\mu s$
$t_{mr64kseq}$	Margin Read time for sequential sequence on 64 KB block.	237.65	—	356.5	$\mu s$
$t_{mr256kseq}$	Margin Read time for sequential sequence on 256 KB block.	893.01	—	1,339.5	$\mu s$

1. Array Integrity times need to be calculated and is dependent on system frequency and number of clocks per read. The equation presented require  $T_{period}$  (which is the unit accurate period, thus for 200 MHz,  $T_{period}$  would equal  $5e-9$ ) and  $N_{read}$  (which is the number of clocks required for read, including pipeline contribution. Thus for a read setup that requires 6 clocks to read with no pipeline,  $N_{read}$  would equal 6. For a read setup that requires 6 clocks to read, and has the address pipeline set to 2,  $N_{read}$  would equal 4 (or  $6 - 2$ ).)
2. The units for Array Integrity are determined by the period of the system clock. If unit accurate period is used in the equation, the results of the equation are also unit accurate.

Table continues on the next page...

**Table 41. DSPI timing (continued)**

No.	Symbol	Parameter	Conditions	Min	Max	Unit
12	$t_{HO}$	Data hold time for outputs	Master (MTFE = 1, CPHA = 0) <sup>10</sup>	—	7 + DSPI IPG Clock Period	ns

			Slave	3.8	—	
			Master (MTFE = 1, CPHA = 0) <sup>10</sup>	-4 + DSPI IPG Clock Period	—	
			Master (MTFE = 1, CPHA = 1)	-4	—	

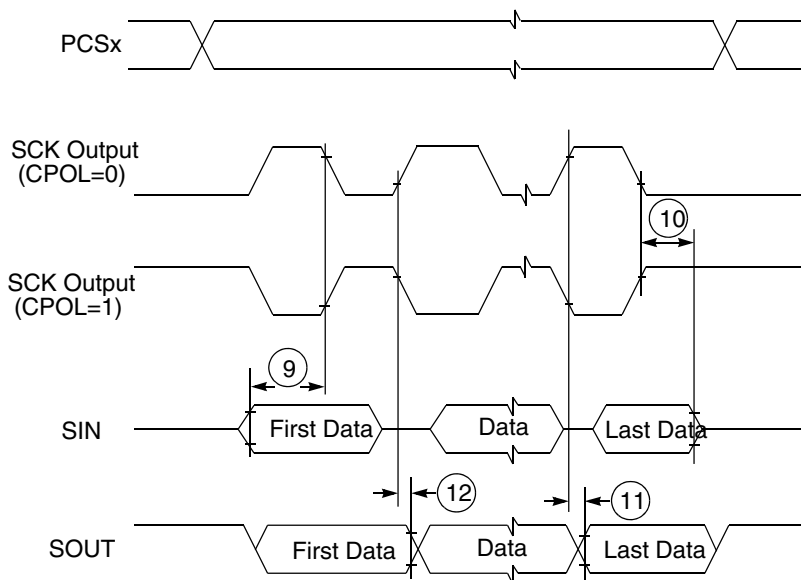

1. Slave Receive Only mode can operate at a maximum frequency of 60 MHz. In this mode, the DSPI can receive data on SIN, but no valid data is transmitted on SOUT.
2. For SPI\_CTARn[PCSSCK] - 'PCS to SCK Delay Prescaler' configuration is '3' (01h) and SPI\_CTARn[CSSCK] - 'PCS to SCK Delay Scaler' configuration is '2' (0000h).
3. For SPI\_CTARn[PASC] - 'After SCK Delay Prescaler' configuration is '3' (01h) and SPI\_CTARn[ASC] - 'After SCK Delay Scaler' configuration is '2' (0000h).
4. The numbers are valid when DSPI is configured for 50/50. Refer to Reference manual for the mapping of duty cycle to each configuration. A change in duty cycle changes the parameter here. For example a configuration providing duty cycle of 33/66 at DSPI translates to Min tSCK/3 - 1.5 ns Max tSCK/3 + 1.5 ns.
5. In slave mode any input duty cycle variation must be seen along with setup and hold timing would be datasheet parameters (input setup hold/output data valid setup/hold) of both master and slave. If the duty cycle is not as per spec it needs to be compensated by master timings.
6. In slave receive only mode any input duty cycle variation must be seen along with setup and hold timing would be datasheet parameters (input setup hold/output data valid setup/hold) of both master and slave. Must meet for min tSCK and for higher tSCK any degradation in duty cycle needs to be compensated by master timings but still cannot be less than tSCKmin/2+1 ns and tSCK/2min-1 ns for slave receive only mode.
7. For SPI\_CTARn[BR] - 'Baud Rate Scaler' configuration is  $\geq 4$ .
8. N=Configured sampling point value in MTFE=1 Mode.
9. Same value is applicable for PCS timing in continuous SCK mode.
10. SMPL\_PTR should be set to 1
11. Same value is applicable for PCS timing in continuous SCK mode

1. Programming IBFD (I<sup>2</sup>C Bus Frequency Divider) with the maximum frequency results in the minimum output timings listed. The I<sup>2</sup>C interface is designed to scale the data transition time, moving it to the middle of the SCL low period. The actual position is affected by the prescale and division values programmed in IBDR.
2. Serial data (SDA) and Serial clock (SCL) reaches peak level depending upon the external signal capacitance and pull up resistor values as SDA and SCL are open-drain type outputs which are only actively driven low by the I<sup>2</sup>C module.

### 8.1.1 General notes for specifications at maximum junction temperature

An estimation of the chip junction temperature,  $T_J$ , can be obtained from this equation:

$$T_J = T_A + (R_{\theta JA} \times P_D)$$

where:

- $T_A$  = ambient temperature for the package (°C)
- $R_{\theta JA}$  = junction to ambient thermal resistance (°C/W)
- $P_D$  = power dissipation in the package (W)

The junction to ambient thermal resistance is an industry standard value that provides a quick and easy estimation of thermal performance. Unfortunately, there are two values in common usage: the value determined on a single layer board and the value obtained on a board with two planes. For packages such as the PBGA, these values can be different by a factor of two. Which value is closer to the application depends on the power dissipated by other components on the board. The value obtained on a single layer board is appropriate for the tightly packed printed circuit board. The value obtained on the board with the internal planes is usually appropriate if the board has low power dissipation and the components are well separated.

When a heat sink is used, the thermal resistance is expressed in the following equation as the sum of a junction-to-case thermal resistance and a case-to-ambient thermal resistance:

$$R_{\theta JA} = R_{\theta JC} + R_{\theta CA}$$

where:

- $R_{\theta JA}$  = junction to ambient thermal resistance (°C/W)
- $R_{\theta JC}$  = junction to case thermal resistance (°C/W)
- $R_{\theta CA}$  = case to ambient thermal resistance (°C/W)

$R_{\theta JC}$  is device related and cannot be influenced by the user. The user controls the thermal environment to change the case to ambient thermal resistance,  $R_{\theta CA}$ . For instance, the user can change the size of the heat sink, the air flow around the device, the interface material, the mounting arrangement on printed circuit board, or change the thermal dissipation on the printed circuit board surrounding the device.

To determine the junction temperature of the device in the application when heat sinks are not used, the Thermal Characterization Parameter ( $\Psi_{JT}$ ) can be used to determine the junction temperature with a measurement of the temperature at the top center of the package case using this equation:

$$T_J = T_T + (\Psi_{JT} \times P_D)$$

where:

- $T_T$  = thermocouple temperature on top of the package ( $^{\circ}\text{C}$ )
- $\Psi_{JT}$  = thermal characterization parameter ( $^{\circ}\text{C}/\text{W}$ )
- $P_D$  = power dissipation in the package (W)

The thermal characterization parameter is measured per JESD51-2 specification using a 40 gauge type T thermocouple epoxied to the top center of the package case. The thermocouple should be positioned so that the thermocouple junction rests on the package. A small amount of epoxy is placed over the thermocouple junction and over about 1 mm of wire extending from the junction. The thermocouple wire is placed flat against the package case to avoid measurement errors caused by cooling effects of the thermocouple wire.

## 10 Reset sequence

This section describes different reset sequences and details the duration for which the device remains in reset condition in each of those conditions.

### 10.1 Reset sequence duration

[Table 51](#) specifies the minimum and the maximum reset sequence duration for the five different reset sequences described in [Reset sequence description](#).

**Table 51. RESET sequences**

No.	Symbol	Parameter	T <sub>Reset</sub>			Unit
			Min	Typ	Max <sup>1</sup>	
1	T <sub>DRB</sub>	Destructive Reset Sequence, BIST enabled	15		50	ms
2	T <sub>DR</sub>	Destructive Reset Sequence, BIST disabled	400		2000	μs
3	T <sub>ERLB</sub>	External Reset Sequence Long, BIST enabled	15		50	ms
4	T <sub>FRL</sub>	Functional Reset Sequence Long, BIST disabled	400		2000	μs
5	T <sub>FRS</sub>	Functional Reset Sequence Short, BIST disabled	1		500	μs

1. The maximum value is applicable only if the reset sequence duration is not prolonged by an extended assertion of RESET\_B by an external reset generator.

## 10.2 Reset sequence description

The figures in this section show the internal states of the device during the five different reset sequences. The dotted lines in the figures indicate the starting point and the end point for which the duration is specified in [Table 51](#).

With the beginning of DRUN mode, the first instruction is fetched and executed. At this point, application execution starts and the internal reset sequence is finished.

The SMPS self test is always triggered during Phase3 after a destructive reset so that duration is included into Phase3 below.

In external regulation mode, the VREG\_POR\_B pin should be de-asserted only when all the design supplies are in operating range. Deassertion of VREG\_POR\_B pin triggers the start of reset sequence in internal as well as external regulation modes.

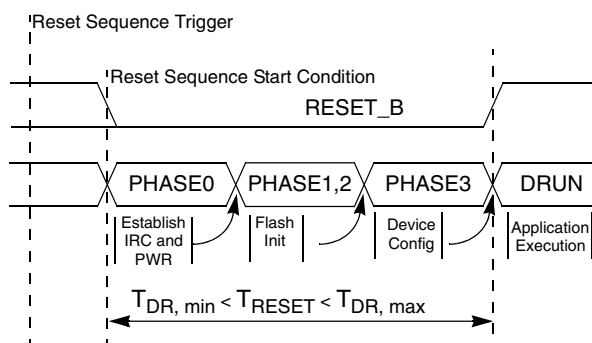

The following figures show the internal states of the device during the execution of the reset sequence and the possible states of the RESET\_B signal pin.

### NOTE

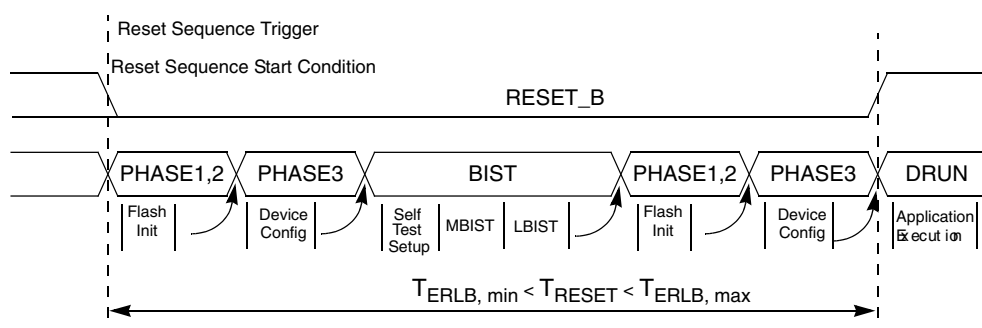

RESET\_B is a bidirectional pin. The voltage level on this pin can either be driven low by an external reset generator or by the device internal reset circuitry. A high level on this pin can only be generated by an external pullup resistor which is strong enough to overdrive the weak internal pulldown resistor. The rising edge on RESET\_B in the following figures indicates the time when the device stops driving it low. The reset sequence durations given in [Table 51](#) are applicable only if the internal reset sequence is not prolonged by an external reset generator keeping RESET\_B asserted low beyond the last Phase3.

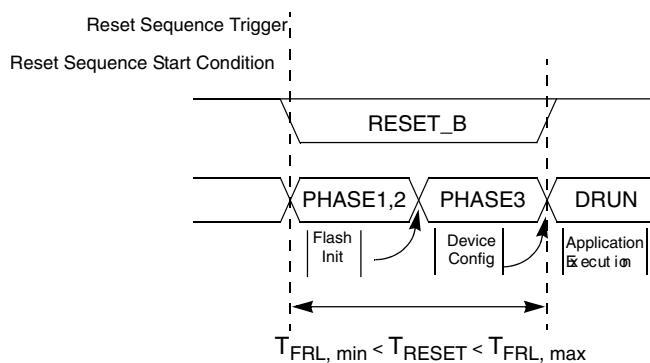

**Figure 37. Destructive reset sequence, BIST enabled**

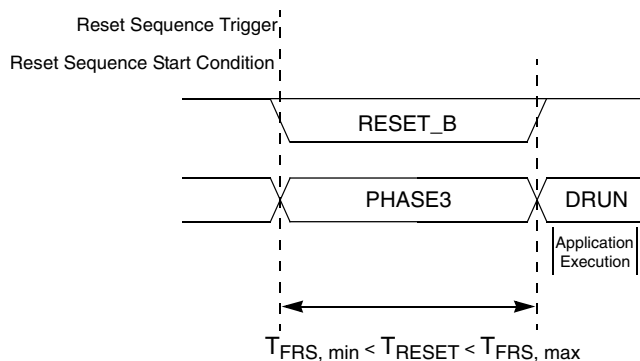

**Figure 38. Destructive reset sequence, BIST disabled**

**Figure 39. External reset sequence long, BIST enabled**

**Figure 40. Functional reset sequence long**

**Figure 41. Functional reset sequence short**

The reset sequences shown in [Figure 40](#) and [Figure 41](#) are triggered by functional reset events. RESET\_B is driven low during these two reset sequences only if the corresponding functional reset source (which triggered the reset sequence) was enabled to drive RESET\_B low for the duration of the internal reset sequence. See the RGM\_FBRE register in the device reference manual for more information.

## 11 Power sequencing requirements

The device does not require any specific power sequencing as far as user follows recommendations in this section.

As mentioned in the previous section, it is expected that the external ASIC which powers up the device in external regulation mode deasserts VREG\_POR\_B pin only when all the power supplies to the design are in operating range.

It should be noted that LVD and HVD detectors on VDD supply are disabled by default in external regulation mode for preventing a conflict with external regulator operation but they can be enabled by software once design is powered up.

While designing the system, it is important to ensure that AFE supplies are powered up before data is sent on its input pads.
