# Sub-One Volt Rail-to-Rail Operational Amplifier with Enable Feature

The NCS2002 is an industry first sub-one volt operational amplifier that features a rail-to-rail common mode input voltage range, along with rail-to-rail output drive capability. This amplifier is guaranteed to be fully operational down to 0.9 V, providing an ideal solution for powering applications from a single cell Nickel Cadmium (NiCd) or Nickel Metal Hydride (NiMH) battery. Additional features include no output phase reversal with overdriven inputs, trimmed input offset voltage of 0.5 mV, extremely low input bias current of 40 pA, and a unity gain bandwidth of 1.1 MHz at 5.0 V.

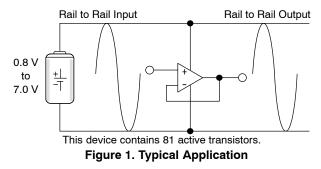

The NCS2002 also has an active high enable pin that allows external shutdown of the device. In the standby mode, the supply current is typically 1.9  $\mu$ A at 1.0 V. Because of its small size and enable feature, this amplifier represents the ideal solution for small portable electronic applications. The NCS2002 is available in the space saving SOT23–6 (TSOP–6) package with two industry standard pinouts.

### Features

- 0.9 V Guaranteed Operation
- Standby Mode:  $I_D = 1.9 \ \mu A$  at 1.0 V, Typical
- Rail-to-Rail Common Mode Input Voltage Range
- Rail-to-Rail Output Drive Capability
- No Output Phase Reversal for Over-Driven Input Signals
- 0.5 mV Trimmed Input Offset
- 10 pA Input Bias Current
- 1.1 MHz Unity Gain Bandwidth at  $\pm 2.5$  V, 1.0 MHz at  $\pm 0.5$  V
- Tiny SOT23-6 (TSOP-6) Package
- NCV Parts AEC-Q100 Qualified and PPAP Capable
- These Devices are Pb-Free and are RoHS Compliant

## **Typical Applications**

- Single Cell NiCd / NiMH Battery Powered Applications
- Cellular Telephones
- Pagers
- Personal Digital Assistants
- Electronic Games
- Digital Cameras
- Camcorders
- Hand Held Instruments

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

Either or both inputs should not exceed the range of V<sub>EE</sub> - 300 mV to V<sub>EE</sub> + 7.0 V.
 Maximum package power dissipation limits must be observed to ensure that the maximum junction temperature is not exceeded.

#### APPLICATION INFORMATION AND OPERATING DESCRIPTION

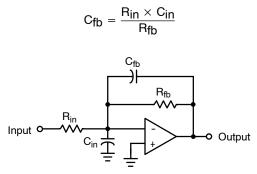

## **GENERAL INFORMATION**

The NCS2002 is an industry first rail-to-rail input, rail-to-rail output amplifier that features guaranteed sub one volt operation. This unique feature set is achieved with the use of a modified analog CMOS process that allows the implementation of depletion MOSFET devices. The amplifier has a 1.0 MHz gain bandwidth product, 1.2 V/ $\mu$ s slew rate and is operational over a power supply range less than 0.9 V to as high as 7.0 V.

#### Inputs

The input topology chosen for this device series is unconventional when compared to most low voltage operational amplifiers. It consists of an N-channel depletion mode differential transistor pair that drives a folded cascade stage and current mirror. This configuration extends the input common mode voltage range to encompass the V<sub>EE</sub> and V<sub>CC</sub> power supply rails, even when powered from a combined total of less than 0.9 volts. Figures 27, 28 and 29 show the input common mode voltage range versus power supply voltage.

The differential input stage is laser trimmed in order to minimize offset voltage. The N-channel depletion mode MOSFET input stage exhibits an extremely low input bias current of less than 10 pA. The input bias current versus temperature is shown in Figure 4. Either one or both inputs can be biased as low as  $V_{EE}$  minus 300 mV to as high as 7.0 V without causing damage to the device. If the input common mode voltage range is exceeded, the output will not display a phase reversal. If the maximum input positive or negative voltage ratings are to be exceeded, a series resistor must be used to limit the input current to less than 2.0 mA. The ultra low input bias current of the NCS2002 allows the use of extremely high value source and feedback resistor without reducing the amplifier's gain accuracy. These high value resistors, in conjunction with the device input and printed circuit board parasitic capacitances  $C_{in}$ , will add an additional pole to the single pole amplifier in Figure 33. If low enough in frequency, this additional pole can reduce the phase margin and significantly increase the output settling time. The effects of  $C_{in}$ , can be canceled by placing a zero into the feedback loop. This is accomplished with the addition of capacitor  $C_{fb}$ . An approximate value for  $C_{fb}$  can be calculated by:

Cin = Input and printed circuit board capacitance

#### Figure 33. Input Capacitance Pole Cancellation

## Output

The output stage consists of complementary P and N channel devices connected to provide rail-to-rail output drive. With a 2.0 k load, the output can swing within 50 mV of either rail. It is also capable of supplying over 75 mA when powered from 5.0 V and 1.0 mA when powered from 0.9 V.

When connected as a unity gain follower, the NCS2002 can directly drive capacitive loads in excess of 820 pF at room temperature without oscillating but with significantly reduced phase margin. The unity gain follower configuration exhibits the highest bandwidth and is most prone to oscillations when driving a high value capacitive load. The capacitive load in combination with the amplifier's output impedance, creates a phase lag that can result in an under-damped pulse response or a continuous oscillation. Figure 35 shows the effect of driving a large capacitive load in a voltage follower type of setup. When driving capacitive loads exceeding 820 pF, it is recommended to place a low value isolation resistor between the output of the op amp and the load, as shown in Figure 34. The series resistor isolates the capacitive load from the output and enhances the phase margin. Refer to Figure 36. Larger values of R will result in a cleaner output waveform but excessively large values will degrade the

large signal rise and fall time and reduce the output amplitude. Depending upon the capacitor characteristics, the isolation resistor value will typically be between 50 to 500  $\Omega$ . The output drive capability for resistive and capacitive loads is shown in Figures 2, 3, and 23.

Isolation resistor R = 50 to 500

Figure 34. Capacitance Load Isolation

Note that the lowest phase margin is observed at cold temperature and low supply voltage.

### Enable Pin

The enable pin allows the user to externally control the device. if the enable pin is pulled below the input disable threshold voltage ( $V_{EN} < 45\% V_{CC}$ ), the amplifier is disabled. Once the enable pin is taken above the threshold voltage ( $V_{EN} = 60\% V_{CC}$ ), the amplifier will turn on. In the event the enable pin is not connected, the amplifier will remain on by default

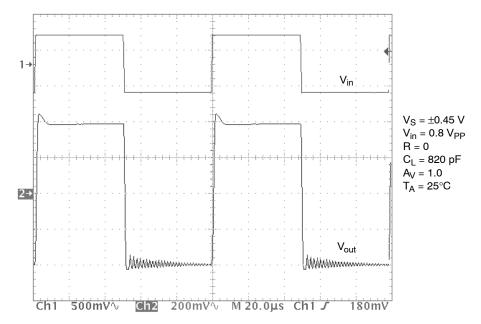

Figure 35. Small Signal Transient Response with Large Capacitive Load

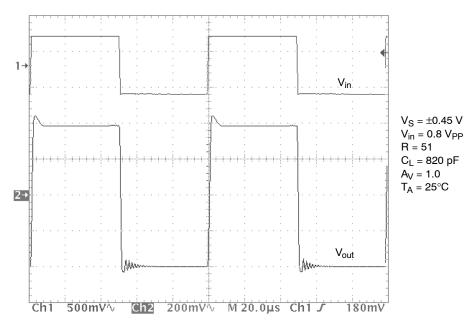

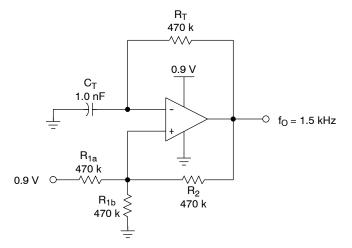

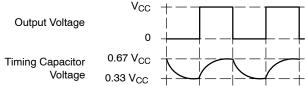

Figure 36. Small Signal Transient Response with Large Capacitive Load and Isolation Resistor.

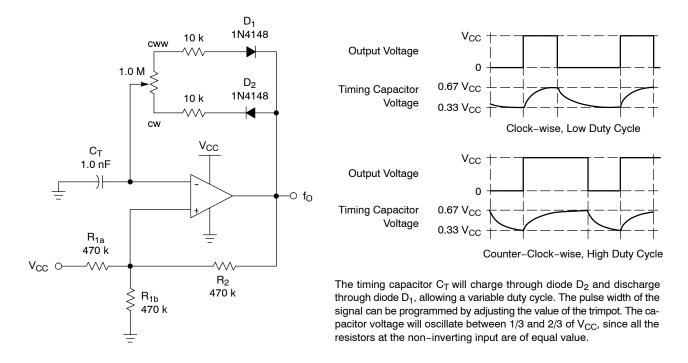

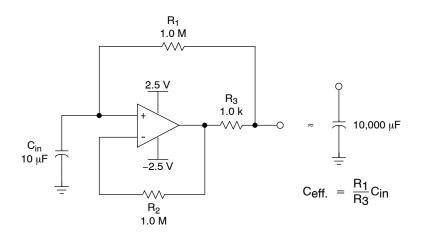

The non-inverting input threshold levels are set so that the capacitor voltage oscillates between 1/3 and 2/3 of V<sub>CC</sub>. This requires the resistors R<sub>1a</sub>, R<sub>1b</sub> and R<sub>2</sub> to be of equal value. The following formula can be used to approximate the output frequency.

$$f_{O} = \frac{1}{1.39 \ R_{T}C_{T}}$$

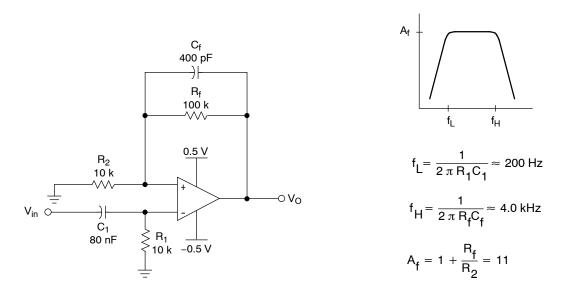

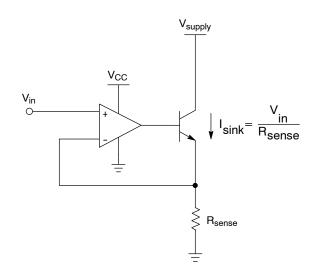

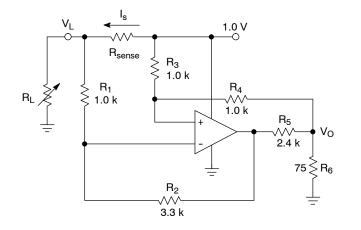

ls	vo
435 mA	34.7 mV
212 mA	36.9 mV

For best performance, use low tolerance resistors.
