LME SERIES – DIGITAL LOW DIFFERENTIAL PRESSURE SENSORS

The LME differential low-pressure sensors are based on thermal flow measurement of gas through a micro-flow channel integrated within the sensor chip. The innovative LME technology features superior sensitivity especially for ultra-low pressures. The extremely low gas flow through the sensor ensures high immunity to dust contamination and long tubing compared to other flow-based pressure sensors.

Features

- Ultra-low pressure ranges from 25 to 2500 Pa (0.1 to 10 inH2O)
- Pressure sensor based on thermal micro-flow measurement
- High flow impedance
- very low flow-through leakage
- high immunity to dust
- no loss in sensitivity using long tubing
- Outstanding long-term stability and precision with patented real-time offset compensation and linearization techniques
- Offset long term stability better than 0.1 Pa/year
- Total accuracy better than 0.5% FS typical
- On-chip temperature sensor
- Linearized digital SPI and analog outputs
- Small footprint, low profile, only 9 mm in height, and robust package
- Pressure ports for direct manifold assemblies
- Highly versatile to fit to application-specific mounting adapters and manifolds
- Minimized internal volume and manifold mount option allow for fast gas purge time
- No position sensitivity

Media compatibility

Dry air and other non-corrosive gases

Certificates

- Quality Management System according to EN ISO 13485 and EN ISO 9001
- RoHS and REACH compliant

Applications

Medical

- Ventilators
- Spirometers
- CPAP
- Sleep diagnostic equipment
- Nebulizers
- Oxygen conservers/concentrators
- Insufflators/endoscopy

Industrial

- HVAC
- VAV
- Filter monitoring
- Burner control
- Fuel cells
- Gas leak detection
- Gas metering
- Fume hood
- Instrumentation
- Security systems

SPI – Serial Peripheral Interface

Introduction

The LME serial interface is a high-speed synchronous data input and output communication port. The serial interface operates using a standard 4-wire SPI bus. The LDE device runs in SPI mode 0, which requires the clock line SCLK to idle low (CPOL = 0), and for data to be sampled on the leading clock edge (CPHA = 0). Figure 5 illustrates this mode of operation.

Care should be taken to ensure that the sensor is properly connected to the master microcontroller. Refer to the manufacturer's datasheet for more information regarding physical connections.

Application circuit

The use of pull-up resistors is generally unnecessary for SPI as most master devices are configured for push-pull mode. There are, however, some cases where it may be helpful to use 33Ω series resistors at both ends of the SPI lines, as shown in Figure 3.

Signal quality may be further improved by the addition of a buffer as shown in Figure 4. These cases include multiple slave devices on the same bus segment, using a master device with limited driving capability and long SPI bus lines.

If these series resistors are used, they must be physically placed as close as possible to the pins of the master and slave devices.

Signal control

The serial interface is enabled by asserting /CS low. The serial input clock, SCLK, is gated internally to begin accepting the input data at MOSI or sending the output data on MISO. When /CS rises, the data clocked into MOSI is loaded into an internal register.

Fig. 3: Application circuit with resistors at both ends of the SPI lines

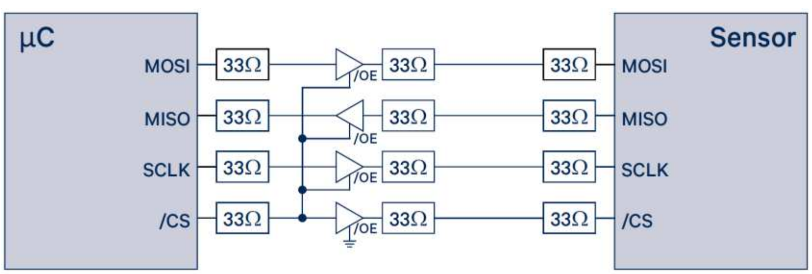

Fig. 4: Application circuit with additional buffer

SPI – Serial Peripheral Interface (cont.)

Data read – pressure

When powered on, the sensor begins to continuously measure pressure. To initiate data transfer from the sensor, the following three unique bytes must be written sequentially, MSB first, to the MOSI pin (see Figure 5):

Step	Hexadecimal	Binary	Description
1	0x2D	B00101101	Poll current pressure measurement
2	0x14	B00010100	Send result to data register
3	0x98	B10011000	Read data register

The entire 16-bit content of the LME register is then read out on the MISO pin, MSB first, by applying 16 successive clock pulses to SCLK with /CS asserted low. Note that the value of the LSB is held at zero for internal signal processing purposes. This is below the noise threshold of the sensor and thus its fixed value does not affect sensor performance and accuracy.

From the digital sensor output the actual pressure value can be calculated as follows:

$$\text{Pressure [Pa]} = \frac{\text{Digital output [counts]}}{\text{Scale factor}\left[\frac{\text{counts}}{\text{Pa}}\right]}$$

For example, for a ±250 Pa sensor (LMES250B...) with a scale factor of 120 a digital output of 30 000 counts (7530'h) calculates to a positive pressure of 250 Pa. Similarly, a digital output of -30 000 counts (8AD0'h) calculates to a negative pressure of -250 Pa

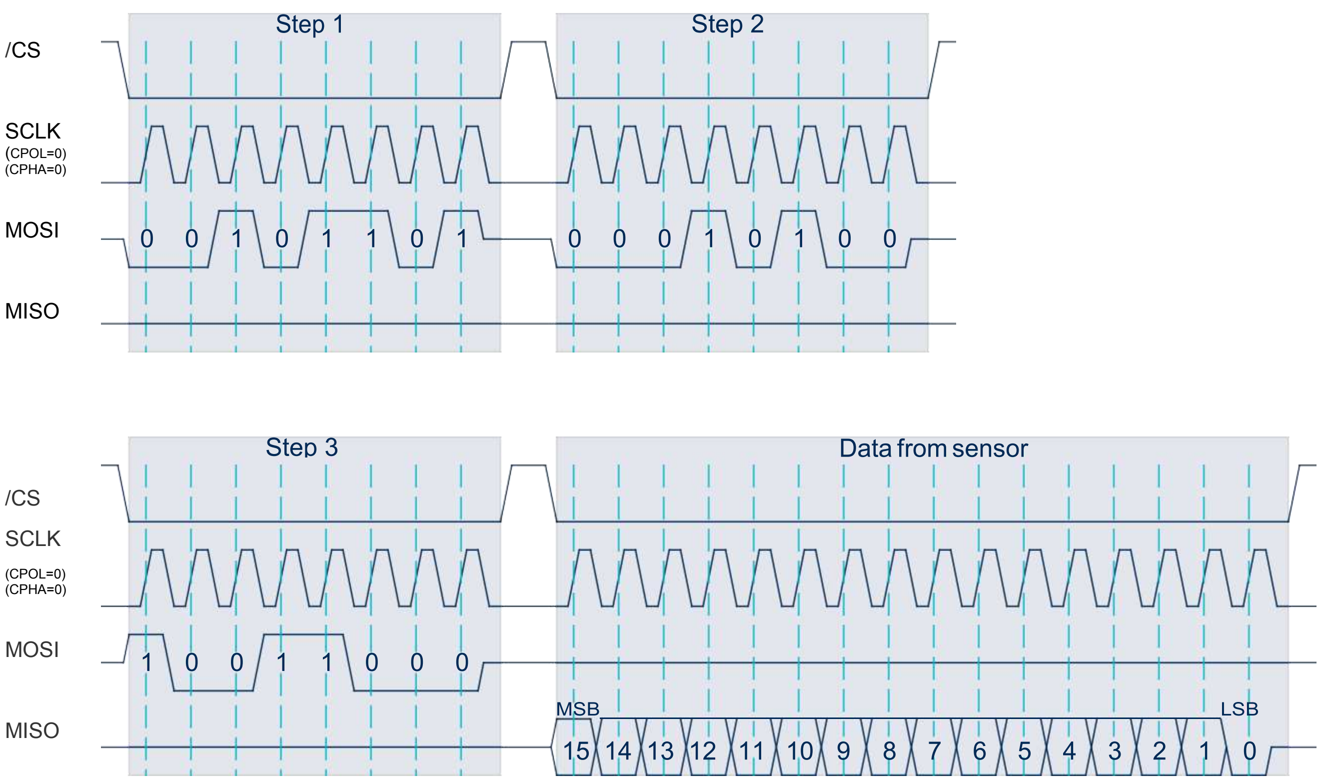

Fig. 5: SPI data transfer

SPI – Serial Peripheral Interface (cont.)

Data read – temperature

The on-chip temperature sensor changes 95 counts/°C over the operating range. The temperature data format is 15-bit plus sign in two's complement format. To read temperature, use the following sequence:

Step	Hexadecimal	Binary	Description
1	0x2A	B00101010	Poll current temperature measurement
2	0x14	B00010100	Send result to data register
3	0x98	B10011000	Read data register

From the digital sensor output, the actual temperature can be calculated as follows

$$\text{Temperature [°C]} = \frac{TS - TS_0 \text{ [counts]}}{\text{Scalefactor}_{TS}\left[\frac{\text{counts}}{\text{°C}}\right]} + T_0\,[\text{°C}]$$

where
TS is the actual sensor readout
TS_0 is the sensor readout at known temperature T[16];
Scale factor$_{TS}$ = 95 counts/°C

Interface specification

Parameter	Symbol	Conditions		Min.	Typ.	Max.	Unit
External clock frequency	f_{ECLK}	V_{CKSEL}=0	Min.		0.2		MHz
			Max.		5		
External master clock input low time	$f_{ECLKIN\ LO}$	$t_{ECLK}=1/f_{ECLK}$		40		60	$\%t_{ECLK}$

Electrical connection

There are two use cases that will change the manner in which the LME series device is connected in-circuit:

Pin	Function	Case 1: Digital signal output	Case 2: Analog signal output
1	VS	+5V	+5V
2	GND	GND	GND
3	Vout	NC	High impedance analog input (e.g. op-amp, ADC)
4	Reserved	NC	NC
5	SCLK	Master device SCLK	GND
6	MOSI	Master device MOSI	GND
7	MISO	Master device MISO	GND
8	/CS	Master device (/CS)	V_S

Hole pattern is provided with reference dimensions only. Please ensure that the final design allows for positioning errors of the PCB assembly process.

Dimensions in mm

Gas mixture change (purge time)

The LME series pressure sensors feature minimized internal volume, which allows for fast response to gas mixture change and high pneumatic impedance at the same time. Purge time (TP) can be estimated by the following equation:

$$T_P = \frac{V_{INT}}{F_{Norm}} = \frac{V_{INT}}{P_{Norm} / Z_p}$$

T_P = Purge time [s]

V_{INT} = Internal volume of the LME sensor [ml]

F_{Nom} = Nominal flow [ml/s]

P_{Nom} = Nominal pressure [Pa]

Z_P = Pneumatic impedance [kPa/(ml/s)]

The typical internal volume of the LME sensor (V_{INT}) is 0.04 ml. With a pneumatic impedance (Z_P) of 15 kPa/(ml/s) and a nominal pressure (P_{Nom}) of 250 Pa, the estimated purge time (T_P) is 2.4 seconds.

Note:

The above product listings are examples of possible product configurations. More standard product configurations are available on request.

In addition, custom specific pressure and temperature ranges as well as mechanical or electronic sensor modifications are widely available.

Please note, not all possible sensor configurations are active products. MOQ may apply.
Please contact your local sensors representative to learn more.

Specification notes

(1) Recommendations only. Actually reflow settings depend on many factors, for example, number of oven heating and cooling zones, type of solder paste/flux used, board and component size, as well as component density. It is the responsibility of the customer to fine tune their processes for optimal results
(2) Handling instruction: Products are packaged in vacuum sealed moisture barrier bag with a floor life of 168hours (<30C, 60% R.H.). If floor life or environmental conditions have been exceeded prior to reflow assembly, baking is recommended. Recommended bake-out procedure is 72 hours @ 60C.
(3) Sweep 20 to 2000 Hz, 8 min, 4 cycles per axis, MIL-STD-883, Method 2007.
(4) 5 shocks, 3 axes, MIL-STD-883E, Method 2002.4.
(5) The max. common mode pressure is 5 bar.
(6) For example, with a LMES500... sensor measuring CO_2 gas, at full-scale output the actual pressure will be:

$$\Delta P_{eff} = \Delta P_{Sensor} \text{ x gas correction factor} = 500 \text{ Pa x } 0.56 = 280 \text{ Pa}$$

ΔP_{eff} = True differential pressure
ΔP_{Sensor}= Differential pressure as indicated by output signal

(7) The sensor is calibrated with a common mode pressure of 1 bar absolute. Due to the mass flow-based measuring principle, variations in absolute common mode pressure need to be compensated according to the following formula:

$$\Delta P_{eff} = \Delta P_{Sensor} \text{ x } 1 \text{ bara}/P_{abs}$$

ΔP_{eff} = True differential pressure
ΔP_{Sensor}= Differential pressure as indicated by output voltage
P_{abs}= Current absolute common mode pressure

(8) Figure based on accelerated lifetime test of 10000 hours at 85 °C biased burn-in.
(9) Please contact TE connectivity for low power options.
(10) The digital output signal is a signed, two complement integers. Negative pressures will result in a negative output
(11) Zero pressure offset accuracy and span accuracy are uncorrelated uncertainties. They can be added according to the principles of error propagation.
(12) Span accuracy below 10% of full scale is limited by the intrinsic noise of the sensor.
(13) Typical value for 250 Pa sensors.
(14) For pressure ranges 1250 Pa and 2500 Pa, more accurate absolute pressure correction procedures than in (5) might be needed. See Application Note "Absolute pressure correction of LME/LMI pressure sensors".
(15) Total accuracy is the combined error from offset and span calibration, non-linearity, repeatability and pressure hysteresis
(16) To be defined by user. The results show deviation (in °C) from the offset calibrated temperature.
