## 1. Electrical Specifications

**Table 1. DC Characteristics<sup>1</sup>**

Parameter	Symbol	Test Condition	Min	Typ	Max	Unit
Supply Voltage Range	V <sub>DD</sub>		1.8	3.3	3.8	V
Power Saving Modes	I <sub>Shutdown</sub>	RC Oscillator, Main Digital Regulator, and Low Power Digital Regulator OFF	—	30	1300	nA
	I <sub>Standby</sub>	Register values maintained and RC oscillator/WUT OFF	—	40	2900	nA
	I <sub>SleepRC</sub>	RC Oscillator/WUT ON and all register values maintained, and all other blocks OFF	—	740	3800	nA
	I <sub>SleepXO</sub>	Sleep current using an external 32 kHz crystal	—	1.7	—	μA
	I <sub>Sensor-LBD</sub>	Low battery detector ON, register values maintained, and all other blocks OFF	—	1	—	μA
	I <sub>Ready</sub>	Crystal Oscillator and Main Digital Regulator ON, all other blocks OFF	—	1.8	—	mA
Preamble Sense Mode Current	I <sub>psm</sub>	Duty cycling during preamble search, 1.2 kbps, 4 byte preamble	—	6	—	mA
	I <sub>psm</sub>	Fixed 1 s wakeup interval, 50 kbps, 5 byte preamble	—	10	—	μA
TUNE Mode Current	I <sub>Tune_RX</sub>	RX Tune, High Performance Mode	—	7.6	—	mA
	I <sub>Tune_TX</sub>	TX Tune, High Performance Mode	—	7.8	—	mA
RX Mode Current	I <sub>RXH</sub>	High Performance Mode (measured at 915 MHz and 40 kbps data rate)	—	13.7	22	mA
	I <sub>RXL</sub>	Low Power Mode (measured at 315 MHz and 40 kbps data rate)	—	10.9	—	mA
TX Mode Current (Si4463)	I <sub>TX_+20</sub>	+20 dBm output power, Class-E match, 915 MHz, 3.3 V	—	88	108	mA
		+20 dBm output power, square-wave match, 169 MHz, 3.3 V	—	68.5	80	mA
		+13 dBm output power, Class-E match, 915 MHz, 3.3 V	—	44.5	60	mA
TX Mode Current (Si4460)	I <sub>TX_+10</sub>	+10 dBm output power, Class-E match, 915/868 MHz, 3.3 V <sup>2</sup>	—	19.7	—	mA
	I <sub>TX_+10</sub>	+10 dBm output power, Class-E match, 169 MHz, 3.3 V <sup>2</sup>	—	18	—	mA
	I <sub>TX_+13</sub>	+13 dBm output power, Class-E match, 915/868 MHz, 3.3 V	—	24	—	mA
TX Mode Current (Si4461)	I <sub>TX_+16</sub>	+16 dBm output power, class-E match, 868 MHz, 3.3 V	—	43	55	mA
	I <sub>TX_+13</sub>	+13 dBm output power, switched-current match, 868 MHz, 3.3 V	—	33.5	40	mA

**Notes:**

1. All minimum and maximum values are guaranteed across the recommended operating conditions of supply voltage and from –40 to +85 °C unless otherwise stated. All typical values apply at V<sub>DD</sub> = 3.3 V and 25 °C unless otherwise stated.
2. Measured on direct-tie RF evaluation board.

Table 2. Synthesizer AC Electrical Characteristics

Parameter	Symbol	Test Condition	Min	Typ	Max	Unit
Synthesizer Frequency Range	F <sub>SYN</sub>		850	—	1050	MHz
			350	—	525	MHz
			284	—	350	MHz
			142	—	175	MHz
Synthesizer Frequency Resolution	F <sub>RES-960</sub>	850–1050 MHz	—	28.6	—	Hz
	F <sub>RES-525</sub>	420–525 MHz	—	14.3	—	Hz
	F <sub>RES-420</sub>	350–420 MHz	—	11.4	—	Hz
	F <sub>RES-350</sub>	283–350 MHz	—	9.5	—	Hz
	F <sub>RES-175</sub>	142–175 MHz	—	4.7	—	Hz
Synthesizer Settling Time	t <sub>LOCK</sub>	Measured from exiting Ready mode with XOSC running to any frequency. Including VCO Calibration.	—	50	—	μs
Phase Noise	L <sub>φ</sub> (f <sub>M</sub> )	ΔF = 10 kHz, 169 MHz, High Perf Mode	—	–117	–108	dBc/Hz
		ΔF = 100 kHz, 169 MHz, High Perf Mode	—	–120	–115	dBc/Hz
		ΔF = 1 MHz, 169 MHz, High Perf Mode	—	–138	–135	dBc/Hz
		ΔF = 10 MHz, 169 MHz, High Perf Mode	—	–148	–143	dBc/Hz
		ΔF = 10 kHz, 915 MHz, High Perf Mode	—	–102	–94	dBc/Hz
		ΔF = 100 kHz, 915 MHz, High Perf Mode	—	–105	–97	dBc/Hz
		ΔF = 1 MHz, 915 MHz, High Perf Mode	—	–125	–122	dBc/Hz
		ΔF = 10 MHz, 915 MHz, High Perf Mode	—	–138	–135	dBc/Hz
<b>Note:</b> All minimum and maximum values are guaranteed across the recommended operating conditions of supply voltage and from –40 to +85 °C unless otherwise stated. All typical values apply at VDD = 3.3 V and 25 °C unless otherwise stated.						

**Table 3. Receiver AC Electrical Characteristics<sup>1,2</sup>**

Parameter	Symbol	Test Condition	Min	Typ	Max	Unit
RX Frequency Range	$F_{RX}$		850	—	1050	MHz
			350	—	525	MHz
			284	—	350	MHz
			142	—	175	MHz
RX Sensitivity 169 MHz <sup>3</sup>	$P_{RX\_0.5}$	(BER < 0.1%) (500 bps, GFSK, BT = 0.5, $\Delta f = \pm 250\text{Hz}$ )	—	-129	—	dBm
	$P_{RX\_40}$	(BER < 0.1%) (40 kbps, GFSK, BT = 0.5, $\Delta f = \pm 20\text{ kHz}$ )	—	-110	-108	dBm
	$P_{RX\_100}$	(BER < 0.1%) (100 kbps, GFSK, BT = 0.5, $\Delta f = \pm 50\text{ kHz}$ )	—	-106	-104	dBm
	$P_{RX\_500}$	(BER < 0.1%) (500 kbps, GFSK, BT = 0.5, $\Delta f = \pm 250\text{ kHz}$ )	—	-98	-96	dBm
	$P_{RX\_9.6}$	(PER 1%) (9.6 kbps, 4GFSK, BT = 0.5, $\Delta f = \pm 2.4\text{ kHz}$ )	—	-110	—	dBm
	$P_{RX\_1M}$	(PER 1%) (1 Mbps, 4GFSK, BT = 0.5, inner deviation = 83.3 kHz)	—	-89	—	dBm
	$P_{RX\_OOK}$	(BER < 0.1%, 4.8 kbps, 350 kHz BW, OOK, PN15 data)	—	-110	-107	dBm
		(BER < 0.1%, 40 kbps, 350 kHz BW, OOK, PN15 data)	—	-103	-100	dBm
		(BER < 0.1%, 120 kbps, 350 kHz BW, OOK, PN15 data)	—	-97	-93	dBm

**Notes:**

1. All minimum and maximum values are guaranteed across the recommended operating conditions of supply voltage and from -40 to +85 °C unless otherwise stated. All typical values apply at VDD = 3.3 V and 25 °C unless otherwise stated.
2. For PER tests, 48 preamble symbols, 4 byte sync word, 10 byte payload and CRC-32 was used.
3. Measured over 50000 bits using PN9 data sequence and data and clock on GPIOs. Sensitivity is expected to be better if reading data from packet handler FIFO especially at higher data rates.

Table 3. Receiver AC Electrical Characteristics<sup>1,2</sup> (Continued)

Parameter	Symbol	Test Condition	Min	Typ	Max	Unit
RX Sensitivity 915/868 MHz <sup>3</sup>	P <sub>RX_0.5</sub>	(BER < 0.1%) (500 bps, GFSK, BT = 0.5, $\Delta f = \pm 250\text{Hz}$ )	—	–127	—	dBm
	P <sub>RX_40</sub>	(BER < 0.1%) (40 kbps, GFSK, BT = 0.5, $\Delta f = \pm 20\text{ kHz}$ )	—	–109	–107	dBm
	P <sub>RX_100</sub>	(BER < 0.1%) (100 kbps, GFSK, BT = 0.5, $\Delta f = \pm 50\text{ kHz}$ )	—	–104	–102	dBm
	P <sub>RX_500</sub>	(BER < 0.1%) (500 kbps, GFSK, BT = 0.5, $\Delta f = \pm 250\text{ kHz}$ )	—	–97	–92	dBm
	P <sub>RX_9.6</sub>	(PER 1%) (9.6 kbps, 4GFSK, BT = 0.5, $\Delta f = \pm 2.4\text{ kHz}$ )	—	–109	—	dBm
	P <sub>RX_1M</sub>	(PER 1%) (1 Mbps, 4GFSK, BT = 0.5, inner deviation = 83.3 kHz)	—	–88	—	dBm
	P <sub>RX_OOK</sub>	(BER < 0.1%, 4.8 kbps, 350 kHz BW, OOK, PN15 data)	—	–108	–104	dBm
		(BER < 0.1%, 40 kbps, 350 kHz BW, OOK, PN15 data)	—	–101	–97	dBm
		(BER < 0.1%, 120 kbps, 350 kHz BW, OOK, PN15 data)	—	–96	–91	dBm
RX Channel Bandwidth	BW		1.1	—	850	kHz
RSSI Resolution	RES <sub>RSSI</sub>	Valid from –110 dBm to –90 dBm	—	±0.5	—	dB
±1-Ch Offset Selectivity, 169 MHz <sup>3</sup>	C/I <sub>1-CH</sub>	Desired Ref Signal 3 dB above sensitivity, BER < 0.1%. Interferer is CW, and desired is modulated with 2.4 kbps $\Delta F = 1.2\text{ kHz}$ GFSK with BT = 0.5, RX channel BW = 4.8 kHz, channel spacing = 12.5 kHz	—	–69	–59	dB
±1-Ch Offset Selectivity, 450 MHz <sup>3</sup>	C/I <sub>1-CH</sub>		—	–60	–50	dB
±1-Ch Offset Selectivity, 868 / 915 MHz <sup>3</sup>	C/I <sub>1-CH</sub>		—	–55	–45	dB
Blocking 1 MHz Offset	1M <sub>BLOCK</sub>	Desired Ref Signal 3 dB above sensitivity, BER = 0.1%. Interferer is CW, and desired is modulated with 2.4 kbps, $\Delta F = 1.2\text{ kHz}$ GFSK with BT = 0.5, RX channel BW = 4.8 kHz	—	–79	–68	dB
Blocking 8 MHz Offset	8M <sub>BLOCK</sub>		—	–86	–75	dB

**Notes:**

1. All minimum and maximum values are guaranteed across the recommended operating conditions of supply voltage and from –40 to +85 °C unless otherwise stated. All typical values apply at VDD = 3.3 V and 25 °C unless otherwise stated.
2. For PER tests, 48 preamble symbols, 4 byte sync word, 10 byte payload and CRC-32 was used.
3. Measured over 50000 bits using PN9 data sequence and data and clock on GPIOs. Sensitivity is expected to be better if reading data from packet handler FIFO especially at higher data rates.

**Table 3. Receiver AC Electrical Characteristics<sup>1,2</sup> (Continued)**

Parameter	Symbol	Test Condition	Min	Typ	Max	Unit
Image Rejection (IF = 468.75 kHz)	Im <sub>REJ</sub>	No image rejection calibration. Rejection at the image frequency. RF = 460 MHz	30	40	—	dB
		With image rejection calibration in Si446x. Rejection at the image frequency. RF = 460 MHz	40	55	—	dB
		No image rejection calibration. Rejection at the image frequency. RF = 915 MHz	30	45	—	dB
		With image rejection calibration in Si446x. Rejection at the image frequency. RF = 915 MHz	40	52	—	dB
		No image rejection calibration. Rejection at the image frequency. RF = 169 MHz	35	45	—	dB
		With image rejection calibration in Si446x. Rejection at the image frequency. RF = 169 MHz	45	60	—	dB

**Notes:**

1. All minimum and maximum values are guaranteed across the recommended operating conditions of supply voltage and from –40 to +85 °C unless otherwise stated. All typical values apply at VDD = 3.3 V and 25 °C unless otherwise stated.
2. For PER tests, 48 preamble symbols, 4 byte sync word, 10 byte payload and CRC-32 was used.
3. Measured over 50000 bits using PN9 data sequence and data and clock on GPIOs. Sensitivity is expected to be better if reading data from packet handler FIFO especially at higher data rates.

Table 4. Transmitter AC Electrical Characteristics

Parameter	Symbol	Test Condition	Min	Typ	Max	Unit
TX Frequency Range	$F_{TX}$		850	—	1050	MHz
			350	—	525	MHz
			284	—	350	MHz
			142	—	175	MHz
(G)FSK Data Rate	$DR_{FSK}$		0.1	—	500	kbps
4(G)FSK Data Rate	$DR_{4FSK}$		0.2	—	1000	kbps
OOK Data Rate	$DR_{OOK}$		0.1	—	120	kbps
Modulation Deviation Range	$\Delta f_{960}$	850–1050 MHz	—	1.5	—	MHz
	$\Delta f_{525}$	420–525 MHz	—	750	—	kHz
	$\Delta f_{420}$	350–420 MHz	—	600	—	kHz
	$\Delta f_{350}$	283–350 MHz	—	500	—	kHz
	$\Delta f_{175}$	142–175 MHz	—	250	—	kHz
Modulation Deviation Resolution	$F_{RES-960}$	850–1050 MHz	—	28.6	—	Hz
	$F_{RES-525}$	420–525 MHz	—	14.3	—	Hz
	$F_{RES-420}$	350–420 MHz	—	11.4	—	Hz
	$F_{RES-350}$	283–350 MHz	—	9.5	—	Hz
	$F_{RES-175}$	142–175 MHz	—	4.7	—	Hz
Output Power Range (Si4463)	$P_{TX63}$	Typical range at 3.3 V with Class E Match optimized for best PA efficiency	–20	—	+20	dBm
Output Power Range (Si4461)	$P_{TX61}$	Typical range at 3.3 V with Class E Match optimized for best PA efficiency	–40	—	+16	dBm
Output Power Range (Si4460)	$P_{TX60}$	Typical range at 3.3 V with Class E Match optimized for best PA efficiency. Efficiency can be traded off for higher Tx output power up to +13 dBm	–20	—	+12.5	dBm

**Notes:**

1. All minimum and maximum values are guaranteed across the recommended operating conditions of supply voltage and from –40 to +85 °C unless otherwise stated. All typical values apply at VDD = 3.3 V and 25 °C unless otherwise stated.
2. The maximum data rate is dependent on the XTAL frequency and is calculated as per the formula: Maximum Symbol Rate =  $F_{xtal}/60$ , where  $F_{xtal}$  is the XTAL frequency (typically 30 MHz).
3. Default API setting for modulation deviation resolution is double the typical value specified.
4. Output power is dependent on matching components and board layout.

**Table 4. Transmitter AC Electrical Characteristics (Continued)**

Parameter	Symbol	Test Condition	Min	Typ	Max	Unit
Output Power Variation (Si4463)		At 20 dBm PA power setting, 915 MHz, Class E match, 3.3 V, 25 °C	19	20	21	dBm
Output Power Variation (Si4460)		At 10 dBm PA power setting, 915 MHz, Class E match, 3.3 V, 25 °C	9	10	11	dBm
Output Power Variation (Si4463)		At 20 dBm PA power setting, 169 MHz, Square Wave match, 3.3 V, 25 °C	18.5	20	21	dBm
Output Power Variation (Si4460)		At 10 dBm PA power setting, 169 MHz, Square Wave match, 3.3 V, 25 °C	9.5	10	10.5	dBm
TX RF Output Steps	$\Delta P_{RF\_OUT}$	Using switched current match within 6 dB of max power using CLE match within 6 dB of max power	—	0.25	0.4	dB
TX RF Output Level Variation vs. Temperature	$\Delta P_{RF\_TEMP}$	–40 to +85 °C	—	2.3	3	dB
TX RF Output Level Variation vs. Frequency	$\Delta P_{RF\_FREQ}$	Measured across 902–928 MHz	—	0.6	1.7	dB
Transmit Modulation Filtering	BT	Gaussian Filtering Bandwidth Time Product	—	0.5	—	

**Notes:**

1. All minimum and maximum values are guaranteed across the recommended operating conditions of supply voltage and from –40 to +85 °C unless otherwise stated. All typical values apply at VDD = 3.3 V and 25 °C unless otherwise stated.
2. The maximum data rate is dependent on the XTAL frequency and is calculated as per the formula: Maximum Symbol Rate = Fxtal/60, where Fxtal is the XTAL frequency (typically 30 MHz).
3. Default API setting for modulation deviation resolution is double the typical value specified.
4. Output power is dependent on matching components and board layout.

Table 5. Auxiliary Block Specifications<sup>1</sup>

Parameter	Symbol	Test Condition	Min	Typ	Max	Unit
Temperature Sensor Sensitivity	TS <sub>S</sub>		—	4.5	—	ADC Codes/ °C
Low Battery Detector Resolution	LBD <sub>RES</sub>		—	50	—	mV
Microcontroller Clock Output Frequency Range <sup>2</sup>	F <sub>MC</sub>	Configurable to Fxtal or Fxtal divided by 2, 3, 7.5, 10, 15, or 30 where Fxtal is the reference XTAL frequency. In addition, 32.768 kHz is also supported.	32.768K	—	Fxtal	Hz
Temperature Sensor Conversion	TEMP <sub>CT</sub>	Programmable setting	—	3	—	ms
XTAL Range <sup>3</sup>	XTAL <sub>Range</sub>		25	—	32	MHz
30 MHz XTAL Start-Up Time	t <sub>30M</sub>	Start-up time will vary with XTAL type and board layout.	—	300	—	μs
30 MHz XTAL Cap Resolution	30M <sub>RES</sub>		—	70	—	fF
32 kHz XTAL Start-Up Time	t <sub>32k</sub>		—	2	—	sec
32 kHz Accuracy using Internal RC Oscillator	32KRC <sub>RES</sub>		—	2500	—	ppm
POR Reset Time	t <sub>POR</sub>		—	—	6	ms

**Notes:**

1. All minimum and maximum values are guaranteed across the recommended operating conditions of supply voltage and from –45 to +85 °C unless otherwise stated. All typical values apply at Vdd=3.3V and 25°C unless otherwise stated.
2. Microcontroller clock frequency tested in production at 1 MHz, 30 MHz, 32 MHz, and 32.768 kHz. Other frequencies tested by bench characterization.
3. XTAL Range tested in production using an external clock source (similar to using a TCXO).

**Table 6. Digital IO Specifications (GPIO\_x, SCLK, SDO, SDI, nSEL, nIRQ, SDN)<sup>1</sup>**

Parameter	Symbol	Test Condition	Min	Typ	Max	Unit
Rise Time <sup>2,3</sup>	$T_{RISE}$	$0.1 \times V_{DD}$ to $0.9 \times V_{DD}$ , $C_L = 10 \text{ pF}$ , $DRV<1:0> = LL$	—	2.3	—	ns
Fall Time <sup>3,4</sup>	$T_{FALL}$	$0.9 \times V_{DD}$ to $0.1 \times V_{DD}$ , $C_L = 10 \text{ pF}$ , $DRV<1:0> = LL$	—	2	—	ns
Input Capacitance	$C_{IN}$		—	2	—	pF
Logic High Level Input Voltage	$V_{IH}$		$V_{DD} \times 0.7$	—	—	V
Logic Low Level Input Voltage	$V_{IL}$		—	—	$V_{DD} \times 0.3$	V
Input Current	$I_{IN}$	$0 < V_{IN} < V_{DD}$	−1	—	1	μA
Input Current If Pullup is Activated	$I_{INP}$	$V_{IL} = 0 \text{ V}$	1	—	4	μA
Drive Strength for Output Low Level	$I_{OmaxLL}$	$DRV[1:0] = LL^3$	—	6.66	—	mA
	$I_{OmaxLH}$	$DRV[1:0] = LH^3$	—	5.03	—	mA
	$I_{OmaxHL}$	$DRV[1:0] = HL^3$	—	3.16	—	mA
	$I_{OmaxHH}$	$DRV[1:0] = HH^3$	—	1.13	—	mA
Drive Strength for Output High Level	$I_{OmaxLL}$	$DRV[1:0] = LL^3$	—	5.75	—	mA
	$I_{OmaxLH}$	$DRV[1:0] = LH^3$	—	4.37	—	mA
	$I_{OmaxHL}$	$DRV[1:0] = HL^3$	—	2.73	—	mA
	$I_{OmaxHH}$	$DRV[1:0] = HH^3$	—	0.96	—	mA
Drive Strength for Output High Level for GPIO0	$I_{OmaxLL}$	$DRV[1:0] = LL^3$	—	2.53	—	mA
	$I_{OmaxLH}$	$DRV[1:0] = LH^3$	—	2.21	—	mA
	$I_{OmaxHL}$	$DRV[1:0] = HL^3$	—	1.70	—	mA
	$I_{OmaxHH}$	$DRV[1:0] = HH^3$	—	0.80	—	mA
Logic High Level Output Voltage	$V_{OH}$	$DRV[1:0] = HL$	$V_{DD} \times 0.8$	—	—	V
Logic Low Level Output Voltage	$V_{OL}$	$DRV[1:0] = HL$	—	—	$V_{DD} \times 0.2$	V

**Notes:**

1. All minimum and maximum values are guaranteed across the recommended operating conditions of supply voltage and from −40 to +85 °C unless otherwise stated. All typical values apply at  $V_{DD} = 3.3 \text{ V}$  and 25 °C unless otherwise stated.
2. 6.7 ns is typical for GPIO0 rise time.
3. Assuming  $V_{DD} = 3.3 \text{ V}$ , drive strength is specified at  $V_{oh}(\text{min}) = 2.64 \text{ V}$  and  $V_{ol}(\text{max}) = 0.66 \text{ V}$  at room temperature.
4. 2.4 ns is typical for GPIO0 fall time.

**Table 7. Thermal Characteristics**

Parameter	Symbol	Value	Unit
Operating Ambient Temperature Range	$T_A$	–40 to +85	°C
Thermal Impedance Junction to Ambient*	$\theta_{JA}$	25	°C/w
Junction Temperature Maximum Value*	$T_j$	+105	°C
Storage Temperature Range	$T_{STG}$	–55 to +150	°C
*Note: $\theta_{JA}$ and $T_j$ are based on RF evaluation board measurements.			

**Table 8. Absolute Maximum Ratings**

Parameter	Value	Unit
$V_{DD}$ to GND	–0.3, +3.8	V
Instantaneous $V_{RF-peak}$ to GND on TX Output Pin	–0.3, +8.0	V
Sustained $V_{RF-peak}$ to GND on TX Output Pin	–0.3, +6.5	V
Voltage on Analog Inputs	–0.7, $V_{DD} + 0.3$	V
RX Input Power	+10	dBm
<b>Note:</b> Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only and functional operation of the device at or beyond these ratings in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Power Amplifier may be damaged if switched on without proper load or termination connected. TX matching network design will influence TX $V_{RF-peak}$ on TX output pin. Caution: ESD sensitive device.		

## 2. Functional Description

The Si446x devices are high-performance, low-current, wireless ISM transceivers that cover the sub-GHz bands. The wide operating voltage range of 1.8–3.8 V and low current consumption make the Si446x an ideal solution for battery powered applications. The Si446x operates as a time division duplexing (TDD) transceiver where the device alternately transmits and receives data packets. The device uses a single-conversion mixer to downconvert the 2/4-level FSK/GFSK or OOK modulated receive signal to a low IF frequency. Following a programmable gain amplifier (PGA) the signal is converted to the digital domain by a high performance  $\Delta\Sigma$  ADC allowing filtering, demodulation, slicing, and packet handling to be performed in the built-in DSP increasing the receiver's performance and flexibility versus analog based architectures. The demodulated signal is output to the system MCU through a programmable GPIO or via the standard SPI bus by reading the 64-byte RX FIFO.

A single high precision local oscillator (LO) is used for both transmit and receive modes since the transmitter and receiver do not operate at the same time. The LO is generated by an integrated VCO and  $\Delta\Sigma$  Fractional-N PLL synthesizer. The synthesizer is designed to support configurable data rates from 100 bps to 1 Mbps. The Si4463/61/60 operate in the frequency bands of 142–175, 283–350, 350–525, and 850–1050 MHz with a maximum frequency accuracy step size of 28.6 Hz. The transmit FSK data is modulated directly into the  $\Delta\Sigma$  data stream and can be shaped by a Gaussian low-pass filter to reduce unwanted spectral content.

The Si4463 contains a power amplifier (PA) that supports output power up to +20 dBm with very high efficiency, consuming only 70 mA at 169 MHz and 85 mA at 915 MHz. The integrated +20 dBm power amplifier can also be used to compensate for the reduced performance of a lower cost, lower performance antenna or antenna with size constraints due to a small form-factor. Competing solutions require large and expensive external PAs to achieve comparable performance. The Si4461 supplies output power up to +16 dBm. The Si4460 is designed to support single coin cell operation with current consumption below 18 mA for +10 dBm output power. Two match topologies are available for the Si4461 and Si4460, class-E and switched-current. Class-E matching provides optimal current consumption, while switched-current matching demonstrates the best performance over varying battery voltage and temperature with slightly higher current consumption. The PA is single-ended to allow for easy antenna matching and low BOM cost. The PA incorporates automatic ramp-up and ramp-down control to reduce unwanted spectral spreading. The Si446x family supports frequency hopping, TX/RX switch control, and antenna diversity switch control to extend the link range and improve performance. Built-in antenna diversity and support for frequency hopping can be used to further extend range and enhance performance. Antenna diversity is completely integrated into the Si446x and can improve the system link budget by 8–10 dB, resulting in substantial range increases under adverse environmental conditions. A highly configurable packet handler allows for autonomous encoding/decoding of nearly any packet structure. Additional system features, such as an automatic wake-up timer, low battery detector, 64 byte TX/RX FIFOs, and preamble detection, reduce overall current consumption and allows for the use of lower-cost system MCUs. An integrated temperature sensor, power-on-reset (POR), and GPIOs further reduce overall system cost and size. The Si446x is designed to work with an MCU, crystal, and a few passive components to create a very low-cost system.

The application shown in Figure 1 is designed for a system with a TX/RX direct-tie configuration without the use of a TX/RX switch. Most applications with output power less than 17 dBm will use this configuration. Figure 2 demonstrates an application for +20 dBm using an external T/R-switch.

## 3. Controller Interface

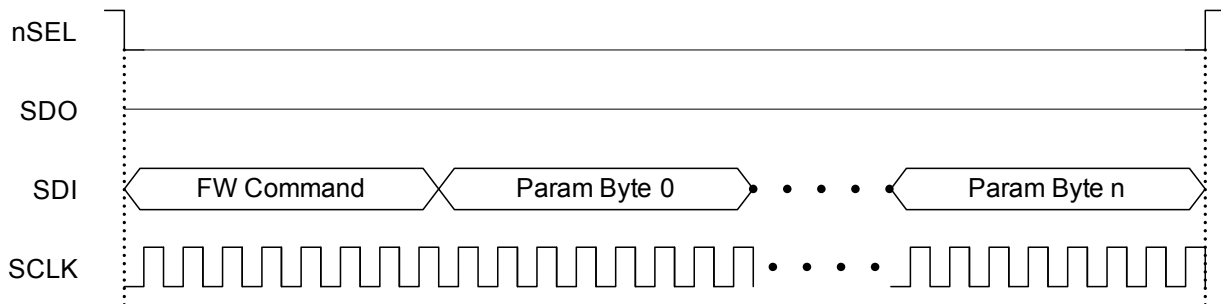

### 3.1. Serial Peripheral Interface (SPI)

The Si446x communicates with the host MCU over a standard 4-wire serial peripheral interface (SPI): SCLK, SDI, SDO, and nSEL. The SPI interface is designed to operate at a maximum of 10 MHz. The SPI timing parameters are demonstrated in Table 9. The host MCU writes data over the SDI pin and can read data from the device on the SDO output pin. Figure 3 demonstrates an SPI write command. The nSEL pin should go low to initiate the SPI command. The first byte of SDI data will be one of the firmware commands followed by n bytes of parameter data which will be variable depending on the specific command. The rising edges of SCLK should be aligned with the center of the SDI data.

**Table 9. Serial Interface Timing Parameters**

Symbol	Parameter	Min (ns)	Max (ns)	Diagram
$t_{CH}$	Clock high time	40		<p>The diagram illustrates the timing relationships for an SPI write command. It shows four signals: SCLK (Serial Clock), SDI (Serial Data In), SDO (Serial Data Out), and nSEL (Chip Select). The SCLK signal is a periodic square wave. The SDI signal is a single pulse that occurs during the clock high periods. The SDO signal is a single pulse that occurs during the clock low periods. The nSEL signal is a pulse that occurs before the first clock edge and after the last clock edge. The timing parameters are labeled as follows: <math>t_{SS}</math> (Select setup time), <math>t_{SH}</math> (Select hold time), <math>t_{SW}</math> (Select high period), <math>t_{CL}</math> (Clock low time), <math>t_{CH}</math> (Clock high time), <math>t_{DS}</math> (Data setup time), <math>t_{DH}</math> (Data hold time), <math>t_{DD}</math> (Output data delay time), <math>t_{DE}</math> (Output disable time), and <math>t_{tsw}</math> (Transition time).</p>
$t_{CL}$	Clock low time	40		
$t_{DS}$	Data setup time	20		
$t_{DH}$	Data hold time	20		
$t_{DD}$	Output data delay time		43	
$t_{DE}$	Output disable time		45	
$t_{SS}$	Select setup time	20		
$t_{SH}$	Select hold time	50		
$t_{SW}$	Select high period	80		

**\*Note:** CL = 10 pF; VDD = 1.8 V; SDO Drive strength setting = 10.

**Figure 3. SPI Write Command**

The Si446x contains an internal MCU which controls all the internal functions of the radio. For SPI read commands a typical MCU flow of checking clear-to-send (CTS) is used to make sure the internal MCU has executed the command and prepared the data to be output over the SDO pin. Figure 4 demonstrates the general flow of an SPI read command. Once the CTS value reads FFh then the read data is ready to be clocked out to the host MCU. The typical time for a valid FFh CTS reading is 20  $\mu$ s. Figure 5 demonstrates the remaining read cycle after CTS is set to FFh. The internal MCU will clock out the SDO data on the negative edge so the host MCU should process the SDO data on the rising edge of SCLK.

Firmware Flow**Figure 4. SPI Read Command—Check CTS Value****Figure 5. SPI Read Command—Clock Out Read Data**

## 3.2. Fast Response Registers

The fast response registers are registers that can be read immediately without the requirement to monitor and check CTS. There are four fast response registers that can be programmed for a specific function. The fast response registers can be read through API commands, 0x50 for Fast Response A, 0x51 for Fast Response B, 0x53 for Fast Response C, and 0x57 for Fast Response D. The fast response registers can be configured by the "FRR\_CTL\_X\_MODE" properties.

The fast response registers may be read in a burst fashion. After the initial 16 clock cycles, each additional eight clock cycles will clock out the contents of the next fast response register in a circular fashion. The value of the FRRs will not be updated unless NSEL is toggled.

## 3.3. Operating Modes and Timing

The primary states of the Si446x are shown in Figure 6. The shutdown state completely shuts down the radio to minimize current consumption. Standby/Sleep, SPI Active, Ready, TX Tune, and RX tune are available to optimize the current consumption and response time to RX/TX for a given application. API commands START\_RX, START\_TX, and CHANGE\_STATE control the operating state with the exception of shutdown which is controlled by SDN, pin 1. Table 10 shows each of the operating modes with the time required to reach either RX or TX mode as well as the current consumption of each mode. The times in Table 9 are measured from the rising edge of nSEL until the chip is in the desired state. Note that these times are indicative of state transition timing but are not guaranteed and should only be used as a reference data point. An automatic sequencer will put the chip into RX or TX from any state. It is not necessary to manually step through the states. To simplify the diagram it is not shown but any of the lower power states can be returned to automatically after RX or TX.

Figure 6. State Machine Diagram

**Table 10. Operating State Response Time and Current Consumption**

State/Mode	Response Time to		Current in State /Mode
	TX	RX	
Shutdown State	15 ms	15 ms	30 nA
Standby State	440 $\mu$ s	440 $\mu$ s	40 nA
Sleep State	440 $\mu$ s	440 $\mu$ s	740 nA
SPI Active State	340 $\mu$ s	340 $\mu$ s	1.35 mA
Ready State	100 $\mu$ s	100 $\mu$ s	1.8 mA
TX Tune State	58 $\mu$ s	—	7.8 mA
RX Tune State	—	60 $\mu$ s	7.6 mA
TX State	—	100 $\mu$ s	18 mA @ +10 dBm
RX State	100 $\mu$ s	75 $\mu$ s	10.9 or 13.7 mA

**Note:** TX→RX and RX→TX state transition timing can be reduced to 70  $\mu$ s if using Zero-IF mode.

Figure 7 shows the POR timing and voltage requirements. The power consumption (battery life) depends on the duty cycle of the application or how often the part is in either Rx or Tx state. In most applications the utilization of the standby state will be most advantageous for battery life but for very low duty cycle applications shutdown will have an advantage. For the fastest timing the next state can be selected in the START\_RX or START\_TX API commands to minimize SPI transactions and internal MCU processing.

### 3.3.1. Power on Reset (POR)

A Power On Reset (POR) sequence is used to boot the device up from a fully off or shutdown state. To execute this process, VDD must ramp within 1ms and must remain applied to the device for at least 10 ms. If VDD is removed, then it must stay below 0.15 V for at least 10 ms before being applied again. See Figure 7 and Table 11 for details.

**Figure 7. POR Timing Diagram**

**Table 11. POR Timing**

Variable	Description	Min	Typ	Max	Units
$t_{PORH}$	High time for VDD to fully settle POR circuit	10			ms
$t_{PORL}$	Low time for VDD to enable POR	10			ms
$V_{RRH}$	Voltage for successful POR	90% x Vdd			V
$V_{RRL}$	Starting Voltage for successful POR	0		150	mV
$t_{SR}$	Slew rate of VDD for successful POR			1	ms

### 3.3.2. Shutdown State

The shutdown state is the lowest current consumption state of the device with nominally less than 30 nA of current consumption. The shutdown state may be entered by driving the SDN pin (Pin 1) high. The SDN pin should be held low in all states except the shutdown state. In the shutdown state, the contents of the registers are lost and there is no SPI access. When coming out of the shutdown state a power on reset (POR) will be initiated along with the internal calibrations. After the POR the POWER\_UP command is required to initialize the radio. The SDN pin needs to be held high for at least 10us before driving low again so that internal capacitors can discharge. Not holding the SDN high for this period of time may cause the POR to be missed and the device to boot up incorrectly. If POR timing and voltage requirements cannot be met, it is highly recommended that SDN be controlled using the host processor rather than tying it to GND on the board.

### 3.3.3. Standby State

Standby state has the lowest current consumption with the exception of shutdown but has much faster response time to RX or TX mode. In most cases standby should be used as the low power state. In this state the register values are maintained with all other blocks disabled. The SPI is accessible during this mode but any SPI event, including FIFO R/W, will enable an internal boot oscillator and automatically move the part to SPI active state. After an SPI event the host will need to re-command the device back to standby through the “Change State” API command to achieve the 40 nA current consumption. If an interrupt has occurred (i.e., the nIRQ pin = 0) the interrupt registers must be read to achieve the minimum current consumption of this mode.

### 3.3.4. Sleep State

Sleep state is the same as standby state but the wake-up-timer and a 32 kHz clock source are enabled. The source of the 32 kHz clock can either be an internal 32 kHz RC oscillator which is periodically calibrated or a 32 kHz oscillator using an external XTAL. The SPI is accessible during this mode but an SPI event will enable an internal boot oscillator and automatically move the part to SPI active mode. After an SPI event the host will need to re-command the device back to sleep. If an interrupt has occurred (i.e., the nIRQ pin = 0) the interrupt registers must be read to achieve the minimum current consumption of this mode.

### 3.3.5. SPI Active State

In SPI active state the SPI and a boot up oscillator are enabled. After SPI transactions during either standby or sleep the device will not automatically return to these states. A “Change State” API command will be required to return to either the standby or sleep modes.

### 3.3.6. Ready State

Ready state is designed to give a fast transition time to TX or RX state with reasonable current consumption. In this mode the Crystal oscillator remains enabled reducing the time required to switch to TX or RX mode by eliminating the crystal start-up time.

### 3.3.7. TX State

The TX state may be entered from any of the state with the “Start TX” or “Change State” API commands. A built-in sequencer takes care of all the actions required to transition between states from enabling the crystal oscillator to ramping up the PA. The following sequence of events will occur automatically when going from standby to TX state.

1. Enable internal LDOs.
2. Start up crystal oscillator and wait until ready (controlled by an internal timer).

3. Enable PLL.
4. Calibrate VCO/PLL.
5. Wait until PLL settles to required transmit frequency (controlled by an internal timer).
6. Activate power amplifier and wait until power ramping is completed (controlled by an internal timer).
7. Transmit packet.

Steps in this sequence may be eliminated depending on which state the chip is configured to prior to commanding to TX. By default, the VCO and PLL are calibrated every time the PLL is enabled. When the START\_TX API command is utilized the next state may be defined to ensure optimal timing and turnaround.

Figure 8 shows an example of the commands and timing for the START\_TX command. CTS will go high as soon as the sequencer puts the part into TX state. As the sequencer is stepping through the events listed above, CTS will be low and no new commands or property changes are allowed. If the Fast Response (FRR) or nIRQ is used to monitor the current state there will be slight delay caused by the internal hardware from when the event actually occurs to when the transition occurs on the FRR or nIRQ. The time from entering TX state to when the FRR will update is 5  $\mu$ s and the time to when the nIRQ will transition is 13  $\mu$ s. If a GPIO is programmed for TX state or used as control for a transmit/receive switch (TR switch) there is no delay.

**Figure 8. Start\_TX Commands and Timing**

### 3.3.8. RX State

The RX state may be entered from any of the other states by using the “Start RX” or “Change State” API command. A built-in sequencer takes care of all the actions required to transition between states. The following sequence of events will occur automatically to get the chip into RX mode when going from standby to RX state:

1. Enable the digital LDO and the analog LDOs.
2. Start up crystal oscillator and wait until ready (controlled by an internal timer).
3. Enable PLL.
4. Calibrate VCO
5. Wait until PLL settles to required receive frequency (controlled by an internal timer).
6. Enable receiver circuits: LNA, mixers, and ADC.
7. Enable receive mode in the digital modem.

Depending on the configuration of the radio, all or some of the following functions will be performed automatically by the digital modem: AGC, AFC (optional), update status registers, bit synchronization, packet handling (optional) including sync word, header check, and CRC. Similar to the TX state, the next state after RX may be defined in the “Start RX” API command. The START\_RX commands and timing will be equivalent to the timing shown in Figure 8.

## 3.4. Application Programming Interface (API)

An application programming interface (API), which the host MCU will communicate with, is embedded inside the device. The API is divided into two sections, commands and properties. The commands are used to control the chip and retrieve its status. The properties are general configurations which will change infrequently. The API descriptions can be found on the [Silicon Labs website](#).

## 3.5. Interrupts

The Si446x is capable of generating an interrupt signal when certain events occur. The chip notifies the microcontroller that an interrupt event has occurred by setting the nIRQ output pin LOW = 0. This interrupt signal will be generated when any one (or more) of the interrupt events (corresponding to the Interrupt Status bits) occur. The nIRQ pin will remain low until the microcontroller reads the Interrupt Status Registers. The nIRQ output signal will then be reset until the next change in status is detected.

The interrupts sources are grouped into three groups: packet handler, chip status, and modem. The individual interrupts in these groups can be enabled/disabled in the interrupt property registers. An interrupt must be enabled for it to trigger an event on the nIRQ pin. The interrupt group must be enabled as well as the individual interrupts in API properties described in the API documentation.

Once an interrupt event occurs and the nIRQ pin is low there are two ways to read and clear the interrupts. All of the interrupts may be read and cleared in the "GET\_INT\_STATUS" API command. By default all interrupts will be cleared once read. If only specific interrupts want to be read in the fastest possible method the individual interrupt groups (Packet Handler, Chip Status, Modem) may be read and cleared by the "GET\_MODEM\_STATUS", "GET\_PH\_STATUS" (packet handler), and "GET\_CHIP\_STATUS" API commands.

The instantaneous status of a specific function maybe read if the specific interrupt is enabled or disabled. The status results are provided after the interrupts and can be read with the same commands as the interrupts. The status bits will give the current state of the function whether the interrupt is enabled or not.

The fast response registers can also give information about the interrupt groups but reading the fast response registers will not clear the interrupt and reset the nIRQ pin.

### 3.6. GPIO

Four general purpose IO pins are available to utilize in the application. The GPIO are configured by the GPIO\_PIN\_CFG command in address 13h. For a complete list of the GPIO options please see the API guide. GPIO pins 0 and 1 should be used for active signals such as data or clock. GPIO pins 2 and 3 have more susceptibility to generating spurious in the synthesizer than pins 0 and 1. The drive strength of the GPIOs can be adjusted with the GEN\_CONFIG parameter in the GPIO\_PIN\_CFG command. By default the drive strength is set to minimum. The default configuration for the GPIOs and the state during SDN is shown below in Table 12. The state of the IO during shutdown is also shown in Table 12. As indicated previously in Table 6, GPIO 0 has lower drive strength than the other GPIOs.

**Table 12. GPIOs**

Pin	SDN State	POR Default
GPIO0	0	POR
GPIO1	0	CTS
GPIO2	0	POR
GPIO3	0	POR
nIRQ	resistive VDD pull-up	nIRQ
SDO	resistive VDD pull-up	SDO
SDI	High Z	SDI
SCLK	High Z	SCLK
NSEL	High Z	NSEL

## 4. Modulation and Hardware Configuration Options

The Si446x supports different modulation options and can be used in various configurations to tailor the device to any specific application or legacy system for drop in replacement. The modulation and configuration options are set in API property, MODEM\_MOD\_TYPE. Refer to the API documentation for details on modem related properties.

### 4.1. Modulation Types

The Si446x supports five different modulation options: Gaussian frequency shift keying (GFSK), frequency-shift keying (FSK), four-level GFSK (4GFSK), four-level FSK (4FSK), and on-off keying (OOK). Minimum shift keying (MSK) can also be created by using GFSK with the appropriate modulation index ( $h = 0.5$ ). GFSK is the recommended modulation type as it provides the best performance and cleanest modulation spectrum. The modulation type is set by the “MOD\_TYPE[2:0]” field in the “MODEM\_MOD\_TYPE” API property. A continuous-wave (CW) carrier may also be selected for RF evaluation purposes. The modulation source may also be selected to be a pseudo-random source for evaluation purposes.

### 4.2. Hardware Configuration Options

There are different receive demodulator options to optimize the performance and mutually-exclusive options for how the RX/TX data is transferred from the host MCU to the RF device.

#### 4.2.1. Receive Demodulator Options

There are multiple demodulators integrated into the device to optimize the performance for different applications, modulation formats, and packet structures. The calculator built into WDS will choose the optimal demodulator based on the input criteria.

##### 4.2.1.1. Synchronous Demodulator

The synchronous demodulator's internal frequency error estimator acquires the frequency error based on a 101010 preamble structure. The bit clock recovery circuit locks to the incoming data stream within four transactions of a “10” or “01” bit stream. The synchronous demodulator gives optimal performance for 2- or 4-level (G)FSK modulation that has a modulation index less than 2.

##### 4.2.1.2. Asynchronous Demodulator

The asynchronous demodulator should be used for OOK modulation and for (G)FSK modulation under one or more of the following conditions:

- Modulation index  $\geq 2$
- Non-standard preamble (not 1010101... pattern)

When the modulation index exceeds 2, the asynchronous demodulator has better sensitivity compared to the synchronous demodulator. An internal deglitch circuit provides a glitch-free data output and a data clock signal to simplify the interface to the host. There is no requirement to perform deglitching in the host MCU. The asynchronous demodulator will typically be utilized for legacy systems and will have many performance benefits over devices used in legacy designs. Unlike the Si4432/31 solution for non-standard packet structures, there is no requirement to perform deglitching on the data in the host MCU. Glitch-free data is output from Si446x devices, and a sample clock for the asynchronous data can also be supplied to the host MCU; so, oversampling or bit clock recovery is not required by the host MCU. There are multiple detector options in the asynchronous demodulator block, which will be selected based upon the options entered into the WDS calculator. The asynchronous demodulator's internal frequency error estimator is able to acquire the frequency error based on any preamble structure.

##### 4.2.2. RX/TX Data Interface With MCU

There are two different options for transferring the data from the RF device to the host MCU. FIFO mode uses the SPI interface to transfer the data, while direct mode transfers the data in real time over a GPIO pin.

#### **4.2.2.1. FIFO Mode**

In FIFO mode, the transmit and receive data is stored in integrated FIFO register memory. The TX FIFO is accessed by writing command 66h followed directly by the data/clock that the host wants to write into the TX FIFO. The RX FIFO is accessed by writing command 77h followed by the number of clock cycles of data the host would like to read out of the RX FIFO. The RX data will be clocked out onto the SDO pin.

In TX FIFO mode, the data bytes stored in FIFO memory are “packaged” together with other fields and bytes of information to construct the final transmit packet structure. These other potential fields include the Preamble, Sync word, and CRC checksum. In TX mode, the packet structure may be highly customized by enabling or disabling individual fields; for example, it is possible to disable both the Preamble and Sync Word fields and to load the entire packet structure into FIFO memory. For further information on the configuration of the FIFOs for a specific application or packet size, see “6. Data Handling and Packet Handler” on page 38. In RX mode, the Packet Handler must be enabled to allow storage of received data bytes into RX FIFO memory. The Packet Handler is required to detect the Sync Word, and proper detection of the Sync Word is required to determine the start of the Payload. All bytes after the Sync Word are stored in RX FIFO memory except the CRC checksum and (optionally) the variable packet length byte(s). When the FIFO is being used in RX mode, all of the received data may still be observed directly (in realtime) by properly programming a GPIO pin as the RXDATA output pin; this can be quite useful during application development. When in FIFO mode, the chip will automatically exit the TX or RX State when either the PACKET\_SENT or PACKET\_RX interrupt occurs. The chip will return to the state programmed in the argument of the “START TX” or “START RX” API command, TXCOMPLETE\_STATE[3:0] or RXVALID\_STATE[3:0]. For example, the chip may be placed into READY mode after a TX packet by sending the “START TX” command and by writing 30h to the TXCOMPLETE\_STATE[3:0] argument. The chip will transmit all of the contents of the FIFO, and the PACKET\_SENT interrupt will occur. When this event occurs, the chip will return to the READY state as defined by TXCOMPLETE\_STATE[3:0] = 30h.

#### **4.2.2.2. FIFO Direct Mode (Infinite Receive)**

In some applications, there is a need to receive extremely long packets (greater than 40 kB) while relying on preamble and sync word detection from the on-chip packet handler. In these cases, the packet length is unknown, and the device will load the bits after the sync word into the RX FIFO forever. Other features, such as Data Whitening, CRC, Manchester, etc., are supported in this mode, but CRC calculation is not because the end of packet is unknown to the device. The RX data and clock are also available on GPIO pins. The host MCU will need to reset the packet handler by issuing a START\_RX to begin searching for a new packet.

#### **4.2.2.3. Automatic TX Packet Repeat**

In TX mode, there is an option to send the FIFO contents repeatedly with a user-defined number of times to repeat. This is limited to the FIFO size, and the entire contents of the packet including preamble and sync word need to be loaded into the TX FIFO. This is selectable via the START\_TX API, and packets will be sent without any gaps between them.

#### **4.2.2.4. Direct Mode**

For legacy systems that perform packet handling within the host MCU or other baseband chip, it may not be desirable to use the FIFO. For this scenario, a Direct mode is provided, which bypasses the FIFOs entirely. In TX Direct mode, the TX modulation data is applied to an input pin of the chip and processed in “real time” (i.e., not stored in a register for transmission at a later time). Any of the GPIOs may be configured for use as the TX Data input function. Furthermore, an additional pin may be required for a TX Clock output function if GFSK modulation is desired (only the TX Data input pin is required for FSK or OOK). To achieve direct mode, the desired GPIO pin must be configured as a digital input by setting the GPIO\_PIN\_CFG API command = enumeration 0x04 in addition to setting the MODEM\_MOD\_TYPE API property to source the TXDATA stream from that same GPIO pin. For GFSK, “TX\_DIRECT\_MODE\_TYPE” must be set to synchronous. For 2FSK or OOK, the type can be set to asynchronous or synchronous. The MOD\_SOURCE[1:0] field within the MODEM\_MOD\_TYPE property should be set = 0x01h for all Direct mode configurations. In RX Direct mode, the RX Data and RX Clock can be programmed for direct (real-time) output to GPIO pins. The microcontroller may then process the RX data without using the FIFO or packet handler functions of the RFIC.

## 4.3. Preamble Length

### 4.3.1. Digital Signal Arrival Detector (DSA)

Traditional preamble detection requires 20 bits to detect preamble. This device introduces a new approach to signal detection that can detect a preamble pattern in as little as one byte. If AFC is enabled, a preamble length of two bytes is sufficient to reliably detect signal arrival and settle a one-shot AFC. The impact of this is significant for low-power solutions as it reduces the amount of time the receiver has to stay active to detect the preamble. This feature is used with Preamble Sense Mode (see "8.6. Preamble Sense Mode" on page 42) and the latest WMBus N modes as well as with features, such as frequency hopping, which may use signal arrival as a condition to hop. The traditional preamble detector is also available to maintain backward compatibility. Note that the DSA is using the RSSI jump detector. When used for collision detection, the RSSI jump detector may need to be reconfigured after preamble detection. Refer to the API documentation for details on how to configure the device to use the signal arrival detector.

### 4.3.2. Traditional Preamble Detection

Optimal performance of the chip is obtained by qualifying reception of a valid Preamble pattern prior to continuing with reception of the remainder of the packet (e.g., Sync Word and Payload). Reception of the Preamble is considered valid when a minimum number of consecutive bits of 101010... pattern have been received; the required threshold for preamble detection is specified by the RX\_THRESH[6:0] field in the PREAMBLE\_CONFIG\_STD\_1 property. The appropriate value of the detection threshold depends upon the system application and typically trades off speed of acquisition against the probability of false detection. If the detection threshold is set too low, the chip may readily detect the short pattern within noise; the chip then proceeds to attempt to detect the remainder of the non-existent packet, with the result that the arrival of an actual valid packet may be missed. If the detection threshold is set too high, the required number of transmitted Preamble bits must be increased accordingly, leading to longer packet lengths and shorter battery life. A preamble detection threshold value of 20 bits is suitable for most applications. The total length of the transmitted Preamble field must be at least equal to the receive preamble detection threshold, plus an additional number of bits to allow for acquisition of bit timing and settling of the AFC algorithm. The recommended preamble detection thresholds and preamble lengths for a variety of operational modes are listed in Table 13.

Configuration of the preamble detection threshold in the RX\_THRESH[6:0] field is only required for reception of a standard Preamble pattern (i.e., 101010... pattern). Reception of a repetitive but non-standard Preamble pattern is also supported in the chip but is configured through the PREAMBLE\_CONFIG\_NSTD and PREAMBLE\_PATTERN properties.

Table 13. Recommended Preamble Length

Mode	AFC	Antenna Diversity	Preamble Type	Recommended Preamble Length	Recommended Preamble Detection Threshold
(G)FSK	Disabled	Disabled	Standard	4 Bytes	20 bits
(G)FSK	Enabled	Disabled	Standard	5 Bytes	20 bits
(G)FSK	Disabled	Disabled	Non-standard	2 Bytes	0 bits
(G)FSK	Enabled		Non-standard	Not Supported	
(G)FSK	Disabled	Enabled	Standard	7 Bytes	24 bits
(G)FSK	Enabled	Enabled	Standard	8 Bytes	24 bits
4(G)FSK	Disabled	Disabled	Standard	40 symbols	16 symbols
4(G)FSK	Enabled	Disabled	Standard	48 symbols	16 symbols
4(G)FSK			Non-standard	Not Supported	
OOK	Disabled	Disabled	Standard	4 Bytes	20 bits
OOK	Disabled	Disabled	Non-standard	2 Bytes	0 bits
OOK	Enabled			Not Supported	

**Notes:**

1. The recommended preamble length and preamble detection thresholds listed above are to achieve 0% PER. They may be shortened when occasional packet errors are tolerable.
2. All recommended preamble lengths and detection thresholds include AGC and BCR settling times.
3. "Standard" preamble type should be set for an alternating data sequence at the max data rate (...10101010...)
4. "Non-standard" preamble type can be set for any preamble type including ...10101010...
5. When preamble detection threshold = 0, sync word needs to be 3 Bytes to avoid false syncs. When only a 2 Byte sync word is available the sync word detection can be extended by including the last preamble Byte into the RX sync word setting.

## 5. Internal Functional Blocks

The following sections provide an overview to the key internal blocks and features.

### 5.1. RX Chain

The internal low-noise amplifier (LNA) is designed to be a wide-band LNA that can be matched with three or four external discrete components to cover any common range of frequencies in the sub-GHz band. The LNA has extremely low noise to suppress the noise of the following stages and achieve optimal sensitivity; so, no external gain or front-end modules are necessary. The LNA has gain control, which is controlled by the internal automatic gain control (AGC) algorithm. The LNA is followed by an I-Q mixer, filter, programmable gain amplifier (PGA), and ADC. The I-Q mixers downconvert the signal to an intermediate frequency. The PGA then boosts the gain to be within dynamic range of the ADC. The ADC rejects out-of-band blockers and converts the signal to the digital domain where filtering, demodulation, and processing is performed. Peak detectors are integrated at the output of the LNA and PGA for use in the AGC algorithm.

The RX and TX pins may be directly tied externally for output powers less than +17 dBm in the higher-frequency bands and can support +20 dBm in the lower bands, such as 169MHz. This reduces BOM cost by saving the expense of a switch for single antenna solutions. See the direct-tie reference designs on the Silicon Labs web site for more details.

#### 5.1.1. RX Chain Architecture

It is possible to operate the RX chain in different architecture configurations: fixed-IF, zero-IF, and scaled-IF. There are trade-offs between the architectures in terms of sensitivity, selectivity, and image rejection. Fixed-IF is the default configuration and is recommended for most applications. With 35 dB native image rejection and autonomous image calibration to achieve 55 dB, the fixed-IF solution gives the best performance for most applications. Fixed-IF obtains the best sensitivity, but it has the effect of degraded selectivity at the image frequency. An autonomous image rejection calibration is included in Si446x devices and described in more detail in "5.2.3. Image Rejection and Calibration" on page 30. For scaled-IF and zero-IF, the sensitivity is degraded for data rates less than 100 kbps or bandwidths less than 200 kHz. The reduction in sensitivity is caused by increased flicker noise as dc is approached. The benefit of zero-IF is that there is no image frequency; so, there is no degradation in the selectivity curve, but it has the worst sensitivity. Scaled-IF is a trade-off between fixed-IF and zero-IF. In the scaled-IF architecture, the image frequency is placed or hidden in the adjacent channel where it only slightly degrades the typical adjacent channel selectivity. The scaled-IF approach has better sensitivity than zero-IF but still some degradation in selectivity due to the image. In scaled-IF mode, the image frequency is directly proportional to the channel bandwidth selected. Figure 9 demonstrates the trade-off in sensitivity between the different architecture options.

Figure 9. RX Architecture vs. Data Rate

## **5.2. RX Modem**

Using high-performance ADCs allows channel filtering, image rejection, and demodulation to be performed in the digital domain, which allows for flexibility in optimizing the device for particular applications. The digital modem performs the following functions:

- Channel selection filter
- TX modulation
- RX demodulation
- Automatic Gain Control (AGC)
- Preamble detection
- Invalid preamble detection
- Radio signal strength indicator (RSSI)
- Automatic frequency compensation (AFC)
- Image Rejection Calibration
- Packet handling
- Cyclic redundancy check (CRC)

The digital channel filter and demodulator are optimized for ultra-low-power consumption and are highly configurable. Supported modulation types are GFSK, FSK, 4GFSK, 4FSK, GMSK, and OOK. The channel filter can be configured to support bandwidths ranging from 850 kHz down to 1.1 kHz. A large variety of data rates are supported ranging from 100 bps up to 1 Mbps. The configurable preamble detector is used with the synchronous demodulator to improve the reliability of the sync-word detection. Preamble detection can be skipped using only sync detection, which is a valuable feature in some applications. The received signal strength indicator (RSSI) provides a measure of the signal strength received on the tuned channel. The resolution of the RSSI is 0.5 dB. This high-resolution RSSI enables accurate channel power measurements for clear channel assessment (CCA), carrier sense (CS), and listen before talk (LBT) functionality. A comprehensive programmable packet handler is integrated to create a variety of communication topologies ranging from peer-to-peer networks to mesh networks. The extensive programmability of the packet header allows for advanced packet filtering, which, in turn enables a mix of broadcast, group, and point-to-point communication. A wireless communication channel can be corrupted by noise and interference, so it is important to know if the received data is free of errors. A cyclic redundancy check (CRC) is used to detect the presence of erroneous bits in each packet. A CRC is computed and appended at the end of each transmitted packet and verified by the receiver to confirm that no errors have occurred. The packet handler and CRC can significantly reduce the load on the system microcontroller allowing for a simpler and cheaper microcontroller. The digital modem includes the TX modulator, which converts the TX data bits into the corresponding stream of digital modulation values to be summed with the fractional input to the sigma-delta modulator. This modulation approach results in highly accurate resolution of the frequency deviation. A Gaussian filter is implemented to support GFSK and 4GFSK, considerably reducing the energy in adjacent channels. The default bandwidth-time product (BT) is 0.5 for all programmed data rates, but it may be adjusted to other values.

### **5.2.1. Automatic Gain Control (AGC)**

The AGC algorithm is implemented digitally using an advanced control loop optimized for fast response time. The AGC occurs within a single bit or in less than 2  $\mu$ s. Peak detectors at the output of the LNA and PGA allow for optimal adjustment of the LNA gain and PGA gain to optimize IM3, selectivity, and sensitivity performance.

### **5.2.2. Auto Frequency Correction (AFC)**

Frequency mistuning caused by crystal inaccuracies can be compensated for by enabling the digital automatic frequency control (AFC) in receive mode. There are two types of integrated frequency compensation: modem frequency compensation and AFC by adjusting the PLL frequency. With AFC disabled, the modem compensation can correct for frequency offsets up to  $\pm 0.25$  times the IF bandwidth. When the AFC is enabled, the received signal is centered in the passband of the IF filter, providing optimal sensitivity and selectivity over a wider range of frequency offsets up to  $\pm 0.35$  times the IF bandwidth. When AFC is enabled, the preamble length needs to be long enough to settle the AFC. As shown in Table 13 on page 27, an additional byte of preamble is typically required to settle the AFC.

## 5.2.3. Image Rejection and Calibration

Since the receiver utilizes a low-IF architecture, the selectivity will be affected by the image frequency. The IF frequency is 468.75 kHz (Fxtal/64), and the image frequency will be at 937.5 kHz (2 x Fxtal/64) below the RF frequency. The native image rejection of the Si446x family is 40 dB. Image rejection calibration is available in the Si446x to improve the image rejection to more than 55 dB. The calibration is initiated with the IRCAL API command. The calibration uses an internal signal source, so no external signal generator is required. The initial calibration takes 250 ms, and periodic re-calibration takes 100 ms. Recalibration should be initiated when the temperature has changed more than 30 °C.

## 5.2.4. Received Signal Strength Indicator

The received signal strength indicator (RSSI) is an estimate of the signal strength in the channel to which the receiver is tuned. The RSSI measurement is done after the channel filter, so it is only a measurement of the in-band signal power (desired or undesired). There are two methods for reading the RSSI value and several different options for configuring the returned RSSI value. The fastest method for reading the RSSI is to configure one of the four fast response registers (FRR) to return a latched RSSI value. The latched RSSI value is measured once per packet and is latched at a configurable amount of time after RX mode is entered. The fast response registers can be read in 16 SPI clock cycles with no requirement to wait for CTS. The RSSI value may also be read out of the GET\_MODEM\_STATUS command. In this command, both the current RSSI and the latched RSSI are available. The current RSSI value represents the signal strength at the instant in time the GET\_MODEM\_STATUS command is processed and may be read multiple times per packet. Reading the RSSI in the GET\_MODEM\_STATUS command takes longer than reading the RSSI out of the fast response register. After the initial command, it takes 33 µs for CTS to be set and then the four or five bytes of SPI clock cycles to read out the respective current or latched RSSI values.

The RSSI configuration options are set in the MODEM\_RSSI\_CONTROL API property. The latched RSSI value may be latched and stored based on the following events: preamble detection, sync detection, or a configurable number of bit times measured after the start of RX mode (minimum of 4 bit times). The requirement for a minimum of four bit times is determined by the processing delay and settling through the modem and digital channel filter. In MODEM\_RSSI\_CONTROL, the RSSI may be defined to update every bit period or to be averaged and updated every four bit periods. If RSSI averaging over four bits is enabled, the latched RSSI value will be delayed to a minimum of seven bits after the start of RX mode to allow for the averaging. The latched RSSI values are cleared when entering RX mode so they may be read after the packet is received or after dropping back to standby mode. If the RSSI value has been cleared by the start of RX but not yet latched, a value of 0 will be returned if it is attempted to be read.

The RSSI value read by the API may be translated into dBm by the following linear equation:

$$\text{RF\_Input\_Level\_dBm} = (\text{RSSI\_value} / 2) - \text{MODEM\_RSSI\_COMP} - 70$$

The MODEM\_RSSI\_COMP property provides for fine adjustment of the relationship between the actual RF input level (in dBm) and the returned RSSI value. That is, adjustment of this property allows the user to shift the RSSI vs RF Input Power curve up and down. This may be desirable to compensate for differences in front-end insertion loss between multiple designs (e.g., due to the presence of a SAW preselection filter, or an RF switch). A value of MODEM\_RSSI\_COMP = 0x40 = 64d is appropriate for most applications.

Clear channel assessment (CCA) or RSSI threshold detection is also available. An RSSI threshold may be set in the MODEM\_RSSI\_THRESH API property. If the Current RSSI value is above this threshold, an interrupt or GPIO may notify the host. Both the latched version and asynchronous version of this threshold are available on any of the GPIOs. Automatic fast hopping based on RSSI is available. See “5.3.1.2. Automatic RX Hopping and Hop Table”.

### 5.2.5. RSSI Jump Indicator (Collision Detection)

The chip is capable of detecting a jump in RSSI in either direction (i.e., either a signal increase or a signal decrease). Both polarities of jump detection may be enabled simultaneously, resulting in detection of a Jump-Up or Jump-Down event. This may be used to detect whether a secondary interfering signal (desired or undesired) has “collided” with reception of the current packet. An interrupt flag or GPIO pin may be configured to notify the host MCU of the Jump event. The change in RSSI level required to trigger the Jump event is programmable through the MODEM\_RSSI\_JUMP\_THRESH API property.

The chip may be configured to reset the RX state machine upon detection of an RSSI Jump, and thus to automatically begin reacquisition of the packet. The chip may also be configured to generate an interrupt.

This functionality is intended to detect an abrupt change in RSSI level and to not respond to a slow, gradual change in RSSI level. This is accomplished by comparing the difference in RSSI level over a programmable time period. In this fashion, the chip effectively evaluates the slope of the change in RSSI level.

The arrival of a desired packet (i.e., the transition from receiving noise to receiving a valid signal) will likely be detected as an RSSI Jump event. For this reason, it is recommended to enable this feature in mid-packet (i.e., after signal qualification, such as PREAMBLE\_VALID.) Refer to the API documentation for configuration options.

## 5.3. Synthesizer

An integrated Sigma Delta ( $\Sigma\Delta$ ) Fractional-N PLL synthesizer capable of operating over the bands from 142–175, 283–350, 350–525, and 850–1050 MHz. Using a  $\Sigma\Delta$  synthesizer has many advantages; it provides flexibility in choosing data rate, deviation, channel frequency, and channel spacing. The transmit modulation is applied directly to the loop in the digital domain through the fractional divider, which results in very precise accuracy and control over the transmit deviation. The frequency resolution in the 850–1050 MHz band is 28.6 Hz with finer resolution in the other bands. The nominal reference frequency to the PLL is 30 MHz, but any XTAL frequency from 25 to 32 MHz may be used. The modem configuration calculator in WDS will automatically account for the XTAL frequency being used. The PLL utilizes a differential LC VCO with integrated on-chip inductors. The output of the VCO is followed by a configurable divider, which will divide the signal down to the desired output frequency band.

### 5.3.1. Synthesizer Frequency Control

The frequency is set by changing the integer and fractional settings to the synthesizer. The WDS calculator will automatically provide these settings, but the synthesizer equation is shown below for convenience. The APIs for setting the frequency are `FREQ_CONTROL_INTE`, `FREQ_CONTROL_FRAC2`, `FREQ_CONTROL_FRAC1`, and `FREQ_CONTROL_FRAC0`.

$$\text{RF\_channel} = \left( \text{fc\_inte} + \frac{\text{fc\_frac}}{2^{19}} \right) \times \frac{2 \times \text{freq\_xo}}{\text{outdiv}} (\text{Hz})$$

**Note:** The  $\text{fc\_frac}/2^{19}$  value in the above formula has to be a number between 1 and 2.

**Table 14. Output Divider (Outdiv) Values for the Si4463/61/60**

Outdiv	Lower (MHz)	Upper (MHz)
24	142	175
12	284	350
10	350	420
8	420	525
4	850	1050

## 5.3.1.1. EZ Frequency Programming

In applications that utilize multiple frequencies or channels, it may not be desirable to write four API registers each time a frequency change is required. EZ frequency programming is provided so that only a single register write (channel number) is required to change frequency. A base frequency is first set by first programming the integer and fractional components of the synthesizer. This base frequency will correspond to channel 0. Next, a channel step size is programmed into the `FREQ_CONTROL_CHANNEL_STEP_SIZE_1` and `FREQ_CONTROL_CHANNEL_STEP_SIZE_0` API registers. The resulting frequency will be:

$$\text{RF Frequency} = \text{Base Frequency} + \text{Channel} \times \text{Stepsize}$$

The second argument of the `START_RX` or `START_TX` is `CHANNEL`, which sets the channel number for EZ frequency programming. For example, if the channel step size is set to 1 MHz, the base frequency is set to 900 MHz with the `FREQ_CONTROL_INTE` and `FREQ_CONTROL_FRAC` API properties, and a `CHANNEL` number of 5 is programmed during the `START_TX` command, the resulting frequency will be 905 MHz. If no `CHANNEL` argument is written as part of the `START_RX/TX` command, it will default to the previously-programmed value. The initial value of `CHANNEL` is 0; so, if no `CHANNEL` value is written, it will result in the programmed base frequency.

## 5.3.1.2. Automatic RX Hopping and Hop Table

The transceiver supports an automatic RX hopping feature that can be fully configured through the API. This functionality is useful in applications where it is desired to look for packets but to hop to the next channel if a packet is not found. The sequence of channel numbers that are visited are specified by entries in a hop table. If this feature is enabled, the device will automatically start hopping through the channels listed in the hop table as soon as the chip enters RX mode.

The hop table can hold up to 64 entries and is maintained in firmware inside the RFIC. Each entry is a channel number, allowing construction of a frequency plan of up to 64 channels. The number of entries in the table is set by `RX_HOP_TABLE_SIZE` API. The specified channels correspond to the EZ frequency programming method for programming the frequency. The receiver starts at the base channel and hops in sequence from the top of the hop table to the bottom. The table will wrap around to the base channel once it reaches the end of the table. An entry of 0xFF in the table indicates that the entry should be skipped. The device will hop to the next entry in the table that contains a non-0xFF value.

There are three conditions that can be used to determine whether to continue hopping or to stay on a particular channel. These conditions are as follows:

- RSSI threshold
- Preamble timeout (invalid preamble pattern)
- Sync word timeout (invalid or no sync word detected after preamble)

These conditions can be used individually, or they can be enabled all together by configuring the `RX_HOP_CONTROL` API. However, the firmware will make a decision on whether or not to hop based on the first condition that is met.

The RSSI that is monitored is the current RSSI value. This is compared to the threshold value set in the `MODEM_RSSI_THRESH` API property, and, if it is above the threshold value, it will stay on the channel. If the RSSI is below the threshold, it will continue hopping. There is no averaging of RSSI done during the automatic hopping from channel to channel. Since the preamble timeout and the sync word timeout are features that require packet handling, the RSSI threshold is the only condition that can be used if the user is in “direct” or “RAW” mode where packet handling features are not used.

The RSSI threshold value may be converted to an approximate equivalent RF input power level through the equation shown in “5.2.4. Received Signal Strength Indicator” on page 30. However, performance should be verified on the bench to optimize the threshold setting for a given application.

The time spent in receive mode will be determined by the configuration of the hop conditions. Manual RX hopping will have the fastest turn-around time but will require more overhead and management by the host MCU.

The following are example steps for using Auto Hop:

1. Set the base frequency (inte + frac) and channel step size.
2. Define the number of entries in the hop table (RX\_HOP\_TABLE\_SIZE).
3. Write the channels to the hop table (RX\_HOP\_TABLE\_ENTRY\_n)
4. Configure the hop condition and enable auto hopping- RSSI, preamble, or sync (RX\_HOP\_CONTROL).
5. Set preamble and sync parameters if enabled.
6. Program the RSSI threshold property in the modem using "MODEM\_RSSI\_THRESH".
7. Set the preamble threshold using "PREAMBLE\_CONFIG\_STD\_1".
8. Program the preamble timeout property using "PREAMBLE\_CONFIG\_STD\_2".
9. Set the sync detection parameters if enabled.
10. If needed, use "GPIO\_PIN\_CFG" to configure a GPIO to toggle on hop and hop table wrap.
11. Use the "START\_RX" API with channel number set to the first valid entry in the hop table (i.e., the first non 0xFF entry).
12. Device should now be in auto hop mode.

### 5.3.1.3. Manual RX Hopping

The RX\_HOP command provides the fastest method for hopping from RX to RX but it requires more overhead and management by the host MCU. The timing is faster with this method than Start\_RX or RX hopping because one of the calculations required for the synthesizer calibrations is offloaded to the host and must be calculated/stored by the host, VCO\_CNT0. For VCO\_CNT values, download the Si446x RX\_HOP PLL calculator spreadsheet from the Si446x product website.

## 5.4. Transmitter (TX)

The Si4463 contains an integrated +20 dBm transmitter or power amplifier that is capable of transmitting from –20 to +20 dBm. The resolution of the programmable steps in output power is less than 0.25 dB when operated within 6 dB of the maximum power setting; the resolution of the steps in output power becomes coarser and more non-linear as the output power is reduced towards the minimum end of its control range. The Si4463 PA is designed to provide the highest efficiency and lowest current consumption possible. The Si4460 is designed to supply +10 dBm output power for less than 20 mA for applications that require operation from a single coin cell battery. The Si4460 can operate with Class-E matching and output up to +13 dBm Tx power at a supply voltage of VDD = 3.3 V. All PA options are single-ended to allow for easy antenna matching and low BOM cost. Automatic ramp-up and ramp-down is automatically performed to reduce unwanted spectral spreading. Refer to "AN627: Si4460/61 Low-Power PA Matching" and "AN648: PA Matching" for details on TX matching options.

The chip's TXRAMP pin is disabled by default to save current in cases where the on-chip PA provides sufficient output power to drive the antenna. In cases where on-chip PA will drive the external PA, and the external PA needs a ramping signal, TXRAMP is the signal to use. To enable TXRAMP, set the API Property PA\_MODE[7] = 1. TXRAMP will start to ramp up, and ramp down at the SAME time as the internal on-chip PA ramps up/down.

However, the time constant of the TXRAMP signal for the external PA is programmed independently of the ramp time constant for the on-chip PA. The ramp time constant for TXRAMP is programmed by the TC[3:0] field in the PA\_RAMP\_EX API property and provides the following approximate ramp times as a function of TC[3:0] value.

**Table 15. Ramp Times as a Function of TC[3:0] Value**

TC	Ramp Time (µs)
0	1.25
1	1.33
2	1.43
3	1.54
4	1.67
5	1.82
6	2.00
7	2.22
8	2.50
9	2.86
10	3.33
11	4.00
12	5.00
13	6.67
14	10.00
15	20.00

The ramping profile is close to a linear ramping profile with smoothed out corner when approaching Vhi and Vlo. The TXRAMP pin can source up to 1 mA without voltage drooping. The TXRAMP pin's sinking capability is equivalent to a 10 kΩ pull-down resistor.

Vhi = 3 V when Vdd > 3.3 V. When Vdd < 3.3 V, the Vhi will be closely following the Vdd, and ramping time will be smaller also.

Vlo = 0 V when NO current needed to be sunk into TXRAMP pin. If 10uA need to be sunk into the chip, Vlo will be 10 µA x 10k = 100 mV.

Number	Command	Summary
0x2200	PA_MODE	Sets PA type.
0x2201	PA_PWR_LVL	Adjust TX power in fine steps.
0x2202	PA_BIAS_CLKDUTY	Adjust TX power in coarse steps and optimizes for different match configurations.
0x2203	PA_TC	Changes the ramp up/down time of the PA.

#### 5.4.1. Si4463: +20 dBm PA

The +20 dBm configuration utilizes a class-E matching configuration for all frequency bands except 169 MHz where it uses a Square Wave match. Typical performance for the 915 MHz band for output power steps, voltage, and temperature are shown in Figures 10–12. The output power is changed in 128 steps through PA\_PWR\_LVL API. For detailed matching values, BOM, and performance at other frequencies, refer to “AN648: PA Matching”.

Figure 10. +20 dBm TX Power vs. PA\_PWR\_LVL

Figure 11. +20 dBm TX Power vs. VDD

Figure 12. +20 dBm TX Power vs. Temp

## 5.5. Crystal Oscillator

The Si446x includes an integrated crystal oscillator with a fast start-up time of less than 250  $\mu$ s. The design is differential with the required crystal load capacitance integrated on-chip to minimize the number of external components. By default, all that is required off-chip is the crystal. The default crystal is 30 MHz, but the circuit is designed to handle any XTAL from 25 to 32 MHz. If a crystal different than 30 MHz is used, the POWER\_UP API boot command must be modified. The WDS calculator crystal frequency field must also be changed to reflect the frequency being used. The crystal load capacitance can be digitally programmed to accommodate crystals with various load capacitance requirements and to adjust the frequency of the crystal oscillator. The tuning of the crystal load capacitance is programmed through the GLOBAL\_XO\_TUNE API property. The total internal capacitance is 11 pF and is adjustable in 127 steps (70 fF/step). The crystal frequency adjustment can be used to compensate for crystal production tolerances. The frequency offset characteristics of the capacitor bank are demonstrated in Figure 13.

Figure 13. Capacitor Bank Frequency Offset Characteristics

Utilizing the on-chip temperature sensor and suitable control software, the temperature dependency of the crystal can be canceled.

A TCXO or external signal source can easily be used in place of a conventional XTAL and should be connected to the XIN pin. The incoming clock signal is recommended to have a peak-to-peak swing in the range of 600 mV to 1.4 V and ac-coupled to the XIN pin. If the peak-to-peak swing of the TCXO exceeds 1.4 V peak-to-peak, then dc coupling to the XIN pin should be used. The maximum allowed swing on XIN is 1.8 V peak-to-peak.

The XO capacitor bank should be set to 0 whenever an external drive is used on the XIN pin. In addition, the POWER\_UP command should be invoked with the TCXO option whenever external drive is used.

6. Data Handling and Packet Handler

6.1. RX and TX FIFOs

Two 64-byte FIFOs are integrated into the chip, one for RX and one for TX, as shown in Figure 14. For dedicated TX or RX, the FIFO size is up to 129 bytes. Writing to command Register 66h loads data into the TX FIFO, and reading from command Register 77h reads data from the RX FIFO. The TX FIFO has a threshold for when the FIFO is almost empty, which is set by the “TX\_FIFO\_EMPTY” property. An interrupt event occurs when the data in the TX FIFO reaches the almost empty threshold. If more data is not loaded into the FIFO, the chip automatically exits the TX state after the PACKET\_SENT interrupt occurs. The RX FIFO has one programmable threshold, which is programmed by setting the “RX\_FIFO\_FULL” property. When the incoming RX data crosses the Almost Full Threshold, an interrupt will be generated to the microcontroller via the nIRQ pin. The microcontroller will then need to read the data from the RX FIFO. The RX Almost Full Threshold indication implies that the host can read at least the threshold number of bytes from the RX FIFO at that time. Both the TX and RX FIFOs may be cleared or reset with the “FIFO\_RESET” command.

Figure 14. TX and RX FIFOs

6.2. Packet Handler

When using the FIFOs, automatic packet handling may be enabled for TX mode, RX mode, or both. The usual fields for network communication, such as preamble, synchronization word, headers, packet length, and CRC, can be configured to be automatically added to the data payload. The fields needed for packet generation normally change infrequently and can therefore be stored in registers. Automatically adding these fields to the data payload in TX mode and automatically checking them in RX mode greatly reduces the amount of communication between the microcontroller and Si446x. It also greatly reduces the required computational power of the microcontroller. The general packet structure is shown in Figure 15. Any or all of the fields can be enabled and checked by the internal packet handler.

Figure 15. Packet Handler Structure

The fields are highly programmable and can be used to check any kind of pattern in a packet structure. The general functions of the packet handler include the following:

- Detection/validation of Preamble quality in RX mode (PREAMBLE\_VALID signal)
- Detection of Sync word in RX mode (SYNC\_OK signal)
- Detection of valid packets in RX mode (PKT\_VALID signal)
- Detection of CRC errors in RX mode (CRC\_ERR signal)
- Data de-whitening and/or Manchester decoding (if enabled) in RX mode
- Match/Header checking in RX mode
- Storage of Data Field bytes into FIFO memory in RX mode
- Construction of Preamble field in TX mode
- Construction of Sync field in TX mode
- Construction of Data Field from FIFO memory in TX mode
- Construction of CRC field (if enabled) in TX mode
- Data whitening and/or Manchester encoding (if enabled) in TX mode

For details on how to configure the packet handler, see “AN626: Packet Handler Operation for Si446x RFICs”.

## 7. RX Modem Configuration

The Si446x can easily be configured for different data rate, deviation, frequency, etc. by using the Radio Configuration Application (RCA) GUI which is part of the Wireless Development Suite (WDS) program.

## 8. Auxiliary Blocks

### 8.1. Wake-up Timer and 32 kHz Clock Source

The chip contains an integrated wake-up timer that can be used to periodically wake the chip from sleep mode. The wake-up timer runs from either the internal 32 kHz RC Oscillator, or from an external 32 kHz XTAL.

The wake-up timer can be configured to run when in sleep mode. If WUT\_EN = 1 in the GLOBAL\_WUT\_CONFIG property, prior to entering sleep mode, the wake-up timer will count for a time specified defined by the GLOBAL\_WUT\_R and GLOBAL\_WUT\_M properties. At the expiration of this period, an interrupt will be generated on the nIRQ pin if this interrupt is enabled in the INT\_CTL\_CHIP\_ENABLE property. The microcontroller will then need to verify the interrupt by reading the chip interrupt status either via GET\_INT\_STATUS or a fast response register. The formula for calculating the Wake-Up Period is as follows:

$$WUT = WUT\_M \times \frac{4 \times 2^{WUT\_R}}{32.768} [\text{ms}]$$

The RC oscillator frequency will change with temperature; so, a periodic recalibration is required. The RC oscillator is automatically calibrated during the POWER\_UP command and exits from the Shutdown state. To enable the recalibration feature, CAL\_EN must be set in the GLOBAL\_WUT\_CONFIG property, and the desired calibration period should be selected via WUT\_CAL\_PERIOD[2:0] in the same API property. During the calibration, the 32 kHz RC oscillator frequency is compared to the 30 MHz XTAL and then adjusted accordingly. The calibration needs to start the 30 MHz XTAL, which increases the average current consumption; so, a longer CAL\_PERIOD results in a lower average current consumption. The 32 kHz XTAL accuracy is comprised of both the XTAL parameters and the internal circuit. The XTAL accuracy can be defined as the XTAL initial error + XTAL aging + XTAL temperature drift + detuning from the internal oscillator circuit. The error caused by the internal circuit is typically less than 10 ppm. Refer to API documentation for details on WUT related commands and properties.

### 8.2. Low Duty Cycle Mode (Auto RX Wake-Up)

The low duty cycle (LDC) mode is implemented to automatically wake-up the receiver to check if a valid signal is available or to enable the transmitter to send a packet. It allows low average current polling operation by the Si446x for which the wake-up timer (WUT) is used. RX and TX LDC operation must be set via the GLOBAL\_WUT\_CONFIG property when setting up the WUT. The LDC wake-up period is determined by the following formula:

$$LDC = WUT\_LDC \times \frac{4 \times 2^{WUT\_R}}{32.768} [\text{ms}]$$

where the WUT\_LDC parameter can be set by the GLOBAL\_WUT\_LDC property. The WUT period must be set in conjunction with the LDC mode duration; for the relevant API properties, see the wake-up timer (WUT) section.

**Figure 16. RX and TX LDC Sequences**

The basic operation of RX LDC mode is shown in Figure 17. The receiver periodically wakes itself up to work on RX\_STATE during LDC mode duration. If a valid preamble is not detected, a receive error is detected, or an entire packet is not received, the receiver returns to the WUT state (i.e., ready or sleep) at the end of LDC mode duration and remains in that mode until the beginning of the next wake-up period. If a valid preamble or sync word is detected, the receiver delays the LDC mode duration to receive the entire packet. If a packet is not received during two LDC mode durations, the receiver returns to the WUT state at the last LDC mode duration until the beginning of the next wake-up period.

**Figure 17. Low Duty Cycle Mode for RX**

In TX LDC mode, the transmitter periodically wakes itself up to transmit a packet that is in the data buffer. If a packet has been transmitted, nIRQ goes low if the option is set in the INT\_CTL\_ENABLE property. After transmitting, the transmitter immediately returns to the WUT state and stays there until the next wake-up time expires.

### 8.3. Temperature, Battery Voltage, and Auxiliary ADC

The Si446x family contains an integrated auxiliary ADC for measuring internal battery voltage, an internal temperature sensor, or an external component over a GPIO. The ADC utilizes a SAR architecture and achieves 11-bit resolution. The Effective Number of Bits (ENOB) is 9 bits. When measuring external components, the input voltage range is 1 V, and the conversion rate is between 300 Hz to 2.44 kHz. The ADC value is read by first sending the GET\_ADC\_READING command and enabling the inputs that are desired to be read: GPIO, battery, or temp. The temperature sensor accuracy at 25 °C is typically  $\pm 2$  °C. Refer to API documentation for details on the command and reply stream.

### 8.4. Low Battery Detector

The low battery detector (LBD) is enabled and utilized as part of the wake-up-timer (WUT). The LBD function is not available unless the WUT is enabled, but the host MCU can manually check the battery voltage anytime with the auxiliary ADC. The LBD function is enabled in the GLOBAL\_WUT\_CONFIG API property. The battery voltage will be compared against the threshold each time the WUT expires. The threshold for the LBD function is set in GLOBAL\_LOW\_BATT\_THRESH. The threshold steps are in increments of 50 mV, ranging from a minimum of 1.5 V up to 3.05 V. The accuracy of the LBD is  $\pm 3\%$ . The LBD notification can be configured as an interrupt on the nIRQ pin or enabled as a direct function on one of the GPIOs.

## 8.5. Antenna Diversity

To mitigate the problem of frequency-selective fading due to multipath propagation, some transceiver systems use a scheme known as antenna diversity. In this scheme, two antennas are used. Each time the transceiver enters RX mode the receive signal strength from each antenna is evaluated. This evaluation process takes place during the preamble portion of the packet. The antenna with the strongest received signal is then used for the remainder of that RX packet. The same antenna will also be used for the next corresponding TX packet. This chip fully supports antenna diversity with an integrated antenna diversity control algorithm. The required signals needed to control an external SPDT RF switch (such as a PIN diode or GaAs switch) are available on the GPIOx pins. The operation of these GPIO signals is programmable to allow for different antenna diversity architectures and configurations. The antdiv[2:0] bits are found in the MODEM\_ANT\_DIV\_CONTROL API property descriptions and enable the antenna diversity mode. The GPIO pins are capable of sourcing up to 5 mA of current; so, it may be used directly to forward-bias a PIN diode if desired. The antenna diversity algorithm will automatically toggle back and forth between the antennas until the packet starts to arrive. The recommended preamble length for optimal antenna selection is 8 bytes.

## 8.6. Preamble Sense Mode

This mode of operation is suitable for extremely low power applications where power consumption is important. The preamble sense mode (PSM) takes advantage of the Digital Signal Arrival detector (DSA), which can detect a preamble within eight bit times with no sensitivity degradation. This fast detection of an incoming signal can be combined with duty cycling of the receiver during the time the device is searching or sniffing for packets over the air. The average receive current is lowered significantly when using this mode. In applications where the timing of the incoming signal is unknown, the amount of power savings is primarily dependent on the data rate and preamble length as the Rx inactive time is determined by these factors. In applications where the sleep time is fixed and the timing of the incoming signal is known, the average current also depends on the sleep time. The PSM mode is similar to the low duty cycle mode but has the benefit of faster signal detection and autonomous duty cycling of the receiver to achieve even lower average receive currents. This mode can be used with the low power mode (LP) which has an active RX current of 10 mA or with the high-performance (HP) mode which has an active RX current of 13 mA.

Figure 18. Preamble Sense Mode

Table 16. Data Rates

	Data Rate				
	1.2 kbps	9.6 kbps	50 kbps	100 kbps	
PM length = 4 bytes	6.48	6.84	8.44	10.43	mA
PM length = 8 bytes	3.83	3.96	4.57	5.33	mA
<b>Note:</b> Typical values. Active RX current is 13 mA.					

## 9. Wireless MBUS support

Wireless MBus is a widely accepted standard for smart meter communication in Europe. The radio supports all WMBus modes per the latest draft specification of the EN13757-4 standard. This includes a much wider deviation error tolerance of  $\pm 30\%$  and frequency error tolerance of  $\pm 4$  kHz, short preamble support (16-bit preamble for 2 and 4 level FSK modes), 3-of-6 encoding and decoding and 169 MHz N modes including N2g.

In addition, Silicon Labs has a production ready WMBus stack available at no additional cost which supports all modes and runs on the EFM32 (32-bit ARM) family of energy friendly microcontrollers. This stack and complete documentation including PHY configuration and test results are available for download from the EZRadioPRO page on the [Silicon Labs website](#).

## 10. ETSI EN300 220 Category 1

The radio is capable of supporting ETSI Category 1 applications (social alarms, healthcare applications, etc.) in the 169 MHz and 868 MHz bands. Blocking performance is improved at the 2 MHz and 10 MHz offsets allowing for additional margin from the regulatory limits. The radio complies with ACS limits at the 25 kHz offset in both, 169 MHz and 868 MHz bands. In the 169 MHz band, there is no need for an external SAW filter for 2 MHz and 10 MHz blocking resulting in a lower system cost. In the 868 MHz band, an external SAW filter is still required to meet the Cat 1 blocking limits. An RF Pico board is available for evaluation specifically for ETSI Cat 1 applications.

Test conditions for ETSI Cat 1 specifications are different from the typical conditions and are stated below.

Data Rate: 3 kbps

Deviation: 2 kHz

Modulation: 2 GFSK

IF mode: Fixed and/or Scaled IF

RX bandwidth: 13 kHz

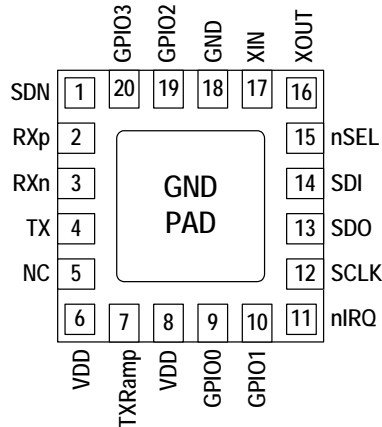

BER target: 0.1%

Blocker signal: CW

	ETSI Cat 1 limits	169 MHz band (no SAW)	868 MHz band (no SAW)
<b><math>\pm 25</math> kHz ACS</b>	54 dB	62 dB	58 dB
<b><math>\pm 2</math> MHz blocking</b>	84 dB	88 dB	76 dB
<b><math>\pm 10</math> MHz blocking</b>	84 dB	90 dB	82 dB
<b>RX sensitivity</b>	-107 dB	-108 dB	-108 dB
<b>Spurious response</b>	35 dB	40 dB	40 dB

For further details on configuring the radio for ETSI Cat 1 applications, refer to the application notes available on the [Silicon Labs website](#).

## 11. Pin Descriptions: Si4463/61/60

Pin	Pin Name	I/O	Description
1	SDN	I	<b>Shutdown Input Pin.</b> 0–VDD V digital input. SDN should be = 0 in all modes except Shutdown mode. When SDN = 1, the chip will be completely shut down, and the contents of the registers will be lost.
2	RXp	I	<b>Differential RF Input Pins of the LNA.</b> See application schematic for example matching network.
3	RXn	I	
4	TX	O	<b>Transmit Output Pin.</b> The PA output is an open-drain connection, so the L-C match must supply VDD (+3.3 VDC nominal) to this pin.
5	NC		It is recommended to connect this pin to GND per the reference design schematic. Not connected internally to any circuitry.
6	VDD	VDD	<b>+1.8 to +3.8 V Supply Voltage Input to Internal Regulators.</b> The recommended VDD supply voltage is +3.3 V.
7	TXRAMP	O	<b>Programmable Bias Output with Ramp Capability for External FET PA.</b> See "5.4. Transmitter (TX)" on page 33.
8	VDD	VDD	<b>+1.8 to +3.8 V Supply Voltage Input to Internal Regulators.</b> The recommended VDD supply voltage is +3.3 V.
9	GPIO0	I/O	<b>General Purpose Digital I/O.</b> May be configured through the registers to perform various functions including: Microcontroller Clock Output, FIFO status, POR, Wake-Up timer, Low Battery Detect, TRSW, AntDiversity control, etc.
10	GPIO1	I/O	
11	nIRQ	O	<b>General Microcontroller Interrupt Status Output.</b> When the Si4463/61 exhibits any one of the interrupt events, the nIRQ pin will be set low = 0. The Microcontroller can then determine the state of the interrupt by reading the interrupt status. No external resistor pull-up is required, but it may be desirable if multiple interrupt lines are connected.

Pin	Pin Name	I/O	Description
12	SCLK	I	<b>Serial Clock Input.</b> 0–VDD V digital input. This pin provides the serial data clock function for the 4-line serial data bus. Data is clocked into the Si4463/61 on positive edge transitions.
13	SDO	O	<b>0–VDD V Digital Output.</b> Provides a serial readback function of the internal control registers.
14	SDI	I	<b>Serial Data Input.</b> 0–VDD V digital input. This pin provides the serial data stream for the 4-line serial data bus.
15	nSEL	I	<b>Serial Interface Select Input.</b> 0–VDD V digital input. This pin provides the Select/Enable function for the 4-line serial data bus.
16	XOUT	O	<b>Crystal Oscillator Output.</b> Connect to an external 25 to 32 MHz crystal, or leave floating when driving with an external source on XIN.
17	XIN	I	<b>Crystal Oscillator Input.</b> Connect to an external 25 to 32 MHz crystal, or connect to an external source.
18	GND	GND	When using an XTAL, leave floating per the reference design schematic. When using a TCXO, connect to TCXO GND, which should be separate from the board's reference ground plane.
19	GPIO2	I/O	<b>General Purpose Digital I/O.</b> May be configured through the registers to perform various functions, including Microcontroller Clock Output, FIFO status, POR, Wake-Up timer, Low Battery Detect, TRSW, AntDiversity control, etc.
20	GPIO3	I/O	
PKG	PADDLE_GND	GND	The exposed metal paddle on the bottom of the Si446x supplies the RF and circuit ground(s) for the entire chip. It is very important that a good solder connection is made between this exposed metal paddle and the ground plane of the PCB underlying the Si446x.

## 12. Ordering Information

Part Number	Description	Package Type	Operating Temperature
Si4463-C2A-GM	ISM EZRadioPRO Transceiver	QFN-Pb-free	–40 to +85 °C
Si4461-C2A-GM	ISM EZRadioPRO Transceiver	QFN-Pb-free	–40 to +85 °C
Si4460-C2A-GM	ISM EZRadioPRO Transceiver	QFN-Pb-free	–40 to +85 °C
<b>Note:</b> Add an “(R)” at the end of the device part number to denote tape and reel option.			

### 13. Package Outline: Si4463/61/60

Figure 19 illustrates the package details for the Si446x. Table 17 lists the values for the dimensions shown in the illustration.

### Figure 19. 20-Pin Quad Flat No-Lead (QFN)

**Table 17. Package Dimensions**

Dimension	Min	Nom	Max
A	0.80	0.85	0.90
A1	0.00	0.02	0.05
A3	0.20 REF		
b	0.18	0.25	0.30
D	4.00 BSC		
D2	2.45	2.60	2.75
e	0.50 BSC		
E	4.00 BSC		
E2	2.45	2.60	2.75
L	0.30	0.40	0.50
aaa	0.15		
bbb	0.15		
ccc	0.10		
ddd	0.10		
eee	0.08		
<b>Notes:</b> 1. All dimensions are shown in millimeters (mm) unless otherwise noted. 2. Dimensioning and tolerancing per ANSI Y14.5M-1994. 3. This drawing conforms to the JEDEC Solid State Outline MO-220, Variation VGGD-8. 4. Recommended card reflow profile is per the JEDEC/IPC J-STD-020 specification for Small Body Components.			

## 14. PCB Land Pattern: Si4463/61/60

Figure 20 illustrates the PCB land pattern details for the Si446x. Table 18 lists the values for the dimensions shown in the illustration.

Figure 20. PCB Land Pattern

**Table 18. PCB Land Pattern Dimensions**

Symbol	Millimeters	
	Min	Max
C1	3.90	4.00
C2	3.90	4.00
E	0.50 REF	
X1	0.20	0.30
X2	2.55	2.65
Y1	0.65	0.75
Y2	2.55	2.65
<b>Notes:</b>		
<b>General</b>		
1. All dimensions shown are in millimeters (mm) unless otherwise noted.		
2. This land pattern design is based on IPC-7351 guidelines.		
<b>Solder Mask Design</b>		
3. All metal pads are to be non-solder mask defined (NSMD). Clearance between the solder mask and the metal pad is to be 60 µm minimum, all the way around the pad.		
<b>Stencil Design</b>		
4. A stainless steel, laser-cut and electro-polished stencil with trapezoidal walls should be used to assure good solder paste release.		
5. The stencil thickness should be 0.125 mm (5 mils).		
6. The ratio of stencil aperture to land pad size should be 1:1 for the perimeter pads.		
7. A 2x2 array of 1.10 x 1.10 mm openings on 1.30 mm pitch should be used for the center ground pad.		
<b>Card Assembly</b>		
8. A No-Clean, Type-3 solder paste is recommended.		
9. The recommended card reflow profile is per the JEDEC/IPC J-STD-020 specification for small body components.		

15. Top Marking

15.1. Si4463/61/60 Top Marking

15.2. Top Marking Explanation

Mark Method	YAG Laser	
Line 1 Marking	Part Number	44632A = Si4463 Rev 2A <sup>1</sup> 44612A = Si4461 Rev 2A <sup>1</sup> 44602A = Si4460 Rev 2A <sup>1</sup>
Line 2 Marking	TTTTTT = Internal Code	Internal tracking code. <sup>2</sup>
Line 3 Marking	YY = Year WW = Workweek	Assigned by the Assembly House. Corresponds to the last significant digit of the year and workweek of the mold date.
<b>Notes:</b> 1. The first letter after the part number is part of the ROM revision. The last letter indicates the firmware revision. 2. The first letter of this line is part of the ROM revision.		

## DOCUMENT CHANGE LIST

### Revision 0.1 to Revision 0.2

- Corrected minor typos in text descriptions.
- Updated several parameters in the Electrical Spec Tables.
- Updated sections 4, 5 and 8.6 for better description of Modem and Hardware configuration options, Internal Functional Blocks and Preamble Sense Mode.
- Updated Table 9, "Serial Interface Timing Parameters," on page 16.
- Updated "12. Ordering Information" on page 46.
- Updated "15. Top Marking" on page 51.

### Revision 0.2 to Revision 1.0

- Updated parameters in "1. Electrical Specifications".
- Minor updates to text descriptions.
- Updated Table 15.
- Updated "11. Pin Descriptions: Si4463/61/60".
