

## MOTOR BRIDGE CONTROLLER

### 1 FEATURES

- OPERATING SUPPLY VOLTAGE 8V TO 28V, OVERVOLTAGE MAX. 40V
- OPERATING SUPPLY VOLTAGE 6V WITH IMPLEMENTED STEPUP CONVERTER
- QUIESCENT CURRENT IN STANDBY MODE LESS THAN 50 $\mu$ A
- ISO 9141 COMPATIBLE INTERFACE
- CHARGE PUMP FOR DRIVING A POWER MOS AS REVERSE BATTERY PROTECTION
- PWM OPERATION FREQUENCY UP TO 30KHZ
- PROGRAMMABLE CROSS CONDUCTION PROTECTION TIME
- OVERVOLTAGE, UNDERVOLTAGE, SHORT CIRCUIT AND THERMAL PROTECTION
- REAL TIME DIAGNOSTIC

Figure 1. Package

Table 1. Order Codes

| Part Number | Package     |
|-------------|-------------|
| L9904       | SO20        |
| L9904TR     | Tape & Reel |

### 2 DESCRIPTION

Control circuit for power MOS bridge driver in automotive applications with ISO 9141bus interface.

Figure 2. Block Diagram

Table 2. Pin Function

| N° | Pin | Description                                                       |
|----|-----|-------------------------------------------------------------------|
| 1  | ST  | Open Drain Switch for Stepup converter                            |
| 2  | DG  | Open drain diagnostic output                                      |
| 3  | PWM | PWM input for H-bridge control                                    |
| 4  | EN  | Enable input                                                      |
| 5  | DIR | Direction select input for H-bridge control                       |
| 6  | PR  | Programmable cross conduction protection time                     |
| 7  | RX  | ISO 9141 interface, receiver output                               |
| 8  | TX  | ISO 9141 interface, transmitter input                             |
| 9  | K   | ISO 9141 Interface, bidirectional communication K-line            |
| 10 | VS  | Supply voltage                                                    |
| 11 | CP  | Charge pump for driving a power MOS as reverse battery protection |
| 12 | GH1 | Gate driver for power MOS highside switch in halfbridge 1         |
| 13 | CB1 | External bootstrap capacitor                                      |
| 14 | S1  | Source/drain of halfbridge 1                                      |
| 15 | GH2 | Gate driver for power MOS highside switch in halfbridge 2         |
| 16 | CB2 | External bootstrap capacitor                                      |
| 17 | S2  | Source/drain of halfbridge 2                                      |
| 18 | GL2 | Gate driver for power MOS lowside switch in halfbridge 2          |
| 19 | GL1 | Gate driver for power MOS lowside switch in halfbridge 1          |
| 20 | GND | Ground                                                            |

**Table 3. Absolute Maximum Ratings**

| Symbol                                                                     | Parameter                        | Value                        | Unit |
|----------------------------------------------------------------------------|----------------------------------|------------------------------|------|
| V <sub>CB1</sub> , V <sub>CB2</sub>                                        | Bootstrap voltage                | -0.3 to 40                   | V    |
| I <sub>CB1</sub> , I <sub>CB2</sub>                                        | Bootstrap current                | -100                         | mA   |
| V <sub>CP</sub>                                                            | Charge pump voltage              | -0.3 to 40                   | V    |
| I <sub>CP</sub>                                                            | Charge pump current              | -1                           | mA   |
| V <sub>DIR</sub> , V <sub>EN</sub><br>, V <sub>PWM</sub> , V <sub>TX</sub> | Logic input voltage              | -0.3 to 7                    | V    |
| I <sub>DIR</sub> , I <sub>EN</sub><br>, I <sub>PWM</sub> , I <sub>TX</sub> | Logic input current              | ±1                           | mA   |
| V <sub>DG</sub> , V <sub>RX</sub>                                          | Logic output voltage             | -0.3 to 7                    | V    |
| I <sub>DG</sub> , I <sub>RX</sub>                                          | Logic output current             | -1                           | mA   |
| V <sub>GH1</sub> , V <sub>GH2</sub>                                        | Gate driver voltage              | -0.3 to V <sub>SX</sub> + 10 | V    |
| I <sub>GH1</sub> , I <sub>GH2</sub>                                        | Gate driver current              | -1                           | mA   |
| V <sub>GL1</sub> , V <sub>GL2</sub>                                        | Gate driver voltage              | -0.3 to 10                   | V    |
| I <sub>GL1</sub> , I <sub>GL2</sub>                                        | Gate driver current              | -10                          | mA   |
| V <sub>K</sub>                                                             | K-line voltage                   | -20 to V <sub>S</sub>        | V    |
| V <sub>PR</sub>                                                            | Programming input voltage        | -0.3 to 7                    | V    |
| I <sub>PR</sub>                                                            | Programming input current        | -1                           | mA   |
| V <sub>S1</sub> , V <sub>S2</sub>                                          | Source/drain voltage             | -2 to V <sub>VS</sub> + 2    | V    |
| I <sub>S1</sub> , I <sub>S2</sub>                                          | Source/drain current             | -10                          | mA   |
| V <sub>ST</sub>                                                            | Output voltage                   | -0.3 to 40                   | V    |
| I <sub>ST</sub>                                                            | Step up output current           | -1                           | mA   |
| V <sub>VSDC</sub>                                                          | DC supply voltage                | -0.3 to 28                   | V    |
| V <sub>VSP</sub>                                                           | Pulse supply voltage (T < 500ms) | 40                           | V    |
| I <sub>VS</sub>                                                            | DC supply current                | -100                         | mA   |

For externally applied voltages or currents exceeding these limits damage of the device may occur!

All pins of the IC are protected against ESD. The verification is performed according to MIL883C, human body model with R=1.5kΩ, C=100pF and discharge voltage ±2kV, corresponding to a maximum discharge energy of 0.2mJ.

**Table 4. Thermal Data**

| Symbol                | Parameter                                            | Value      | Unit |
|-----------------------|------------------------------------------------------|------------|------|
| T <sub>J</sub>        | Operating junction temperature                       | -40 to 150 | °C   |
| T <sub>JSD</sub>      | Junction temperature thermal shutdown threshold      | min 150    | °C   |
| T <sub>JSDH</sub>     | Junction thermal shutdown hysteresis                 | typ 15     | °C   |
| R <sub>th j-amb</sub> | Thermal resistance junction to ambient <sup>1)</sup> | 85         | °C/W |

1. see application note 110 for SO packages.

**Table 5. Electrical Characteristics**

( $8V < V_{VS} < 20V$ ,  $V_{EN} = \text{HIGH}$ ,  $-40^{\circ}\text{C} \leq T_J \leq 150^{\circ}\text{C}$ , unless otherwise specified. The voltages are referred to GND and currents are assumed positive, when current flows into the pin

| Symbol                                                        | Parameter                                                 | Test Condition                                                                                                                                                                                                                                                              | Min. | Typ. | Max. | Unit             |

### 3 FUNCTIONAL DESCRIPTION

#### 3.1 General

The L9904 integrated circuit (IC) is designed to control four external N-channel MOS transistors in H-Bridge configuration for DC-motor driving in automotive applications. It includes an ISO9141 compatible interface. A typical application is shown in fig.9.

#### 3.2 Voltage supply

The IC is supplied via an external reverse battery protection diode to the  $V_{VS}$  pin. The typical operating voltage range is down to 8V.

The supply current consumption of the IC composes of static and a dynamic part. The static current is typically 5.8mA. The dynamical current  $I_{dyn}$  is depending of the PWM frequency  $f_{PWM}$  and the required gate charge  $Q_{Gate}$  of the external power mos transistor. The current can be estimated by the expression:

$$I_{dyn} = 2 \cdot f_{PWM} \cdot Q_{Gate}$$

An external power transistor with a gate charge of  $Q_{Gate} = 160\text{nC}$  and a PWM frequency of  $f_{PWM} = 20\text{kHz}$  requires a dynamical supply current of  $I_{dyn} = 6.4\text{mA}$ .

The total supply current consumption is  $I_{VS} = 5.8\text{mA} + 6.4\text{mA} = 12.2\text{mA}$ .

#### 3.3 Extended supply voltage range (ST)

The operating battery voltage range can be extended down to 6V using the additional components shown in fig.7. A small inductor of  $L \sim 150\mu\text{H}$  ( $I_{peak} \sim 500\text{mA}$ ) in series to the battery supply builds up a step up converter with the switching open drain output ST. The switching frequency is typical 100kHz with a fixed duty cycle of 50%. The step up converter starts below  $V_{VS} < 8\text{V}$ , increases the supply voltage at the  $V_S$  pin and switches off at  $V_{VS} > 10\text{V}$  to avoid EME at nominal battery voltage. The diode D2 in series with the ST pin is necessary only for systems with negative battery voltage. No additional load can be driven by the step up converter.

Figure 10.

### 3.4 Control inputs (EN, DIR, PWM)

The cmos level inputs drive the device as shown in fig.7 and described in the truth table.

The device is activated with enable input HIGH signal. For enable input floating (not connected) or VEN=0V the device is in standby mode. When activating the device a wake-up time of 50µs is recommended to stabilize the internal supplies.

The DIR and PWM inputs control the driver of the external H-Bridge transistors. The motor direction can be choosen with the DIR input, the duty cycle and frequency with the PWM input. Unconnected inputs are defined by internal pull up resistors. During wake-up and braking and before disactivating the IC via enable both inputs should be driven HIGH.

**Table 6. Truth table:**

Symbols: x Don't care

0: Logic LOW or not active

1: Logic HIGH or active

R:Resistive output

L: Output in sink condition

H: Output in source condition

T: Tristate

TS:Thermal shutdown

OV:Overvoltage

UV:Undervoltage

SC:Short Circuit

6. Only those external MOS transistors of the H-Bridge which are in short circuit condition are switched off. All others remain driven by DIR and PWM.

7. See Application Note AN2229

### 3.5 Thermal shutdown

When the junction temperature exceeds  $T_{JSD}$  all driver are switched in sink condition (L), the K- output is off and the diagnostic DG is LOW until the junction temperature drops below  $T_{JSD} - T_{JHYST}$ .

### 3.6 Overvoltage Shutdown

When the supply voltage  $V_{VS}$  exceeds the overvoltage threshold  $V_{VSOVH}$  all driver are switched in sink condition (L), the K- output is off and the diagnostic DG is LOW.

### 3.7 Undervoltage Shutdown

For supply voltages below the undervoltage disable threshold the gate driver remains in sink condition (L) and the diagnostic DG is low.

### 3.8 Short Circuit Detection

The output voltage at the S1 and S2 pin of the H-Bridge is monitored by comparators to detect shorts to ground or battery. The activated external highside MOS transistor will be switched off if the voltage drop remains below the comparator threshold voltage  $V_{S1TH}$  and  $V_{S2TH}$  for longer than the short current detection time  $t_{SCd}$ . The transistor remains in off condition, the diagnostic output goes LOW until the DIR or PWM input status will be changed. The status doesn't change for the other MOS transistors. The external lowside MOS transistor will be switched off if the voltage drop passes over the comparator threshold voltage  $V_{S1TH}$  and  $V_{S2TH}$  for longer than the short current detection time  $t_{SCd}$ . The transistor remains in off condition, the diagnostic output goes LOW until the DIR or PWM input status will be changed. The status doesn't change for the other MOS transistors.

### 3.9 Diagnostic Output (DG)

The diagnostic output provides a real time error detection, if monitors the following error stacks: Thermal shutdown, overvoltage shutdown, undervoltage shutdown and short circuit shutdown. The open drain output with internal pull up resistor is LOW if an error is occurring.

### 3.10 Bootstrap capacitor (CB1,CB2)

To ensure, that the external power MOS transistors reach the required  $R_{DS(on)}$ , a minimum gate source voltage of 5V for logic level and 10V for standard power MOS transistors has to be guaranteed. The highside transistors require a gate voltage higher than the supply voltage. This is achieved with the internal chargepump circuit in combination with the bootstrap capacitor. The bootstrap capacitor is charged, when the highside MOS transistor is OFF and the lowside is ON. When the lowside is switched OFF, the charged bootstrap capacitor is able to supply the gate driver of the highside power MOS transistor. For effective charging the values of the bootstrap capacitors should be larger than the gate-source capacitance of the power MOS and respect the required PWM ratio.

### 3.11 Chargepump circuit (CP)

The reverse battery protection can be obtained with an external N-channel MOS transistor as shown in fig.6. In this case its drain-bulk diode provides the protection. The output CP is intended to drive the gate of this transistor above the battery voltage to switch on the MOS and to bypass the drain-bulk diode with the  $R_{DS(on)}$ . The CP has a connection to VS through an internal diode and a 20k $\Omega$  resistor.

### 3.12 Gate drivers for the external N-channel power MOS transistors (GH1, GH2, GL1, GL2)

High level at EN activates the driver of the external MOS under control of the DIR and PWM inputs (see truth table and driving sequence fig.4). The external power MOS gates are connected via series resistors to the device to reduce electro magnetic emission (EME) of the system. The resistors influence the switching behaviour. They have to be chosen carefully. Too large resistors enlarge the charging and discharging time of the power MOS gate and can generate cross current in the halfbridges. The driver assures a longer switching delay time from source to sink stage in order to prevent the cross conduction.

The gate source voltage is limited to 14V. The charge/discharge current is limited by the  $R_{DS(on)}$  of the driver. The drivers are not protected against shorts.

### 3.13 Programmable cross conduction protection

The external power MOS transistors in H-Bridge (two half bridges) configuration are switched on with an additional delay time  $t_{CCP}$  to prevent cross conduction in the halfbridge. The cross conduction protection time  $t_{CCP}$  is determined by the external capacitor  $C_{PR}$  and resistor  $R_{PR}$  at the PR pin. The capacitor  $C_{PR}$  is charged up to the voltage limit  $V_{PRH}$ . A level change on the control inputs DIR and PWM switches off the concerned external MOS transistor and the charging source at the PR pin. The resistor  $R_{PR}$  discharges the capacitor  $C_{PR}$ . The concerned external power MOS transistor will be switched on again when the voltage at PR reaches the value of  $V_{PRL}$ . After that the CPR will be charged again. The capacitor  $C_{PR}$  should be chosen between 100pF and 1nF. The resistor  $R_{PR}$  should be higher than 7k $\Omega$ . The delay time can be expressed as follows:

$$t_{CCP} = R_{PR} \cdot C_{PR} \cdot \ln N_{PR}$$

$$\text{with } N_{PR} = V_{PRH} / V_{PRL} = 2$$

$$t_{CCP} = 0.69 \cdot R_{PR} \cdot C_{PR}$$

### 3.14 ISO-Interface

The ISO-Interface provides the communication between the micro controller and a serial bus with a baud rate up to 60kbit/s via a single wire which is  $V_{BAT}$  and GND compatible. The logic level transmission input TX drives the open drain K-output. The K output can be connected to a serial bus with a pull up resistor to  $V_{BAT}$ . The K-pin is protected against overvoltage, short to GND and VS and can be driven beyond  $V_{VS}$  and GND. During lack of  $V_{VS}$  or GND the output shows high impedance characteristic. The open drain output RX with an internal pull up resistor monitors the status at the K-pin to read the received data and control the transmitted data. Short circuit condition at K-pin is recognized if the internal open drain transistor isn't able to pull the voltage potential at K-pin below the threshold of  $0.45 \cdot V_{VS}$ . Then the RX stays in high condition. A timer starts and switches the open drain transistor after typ. 20 $\mu$ s off. A next low at the TX input resets the timer and the open drain transistor switches on again.
