# HIGH VOLTAGE IGNITION COIL DRIVER POWER I.C.

TYPE	$V_{cl}$	$I_{cl}$	$I_{cc}$
VB326SP	360V	10A	150mA

- PRIMARY COIL VOLTAGE INTERNALLY SET
- COIL CURRENT LIMIT INTERNALLY SET
- LOGIC LEVEL COMPATIBLE INPUT
- DRIVING CURRENT QUASI PROPORTIONAL TO COLLECTOR CURRENT
- SINGLE FLAG-ON COIL CURRENT
- LOW VOLTAGE CLAMP THERMAL SHUTDOWN

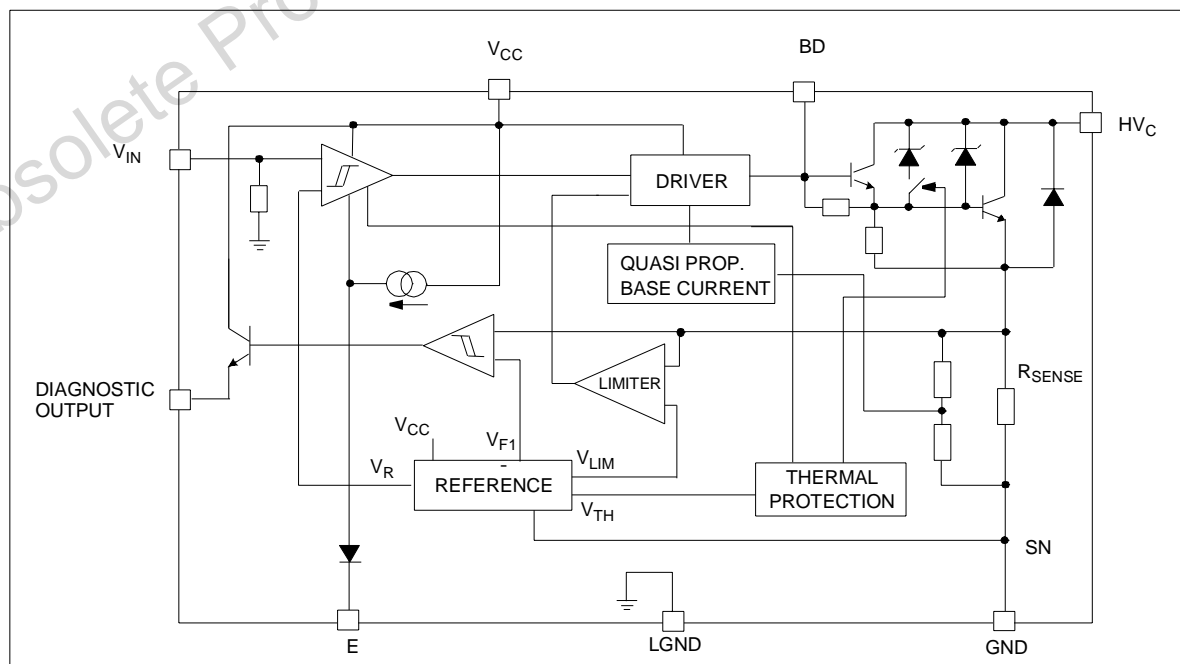

### DESCRIPTION

The VB326SP is a high voltage power integrated circuit made using the STMicroelectronics VIPower™ M1-3 technology, with vertical current flow power darlington and logic level compatible driving circuit. The enable pin allows to externally block the switch when the input is on. Built-in protection circuit for coil current limiting and collector voltage clamping allows the device to be used as smart, high voltage, high current interface

in advanced electronic ignition system. If the input signal from the micro happens to remain high, the device protects itself against over-heating by forcing collector current to smooth decrease (low voltage clamp feature) and no undesired spark occurs (see figure 4).

**PRINCIPLE OF OPERATION**

The VB326SP is mainly intended as a high voltage power switch device driven by a logic level input and interfaces directly to a high energy electronic ignition coil.

The input  $V_{IN}$  of the VB326SP is fed from a low power signal generated by an external controller that determines both dwell time and ignition point. During  $V_{in}$  high ( $\geq 4V$ ) the VB326SP increases current in the coil to the desired, internally set current level.

After reaching this level, the coil current remains constant until the ignition point, that corresponds to the transition of  $V_{in}$  from high to low (typ. 1.9V threshold).

During the coil current switch-off, the primary voltage  $HV_C$  is clamped at an internally set value

$V_{cl}$ , typically 380V. The transition from saturation to desaturation, coil current limiting phase, must have the ability to accommodate an overvoltage.

A maximum overshoot of 20V is allowed.

**FEEDBACK**

When the collector current exceeds 6.5A, the feedback signal is turned high and it remains so, until the input voltage is turned-off.

**OVERVOLTAGE**

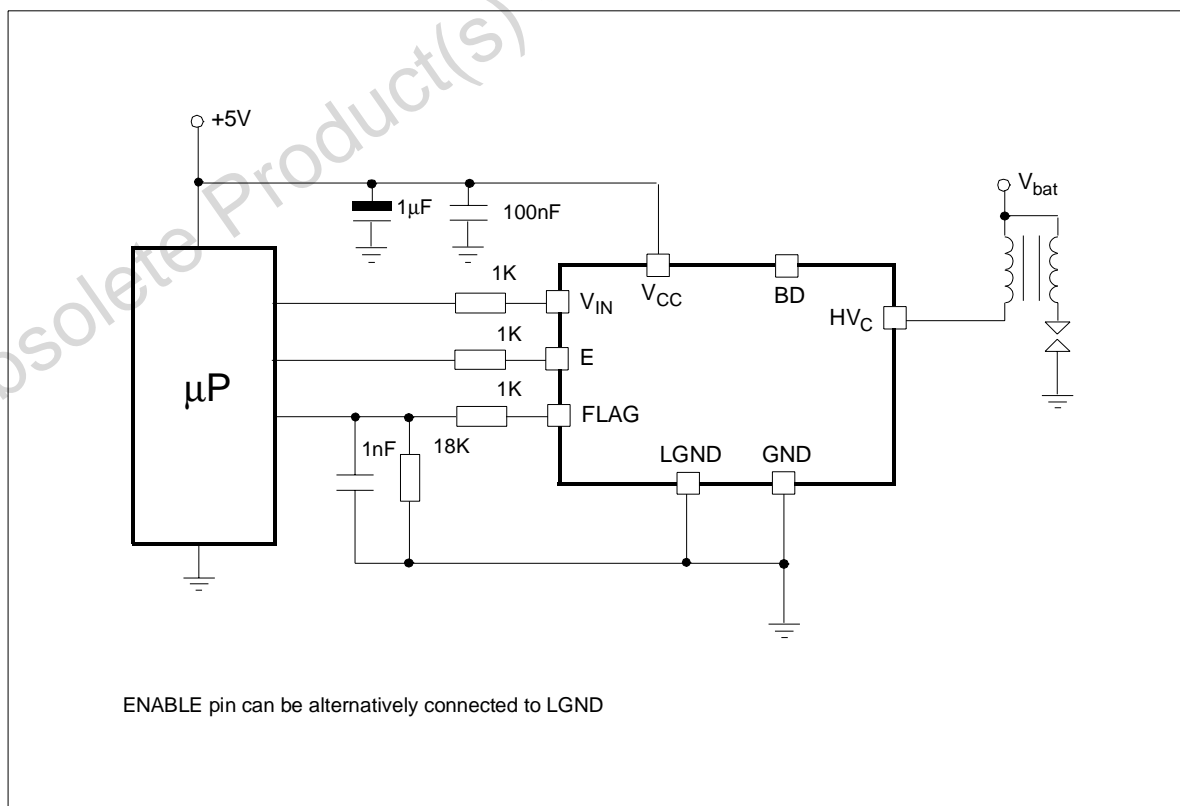

The VB326SP can withstand the following transients of the battery line:

-100V/2msec ( $R_i=10\ \Omega$ )

+100V/0.2msec ( $R_i=10\ \Omega$ )

+50V/400msec ( $R_i=4.2\ \Omega$ , with  $V_{IN}=3V$ )
