## **Important Notices**

Make sure to read read this chapter before using the product.

### 1 Serial bus interface

There are restrictions on the use of I2C bus mode when the multi-master function is used.

#### 1.1 Description

When the multi-master function is used in I2C bus mode, if these masters start the communications simultaneously, the following phenomena may occur:

- 1. Communications may be locked up.
- 2. SCL pulse widths shorten; therefore these pulses may not satisfy I2C Specifications.

#### 1.2 Condition

These phenomena occur only when the multi-master function is used in I2C bus mode. If a single master is used, these phenomena do not occur.

#### 1.3 Workaround

There is no workaround for these phenomena. Perform recovery process by software.

#### 1.4 How to Recover from These Phenomena

Perform recovery process by software.

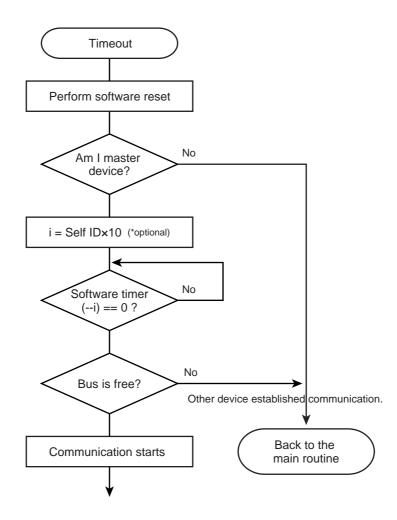

By using a timer, add timeout process to check whether communication is in a lock-up state.

#### An example of recovery process:

- 1. Start a timer count synchronously with start of the transmission.
- 2. If a serial interface interrupt (INTSBIx) does not occur in a certain period, the MCU determines the timeout.
- 3. If the MCU determines the timeout, communications may be locked up. Perform software reset on the serial bus interface circuit. This circuit is initialized to release communication from the lock up state.
- 4. Resend transmission data.

Mostly, Process 1 to 4 are enough to recovery; however if the multiple products are connected to the same bus line, add a delay time between each product's recovery process before Process 4 (resending data) is performed. This delay makes a time difference between each master; therefore bus collision can be avoided when the data is sent again.

#### Example: Recovery process after a timeout is detected.

#### 2 Transitions to Low-power Consumption Mode and Generating a Nonmaskable Interrupt

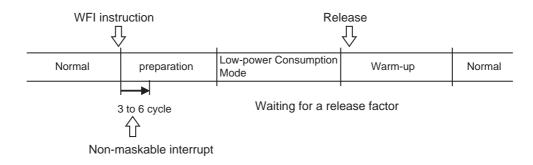

This chapter describes the precautions at which non-maskable interrupt (NMI) occurs when the MCU enters lowpower consumption mode.

• STOP1

#### 2.1 Description

When the WFI instruction is executed to enter the above-mentioned low-power consumption mode, if a nonmaskable interrupt (NMI) occurs, the MCU may enter low-power consumption mode without the process for releasing low-power consumption mode.

- Note 1: An NMI notice and flag setting to the CPU are normal; therefore the NMI process after low-power consumption mode is released can be performed.
- Note 2: When the MCU has entered low-power consumption mode, factors other than an NMI are accepted; however an NMI may not be accepted.

#### 2.2 Conditions

- The WFI instruction is executed to enter low-power consumption mode.
- A non-maskable interrupt occurs after WFI instruction execution and within 3 to 6 cycles.

#### 2.3 Workaround

Do not use a non-maskable interrupt as a release factor for the above-mentioned low-power consumption modes.

To avoid generating a non-maskable interrupt, the following settings should be specified before the MCU enters the above-mentioned low-power consumption mode.

- NMI pin: This input pin must be fixed to "High".
- Watchdog timer: Stop the watchdog timer or set the reset function.
- Voltage detection circuit: Stop the voltage detection circuit or set the reset function.

Base Address = 0x0000 0000

#### Introduction: Notes on the description of SFR (Special Function Register) under this specification

An SFR (Special Function Register) is a control register for periperal circuits (IP).

The SFR addressses of IPs are described in the chapter on memory map, and the details of SFR are given in the chapter of each IP.

Definition of SFR used in this specification is in accordance with the following rules.

- a. SFR table of each IP as an example
  - SFR tables in each chapter of IP provides register names, addresses and brief descriptions.
  - All registers have a 32-bit unique address and the addresses of the registers are defined as follows, with some exceptions: "Base address + (Unique) address"

Register name	Address(Base+)		
Control register	SAMCR	0x0004	
		0x000C	

Note: SAMCR register address is 32 bits wide from the address 0x0000\_0004 (Base Address(0x00000000) + unique address (0x0004)).

## Note: The register shown above is an example for explanation purpose and not for demonstration purpose. This register does not exist in this microcontroller.

#### b. SFR(register)

- Each register basically consists of a 32-bit register (some exceptions).
- The description of each register provides bits, bit symbols, types, initial values after reset and functions.

#### 1.2.2 SAMCR(Control register)

	31	30	29	28	27	26	25	24
bit symbol	-	-	-	-	-	_	-	-
After reset	0	0	0	0	0	0	0	0
	23	22	21	20	19	18	17	16
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8
bit symbol	-	-	-	-	-	-	MC	DE
After reset	0	0	0	0	0	0	0	0
	7	6	5	4	3	2	1	0
bit symbol	MODE				TDATA			
					0	0	0	0

Bit	Bit Symbol	Туре	Function
31-10	-	R	"0" can be read.
9-7	MODE[2:0]	R/W	Operation mode settings 000 : Sample mode 0 001 : Sample mode 1 010 : Sample mode 2 011 : Sample mode 3
			The settings other than those above: Reserved
6-0	TDATA[6:0]	W	Transmitted data

#### Note: The Type is divided into three as shown below.

R / W	READ WRITE
R	READ
W	WRITE

#### c. Data descriptopn

Meanings of symbols used in the SFR description are as shown below.

- x:channel numbers/ports
- n,m:bit numbers

#### d. Register descriptoption

Registers are described as shown below.

• Register name <Bit Symbol>

Exmaple: SAMCR<MODE>="000" or SAMCR<MODE[2:0]>="000"

<MODE[2:0]> indicates bit 2 to bit 0 in bit symbol mode (3bit width).

• Register name [Bit]

Example: SAMCR[9:7]="000"

It indicates bit 9 to bit 7 of the register SAMCR (32 bit width).

## 20. Package Dimensions

## TMPM365FYXBG

The TMPM365FYXBG is a 32-bit RISC microprocessor series with an ARM Cortex™-M3 microprocessor core.

Product Name	ROM (FLASH)	RAM	Package
TMPM365FYXBG	256 Kbyte	24 Kbyte	LFBGA105

Features of the TMPM365FYXBG are as follows:

#### 1.1 Features

- 1. ARM Cortex-M3 microprocessor core
  - a. Improved code efficiency has been realized through the use of Thumb® -2 instruction.
    - · New 16-bit Thumb instructions for improved program flow
    - New 32-bit Thumb instructions for improved performance
    - New Thumb mixed 16-/32-bit instruction set can produce faster, more efficient code.
  - b. Both high performance and low power consumption have been achieved.

[High performance]

- A 32-bit multiplication  $(32 \times 32 = 32 \text{ bit})$  can be executed with one clock.
- · Division takes between 2 and 12 cycles depending on dividend and devisor

[Low power consumption]

- Optimized design using a low power consumption library
- Standby function that stops the operation of the micro controller core
- c. High-speed interrupt response suitable for real-time control
  - An interruptible long instruction.
  - · Stack push automatically handled by hardware.
- 2. On Chip program memory and data memory
  - On chip Flash ROM : 256 Kbyte
  - On chip SRAM : 24 Kbyte
- 3. DMA controller(DMAC): 2 channels

Memory / Peripheral function / External memory

- 4. 16-bit timer(TMRB): 10 channels
  - 16-bit interval timer mode
  - 16-bit event counter mode
  - 16-bit PPG output
  - · Input capture function

5. Watchdog timer (WDT): 1 channel

Watchdog timer generates a reset or a non-maskable interrupt(NMI).

6. Serial channel (SIO/UART): 2 channels

Either UART mode or synchronous communication mode can be selected (4byte FIFO)

- Serial bus interface (I2C/SIO): 2 channels
   Either I2C bus mode or Clock-synchronous 8-bit SIO mode can be selected.
- 8. USB Device controller (USBD) : 1channel
  - · Compliance Universal Serial Bus Specification Rev.2.0.
  - · Supports full communication speed (12Mbps) (dose not support Low Speed).
  - · Supports 8 endpoints.

End -point 0 : Control 64 bytes × 1-FIFO

End -point 1 : Bulk ( Device  $\rightarrow$  Host : IN transfer ) 64 bytes  $\times$  2-FIFO

End -point 2 : Bulk (Host  $\rightarrow$  Device : OUT transfer) 64 bytes  $\times$  2-FIFO

End -point 3 : Bulk ( Device  $\rightarrow$  Host : IN transfer ) 64 bytes  $\times$  2-FIFO

End -point 4 : Bulk (Host  $\rightarrow$  Device : OUT transfer) 64 bytes  $\times$  2-FIFO

End -point 5 : Bulk ( Device  $\rightarrow$  Host : IN transfer ) 64 bytes  $\times$  2-FIFO

- End -point 6 : Bulk (Host  $\rightarrow$  Device : OUT transfer) 64 bytes  $\times$  2-FIFO
- End -point 7 : Interrupt ( Device  $\rightarrow$  Host : IN transfer ) 64 bytes  $\times$  2-FIFO
- From End-point 1 to 7 can be support 4 transfer modes.
- 9. 12-bit AD converter (ADC): 12channels
  - · Start up with 16-bit timer / Start up with an external trigger input
  - Fixed-channel / Scan channel mode
  - AD monitoring 2ch
  - Conversion time 1µs. (@fsys = 40MHz),1.67µs. (@fsys = 48MHz)

#### 10. Interrupt source

- Internal : 47 factors. The order of precedence can be set over 7 levels (except the watchdog timer interrupt).
- External : 10 factors. The order of precedence can be set over 7 levels.
- 11. Non-maskable interrupt (NMI)

Non-maskable interrupt (NMI) is generated by a watchdog timer or a NMI pin.

- 12. Input/ output ports (PORT): 74 pins (One 5V tolerant input include)
- 13. Low power consumption mode

Low power consumption mode: IDLE, STOP1

- 14. Clock generator (CG)
  - On-chip PLL (x8, the system clock is devided by 2)

- Clock gear function: The high-speed clock can be divided into 1/1, 1/2, 1/4, 1/8 or 1/16.
- 15. Endian

Little endian

- 16. Debug interface JTAG / SWD / SWV / TRACE (DATA 4bit)
- 17. JTAG interface

Boundary scan

- 18. Maximum operating frequency: 48 MHz
- 19. Operating voltage range

2.7 V to 3.6 V (with on-chip regulator)

3.0 V to 3.45 V (when USB is used)

#### 20. Temperature range

- -40 to 85 degrees (except during Flash writing/ erasing)
- 0 to 70 degrees (during Flash writing/ erasing)
- 21. Package

LFBGA105 (9mm × 9mm, 0.5mm pitch)

# 1.6 Internal regulator pins

REGOUT and REGIN pin are connect to capacitor which is for stability of internal regulator.

REGOUT and REGIN must be connected to RVSS through capacitor for supply power to internal regulator.

Please connect the capacitor by the shortest distance.

Is not power supply to external circuits from these terminals.

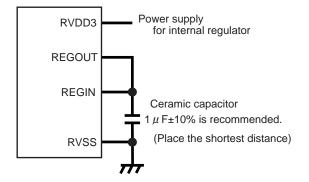

Figure 1-3 Internal regulator pins

# 2. Processor Core

The TX03 series has a high-performance 32-bit processor core (the ARM Cortex-M3 processor core). For information on the operations of this processor core, please refer to the "Cortex-M3 Technical Reference Manual" issued by ARM Limited. This chapter describes the functions unique to the TX03 series that are not explained in that document.

# 2.1 Information on the processor core

The following table shows the revision of the processor core in the TMPM365FYXBG.

Refer to the detailed information about the CPU core and architecture, refer to the ARM manual "Cortex-M series processors" in the following URL:

http://infocenter.arm.com/help/index.jsp

Product Name	Core Revision
TMPM365FYXBG	r2p0

# 2.2 Configurable Options

The Cortex-M3 core has optional blocks. The optional blocks of the revision r2p0 are ETM<sup>™</sup>, MPU and WIC. The following table shows the configurable options in the TMPM365FYXBG.

Configurable Options	Implementation
FPB	Two literal comparators Six instruction comparators
DWT	Four comparators
ITM	Present
MPU	Absent
ETM	Present
AHB-AP	Present
AHB Trace Macrocell In- terface	Absent
TPIU	Present
WIC	Absent
Debug Port	JTAG / Serial wire

# 2.3 Exceptions/ Interruptions

Exceptions and interruptions are described in the following section.

#### 2.3.1 Number of Interrupt Inputs

The number of interrupt inputs can optionally be defined from 1 to 240 in the Cortex-M3 core.

TMPM365FYXBG has 57 interrupt inputs. The number of interrupt inputs is reflected in <INTLINESNUM [4:0]> bit of NVIC register. In this product, if read <INTLINESNUM[4:0]> bit, 0x01 is read out.

#### 2.3.2 Number of Priority Level Interrupt Bits

The Cortex-M3 core can optionally configure the number of priority level interrupt bits from 3 bits to 8 bits.

TMPM365FYXBG has 3 priority level interrupt bits. The number of priority level interrupt bits is used for assigning a priority level in the interrupt priority registers and system handler priority registers.

#### 2.3.3 SysTick

The Cortex-M3 core has a SysTick timer which can generate SysTick exception.

For the detail of SysTick exception, refer to the section of "SysTick" in the exception and the register of SysTick in the NVIC register.

### 2.3.4 SYSRESETREQ

The Cortex-M3 core outputs SYSRESETREQ signal when <SYSRESETREQ> bit of Application Interrupt and Reset Control Register are set.

TMPM365FYXBG provides the same operation when SYSRESETREQ signal are output.

### 2.3.5 LOCKUP

When irreparable exception generates, the Cortex-M3 core outputs LOCKUP signal to show a serious error included in software.

TMPM365FYXBG does not use this signal. To return from LOCKUP status, it is necessary to use non-maskable interruput (NMI) or reset.

#### 2.3.6 Auxiliary Fault Status register

The Cortex-M3 core provides auxiliary fault status registers to supply additional system fault information to software.

However, TMPM365FYXBG is not defined this function. If auxiliary fault status register is read, always "0x0000\_0000" is read out.

## 2.4 Events

The Cortex-M3 core has event output signals and event input signals. An event output signal is output by SEV instruction execution. If an event is input, the core returns from low-power consumption mode caused by WFE instruction.

TMPM365FYXBG does not use event output signals and event input signals. Please do not use SEV instruction and WFE instruction.

# 2.5 Power Management

The Cortex-M3 core provides power management system which uses SLEEPING signal and SLEEPDEEP signal. SLEEPDEEP signals are output when <SLEEPDEEP> bit of System Control Register is set.

These signals are output in the following circumstances:

-Wait-For-Interrupt (WFI) instruction execution

-Wait-For-Event (WFE) instruction execution

-the timing when interrupt-service-routine (ISR) exit in case that <SLEEPONEXIT> bit of System Control Register is set.

TMPM365FYXBG does not use SLEEPDEEP signal so that <SLEEPDEEP> bit must not be set. And also event signal is not used so that please do not use WFE instruction.

For detail of power management, refer to the Chapter "Clock/Mode control."

## 2.6 Exclusive access

In Cortex-M3 core, the DCode bus system supports exclusive access. However TMPM365FYXBG does not use this function.

- 2. Processor Core
- 2.6 Exclusive access

# 3. Debug Interface

## 3.1 Specification Overview

TMPM365FYXBG contains the Serial Wire JTAG Debug Port (SWJ-DP) unit for interfacing with the debugging tools and the Embedded Trace Macrocell<sup>TM</sup>(ETM) unit for instruction trace output. Trace data is output to the dedicated pins(TRACEDATA[3:0], SWV) for the debugging via the on-chip Trace Port Interface Unit (TPIU).

For details about SWJ-DP, ETM and TPIU, refer to "Cortex-M3 Technical Reference Manual" .

# 3.2 SWJ-DP

SWJ-DP supports the Serial Wire Debug Port (SWCLK, SWDIO) and the JTAG Debug Port (TDI, TDO, TMS, TCK, TRST).

### 3.3 ETM

ETM supports four data signal pins (TRACEDATA[3:0]), one clock signal pin (TRACECLK) and trace output from Serial Wire Viewer (SWV).

# 3.4 Pin Functions

The debug interface pins can also be used as general-purpose ports.

The PI3 and PI4 pins are shared between the JTAG debug port function and the Serial Wire Debug Port function. The PI5 pin is shared between the JTAG debug port function and the SWV trace output function.

SWJ-DP	General-	JTAG Debug Function		SW Debug Function		
Pin Name	purpose Port Name	Ι/Ο	Explanation	Ι/Ο	Explanation	
TMS / SWDIO	PI4	Input	JTAG Test Mode Selection	I / O	Serial Wire Data Input/Output	
TCK / SWCLK	PI3	Input	JTAG Test Check	Input	Serial Wire Clock	
TDO / SWV	PI5	Output	JTAG Test Data Output	(Output)(Note)	(Serial Wire Viewer Output)	
TDI	PI6	Input	JTAG Test Data Input	-	-	
TRST	PI7	Input	JTAG Test RESET	-	-	
TRACECLK	PI2	Output	TRACE Clock Output			
TRACEDATA0	PI1	Output	TRACE DATA Output0			
TRACEDATA1	PI0	Output	TRACE DATA Output1			
TRACEDATA2	PH0	Output	TRACE DATA Output2			
TRACEDATA3	PH1	Output	TRACE DATA Output3			

Table 3-1 SWJ-DP, ETM Debug Functions

Note: When SWV function is enabled.

After reset, PI3, PI4, PI5, PI6 and PI7 pins are configured as debug port function pins. The functions of other debug interface pins need to be programmed as required.

When using a low power consumption mode, take note of the following points.

Note: If PI4 and PI5 are configured as TMS/SWDIO and TDO/SWV, output continues to be enabled even in STOP1 mode regardless of the setting of the CGSTBYCR<DRVE> bit.

Table 3-2 summarizes the debug interface pin and related port settings after reset.

Dether		Value of Related port settings after reset						
Port Name (Bit Name)	Debug Function	Function (PxFR)	Input (PxIE)	Output (PxCR)	Pull-up (PxPUP)	Pull-down (PxPDN)		
Pl4	TMS/SWDIO	1	1	1	1	-		
PI3	TCK/SWCLK	1	1	0	-	1		
PI5	TDO/SWV	1	0	1	0	-		
PI6	TDI	1	1	0	1	-		
PI7	TRST	1	1	0	1	-		
PI2	TRACECLK	0	0	0	0	-		
PI1	TRACEDATA0	0	0	0	0	-		
P10	TRACEDATA1	0	0	0	0	-		
PH0	TRACEDATA2	0	0	0	0	-		
PH1	TRACEDATA3	0	0	0	0	-		

#### Table 3-2 Debug Interface Pins and Related Port Settings after Reset

- : Don't care

# 3.5 Peripheral Functions in Halt Mode

When the Cortex-M3 core enters in the halt mode, the watchdog-timer (WDT) automatically stops. Other peripheral functions continue to operate.

# 3.6 Connection with a Debug Tool

#### 3.6.1 About connection with debug tool

Concerning a connection with debug tools, refer to manufactures recommendations.

Debug interface pins contain a pull-up resistor and a pull-down resistor. When debug interface pins are connected with external pull-up or pull-down, please pay attention to input level.

Note:Ensure that to measure the power-consumption with debug tool connected in STOP1 mode is prohibitted.

#### 3.6.2 Important points of using debug interface pins used as general-purpose ports

When setting a debugging interface terminal to a general-purpose port by a user's program after reset release, after that the control from a debugging tool is impossible.

Please note that it is necessary to prepare for the structure which changes the general-purpose port to the debugging interface function by some kind of methods to connect a debugging tool again.

	Debug interface pins							
	TRST	TDI	TDO / SWV	TCK / SWCLK	TMS / SWDIO	TRACE DATA[3:0]	TRACE CLK	
JTAG+SW (After reset)	0	0	0	0	0	×	×	
JTAG+SW (without TRST)	×	0	0	0	0	×	×	
JTAG+TRACE	0	0	0	0	0	0	0	
SW	×	×	×	о	0	×	×	
SW+SWV	×	×	0	о	0	×	×	
Debugging function disabled	×	×	×	×	×	×	×	

#### Table 3-3 Example Table of using debug interface pins

o : Enabled × : Disabled (Usable as general-purpose port)

# 4. JTAG Interface

### 4.1 Overview

The TMPM365FYXBG provides a boundary-scan interface that is compatible with Joint Test Action Group (JTAG) specifications and uses the industry-standard JTAG protocol (IEEE Standard 1149.1 • 1990 <Includes IEEE Standard 1449.1a • 1993>).

This chapter describes the JTAG interface, with the descriptions of boundary scan and the pins and signals used by the interface.

1. JTAG standard version

IEEE Standard 1149.1 • 1990 (Includes IEEE Standard 1149.1a • 1993)

2. JTAG instructions

Standard instructions (BYPASS, SAMPLE/PRELOAD, EXTEST)

HIGHZ instruction

CLAMP instruction

However, the SAMPLE/RELOAD instruction doesn't function because internal circuit reset starts as for TMPM365FYXBG while JTAG is operating.

3. IDCODE

Not available

- 4. Pins excluded from boundary scan register (BSR)
  - a. Oscillator circuit pins (X1, X2)
  - b. JTAG control pins (BSC)
  - c. Power supply/GND pins (including reference supply pin for ADC)
  - d. TEST pins (FTEST3)
  - e. Function pins (RESET)
  - f. Control pins (MODE )

Note: As for PF0 pin is always pull-up, the pin is output high-level while in HIGHZ instruction.

Note: Please note the input level to the analog input pins.

# 4.2 Signal Summary and Connection Example

The JTAG interface signals are listed below.

-	TDI	JTAG serial data input
-	TDO	JTAG serial data output
-	TMS	JTAG test mode select
-	ТСК	JTAG serial clock input
-	TRST	JTAG test reset input
	BSC	ICE/JTAG test select input (compatible with the Enable signal)
-	B3C	0: ICE, 1: JTAG

The TMPM365FYXBG supports debugging by connecting the JTAG interface with a JTAG-compliant development tool.

For information about debugging, refer to the specification of the development tool used.

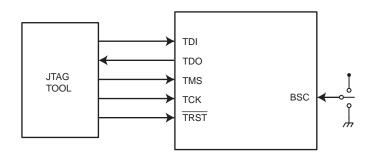

Figure 4-1 Example of connection with a JTAG development tool

Mode Setting Pin (BSC)	Operation mode		
0	Set this pin to 0 except for Boundary Scan Mode. The TMPM365FYXBG operates as regular Debug Mode. Note: Debugging is not available if the internal BOOT is run- ning.		
1	The TMPM365FYXBG operates in Boundary Scan Mode.		

# 4.3 Outline

With the evolution of ever-denser integrated circuits (ICs), surface-mounted devices, double-sided component mounting on printed-circuit boards (PCBs), and set-in recesses, in-circuit tests that depend upon physical contact like the connection of the internal board and chip has become more and more difficult to use. The more ICs have become complex, the larger and more difficult the test program became.

As one of the solutions, boundary-scan circuits started to be developed. A boundary-scan circuit is a series of shift register cells placed between the pins and the internal circuitry of the IC to which the said pins are connected. Normally, these boundary-scan cells are bypassed; when the IC enters test mode, however, the scan cells can be directed by the test program to pass data along the shift register path and perform various diagnostic tests. To accomplish this, the tests use the five signals, TCK, TMS, TDI, TDO and TRST.

The JTAG boundary-scan mechanism (hereinafter referred to as JTAG mechanism in the chapter) allows testing of the connections between the processor, the printed circuit board to which it is attached, and the other components on the circuit board.

The JTAG mechanism cannot test the processor alone.

# 4.4 JTAG Controller and Registers

The processor contains the following JTAG controller and registers.

- Instruction register
- Boundary scan register
- Bypass register
- Device identification register
- Test Access Port (TAP) controller

JTAG basically operates to monitor the TMS input signal with the TAP controller state machine. When the monitoring starts, the TAP controller determines the test functionality to be implemented. This includes both loading the JTAG instruction register (IR) and beginning a serial data scan through a data register (DR), as shown in Table 4-1. As the data is scanned, the state of the TMS pin signals each new data word and indicates the end of the data stream. The data register is selected according to the contents of the instruction register.

# 4.5 Instruction Register

The JTAG instruction register includes four shift register-based cells. This register is used to select the test to be performed and/or the test data register to be accessed. As listed in Table 4-1, this instruction codes select either the boundary scan register or the bypass register.

Instruction code (MSB to LSB)	Instruction	Selected data register	
0000	EXTEST	Boundary scan register	
0001	SAMPLE/PRELOAD	Boundary scan register	
0100 to 1110	Reserved	Reserved	
0010	HIGHZ	Bypass register	
0011	CLAMP	Bypass register	
1111	BYPASS	Bypass register	

Table 4-1 JTAG Instruction Register Bit Configuration

Figure 4-2 shows the format of the instruction register.

Figure 4-2 Instruction register

The instruction code is shifted out to the instruction register from the LSB.

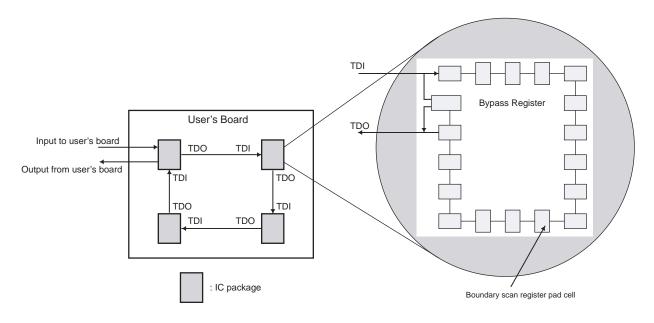

Figure 4-3 Instruction Register Shift Direction

The bypass register is 1 bit wide. When the TAP controller is in the Shift-DR (bypass) state, the data on the TDI pin is shifted into the bypass register, and the bypass register output shifts to the data out on the TDO output pin.

In essence, the bypass register is an alternative route which allows bypassing of board-level devices in the serial boundary-scan chain, which are not required for a specific test. The logical location of the bypass register in the boundary-scan chain is shown in Figure 4-4.

Use of the bypass register speeds up access to the boundary scan register in the IC that remains active in the board-level test data path.

# 4.6 Boundary Scan Register

The boundary scan register provides all the inputs and outputs of the TMPM365FYXBG processor except some analog outputs and control signals. The pins of the TMPM365FYXBG allow any pattern to be driven by scanning the data into the boundary scan register in the Shift-DR state. Incoming data to the processor is examined by enabling the boundary scan register and shifting the data when the BSR is in the Capture-DR state.

The boundary scan register is a single, 231-bit-wide, shift register-based path containing cells connected to the input and output pads on the TMPM365FYXBG.

The TDI input is loaded to the LSB of the boundary scan register. The MSB of the boundary scan register is shifted out on the TDO output.

# 4.7 Test Access Port (TAP)

The Test Access Port (TAP) consists of the five signal pins: TRST, TDI, TDO, TMS and TCK. These pins control a test by communicating the serial test data and instructions.

As Figure 4-5 shows, data is serially scanned into one of the three registers (instruction register, bypass register or boundary scan register) on the TDI pin, or it is scanned out from one of these three registers on the TDO pin.

The TMS input controls the state transitions of the main TAP controller state machine. The TCK input is a special test clock that allows serial JTAG data to be shifted synchronously, independent of any chip-specific or system clocks.

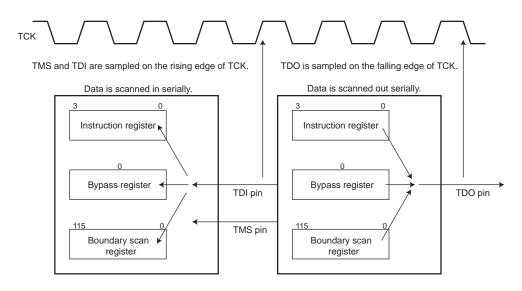

Figure 4-5 JTAG Test Access Port

Data on the TDI and TMS pins are sampled on the rising edge of the TCK input clock signal. Data on the TDO pin changes on the falling edge of the TCK clock signal.

# 4.8 TAP Controller

The processor incorporates the 16-state TAP controller stipulated in the IEEE JTAG specification.

# 4.9 Resetting the TAP Controller

The TAP controller state machine can be put into the Reset state by the following method.

Assertion of the TRST signal input (low) resets the TAP controller. After the processor reset state is released, keep the TMS input signal asserted through five consecutive rising edges of TCK input. Keeping TMS asserted maintains the Reset state.

# 4.10 State Transitions of the TAP Controller

The state transition diagram of the TAP controller is shown in Figure 4-6. Each arrow between states is labeled with a 1 or 0, indicating the logic value of TMS that must be set up before the rising edge of TCK to cause the transition.

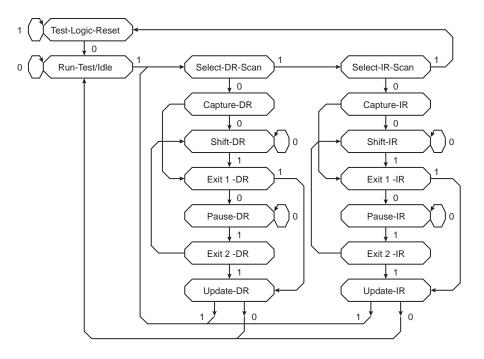

Figure 4-6 TAP Controller State Transition Diagram

The following paragraphs describe each of the controller states. The left column in Figure 4-6 is the data column, and the right column is the instruction column. The data column and instruction column reference the data register (DR) and the instruction register (IR), respectively.

Test-Logic-Reset

When the TAP controller is in the Reset state, the device identification register is selected by default. The MSB of the boundary scan register is cleared to 0 which disables the outputs.

The TAP controller remains in this state while TMS is high. If TMS is held low while the TAP controller is in this state, then the controller moves to the Run-Test/Idle state.

• Run-Test/Idle

In the Run-Test/Idle state, the IC is put in test mode only when certain instructions such as a built-in self test (BIST) instruction are present. For instructions that do not cause any activities in this state, all test data registers selected by the current instruction retain their previous states.

The TAP controller remains in this state while TMS is held low. When TMS is held high, the controller moves to the Select-DR-Scan state.

• Select-DR-Scan

This is a temporary controller state. Here, the IC does not execute any specific functions.

If TMS is held low when the TAP controller is in this state, the controller moves to the Capture-DR state. If TMS is held high, the controller moves to the Select-IR-Scan state.

• Select-IR-Scan

This is a temporary controller state. Here, the IC does not execute any specific functions.

If TMS is held low when the TAP controller is in this state, the controller moves to the Capture-IR state. IF TMS is held high, the controller returns to the Test-Logic-Reset state.

#### · Capture-DR

In this state, if the test data register selected by the current instruction has parallel inputs, then data is parallel-loaded into the shift portion of the data register. If the test data register does not have parallel inputs, or if data needs not be loaded into the selected data register, then the data register retains its previous state.

If TMS is held low when the TAP controller is in this state, the controller moves to the Shift-DR state. If TMS is held high, the controller moves to the Exit 1-DR state.

#### Shift-DR

In this controller state, the test data register connected between TDI and TDO shifts data out serially.

When the TAP controller is in this state, then it remains in the Shift-DR state if TMS is held low, or moves to the Exit 1-DR state if TMS is held high.

• Exit 1-DR

This is a temporary controller state.

If TMS is held low when the TAP controller is in this state, the controller moves to the Pause-DR state. If TMS is held high, the controller moves to the Update-DR state.

Pause-DR

This state allows the shifting of the data register selected by the instruction register to be temporarily suspended. Both the instruction register and the data register retain their current states.

When the TAP controller is in this state, then it remains in the Pause-DR state if TMS is held low, or moves to the Exit 2-DR state if TMS is held high.

• Exit 2-DR

This is a temporary controller state.

When the TAP controller is in this state, it returns to the Shift-DR state if TMS is held low, or moves on to the Update-DR state if TMS is held high.

• Update-DR

In this state, data is latched, on the rising edge of TCK, onto the parallel outputs of the data registers from the shift register path. The data held at the parallel output does not change while data is shifted in the associated shift register path.

When the TAP controller is in this state, it moves to either the Run-Test/Idle state if TMS is held low, or the Select-DR-Scan state if TMS is held high.

• Capture-IR

In this state, data is parallel-loaded into the instruction register. The data to be loaded is 0y0001. The Capture-IR state is used for testing the instruction register. Faults in the instruction register, if any, may be detected by shifting out the loaded data.

When the TAP controller is in this state, it moves to either the Shift-IR state if TMS is held low, or the Exit 1-IR state if TMS is high.

Shift-IR

In this state, the instruction register is connected between TDI and TDO and shifts the captured data toward its serial output on the rising edge of TCK.

When the TAP controller is in this state, it remains in the Shift-IR state if TMS is low, or moves to the Exit 1-IR state if TMS is high.

Exit 1-IR

This is a temporary controller state.

When the TAP controller is in this state, it moves to either the Pause-IR state if TMS is held low, or the Update-IR state if TMS is held high.

#### • Pause-IR

This state allows the shifting of the instruction register to be temporarily suspended. Both the instruction register and the data register retain their current states.

When the TAP controller is in this state, it remains in the Pause-IR state if TMS is held low, or moves to the Exit 2-IR state if TMS is held high.

• Exit 2-IR

This is a temporary controller state.

When the TAP controller is in this state, it moves to either the Shift-IR state if TMS is held low, or the Update-IR state if TMS is held high.

• Update-IR

This state allows the instruction previously shifted into the instruction register to be output in parallel on the rising edge of TCK. Then it becomes the current instruction, setting a new operational mode.

When the TAP controller is in this state, it moves to either the Run-Test/Idle state if TMS is low, or the Select-DR-Scan state if TMS is high.

# 4.11 Boundary Scan Order

The below table shows the boundary scan order with respect to the processor signals.

 $\text{TDI} \rightarrow 1 \text{ (PK3)} \rightarrow 2(\text{PK2}) \rightarrow - \rightarrow 69(\text{PI1}) \rightarrow 70(\text{PI2}) \rightarrow \text{TDO}$ 

No.	Pin Name	No.	Pin Name	No.	Pin Name	No.	Pin Name
	TDI						
1	PK3	21	PE0	41	PA4	61	PG4
2	PK2	22	PD0	42	PA3	62	PG5
3	PK1	23	PD1	43	PA2	63	PH4
4	PK0	24	PD2	44	PA1	64	PH3
5	PJ7	25	PD3	45	PA0	65	PH2
6	PJ6	26	PD4	46	PF7	66	PH1
7	PJ5	27	PD5	47	PF6	67	PH0
8	PJ4	28	PD6	48	PF5	68	PI0
9	PJ3	29	PD7	49	PF4	69	PI1
10	PJ2	30	PB7	50	PF3	70	PI2
11	PJ1	31	PB6	51	PF2		TDO
12	PJ0	32	PB5	52	PF1		
13	PE7	33	PB4	53	PF0		
14	PE6	34	PB3	54	PC2		
15	PE5	35	PB2	55	PC1		
16	PE4	36	PB1	56	PC0		
17	NMI	37	PB0	57	PG0		
18	PE3	38	PA7	58	PG1		
19	PE2	39	PA6	59	PG2		
20	PE1	40	PA5	60	PG3		

Table 4-2 JTAG Scan Order of the TMPM365FYXBG Processor Pins

# 4.12 Instructions Supported by the JTAG Controller Cells

This section describes the instructions supported by the JTAG controller cells of the TMPM365FYXBG.

#### 1. EXTEST instruction

The EXTEST instruction is used for external interconnect tests. The EXTEST instruction permits BSR cells at output pins to shift out test patterns in the Update-DR state and those at input pins to capture test results in the Capture-DR state.

Typically, before EXTEST is executed, the initialization pattern is shifted into the boundary scan register using the SAMPLE/PRELOAD instruction. If the boundary scan register is not reset, indeterminate data will be transferred in the Update-DR state and bus conflicts between ICs may occur. Figure 4-7 shows data flow when the EXTEST instruction is selected.

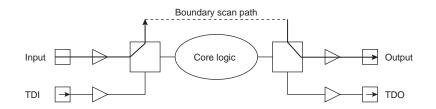

Figure 4-7 Test Data Flow when the EXTEST Instruction is Selected

The following steps describe the basic test procedure of the external interconnect test.

- 1. Reset the TAP controller to the Test-Logic-Reset state.
- 2. Load the instruction register with the SAMPLE/PRELOAD instruction. This causes the boundary scan register to be connected between TDI and TDO.
- 3. Reset the boundary scan register by shifting certain data in.
- 4. Load the test pattern into the boundary scan register.
- 5. Load the instruction register with the EXTEST instruction.
- 6. Capture the data applied to the input pin into the boundary scan register.
- 7. Shift out the captured data while simultaneously shifting the next test pattern in.
- 8. Send out the test pattern in the boundary scan register at the output on the output pin.

Repeat steps 6 to 8 for each test pattern.

#### 2. SAMPLE/PRELOAD instruction

This instruction targets the boundary scan register between TDI and TDO. As its name implies, the SAM-PLE/PRELOAD instruction provides two functions.

SAMPLE allows the input and output pads of an IC to be monitored. While it does so, it does not disconnect the system logic from the IC pins. SAMPLE is executed in the Capture-DR state. It is mainly used to capture the values of the IC's I/O pins on the rising edge of TCK during normal operation. Figure 4-8 shows the flow of data for the SAMPLE phase of the SAMPLE/PRELOAD instruction.

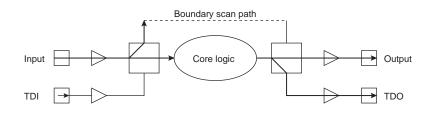

Figure 4-8 Test Data Flow while the SAMPLE is Selected

PRELOAD allows the boundary scan register to be reset before any other instruction is selected. For example, prior to selection of the EXTEST instruction, PRELOAD is used to load reset data into the boundary scan register. PRELOAD permits data shifting of the boundary scan register without interfering with the normal operation of the system logic. Figure 4-9 shows the data flow for the PRELOAD phase of the SAMPLE/PRELOAD instruction.

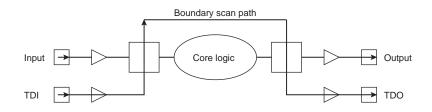

Figure 4-9 Test Data Flow while PRELOAD is Selected

3. BYPASS instruction

This instruction targets the bypass register between JTDI and JTDO. The bypass register provides the shortest serial path that bypasses the IC (between JTDI and JTDO) when the test does not require control or monitoring of the IC. The BYPASS instruction does not cause interference in the normal operation of the on-chip system logic. Figure 4-10 shows the data flow through the bypass register when the BY-PASS instruction is selected.

Figure 4-10 Test Data Flow when the BYPASS Instruction is Selected

4. CLAMP instruction

The CLAMP instruction outputs the value that boundary scan register is programmed according to the PRELOAD instruction, and execute Bypass operation.

The CLAMP instruction selects the bypass register between TDI and TDO.

#### 5. HIGHZ instruction

The HIGHZ instruction disables the output of the internal logical circuits. When the HIGHZ instruction is executed, it places the 3-state output pins in the high-impedance state.

The HIGHZ instruction also selects the bypass register between TDI and TDO.

• Notes

This section describes the cautions of the JTAG boundary-scan operations specific to the processor.

- 1. As for a PF0 pin is always pull-up, whenever HIGHZ is ordered, High is output.
- 2. Please note the input level to the analog input pins.
- The JTAG circuit can be released from the reset state by either of the following two methods: Assert TRST, initialize the JTAG circuit, and then deassertion TRST.
   Supply the TCK signal for 5 or more clock pulses to TCK while pulling the TMS pin High.

4.12 Instructions Supported by the JTAG Controller Cells

# 5. Memory Map

## 5.1 Memory map

The memory maps for the TMPM365FYXBG are based on the ARM Cortex-M3 processor core memory map.

The internal ROM is mapped to the code of the Cortex-M3 core memory, the internal RAM is mapped to the SRAM region and the special function register (SFR) is mapped to the peripheral region respectively.

The special function register (SFR) indicates I/O ports and control registers for the peripheral function. The SRAM and SFR regions are all included in the bit-band region.

The CPU register region is the processor core's internal register region.

For more information on each region, see the "Cortex-M3 Technical Reference Manual".

Note that access to regions indicated as "Fault" causes a memory fault if memory faults are enabled or a hard fault if memory faults are disabled. Do not access the vendor-specific region.

# 5.1.1 Memory map of the TMPM365FYXBG

Figure 5-1shows the memory map of the TMPM365FYXBG.

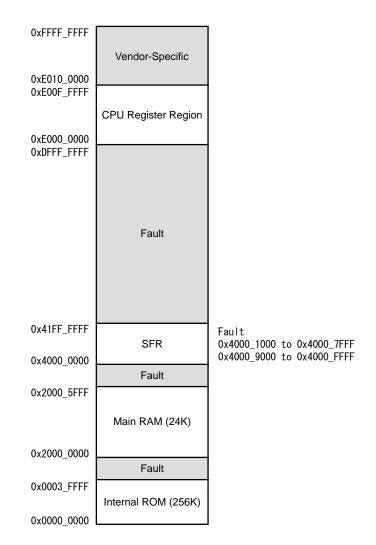

Figure 5-1 Memory Map

# 5.2 SFR area detail

This section contains the list of addresses in the SFR area (0x4000\_0000 through 0x41FF\_FFFF) assigned to peripheral function.

Access to the Reserved areas in the Table 5-1, the address not specified and the Reserved area in each chapter are prohibited. As for the SFR area, the areas not specified in each chapter is read an undefined value. Writing this area is ignored.

Start Address	End Address	Peripheral	Reserved

Table 5-1 SFR area detail

5. Memory Map

#### 5.2 SFR area detail

# 6. Reset

The TMPM365FYXBG has four reset sources: an external reset pin ( $\overline{\text{RESET}}$ ), a watchdog timer (WDT) and the setting <SYSRESETREQ> in the Application Interrupt and Reset Control Register.

For reset from the WDT, refer to the chapter on the WDT.

For reset from <SYSRESETREQ>, refer to "Cortex-M3 Technical Reference Manual".

### 6.1 Initial state

The internal circuits of the TMPM365FYXBG are undefined right after the power-on.

The register settings and pin status are undefined until the external reset pin ( $\overline{\text{RESET}}$ ) receives low level after all the power supply voltage (DVDD3A, DVDD3C, RVDD3 and AVDD3) is applied.

# 6.2 Cold reset

The power-on sequence must include the time for the internal regulator, internal flash memory and internal oscillator to be stable.

In the TX03, the internal circuit automatically insert the time for the internal regulator, internal flash memory and internal oscillator. To keep this time, the reset pin must be hold "Low" level during 1ms or more after the voltage level of power supply is within the operation voltage level.

The internal reset signal is released after the level of reset pin (RESET) is "High" and it takes aproximate 0.8ms.

Figure 6-1 shows the cold reset sequence after power-on.

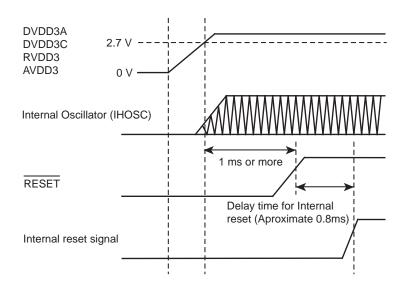

Figure 6-1 Cold Reset Sequence

Note: The above sequence is applied as well when restoring power.

# 6.3 Warm reset

#### 6.3.1 Reset period

As a precondition, ensure that the power supply voltage is within the operating range and the internal high-frequency oscillator is providing stable oscillation.

To reset the TMPM365FYXBG, keeps the external reset pin (RESET) for a minimum duration of 12 systemclocks.

The internal reset signal is released after the level of reset pin ( $\overline{\text{RESET}}$ ) is "High" and it takes approximate 0.8ms.

# 6.4 After reset

A reset initializes the majority of the Cortex-M3 processor core's system control registers and internal function registers.

The processor core's system debug components (FPB, DWT, ITM) register, the clock generator's CGRSTFLG register and the FCSECBIT register are initialized by cold reset.

After reset, the PLL multiplication circuit is inactive and must be enabled if needed.

When the reset exception handling is completed, the program branches to the reset interrupt service routine.

Note: The reset operation may alter the internal RAM state.

# 7. Watchdog Timer(WDT)

The watchdog timer (WDT) is for detecting malfunctions (runaways) of the CPU caused by noises or other disturbances and remedying them to return the CPU to normal operation.

If the watchdog timer detects a runaway, it generates a INTWDT interrupt or reset.

Note: INTWDT interrupt is a factor of the non-maskable interrupts (NMI).

Also, the watchdog timer notifies of the detecting malfunction to the external peripheral devices from the watchdog timer pin (WDTOUT) by outputting "Low".

Note: This product does not have the watchdog timer out pin (WDTOUT).

# 7.1 Configuration

Figure 7-1shows the block diagram of the watchdog timer.

# 7.3 Operations

## 7.3.1 Basic Operation

The Watchdog timer is consists of the binary counters that work using the system clock (fsys) as an input. Detecting time can be selected between  $2^{15}$ ,  $2^{17}$ ,  $2^{19}$ ,  $2^{21}$ ,  $2^{23}$  and  $2^{25}$  by the WDMOD<WDTP[2:0]>. The detecting time as specified is elapsed, the watchdog timer interrupt (INTWDT) generates, and the watchdog timer out pin (WDTOUT) output "Low".

To detect malfunctions (runaways) of the CPU caused by noise or other disturbances, the binary counter of the watchdog timer should be cleared by software instruction before INTWDT interrupt generates. If the binary counter is not cleared, the non-maskable interrupt generates by INTWDT. Thus CPU detects malfunction (runway), malfunction countermeasure program is performed to return to the normal operation.

Additionally, it is possible to resolve the problem of a malfunction (runaway) of the CPU by connecting the watchdog timer out pin to reset pins of peripheral devices.

Note: This product does not include a watchdog timer out pin (WDTOUT).

### 7.3.2 Operation Mode and Status

The watchdog timer begins operation immediately after a reset is cleared.

If not using the watchdog timer, it should be disabled.

The watchdog timer cannot be used as the high-speed frequency clock is stopped. Before transition to below modes, the watchdog timer should be disabled.In IDLE mode, its operation depends on the WDMOD <I2WDT> setting.

- STOP1 mode

Also, the binary counter is automatically stopped during debug mode.

# 7.4 Operation when malfunction (runaway) is detected

## 7.4.1 INTWDT interrupt generation

In the Figure 7-2 shows the case that INTWDT interrupt generates (WDMOD<RESCR>="0").

When an overflow of the binary counter occurs, INTWDT interrupt generates. It is a factor of non-maskable interrupt (NMI). Thus CPU detects non-maskable interrupt and performs the countermeasure program.

The factor of non-maskable interrupt is the plural. CGNMIFLG identifies the factor of non-maskable interrupts. In the case of INTWDT interrupt, CGNMIFLG<NMIFLG0> is set.

When INTWDT interrupt generates, simultaneously the watchdog timer out ( $\overline{WDTOUT}$ ) output "Low".  $\overline{WDTOUT}$  becomes "High" by the watchdog timer clearing that is writing clear code 0x4E to the WDCR register.

Note: This product does not have the watchdog timer output pin(WDTOUT).

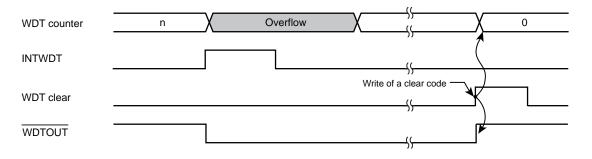

Figure 7-2 INTWDT interrupt generation

## 7.4.2 Internal reset generation

Figure 7-3 shows the internal reset generation (WDMOD<RESCR>="1").

MCU is reset by the overflow of the binary counter. In this case, reset status continues for 32 states. A clock is initialized so that input clock (fsys) is the same as a internal high-speed frequency clock (fosc). This means fsys = fosc.

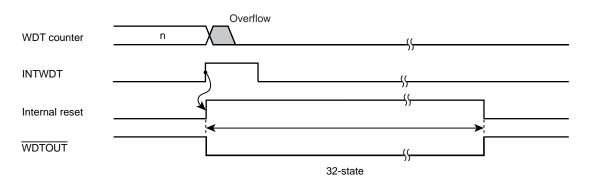

Figure 7-3 Internal reset generation

# 7.5 Control register

The watchdog timer (WDT) is controlled by two control registers WDMOD and WDCR.

## 7.5.1 Watchdog Timer Mode Register (WDMOD)

1. Specifying the detection time of the watchdog timer <WDTP[2:0]>.

Set the watchdog timer detecting time to WDMOD<WDTP[2:0]>. After reset, it is initialized to WDMOD<WDTP[2:0]> = "000".

2. Enabling/disabling the watchdog timer <WDTE>.

When resetting, WDMOD <WDTE> is initialized to "1" and the watchdog timer is enabled.

To disable the watchdog timer to protect from the error writing by the malfunction, first <WDTE> bit is set to "0", and then the disable code (0xB1) must be written to WDCR register.

To change the status of the watchdog timer from "disable" to "enable," set the <WDTE> bit to "1".

3. Watchdog timer out reset connection <RESCR>

This register specifies whether WDTOUT is used for internal reset or interrupt. After reset, WDMOD<RESCR> is initialized to "1", the internal reset is generated by the overflow of binary counter.

### 7.5.2 Watchdog Timer Control Register(WDCR)

This is a register for disabling the watchdog timer function and controlling the clearing function of the binary counter.

## 7.5.3 Setting example

#### 7.5.3.1 Disabling control

By writing the disable code (0xB1) to this WDCR register after setting WDMOD <WDTE> to "0," the watchdog timer can be disabled and the binary counter can be cleared.

7 6 5 4 3 2 1 0 WDMOD \_ Set <WDTE> to "0". 0 \_ \_ \_ WDCR 1 0 0 0 1 Writes the disable code (0xB1). 1 0 1

#### 7.5.3.2 Enabling control

- 7.5 Control register

# 8. Clock/Mode control

## 8.1 Features

The clock/mode control block enables to select clock gear, prescaler clock and warm-up of the PLL clock multiplication circuit and oscillator.

There is also the low power consumption mode which can reduce power consumption by mode transitions.

This chapter describes how to control clock operating modes and mode transitions.

The clock/mode control block has the following functions:

- Controls the system clock
- Controls the prescaler clock
- Controls the PLL multiplication circuit
- Controls the warm-up timer

In addition to NORMAL mode, the TMPM365FYXBG can operate in low power mode to reduce power consumption according to its usage conditions.

# 8.2 Registers

## 8.2.1 Register List

The following table shows the CG-related registers and addresses.

		Base Address = 0x400F_3000
Register name		Address(Base+)
System control register	CGSYSCR	0x0000
Oscillation control register	CGOSCCR	0x0004

			Except 0xC1 : Register write disable
			Initial value is "0xC1" as writing enable to each register and when writing except "0xC1", each register except CGPROTECT regiser can not be written.

# 8.3 Clock control

### 8.3.1 Clock type

Each clock is defined as follows:

fosc	: Clock generated by internal oscillator. Clock input from the X1 and X2 pins.
f <sub>PLL</sub>	: Clock multiplied by 8 by PLL.
fc	: Clock specified by CGPLLSEL <pllsel> (high-speed clock)</pllsel>
fgear	: Clock specified by CGSYSCR <gear[2:0]> (Gear clock)</gear[2:0]>
fsys	: Clock specified by same as fgear clock (system clock)
fperiph	: Clock specified by CGSYSCR <fpsel></fpsel>
φT0	: Clock specified by CGSYSCR <prck[2:0]> (prescaler clock)</prck[2:0]>

The gear clock fgear and the prescaler clock  $\phi T0$  are dividable as follows.

High-speed clock	: fc, fc/2, fc/4, fc/8, fc/16
Prescaler clock	: fperiph, fperiph/2, fperiph/4, fperiph/8, fperiph/16, fperiph/32

### 8.3.2 Initial Values after Reset

Reset operation initializes the clock configuration as follows.

internal high-speed oscillator	: oscillating
external high-speed oscillator	: stop
PLL (phase locked loop circuit)	: stop
High-speed clock gear	: fc (no frequency dividing)

Reset operation causes all the clock configurations to be the same as fosc.

fc = foscfsys = fosc $\phi T0 = fosc$ 

## 8.3.3 Clock system Diagram

Figure 8-1 shows the clock system diagram.

The input clocks to selector shown with an arrow are set as default after reset.

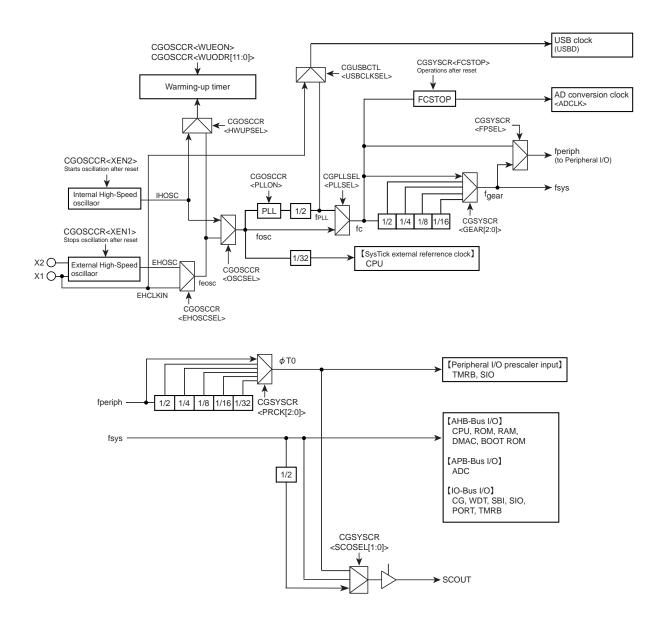

Figure 8-1 Clock Block Diagram

#### 8. Clock/Mode control

#### 8.3.4 Warm-up function

The warm-up function secures the stability time for the oscillator and the PLL with the warm-up timer. The detail of warm-up function is described in "8.6.6 Warm-up".

How to configure the warm-up function.

1. Specify the count up clock

Specify the count up clock for the warm-up counter in the CGOSCCR<HWUPSEL>

2. Specify the warm-up counter value

The value can be calculated by following formula with round lower 4 bit off, set to the bit of <WUODR[11:0]>. The warm-up time can be selected by setting the CGOSCCR<WUODR[11:0]>.

number of warm-up cycle =  $\frac{\text{warm-up time to set}}{\text{input frequency cycle (s)}}$ 

<example 1> When using high-speed oscillator 8MHz, and set warm-up time 5ms.

 $\frac{\text{warm-up time to set}}{\text{input frequency cycle (s)}} = \frac{5\text{ms}}{1/8\text{MHz}} = 40000 \text{ cycle} = 0x9C40$ 

Round lower 4 bit off, set 0x9C4 to CGOSCCR<WUODR[11:0]>

3. confirm the start and completion of warm-up

The CGOSCCR<WUEON><WUEF> is used to confirm the start and completion of warm-up through software (instruction).

When CGOSCCR<WUEON> is set to "1", the warm-up start a count up. The completion of warm-up can be confirmed with CGOSCCR<WUEF>.

The example of warm-up function setup.

Table 8-1 <example> from STOP mode to NORMAL mode transition (internal high-speed oscillator is selected)

CGOSCCR <wuodr[11:0]> = "0x9C4"</wuodr[11:0]>	: Specify the warm-up time
CGOSCCR <wuodr[11:0]> read</wuodr[11:0]>	: Confirm warm-up time reflecting
CGOSCCR <xen2> = "1"</xen2>	: Internal high-speed oscillator (IHOSC) enable
CGOSCCR <wueon> = "1"</wueon>	: Start the warm-up timer (WUP)
CGOSCCR <wuef> read</wuef>	: Wait until the state becomes "0" (warm-up is finished)

Note 1: It is not required the warm-up time in using the external clock to be stabled.

- Note 2: The warm-up timer operates according to the oscillation clock, and it may contain errors if there is any fluctuation in the oscillation frequency. Therefore, the warm-up time should be taken as approximate time.
- Note 3: Setting warm-up count value to CGOSCCR<WUODR[11:0]>, wait until this value is reflected, then transit to standby mode by executing a command "WFI"
- Note 4: When returning from STOP1 mode, related bits CGPLLSEL<PLLSEL>, CGOSCCR<HWUPSEL>, <OSCSEL>, <XEN2>, <XEN1> and <PLLON> are initialized because of internal high-speed oscillator starting, and CGOSCCR<WUODR[11:0]> is not initialized.

### 8.3.5 Clock Multiplication Circuit (PLL)

This circuit outputs the  $f_{PLL}$  clock that is multiplied by 8 of the high-speed oscillator output clock (fosc). As a result, the input frequency to oscillator can be low frequency, and the internal clock be made high-speed.

#### 8.3.5.1 Start operation

The PLL is disabled after reset.

In order to use PLL, set a multiplication value to CGPLLSEL<PLLSET> while CGOSCCR<PLLON> is "0". Then wait until approximately 100 $\mu$ s has elapsed as a PLL initial stabilization time, and set "1" to <PLLON> to start PLL operation. After that, in order to use f<sub>PLL</sub>clock, wait until approximately 100 $\mu$ s has elapsed as a lock up time, then after set "1" to CGPLLSEL<PLLSEL>. This allows fosc to be multiplied by 8-fold. Note that a warm-up time is required until PLL operation becomes stable using warm-up function.

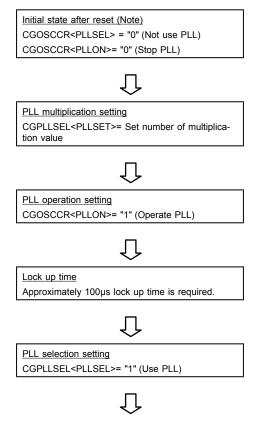

Note: Do not use PLL while internal oscillator (IHOSC) is used.

As for the 8 multiplying value, only the following setting are permitted.

Multiplying	<pllsel></pllsel>
8	0x381E

The sequence of starting PLL is shown belows.

#### (1) PLL Operation Start Procedure

Multiplied system clock can be used.

#### 8.3.6 System clock

The internal high-speed oscillation clock and the external high-speed oscillation clocks which are an oscillator connecting or an inputting clock can be used as a source clock of the system clock.

When using internal high-speed oscillation clock, do not use it as system clock which high accuracy assurance is required.

When using external high-speed oscilltion clock, the PLL function can be used by multiplying.

Sou	rce clock	Frequency	Using PLL
Internal high-spe	Internal high-speed oscillation (IHOSC)		can not use
External high-speed	ernal high-speed Oscillator (EHOSC)		disused or 8 multi-
oscillation	<b>U</b>		plying

The clock two dividing can be used as a system clock and an ADC clock. The frequency that can be used respectively is as follows.

	System clock	ADC clock
Operation frequency (MHz)	1 to 48	40 (Max.)

The system clock can be divided by CGSYSCR<GEAR[2:0]>. Although the setting can be changed while operating, the actual switching takes place after a slight delay.

Table 8-2 shows the example of the operation frequency by the setting of PLL and the clock gear.

Table 8-2 The setting example of operation frequency depended on PLL multiplying and the clock gear setting

External	External	PLL	Max. oper- ation freq.	A/DC Max. op-			k gear LL = O	. ,				k gear _L = Of	. ,	
oscillator (MHz)	clock input (MHz)	multiplying	(fc) (MHz)	eration freq. (MHz)	1/1	1/2	1/4	1/8	1/16	1/1	1/2	1/4	1/8	1/16
8	8		32	32	32	16	8	4	2	8	4	2	1	-
10	10	8	40	40	40	20	10	5	2.5	10	5	2.5	1.25	-
12	12		48	24 <sub>Note1)</sub>	48	24	12	6	3	12	6	3	1.5	-
-	48	-	48	24 Note1)	-	-	-	-	-	48	24	12	6	3

↑ Initial value after reset

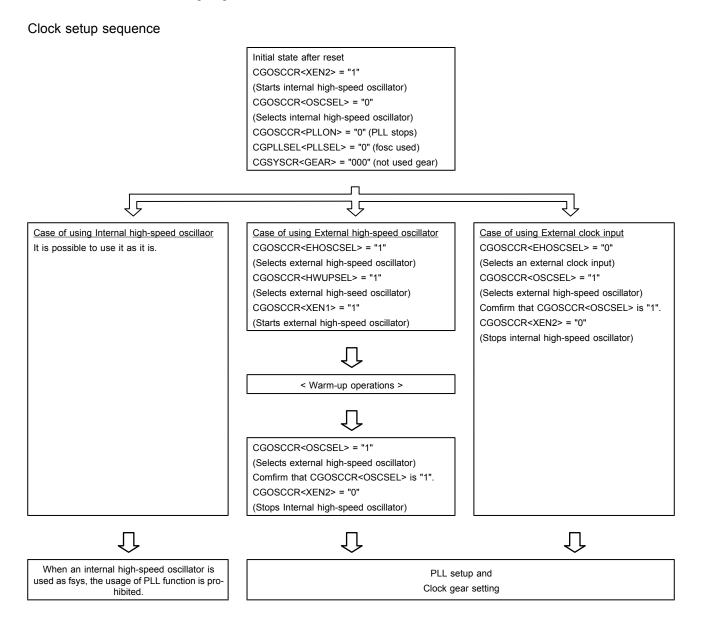

Note 1: Maximum Operating Frequency of ADC is 40MHz, which is 2 dividing fc/2 frequency specified by ADxCLK<ADCLK.> register.

Note 2: Don't use 1/16 when SysTick is used.

#### 8.3.6.1 System Clock setting

The system clock can be selected by setting the CGOSCCR. After the clock is selected, the PLL setting is done if necessary with CGPLLSEL and CGOSCCR. And, the clock gear is set with CGSYSCR.

The clock setup sequence is shown as follow.

# 8.3.7 Prescaler Clock Control

Peripheral function has a prescaler for dividing a clock. As the clock  $\phi$ T0 to be input to each prescaler, the "fperiph" clock specified in the CGSYSCR<FPSEL> can be divided according to the setting in the CGSYSCR<PRCK[2:0]>. After the controller is reset, fperiph/1 is selected as  $\phi$ T0.

Note 1: To use the clock gear, ensure that you make the time setting such that prescaler output  $\phi$ Tn from each peripheral function is slower than fsys ( $\phi$ Tn ≤ fsys). Do not switch the clock gear while the timer counter or other peripheral function is operating.

Only when TBxCR<FT0SEL> is "1",  $\phi Tn$  can be less or equal than fsys.

Note 2: Don't change prescaler for dividing until the peripheral function such as TMRB is operated.

# 8.3.8 System Clock Pin Output Function

The TX03 enables to output the system clock from a pin. The PD7/SCOUT pin can output the system clock fsys and fsys/2, and the prescaler input clock for peripheral I/O  $\phi$ T0.

- Note 1: The phase difference (AC timing) between the system clock output by the SCOUT and the internal clock is not guaranteed.
- Note 2: When fsys is output from SCOUT pin, SCOUT pin outputs the unexpected waveform just after changing clock gear. In the case of influencing to system by the unexpected waveform, the output of SCOUT pin shold be disabled when changing the clock gear.

Regarding to setting when port is used as SCOUT, refer to "Input/Output port".

Table 8-3 shows the pin status in each mode when the SCOUT pin is set to the SCOUT output.

### Table 8-3 SCOUT Output Status in Each Mode

Mode		Low power con	sumption mode
SCOUT selection CGSYSCR	NORMAL	IDLE	STOP1
<scosel[1:0]> = "00"</scosel[1:0]>	Reserved		
<scosel[1:0]> = "01"</scosel[1:0]>	Output the fsys/2 clock		
<scosel[1:0]> = "10"</scosel[1:0]>	Output the fsys clock		
<scosel[1:0]> = "11"</scosel[1:0]>	Output the $\phi$ T0 clock	Fixed to '	'0" or "1".

# TOSHIBA

# 8.4 Modes and Mode Transitions

### 8.4.1 Mode Transitions

The IDLE and STOP1 modes can be used as the low power consumption mode that enables to reduce power consumption by halting processor core operation.

Figure 8-2 shows a mode transition diagram.

For a detail of sleep-on-exit, refer to "Cortex-M3 Technical Reference Manual."

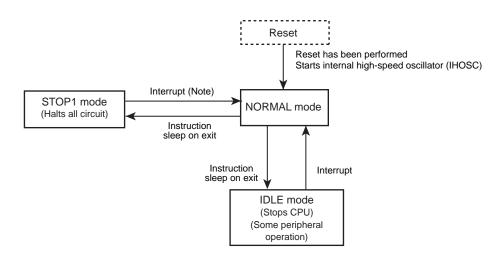

Figure 8-2 Mode Transition Diagram

Note: The warm-up is needed. The warm-up time must be set in NORMAL mode before changing to STOP1 mode. Regarding warm-up time, refer to "8.6.6 Warm-up".

# 8.5 Operation mode

### 8.5.1 NORMAL mode

This mode is to operate the CPU core and the peripheral hardware by using the high-speed clock.

It is shifted to the NORMAL mode after reset.

# 8.6 Low Power Consumption Modes

The TX03 has two low power consumption modes: IDLE and STOP1. To shift to the low power consumption mode, specify the mode in the system control register CGSTBYCR<STBY[2:0]> and execute the WFI (Wait For Interrupt) instruction. In this case, execute reset or generate the interrupt to release the mode. Releasing by the interrupt requires settings in advance. See the chapter "Exceptions" for details.

- Note 1: The TX03 does not offer any event for releasing the low power consumption mode. Transition to the low power consumption mode by executing the WFE (Wait For Event) instruction is prohibited.
- Note 2: The TX03 does not support the low power consumption mode configured with the SLEEPDEEP bit in the Cortex-M3 core. Setting the <SLEEPDEEP> bit of the system control register is prohibited.

The features of IDLE, STOP1 mode are described as follows.

#### 8.6.1 IDLE mode

Only the CPU is stopped in this mode. Each peripheral function has one bit in its control register for enabling or disabling operation in the IDLE mode. When the IDLE mode is entered, peripheral functions for which operation in the IDLE mode is disabled stop operation and hold the state at that time.

The following peripheral functions can be enabled or disabled in the IDLE mode. For setting details, see the chapter on each peripheral function.

- 16-bit timer/event counter (TMRB)
- Serial channel (SIO/UART)
- Serial bus interface (I2C/SIO)
- Analog Digital converter (ADC)
- Watch dog timer (WDT)

Note 1: Pay attention that the counter of watch dog timer function can not be cleared by CPU while in IDLE mode. Note 2: Please stop the clocks to the USB before the transition to the IDLE mode. (CGUSBCTL<USBCLKEN>="0")

### 8.6.2 STOP1 mode

When STOP1 mode is released, an internal oscilator starts and the operation mode is changed to NOR-MAL mode.

The STOP1 mode enables to select the pin status by setting the CGSTBYCR<DRVE>. Table 8-4 shows the pin status in the STOP1 mode.

- Note 1: It is necessary to warm-up when the operation mode is changed from STOP1 mode to NORMAL mode. Warm-up is required when MCU returning. Warm-up time must be set in the previous mode (NORMAL mode) entering before STOP1 mode. For details of warm-up time, refer to "8.3.4 Warm-up function".
- Note 2: When returning from STOP1 mode, related bits CGPLLSEL<PLLSEL>, CGOSCCR<HWUPSEL>, <OS-CSEL>, <XEN2>, <XEN1> and <PLLON> are initialized because of internal high-speed oscillator starting, and CGOSCCR<WUODR[11:0]> is not initialized.

Table 8-4 Pin States in the STOP1 mod	ole 8-4 Pin States i	the STOP1	mode
---------------------------------------	----------------------	-----------	------

E sultas		1/0	STOP1

	(TMS/SWDIO) (Debug I/F setting, case of PxFRn <pxmfn>="1")</pxmfn>	Output	Enabled when data is valid. Disabled when data is invalid.		
PORT	PI5, PI2, PI1, PI0, PH0, PH1 (TDO/SWV, TRACECLK, TRACEDATA0 to 3) (Debug I/F setting, case of PxFRn <pxmfn>="1")</pxmfn>	Output	Depends on PxCR[m].		
	PG3, PG5, PK0, PK1, PE7, PE3, PF4, PF5, PH4,PJ7 (INT0 to 9) (Interrupt setting, case of PxFRn <pxmfn>="1" and PxIE<pxmie>="1")</pxmie></pxmfn>	Input	O	0	
	If using other than listed above	Input	×	Depends on PxIE[m].	
	If using other than listed above	Output	×	Depends on PxCR[m].	

o : Valid input or output.

× : Invalid input or output.

Note:x: port number / m: corresponding bit / n: function register number

## 8.6.3 Low power Consumption Mode Setting

The low power consumption mode is specified by the setting of CGSTBYCR<STBY[2:0]>.

Table 8-5 shows the mode setting in the <STBY[2:0]>.

Table 8-5 Low power	consumption	mode setting
---------------------	-------------	--------------

Mode	CGSTBYCR <stby[2:0]></stby[2:0]>
STOP1	001
IDLE	011

Note: Do not set any value other than those shown above in <STBY[2:0]>.

## 8.6.4 Operational Status in Each Mode

Table 8-6 show the operational status in each mode.

Table 8-6 Operational	Status in	Each Mode
-----------------------	-----------	-----------

Block	NORMAL Internal high- speed oscillator use (IHOSC)	NORMAL External high- speed oscillator use (EHOSC)	IDLE Internal high- speed oscillator use (IHOSC)	IDLE External high- speed oscillator use (EHOSC)	STOP1 (Note 1)
Processor core	0	0	-	-	-
DMAC	0	0	0	0	-
I/O port	0	0	0	0	o(Note 2)
SIO/UART	0	0	Δ	Δ	-
I2C/SIO	0	0	Δ	Δ	-
TMRB	0	0	Δ	Δ	-
WDT	0	0	Δ(Note 4)	Δ(Note 4)	-
USB	0	0	0	0	-
12-bit ADC	0	0	Δ	Δ	-
CG	0	0	0	0	0
PLL	0	0	Δ	Δ	-
External high-speed oscilla- tor (EHOSC)	Δ	o	Δ	o	_
Internal high-speed oscilla- tor (IHOSC)	0	o(Note 3)	o	o(Note 3)	_
Main RAM	0	0	0	0	0

o : Operation is available when in the target mode.

- : The clock to module stops automatically when transiting to the target mode.

 $\Delta$  : Enables to select enabling or disabling module operation by software when in the target mode.

Note 1: Before transit to STOP1 mode, stop peripheral functions of "-"and "×". It is available to reduce leakage current by stopping reference voltage for AD converter.

Note 2: The status depends on the CGSTBYCR<DRVE>.

Note 3: After reset or STOP1 mode released, clock is provided from internal high-speed oscillator.

Note 4: Pay attention that the counter of watch dog timer function can not be cleared by CPU while in IDLE mode.

### 8.6.5 Releasing the Low Power Consumption Mode

The low power consumption mode can be released by an interrupt request, Non-Maskable Interrupt (NMI) or reset. The release source that can be used is determined by the low power consumption mode selected.

Details are shown in Table 8-7.

Table 8-7 Release Source in Each Mode

	Low po	wer consumption mode	IDLE	STOP1
		INT0 to 9 (Note1)	0	0
		INTTB0 to 9	0	×
		INTCAP00 to 91	0	×
		INTRX0 to 1, INTTX0 to 1	0	×
	Interrupt	INTSBI0 to 1	0	×
Release		INTUSB	0	0
source		INTUSBWKUP	0	0
	INTAD / INTADHP / INTADM0 to 1		0	×
		INTDMAC0TC, INTDMAC0ERR	0	×
	SysTick inte	errupt	0	×
	Non-Maskable Interrupt (INTWDT)		0	×
	Non-Maska	ble Interrupt (NMI pin)	0	0
	RESET (RE	SET pin)	0	0

o: Starts the interrupt handling after the mode is released. (The reset initializes the LSI)

× : Unavailable

- Note 1: For shifting to the low power consumption mode, set the CPU to prohibit all the interrupts other than the release source. If not, releasing may be executed by an unspecified interrupt.
- Note 2: When releasing from IDLE,STOP1 mode by interrupting level mode, hold the level until the interrupt handling starts. If the level is changed before that, the correct interrupt handling cannot be started.
  - <u>Release by interrupt request</u>

To release the low power consumption mode by an interrupt, the CPU must be set in advance to detect the interrupt. In addition to the setting in the CPU, the clock generator must be set to detect the interrupt to be used to release the STOP1 modes.

• Release by Non-Maskable Interrupt (NMI)

INTWDT can only be used in the IDLE mode.

• <u>Release by reset</u>

Any low power consumption mode can be released by reset from the  $\overline{\text{RESET}}$  pin. After that, the mode switches to the NORMAL mode and all the registers are initialized as is the case with normal reset.

Note that returning to the STOP1 mode by reset does not induce the automatic warm-up. Keep the reset signal valid until the oscillator operation becomes stable.

<u>Release by SysTick</u>

SysTick interrupt is used in the IDLE mode.

Refer to "Interrupts" for details.

#### 8.6.6 Warm-up

Mode transition may require the warm-up so that the internal oscillator provides stable oscillation.

In the mode transition from STOP1 to the NORMAL, the warm-up counter and the internal oscillator are activated automatically. And then the system clock output is started after the elapse of warm-up time.

It is necessary to set a warm-up time in the CGOSCCR<WUODR[11:0]> before executing the instruction to enter the STOP1 mode.

Note: When returning from STOP1 mode, related bits CGPLLSEL<PLLSEL>, CGOSCCR<HWUPSEL>, <OSCSEL>, <XEN2>, <XEN1> and <PLLON> are initialized because of internal high-speed oscillator starting, and CGOSCCR<WUODR[11:0]> is not initialized.

Table 8-8 shows whether the warm-up setting of each mode transition is required or not.

Mode transition	Warm-up setting
$NORMAL \to IDLE$	Not required
NORMAL $\rightarrow$ STOP1	Not required
$IDLE \to NORMAL$	Not required
$STOP1 \to NORMAL$	Auto-warm-up (Note)

#### Table 8-8 Warm-up setting in mode transition

Note: Returning to NORMAL mode by reset does not induce the automatic warm-up. Input the reset signal as same as cold reset.

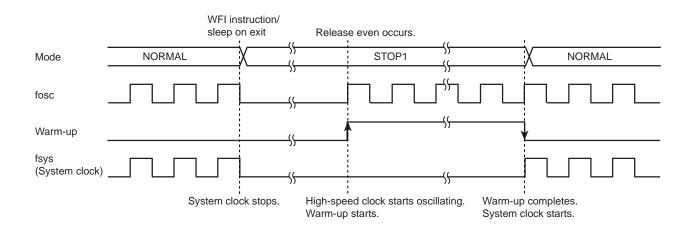

### 8.6.7 Clock Operations in Mode Transition

The clock operations in mode transition are described as follows.

#### 8.6.7.1 Transition of operation modes: NORMAL $\rightarrow$ STOP1 $\rightarrow$ NORMAL

When returning to the NORMAL mode from the STOP1 mode, the warm-up is activated automatically. It is necessary to set the warm-up time 0x119 into CGOSCCR<WUODR[11:0]>, which is the stable time for internal flash, before entering the STOP1 mode.

Returning to the NORMAL mode by reset does not induce the automatic warm-up. Input the reset signal as same as cold reset.

# 9. Exceptions

This chapter describes features, types and handling of exceptions.

Exceptions have close relation to the CPU core. Refer to "Cortex-M3 Technical Reference Manual" if needed.

# 9.1 Overview

An exception causes the CPU to stop the currently executing process and handle another process.

There are two types of exceptions: those that are generated when some error condition occurs or when an instruction to generate an exception is executed; and those that are generated by hardware, such as an interrupt request signal from an external pin or peripheral function.

All exceptions are handled by the Nested Vectored Interrupt Controller (NVIC) in the CPU according to the respective priority levels. When an exception occurs, the CPU stores the current state to the stack and branches to the corresponding interrupt service routine (ISR). Upon completion of the ISR, the information stored to the stack is automatically restored.

## 9.1.1 Exception Types

The following types of exceptions exist in the Cortex-M3.

For detailed descriptions on each exception, refer to "Cortex-M3 Technical Reference Manual".

- Reset
- Non-Maskable Interrupt (NMI)
- Hard Fault
- Memory Management
- Bus Fault
- Usage Fault
- SVCall (Supervisor Call)
- Debug Monitor
- PendSV
- SysTick
- External Interrupt

## 9.1.2 Handling Flowchart

Each step is described later in this chapter.

Processing	Description	See
Detection by CG/CPU	The CG/CPU detects the exception request.	Section 9.1.2.1
Handling by CPU	The CPU handles the exception request.	
		Section 9.1.2.2
Branch to ISR	The CPU branches to the corresponding interrupt service routine (ISR).	
Execution of ISR	Necessary processing is executed.	Section 9.1.2.3
		000001 9.1.2.9
Return from exception	The CPU branches to another ISR or returns to the previous program.	Section 9.1.2.4

#### 9.1.2.1 Exception Request and Detection

#### (1) Exception occurrence

Exception sources include instruction execution by the CPU, memory accesses, and interrupt requests from external interrupt pins or peripheral functions.

An exception occurs when the CPU executes an instruction that causes an exception or when an error condition occurs during instruction execution.

An exception also occurs by an instruction fetch from the Execute Never (XN) region or an access violation to the Fault region.

An interrupt request is generated from an external interrupt pin or peripheral function.For interrupts that are used for releasing a standby mode, relevant settings must be made in the clock generator.For details, refer to "9.5 Interrupts".

#### (2) Exception detection

If multiple exceptions occur simultaneously, the CPU takes the exception with the highest priority.

Table 9-1 shows the priority of exceptions. "Configurable" means that you can assign a priority level to that exception. Memory Management, Bus Fault and Usage Fault exceptions can be enabled or disabled. If a disabled exception occurs, it is handled as Hard Fault.

No.	Exception type	Priority	Description
1	Reset	-3 (highest)	Reset pin, WDT or SYSRETREQ
2	Non-Maskable Interrupt	-2	NMI pin or WDT
3	Hard Fault	-1	Fault that cannot activate because a higher-priority fault is being han- dled or it is disabled
4	Memory Management	Configurable	Exception from the Memory Protection Unit (MPU) (Note 1) Instruction fetch from the Execute Never (XN) region
5	Bus Fault	Configurable	Access violation to the Hard Fault region of the memory map
6	Usage Fault	Configurable	Undefined instruction execution or other faults related to instruction ex- ecution
7~10	Reserved	-	
11	SVCall	Configurable	System service call with SVC instruction
12	Debug Monitor	Configurable	Debug monitor when the CPU is not faulting
13	Reserved	-	
14	PendSV	Configurable	Pendable system service request
15	SysTick	Configurable	Notification from system timer
16~	External Interrupt	Configurable	External interrupt pin or peripheral function (Note 2)

Note 1: This product does not contain the MPU.

Note 2: External interrupts have different sources and numbers in each product. For details, see "9.5.1.5 List of Interrupt Sources".

#### (3) Priority setting

· Priority levels

The external interrupt priority is set to the interrupt priority register and other exceptions are set to <PRI\_n> bit in the system handler priority register.

The configuration <PRI\_n> can be changed, and the number of bits required for setting the priority varies from 3 bits to 8 bits depending on products. Thus, the range of priority values you can specify is different depending on products.

In the case of 8-bit configuration, the priority can be configured in the range from 0 to 255. The highest priority is "0". If multiple elements with the same priority exist, the smaller the number, the higher the priority becomes.

#### Note: <PRI\_n> bit is defined as a 3-bit configuration with this product.

#### Priority grouping

The priority group can be split into groups. By setting the <PRIGROUP> of the application interrupt and reset control register, <PRI\_n> can be divided into the pre-emption priority and the sub priority.

A priority is compared with the pre-emption priority. If the priority is the same as the preemption priority, then it is compared with the sub priority. If the sub priority is the same as the priority, the smaller the exception number, the higher the priority. The Table 9-2 shows the priority group setting. The pre-emption priority and the sub priority in the table are the number in the case that  $\langle PRI_n \rangle$  is defined as an 8-bit configuration.

<prigroup[2:0]> setting</prigroup[2:0]>	<pri_n[7:0]> Pre-emption Subpriority field field</pri_n[7:0]>		Number of pre-emption priorities	Number of subpriorities
000	[7:1]	[0]	128	2
001	[7:2]	[1:0]	64	4
010	[7:3]	[2:0]	32	8
011	[7:4]	[3:0]	16	16
100	[7:5]	[4:0]	8	32
101	[7:6]	[5:0]	4	64
110	[7]	[6:0]	2	128
111	None	[7:0]	1	256

#### Table 9-2 Priority grouping setting

Note: If the configuration of <PRI\_n> is less than 8 bits, the lower bit is "0". For the example, in the case of 3-bit configuration, the priority is set as <PRI\_n[7:5]> and <PRI\_n[4:0] > is "00000".

#### 9.1.2.2 Exception Handling and Branch to the Interrupt Service Routine (Pre-emption)

When an exception occurs, the CPU suspends the currently executing process and branches to the interrupt service routine. This is called "pre-emption".

#### (1) Stacking

When the CPU detects an exception, it pushes the contents of the following eight registers to the stack in the following order:

- Program Counter (PC)
- Program Status Register (xPSR)
- r0 r3
- r12
- Link Register (LR)

The SP is decremented by eight words by the completion of the stack push. The following shows the state of the stack after the register contents have been pushed.

Old SP $\rightarrow$	<previous></previous>
	xPSR
	PC
	LR
	r12
	r3
	r2
	r1
$SP \to$	rO

#### (2) Fetching an ISR

The CPU enables instruction to fetch the interrupt processing with data store to the register.

Prepare a vector table containing the top addresses of ISRs for each exception.After reset, the vector table is located at address 0x0000\_0000 in the Code area.By setting the Vector Table Offset Register, you can place the vector table at any address in the Code or SRAM space.

The vector table should also contain the initial value of the main stack.

#### (3) Late-arriving

If the CPU detects a higher priority exception before executing the ISR for a previous exception, the CPU handles the higher priority exception first. This is called "late-arriving".

A late-arriving exception causes the CPU to fetch a new vector address for branching to the corresponding ISR, but the CPU does not newly push the register contents to the stack.

#### (4) Vector table

The vector table is configured as shown below.

You must always set the first four words (stack top address, reset ISR address, NMI ISR address, and Hard Fault ISR address).Set ISR addresses for other exceptions if necessary.

Offset	Exception	Contents	Setting
0x00	Reset	Initial value of the main stack	Required
0x04	Reset	ISR address	Required
0x08	Non-Maskable Interrupt	ISR address	Required
0x0C	Hard Fault	ISR address	Required
0x10	Memory Management	ISR address	Optional
0x14	Bus Fault	ISR address	Optional
0x18	Usage Fault	ISR address	Optional
0x1C ~ 0x28	Reserved		
0x2C	SVCall	ISR address	Optional
0x30	Debug Monitor	ISR address	Optional
0x34	Reserved		
0x38	PendSV	ISR address	Optional
0x3C	SysTick	ISR address	Optional
0x40	External Interrupt	ISR address	Optional

#### 9.1.2.3 Executing an ISR

An ISR performs necessary processing for the corresponding exception. ISRs must be prepared by the user.

An ISR may need to include code for clearing the interrupt request so that the same interrupt will not occur again upon return to normal program execution.

For details about interrupt handling, see "9.5 Interrupts".

If a higher priority exception occurs during ISR execution for the current exception, the CPU abandons the currently executing ISR and services the newly detected exception.

#### 9.1.2.4 Exception exit

#### (1) Execution after returning from an ISR

When returning from an ISR, the CPU takes one of the following actions:

• Tail-chaining

If a pending exception exists and there are no stacked exceptions or the pending exception has higher priority than all stacked exceptions, the CPU returns to the ISR of the pending exception.

In this case, the CPU skips the pop of eight registers and push of eight registers when exiting one ISR and entering another. This is called "tail-chaining".

• Returning to the last stacked ISR

If there are no pending exceptions or if the highest priority stacked exception is of higher priority than the highest priority pending exception, the CPU returns to the last stacked ISR.

· Returning to the previous program

If there are no pending or stacked exceptions, the CPU returns to the previous program.

#### (2) Exception exit sequence

When returning from an ISR, the CPU performs the following operations:

• Pop eight registers

Pops the eight registers (PC, xPSR, r0 to r3, r12 and LR) from the stack and adjust the SP.

· Load current active interrupt number

Loads the current active interrupt number from the stacked xPSR. The CPU uses this to track which interrupt to return to.

• Select SP

If returning to an exception (Handler Mode), SP is SP\_main. If returning to Thread Mode, SP can be SP\_main or SP\_process.

# 9.2 Reset Exceptions

Reset exceptions are generated from the following three sources.

Use the Reset Flag (CGRSTFLG) Register of the Clock Generator to identify the source of a reset.

• External reset pin

A reset exception occurs when an external reset pin changes from "Low" to "High".

• Reset exception by WDT

The watchdog timer (WDT) has a reset generating feature. For details, see the chapter on the WDT.

Reset exception by SYSRESETREQ

A reset can be generated by setting the SYSRESETREQ bit in the NVIC's Application Interrupt and Reset Control Register.

# 9.3 Non-Maskable Interrupts (NMI)

Non-maskable interrupts are generated from the following two sources.

Use the NMI Flag (CGNMIFLG) Register of the clock generator to identify the source of a non-maskable interrupt.

• External  $\overline{\text{NMI}}$  pin

A non-maskable interrupt is generated when an external  $\overline{\text{NMI}}$  pin changes from "High" to "Low".

• Non-maskable interrupt by WDT

The watchdog timer (WDT) has a non-maskable interrupt generating feature. For details, see the chapter on the WDT.

# 9.4 SysTick

SysTick provides interrupt features using the CPU's system timer.

When you set a value in the SysTick Reload Value Register and enable the SysTick features in the SysTick Control and Status Register, the counter loads with the value set in the Reload Value Register and begins counting down.When the counter reaches "0", a SysTick exception occurs.You may be pending exceptions and use a flag to know when the timer reaches "0".

The SysTick Calibration Value Register holds a reload value for counting 10 ms with the system timer. The count clock frequency varies with each product, and so the value set in the SysTick Calibration Value Register also varies with each product.

Note: In this product, fosc which is selected by CGOSCCR <OSCSEL> <EHOSCSEL> by 32 is used as external reference clock.

# 9.5 Interrupts

This chapter describes routes, sources and required settings of interrupts.

The CPU is notified of interrupt requests by the interrupt signal from each interrupt source.

It sets priority on interrupts and handles an interrupt request with the highest priority.

Interrupt requests for clearing a standby mode are notified to the CPU via the clock generator. Therefore, appropriate settings must be made in the clock generator.

## 9.5.1 Interrupt Sources

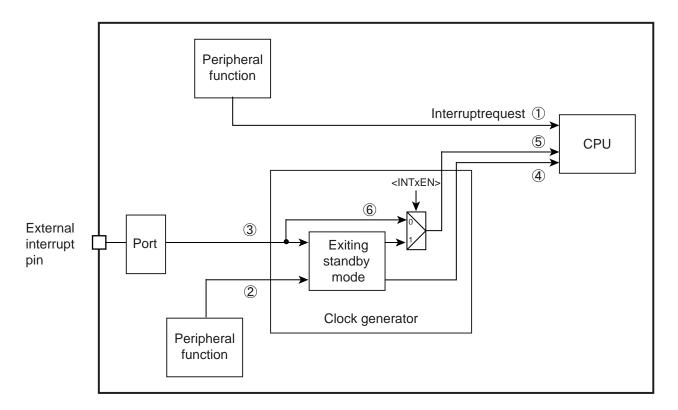

#### 9.5.1.1 Interrupt Route

Figure 9-1 shows an interrupt request route.

The interrupts issued by the peripheral function that is not used to release standby are directly input to the CPU (route1).

The peripheral function interrupts used to release standby (route 2) and interrupts from the external interrupt pin (route 3) are input to the clock generator and are input to the CPU through the logic for releasing standby (route 4 and 5).

If interrupts from the external interrupt pins are not used to release standby, they are directly input to the CPU, not through the logic for standby release (route 6).

#### 9.5.1.2 Generation

An interrupt request is generated from an external pin or peripheral function assigned as an interrupt source or by setting the NVIC's Interrupt Set-Pending Register.

• From external pin

Set the port control register so that the external pin can perform as an interrupt function pin.

• From peripheral function

Set the peripheral function to make it possible to output interrupt requests.

See the chapter of each peripheral function for details.

· By setting Interrupt Set-Pending Register (forced pending)

An interrupt request can be generated by setting the relevant bit of the Interrupt Set-Pending Register.

#### 9.5.1.3 Transmission

An interrupt signal from an external pin or peripheral function is directly sent to the CPU unless it is used to exit a standby mode.

Interrupt requests from interrupt sources that can be used for clearing a standby mode are transmitted to the CPU via the clock generator. For these interrupt sources, appropriate settings must be made in the clock generator in advance. External interrupt sources not used for exiting a standby mode can be used without setting the clock generator.

#### 9.5.1.4 Precautions when using external interrupt pins

If you use external interrupts, be aware the followings not to generate unexpected interrupts.

If input disabled (PxIE<PxmIE>="0"), inputs from external interrupt pins are "High". Also, if external interrupts are not used as a trigger to release standby (route 6 of "Figure 9-1 Interrupt Route"), input signals from the external interrupt pins are directly sent to the CPU. Since the CPU recognizes "High" input as an interrupt, interrupts occur if corresponding interrupts are enabled by the CPU as inputs are being disabled.

To use the external interrupt without setting it as a standby trigger, set the interrupt pin input as "Low" and enable it. Then, enable interrupts on the CPU.

## 9.5.1.5 List of Interrupt Sources

Table 9-3 shows the list of interrupt sources.

### Table 9-3 List of Interrupt Sources

No.	Interrupt Source		active level (Release standby and in- terrupt)	CG interrupt mode control register
0	INT0	Interrupt pin 0		
1	INT1	Interrupt pin 1		CGIMCGA

63	INTABTLOSS1 I2C arbitration lost interrupt 1			

## Table 9-3 List of Interrupt Sources

#### 9.5.1.6 Active level

The active level indicates which change in signal of an interrupt source triggers an interrupt. The CPU recognizes interrupt signals in "High" level as interrupt. Interrupt signals directly sent from peripheral functions to the CPU are configured to output "High" to indicate an interrupt request.

Active level is set to the clock generator for interrupts which can be a trigger to release standby. Interrupt requests from peripheral functions are set as rising-edge or falling-edge triggered. Interrupt requests from interrupt pins can be set as level-sensitive ("High" or "Low") or edge-triggered (rising or falling).

If an interrupt source is used for clearing a standby mode, setting the relevant clock generator register is also required. Enable the CGIMCGx<INTxEN> bit and specify the active level in the CGIMCGx<EMCGx> bits. You must set the active level for interrupt requests from each peripheral function as shown in Table 9-3.

An interrupt request detected by the clock generator is notified to the CPU with a signal in "High" level.

# 9.5.2 Interrupt Handling

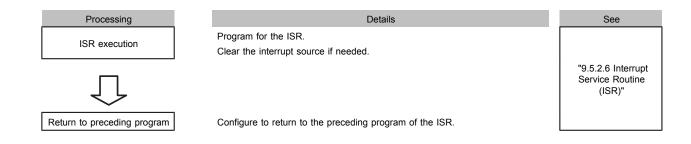

#### 9.5.2.1 Flowchart

The following shows how an interrupt is handled.

Processing	Details	See
Settings for detection	Set the relevant NVIC registers for detecting interrupts. Set the clock generator as well if each interrupt source is used to clear a stand- by mode. oCommon setting NVIC registers oSetting to clear standby mode Clock generator	"9.5.2.2 Preparation"
Settings for sending interrupt signal	Execute an appropriate setting to send the interrupt signal depending on the in- terrupt type. oSetting for interrupt from external pin Port oSetting for interrupt from peripheral function Peripheral function (See the chapter of each peripheral function for details.)	9.5.2.2 Preparation
Interrupt generation	An interrupt request is generated.	
Not clearing standby mode Clearing standby mode CG detects interrupt (clearing standby mode)	Interrupt lines used for clearing a standby mode are connected to the CPU via the clock generator.	"9.5.2.3 Detection by Clock Generator"
CPU detects interrupt	The CPU detects the interrupt. If multiple interrupt requests occur simultaneously, the interrupt request with the highest priority is detected according to the priority order.	"9.5.2.4 Detection by CPU"
CPU handles interrupt	The CPU handles the interrupt. The CPU pushes register contents to the stack before entering the ISR.	"9.5.2.5 CPU pro- cessing"
$\bigcirc$		

# TOSHIBA

#### 9.5.2.2 Preparation

When preparing for an interrupt, you need to pay attention to the order of configuration to avoid any unexpected interrupt on the way.

Initiating an interrupt or changing its configuration must be implemented in the following order basically. Disable the interrupt by the CPU. Configure from the farthest route from the CPU. Then enable the interrupt by the CPU.

To configure the clock generator, you must follow the order indicated here not to cause any unexpected interrupt. First, configure the precondition. Secondly, clear the data related to the interrupt in the clock generator and then enable the interrupt.

The following sections are listed in the order of interrupt handling and describe how to configure them.

- 1. Disabling interrupt by CPU
- 2. CPU registers setting
- 3. Preconfiguration (1) (Interrupt from external pin)
- 4. Preconfiguration (2) (Interrupt from peripheral function)
- 5. Preconfiguration (3) (Interrupt Set-Pending Register)
- 6. Configuring the clock generator
- 7. Enabling interrupt by CPU

#### (1) Disabling interrupt by CPU

To make the CPU for not accepting any interrupt, write "1" to the corresponding bit of the PRI-MASK Register. All interrupts and exceptions other than non-maskable interrupts and hard faults can be masked.

Use "MSR" instruction to set this register.

Interrupt mask register			
PRIMASK	Ļ	"1" (interrupt disabled)	

Note 1: PRIMASK register cannot be modified by the user access level.

Note 2: If a fault causes when "1" is set to the PRIMASK register, it is treated as a hard fault.

#### (2) CPU registers setting

You can assign a priority level by writing to <PRI\_n> field in an Interrupt Priority Register of the NVIC register.

Each interrupt source is provided with eight bits for assigning a priority level from 0 to 255, but the number of bits actually used varies with each product. Priority level 0 is the highest priority level. If multiple sources have the same priority, the smallest-numbered interrupt source has the highest priority.

You can assign grouping priority by using the PRIGROUP field in the Application Interrupt and Reset Control Register.

NVIC register		
<pri_n></pri_n>	Ļ	"priority"
<pre><prigroup></prigroup></pre>	Ļ	"group priority"(This is configurable if required.)

Note: "n" indicates the corresponding exceptions/interrupts. This product uses three bits for assigning a priority level.

#### (3) Preconfiguration (1) (Interrupt from external pin)

Set "1" to the port function register of the corresponding pin. Setting PxFRn[m] allows the pin to be used as the function pin. Setting PxIE[m] allows the pin to be used as the input port.

Port register			
PxFRn <pxmfn></pxmfn>	Ļ	"1"	
PxIE <pxmie></pxmie>	←	"1"	

Note:x: port number / m: corresponding bit / n: function register number

In modes other than STOP mode, setting PxIE to enable input enables the corresponding interrupt input regardless of the PxFR setting. Be careful not to enable interrupts that are not used. Also, be aware of the description of "9.5.1.4 Precautions when using external interrupt pins".

#### (4) Preconfiguration (2) (Interrupt from peripheral function)

The setting varies depending on the peripheral function to be used. See the chapter of each peripheral function for details.

#### (5) Preconfiguration (3) (Interrupt Set-Pending Register)

To generate an interrupt by using the Interrupt Set-Pending Register, set "1" to the corresponding bit of this register.

NVIC register						
Interrupt Set-Pending [m]	Ļ	"1"				

Note: m: corresponding bit

#### (6) Configuring the clock generator

For an interrupt source to be used for exiting a standby mode, you need to set the active level and enable interrupts in the CGIMCG register of the clock generator. The CGIMCG register is capable of configuring each source.

Before enabling an interrupt, clear the corresponding interrupt request already held. This can avoid unexpected interrupt. To clear corresponding interrupt request, write a value corresponding to the interrupt to be used to the CGICRCG register. See "9.6.3.4 CGICRCG(CG Interrupt Request Clear Register)" for each value.

Interrupt requests from external pins can be used without setting the clock generator if they are not used for exiting a standby mode. However, an "High" pulse or "High"-level signal must be input so that the CPU can detect it as an interrupt request. Also, be aware of the description of "9.5.1.4 Precautions when using external interrupt pins".

Clock generator register						
CGIMCGn <emcgm></emcgm>	Ļ	active level				
CGICRCG <icrcg></icrcg>	Ļ	Value corresponding to the interrupt to be used				
CGIMCGn <intmen></intmen>	Ļ	"1" (interrupt enabled)				

Note:n: register number / m: number assigned to interrupt source

#### (7) Enabling interrupt by CPU

Enable the interrupt by the CPU as shown below.

Clear the suspended interrupt in the Interrupt Clear-Pending Register. Enable the intended interrupt with the Interrupt Set-Enable Register. Each bit of the register is assigned to a single interrupt source.

Writing "1" to the corresponding bit of the Interrupt Clear-Pending Register clears the suspended interrupt. Writing "1" to the corresponding bit of the Interrupt Set-Enable Register enables the intended interrupt.

To generate interrupts in the Interrupt Set-Pending Register setting, factors to trigger interrupts are lost if pending interrupts are cleared. Thus, this operation is not necessary.

At the end, PRIMASK register is zero cleared.

NVIC register							
Interrupt Clear-Pending [m]	←	"1"					
Interrupt Set-Enable [m]	←	"1"					
Interrupt mask register							
PRIMASK	<b>←</b>	"0"					

Note 1: m : corresponding bit

Note 2: PRIMASK register cannot be modified by the user access level.

#### 9.5.2.3 Detection by Clock Generator

If an interrupt source is used for exiting a standby mode, an interrupt request is detected according to the active level specified in the clock generator, and is notified to the CPU.

An edge-triggered interrupt request, once detected, is held in the clock generator. A level-sensitive interrupt request must be held at the active level until it is detected, otherwise the interrupt request will cease to exist when the signal level changes from active to inactive.

When the clock generator detects an interrupt request, it keeps sending the interrupt signal in "High" level to the CPU until the interrupt request is cleared in the CG Interrupt Request Clear (CGICRCG) Register. If a standby mode is exited without clearing the interrupt request, the same interrupt will be detected again when normal operation is resumed. Be sure to clear each interrupt request in the ISR.

#### 9.5.2.4 Detection by CPU

The CPU detects an interrupt request with the highest priority.

#### 9.5.2.5 CPU processing

On detecting an interrupt, the CPU pushes the contents of PC, PSR, r0-r3, r12 and LR to the stack then enter the ISR.

#### 9.5.2.6 Interrupt Service Routine (ISR)

An ISR requires specific programming according to the application to be used. This section describes what is recommended at the service routine programming and how the source is cleared.

#### (1) Pushing during ISR

An ISR normally pushes register contents to the stack and handles an interrupt as required. The Cortex-M3 core automatically pushes the contents of PC, PSR, r0-r3, r12 and LR to the stack. No extra programming is required for them.

Push the contents of other registers if needed.

Interrupt requests with higher priority and exceptions such as NMI are accepted even when an ISR is being executed. We recommend you to push the contents of general-purpose registers that might be rewritten.

#### (2) Clearing an interrupt source

If an interrupt source is used for clearing a standby mode, each interrupt request must be cleared with the CG Interrupt Request Clear (CGICRCG) Register.

If an interrupt source is set as level-sensitive, an interrupt request continues to exist until it is cleared at its source. Therefore, the interrupt source must be cleared. Clearing the interrupt source automatically clears the interrupt request signal from the clock generator.

If an interrupt is set as edge-sensitive, clear an interrupt request by setting the corresponding value in the CGICRCG register. When an active edge occurs again, a new interrupt request will be detected.

# 9.6 Exception/Interrupt-Related Registers

The CPU's NVIC registers and clock generator registers described in this chapter are shown below with their respective addresses.

# 9.6.1 Register List

NVIC registers	Base Address = 0xE000_E000
Register name	Address
SysTick Control and Status Register	0x0010
SysTick Reload Value Register	0x0014
SysTick Current Value Register	0x0018
SysTick Calibration Value Register	0x001C

### 9.6.2.9 Interrupt Set-Pending Register 1

Bit	Bit Symbol	Туре	Function
31	-	R	Read as 0.
30-14	SETPEND	R/W	Interrupt number [30:14]
			[Write]
			1: Pend
			[Read]
			0: Not pending
			1: Pending
			Each bit corresponds to the specified number can force interrupts into the pending state and determines which interrupts are currently pending.
			Writing "1" to a bit in this register pends the corresponding interrupt. However, writing "1" has no effect on
			an interrupt that is already pending or is disabled. Writing "0" has no effect.
			Reading the bit returns the current state of the corresponding interrupts.
			Writing "1" to a corresponding bit in the Interrupt Clear-Pending Register clears the bit in this register.
13	-	R	Read as 0.
12-0	SETPEND	R/W	Interrupt number [12:0]
			[Write]
			1: Pend
			[Read]
			0: Not pending
			1: Pending
			Each bit corresponds to the specified number can force interrupts into the pending state and determines which interrupts are currently pending.
			Writing "1" to a bit in this register pends the corresponding interrupt. However, writing "1" has no effect on
			an interrupt that is already pending or is disabled. Writing "0" has no effect.
			Reading the bit returns the current state of the corresponding interrupts.
			Writing "1" to a corresponding bit in the Interrupt Clear-Pending Register clears the bit in this register.

			Reading the bit returns the current state of the corresponding interrupts.
1-0	-	R	Read as 0.

### 9.6.2.13 Interrupt Priority Register

Each interrupt is provided with eight bits of an Interrupt Priority Register.

The following shows the addresses of the Interrupt Priority Registers corresponding to interrupt numbers.

	31 24	23 16	15 8	7 0
0xE000_E400	PRI_3	PRI_2	PRI_1	PRI_0
0xE000_E404	PRI_7	PRI_6	PRI_5	PRI_4
0xE000_E408	PRI_11	PRI_10	PRI_9	PRI_8
0xE000_E40C	PRI_15	PRI_14	-	PRI_12
0xE000_E410	PRI_19	PRI_18	PRI_17	PRI_16
0xE000_E414	PRI_23	PRI_22	PRI_21	PRI_20
0xE000_E418	PRI_27	PRI_26	PRI_25	PRI_24
0xE000_E41C	-	PRI_30	PRI_29	PRI_28
0xE000_E420	-	PRI_34	-	-
0xE000_E424	PRI_39	PRI_38	PRI_37	PRI_36
0xE000_E428	PRI_43	PRI_42	PRI_41	PRI_40
0xE000_E42C	PRI_47	PRI_46	PRI_45	PRI_44
0xE000_E430	PRI_51	PRI_50	PRI_49	PRI_48
0xE000_E434	PRI_55	PRI_54	PRI_53	PRI_52
0xE000_E438	-	-	PRI_57	PRI_56
0xE000_E43C	PRI_63	PRI_62	PRI_61	PRI_60

The number of bits to be used for assigning a priority varies with each product. This product uses three bits for assigning a priority.

The following shows the fields of the Interrupt Priority Registers for interrupt numbers 0 to 3. The Interrupt Priority Registers for all other interrupt numbers have the identical fields. Unused bits return "0" when read, and writing to unused bits has no effect.

	31	30	29	28	27	26	25	24
bit symbol		PRI_3		-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	23	22	21	20	19	18	17	16
bit symbol		PRI_2		-	-	-	-	-
After reset	0	0 0		0	0	0	0	0
	15	14	13	12	11	10	9	8
bit symbol		PRI_1		-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	7	6	5	4	3	2	1	0
bit symbol	PRI_0			-	-	-	-	-
After reset	0	0	0	0	0	0	0	0

Bit	Bit Symbol	Туре	Function
31-29	PRI_3	R/W	Priority of interrupt number 3
28-24	-	R	Read as 0.
23-21	PRI_2	R/W	Priority of interrupt number 2
20-16	-	R	Read as 0.
15-13	PRI_1	R/W	Priority of interrupt number 1
12-8	-	R	Read as 0.
7-5	PRI_0	R/W	Priority of interrupt number 0
4-0	-	R	Read as 0.

	31	30	29	28	27	26	25	24
bit symbol	-	-	TBLBASE			TBLOFF

After reset	0	0	0	0	0	0	0	0
	7	6	5	4	3	2	1	0
bit symbol	-	-	-	-	-	SYSRESET REQ	VECTCLR ACTIVE	VECTRESET
After reset	0	0	0	0	0	0	0	0

#### 9.6.2.15 Application Interrupt and Reset Control Register

Bit	Bit Symbol	Туре	Function
31-16	VECTKEY (Write)/ VECTKEY- STAT(Read)	R/W	Register key [Write] Writing to this register requires 0x5FA in the <vectkey> field. [Read] Read as 0xFA05.</vectkey>
15	ENDIANESS	R/W	Endianness bit:(Note1) 1: big endian 0: little endian
14-11	-	R	Read as 0.
10-8	PRIGROUP	R/W	Interrupt priority grouping 000: seven bits of pre-emption priority, one bit of subpriority 001: six bits of pre-emption priority, two bits of subpriority 010: five bits of pre-emption priority, three bits of subpriority 011: four bits of pre-emption priority, four bits of subpriority 100: three bits of pre-emption priority, five bits of subpriority 101: two bits of pre-emption priority, six bits of subpriority 101: two bits of pre-emption priority, seven bits of subpriority 110: one bit of pre-emption priority, seven bits of subpriority 111: no pre-emption priority, eight bits of subpriority The bit configuration to split the interrupt priority register <pri_n> into pre-emption priority and sub priority.</pri_n>
7-3	-	R	Read as 0.
2	SYSRESET REQ	R/W	System Reset Request. 1=CPU outputs a SYSRESETREQ signal. (note2)
1	VECTCLR ACTIVE	R/W	Clear active vector bit 1: clear all state information for active NMI, fault, and interrupts 0: do not clear. This bit self-clears. It is the responsibility of the application to reinitialize the stack.
0	VECTRESET	R/W	System Reset bit 1: reset system 0: do not reset system Resets the system, with the exception of debug components (FPB, DWT and ITM) by setting "1" and this bit is also zero cleared.

Note 1: Little-endian is the default memory format for this product.

Note 2: When SYSRESETREQ is output, warm reset is performed on this product. <SYSRESETREQ> is cleared by warm reset.

#### 9.6.2.16 System Handler Priority Register

Each exception is provided with eight bits of a System Handler Priority Register.

The following shows the addresses of the System Handler Priority Registers corresponding to each exception.

	31 24	23 16	15 8	7 0
0.000 5018	PRI_7	PRI_6	PRI_5	PRI_4
0xE000_ED18		(Usage Fault)	(Bus Fault)	(Memory Management)
	PRI_11	PRI_10	PRI_9	PRI_8
0xE000_ED1C	(SVCall)			
0.000 5000	PRI_15	PRI_14	PRI_13	PRI_12
0xE000_ED20	(SysTick)	(PendSV)		(Debug Monitor)

The number of bits to be used for assigning a priority varies with each product. This product uses three bits for assigning a priority.

The following shows the fields of the System Handler Priority Registers for Memory Management, Bus Fault and Usage Fault. Unused bits return "0" when read, and writing to unused bits has no effect.

	31	30	29	28	27	26	25	24
bit symbol		PRI_7		-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	23	22	21	20	19	18	17	16

After reset	0	0	0	0	0	0	0	0
	7	6	5	4	3	2	1	0
bit symbol	SVCALLACT	-	-	-	USGFAULT ACT	-	BUSFAULT ACT	MEMFAULT ACT
After reset	0	0	0	0	0	0	0	0

#### 9.6.2.17 System Handler Control and State Register

Bit	Bit Symbol	Туре	Function
31-19	-	R	Read as 0.
18	USGFAULT	R/W	Usage Fault
	ENA		0: Disabled
			1: Enable
17	BUSFAUL	R/W	Bus Fault
	TENA		0: Disabled
			1: Enable
16	MEMFAULT	R/W	Memory Management
	ENA		0: Disabled
			1: Enable
15	SVCALL	R/W	SVCall
	PENDED		0: Not pended
			1: Pended
14	BUSFAULT	R/W	Bus Fault
	PENDED		0: Not pended
			1: Pended
13	MEMFAULT	R/W	Memory Management
	PENDED		0: Not pended
			1: Pended
12	USGFAULT	R/W	Usage Fault
	PENDED		0: Not pended
			1: Pended
11	SYSTICKACT	R/W	SysTick
			0: Inactive
			1: Active
10	PENDSVACT	R/W	PendSV
			0: Inactive
			1: Active
9	-	R	Read as 0.
8	MONITORACT	R/W	Debug Monitor
			0: Inactive
			1: Active
7	SVCALLACT	R/W	SVCall
			0: Inactive
			1: Active
6-4	-	R	Read as 0.

Bit	Bit Symbol	Туре	Function
3	USGFAULT	R/W	Usage Fault
	ACT		0: Inactive
			1: Active
2	-	R	Read as 0.
1	BUSFAULT	R/W	Bus Fault
	ACT		0: Inactive
			1: Active
0	MEMFAULT	R/W	Memory Management
	ACT		0: Inactive
			1: Active

Note: You must clear or set the active bits with extreme caution because clearing and setting these bits does not repair stack contents.

Note 1: <EMSTx> is effective only when <EMCGx[2:0]> is set to "100" for both rising and falling edge. The active level used for the reset of standby can be checked by referring <EMSTx>. If interrupts are cleared with the CGICRCG register, <EMSTx> is also cleared.

Note 2: Please specify the bit for the edge first and then specify the bit for the <INTxEN>. Setting them simultaneously is prohibited.

Bit	Bit Symbol	Туре	Function			
31-5	-	R	Read as 0.			
4	DBGRSTF	R/W	bug reset flag (Note1) "0" is written Reset from SYSRESETREQ			
3	-	R/W	Read as undefined. Write as 0.			
2	WDTRSTF	R/W	WDT reset flag 0: "0" is written 1: Reset from WDT			
1	-	R/W	Read as undefined. Write as 0.			
0	PINRSTF	R/W	RESET pin flag         0: "0" is written         1: Reset from RESET pin.			

Note 1: This flag indicates a reset generated by the SYSRESETREQ bit of the Application Interrupt and Reset Control Register of the CPU's NVIC.

Note 2: This product is initialized by the external reset.

# 10. Input/Output Ports

## 10.1 Port Functions

#### 10.1.1 Function Lists

TMPM365FYXBG has 74 ports. Besides the ports function, these ports can be used as I/O pins for peripheral functions.

Table 10-1, Table 10-2 and Table 10-3 show the port function table.

Port	pin	Input / Output	Pull-up Pull-down	Schmitt Input	Noise Filter	Program- mable Open-drain	Function pin
PORTA					·

#### Table 10-3 Port Function List (Port H to K)

o : Exist

- : Not Exist

Note: The noise elimination width of the noise filter is approximately 30 ns under typical conditions.

#### 10.1.2 Port Registers Outline

The following registers need to be configured to use ports.

• PxDATA: Port x data register

To read/ write port data.

- PxCR: Port x output control register To control output.
   PxIE needs to be configured to control input.
- PxFRn: Port x function register n

To set functions. An assigned function can be activated by setting "1".

• PxOD: Port x open drain control register

To control the programmable open drain.

Programmable open drain is function to be materialized pseudo-open-drain by setting the PxOD. When PxOD is set "1",output buffer is disabled and pseudo-open-drain is materialized.

- PxPUP: Port x pull-up control register To control program pull ups.
- PxPDN: Port x pull-down control register To control programmable pull downs.
- PxIE: Port x input control register

To control inputs.

For avoided through current, default setting prohibits inputs.

## 10.1.3 Port States in STOP1 Mode

Input and output in STOP1 mode are enabled/disabled by the CGSTBYCR<DRVE> bit.

If PxIE or PxCR is enabled with <DRVE>="1", input or output is enabled respectively in STOP1 mode. If <DRVE>="0", both input and output are disabled in STOP1 mode except for some ports even if PxIE or PxCR are enabled.

Table 10-4 shows the pin conditions in STOP mode.

<b>F</b>	Pin Name	I/O	STO	OP1	STOP2	
Function			<drve> = 0</drve>	<drve> = 1</drve>	<ptkeep> = 0</ptkeep>	<ptkeep> = 1</ptkeep>
Control Pin	RESET, NMI, MODE, BSC	Input	0	0	×	0
Ossillatar	X1/EHCLKIN	Input (Note1	×	×	×	×
Oscillator	X2	Output (Note1	"High" level out- put.	"High" level out- put.	×	×
	PI3 to PI5 (TRST, TDI, SWCLK/TCK) (Debug I/F setting, case of PxFRn <pxmfn>="1")</pxmfn>	Input	Depends o	n (PxIE[m])	×	Input holding, but Depends on (PxIE[m])
	PI4 (SWDIO/TMS)	Input	Depends on (PxIE[m])		×	Input holding, but Depends on (PxIE[m])
	(Debug I/F setting, case of PxFRn <pxmfn>="1")</pxmfn>	Output		n data is valid. data is invalid.	×	Output holding, but Depends on (PxCR[m])
Port	PI5, PI2, PI1, PI0, PH0, PH1 (TDO/SWV, TRACECLK, TRACE- DATA0 to 3) (Debug I/F setting, case of PxFRn <pxmfn>="1")</pxmfn>	Output	Depends or	ו (PxCR[m])	×	Output holding, but Depends on (PxCR[m])
	PG3, PG5, PK0, PK1, PE7, PE3, PF4, PF5, PH4, PJ7 (INT0 to 9) (Interrupt setting, case of PxFRn <pxmfn>="1" and PxIE<pxmie>="1")</pxmie></pxmfn>	Input	0	0	×	0
	If using other than listed share	Input	×	Depends on (PxIE[m])	×	Input holding, but Depends on (PxIE[m])
	If using other than listed above	Output	×	Depends on (PxCR[m])	×	Output holding, but Depends on (PxCR[m])

#### Table 10-4 Port conditions in STOP mode

o : Input or output enabled.

× : Input or output disabled.

Note:"x" indicates a port number, "m" a corresponding bit and "n" a function register number.

## 10.2 Port functions

This chapter describes the port registers detail.

This chapter describes only "circuit type" reading circuit configuration. For detailed circuit diagram, refer to "10.3 Block Diagrams of Ports".

#### 10.2.1 Port A (PA0 to PA7)

The port A is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits.

Reset initializes all bits of the port A as general-purpose ports with input, output and pull-up disabled.

#### 10.2.1.1 Port A register

31-8	-	R	Read as 0.
7-0	PB7IE-PB0IE	R/W	Input 0: Disable 1: Enable

#### 10.2.3 Port C (PC0 to PC2)

The port C is a general-purpose, 3-bit input/output port. For this port, inputs and outputs can be specified in units of bits. Besides the general-purpose input/output function, the port C performs the general purpose serial interface (UART/SIO) and the 16-bits timer (TMRB).

Reset initializes all bits of the port C as general-purpose ports with input, output and pull-up disabled.

The port C has three types of function register. If you use the port C as a general-purpose port, set "0" to the corresponding bit of the four registers. If you use the port C as other than a general-purpose port, set "1" to the corresponding bit of the function register. Do not set "1" to the other function registers at the same time.

10.2.3.1 Port C Register

## 10.2.4 Port D (PD0 to PD7)

The port D is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits. Besides the general-purpose input/output function, the port D performs the 16-bits timer (TMRB), the clock output and the ADC trigger input.

Reset initializes all bits of the port D as general-purpose ports with input, output and pull-up disabled.

The port D has a type of function register. If you use the port D as a general-purpose port, set "0" to the corresponding bit of the three registers. If you use the port D as other than a general-purpose port, set "1" to the corresponding bit of the function register.

10.2.4.1	Port D Register

7-0	PD7IE-PD0IE	R/W	Input 0: Disable 1: Enable

. ....

. . .

### 10.2.5 Port E (PE0 to PE7)

The port E is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits. Besides the general-purpose input/output function, the port E performs the general purpose serial interface (SIO/UART), the external interrupt input, the 16-bits timer (TMRB) and the serial bus interface (I2C/SIO).

Reset initializes all bits of the port E as general-purpose ports with input, output and pull-up disabled.

The port E has three types of function register. If you use the port E as a general-purpose port, set "0" to the corresponding bit of the four registers. If you use the port E as other than a general-purpose port, set "1" to the corresponding bit of the function register. Do not set "1" to the other function registers at the same time.

Note: In modes other than STOP mode, interrupt input is enabled regardless of the PxFR register setting if input is enabled in PxIE. Make sure to disable unused interrupts when programming the device.

### 10.2.5.9 PEIE (Port E input control register)

Bit	Bit Symbol	Туре	Function
31-8	-	R	Read as 0.
7-0	PE7IE-PE0IE	R/W	Input 0: Disable 1: Enable

#### 10.2.6 Port F (PF0 to PF7)

The port F is a general-purpose, 1-bit output port and 7-bit input/output port. For this port, inputs and outputs can be specified in units of bits. Besides the general-purpose port function, the port F performs the functions of the external interrupt input, 16-bit timer (TMRB) and the mode setting function.

The port F has two types of function register. If you use the port F as a general-purpose port, set "0" to the corresponding bit of the three registers. If you use the port F as other than a general-purpose port, set "1" to the corresponding bit of the function register. Do not set "1" to the other function registers at the same time.

Reset initializes all bits of the port F as general-purpose ports. The bit of PF0 output is disabled and the pull-up setting is enabled, the bits of PF<7:1> input/output and all bits of pull-up setting are disabled.

According to the mode setting function, while a reset signal is in "Low" state, the PF0/BOOT input and pullup are enabled. At the rising edge of the reset signal, if PF0 is "High", the device enters single chip mode and boots from the on-chip flash memory. If PF0 is "Low", the device enters single BOOT mode and boots from the internal BOOT program. For details of single BOOT mode, refer to "Flash Memory Operation".

Note: In modes other than STOP1 mode, interrupt input is enabled regardless of the PxFR register setting if input is enabled in PxIE. Make sure to disable unused interrupts when programming the device.

# 10.2.7 Port G (PG0 to PG5)

The port G is a general-purpose, 6-bit input/output port. For this port, inputs and outputs can be specified in units of bits. Besides the general-purpose input/output function, the port G performs the serial bus interface (I2C/SIO), the external interrupt input,16-bits timer (TMRB) and the Detection function of USB connector connection with V-bus(USBPON).

Reset initializes all bits of the port G as general-purpose ports with input, output and pull-up disabled.

The port G has three types of function register. If you use the port G as a general-purpose port, set "0" to the corresponding bit of the three registers. If you use the port G as other than a general-purpose port, set "1" to the corresponding bit of the function register. Do not set "1" to the other function registers at the same time.

- Note 1: In modes other than STOP mode, interrupt input is enabled regardless of the PxFR register setting if input is enabled in PxIE. Make sure to disable unused interrupts when programming the device.
- Note 2: Only when input is enabled, PG5 tolerate 5V inputs. Note that these pins cannot be pulled up over the power supply voltage when using as open-drain output.

### 10.2.8 Port H (PH0 to PH4)

The port H is a general-purpose, 5-bit input/output port. For this port, inputs and outputs can be specified in units of bits. Besides the general-purpose input/output function, the port H performs the debug trace interface, the external interrupt input, and the 16bits-timer(TMRB).

Reset initializes all bits of the port H as general-purpose ports with input, output and pull-up disabled.

The port H has two types of function register. If you use the port H as a general-purpose port, set "0" to the corresponding bit of the four registers. If you use the port H as other than a general-purpose port, set "1" to the corresponding bit of the function register. Do not set "1" to the other function registers at the same time.

Note: In modes other than STOP mode, interrupt input is enabled regardless of the PxFR register setting if input is enabled in PxIE. Make sure to disable unused interrupts when programming the device.

31-5	-	R	Read as 0.
4-0	PH4IE-PH0IE	R/W	Input 0: Disable
			1: Enable

#### 10.2.9 Port I (PI0 to PI7)

The port I is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits. Besides the general-purpose input/output function, the port I performs the debug interface and the debug trace interface.

PI3, PI4, PI5, PI6 and PI7 are assigned as the debug interface after reset. PI7 is initialized as the TRST pin with input and pull-up enabled. PI6 is initialized as the TDI pin with input and pull-up enabled. PI3 is initialized as the TCK/SWCLK pin with input and pull-down enabled. PI4 is initialized as the TMS/SWDIO pin with input, output and pull-up enabled. PI5 is initialized as the TDO/SWV pin with output enabled. The other pins operate as general-purpose-ports, and input, output and pull-up are disabled.

- Note 1: If PI4 or PI5 is configured as the TMS/SWDIO or TDO/SWV pin, output is enabled even in STOP1 mode regardless of the CGSTBYCR<DRVE> bit setting
- Note 2: If PI3 is configured as the TCK/SWCLK pin, it prevents the low power consumption mode from being fully effective. Configure PI3 to function as a general-purpose port if the TCK/SWCLK is not used.

7-0	PI7IE-PI0IE	R/W	Input 0: Disable 1: Enable

### 10.2.10 Port J (PJ0 to PJ7)

The port J is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits. Besides the general-purpose input/output function, the port J performs the AD converter, the external interrupt input, the 16-bit timer (TMRB).

Reset initializes all bits of the port J as general-purpose ports with input, output and pull-up disabled.

The port J has two types of function register. If you use the port J as a general-purpose port, set "0" to the corresponding bit of the two registers. If you use the port J as other than a general-purpose port, set "1" to the corresponding bit of the function register. Do not set "1" to the both function registers at the same time.

To use the Port J as an analog input of the AD converter, disable input on PJIE and disable pull-up on PJPUP.

- Note 1: Unless you use all the bits of port J and port K as analog input pins, conversion accuracy may be reduced. Be sure to verify that this causes no problem on your system.
- Note 2: In modes other than STOP1 mode, interrupt input is enabled regardless of the PxFR register setting if input is enabled in PxIE. Make sure to disable unused interrupts when programming the device.

### 10.2.11 Port K (PK0 to PK3)

The port K is a general-purpose, 4-bit input/output port. For this port, inputs and outputs can be specified in units of bits. Besides the general-purpose input/output function, the port K performs the AD converter, the external interrupt input and the 16-bit timer (TMRB).

The port K has two types of function register. If you use the port K as a general-purpose port, set "0" to the corresponding bit of the two registers. If you use the port K as other than a general-purpose port, set "1" to the corresponding bit of the function register. Do not set "1" to the both function registers at the same time.

Reset initializes all bits of the port J as general-purpose ports with input, output and pull-up disabled.

To use the Port K as an analog input of the AD converter, disable input on PKIE and disable pull-up on PKPUP.

- Note 1: Unless you use all the bits of port J and port K as analog input pins, conversion accuracy may be reduced. Be sure to verify that this causes no problem on your system.
- Note 2: In modes other than STOP1 mode, interrupt input is enabled regardless of the PxFR register setting if input is enabled in PxIE. Make sure to disable unused interrupts when programming the device.

### 10.4 Appendix (Port setting List)

The following table shows the register setting for each function.

Initialization of the ports where the [o] does not exist in the "After reset" field is set to "0" for all register settings. Setting for the bit "x" can be arbitrarily-specified.

#### 10.4.1 Port A Setting

Table 10-16 Port Setting List (Port K)

# TOSHIBA

# 11. DMA Controller(DMAC)

#### 11.1 Overview

The table below lists its major functions.

#### Table 11-1 DMA controller functions (1 Unit)

Item	Fu	nction	Description		
Number of channels	2ch		-		
Number of DMA re- quest	16		-		
DMA Start up	Hardware start		Started with DMA request for peripheral cir- cuit.		
trigger	Software start		Started with a write to the DMACxSoftBReq register.		
Bus master	32bit × 1 (AHB)		-		
Priority	High : CH0 Low : CH1		Fixed		
FIFO	4word × 2ch (1word = 32bit)		-		
Bus width	8/16/32bit		Settable individually for transfer source and destination.		
Burst size	1/4/8/16/32/64/128/256		-		
Number of transfers	up to 4095		-		
Address	Transfer source address	increment not increment	It is possible to specify whether Source and Destination addresses should increment or		
	Transfer destination address	increment not increment	should not increment. (Address wrapping is not supported.)		
Endian	Littleendian is supported.		-		
Transfer type	Peripheral to Memory Memory to Peripheral Memory to Memory		When "Memory to Memory" is selected, hard- ware start for DMA startup is not supported. Refer to the DMACxCnConfiguration for		
	Peripheral to Peripheral		more information. Particular peripheral can be assigned as Source or Distination when "Peripheral to Pe- ripheral" is selected. Regarding to peripheral assigned, refer to "11.4.1 Peripheral function supported with Peripheral to Peripheral Trans- fer".		
Interrupt function	Transfer end interrupt (INTDMAC Error interrupt (INTDMACxERR)	xTC)	-		
Special Function	Scatter/gather function		-		

### 11.2 DMA transfer type

Table 11-2 DMA transfer type

No.	DMA transfer type	Circuit generated DMA request	DMA request type	Description				
1	Memory to Pe- ripheral	Peripheral (Destination)	Burst request	In case of 1word transmission, set to the "1" for burst size of DMA controller.				
2	Peripheral to Memory	Peripheral (Source)	Burst request / single request	If the amount of transfer data is not an integral multiple of the burst size, both burst and single request can be used. If amount of transfer data is more or equal than burst size, the single request is ig- nored and the burst transfer is used. If it becomes less than burst size, the single transfer is used.				
3	Memory то Memory	DMAC	None	Enabling the DMAC starts data transfer without DMAC request. (Select Memory to Memory mode, set DMACxCnConfiguration <e> to "1") When All transfer data is transferred completely or when the DMAC channel is dis- abled, DMAC is stopped.</e>				
4	Peripheral to Peripheral	Peripheral (Source)	Burst request / single request	Transfer size (1)An integral multiple of the burst size	Source Burst request	Destination Burst request		
	renphera	Peripheral (Destination) Burst re		(2)Not an integral multiple of the burst size	Burst request / single request	-		

Note: When much data is transferred in memory to memory, we recommend that a lower priority channel is used. If a lower priority channel is used, a higher priority channel can be started to transfer during a lower priority channel is transferring. If a higher priority channel is used, a lower priority channel can not be started to transfer during a higher priority channel is transferring.

#### 11.3 Block diagram

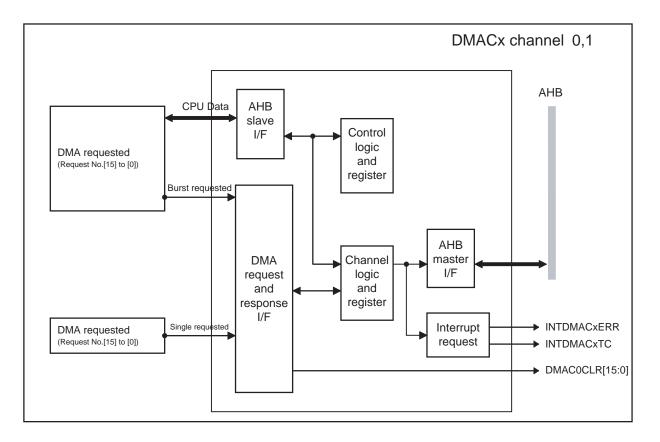

Figure 11-1 DMAC Block diagram

### 11.4 Product information of TMPM365FYXBG

#### 11.4.1 Peripheral function supported with Peripheral to Peripheral Transfer

Peripheral functions (Register) supported with Peripheral to Peripheral Transfer are shown below.

Source	Destination
	SCxBUF
	(x=0 to 1)
Derinheral register	TBxREG0 to 1
Peripheral register	(x=0 to 9)
	TBxCP0 to 1
	(x=0 to 9)
SCxBUF	
(x=0 to1)	
TBxREG0 to 1	Deviah evel versister
(x=0 to 9)	Peripheral register
TBxCP0 to 1	
(x=0 to 9)	

#### 11.4.2 DMA request

DMA request against each DMA request no. are shown as bellows.

Table 11-3 DMA request factor

	Corresponding peripheral				
DMA request No.	ch0,ch1				
request No.	Burst request	Single request			
0	SIO0/UART0 Reception	-			
1	SIO0/UART0 Transmission	-			
2	SIO1/UART1 Reception	-			
3	SIO1/UART1 Transmission	-			
4	TMRB8 compare match	-			
5	TMRB9 compare match	-			
6	TMRB0 input capture 0	-			
7	TMRB4 input capture 0	-			
8	TMRB4 input capture 1	-			
9	TMRB5 input capture 0	-			
10	TMRB5 input capture 1	-			
11	Normal AD Conversion End	-			
12	I2C0 / SIO0 Reception (Note)	-			
13	I2C0 / SIO0 Transmission (Note)	-			
14	I2C1 / SIO1 Reception (Note)	-			
15	I2C1 / SIO1 Transmission (Note)	_			

Note: DMAC can be used in I2C mode. It must not be used in SIO mode.

# 11.4.3 Interrupt request

Transfer complete interrupt	Error interrupt		
INTDMAC0TC	INTDMAC0ERR		

# 11.4.4 Base address of registers

Base Address
0x4000_0000

#### 11.5 Description of Registers

#### 11.5.1 DMAC register list

The function and address for each register are shown bellow.

Register Name		Address (Base+)
DMAC Interrupt Status Register	DMACxIntStaus	0x0000
DMAC Interrupt Terminal Count Status Register	DMACxIntTCStatus	0x0004
DMAC Interrupt Terminal Count Clear Register	DMACxIntTCClear	0x0008
DMAC Interrupt Error Status Register	DMACxIntErrorStatus	0x000C
DMAC Interrupt Error Clear Register	DMACxIntErrClr	0x0010
DMAC Raw Interrupt Terminal Count Status Register	DMACxRawIntTCStatus	0x0014
DMAC Raw Error Interrupt Status Register	DMACxRawIntErrorStatus	0x0018
DMAC Enabled Channel Register	DMACxEnbldChns	0x001C
DMAC Software Burst Request Register	DMACxSoftBReq	0x0020
DMAC Software Single Request Register	DMACxSoftSReq	0x0024
Reserved	-	0x0028
Reserved	-	0x002C
DMAC Configuration Register	DMACxConfiguration	0x0030
Reserved	-	0x0034
DMAC Channel0 Source Address Register	DMACxC0SrcAddr	0x0100
DMAC Channel0 Destination Address Register	DMACxC0DestAddr	0x0104

DMAC Channel0 Control Register	DMACxC0Control	0x010C
DMAC Channel0 Configuration Register	DMACxC0Configuration	0x0110
DMAC Channel1 Source Address Register	DMACxC1SrcAddr	0x0120
DMAC Channel1 Destination Address Register	DMACxC1DestAddr	0x0124
DMAC Channel1 Linked List Item Register	DMACxC1LLI	0x0128
DMAC Channel1 Control Register	DMACxC1Control	0x012C
DMAC Channel 1 Configuration Register	DMACxC1Configuration	0x0130

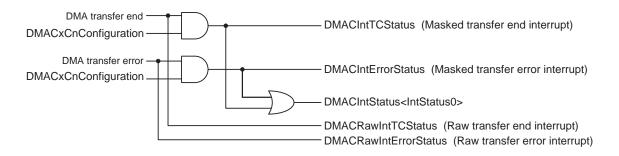

Note 1: Access the registers by using word (32bit) reads and word writes.

- Note 2: Access to the "Reserved" area is prohibited.
- Note 3: For the registers prepared for every channel, if the channel structure is the same, unit number is expressed as "x" and channel number is expresses as "n".
- Note 4: When the register which is not assigned with an each channel is read after the register which is assigned with an each channel is written, one machine cycle is inserted between the instructions or read the register which is not assigned with an each channel twice.

0	E	R/W	DMA circuit control
			0 : Stop
			1 : Operate
			When circuit stops, the registers for the DMA circuit cannot be written or read. When operating the DMA, al- ways set <e>="1".</e>

#### 11.5 Description of Registers

	31	30	29	28	27	26	25	24
bit symbol			SrcAddr					
After reset	0	0	0	0	0	0	0	0
	23	22	21	20	19	18	17	16
bit symbol				Src	Addr			
After reset	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8
bit symbol				Src	Addr			
After reset	0	0	0	0	0	0	0	0
	7	6	5	4	3	2	1	0
bit symbol				Src	Addr			
After reset	0	0	0	0	0	0	0	0

### 11.5.13 DMACxCnSrcAddr (DMAC Channelx Source Address Register)

Bit	Bit Symbol	Туре		Function					
31-0	SrcAddr[31:0]	R/W	Sets a DMA transfer source address. Make sure to confirm the source addre The below are the restrictions in settin	3					
			Source address bit width DMACxCnControl <swidth[2:0]></swidth[2:0]>	Setting of least significant address					
			000 : Byte (8 bits)	no restriction					
			001 :Half word (16 bits)	Setting as multiples of 2, (0x0,0x02,0x4,0x06,0x8,0xA,0xC)					
			010 : Word (32 bits)	Setting as multiples of 4, (0x0,0x4,0x8,0xC)					

Because enabling channel "n" (DMACxCnConfiguration<E>="1") updates the data written in the registers, set DMACxCnSrcAddr before enabling the channels.

When the DMA is operating, the value in the DMACxCnSrcAddr register sequentially changes, so the read values are not fixed.

And do not update DMACxCnSrcAddr during transfer. To change DMACxCnSrcAddr, be sure to disable the channel "n" (DMACxCnConfiguration<E>="0") before change.

### 11.5.14 DMACxCnDestAddr (DMAC Channelx Destination Address Register)

	31	30	29	28	27	26	25	24
bit symbol				Dest	Addr			
After reset	0	0	0	0	0	0	0	0
	23	22	21	20	19	18	17	16
bit symbol				Dest	Addr			
After reset	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8
bit symbol				Dest	Addr			
After reset	0	0	0	0	0	0	0	0
	7	6	5	4	3	2	1	0
bit symbol				Dest	Addr			
After reset	0	0	0	0	0	0	0	0

Bit	Bit Symbol	Туре		Function					
31-0	DestAddr[31:0]	R/W	Sets a DMA transfer destination addre Make sure to confirm the destination a The below are the restrictions in settin	address and the bit width before setting.					
			Destination address bit width DMACxCControl <dwidth[2:0]></dwidth[2:0]>	Setting of least significant address					
			000 : Byte (8 bits)	no restriction					
			001 : Half word (16 bits)	Setting as multiples of 2, (0x0,0x02,0x4,0x06,0x8,0xA,0xC)					
			010 : Word (32 bits)	Setting as multiples of 4, (0x0,0x4,0x8,0xC)					

Do not update DMACxCnDestAddr during transfer. To change DMACxCnDestAddr, be sure to disable the channel "n" (DMACxCnConfiguration $\leq E \geq ="0"$ ) before change.

17-15	DBSize[2:0]	R/W	Transfer destination burst size: (Note 1)						
17-15	DBSize[z.0]	12/14	000: 1 beat $100$ : 32 beats						
			001: 4 beats 101: 64 beats						
			010: 8 beats 110: 128 beats						
			011: 16 beats 111: 256 beats						
			Refer to Table 11-4 for the setting value.						

Bit	Bit Symbol	Туре				Function
14-12	SBSize[2:0]	R/W	Transfer source burst s	ize: (Note 1)		
			000: 1 beat	10	00:	32 beats
			001: 4 beats	10	)1:	64 beats
			010: 8 beats	11	10:	128 beats
			011: 16 beats	11	11:	256 beats
			Refer to Table 11-4 for	the setting value.		
11-0	TransferSize	R/W	Set the total number of	transfers.		
	[11:0]		Amount of transfer data set into <transdersize[< td=""><td>11:0]&gt;. Because the b</td><td>ourst</td><td>size shows amount</td></transdersize[<>	11:0]>. Because the b	ourst	size shows amount

[11:0]	Amount of transfer data per a bit width specified by transfer source bit width (4 bytes / 2 bytes / 1byte) is set into <transdersize[11:0]>. Because the burst size shows amount of transfer data at every DMA request internally, amount of transfer data is never changed even if any burst size is set when transfer source bit width and total number of transfers are not changed.</transdersize[11:0]>
	The value of <transfersize[11:0]> is decremented to 0 by the DMA transferring.</transfersize[11:0]>
	If this is read, the value which is the number of data not to transfer.
	The total number of transfers is used as the unit for the transfer source bit width.
	For examples:
	When <swidth>="000" (8bit), the number of transfers is expressed in the units of byte.</swidth>
	When <swidth>="001" (16bit), the number of transfers is expressed in the units of half word.</swidth>
	When <swidth>="010" (32bit), the number of transfers is expressed in the units of word.</swidth>

Note: The burst size to be set with DBsize and SBsize has no connections with the HBURST for the AHB bus.

Table 11-4 How to decide the value of <dwidth< th=""><th>12:01&gt;.<swidth[2:01>.</swidth[2:01></th><th><dbsize[2:0]>, <sbsize[2:0]></sbsize[2:0]></dbsize[2:0]></th><th>&gt;</th></dwidth<>	12:01>. <swidth[2:01>.</swidth[2:01>	<dbsize[2:0]>, <sbsize[2:0]></sbsize[2:0]></dbsize[2:0]>	>

<dwidth[2:0]> / <swidth[2:0]></swidth[2:0]></dwidth[2:0]>	Set the number so that the following expression is satisfied: Transfer source bit width × Total number of transfers = Transfer destination bit width × N (N : Integer number)						
	(ex.1) Bit width of transfer source:8 bit, bit width of transfer destination:32 bit, total number of transfers:25 times						
	8 bit × 25 times = 200 bit (25 byte)						
	N = 200 ÷ 32 = 6.25 word						
	Since 6.25 is not an integer number, the above setting is invalid.						
	If the transfer source bit width is smaller than the transfer destination bit width, care must be taken when setting the total number of transfers.						
	(ex.2) Bit width of transfer source :32 bit, bit width of transfer destination:16 bit, total number of transfers: 13 times						
	32 bit × 13 times = 416 bit (13 word)						
	$N = 416 \div 16 = 26 half_word$						
	Since 26 is an integer number, the above setting is valid.						
<dbsize[2:0]> / <sbsize[2:0]></sbsize[2:0]></dbsize[2:0]>	When "Peripheral to Memory" or "Memory to Peripheral" is performed, peripheral circuits generates DMA request signal to indicate the preparation is ready. This signal triggers to execute data transfers. (In the case of "Memory to Memory", only software start is used.)						
	Set the burst size to define the amount of data transferred from peripherals per DMA request signal. This reg- ister is used with FIFO buffer that can be contained multiple data.

			When a memory is the transfer destination, this setting is ignored.						
5	-	W	Write as zero.						
4-1	SrcPeripheral	R/W	Sets transfer source peripheral (Note 2)						
	[3:0]		Refer to "11.4.2 DMA request".						
	When a memory is the transfer source, this setting is ignored.								

Bit	Bit Symbol	Туре	Function
0	E	R/W	Channel enable
			0 : Disable
			1 : Enable
			This bit can be used to enable/disable the channels. (This bit works as start bit when "Memory to Memory" is selected.)
			Amount of transfer data specified by DMACxCnControl <transfersize> is completed, the corresponding <e> is cleared to "0" automatically.</e></transfersize>
			Disabling channels during transfer loses the data in the FIFO. Initialize all the channels before restart.
			To pause the transfer, stop the DMA request by using the <halt>, and poll the data until the <active> becomes "0" and then disable the channel with the <e> bit.</e></active></halt>

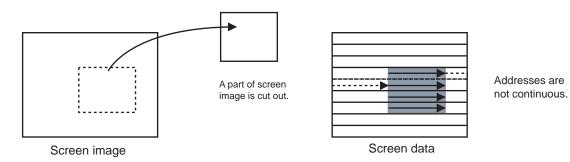

Note 1: When "Memory to Memory" is selected, hardware start for DMA startup is not supported. Write "1" <E> for starting transfer.

Note 2: When DMACxENableChns<EnabledCHx> is enabled and the corresponding DMACxCnConfiguration<Halt> is set to "1", write them after channel enable bit (E:bit0) is clear to "0". Without this, in the case of the slave error is occurred when writing them, the error is recovered by reset. Regarding slave error, when the width and address of transfer have mismatch, this error is occurred.

### 11.6 Special Functions

### 11.6.1 Scatter/gather function

When removing a part of image data and transferring it, image data cannot be handled as consecutive data, and the address changes dramatically depending on the special rule. Since DMA can transfer data only by using consecutive addresses, it is necessary to make required settings at locations where addresses changes.

The scatter/gather function can consecutively operate DMA settings (transfer source address, destination address, number of transfers, and transfer bus width) by re-loading them each time a specified number of DMA executions have completed via a pre-set "Linked List" where the CPU does not need to control the operation.

Setting "1" in the DMACxCnLLI register enables/disables the operation.

The items that can be set with Linked List are configured with the following 4 words:

- 1. DMACxCnSrcAddr
- 2. DMACxCnDestAddr
- 3. DMACxCnLLI
- 4. DMACxCnControl

They can be used with the interrupt operation.

An interrupt depends on the count end interrupt enable bit of the DMACxCnControl register, and can be generated at the end of each LLI. When this bit is used, a condition can be added even during transfer using LLI to perform branch operation, etc. To clear the interrupt, control the appropriate bit of the DMACxIntTCClear register.

### 11.6.2 Linked list operation

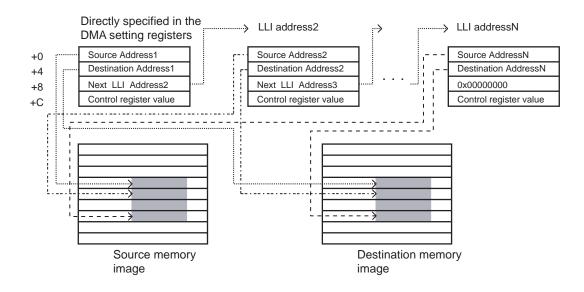

To operate the scatter/gather function, a transfer source and source data areas need to be defined by creating a set of Linked Lists first.

Each setting is called LLI (LinkedList).

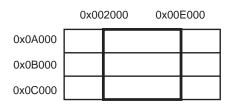

Each LLI controls the transfer of one block of data. Each LLI indicates normal DMA setting and controls transfer of successive data. Each time each DMA transfer is complete, the next LLI setting will be loaded to continue the DMA operation (Daisy Chain).

An example of the setting is shown below.

- 1. The first DMA transfer setting should be made directly in the DMA register.
- 2. The second and subsequent DMA transfer settings should be written in the addresses of the memory set in "next LLI AddressX."
- 3. To stop up to N'th DMA transfer, set "next LLI AddressX" to 0x0000\_0000.

When transferring data in the area enclosed by the square

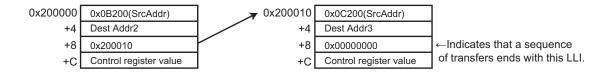

Setting register	
------------------	--

+0 DMACxCnSrcAddr :0x0A200

- +4 DMACxCnDestAddr :Destination address 1
- +8 DMACxCnLLI :0x200000
- +C DMACxCnControl :Set the number of burst transfers and the number of transfers, etc.

#### 11.6 Special Functions

# TOSHIBA

# 12. 16-bit Timer/Event Counters(TMRB)

# 12.1 Outline

TMRB operate in the following four operation modes:

- 16-bit interval timer mode
- 16-bit event counter mode
- 16-bit programmable pulse generation mode (PPG)
- Timer synchronous mode

The use of the capture function allows TMRB to perform the following three measurements.

- Frequency measurement
- Pulse width measurement
- Time difference measurement

In the following explanation of this section, "x" indicates a channel number.

# 12.2 Differences in the Specifications

TMPM365FYXBG contains 10-channel of TMRB.

Each channel functions independently and the channels operate in the same way except for the differences in their specification as shown in Table 12-1.

Some of the channels can put the capture trigger and the synchronous start trigger on other channels.

- 1. The flip-flop output of TMRB 7 through TMRB 9 can be used as the capture trigger of other channels.
  - TB7OUT  $\rightarrow$  available for TMRB0 through TMRB1
  - TB8OUT  $\rightarrow$  available for TMRB2 through TMRB3
  - TB9OUT  $\rightarrow$  available for TMRB4 through TMRB6
- 2. The start trigger of the timer synchronous mode (with TBxRUN)
  - TMRB0  $\rightarrow$  can start TMRB0 through TMRB3 synchronously
  - TMRB4  $\rightarrow$  can start TMRB4 through TMRB7 synchronously
- 3. The start trigger of the timer prescaler synchronous mode (with TBxPRUN)
  - TMRB0  $\rightarrow$  can start TMRB0 through TMRB3 synchronously
  - TMRB4  $\rightarrow$  can start TMRB4 through TMRB7 synchronously

### 12.3 Configuration

Each channel consists of a 16-bit up-counter, two 16-bit timer registers (double-buffered), two 16-bit capture registers, two comparators, a capture input control, a timer flip-flop and its associated control circuit. Timer operation modes and the timer flip-flop are controlled by a register.

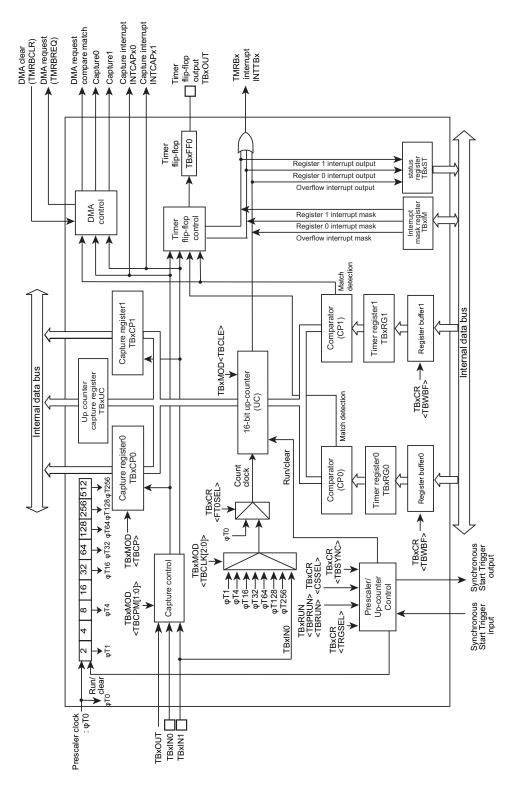

Figure 12-1 TMRBx Block Diagram(x= 0 to 9)

# 12.4 Registers

### 12.4.1 Register list according to channel

The following table shows the register names and addresses of each channel.

Channel x	Base Address
Channel0	0x400C_4000
Channel1	0x400C_4100
Channel2	0x400C_4200
Channel3	0x400C_4300
Channel4	0x400C_4400
Channel5	0x400C_4500
Channel6	0x400C_4600
Channel7	0x400C_4700
Channel8	0x400C_4800
Channel9	0x400C_4900

Register name(x=0~9)		Address(Base+)	
Enable register	TBxEN	0x0000	
RUN register	TBxRUN	0x0004	
Control register	TBxCR	0x0008	
Mode register	TBxMOD	0x000C	
Flip-flop control register	TBxFFCR	0x0010	
Status register	TBxST	0x0014	
Interrupt mask register	TBxIM	0x0018	
Up counter capture register	TBxUC	0x001C	
Timer register 0	TBxRG0	0x0020	
Timer register 1	TBxRG1	0x0024	
Capture register 0	TBxCP0	0x0028	
Capture register 1	TBxCP1	0x002C	
DMA request enable register	TBxDMA	0x0030	

Note: Timer control register, timer mode register and timer flip-flop control register can not be changed during timer operation. Make any changes of the above regsters after timer stopped.

			By setting "1", the timer-flip-flop reverses when an up-counter value is matched with the Timer register 0 (TBxRG0).
1-0	TBFF0C[1:0]	R/W	TBxFF0 control
			00: Invert
			Reverses the value of TBxFF0 (reverse by using software).
			01: Set
			Sets TBxFF0 to "1".
			10: Clear
			Clears TBxFF0 to "0".
			11: Don't care
			This is always read as "11".

### 12.4.7 TBxST (Status register)

Bit	Bit Symbol	Туре	Function				
31-3	-	R	Read as 0.				
2	INTTBOF	R	Overflow flag 0:No overflow occurs 1:Overflow occurs				
			When an up-counter is overflow, "1" is set.				
1	INTTB1	R	Match flag (TBxRG1) 0:No detection of a mach 1:Detects a match with TBxRG1 When a match with the timer register 1 (TBxRG1) is detected,"1" is set.				
0	INTTB0	R	Match flag (TBxRG0) 0:No match is detected 1:Detects a match with TBxRG0 When a match with the timer register 0 (TBxRG0) is detected, "1" is set.				

Note 1: To clear the flag, TBxST register should be read.

Note 2: When the interrupt mask configuration is disabled by the corresponding bit of TBxIM register, the interrupt is issued to the CPU.

Note 3: Even if mask configuration by TBxIM register is valid, the status is set to TBxST register.

# 12.4.8 TBxIM (Interrupt mask register)

Bit	Bit Symbol	Туре	Function
31-3	-	R	Read as 0.
2	TBIMOF	R/W	Overflow interrupt mask
			0:Disable
			1:Enable
			Sets the up-counter overflow interrupt to disable or enable.
1	TBIM1	R/W	Match interrupt mask (TBxRG1)
			0:Disable
			1:Enable
			Sets the match interrupt mask with the Timer register 1 (TBxRG1) to enable or disable.
0	твімо	R/W	Match interrupt mask (TBxRG0)
			0:Disable
			1:Enable
			Sets the match interrupt mask with the Timer register 0 (TBxRG0) to enable or disable.

Note: Even if mask configuration by TBxIM register is valid, the status is set to TBxST register.

### 12.4.14 TBxDMA(DMA request enable register)

Bit	Bit Symbol	Туре	Function
31-3	-	R	Read as 0.
2	TBDMAEN2	R/W	Selects DMA request:compare match. 0: Disabled 1 :Enabled
1	TBDMAEN1	R/W	Selects DMA request:input capture 1 0: Disabled 1: Enabled
0	TBDMAEN0	R/W	Selects DMA request:input capture 0 0: Disabled 1: Enabled

Note 1: When mask configuration by TBxIM register is valid, DMA request does not issue even if it is enabled.

Note 2: The assignment of DMA request factor differs by channel, TMRB0 to 9 . Refer to Chapter "DMAC " for details.

### 12.5 Description of Operations for Each Circuit

The channels operate in the same way, except for the differences in their specifications as shown in Table 12-1.

### 12.5.1 Prescaler

There is a 4-bit prescaler to generate the source clock for up-counter UC.

The prescaler input clock  $\phi$ T0 is fperiph/1, fperiph/2, fperiph/4, fperiph/8, fperiph/16 or fperiph/32 selected by CGSYSCR<PRCK[2:0]> in the CG.The peripheral clock, fperiph, is either fgear, a clock selected by CGSYSCR<FPSEL> in the CG, or fc, which is a clock before it is divided by the clock gear.

The operation or the stoppage of a prescaler is set with TBxRUN<TBPRUN> where writing "1" starts counting and writing "0" clears and stops counting. Table 12-2 and Table 12-3 show prescaler output clock resolutions.

Select	Clock gear value Select Prescaler output		Prescaler output	ut clock function

Note 1: The prescaler output clock  $\phi$ Tn must be selected so that  $\phi$ Tn < fsys is satisfied (so that  $\phi$ Tn is slower than fsys).

Note 2: Only when it is set as TBxCR<FT0SEL>="1", the prescaler output clock  $\phi$ Tn can be used also on condition of  $\phi$ Tn  $\leq$  fsys.

Note 3: Do not change the clock gear while the timer is operating.

Note 4: "-" denotes a setting prohibited.

Note 1: The prescaler output clock  $\phi$ Tn must be selected so that  $\phi$ Tn < fsys is satisfied (so that  $\phi$ Tn is slower than fsys).

Note 2: Do not change the clock gear while the timer is operating.

Note 3: "-" denotes a setting prohibited.

### 12.5.2 Up-counter (UC)

UC is a 16-bit binary counter.

Source clock

UC source clock, specified by TBxMOD<TBCLK[2:0]> and TBxCR<FT0SEL>, can be selected from  $\phi$ T0,  $\phi$ T1,  $\phi$ T4,  $\phi$ T16,  $\phi$ T32,  $\phi$ T64,  $\phi$ T128 or  $\phi$ T256 or the external clock of the TBxIN0 pin.

Only when it is set as TBxCR<FT0SEL>="1", the prescaler output clock  $\phi$ Tn  $\leq$  fsys.

Count start/ stop

Counter operation is specified by TBxRUN<TBRUN>. UC starts counting if  $\langle TBRUN \rangle = "1"$ , and stops counting and clears counter value if  $\langle TBRUN \rangle = "0"$ .

- Timing to clear UC
  - 1. When a match is detected

By setting TBxMOD<TBCLE> = "1", UC is cleared if when the comparator detects a match between counter value and the value set in TBxRG1. UC operates as a free-running counter if TBxMOD<TBCLE> = "0".

2. When UC stops

UC stops counting and clears counter value if TBxRUN<TBRUN> = "0".

• UC overflow

If UC overflow occurs, the INTTBx overflow interrupt is generated.

### 12.5.3 Timer registers (TBxRG0, TBxRG1)

TBxRG0 and TBxRG1 are registers for setting values to compare with up-counter values and two registers are built into each channel. If the comparator detects a match between a value set in this timer register and that in a UC up-counter, it outputs the match detection signal.

TBxRG0 and TBxRG1 are consisted of the double-buffered configuration which are paired with register buffers. The double buffering is disabled in the initial state.

Controlling double buffering disable or enable is specified by TBxCR<TBWBF> bit. If  $\langle$ TBWBF> = "0", the double buffering becomes disable. If  $\langle$ TBWBF> = "1", it becomes enable. When the double buffering is enabled, a data transfer from the register buffer to the timer register (TBxRG0/1) is done in the case that UC is matched with TBxRG1. When the counter is stopped even if double buffering is enabled, the double buffering operates as a single buffer, and an immediate data can be written to the TBxRG0 and TBxRG1.

### 12.5.4 Capture

This is a circuit that controls the timing of latching values from the UC up-counter into the TBxCP0 and TBxCP1 capture registers. The timing with which to latch data is specified by TBxMOD<TBCPM[1:0]>.

Software can also be used to import values from the UC up-counter into the capture register; specifically, UC values are taken into the TBxCP0 capture register each time "0" is written to TBxMOD<TBCP>.

## 12.5.5 Capture registers (TBxCP0, TBxCP1)

This register captures an up-counter (UC) value.

### 12.5.6 Up-counter capture register (TBxUC)

Other than the capturing functions shown above, the current count value of the UC can be captured by reading the TBxUC registers.

## 12.5.7 Comparators (CP0, CP1)

This register compares with the up-counter (UC) and the value setting of the Timer Register (TBxRG0 and TBxRG1) to detect whether there is a match or not. If a match is detected, INTTBx is generated.

## 12.5.8 Timer Flip-flop (TBxFF0)

The timer flip-flop (TBxFF0) is reversed by a match signal from the comparator and a latch signal to the capture registers. It can be enabled or disabled to reverse by setting the TBxFFCR<TBC1T1, TBC0T1, TBE1T1, TBE0T1>.

The value of TBxFF0 becomes undefined after a reset. The flip-flop can be reversed by writing "00" to TBxFFCR<TBFF0C[1:0]>. It can be set to "1" by writing "01," and can be cleared to "0" by writing "10."

The value of TBxFF0 can be output to the Timer output pin (TBxOUT). If the timer output is performed, the corresponding port settings must be programmed beforehand.

## 12.5.9 Capture interrupt (INTCAPx0, INTCAPx1)

Interrupts INTCAPx0 and INTCAPx1 can be generated at the timing of latching values from the UC up-counter into the TBxCP0 and TBxCP1 capture registers. The interrupt timing is specified by the CPU.

## 12.6 Description of Operations for Each Mode

## 12.6.1 16-bit Interval Timer Mode

In the case of generating constant period interrupt, set the interval time to the Timer register (TBxRG1) to generate the INTTBx interrupt.

		7	6	5	4	3	2	1	0	
TBxEN	←	1	Х	Х	х	Х	Х	Х	Х	Enables TMRBx operation.
TBxRUN	←	Х	Х	Х	х	Х	0	Х	0	Stops count operation.
Interrupt Set-Enable Register	←	*	*	*	*	*	*	*	*	Permits INTTBx interrupt by setting corresponding bit to "1".
TBxFFCR	←	Х	Х	0	0	0	0	1	1	Disable to TBxFF0 reverse trigger
TBxMOD	←	0	1	0	0	1	*	*	*	Changes to prescaler output clock as input clock. Specifies
						(*	** = 0	01 to	111)	Capture function to disable.
TBxRG1	←	*	*	*	*	*	*	*	*	Specifies a time interval. (16 bits)
	←	*	*	*	*	*	*	*	*	
TBxRUN	←	*	*	*	*	*	1	Х	1	Starts TMRBx.

Note: X; Don't care -; No change

## 12.6.2 16-bit Event Counter Mode

It is possible to make it the event counter by using an input clock as an external clock (TBxIN0 pin input).

The up-counter counts up on the rising edge of TBxIN0 pin input. It is possible to read the count value by capturing value using software and reading the captured value.

UI DAINU.
igger
t clock
r

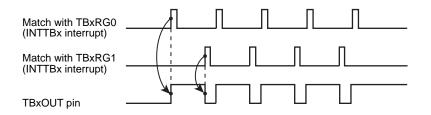

Note 1: m: corresponding bit of port Note 2: X; Don't care -; No change

## 12.6.3 16-bit PPG (Programmable Pulse Generation) Output Mode

Square waves with any frequency and any duty (programmable square waves) can be output. The output pulse can be either low-active or high-active.

Programmable square waves can be output from the TBxOUT pin by triggering the timer flip-flop (TBxFF) to reverse when the set value of the up-counter (UC) matches the set values of the timer registers (TBxRG0 and TBxRG1). Note that the set values of TBxRG0 and TBxRG1 must satisfy the following requirement:

(Set value of TBxRG0) < (Set value of TBxRG1)

## Figure 12-2 Example of Output of Programmable Pulse Generation (PPG)

In this mode, by enabling the double buffering of TBxRG0, the value of register buffer 0 is shifted into TBxRG0 when the set value of the up-counter matches the set value of TBxRG1. This facilitates handling of small duties.

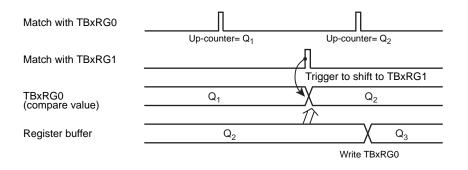

Figure 12-3 Register Buffer Operation

12.6 Description of Operations for Each Mode

PxCR[m]	←						1			Allocates corresponding port to TBxOUT.
PxFR1[m]	←						1			Anocales corresponding por to TEXOUT.
TBxRUN	←	*	*	*	*	*	1	Х	1	Starts TMRBx.

Note 1: m: corresponding bit of port Note 2: X; Don't care

-; No change

## 12.6.4 Timer synchronous mode

This mode enables the timers to start synchronously.

If the mode is used with PPG output, the output can be applied to drive a motor.

TMRB is consisted of two pairs of 4-channel TMRB. If one channel starts, remaining 3 channels can be start synchronously. In the TMPM365FYXBG, the following combinations allow to use.

Start trigger channel (Master channel)	Synchronous operation channel (Slave channel)
TMRB0	TMRB1, TMRB2, TMRB3
TMRB4	TMRB5, TMRB6, TMRB7

Use of the timer synchronous mode is specified in TBxCR<TBSYNC> bit.

- <TBSYNC> = "0" : Timer operates individually.
- <TBSYNC> = "1" : Timers operates synchronously.

Set "0" to the <TBSYNC> bit in the master channel.

If <TBSYNC>= "1" is set in the slave channel, the start timing is synchronized with master channel start timing. Setting of start timing for TBxRUN<TBPRUN, TBRUN> bit in the slave channel is not required.

- Note 1: Set TBxCR<TBSYNC> to "0" unless the timer synchronous mode is used. The timer synchronous mode keeps the other channels operation waiting until TMRB0 and TMRB4 start operation.
- Note 2: TMRB0 and TMRB4 are the master clocks of the timer synchronous mode. Therefore, their <TBSYNC> bit must be set to "0".
- Note 3: This mode cannot be applied to TMRB8 and TMRB9.

## 12.6.5 External trigger count start mode

The external trigger count start mode can be set to start counting by an external signal.

Set TBxCR<CSSEL> to select the count start mode.

- <CSSEL> = "0" : Start counting according to the timing of each timer channel.
- <CSSEL> = "1" : Start counting by an external signal.

Set TBxCR<TRGSEL> to select the active edge of the external trigger signal.

- <TRGSEL> = "0" : The rising edge of TBxIN0 is selected.
- <TRGSEL> = "1" : The falling edge of TBxIN0 is selected.

Timer synchronous mode has a priority if its mode is specified.

## 12.7 Applications using the Capture Function

The capture function can be used to develop many applications, including those described below:

- 1. One-shot pulse output triggered by an external pulse
- 2. Frequency measurement
- 3. Pulse width measurement
- 4. Time difference measurement

### 12.7.1 One-shot pulse output triggered by an external pulse

One-shot pulse output triggered by an external pulse is carried out as follows:

The 16-bit up-counter is made to count up by putting it in a free-running state using the prescaler output clock. An external pulse is input through the TBxIN0 pin. A trigger is generated at the rising of the external pulse by using the capture function and the value of the up-counter is taken into the capture registers (TBxCP0).

The CPU must be programmed so that an interrupt INTCAPx0 is generated at the rising of an external trigger pulse. This interrupt is used to set the timer registers (TBxRG0) to the sum of the TBxCP0 value (c) and the delay time (d), (c + d), and set the timer registers (TBxRG1) to the sum of the TBxRG0 values and the pulse width (p) of one-shot pulse, (c + d + p).[TBxRG1 change must be completed before the next match.]

In addition, the timer flip-flop control registers(TBxFFCR<TBE1T1, TBE0T1>) must be set to "11". This enables triggering the timer flip-flop (TBxFF0) to reverse when TBxUC matches TBxRG0 and TBxRG1. This trigger is disabled by the INTTBx interrupt after a one-shot pulse is output.

Symbols (c), (d) and (p) used in the text correspond to symbols c, d and p in "Figure 12-5 One-shot Pulse Output (With Delay)".

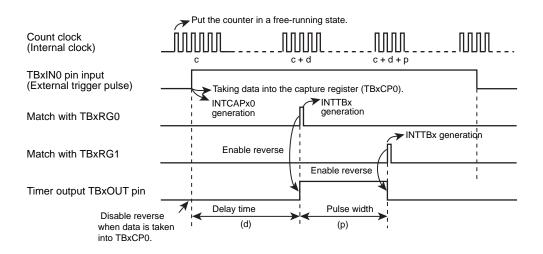

Figure 12-5 One-shot Pulse Output (With Delay)

The followings show the settings in the case that 2 ms width one-shot pulse is output after 3ms by triggering TBxIN0 input at the rising edge. ( $\Phi$ T1 is selected for counting.)

Changes source clock to  $\Phi$ T1. Fetches a count value into the TBxCP0 at the rising edge of TBxIN0.

Interrupt Set-Enable Register	←	*	*	*	*	*	*	*	*	Permits to generate interrupt specified by INTTBx interrupt corresponding bit setting to "1".
[Processing of INTTBx inte	rrupt	servi	ce ro	utine]	Outp	ut dis	able			
TBxFFCR	←	Х	Х	-	-	0	0	-	-	Clears TBxFF0 reverse trigger setting.
Interrupt enable clear register	~	*	*	*	*	*	*	*	*	Prohibits interrupts specified by INTTBx interrupt correspond- ing bit by setting to "1".

Note 1: m: corresponding bit of port Note 2: X; Don't care -; No change

If a delay is not required, TBxFF0 is reversed when data is taken into TBxCP0, and TBxRG1 is set to the sum of the TBxCP0 value (c) and the one-shot pulse width (p), (c + p), by generating the INTCAPx0 interrupt. (TBxRG1 change must be completed before the next match.)

TBxFF0 is enabled to reverse when UC matches with TBxRG1, and is disabled by generating the INTTBx interrupt.

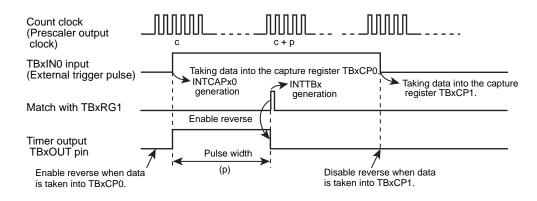

Figure 12-6 One-shot Pulse Output Triggered by an External Pulse (Without Delay)

### 12.7.2 Frequency measurement

The frequency of an external clock can be measured by using the capture function.

To measure frequency, another 16-bit timer is used in combination with the 16-bit event counter mode. As an example, we explain with TMRB3 and TMRB8. TB8OUT of the 16-bit timer TMRB8 is used to specify the measurement time.

TMRB3 count clock selects TB3IN0 input and performs count operation by using external clock input. If TB3MOD<TBCPM[1:0]> is set "11", TMRB3 count clock takes the counter value into the TB3CP0 at the rising edge of TB8OUT and takes the counter value into TB3CP1 at the falling edge of TB8OUT.

This setting allows a count value of the 16-bit up-counter UC to be taken into the capture register (TB3CP0) upon rising of a timer flip-flop output (TB8OUT) of the 16-bit timer (TMRB8), and an UC counter value to be taken into the capture register (TB3CP1) upon falling of TB8OUT of the 16-bit timer (TMRB8).

A frequency is then obtained from the difference between TB3CP0 and TB3CP1 based on the measurement, by generating the INTTB8 16-bit timer interrupt.

For example, if the difference between TB3CP0 and TB3CP1 is 100 and the level width setting value of TB8OUT is 0.5 s, the frequency is 200 Hz ( $100 \div 0.5 \text{ s} = 200 \text{ Hz}$ ).

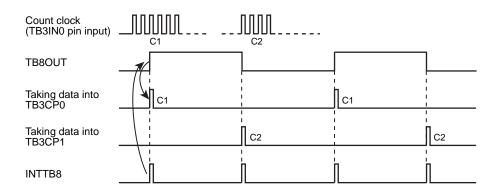

Figure 12-7 Frequency Measurement

### 12.7.3 Pulse width measurement

By using the capture function, the "High" level width of an external pulse can be measured. Specifically, by putting it in a free-running state using the prescaler output clock, an external pulse is input through the TBxIN0 pin and the up-counter (UC) is made to count up. A trigger is generated at each rising and falling edge of the external pulse by using the capture function and the value of the up-counter is taken into the capture registers (TBxCP0, TBxCP1). The CPU must be programmed so that INTCAPx1 is generated at the falling edge of an external pulse input through the TBxIN0 pin.

The "High" level pulse width can be calculated by multiplying the difference between TBxCP0 and TBxCP1 by the clock cycle of an internal clock.

For example, if the difference between TBxCP0 and TBxCP1 is 100 and the cycle of the prescaler output clock is 0.5  $\mu$ s, the pulse width is 100 × 0.5  $\mu$ s = 50  $\mu$ s.

Caution must be exercised when measuring pulse widths exceeding the UC maximum count time which is dependant upon the source clock used. The measurement of such pulse widths must be made using software.

The "Low" level width of an external pulse can also be measured. In such cases, the difference between C2 generated the first time and C1 generated the second time is initially obtained by performing the second stage of INTCAPx0 interrupt processing as shown in "Figure 12-8 Pulse Width Measurement" and this difference is multiplied by the cycle of the prescaler output clock to obtain the "Low" level width.

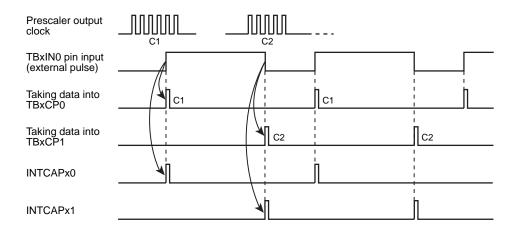

Figure 12-8 Pulse Width Measurement

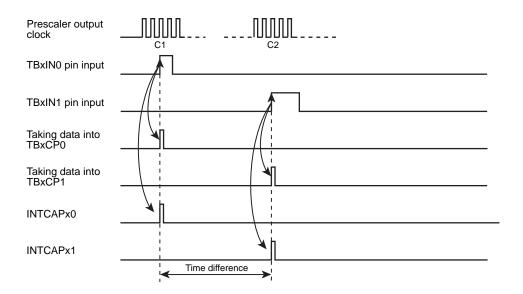

### 12.7.4 Time Difference Measurement

The time difference of two events can be measured by the capture function. The up-counter (UC) is made to count up by putting it in a free-running state using the prescaler output clock.

The value of UC is taken into the capture register (TBxCP0) at the rising edge of the TBxIN0 pin input pulse. The CPU must be programmed to generate INTCAPx0 interrupt at this time.

The value of UC is taken into the capture register (TBxCP1) at the rising edge of the TBxIN1 pin input pulse. The CPU must be programmed to generate INTCAPx1 interrupt at this time.

The time difference can be calculated by multiplying the difference between TBxCP1 and TBxCP0 by the clock cycle of an internal clock.

#### 12. 16-bit Timer/Event Counters(TMRB)

12.7 Applications using the Capture Function

# 13. USB Device Controller (USBD)

This section describes about USB device controller. An endpoint is described as EP in this section.

## 13.1 Outline

- 1. Conforming to Universal Serial Bus Specification Rev.2.0.
- 2. Supports Full-Speed (Low-Speed is not supported).
- 3. USB protocol processing
- 4. Detects SOF/USB\_RESET/SUSPEND/RESUME.
- 5. Generates and checks packet IDs.
- 6. Checks CRC5. Generates and checks CRC16.
- 7. Supports 4 transfer modes (Control/Interrupt /Bulk/ Isochronous).
- 8. Supports 8 EPs.

Table 13-1 Endpoints

EP0:	Control	64byte × 1 FIFO
EP1:	Control / Interrupt / Bulk / Isochronous (IN)	64byte × 2 FIFO
EP2:	Control / Interrupt / Bulk / Isochronous (OUT)	64byte × 2 FIFO
EP3:	Control / Interrupt / Bulk / Isochronous (IN)	64byte × 2 FIFO
EP4:	Control / Interrupt / Bulk / Isochronous (OUT)	64byte × 2 FIFO
EP5:	Control / Interrupt / Bulk / Isochronous (IN)	64byte × 2 FIFO
EP6:	Control / Interrupt / Bulk / Isochronous (OUT)	64byte × 2 FIFO
EP7:	Control / Interrupt / Bulk / Isochronous (IN)	64byte × 2 FIFO

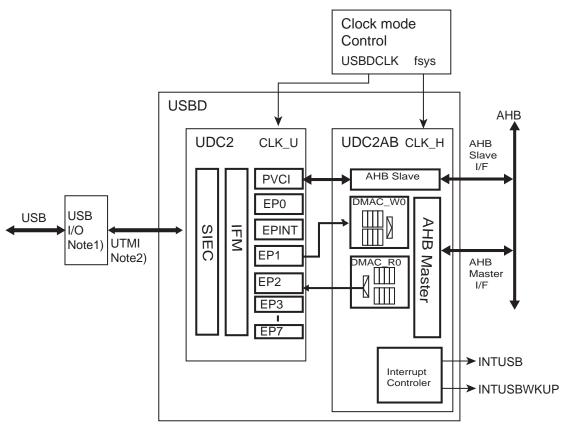

9. Supports Dual Packets Mode (except for EP 0)

10. Interrupt source signals to the interrupt controller: INTUSB, INTUSBWKUP

## 13.2 System Structure

The USB device controller consists of the USB-Spec2.0 device controller (hereinafter called UDC2) and the bus bridge (hereinafter called UDC2AB) which connects the UDC2 and the AHB bus.

In this section, "13.2.1 AHB Bus Bridge (UDC2AB)" describes the configuration of the UDC2AB, and "13.2.2 Toshiba USB-Spec2.0 Device Controller (UDC2)" describes that of the UDC2.

Note1) TMPM365FYXBG has USB I/O which can be used for Full Speed mode not Low speed mode. The word "PHY" in this section should be read as USB I/O. Note2) USB2.0 Transceiver Macrocell Interface

Figure 13-1 Block diagram of the USB device controller

## 13.2.1 AHB Bus Bridge (UDC2AB)

UDC2AB is the bus bridge between the Toshiba USB-Spec2.0 device controller (hereinafter called UDC2) and the AHB.

UDC2AB has the DMA controller that supports the AHB master transfer and controls transfer between the specified address on the AHB and the Endpoints-FIFO (EP I/F) in the UDC2.

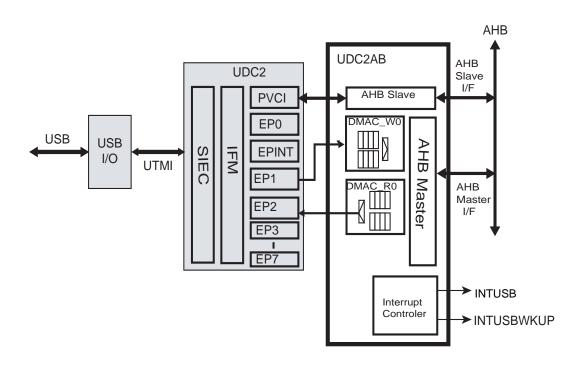

Figure 13-2 UDC2AB Block Diagram

#### 13.2.1.1 Functions and Features

UDC2AB has the following functions and features:

1. Connections with UDC2

There is no specific restriction on the EP configuration for the UDC2 to be connected. However, the DMA controller in UDC2AB (AHB master function) can be connected with one Rx-EP and one Tx-EP. Accesses to other EPs (including EP0) should be made through PVCI I/F of UDC2 using the AHB slave function. Please note the EPx\_FIFO register of a UDC2 EP in master transfer with the DMA controller cannot be accessed through PVCI I/F.

If the maximum packet size of the EP to be connected with the AHB master read function is an odd number, there are some restrictions on the usage. See "(3) Setting the maximum packet size in Master Read transfers" for more information.

2. AHB functions

AHB master and AHB slave functions are provided.

a. AHB master function

There are two DMA channels available for the USB device controller. One channel is allocated to the Rx-Ep and the Tx-Ep each.

Supported
Supported
Supported
Supported

32-bit
Supported

Table 13-2 AHB Master Functions

The image of Endian conversion is as shown below.

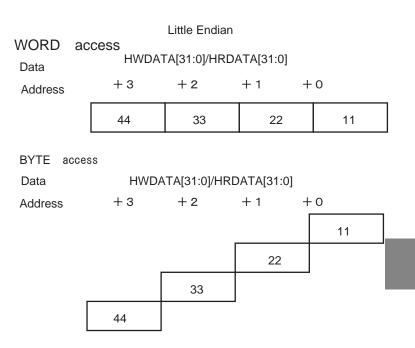

Figure 13-3 Image of Endian conversion in AHB Master function

b. AHB Slave Function

Specification of the AHB Slave function.

Little Endian	Supported
Single transaction	Supported
Address width	32-bit
Data width	32-bit
Transaction in bytes or words	Supported

The image of Endian conversion is as shown below.

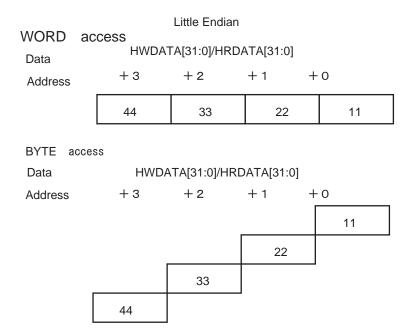

Figure 13-4 Image of Endian conversion in AHB Slave function

#### 13.2.1.2 Configuration

UDC2AB mainly consists of the AHB Slave function that controls the access to the UDC2AB internal registers and UDC2 registers (UDC2 PVCI I/F) and the AHB Master function that controls the DMA access to the UDC2 EP I/F.

The AHB Master function has two built-in channels; Master Read Channel (AHB to UDC2) and Master Write Channel (UDC2 to AHB), which enable DMA transfer between the EP I/F of Rx-EP and Tx-EP of UDC2. Each channel has two built-in 8-word buffers (four in total).

#### 13.2.1.3 Clock Domain

fsys provided by the clock/mode control circuit is connected to CLK\_H of the UDC2AB. fsys stops or starts according to the low-power consumption mode of the TMPM365FYXBG.

Since CLK\_H is not provided during the fsys being stopped in the low-power consumption mode, IN-TUSBwill not be generated.

Therefore, to detect the connection and disconnection of the VBUS, an interrupt to used needs to be selected from INTUSBPON generated by the USBPON pin and INTUSB at the moment when CLK\_H starts or stops. Refer to "13.5.5.2 Sequence of USB Bus Power (VBUS) Connection/Disconnection" for more information.

USBDCLK provided from clock / mode control circuit is connected to CLK\_U of UDC2. USBDCLK stops or starts according to the register. To stop or start CLK\_U by detecting status such as suspend and resume, configure clock / mode control circuit using software.

## 13.2.2 Toshiba USB-Spec2.0 Device Controller (UDC2)

UDC2 controls the connection of USB functions to the Universal Serial Bus. UDC2 automatically processes the USB protocol and its PHY-end interface can be accessed via UTMI.

1. SIEC (Serial Interface Engine Control) block

This block manages the protocol in USB. Its major functions are:

- Checks and generates PIDs
- Checks and generates CRCs
- Checks device addresses
- 2. IFM block

This block controls SIEC and EPs. Its major functions are:

- Writes the received data to the relevant EPs when received an OUT-Token.
- Reads the transmit data from the relevant EPs when an IN-Token is received.
- Controls and manages the status of UDC2.0.
- 3. PVCI-I/F block

This block controls reading and writing between IFM and external register access bus (PVCI).

PVCI bus accesses via UDC2AB.

4. EP0 block

This block controls sending and receiving data in Control transfers. When sending or receiving data with DATA-Stage of Control transfers, you should access the FIFO in this block via PVCI-I/F.

5. EPx block

This block controls sending and receiving data of EPx (x = 1 to 7). FIFO can be directly accessed via the EP-I/F. The EP-I/F can make burst transfers.

Please note there are two EPs; one for sending (EPTX) and another for receiving (EPRX). Direction of EPs (send/receive) will be fixed on a hardware basis.

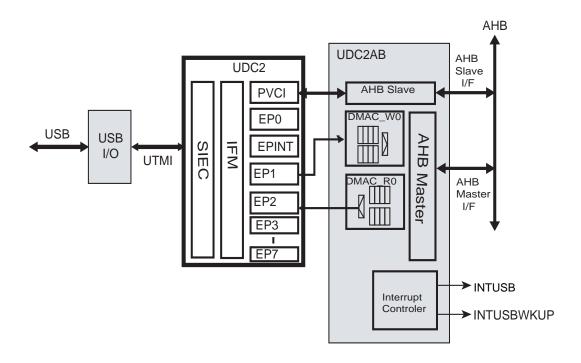

Figure 13-5 Block diagram of UDC2

#### 13.2.2.1 Features and Functions

The main features and functions are as follows:

- 1. Complies with Universal Serial Bus Specification Rev. 2.0.
- 2. Complies with Full-Speed (FS) (not complies with Low-Speed).
- 3. USB protocol processing
- 4. Detects SOF/USB\_RESET/SUSPEND/RESUME.
- 5. Generates and checks packet IDs.
- 6. Checks CRC5. Generates and checks CRC16.
- 7. Supports 4 transfer modes (Control/Interrupt/Bulk/Isochronous).
- 8. Supports up to 8 EPs.
- 9. Supports Dual Packet Mode (EP 0 excluded)
- 10. EP 1 to 7 can directly access FIFO (EP-I/F)
- 11. Complies with USB 2.0 Transceiver Macrocell Interface (UTMI) (8 bits @ 48 MHz)

#### 13.2.2.2 Specifications of Flags

The UDC2 core outputs various events on USB as flags when they occur. This section discusses those flags.

#### 1. USB RESET

Asserts "High" while receiving USB\_RESET. Since UDC2 returns to the Default-State by receiving USB RESET, the application also needs to return to the Default-State.

In Full-Speed operation, UDC2 asserts this flag when SE0 on the USB bus was recognized for 2.5 s or longer. Then, after UDC2 has driven Chirp-K for about 1.5 ms the flag will be deasserted when either one of the following states was recognized:

- a. Chirp from the host (K-J-K-J-K-J) was recognized.
- b. 2 ms or longer has passed without recognizing Chirp from the host (K-J-K-J-K-J).
- Note: While the time when the host begins Chirp and the driving time of Chirp-K and Chirp-J depend on the host, asserting period of the USB\_RESET flag is around 1.74 ms to 3.5 ms.

#### 2. INT SETUP

In Control transfers, asserts "High" after receiving the Setup-Token. When this interrupt is recognized, the software should read the Setup-Data storage register (8 bytes) to make judgment of request. This interrupt will be deasserted by writing 1 into the UDFS2INT<i\_setup>. UDFS2INT should be cleared at the point the interrupt was recognized.

#### 3. INT\_STATUS\_NAK

In Control transfers, when the host proceeds to the STATUS-Stage and transmits packets while UDC2 is processing the DATA-Stage (before issuing the "Setup\_Fin" command), UDC2 will return "NAK" and asserts this flag to "High". When this interrupt is recognized, the software should issue the "Setup\_Fin" command from the Command register to make the STATUS-Stage of UDC2 end. This interrupt will be deasserted by writing 1 into the UDFS2INT<i\_status\_nak>. UDFS2INT should be cleared at the point the interrupt was recognized.

#### 4. INT\_STATUS

In Control transfers, asserts "High" after finishing the STATUS-Stage normally. This interrupt will be deasserted by writing 1 into the UDFS2INT<i\_status>. UDFS2INT should be cleared at the point the interrupt was recognized.

5. INT\_EP0

In the DATA-Stage of Control transfers, asserts "High" when "ACK" was sent or received (when the transaction finished normally). This interrupt will be deasserted by writing 1 to the UDFS2INT $\leq i_{ep0}$ . UDFS2INT should be cleared at the point the interrupt was recognized.

#### 6. INT\_EP

In EPs other than EP 0, asserts "High" when "ACK" was sent or received (when the transaction finished normally). In that case, which EP the transfer was made can be identified by checking UDFS2INTEP. This interrupt will be deasserted by writing 1 into the UDFS2INT<i\_ep>, or by writing 1 into all bits set in UDFS2INTEP. UDFS2INT should be cleared at the point the interrupt was recognized.

7. INT\_RX\_ZERO

"High" is asserted when Zero-Length data is received. In Control transfers, however, "High" is asserted only when Zero-Length data is received in the DATA-Stage. It will not be asserted when Zero-Length data is received in the STATUS-Stage. Which EP has received the data can be identified by reading the UDFS2CMD<rx\_nulpkt\_ep> or checking UDFS2INTRX0. This interrupt will be deasserted by writing 1 into the UDFS2INT<i\_rx\_data0>, or by writing 1 into all bits set in UDF2INTRX0. UDFS2INTRX0 should be cleared at the point the interrupt was recognized.

#### 8. INT SOF

Asserts "High" when SOF was received. This interrupt will be deasserted by writing 1 into the UDFS2INT<i\_osf>. UDFS2INT should be cleared at the point the interrupt was recognized.

SOF is a packet indicating the start of a frame. It is transmitted from the host to devices every 1ms in the Full-Speed transfers.

9. INT\_NAK

In EPs other than EP 0, asserts "High" when NAK is transmitted. In that case, which EP has transmitted the NAK can be identified by checking UDFS2INTNAK. This interrupt will be deasserted by writing 1 into the UDFS2INT<i\_nak>, or by writing 1 into all bits set in UDFS2INTNAK. By default, this flag will not be asserted when NAK was transmitted. Therefore, you should write 0 into the relevant EP of UDFS2INTNAKMASK to release the mask in order to use this flag.

#### 13.2.2.3 Commands to EP

This section describes about the commands to be issued by UDFS2CMD<com> for the EP specified by UDFS2CMD<ep>.

1. 0x0 : Reserved

Not to be specified.

2. 0x1 : Setup\_Fin

Should be issued only for EP0.

This is a command for setting the end of DATA-Stage in Control transfers. As UDC2 continues to send back "NAK" to the STATUS-Stage until this command is issued, the command should be issued when the DATA-Stage finishes or INT\_STATUS\_NAK was received.

- Note: During Control-WR transfer, read all data received during the Data-Stage first, and then Issue the Setup-Fin command.
  - 3. 0x2 : Set\_DATA0

Can be issued to EPs except EP0. Should not be issued to EP0.

A command for clearing toggling of EPs. While toggling is automatically updated by UDC2 in normal transfers, this command should be issued if it needs to be cleared by software.

4. 0x03 : EP\_Reset

Can be issued to any EP.

A command for clearing the data and status of EPs. Issue this command when you want to reset an EP in such cases as setting EPs of Set\_Configuration and Set\_Interface or resetting the EP by Clear\_Feature. This command will reset the following 5 points:

- a. Clear the UDFS2EP0STS<toggle> / UDFS2EPxSTS<toggle> to DATA0.
- b. Clear the UDFS2EP0STS<status> / UDFS2EPxSTS<status> to Ready.
- c. Clear the UDFS2EP0MSZ<dset> / UDFS2EPxMSZ<dset> and the UDFS2EP0DSZ / UDFS2EPxDSZ.
- d. Clear UDFS2EP0MSZ<tx0\_data> / UDFS2EPxMSZ<tx\_0data>.
- e. Clear the UDFS2EPxSTS<disable>.

UDC2 makes toggling control by hardware for every transfer. If this command is issued when a transfer of EPs is in progress, toggling of the relevant EP will also be cleared which may cause the synchronization with the host be lost. As in the case of receiving requests as mentioned above, the command should be issued when it is possible to make synchronization with the host.

5. 0x4 : EP\_Stall

Can be issued to EPs except EP0. Should not be issued to EP0.

A command for setting the status of EPs to "Stall". Issue this command when you want to set the status of an EP to "Stall" in such cases as stalling an EP by Set\_Feature. When this command is issued, "STALL" will be always sent back for the EP set. However, the Stall status of EP0 will be cleared when the Setup-Token is received.

This command should not be issued for EPs where Isochronous transfers are used, since transfers are made without Handshake in Isochronous transfers. Even if this command is issued for EPs where Isochronous transfers are set (by UDFS2EOxSTS<t\_type>), "STALL" will not be sent back.

6. 0x5 : EP\_Invalid

Can be issued to EPs except EP0. Should not be issued to EP0.

A command for setting the status of EPs to "Invalid". Please issue this command when disabling EPs that will not be used when using Set\_Config or Set\_Interface to set EPs. When this command is issued, the EPs set will make no response. This command should not be issued while transfers of each EP are in progress.

7. 0x6 : Reserved

Not to be specified.

8. 0x7 : EP Disable

Can be issued to EPs except EP0. Should not be issued to EP0.

A command for making an EP disabled. When this command is issued, "NAK" will be always sent back from the EP set. This command should not be issued for EPs where Isochronous transfers are used, since transfers are made without Handshake in Isochronous transfers. Even if this command is issued for EPs where Isochronous transfers are set (by UDFS2EPxSTS<t\_type>), "NAK" will not be sent back.

9. 0x8 : EP Enable

Can be issued to EPs except EP0. Should not be issued to EP0.

A command for making an EP enabled. Issue this command to cancel the disabled status set by "EP\_Disable" command.

10. 0x9 : All\_EP\_Invalid

Setting for EP is invalid.

A command for setting the status of all EPs other than EP0 to "Invalid". Issue this command when you want to apply the "EP\_Invalid" command for all EPs. Issue this command when processing Set\_Configuration and Set\_Interface like the "EP\_Invalid" command.

11. 0xA : USB\_Ready

Should be issued only for EP0.

A command for making connection with the USB cable. Issue this command at the point when communication with the host has become effective after confirming the connection with the cable. Pull-Up of D+ will be made only after this command is issued, and the status of cable connection will be sent to the host.

Please note that the device state of UDC2 (UDFS2ADR<configued> <addressed> <default>) will be set to "Default" when this command was issued.

12. 0xB : Setup\_Received

Should be issued for EP0.

A command for informing UDC2 that the SETUP-Stage of a Control transfer was recognized. Issue this command after accepting the INT\_SETUP interrupt and the request code was recognized. As UDC2 continues to send back "NAK" to the DATA-Stage/STATUS-Stage until this command is issued, the command should be issued at the end of the INT\_SETUP interrupt processing routine.

13. 0xC : EP EOP

Can be issued to any EP.

A command for informing UDC2 that the transmit data has been written. Issue this command when transmitting data with byte size smaller than the maximum transfer bytes (FIFO capacity of the EP or MaxPacketSize, whichever smaller). Issuing this command will set the Data set flag and the data will be sent back to IN-Token from the host. It should not be used when setting Zero-Length data or data of MaxPacketSize.

14. 0xD : EP\_FIFO\_Clear

Can be issued to any EP.

A command for clearing the data of an EP. The UDFS2EPxMSZ<dset> and the UDFS2EPxDSZ will be cleared at the same time. Issue this command when you want to clear the data currently stored in the FIFO before transmitting the data to the host and set the latest data, for instance in Interrupt transfers. If this command is issued while accessing the EP-I/F, the FIFO of the EP will not be successfully cleared. When issuing this command, epx\_val of EP-I/F should be set to 0 before issuing.

15. 0xE : EP\_TX\_0DATA

Can be issued to any EP.

A command for setting Zero-Length data to an EP. Issue this command when you want to transmit Zero-Length data. In the case of transmitting Zero-Length data in Bulk-IN transfers and others to indicate the final transfer, read UDFS2EPxDSZ and confirm it is 0 (no data ex-

ists in the FIFO of EPx) before setting this command. In the case of writing data from EP-I/F, set this command after the data was written and epx\_val became 0. When this command was set, UDFS2EPxMS<tx 0data> of the EP will be set.

Set the next data when the UDFS2EPxMS<tx\_0data> is confirmed to be 0. During Isochronous-IN transfer, Zero -Length data is automatically transferred to the IN-Token if data is not set in the FIFO of EP. Do not issue this command.

- 16. 0xF : Reserved
  - Not to be specified.

Settings for the following commands will be suspended when issued during a USB transfer, which will be executed after the USB transfer has finished. Suspension of the command will take place for each EP.

- 0x2: Set\_DATA0
- 0x3: EP\_Reset
- 0x4: EP\_Stall
- 0x5: EP\_Invalid
- 0x7: EP\_Disable
- 0x8: EP\_Enable
- 0x9: All\_EP\_Invalid
- 0xD: EP\_FIFO\_Clear
- 0xE: EP\_TX\_0DATA

Therefore, when commands were issued successively for the same EP while a USB transfer is in progress, commands will be overwritten and only the one last issued will be valid. If you need to issue commands to an EP successively, poll UDFS2EPxSTS / UDFS2EPxDSZ to confirm that the command has become valid before issuing next ones. Also, when making an access to the EP-I/F immediately after clearing the FIFO using the EP\_Reset/EP\_FIFO\_Clear command, poll UDFS2EPxDSZ to confirm that the command has become valid before resuming the access to the EP-I/F.

For EP 0, the following commands will be invalid until the Setup\_Received command is issued after receiving the Setup-Token:

- 0x1: Setup\_Fin
- 0x2: Set\_DATA0
- 0x3: EP\_Reset
- 0x4: EP\_Stall
- 0xC: EP EOP
- 0xD: EP FIFO Clear
- 0xE: EP\_TX\_0DATA

When the "EP\_Stall" command was set to EPx, "Stall" will be set to the UDFS2EPxSTS<status>. When EP\_Disable was set, 1 will be set to the UDFS2EPxSTS<disable>. When these two commands (EP\_Stall and EP\_Disable) were set to the same EPx and the status becomes "Stall" with UDFS2EPxSTS<disable> = 1, "STALL" will be transmitted in the transfer.

When the "EP\_Invalid" command was set to EPx, "Invalid" will be set to the UDFS2EPxSTS<status>. When the two commands (EP\_Invalid and EP\_Disable) were set to the same EPx and the status becomes "Invalid" with UDFS2EPxSTS<disable> = 1, no response will be made in the transfer.

When UDFS2EPxSTS<disable> is 1 and UDFS2EPxMSZ<tx\_0data> is 1, Zero-Length data will be transmitted once in the transfer. After the Zero-Length data was successfully transferred, "NAK" will be transmitted.

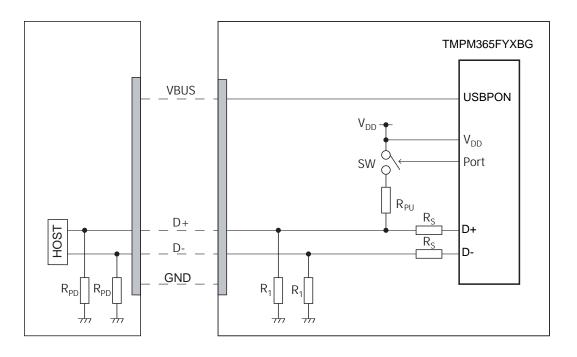

## 13.3 How to connect with the USB bus

The circuit below shows how to connect TMPM365FYXBG with the USB bus.

Input the VBUS signal to USBPON pin to detect the connection of the USB power (VBUS).

The Pull-Up process using the pull-up resistor of the USB-DDP and the in-line damping resistor to the USB-DDM are required. Also, a ON/OFF control using a port needs to be added to the pull-up resistor. The pull-up resistor should be disconnected when voltage is not applied to the VBUS.

If USB-DDP and USB-DDM are unstable, we recommend to add a pull-down resistor to R1.

## Figure 13-6 Connection example of the USB bus and TMPM365FYXBG.

Note: R<sub>1</sub>=500k $\Omega$  or higher (recommended value), R<sub>S</sub>=33 $\Omega$  (recommended value), R<sub>PU</sub>=1.5k $\Omega$  (recommended value)

## 13.4 Registers

The register map of the USBD consists of registers for setting the UDC2AB and that for the UDC2.

When the registers for setting UDC2 are accessed, UDC2AB automatically accesses UDC2 via PVCI I/F.

The register for setting the UDC2AB is 32-bit width. The register for setting the UDC2 is 16-bit width, which is allocated to [15:0]. [31:16] is allocated to the read-only, for indefinite values.

## 13.4.1 UDC2AB Register

#### 13.4.1.1 UDC2AB Register list

		BaseAddress=0x4000_8000
Register name		Address(Base+)
Interrupt Status Register	UDFSINTSTS	0x0000
Interrupt Enable Register	UDFSINTENB	0x0004
Master Write Timeout Register	UDFSMWTOUT	0x0008
UDC2 Setting Register	UDFSC2STSET	0x000C
DMAC Setting register	UDFSMSTSET	0x0010
DMAC Read Request Register	UDFSDMACRDREQ	0x0014
DMAC Read Value Register	UDFSDMACRDVL	0x0018
UDC2 Read Request Register	UDFSUDC2RDREQ	0x001C
UDC2 Read Value Register	UDFSUDC2RDVL	0x0020
-	Reserved	0x0024 to 0x0038 (note 2)
Arbiter Setting Register	UDFSARBTSET	0x003C
Master Write Start Address Register	UDFSMWSADR	0x0040
Master Write End Address Register	UDFSMWEADR	0x0044
Master Write Current Address Register	UDFSMWCADR	0x0048 (note 1)
Master Write AHB Address Register	UDFSMWAHBADR	0x004C
Master Read Start Address Register	UDFSMRSADR	0x0050
Master Read End Address Register	UDFSMREADR	0x0054
Master Read Current Address Register	UDFSMRCADR	0x0058 (note 1)
Master Read AHB Address Register	UDFSMRAHBADR	0x005C
-	Reserved	0x0060 to 0x007C (note 2)
Power Detect Control Register	UDFSPWCTL	0x0080
Master Status Register	UDFSMSTSTS	0x0084
Timeout Count Register	UDFSTOUTCNT	0x0088 (note 1)
-	Reserved	0x008C to 0x1FC

Note 1: Be sure to make Read accesses via UDFSDMACRDREQ.

Note 2: Those shown as "Reserved" above are prohibited to access. Read / Write is prohibited to those "Reserved" areas.

## 13.4.1.2 UDFSINTSTS (Interrupt Status Register)

Bit	Bit Symbol	Туре	Function
31-30	-	R	Read as undefined.
29	int_mw_rerror	R/W	Will be set to 1 when the access to the EP has started Master Write transfer during the setting of common bus access (UDFS2EPxSTS <bus_sel> is 0).(UDFS2EPxSTS<bus_sel> is 0) 0: Not detected 1: EP read error occurred during master write.</bus_sel></bus_sel>
28	int_ powerdetect	R/W	When the status of VBUSPOWER input of UDC2AB changed, it is set to "1". 0:No changed 1:Status changed
27-26	-	R	Read as undefined.
25	int_dmac_ reg_rd	R/W	Will be set to 1 when the register access executed by the setting of UDFSDMACRDREQ is completed and the value read to UDFSDMACCRDVL is set. 0: Not detected. 1:Register read completed.
24	int_udc2_reg_ rd	R/W	<ul> <li>Will be set to 1 when the UDC2 access executed by the setting of UDFSDMACRDREQ is completed and the value read to UDFSDMACRDLV is set.</li> <li>Also set to 1 when Write access to the internal register of UDC2 is completed.</li> <li>0: Not detected.</li> <li>1: Register read/write completed.</li> </ul>
23	int_mr_ahberr	R/W	This status will be set to 1 when the AHB error has occurred during the operation of Master Read transfer. After this interrupt has occurred, the Master Read transfer block needs to be reset by the UDFSMST- SET <mr_reset>. 0: Not detected. 1: AHB error occurred.</mr_reset>
22	int_mr_ep_dset	R/W	<ul><li>Will be set to 1 when the FIFO of EP for UDC2 Tx to be used for Master Read transfer becomes writable (not full).</li><li>0: FIFO is not writable</li><li>1: FIFO is writable</li></ul>
21	int_mr_end_ add	R/W	<ul><li>Will be set to 1 when the Master Read transfer has finished.</li><li>0: Not detected</li><li>1: Master Read transfer finished</li></ul>
20	int_mw_ahberr	R/W	This status will be set to 1 when the AHB error has occurred during the operation of Master Write transfer. After this interrupt has occurred, the Master Write transfer block needs to be reset by UDFSMSTSET <mw_re- set&gt;. 0: Not detected. 1: AHB error occurred.</mw_re- 

Bit	Bit Symbol	Туре	Function
19	int_mw_ timeout	R/W	This status will be set to 1 when time-out has occurred during the operation of Master Write transfer. 0: Not detected. 1: Master Write transfer timed out.
18	int_mw_end_ add	R/W	<ul><li>Will be set to 1 when the Master Write transfer has finished.</li><li>0: Not detected.</li><li>1: Master Write transfer timed out.</li></ul>
17	int_mw_set_ add	R/W	<ul><li>Will be set to 1 when the data to be sent by Master Write transfer is set to the corresponding EP of Rx while the Master Write transfer is disabled.</li><li>0: Not detected.</li><li>1: Master Write Transfer address request.</li></ul>
16-11	-	R	Read as undefined.
10	int_usb_reset_ end	R/W	Indicates whether UDC2 has deasserted the usb_reset signal. The timing in which UDC2 sets the UDC2 register to the initial value after USB_RESET is after the usb_reset signal is deasserted. To detect this timing, use this bit. The status of the usb_reset signal can be checked using UDFSPWCTL <usb_reset>. 0: UDC2 has not deasserted the usb_reset signal after this bit was cleared. 1: Indicates UDC2 has deasserted the usb_reset signal.</usb_reset>
9	int_usb_reset	R/W	Indicates whether UDC2 has asserted the usb_reset signal. The status of the usb_reset signal can be checked using UDFSPWCTL <usb_reset>. 0: UDC2 has not asserted the usb_reset signal after this bit was cleared. 1:Indicates UDC2 has asserted the usb_reset signal.</usb_reset>
8	int_suspend_ resume	R/W	Asserts 1 each time the suspend_x signal of UDC2 changes. The status can be checked using the UDFSPWCTL <suspend_x>. 0:Status has not changed. 1: Status has changed.</suspend_x>
7	int_nak	R	The int_nak signal of UDC2 can be directly read. To clear it, clear the corresponding bit of UDFS2INT or UDFS2INTNAK of UDC2.
6	int_ep	R	The int_ep signal of UDC2 can be directly read. To clear it, clear the corresponding bit of UDFS2INT or UDFS2INTEP.
5	int_ep0	R	The int_ep0 signal of UDC2 can be directly read. To clear it, clear the corresponding bit of UDFS2INT.
4	int_sof	R	The int_ep0 signal of UDC2 can be directly read. To clear it, clear the corresponding bit of UDFS2INT.
3	int_rx_zero	R	The int_rx_zero signal of UDC2 can be directly read. To clear it, clear the corresponding bit of UDFS2INT or UDFS2INTRX0.
2	int_status	R	The int_status signal of UDC2 can be directly read. To clear it, clear the corresponding bit of UDFS2INT.
1	int_status_nak	R	The int_status_nak signal of UDC2 can be directly read. To clear it, clear the corresponding bit of UDFS2INT.
0	int_setup	R	The int_setup signal of UDC2 can be directly read. To clear it, clear the corresponding bit of UDFS2INT.

UDC2		UDC2AB

## 13.4.1.4 UDFSMWTOUT(Master Write Timeout Register)

Bit	Bit Symbol	Туре	Function
31-1	timeoutset	R/W	The setting should not be changed during the Master Write transfer. Timeout occurs when the number of times CLK_U was set is counted after the data of Master Write (Rx) EP is exhausted.
			The timeout counter comprises 32 bits of which upper 31 bits can be set by timeoutset [31:1] of this register, while the lowest bit of the counter is set to 1.
			As CLK_U is 48 MHz, approximately 20 [ns] to 89 [s] can be set as a timeout value.
			While CLK_U stopped (PHY is being suspended and so on), no timeout interrupt will occur as the counter does not work.
0	timeout_en	R/W	Used to enable Master Write timeout. It is set to Enable by default.
			The setting should not be changed during the Master Write transfer.
			0: Disable
			1: Enable

## 13.4.1.5 UDFSC2STSET(UDC2 Setting Register)

Bit	Bit Symbol	Туре	Function
31-5	-	R	Read as undefined.
4	eopb_enable	R/W	Used to enable Master Read EOP. It is set to Enable by default. The setting should not be changed dur- ing the Master Read transfer.
			If this bit is 0, the final data transfer to UDC2 will not take place when the last word is 1 byte. If the last word is 2 bytes, the final data transfer to UDC2 will take place when epx_w_eop = 0.
			If this bit is 1, the final data transfer to UDC2 will take place when epx_w_eop = 1 regardless of byte number of the last word.
			Note: See the section"13.5.4.1 Master Read transfer" for more information.
			0: Master Read EOP Disabled.
			1: Master Read EOP Enabled.
3-1	-	R	Read as undefined.
0	tx0	R/W	Used to transmit NULL packets at an EP connected to the Master Read operation side. Only valid when the UDFSMSTSTS <mrepempty> is 1, otherwise this bit is ignored. It will be automatically cleared to 0 after writing.</mrepempty>
			Setting 1 to this bit will assert the epx_tx0data signal of the UDC2 EP-I/F and the value of 1 is retained dur- ing the transmission of NULL packets. After this bit is set, next data setting for Tx-EP should not be made un- til it is cleared.
			0: No operation
			1: Transmits NULL packets.

	31	30	29	28	27	26	25	24

## 13.4.1.6 UDFSMSTSET(DMAC Setting Register)

Bit	Bit Symbol	Туре	Function
31-9	-	R	Read as undefined.
8	m_burst_type	R/W	Selects the type of HBURST[2:0] when making a burst transfer in Master Write/Read transfers. The type of burst transfer made by UDC2AB is INCR8 (burst of 8 beat increment type). Accordingly, 0 (initial value) should be set in normal situation. However, in case INCR can only be used as the type of burst transfer based on the AHB specification of the system, set 1 to this bit. In that case, UDC2AB will make INCR transfer of 8 beat. Please note the number of beat in burst transfers cannot be changed. Setting of this bit should be made in the initial setting of UDC2AB. The setting should not be changed after
			the Master Write/Read transfers started. Note: UDC2AB does not make burst transfers only in Master Write/Read transfers. It combines burst trans- fers and single transfers. This bit affects the execution of burst transfers only.
			0: INCR8 1: INCR
7	-	R	Read as undefined.
6	mr_reset	R/W	Initializes the Master Read transfer block of UDC2AB. However, as the FIFOs of EPs are not initialized, you need to access the UDFS2CMD of UDC2 to initialize the corresponding EP separately from this reset. This reset should be used after stopping the Master operation. This bit will be automatically cleared to 0 after being set to 1. Subsequent Master Read transfers should not be made until it is cleared.
			0: No operation
			1: Reset
5	mr_abort	W	Controls Master Read transfers. Master Read operations can be stopped by setting 1 to this bit.
			When aborted during transfers, transfer of buffers for Master Read to UDC2 is interrupted and the <mr_ena- ble&gt; bit is cleared, stopping the Master Read transfer.</mr_ena- 
			Aborting completes when the <mr_enable> bit is disabled to 0 after setting this bit to 1.</mr_enable>
			0: No operation 1: Abort
4	mr_enable	R/W	Controls Master Read transfers. Enabling should be made when setting the transfer address is completed. It will be automatically disabled as the master transfer finishes. Since Master Read operations cannot be dis- abled with this register, use the <mr_abort> bit if the Master Read transfer should be stopped.</mr_abort>
			0: Disable
			1: Enable
3	-	R	Read as undefined.
2	mw_reset	R/W	Initializes the Master Write transfer block. However, as the FIFOs of EPs are not initialized, you need to ac- cess the UDFS2CMD of UDC2 to initialize the corresponding EP separately from this reset.
			This reset should be used after stopping the Master operation.
			This bit will be automatically cleared to 0 after being set to 1. Subsequent Master Write transfers should not be made until it is cleared.
			0: No operation
			1: Reset
1	mw_abort	w	Controls Master Write transfers. Master Write operations can be stopped by setting 1 to this bit. When aborted during transfers, transfer of buffers for Master Write from UDC2 is interrupted and the <mw_en- able&gt; bit is cleared, stopping the Master Write transfer. Aborting completes when the <mw_enable> bit is dis- abled to 0 after setting this bit to 1.</mw_enable></mw_en- 
			0:No operation
			1: Abort
0	mw_enable	R/W	Controls Master Write transfers. Enabling should be made when setting the transfer address is completed. It will be automatically disabled as the master transfer finishes. Since Master Write operations cannot be disabled with this register, use the <mw_abort> bit if the Master Write transfer should be stopped.</mw_abort>
			0: Disable
			1: Enable

	31	30	29	28	27	26	25	24

## 13.4.1.7 UDFSDMACRDREQ(DMAC Read Request Register)

Bit	Bit Symbol	Туре	Function
31	dmardreq	R/W	The bit for requesting read access to the DMAC registers. Setting this bit to 1 will make a read access to the address specified by <dmardadr>. When the read access is complete and the read value is stored in the UDFSDMACRDVL, this bit will be automatically cleared and the UDFSINTSTS<dmac_reg_rd> will be set to 1.</dmac_reg_rd></dmardadr>
			0: No operation
			1: Issue a read request
30	dmardclr	R/W	The bit for forcibly clearing the register read access request associated with DMAC. Setting this bit to 1 will forcibly stop the register read access request by <dmardreq> and the value of <dmardreq> will be cleared to 0. After the forced clearing completes, this bit will be automatically cleared.</dmardreq></dmardreq>
			0: No operation
			1: Issue forced clearing
29-8	-	R	Read as undefined.
7-2	dmardadr[5:0]	R/W	Sets the address of the register (upper 6 bits) to be read. It should be set in combination with the <dmar- dreq&gt; mentioned above.</dmar- 
			Any one of the following addresses should be set:
			0x48: Read the UDFSMWCADR.
			0x58: Read the UDFSMRCADR.
			0x88: read the UDFSTOUTCNT.
1-0	-	R	Read as undefined.

# 13.4.1.9 UDFSUDC2RDREQ(UDC2 Read Request Register)

Bit	Bit Symbol	Туре	Function
31	udc2rdreq	R/W	The bit for requesting read access to the UDC2 registers. Setting this bit to 1 will make a read access to the address set in the udc2rdadr bit. When the read access is complete and the read value is set to UDFSD-MACRDVL, this bit will be automatically cleared and the UDINTSTS <int_udc2_reg_rd> bit of Interrupt Status register will be set to 1.</int_udc2_reg_rd>
			During a write access to UDC2 registers, it works as a status bit which indicates the access being made to display the value of 1. Subsequent accesses to UDC2 registers should not be made while this bit is set to 1.
			0: No operation
			1: Issue a read request
30	udc2rdclr	R/W	The bit for forcibly clearing the read/write access request of UDC2 registers. Setting this bit to 1 will forci- bly stop the register read request/UDC2 write access by udc2rdreq and the value of udc2rdreq will be 0. Af- ter the forced clearing completes, this bit will be automatically cleared to 0. When interrupted, the read and write values during the access will not be secured.
			0 : No operation
			1 : Issue forced clearing
29-10	-	R	Read as undefined.
9-2	udc2rdadr[7:0]	R/W	Set the address of the UDC2 register [9:2] to be read. Refer to "13.4.1.1 UDC2AB Register list" for informa- tion about the register address of the UDC2. The offset addresses in the above register table (0x0200 to 0x0334) are releant. Set it with the above udc2rdreq.
1-0	-	R	Read as undefined.

# 13.4.1.11 UDFSARBTSET(Arbiter Setting Register)

Bit	Bit Symbol	Туре	Function
-			
31	abt_en	R/W	Enables the arbiter operation when making an access between DMAC and AHB.
			0 should be set to this bit when setting the <abtmod>, <abtpri_w1>, <abtpri_w0>, <abtpri_r1> and <abt- pri_r0&gt; of this register.</abt- </abtpri_r1></abtpri_w0></abtpri_w1></abtmod>
			Be sure to set this bit to 1 before starting a DMA access.
			0: Disable (DMA access not allowed)
			1: Enable
30-29	-	R	Read as undefined.
28	abdmod	R/W	Sets the mode of arbiter. Write access is only available when the <abt_en> bit is set to 0.</abt_en>
			If 0 is set to this bit, access rights to the AHB bus will be given in a round-robin fashion regardless of the values set to each <abtpri_w1>, <abtpri_w0>, <abtpri_r1> and <abtpri_r0> bit.</abtpri_r0></abtpri_r1></abtpri_w0></abtpri_w1>
			If 1 is set to this bit, access rights to the AHB bus will be given in accordance with the access priority based on the values set to each <abtpri _="" w1="">, <abtpri _="" w0="">, <abtpri _="" r1=""> and <abtpri _="" r0=""> bit.</abtpri></abtpri></abtpri></abtpri>
			0: Round-robin
			1: Fixed-priority
27-14	-	R	Read as undefined.
13-12	abtpri_w1	R/W	Set the priority of DMA accesses for Master Write 1 when the fixed priority mode is selected. Write access is only available when the <abt_en> bit is set to 0.</abt_en>
			Priority ranges from 00 (highest) to 11 (lowest).
11-10	-	R	Read as undefined.
9-8	abtpri_w0	R/W	Set the priority of DMA accesses for Master Write 0 when the fixed priority mode is selected. Write access is only available when the <abt_en> bit is set to 0.</abt_en>
			Priority ranges from 00 (highest) to 11 (lowest).
7-6	-	R	Read as undefined.
5-4	abtpri_r1	R	Set the priority of DMA accesses for Master Read 1 when the fixed priority mode is selected. Write access is only available when the <abt_en> bit is set to 0.</abt_en>
			Priority ranges from 00 (highest) to 11 (lowest).
3-2	-	R	Read as undefined.
1-0	abtpri_r0	R/W	Set the priority of DMA accesses for Master Read 0 when the fixed priority mode is selected. Write access is only available when the <abt_en> bit is set to 0.</abt_en>
			Priority ranges from 00 (highest) to 11 (lowest).

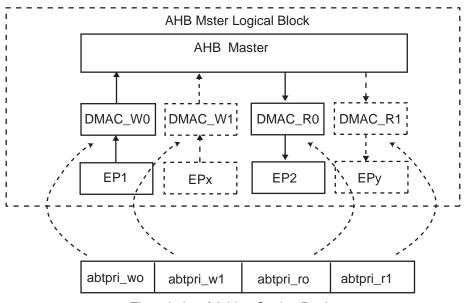

Note:Be sure to set different priority values for the <abtpri\_w1>, <abtpri\_w0>, <abtpri\_r1>, and <abtpri\_r0> bits. If the same priority values are set, you will not be able to set 1 to <abt\_en>.

(1) Relationship of DMAC and the priority area of the Arbiter setting register

Current UDC2AB specification supports one DMAC for Master Write (DMAC\_W0) and one DMAC for Master Read (DMAC\_R0). The second DMAC for Master Write (DMAC\_W1) and the second DMAC for Master Read (DMAC\_R1) are not supported.

Accordingly, setting priority for DMAC\_W1 and DMAC\_R1 has virtually no meaning, but you should be sure to set different priority values for the abtpri\_w1, abtpri\_w0, abtpri\_r1, and abtpri\_r0 bits as mentioned above.

There will be no problem to set values for the corresponding register areas of an unpackaged DMAC. The priority areas of Arbiter Setting register correspond with DMAC as shown below.

The priority of Arbiter Setting Register

## 13.4.1.20 UDFSPWCTL(Power Detect Control Register)

Bit	Bit Symbol	Туре	Function
31-8	-	R	Read as 0.
7	wakeup_en	R/W	Set this bit to '1' if you want to shift the TMPM365FYXBG to low-power consumption mode to stop CLK_H when the USB is suspended.
			If this bit is set to '1', the WAKEUP signal will be asserted to 0 asynchronously when the suspended status ( <suspend_x>=1) is cancelled. This allows TMPM365FYXBG to resuming from the low-power consumption mode using INTUSBWKUP.</suspend_x>
			Refer to "13.5.7 Suspend / Resume" for more information about how to use this bit.
			0: Do not assert the WAKEUP signal.
			1:Assert the WAKEUP signal.
6	phy_remo- to_wkup	R/W	This bit is used to perform the remote wakeup function of USB. Setting this bit to 1 makes it possible to assert the udc2_wakeup output signal (wakeup input pin of UDC2) to 1. However, since setting this bit to 1 while no suspension is detected by UDC2 (when suspend_x = 1) will be ignored (not to be set to 1), be sure to set it only when suspension is detected. It will be automatically cleared to 0 when resuming the USB is completed (when suspend_x is deasserted). See also "1.3.24.8 Suspend / Resume" for more information on using this bit.
			Refer to "13.5.7 Suspend / Resume" for more information about how to use this bit.
			0: No operation
			1: Wakeup
5	phy_resetb	R/W	Setting this bit to 0 will make the PHYRESET output signal asserted to 1. The PHYRESET signal can be used to reset PHY. Since this bit will not be automatically released, be sure to clear it to 1 after the specified reset time of PHY.
			0: Reset asserted
			1: Reset deasserted
4	suspend_x	R	Detects the suspend signal (a value of the suspend_x signal from UDC2 synchronized).
			0: Suspended ( <suspend_x> = 0)</suspend_x>
			1: Unsuspended ( <suspend_x> = 1)</suspend_x>
3	phy_suspend	R/W	Setting this bit to 1 will make the PHYSUSPEND output signal asserted to 0 (CLK_H synchronization). It can be used as a pin for suspending PHY.
			Setting this bit to 1 makes the UDC2 register and UDFSDMACRDREQ not accessible.
			It will be automatically cleared to 0 when resumed (when suspend_x of UDC2 is deasserted).
			Refer to "13.5.7 Suspend / Resume" for more information about how to use this bit.
			0: Not suspended.
			1: Suspended
2	pw_detect	R	Indicates the status of the VBUSPOWER input of the UDC2AB.
			0: USB bus disconnected (VBUSPOWER = 0)
			1: USB bus connected (VBUSPOWER = 1)
1	pw_resetb	R/W	Software reset for UDC2AB(See "13.5.1 Reset" for details). Setting this bit to 0 will make the PW_RE- SETB output pin asserted to 0.
			Resetting should be made while the master operation is stopped.
			Since this bit will not be automatically released, be sure to clear it.
			0: Reset asserted.
			1: Rest deasserted.
0	usb_reset	R	The value of the usb_reset signal from the UDC2 synchronized.
			0: usb_reset = 0
			1: usb_reset = 1

# 13.4.1.21 UDFSMSTSTS(Master Status Register)

Bit	Bit Symbol	Туре	Function
31-5	-	R	Reset as undefined.
4	mrepempty	R	This is a register that indicates the EP for UDC2Rx is empty. Ensure that this bit is set to 1 when sending a NULL packet using the UDFSC2STSET <tx0>. (This bit is the eptx_empty input signal with CLK_H synchronization.)</tx0>
			0: Indicates the EP contains some data.
			1: Indicates the EP is empty.
3	mrbfemp	R	Indicates whether or not the buffer for the Master Read DMA in UDC2AB is empty.
			0: Indicates the buffer for the Master Read DMA contains some data.
			1: Indicates the buffer for the Master Read DMA is empty.
2	mwbfemp	R	Indicates whether or not the buffer for the Master Write DMA in UDC2AB is empty.
			0: Indicates the buffer for the Master Write DMA contains some data.
			1: Indicates the buffer for the Master Write DMA is empty.
1	mrepdset	R	This bit will be set to 1 when the data to be transmitted is set to the Tx-EP of UDC2 by Master Read DMA transfer, making no room to write in the EP. It will turn to 0 when the data is transferred from UDC2 by the IN-Token from the host. While this bit is set to 0, DMA transfers to the EP can be made. (This bit is the eptx_dataset input signal with CLK_H synchronization.)
			0: Data can be transferred into the EP.
			1: There is no space to transfer data in the EP.
0	mwepdset	R	This bit will be set to 1 when the data received is set to the Rx-EP of UDC2. It will turn to 0 when the en- tire data was read by the DMA for Master Write. (This bit is the eprx_dataset input signal with CLK_H synchro- nization.)
			0: No data exists in the EP.
			1: There is some data to be read in the EP.

## 13.4.1.22 UDFSTOUTCNT(Timeout Count Register)

Bit	Bit Symbol	Туре	Function
31-0	tmoutcnt[31:0]	R	This is used for debugging. Values of the timer can be read when the UDFSMWTOUT <timeout_en> is enabled. It will be decremented each time CLK_U is counted after the EP for Master Write (Rx-EP) becomes empty. This register cannot be read by directly specifying the address. In order to read it, set a value to the UDFSD-MACRDREQ and then read the value from UDFSDMACRDVL.</timeout_en>

Note: Those shown as "Reserved" above and the area from 0x0400 to 0x0FFF are prohibited to access. Read / Write is prohibited to these areas.

13.4.2.2 How to access the UDC2 register

The bits 15-0 of the AHB data bus of UDC2AB are connected to the UDC data bus.

The bit31-16 are read-only (read value: undefined).

Make a WORD (32-bit) access for both write and read. (However, a BYTE (8-bit) access may be made for Write accesses to the EPx FIFO register. Details will be described later).

It will take some time to complete an access for both write and read.

Be sure to begin subsequent accesses after the previous UDC2 register access is completed, using the int\_udc2\_reg\_rd interrupt. (You can also use the UDFSUDC2RDREQ<udc2rdreq> to confirm the access status when reading.)

• Write access

When making a write access to the UDC2 register, write it directly in the relevant address.

Read access

When making a read access to the UDC2 register, use UDFSUDC2RDREQ and DFSUDC2RDVL.

First, you set the address to access to the UDFSUDC2RDREQ and then read the data from the UDFSUCS2RDVL for reading. You cannot read the data directly from the address shown in the "13.4.2.1 UDC2 Registers".

EPx\_FIFO register

When making a write access to the EPx\_FIFO register, a lower 1-byte access may be required in UDC2 PVCI I/F. In such a case, make a BYTE access to the lower 1 byte for UDC2AB.

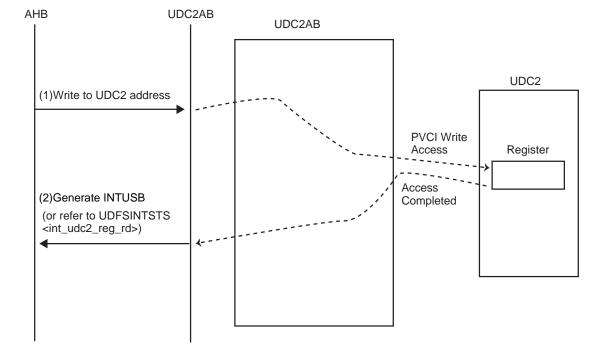

If a lower 1-byte access is required when making a read access, make an access via UDF-SUDC2RDREQ as usual and read the data from UDFSUDC2RDVL. In that case, the access to UDFSAUDC2RDVL can be either by WORD or BYTE.

• Reserved Register in UDC2

Do not make any access to registers of EPs not supported by UDC2 to be connected and to "Reserved" registers. (In case those registers are accessed, the access from UDC2AB to UDC2 itself will take place. It will be a Dummy write to UDC2 in case of write accesses. In case of read accesses, the read data from UDC2 (udc2\_rdata) will be an indefinite value and the indefinite value will be set to the UDFSUDC2RDVL.)

Accesses when UDC2 is suspended

When UDC2 is in the suspended status, register accesses to UDC2 become unavailable if the clock (= CLK\_U) supply from clock/mode control circuit is stopped. Make no register accesses to UDC2 in such cases. If the UDC2 register is accessed when the UDFSPWCTL<phy\_suspend> is set to 1, an AHB error will be returned.

Access flow diagram for UDC2 register is shown below.

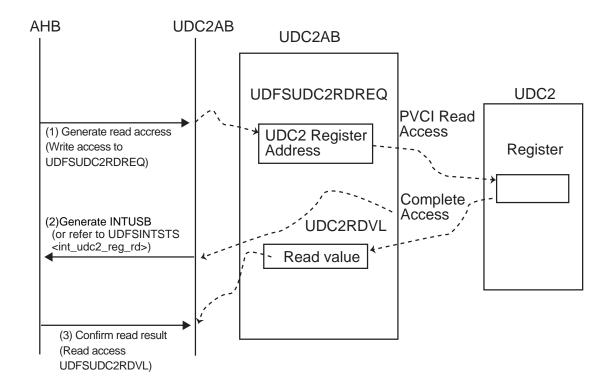

Figure 13-10 Read Access Flow Diagram of the UDC2 Register

## 13.4.2.3 UDFS2ADR(Address-State register)

Bit	Bit Symbol	Туре	Function			
31-16	-	R	Read as undefined.			
15	stage_err	R/W	Indicates whether Control transfers finished normally up to the STATUS-Stage. 1 will be set when the Setup- Token is received in DATA-Stage/STATUS-Stage or in the case of "STALL" transmission. When set, it will be cleared when the next Control transfer has been finished normally. 0: Other than above conditions.			
			1: Received the Setup-Token in DATA-Stage/STATUS-Stage or "STALL" transmission.			
14	ep_bi_mode	R/W	Selects whether to use the EP bidirectionally as a driver. Setting this bit to 1 will enable an EP number to be used bidirectionally in USB communication.			
			0: Single direction			
			1: Dual direction			
13-12	cur_speed[1:0]	R	Indicates the present transfer mode on the USB bus.			
			00: Reserved			
			01: Full-Speed			
			10: Reserved			
			11: Reserved			
11	suspend	R	Indicates whether or not UDC2 is in suspended state.			
			0: Normal			
			1: Suspend			
10	configured	R/W	Set the present device state of UDC2. This should be set in accordance with the request received from the host. Please note that you should not set 1 to more than one bit.			
9	addressed	R/W	001: default (to be set when the DeviceAddress = 0 was specified by the Set_address request in Default / Address state (this will be set by the hardware when USB_RESET is received))			
8	default	R/W	010: addressed (to be set when ConfigurationValue = 0 was specified by the Set_configuration request af- ter the Set_address request finished normally and in the Address/Configured state).			
			100: configured (to be set when the Set_configuration request is received).			
7	-	R	Read as undefined.			
6-0	dev_adr[6:0]	R/W	Sets the device address assigned by the host. The device address should be set after Set_address has fin- ished normally (after STATUS-Stage finished normally).

## 13.4.2.4 UDFS2FRM(Frame register)

Bit	Bit Symbol	Туре	Function			
31-16	-	R	Read as undefined.			
15	create_sof	R/W	Sets whether to generate the SOF flag internally when the SOF from the host is unavailable due to a bus er- ror. This should be set if you wish to synchronize frames by SOF in Isochronous transfers. If enabled, the in- ternal frame time counter will operate and the SOF flag will be output even when the SOF-Token could not be received successfully. 0: Generates no flag 1: Generates a flag			
14	-	R	read as undefined.			
13-12	f_status[1:0]	R	Indicates the status of the frame number.			
			00: Before: Will be set if the Micro SOF/SOF was not received when 1frame-time (Full-Speed:1 ms) has passed after receiving the Micro SOF/SOF when <create_sof> is enabled. In the Frame register, the frame number received in the last Micro SOF/SOF has been set.</create_sof>			
			01: Valid: Will be set when the Micro SOF/SOF was received. Indicates a valid frame number is set in the Frame register.			
			<ol> <li>Lost: Indicates that the frame number maintained by the host is not synchronized with the value of UDFS2FRM. Accordingly, this will be set in the following cases:</li> </ol>			
			1. When the system was reset or suspended.			
			<ol><li>If the next Micro SOF/SOF was not received when 2 frame-time (Full-Speed: 1 x 2 ms) has passed after receiving the previous Micro SOF/SOF when <create_sof> is enabled.</create_sof></li></ol>			
			Also note that transition to the Lost status only happens after the system was reset or when it is suspen- ded if <create_sof> is disabled.</create_sof>			
11	-	R	Read as undefined.			
10-0	frame[10:0]	R	Indicates the frame number when SOF is received.			
			This will be valid when <f_status> is "Valid".</f_status>			
			Should not be used if <f_status> is "Before" or "Lost" as correct values are not set.</f_status>			

# 13.4.2.5 UDFS2CMD(Command register)

	31	30	29	28	27	26	25	24
bit symbol	-	-	-	-	-	-	-	-

8	m_setup	R/W	Sets whether or not to output <i_setup> to INT_SETUP pin.</i_setup>
			0: output
			1: no output
7	i_nak	R/W	This will be set to 1 when NAK is transmitted by EPs except EP0.
			(EPs to which you wish to output the INT_NAK flag can be selected using UDFS2INTNAKMASK). Writing 1 to this bit will make each bit of UDFS2INTNAK cleared to 0.
6	i_ep	R/W	This will be set to 1 when transfers to EPs other than EP0 have successfully finished
			(EPs to which you wish to output the flag can be selected using UDFS2INTNAKMASK). Writing 1 to this bit will make each bit of UDFS2INTEP cleared to 0.
5	i_ep0	R/W	This will be set to 1 when the transfer to EP0 has successfully finished.
4	i_sof	R/W	This will be set to 1 when the SOF-token is received or after 1 frame-time was counted in the create_sof mode.
3	i_rx_data0	R/W	This will be set to 1 when Zero-Length data is received. (EPs to which you wish to output the flag can be se- lected using UDFS2INTNAKMASK). Writing 1 to this bit will make each bit of UDFSINTTRX0 cleared to 0. This will not be set to 1 when Zero-Length data is received in the STATUS-Stage of Control-RD transfers.

Bit	Bit Symbol	Туре	Function
2	i_status	R/W	This will be set to 1 when the STATUS-Stage has successfully finished in Control transfers at EP0. (This will be set to 1 when Zero-Length data is received in the STATUS-Stage and successfully finished in Control-RD transfers, and when Zero-Length data is transmitted in the STATUS-Stage and successfully finished in Control-WR transfers.)
1	i_status_nak	R/W	This will be set to 1 when the packet of STATUS-Stage is received in the Control-RD transfers at EP0. When this bit was set which means the DATA-Stage has finished, set the "Setup-Fin" command by the UDFS2CMD to make the stage of UDC2 proceed to the STATUS-Stage. When receiving the data having the size of an integral multiple of MaxPacketSize (64 bytes) in the DATA-Stage of Control-WR transfers, Zero-Length data may be received to indicate the end of the DATA-Stage. After that, as the end of the DATA- Stage can be recognized by this i_status_nak when receiving the In-token in the STATUS-Stage, make UDC2 proceed to the STATUS-Stage.
0	i_setup	R/W	This will be set to 1 when the Setup-Token was received in Control transfers at EP0.

#### 13.4.2.12 UDFS2INTEPMSK(INT\_EP\_MASK register)

Bit	Bit Symbol	Туре	Function
31-16	-	R	Read as undefined.
15-8	Reserved	R/W	Write as "0".
7-0	m_ep7 to m_ep0	R/W	Mask control of flag output. 0 : output 1: no output Sets whether or not to output flags of UDFS2INTEP and UDFS2INTRX0 to the int_ep pin and the int_rx_zero pin respectively. When an EP is masked, each bit of UDFS2INTEP will be set when the trans- fer of the relevant EP has successfully finished, but the int_ep pin will not be asserted. Similarly, when an EP is masked, each bit of UDFS2INTRX0 will be set when Zero-Length data is received at the relevant EP, but the int_rx_zero pin will not be asserted. However, bit 0 is only valid for UDFS2INTRX0.

#### (1) How to use UDFS2INT / UDFS2INTEP / UDFS2INTEPMSK

An example of using UDFS2INT / UDFS2INTEP / UDFS2INTEPMSK is provided for EP1 to 3.

1. When using EP 1 and EP 2 with DMA (EP I/F) and using only EP3 via PVCI-I/F

	<i_ep></i_ep>	Used as the interrupt source of EP3. This bit is also used when clearing.
UDFS2INT	<m_ep></m_ep>	Used as the mask of the interrupt source of EP3.
	<i_ep1></i_ep1>	Don't care
UDFS2INTEP	<i_ep2></i_ep2>	Don't care
	<i_ep3></i_ep3>	Don't care
	<m_ep1></m_ep1>	Set 1 to mask the bit.
UDFS2IN- TEPMSK	<m_ep2></m_ep2>	Set 1 to mask the bit.
	<m_ep3></m_ep3>	Write 0.

2. When using EP2 and EP3 via PVCI-I/F and using EP1 with DMA

After initialization, set 1 to UDFS2INTEPMSK of the EP to be used with DMA to mask it. When making interrupt responses for more than one EPs, be sure to use UDFS2INTEP. Ignore UDFS2INT<i\_ep> and always enable  $<m_ep>$  as 0.

Do not clear the source using UDFS2INT $<i_ep>$ . After the interrupt has occurred, you need to check UDFS2INT and UDFS2INTEP to determine the source. When clearing the source, use each source bit of UDFS2INT interrupt to clear it.

	<i_ep></i_ep>	Write as 0.
UDFS2INT	<m_ep></m_ep>	Write as 0.
	<i_ep1></i_ep1>	Don't care
UDFS2INTEP	<i_ep2></i_ep2>	Used as the interrupt source of EP2. This bit is also used when clearing.
	<i_ep3></i_ep3>	Used as the interrupt source of EP3. This bit is also used when clearing.
	<m_ep1></m_ep1>	Set 1 to mask the bit.
UDFS2IN- TEPMSK	<m_ep2></m_ep2>	Used as the mask of the interrupt source of EP2. Write as "0".
	<m_ep3></m_ep3>	Used as the mask of the interrupt source of EP3. Write as "0".

## 13.4.2.20 UDFS2EPxMSZ(EPx\_MaxPacketSizeRegister)

Bit	Bit Symbol	Туре	Function
31-16	-	R	Read as undefined.
15	tx_0data	R	When the "EPx_TX_0DATA" command is issued to EPx by UDFS2CMD or Zero-Length data has been set at EP-I/F, this bit will be set to 1. It will be cleared to 0 after the Zero-Length data has been transmitted.
14-13	-	R	Read as undefined.
12	dset	R	Indicates the status of EPx_FIFO. 0: No valid data exists 1: Valid data exists
11	-	R	Read as undefined.
10-0	max_pkt[10:0]	R/W	Sets MaxPacketSize of EPx. Set this when configuring the EP when Set_Configuration and Set_Interface are received. Set an even number for a transmit EP. On USB, when MaxPacketSize of a transmit EP is an odd number, set an even number to max_pkt and make the odd number of accesses to the EP. (For instance, set 1024 to max_pkt when the MaxPacketSize should be 1023 bytes.) Note: For details, refer to "13.9.2 Appendix B About Setting an Odd Number of Bytes as MaxPacketSize".

- Note 1: The initial value of <dset> after reset is 1 when the EPx is a transmit EP, while it is 0 when the EPx is a receive EP.
- Note 2: The initial value of <dset > after USB\_RESET is 1 when the EPx is a transmit EP, while it is "Retain" when the EPx is a receive EP.

Note 3: x=1 to 7

## 13.4.2.21 UDFS2EPxSTS(EPx\_Status register)

Bit	Bit Symbol	Туре	Function
31-16	-	R	Read as undefined.
15	pkt_mode	R/W	Selects the packet mode of EPx. Selecting the Dual mode makes it possible to retain two pieces of packet data for the EPx. 0: Single mode
			1: Dual mode
14	bus_sel	R/W	Select the bus to access to the FIFO of EPx.
			0: Common bus access
			1: Direct access
13-12	toggle[1:0]	R	Indicates the present toggle value of EPx.
			00: DATA0
			01: DATA1
			10: DATA2
			11: MDATA
11-9	status[2:0]	R	Indicates the present status of EPx. By issuing EP_Reset from UDFSCMD, the status will be "Ready."
			000: Ready (Indicates the status is normal)
			001: Reserved
			010: Error (To be set in case a receive error occurred in the data packet, or when timeout has occurred after transmission. However, it will not be set when "Stall" or "Invalid" has been set.)
			011: Stall (To be set when "EP-Stall" was issued by UDFS2CMD.)
			100 to 110: Reserved
			111: Invalid (Indicates this EP is invalid)
8	disable	R	Indicates whether transfers are allowed for EPx. If "Not Allowed," "NAK" will be always returned for the To- ken sent to this EP.
			0: Allowed
			1: Not Allowed
7	dir	R/W	Sets the direction of transfers for this EP.
			0: OUT (Host-to-device)
			1: IN (Device-to-host)
6-4	-	R	Read as undefined.
3-2	t_type[1:0]	R/W	Sets the transfer mode for this EP.
			00: Control
			01: Isochronous
			10: Bulk
			11: Interrupt
1-0	num_mf[1:0]	R/W	When the Isochronous transfer is selected, set how many times the transfer should be made in the frames.
			00: 1-transaction
			01: 2-transaction
			10: 3-transaction
			11: Reserved

- Note 1: Setting for this register should be made when configuring the EP when Set\_Configuration and Set\_Interface are received.
- Note 2: x=1 to 7
- Note 3: Each EP depend on the product specification. For EP1, EP3, EP5, EP7 which is fixed for IN transfers, <dir> can be set to "1" only. For EP2, EP4, EP6 which is fixed for OUT transfers, dir can be set to "0" only.

## 13.4.2.23 UDFS2EPxFIFO(EPx\_FIFO register)

Bit	Bit Symbol	Туре	Function
31-16	-	R	0.
15-0	data[15:0]	R/W	Used for accessing data from PVCI-I/F to EPx.

Note:x=1 to 7

## 13.5 Description of UDC2AB operation

## 13.5.1 Reset

UDC2AB supports software reset by the UDFSPWCTL<pw\_resetb>.

It also supports master channel reset (UDFSMSTSET<mr\_reset>/<mw\_reset>) for DMAC master transfers.

Software reset (UDFSPWCTL<pw\_resetb>)

Some bits of each register are initialized by hardware reset but not initialized by software reset with the values retained. As details are provided in the descriptions of each register, refer to "13.4.1.1 UDC2AB Register list".

When the USB bus power is detected, make software reset as initialization is needed.

Master channel reset (UDFSMSTSET<mr\_reset><mw\_reset>

While the <mw\_reset> bit is provided for the Master Write transfer block and the <mr\_reset> bit for the Master Read transfer block, only the relevant master blocks are initialized and the UDC2AB register will not be initialized. For more information on using each reset, see "13.4.1.6 UDFSMSTSET(DMAC Setting Register)".

## 13.5.2 Interrupt Signals

There are two interrupt output signals of UDC2AB, INTUSB and INTUSBWKUP.

## 13.5.2.1 INTUSB Interrupt Signal

Interrupt output signal of INTUSB consists of interrupts generated by UDC2 and that generated by other sources.

Once the interrupt condition is met, UDC2AB sets the corresponding bit of its UDFSINTSTS. When that bit is set, INTUSB will be asserted if the relevant bit of UDFSINTENB has been set to "Enable."

When the relevant bit of UDFSINTENB has been set to "Disable," 1 will be set to the corresponding bit of UDFSINTSTS while INTUSB will not be asserted.

When the relevant bit of UDFSINTENB is set to "Enable" with UDFSINTSTS set, INTUSB will be asserted immediately after the setting is made.

Initial values for UDFSINTENB are all 0 (Disable).

Interrupt output signal of INTUSB will not be generated while CLK\_H is stopped.

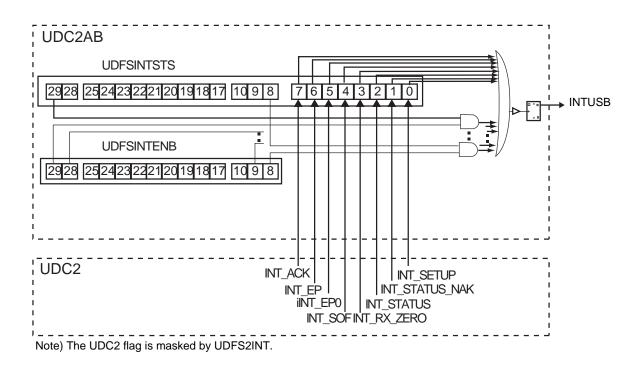

Figure 13-13 Relationship of INTUSB and registers

## 13.5.2.2 INTUSBWKUP Interrupt

INTUSBWKUP interrupt occurs at the falling edge of the WAKEUP output signal.

WAKEUP will be asserted when the following conditions match:UDFSPWCTL<wakeup\_en> is 1 and the suspended condition is cancelled (UDFSPWCTL<suspend\_x>=1). WAKEUP will be asserted when VBUS is disconnected (VBUSPOWER=0) as well.

INTUSBWKUP interrupt occurs regardless of the status of CLK\_H.

## 13.5.3 Operation Sequence

The operation sequence of UDC2AB is as follows:

- 1. Hardware reset
- 2. Set the interrupt signal

Configure the INTUSB interrupt, the INTUSBWKUP interrupt and the USBPON interrupt.

3. VBUS detection (connect) and reset

Refer to "13.5.5.2 Sequence of USB Bus Power (VBUS) Connection/Disconnection" and "13.5.1 Reset" for details.

4. USB enumeration response

Refer to "13.6 USB Device Response" for details.

- 5. Master Read / Master Write transfer
  - a. Master Read transfer

Make a Master Read transfer corresponding to the receiving request from the USB host. Refer to "13.5.4.1 Master Read transfer" for details.

b. Master Write transfer

Make a Master Write transfer corresponding to the sending request from the USB host. Refer to "13.5.4.2 Master Write transfer" for details.

6. VBUS detection (disconnect)

The USB bus power supply may be disconnected at any time.

Refer to "13.5.5.2 Sequence of USB Bus Power (VBUS) Connection/Disconnection" for details.

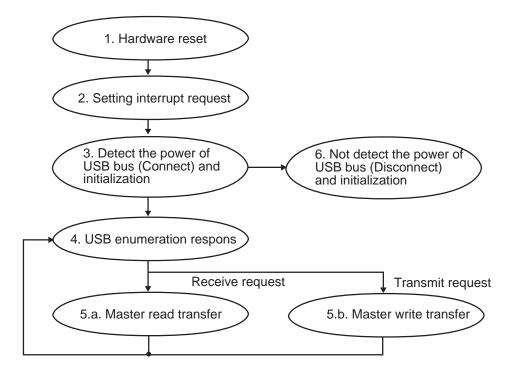

Figure 13-14 Operation Sequence

## 13.5.4 Master Transfer Operation

This section describes the master transfer operation of UDC2AB.

When you start a master transfer, be sure to set the transfer setting of the relevant EP of UDC2 (UDFS2EPxSTS<bus\_sel>) to the direct access mode. It is prohibited to start DMAC when it is set to "Common bus access."

### 13.5.4.1 Master Read transfer

#### (1) Master Read mode

There are two modes of the master read mode: EOP enable mode and EOP disable mode.

#### (a) EOP enable mode

Master Read transfers when UDC2STSET<eopb\_enable> is set to 1 (Master Read EOP enable) are described here. Master Read operations will be as follows:

- 1. Set UDFSMWSADR and UDFSMWEADR.
- 2. Set the bits associated to the master read operation of UDFSMSTSET and set 1 to <mr\_enable>.
- 3. UDC2AB starts the data transfer to the EP of UDC2. UDC2 transfers the data to the IN token from the USB host.
- 4. When the Master Read transfer reaches the Master Read end address, UDC2AB asserts the mr\_end\_add interrupt.
- 5. After the handling by the software ended, return to 1.
  - About Short packets

If the transfer size (Master Read End Address - Master Read Start Address Å $\{1\}$  is not the same size as the Max packet size, the last IN transfer will be the transfer of short packets.

Example: In case Master Read transfer size 139 bytes and the Max packet size 64 bytes.

Transfer will take pla	ce in:			
1st time	$\rightarrow$	2nd time		3rd time
64 bytes	$\rightarrow$	64 bytes	$\rightarrow$	11 bytes

About mr\_end\_add interrupt

The mr\_end\_add interrupt occurs when the data transfer to the UDC2 EP is finished. In order to confirm whether the entire data has been transferred from UDC2 to the USB host, check the UDFSMSTSTS<mrepempty>.

#### (b) EOP Disable mode

Master Read transfers when UDC2STSET<eopb\_enable > is set to 0 (Master Read EOP disable) are described here. Master Read operations will be as follows:

- 1. Set the register associated to the UDFSMWSADR and UDFSMWEADR.
- 2. Set the bits associated to the Master Read operation of UDFSMSTSET and set 1 to the <mr\_enable>.
- 3. UDC2AB starts the data transfer to the EP of UDC2. UDC2 transfers the data to the IN token from the USB host.
- 4. When the Master Read transfer reaches the Master Read end address, UDC2AB asserts the mr\_end\_add interrupt. If the FIFO of the EP has reached the MAX packet size during Master Read transfer, UDC2 transfers the data to the IN token from the USB host. However, if it has not reached yet, data will remain in the FIFO to the next transfer.
- 5. After the handling by the software ended, return to 1.
- Note: When UDC2AB is used in the EOP Disable mode, short packets will not be sent out even if the data string to be sent has been transferred. EOP Disable mode should be used only in case the size of the data string is a multiple of the maximum packet size.

The mode can be used if the total size of data string is a multiple of the maximum packet size. For example, the following transfer may be allowed:

Example:	
Size of the first Master Read transfer	:100 bytes
Size of the second Master Read transfer	:28 bytes (total of first and second transfer = 128bytes)
Max packet size	:64 bytes

A transfer of 64 bytes will be made twice for the IN transfer.

#### (2) Aborting of Master Read transfer

You can abort Master Read transfers with the following operation.

- 1. Use UDC2 Command register to set the status of the relevant EP to Disabled (EP\_Disable). (If aborted without making the EP disabled, unintended data may be sent to the USB host.)
- 2. In order to stop the Master Read transfer, set 1 (Abort) to UDFSMSTSET <mr\_abort>.
- 3. In order to confirm that the transfer is aborted, check that the UDFSMSTSET<mr\_enable> was disabled to 0. Subsequent operations should not be made while the mr enable bit is 1.

(Information on the address where the transfer ended when aborted can be confirmed with Master Read Current Address and Master Read AHB Address registers.)

- 4. In order to initialize the Master Read transfer block, set 1 (Reset) to UDFSMSTSET<mr\_reset>.
- 5. Use the Command register (EP\_FIFO\_Clear) to initialize the FIFO for the relevant EP.
- 6. Use the Command register (EP\_Enable) to enable the relevant EP.

(3) Setting the maximum packet size in Master Read transfers

If the maximum packet size of the EP to be connected with the Master Read function of UDC2AB will be an odd number, there will be following restrictions to which you should pay attention:

- Even if the maximum packet size of the EP should be handled as an odd number, the setting of the UDFS2EPxMSZ<max\_pkt> should be an even number.
- Note: Refer to the "13.9.2 Appendix B About Setting an Odd Number of Bytes as MaxPacketSize" for details.
  - Set the UDC2STSET<eopb enable> to 1 (Master Read EOP enable).
  - Make the transfer size to be specified for one Master Read transfer (Master Read End Address Master Read Start Address + 1) not exceed the maximum packet size of an odd number.

```
Example:
```

Set the maximum packet size of EP (value to pass to the USB host) to be 63bytes. Make the setting of the UDFS2EPxMSZ<max\_pkt> to be 64 bytes. Keep the transfer size to be specified for one Master Read transfer to 63 bytes or less.

#### 13.5.4.2 Master Write transfer

(1) Master Write Transfer Sequence

Master Write operations will be as follows:

- 1. Set UDFSMWSADR and UDFSMWEADR.
- 2. Set the bits associated to the UDFSMSTSET and set 1 to the <mw\_enable>.
- 3. UDC2AB makes a Master Write transfer to the data in the EP received from the USB host.
- 4. Since the mw\_end\_add interrupt will be asserted when the writing ended to reach the Master Write End Address (with no timeout processed), you should make necessary arrangement with the software. UDC2 will return to 1 after receiving the correct packet.

#### (2) Timeout

Master Write transfers would not finish if the OUT transfer from the USB host should stagnate before reaching the Master Write End Address during the transfer. In order to cope with such circumstances, you can set the timeout function.

When this timeout function is used, all data stored in the buffer in UDC2AB at the point of timeout will be transferred to AHB.

Timeout can be processed with the following operation.

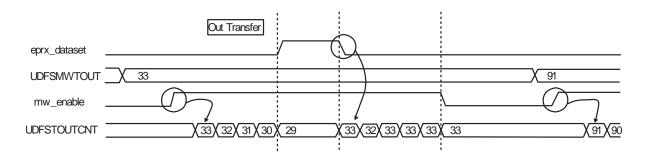

- 1. Make an access to the UDFSMWTOUT before starting a Master Write transfer and set timeoutset (timeout time) to make <timeout\_en> enabled 1.
- 2. Start the Master Write transfer in accordance with the instruction in the preceding section.

Note: UDC2AB will assert the mw\_set\_add interrupt when the packet is received normally from the USB host with the UDFSMSTSET<mw\_enable disabled.

- 3. When the timeout has occurred, the mw\_timeout interrupt will be asserted. (The mw\_end\_add interrupt will not be asserted.) In that case, the Master Write transfer is not completed to reach the Master Write End Address. UDC2AB clears the UDFSMSTSET<mw\_enable> to 0.
- 4. In UDFSMWCADR, the address to which the transfer has completed to the AHB end can be confirmed.

Please note that the timeout counter advances during the Master Write transfer with the timeout function enabled, but the counter will be reset to the preset value when the OUT transfer from the USB host to the relevant EP is received and begin recounting (see the Figure 13-15). It means that the time until timeout is "from the point when the last transfer from the USB host to the relevant EP has occurred during the Master Write transfer to the preset time," rather than "from the point when the Master Write transfer has begun to the preset time."

If you do not use the timeout function, be sure to set the UDFSMWTOUT<timeout\_en> to "Disable 0" before starting the Master Write transfer. In that case, the transfer will not finish until reaching the preset Master Write End Address.

#### (3) Aborting of Master Write transfers

You can abort Master Write transfers with the following operation.

- 1. Use UDFS2CMD to set the status of the relevant EP to Disable (EP\_Disable).
- 2. In order to stop the Master Write transfer, set 1 (Abort) to the UDFSMSTSET<mw\_abort>.
- 3. In order to confirm the transfer is aborted, check the UDFSMSTSET<mw\_enable> was disabled to 0. Subsequent operations should not be made while the <mw\_enable> is 1. (Information on the address where the transfer ended when aborted can be confirmed with Master Write Current Address and Master Write AHB Address registers.)
- 4. In order to initialize the Master Write transfer block, set 1 (Reset) to the UDFSMST-SET<mw\_reset>.
- 5. Use UDFS2CMD (EP\_FIFO\_Clear) to initialize the FIFO for the relevant EP.
- 6. Use UDFS2CMD to set the status of the relevant EP to Enable (EP\_Enable).

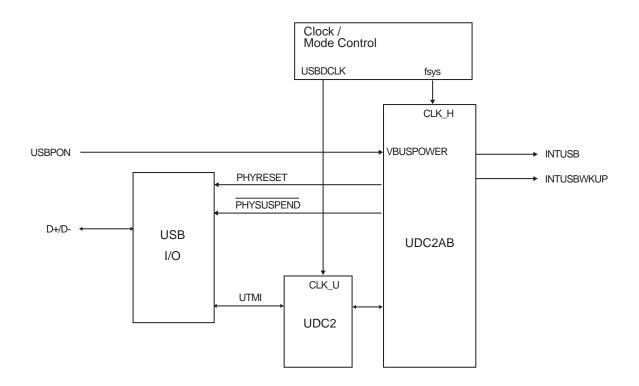

## 13.5.5 USB Power Management Control

In USB, operations related to power management including detection of USB bus power supply, suspending and resuming are also prescribed in addition to normal packet transfers. This section discusses about how to control those operations.

Note: Be sure to see the USB 2.0 Specification for details of operations.

### 13.5.5.1 Connection Diagram of Power Management Control Signal

Below is a connection diagram of signals related to power management control.

## Figure 13-16 Connection Diagram of Power Management Control Signal

## 13.5.5.2 Sequence of USB Bus Power (VBUS) Connection/Disconnection

### (1) Connect

If CLK\_H is operating, the USB bus power (VBUS) connection is detected using the INTUSB(powerdetect) interrupt and UDFSPWCTL<pw\_detect>. If UCLK\_H is stopped, the USB power connection (VBUS) is detected using the INTUSBPON interrupt signal.

After detecting bus power (VBUS), initialize UDC2AB and UDC2 following sequence.

- 1. Use the UDFSPWCTL<pw\_resetb> to make software reset. (The <pw\_resetb> bit is not automatically released and should be cleared by software.).
- 2. Make an access to UDC2AB and UDC2 registers to make necessary initial settings.
- 3. Use UDFS2CMD to issue the USB Ready command. UDC2 notifies the USB host of the connection via PHY. This condition enables UDC2 to accept USB\_RESET from the USB host.
- 4. Once USB\_RESET from the USB host is detected, UDC2 initializes the registers inside UDC2 and enumeration with the USB host becomes available. When USB\_RESET is detected, the usb\_reset / usb\_reset\_end interrupt occurs.

#### (2) Disconnect

If CLK\_H is operating, the USB bus power (VBUS) disconnection is detected using the INTUSB (powerdetect) interrupt and UDFSPWCTL<pw\_detect>. If CLK\_H is stopped, the USB power (VBUS) disconnection is detected using the INTUSBWKUP interrupt.ÅB

When the disconnection of the USB bus power (VBUS) is detected, each master transfer will not automatically stop. Then use the pw\_resetb bit of Power Detect Control register to make software reset.

## 13.5.6 USB Reset

USB\_RESET may be received not only when the USB host is connected but also at any timing.

UDC2AB asserts the usb\_reset / usb\_reset\_end interrupt when UDC2 has received USB\_RESET and returns to the default state. At this time, master transfers will not automatically stop. Use the abort function to end the transfers. Values are initialized by USB\_RESET for some registers of UDC2, while they are retained for other registers (refer to the section of UDC2).

Resetting of UDC2 registers when USB\_RESET is recognized should be made after the usb\_reset\_end interrupt has occurred. This is because UDC2 initializes UDC2 registers at the time it deasserts the usb\_reset signal.

## 13.5.7 Suspend / Resume

### 13.5.7.1 Shift to the suspended state

UDC2AB makes notification of detecting the suspended state of UDC2 by the INTUSB (suspend\_resume) interrupt and the UDFSPWCTL<suspend\_x>.

Since master transfers will not automatically stop in this circumstance, you should use the aborting function of each master transfer to make forcible termination if needed.

In case PHY needs to be suspended (clock stop) after the necessary processes finished by software, you can set the UDFSPWCTL<phy\_suspend> to make UDC2AB assert PHYSUSPEND which will put PHY in suspended state.

# TOSHIBA

## 13.5.7.2 Resuming from suspended state (resuming from the USB host)

The procedures to resume from the suspended state is performed based o the condition of the CLK\_H. When resuming is recognized, make settings again for restarting master transfers.

1. Stopping the CLK\_H

The procedures to stop the CLH\_H and the signal variation are as shown below.

		a	bc d	e	f g	h,	i	j k	ζ.
suspend_x		j		/					
<suspend_resume_en>, <power_detect_en></power_detect_en></suspend_resume_en>		<u>/</u>							
suspend_resume interrupt re	equest	ĺ.		/					
<wakeup_en></wakeup_en>									
WAKEUP									
INTUSBWKUP interrupt rec	uest								
VBUSPOWER	"H"								
<pw_detect></pw_detect>	"H"								
power_detect interrupt req	uest								
<phy_suspend>.</phy_suspend>									
PHYSUSPEND									
CGUSBCTL <usbclken></usbclken>									
CLK_U		ψ̈́лл		Π		•∄∐			MMM
CLK_H		ΰM	hhi	תלית	<u> </u>	υĻ		hni	

## Figure 13-17 Signal operations when suspended and resumed (when CLK\_H is stopped)

- a. The suspend\_x of the UDC2 is asserted to zero by detecting the suspend state on the USB bus, and the INTUSB(suspend\_resume) interrupt occurs.
- b. The service routine of the INTUSB(suspend\_resume) interrupt clears the interrupt factor.
- c. Set the UDFSPWCTL<phy\_suspend> to "1". Setting the <phy\_suspend> to "1" asserts the PHYSUSPEND output signal to "0".

Zero clear the CGUSBCTL<USBCLKEN> of the clock/mode control circuit CGUSBCTL<USBCLKEN> to stop the CLK\_U.

- d. Set the UDFSPWCTL<wakeup\_en> to "1". Zero clear the UDFSINTENB<power\_detect\_en><suspend\_resume\_en> not to generate the INTUSBD(power\_detect, suspend\_resumu) interrupt.
- e. With the INTUSBWKUP interrupt, the operation mode moves into the low-power consumption mode and stops the CLK\_H.

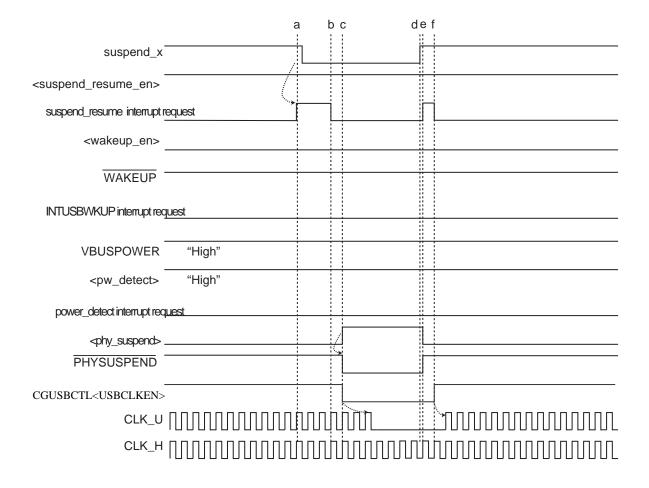

- f. By detecting Resume on the USB bus, the WAKEUP output signal will be asserted to 0 asynchronously.By WAKEUP output signal, INTUSBWKUP occurs and the low-power consumption mode is cancelled. Then, supply of CLK\_H starts.
- g. With the supply of CLK\_H, PHYSUSPEND output signal is automatically asserted to "1", and <phy\_suspend> is zero-cleared.

Set CGUSBCTL<USBCLKEN> of the clock/mode control circuit to "1" to activate the CLK\_U.

- h. 2.5 s after the interrupt is asserted (time required for the signal to stabilize when VBUS is disconnected) and check UDFSPWCTL<pw\_detect>. If the UDFSPWCTL<pw\_detect> is "1", WAKEUP is asserted by Resume. If UDFSPWCTL<pw\_detect> is "0", WAKEUP is asserted by disconnection of the VBUS.
- i. To resume, perform the sequences below. To disconnect, perform the sequences of the "13.5.7.3 Resuming from the suspend state (disconnect)".
- j. Clears the interrupt factor and <wakeup\_en> to deassert the WAKEUP output signal. Set <suspend\_resume\_en> to "1".
- k. Resumes from the suspended state.

2. For CLK\_H to work

The procedures to get the CLK\_H work and the signal changes are shown as below.

## Figure 13-18 Operation of suspend/resume signals (to get the CLK\_H work)

- a. INTUSB(suspend\_resume) interrupt occurs by detecting the suspended state on the USB bus.
- b. Clears the interrupt source in the INTUSB(suspend\_resume) interrupt service routine.
- c. Set "1" to UDFSPWCTL<phy\_suspend>. Setting  $\langle phy_suspend \rangle$  to "1" assert the PHYS-USPEND output signal to "0".

Set CGUSBCTL<USBCLKEN> of the clock/mode circuit to "0" to stop the CLK\_U.

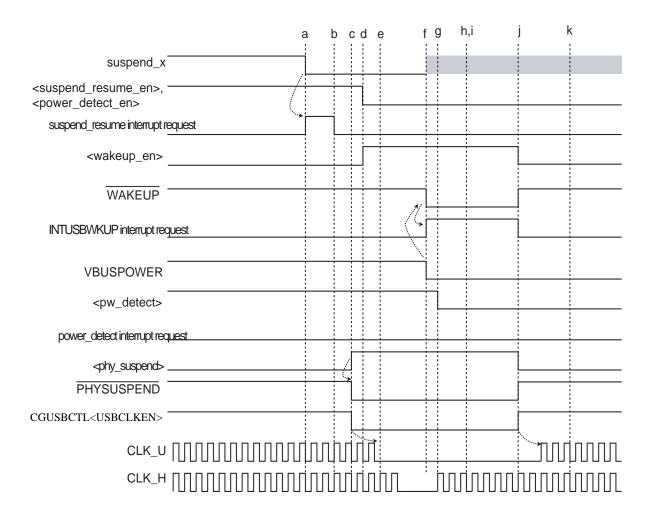

d. The suspend\_x becomes "1" by detecting resume on the USB bus.

Aslo,  $\overline{PHYSUSPEND}$  output signal is deasserted to "1" by detecting the rising edge of the suspend\_x.

- e. INTUSB(suspend\_resume) interrupt occurs.
- f. Interrupt source is zero cleared in the service routine of the INTUSBD(suspend\_resume). Set CGUSBCTL<USBCLKEN> of the clock/mode circuit to "1" to get CLK U work.
- g. Deasserting the PHYSUSPEND output signal will resume the supply of the CLK\_U.
- h. Resumes from the suspend state.

## 13.5.7.3 Resuming from the suspend state (disconnect)

The procedures to resume from the suspended state (disconnection) and the signal change are shown as below.

## Figure 13-19 Operation of suspend/disconnect signals (to stop CLK\_H)

- a. 0 is asserted to the suspend\_x of the UDC2 by detecting the suspend state on the USB bus and this generates the INTUSB(suspend\_resume) interrupt.
- b. Interrupt source is cleared by the service routine of the INTUSB(suspend\_resume) interrupt.
- c. <u>Set UDFSPWCTL<phy\_suspend></u> to "1". Setting the <phy\_suspend> to "1" asserts the  $\overline{PHYS-USPEND}$  output signal to "0".

Set CGUSBCTL<USBCLKEN> of the clock/mode circuit to "0" to stop the CLK\_U.

- d. Set the UDFSPWCTL<wakeup\_en> to "1". Zero clear the UDFSINTENB<power\_detect\_en><suspend\_resume\_en> not to generate INTUSBD(power\_detect, suspend\_resumu) interrupt.
- e. With the INTUSBWKUP interrupt, the operating mode moves into the low-power consumption mode to stop the CLK\_H.
- f. If disconnection is detected on the USB bus, the VBUSPOWER pin becomes "0" and the  $\overline{WAKE}$ - $\overline{UP}$  output signal will be asynchronously asserted to "0".
- g. INTUSBWKUP interrupt is generated by the WAKEUP output signal and low-power consumption mode is cancelled. The supply of CLK\_H starts.

- h. 2.5 s after the interrupt is asserted (time required for the signal to stabilize when VBUS is disconnected), check the UDFSPWCTL<pw\_detect>. If UDFSPWCTL<pw\_detect> is "1", WAKE-UP is asserted by resume. If UDFSPWCTL<pw\_detect> is "0", WAKEUP is asserted by disconnection of VBUS.
- i. If the factor is the resume, perform the sequence written in the "13.5.7.2 Resuming from suspended state (resuming from the USB host)". If the factor is disconnection, perform the sequence below.
- j. Zero clear the <phy\_suspend> to deassert the PHYSYSPEND output signal.

Set the CGUSBCTL<USBCLKEN> of the clock/mode circuit to "1" to get the CLK\_U work.Clear the interrupt factor and <wakeup\_en> to deassert the WAKEUP output signal.

k. Set UDFSPWCTL<pw\_resetb> using software, initialize the UDC2AB.

### 13.5.7.4 Remote wakeup from the suspended state

The procedure of remote wakeup from the suspended state and the signal change are shown below.

	ć	a b	C	d (	e f	Ç	9		
suspend_x				÷					
<suspend_resume_en></suspend_resume_en>	(								
suspend_resume interrupt re	quext								
<wakeup_en></wakeup_en>									
WAKEUP

INTUSBWKUP interrupt	request								
VBUSPOWER	"High"								
<pw_detect></pw_detect>	"High"								
power_detect interrupt rec	uest								
<phy_remote_wkup>_</phy_remote_wkup>									
			4						
PHYSUSPEND									
CGUSBCTL <usbclken></usbclken>									
CLK_U							սոս	UUU	սու
CLK_H			ψm	ĴΛ		W		MM	UUU

## Figure 13-20 Operation of suspend/remote wakeup signals

- a. suspend\_x of the UDC2 is asserted to 0 by detecting the suspended state on the USB bus and the INTUSB(suspend\_resume) interrupt occurs.
- b. Clears the interrupt source in the service routine of the INTUSB(suspend\_resume) interrupt.
- c. Set the UDFSPWCTL<phy\_suspend> to "1". PHYSUSPEND output signal is asserted to "0" by setting <phy\_suspend> to "1"

Set the CGUSBCTL<USBCLKEN> of the clock/mode circuit to "0" to stop the CLK\_U.

- d. When requesting remote wakeup, set the UDFSPWCTL<phy\_remote\_wkup> to 1. Setting the <phy\_remote\_wkup> to "1" will cause the UDC2 to make a remote wakeup request on the USB bus. Also, <suspend\_x> will be deasserted to 1 asynchronously.
- e. <u>Deasserting <suspend\_x></u> will cause the INTUSB(suspend\_resume) interrupt to occur and the <u>PHYSUSPEND</u> output signal to be deasserted to 1.
- f. Set the CGUSBCTL<USBCLKEN> of the clock/mode circuit to "1" to get the CLK\_U work.

When the CLK\_U starts operating, <phy\_remote\_wkup> is automatically cleared to "0".

g. Clear the interrupt source.

## 13.6 USB Device Response

UDC2 initializes the inside of UDC2 and sets various registers when hardware reset is detected, USB\_RESET is detected, and an enumeration response is made. This section discusses the operations of UDC2 in each status as well as how to control them externally.

1. When hardware reset is detected

Be sure to reset hardware for UDC2 after the power-on operation. After the hardware reset, UDC2 initializes internal registers and all EPs are in the invalid status, which means the device itself is "Disconnected."

In order to make the status of UDC2 to "Default," issue the "USB\_Ready" command. Issuing this command will put UDC2 in the "Full-Speed" mode, enable the Pull-Up resistance of D+ and notify the host of "Connect".

In this status, only the USB\_RESET signal is accepted from the host.

2. When USB\_RESET is detected

UDC2 initializes internal registers when Bus Reset (USB\_RESET) is detected on the USB signal, putting the device in the "Default" status. In this status only EP 0 gets "Ready" enabling enumeration with the host.

3. When "Set\_address" request is received

By setting 010 to the UDFS2ADR<configured> <addressed> <default> and the received address value to the <dev\_adr> after receiving the "Set\_address" request, UDC2 will be in the "Addressed" status. Setting for this register should be made after the Control transfer has successfully finished (after the STATUS-Stage has ended).

Transfers to EPs other than EP 0 cannot be made in this status.

4. When "Set\_configuration" and "Set\_interface" requests are received

By setting 100 to the UDFS2ADR<configured> <addressed> <default> after receiving the "Set\_configuration" and "Set\_interface" requests, UDC2 will be in the "Configured" status.

In the "Configured" status, you can make transfers to the EP to which status settings have been made.

- In order to make the EP "Ready," the following settings should be made:
- · Set the maximum packet size to UDFS2EPxMSZ
- Set the transfer mode to UDFS2EPxSTS
- Issue the EP\_Reset command to UDFS2CMD

EPs will be available for transmitting and receiving data after these settings have been made.

Figure 13-21 shows the "Device State Diagram".

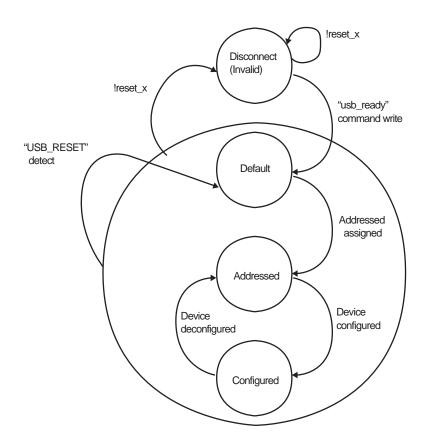

Figure 13-21 Device state diagram

## 13.7 Flow of Control in Transfer of EPs

## 13.7.1 EP0

EP0 supports Control transfer and is used as device control for enumeration. EP0 supports only Single packet mode.

Control transfers have SETUP-Stage, DATA-Stage and STATUS-Stage

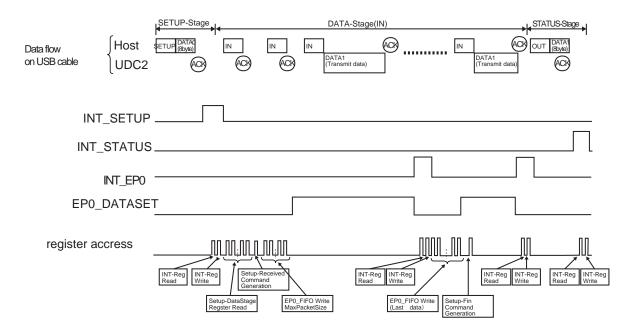

The types of transfer are categorized into the following major types:

- Control-RD transfer
- Control-WR transfer (without DATA-Stag)
- Control-WR transfer (with DATA-Stage)

UDC2 makes control of those three stages by hardware. Flows in each type of transfer are described below.

### 13.7.1.1 Control-RD transfer

The flow of control in Control-RD transfers is shown below.

## Figure 13-22 Flow of the control in Control-RD transfer

The following description is based on the assumption that the UDFS2EP0MSZ<dset> is set to "EP0\_DA-TASET flag".

## (1) SETUP-Stage

UDC2 asserts the INT\_SETUP flag when it has received the Setup-Token. This flag can be cleared by writing 1 into the UDFS2INT<i\_setup>. In case flags are combined externally, read the UDFS2INT to confirm which flag is asserted and write "1" into the relevant bit.

Then read Setup-Data storage registers (bRequest-bmRequestType, wValue, wIndex, and wLength registers) to determine the request.

Finally, issue the "Setup\_Received" command to inform UDC2 that the SETUP-Stage has finished. Since UDC2 does not allow writing data into the EP0-FIFO before this command is issued, it will keep returning "NAK" to the IN-Token from the host until the command is issued.

### (2) DATA-Stage

Write the data to be transmitted to the IN-Token into the EP0-FIFO. If the byte size of the data to send is larger than the MaxPacketSize, divide them into groups of MaxPacketSize before writing. When the number of data reached the MaxPacketSize, the EP0\_DATASET flag is asserted.

When the data have been transmitted to the IN-Token from the host with no problem, UDC2 deasserts the EP0\_DATASET flag and asserts INT\_EP0. Any data remaining to be transmitted should be written into the EP0-FIFO.

If the size of the data to be written is smaller than the MaxPacketSize, issue the "EP\_EOP" command to EP0 to inform UDC2 that it is a short packet. With this command, UDC2 recognizes the end of the packet and transmits the short packet data.

Finally, issue the "Setup\_Fin" command to inform UDC2 that the DATA-Stage has finished.

### (3) STATUS-Stage

When the "Setup\_Fin" command is issued, UDC2 will automatically make Handshake for the STA-TUS-Stage. When the STATUS-Stage finished with no problem, the INT\_STATUS flag is asserted. When received a packet of STATUS-Stage from the host before the "Setup\_Fin" command is issued, UDC2 will return "NAK" and asserts the INT\_STATUS\_NAK flag. Therefore, if this flag is asserted, be sure to issue the "Setup\_Fin" command.

## 13.7.1.2 Control-WR transfer (without DATA-Stage)

The flow of control in Control-WR transfer (without DATA-Stage) is shown below.

	SETUP-Stage	STATUS-Stage(IN)	<b> </b>
Data flow on USB cable {Host UDC2	SETUP DATAO (Bbyte) IN ACR WAR	) )	DATA1 (Obyte)
INT_SETUP			
INT_STATUS_			
INT_EP0			
EP0_DATASET	-		
Register access	INT-Reg Read Setup-DataStage Register Read	ietup_Received issue Setup_Fin Command	INT-Reg Read Write

Figure 13-23 Flow of control in Control-WR transfer (without DATA-Stage)

## (1) SETUP-Stage

Perform the same procedure described in "13.7.1.1 Control-RD transfer".

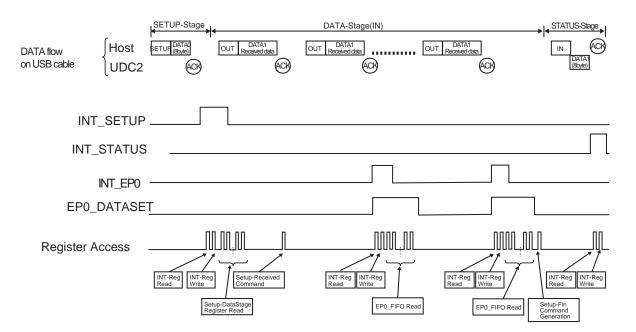

## (2) STATUS-Stage

After issuing the "Setup\_Received" command, make register accesses to UDC2 based on each request. Issue the "Setup\_Fin" command when all the register accesses to UDC2 have finished. Subsequent processes are basically the same as the STATUS-Stage described in "13.7.1.1 Control-RD transfer". UDC2 will keep on returning "NAK" until the "Setup\_Fin" command is issued.

Note: While register accesses required for each request are made to UDC2 between 'Issuing the "Setup\_Received" command' and 'Issuing the "Setup\_Fin" command', register accesses are needed after the end of STATUS-Stage in some cases such as Set Address request and Set Feature (TEST\_MODE). Processes required for the standard requests are described in "13.7.1.5 Processing when standard request".

## 13.7.1.3 Control-WR transfer (with DATA-Stage)

The flow of control in Control-WR transfer (with DATA-Stage) is shown below.

## (1) SETUP-Stage

To be processed in the same way of SETUP-Stage as described in"13.7.1.1 Control-RD transfer".

## (2) DATA-Stage

When the data is received from the host with no problem, UDC2 asserts the EP0\_DATASET flag and asserts the INT\_EP0 flag. When this flag is asserted, read the data from EP0\_FIFO after confirming the received data size in the UDFS2EP0FIFO, or read the data from EP0\_FIFO polling the EP0\_DATASET flag.

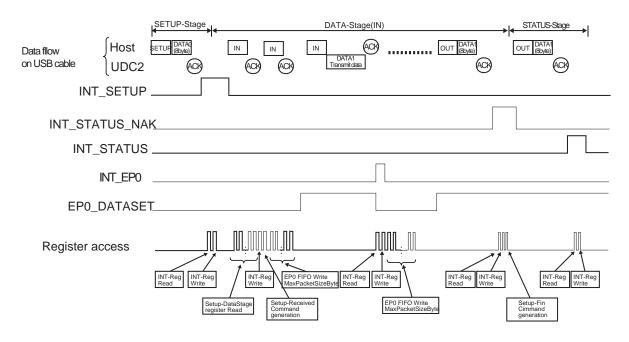

When the byte size of received data has been read, UDC2 deasserts the EP0\_DATASET flag.

## (3) STATUS-Stage

To be processed in the same way as in the STATUS-Stage described in "13.7.1.1 Control-RD transfer".

## 13.7.1.4 Example of using the INT\_STATUS\_NAK flag

When processing requests without DATA-Stage, the INT\_STATUS\_NAK flag may get asserted by receiving STATUS-Stage from the host before clearing the INT\_SETUP flag after it has been asserted, especially in High-Speed transfers. In case such multiple interrupts should be avoided as much as possible, you can use a method to mask the INT\_STATUS\_NAK flag for request having no DATA-Stage. In such case, basically set 1 to UDFS2INT<m\_status\_nak>, while 0 should be set only when requests having DATA-Stage are received. (An example for Control-RD transfers is provided below.)

## Figure 13-25 Example of using the INT\_STATUS\_NAK flag in Control-RD transfers

## (1) SETUP-Stage

After the INT\_SETUP flag was asserted, clear the UDFS2INT $\leq$ i\_setup> is set to 1, it should be also cleared.

Then, if the request was judged to have DATA-Stage by reading Setup-Data storage registers, set the UDFS2INT<m\_status\_nak> to 0. Then issue the "Setup\_Received" command.

## (2) DATA-Stage→STATUS-Stage

When the INT\_STATUS\_NAK flag was asserted, the device should also proceed to the STATUS-Stage. Clear the UDFS2INT<i\_status\_nak> and then issue the "Setup\_Fin" command. Also, set 1 to the UDFS2INT<m\_status\_nak> in order to get ready for subsequent transfers.

#### 13.7.1.5 Processing when standard request

Examples of making register accesses to UDC when standard requests are received are provided below. Descriptions of each request are basically provided for each state of the device (Default, Address, and Configured).

For the information on register accesses common to each request, see 13.7.1.1, 13.7.1.2 and 13.7.1.3.

You should note, however, descriptions provided below do not include the entire details of standard requests in USB 2.0. Since methods to access registers may vary depending on each user's usage, be sure to refer to the USB 2.0 specifications. You should also refer to the USB 2.0 specifications for "Recipient," "Descriptor Types," "Standard Feature Selectors," "Test Mode Selectors" and other terms appear in the descriptions below.

• Standard requests for "13.7.1.1 Control-RD transfer".

Get Status Get Description Get Configuration

Standard requests for "13.7.1.2 Control-WR transfer (without DATA-Stage)".

Clear Feature Set Feature Set Address

Set Configuration Set Interface

• Standard requests for "13.7.1.3 Control-WR transfer (with DATA-Stage)"

Set Description

Note 1: Descriptions with double underlines refer to register accessed to UDC2.

Note 2: Writing accesses to UDFS2CMD are described in the following manner for simplicity:

(Example 1) When writing 0x0 to UDFS2CMD<ep> and 0x4 to <com>

 $\rightarrow$ Issue the EP-Stall command to EP0

(Example 2) When writing the relevant EP to UDFS2CMD<ep> and 0x5 to <com>

 $\rightarrow$ Issue the EP-Invalid command to the relevant EP

#### (1) Get Status Request

To meet this request, the status of the specified receiving end (recipient) is returned.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
1000_0000 1000_0001 1000_0010	GET_STATUS	Zero	Zero Interface EP	Two	Device Interface, or EP Status

• Common to all states:

If the EP/Interface specified by wIndex does not exist, issue the EP-Stall command to  $\underline{EP0}$ .

• Default state:

Nothing is specified for the operation of devices by the USB 2.0 specifications.

Address state:

<recipient> = Device : Write the information on the device (Table 13-3) to UDFS2EP0FIFO.
<recipient> = Interface: Issue the EP-Stall command to EP0
<recipient> = EP : If wIndex=0(EP0), write the information on EP0 (Table 13-5) to UDFS2EP0FIFO. If
wIndex≠0(EPx), issue the EP-Stall command to EP0.

## Configured state:

<recipient> = Device :</recipient>	Write the information on the device (Table 13-3) to UDFS2EP0FIFO.
<recipient> = Interface:</recipient>	If the interface specified by lwIndex, write the information on the interface (Table 13-4) to UDFS2EP0FIFO.
<recipient> = EP :</recipient>	If the EP specified by wIndex, <u>write the information on the relevant EP(Table 13-5) to UDFS2EP0FIFO.</u>

## Table 13-3 Information on the device to be returned by Get Status request

D15	D14	D13	D12	D11	D10	D9	D8
0	0	0	0	0	0	0	0
D7	D6	D5	D4	D3	D2	D1	D0
0	0	0	0	0	0	Remote Wakeup	Self Powered

RemoteWakeup 0 indicates the bus power while 1 indicates the selfpower.

(D1)

SelfPowered (D0)

0 indicates the remote wakeup function is disabled while 1 indicates it is enabled.

## Table 13-4 Information on the interface to be returned by Get Status

D15	D14	D13	D12	D11	D10	D9	D8
0	0	0	0	0	0	0	0
D7	D6	D5	D4	D3	D2	D1	D0
0	0	0	0	0	0	0	0

Please note that all bits are 0.

## Table 13-5 Information on the EP to be returned by Get Status request

D15	D14	D13	D12	D11	D10	D9	D8
0	0	0	0	0	0	0	0
D7	D6	D5	D4	D3	D2	D1	D0
0	0	0	0	0	0	0	Halt

Halt If this bit is 1, it indicates that the relevant EP is in the "Halt" state. (D1)

### (2) Clear Feature Request

To meet this request, the particular functions are cleared and disabled.

bmRequesType	bRequest	wValue	wIndex	wLength	Data
1000_0000			Zero		
1000_0001	CLEAR_FEATURE	Feature Selector	Interface	Zero	None
1000_0010			EP		

· Common to all states:

If Feature Selector (wValue) which cannot be cleared (disabled) or does not exist is specified, issue the EP-Stall command to EP0.

If the EP/Interface specified by wIndex does not exist, issue the EP-Stall command to EP0.

• Default state:

Nothing is specified for the operation of devices by the USB 2.0 specifications.

• Address state:

<recipient> = Device :</recipient>	If wValue=1, disable the DEVICE_REMOTE_WAKEUP function at the user program. No register access to UDC2 is required.
<recipient> = Interface:</recipient>	Issue the EP-Stall command to EP0.
<recipient> = EP :</recipient>	If wIndex≠0(EPx), issue the EP-Stall command to EP0.
	If wValue=0 andwIndex=0(EP0), clear the Halt state of EP0 but no register access to UDC2 is required.
Configured state:	
craciniants - Davica :	If w/value=1, disable the DEV/CE REMOTE WAKELIP function at the user program

<pre></pre>	No register access to UDC2 is required.
<recipient> = Interface:</recipient>	Issue the EP-Stall command to EPO.(note)
<recipient> = EP :</recipient>	If wValue=0 and wIndex=0(EPx), <u>issue the EP-Reset command to the relevant com-</u> <u>mand.</u> If wValue=0 and wIndex=0(EP0), clear the Halt state of EP0 but no register access to UDC2 is required.

Note: EP 0 is to be stalled based on the interpretation of the USB 2.0 specifications that "No Feature Selector exists for Interface" here. For more information, see the USB Specification.

#### (3) Set Feature Request

To meet this request, the specific functions are set or enabled.

BmRequesetType	BRequesdt	wValue	wl	ndex	wLength	Data
1000_0000 1000_0001 1000_0010	SET_FEATURE	Feature Selector	Zero Interface EP	Test Selector	Zero	None

• Common to all state:

If Feature Selector (wValue) which cannot be set (enabled) or does not exist is specified, <u>Eissue the EP-Stall command to the EP0.</u>

If the EP/Interface specified by the lower byte of wIndex does not exist, <u>issue the EP-</u> <u>Stall command to EP0.</u>

- Note: When using a vendor-specific nonstandard Test Selector, the appropriate operation should be made.
  - Default state:

Nothing is specified for the operation of devices by the USB 2.0 specifications except for the above-mentioned TEST\_MODE.

· Address state:

<recipient> = Device :</recipient>	If wValue=1, disable the DEVICE_REMOTE_WAKEUP function at the userÅfs end. No register access to UDC2 is required.
<recipient> = Interface:</recipient>	Issue the EP-Stall command to EP0.
<recipient> = EP :</recipient>	If the lower byte of wIndex ≠0 (EPx), issue the EP-Stall to EP0.
	If wValue=0 and the lower byte of wIndex=0 (EP0), make EP0 to Halt state. (note 2)
Configured state:	
<recipient> = Device :</recipient>	If wValue=1, enalbe the DEVICE_REMOTE_WAKEUP function at the userAfs end. No register access to UDC2 is required.
<recipient> = Interface:</recipient>	Issue the EP-Stall command to EPO.(note 1)
<recipient> = EP :</recipient>	If wValue=0 and the lower byte of wIndex≠0(EPx), <u>issue the EP-Stall command to EP0.</u> If wValue=0 and the lower byte of wIndex=0(EP0), make EP0 to Halt state.(note 2)

- Note 1: EP 0 is to be stalled based on the interpretation of the USB specifications that "No Feature Selector exists for Interface" here. For more information, see the USB specifications.
- Note 2: USB 2.0 specifications include such description that "Performing the Halt function for EP 0 is neither necessary nor recommended." Accordingly, it can be interpreted that it is not necessary to set UDC2 to the Stall state in this case.

In order to actually make EP 0 be in the Halt state, users have to manage the "Halt state.

Then, when a request is received in the "Halt state", such processes as to issue the EP-Stall command to EP0 in DATA-Stage/STATUS-Stage will be required. (Even if EP0 is set to the Stall state, UDC2 will cancel the Stall state when the Setup-Token is received and will return "ACK.")

As such, the process when SetFeature/ClearFeature is received for EP 0 varies depending on user's usage.

## (4) Set Address Request

To meet this request, device addresses are set.

BmRequesetType	BRequesdt	wValue	wIndex	wLength	Data
0000_0000	SET_ADDRESS	Device Address	Zero	Zero	None

For this request, make register accesses shown below within 2 ms after the STATUS-Stage has ended.

(The device address should not be changed before the Setup\_Fin command is issued.)

- Default state:
- wValue=0: Keep the default state. No register access to UDC2 is required.
  wValue≠0: Set wValue to UDFS2ADR<dev\_adr> and set 010 to <configured>, <addressed> and <default>. UDC2 will be put in the address state.
  Address state:
  wValue=0: Set 0x00 to UDFS2ADR<dev\_adr> and 010 to <configured>, <addressed> and <default>. UDC2 will be put in the default state.

wValue≠0: <u>Set wValue to UDFS2ADR<dev\_adr>.</u> UDC2 will be set to a new device address.

• Configured state:

Nothing is specified for the operation of devices by the USB 2.0 specification.

## (5) Get Descriptor Request

To this request, the specified descriptor is returned.

BmRequesetType	BRequesdt	wValue	wIndex	wLength	Data
1000_0000	GET_DESCRIPTOR	Descriptor Type and Descriptor Index	Zero or Language ID	Descriptor Length	Descriptor

Common to all states:

<u>Write the descriptor information specified by wValue to UDFS2EP0FIFO</u> for the byte size specified by wLength. If the byte size to write is larger than the MaxPacketSize of EP 0, you need to divide the data to write it several times (refer to "13.7.1.1 Control-RD transfer" for details). (If the length of the descriptor is longer than wLength, write the information for wLength bytes from the beginning of the descriptor. If the length of the descriptor is shorter than wLength, write the full information for the descriptor.)

If the descriptor specified by wValue is not supported by the user, <u>issue the EP-Stall command to EP0.</u>

#### (6) Set Descriptor Request

BmRequesetType	BRequesdt	wValue	wIndex	wLength	Data
0000_0000	SET_DESCRIPTOR	Device Type and Descriptor Index	Language ID or Zero	Descriptor Length	Descriptor

• Common to all states:

When this request is not supported, issue the EP-Stall command to EPO.

• Default state:

Nothing is specified for the operation of devices by the USB 2.0 specifications.

• Address state & Configured state:

Read the information on the description received by UDC2 from UDFS2EP0FIFO.

#### 13.7 Flow of Control in Transfer of EPs

#### (7) Get Configuration Request

BmRequesetType BRequesdt		wValue	wIndex	wLength	Data	
1000 0000	GET_CONFIGURATION	Zero	Zero	One	Configuration Value	

• Default state:

To this request, the Configuration value of the current device is returned.

• Address state:

Write 0x00 to UDFS2EP0FIFO. As this is not configured, 0 should be returned.

• Configured state:

Write the current configuration value to the UDFS2EP0FIFO.

Since this has been configured, values other than 0 should be returned.

#### (8) Set Configuration Request

To meet this request, Device Configuration is set.

BmRequesetType	BRequesdt	wValue	wIndex	wLength	Data
0000 0000	SET_CONFIGURATION	Configuration Value	Zero	Zero	None

• Default state:

Nothing is specified for the operation of devices by the USB 2.0 specifications.

Address state:

-

- When wValue = 0:
- Keeps the address state. No register access to UDC2 is required.
- When wValue≠0 and the wValue is a Configuration value matching the descriptor :
- Set 100 to UDFS2ADR<configured> <addressed> <default>.

<For EPs to use>

- <u>Set MaxPacketSize to UDFS2EPxMSZ<max\_pkt>.</u>
- <u>Set respective values to UDFS2EPxSTS<pkt\_mode>, <bus\_sel>, <dir>, <t\_type> and <num\_mf>.</u>
- Issue the EP-Reset coomand to the relevant EPs.
- When wValue $\neq 0$  and the wValue is a Configuration value not matching the descriptor:
- Issue the EP-Stall command to EP0.
- Configured state:

When wValue = 0:

- <u>Set 010 to UDFS2ADR<configured> <addressed> <default>.</u>
- Issue the All-EP-Invalid command.

When Value  $\neq 0$  and it is a Configuration value matching the descriptor:

<For EPs to use>

- <u>Set the MaxPacketSize to UDFS2EPxMSZ<max\_pkt>.</u>
- <u>Set respective values to UDFS2EPxSTS<pkt\_mode>, <bus\_sel>, <dir>, <t\_type> and <num\_mf>.</u>
- Issue the EP-Reset command to the relevant EPs.

<For EPs to become unused>

- Issue the EP-Invalid command to the relevant EPs.

When wValue ≠0 and the wValue is a Configuration value not matching the descriptor :

- Issue the EP-Stall command to EP0.

#### (9) Get Interface Request

To meet this request, the AlternateSetting value set by the specified interface is returned.

BmRequesetType	BRequesdt	wValue	wIndex	wLength	Data	
1000_0001	GET_INTERFACE	Zero	Interface	One	Alternate Setting	

• Common to all states:

If the interface specified by wIndex, issue the EP-Stall command to EPO.

• Default state:

Nothing is specified for the operation of devices by the USB 2.0 specifications.

- Address state:
  - Issue the EP-Stall to EP0.
- Configured state:

Write the current alternate setting value of the interface specified by the wIndex to UDFS2EP0FIFO.

#### (10) Set Interface Request

To meet this request, the Alternate Setting value of the specified interface is set.

BmRequesetType	BRequesdt	wValue	wIndex	wLength	Data	
0000_0001	SET_INTERFACE	Alternate Setting	Interface	Zero	None	

• Common to all states:

If the interface specified by wIndex does not exist or if the Alternate Setting specified by wValue does not exist, <u>issue the EP-Stall command to EP0.</u>

• Default state:

Nothing is specified for the operation of devices by the USB 2.0 specifications.

Address state:

Issue the EP-Stall command to EPO.

· Configured state:

<For the EPs to use in Alternate Setting of the specified interface>

- <u>Set MaxPacketSize to UDFS2EPxMSZ<max\_pkt>.</u>
- <u>Set respective values to UDFS2EPxSTS<pkt\_mode>, <bus\_sel>, <dir>, <t\_type> and <num\_mf>.</u>
- EP-ResetIssue the EP-Reset command to the relevant EPs.

<For EPs to become unused>

- Issue the EP-Invalid command to the relevant EPs.

#### (11) Synch Frame Request

To meet this request, the Synch Frame of the EP is returned.

BmRequesetType	BRequesdt	wValue	wIndex	wLength	Data	
1000 0010	SYNCH_FRAME	Zero	EP	Two	Frame Number	

Common to all states:

If this request is not supported by the EP specified by wIndex, issue the EP-Stall command to EP0.

Default state:

Nothing is specified for the operation of devices by the USB 2.0 specifications.

Address state:

Issue the EP-Stall command to EP0.

• Configured state:

Write the Frame Number of the EP specified by wIndex to UDFS2EP0FIFO.

#### 13.7.2 EPs other than EP0

EPs other than EP 0 support Bulk (send/receive), Interrupt (send/receive), and Isochronous (send/receive) transfers and are used to transmit and receive data. They also support the Dual Packet mode which enables high-speed data communication.

### 13.8 Suspend/Resume State

UDC2 enters into a suspended state based on the signal condition from the host. It also returns from the suspended state by resuming operation by the host or UDC2.

Shifting between the states is described below.

#### 13.8.1 Shift to the suspended state

Though the host issues SOF with given intervals (FS: 1 ms) in the normal state, it will stop issuing this SOF to the device when it tries to make the device suspended and the data on the USB signal line will be unchanged keeping the idle state. UDC2 is always monitoring the "line\_state" from PHY and makes judgment of whether it is in the suspended state or USB\_RESET when the idle state is detected for 3 ms or longer. If judged to be in the suspended state, it will assert "suspend\_x" to "Low" and enter in the suspended state.

Please note accesses to registers will be unavailable while UDC2 is suspended, since supply of CLK from clock/mode control circuit.

#### 13.8.2 Resuming from suspended state

Resuming from the suspended state can be made in two ways; by outputting a resuming state from the host and by way of remote wakeup from UDC2 (outputting a resuming state).

Resuming process in each case is described below.

#### 13.8.2.1 Resuming by an output from the host

When a resuming state is output by the host, UDC2 deasserts suspend\_x to "High" to declare resuming from the suspend state.

#### 13.8.2.2 Resuming by way remote wakeup from UDC2

The remote wakeup function may not be supported by some applications, and it needs to be permitted by the USB host at the time of bus enumeration. You should not assert "wakeup" unless permitted by the system.

If permitted by the system, asserting the "wakeup" pin will make UDC2 output a resuming state to the host to start resuming. Please note that the clock supply from clock/mode control circuit is stopped when UDC2 is suspended, so you should keep asserting wakeup until it resumes. The remote wakeup should be operated after 2 ms or more has passed after suspend\_x was asserted to "Low".

## TOSHIBA

### 13.9 USB-Spec2.0 Device Controller Appendix

#### 13.9.1 Appendix A System Power Management

In USB, operations related to the enumeration and power control signals (D+/D-) for reset and suspend from the host are also prescribed, in addition to normal transfer operations. This Appendix provides information about the specifications of USB 2.0 PHY to be connected and clock control on the system level required for processes related to the D+/D- signals. For details of each process, please be sure to check the USB Specification Revision 2.0, USB-I/O specification.

The words in Appendix A are described below.

1. Reset:

The operation of the D+/D- signals for initializing the USB device (hereafter called "the device") from the USB host (hereafter called "the host"). After reset, enumeration is performed and then normal transfer operations such as Bulk transfers begin. Upon being connected, the device is always reset. The device also needs to support reset operation at any other arbitrary timing.

2. Suspend

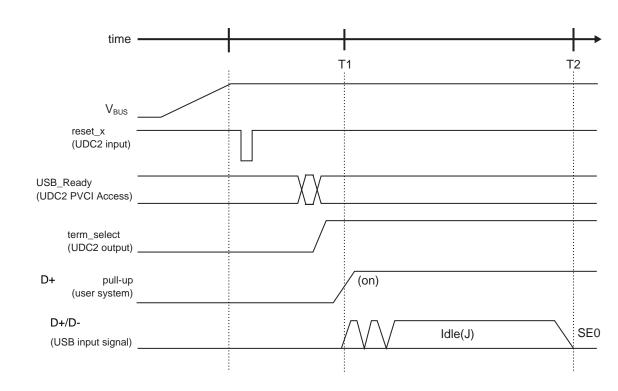

If no bus activity on the D+/D- lines including SOF is initiated by the host for 3 ms or longer, the device needs to be put in the suspend mode to reduce power consumption. In this case, the device is required to perform certain operations such as stopping the clock.

3. Resume

The operation of the D+/D- signals for resuming normal operation from the suspend mode. Resume operation can be initiated either by the host or the device. Resume operation from the device is called "remote wakeup".

The each operation is described below. The time in ( ) is value in the USB 2.0 Specification.

#### 13.9.1.1 Connect / Disconnect Operations

(1) Connect Operation

• T0: VBUS detection

When Vbus is detected, a system reset (reset\_x input) should be applied to UDC2.

xcvr\_select is "High" and term\_select is "Low".

• T1: Device connect (no later than 100ms after T0)

The device must enable D+ no later than 100 ms after Vbus detection (T0) to notify the host of the connected state. Therefore, when Vbus is detected and the device is ready to communicate with the host, the system should access the UDFS2CMD in UDC2 to set the USB\_Ready command. After that, the user system sets the port using software to enable the D+ pull-up.

• T2:USB Reset Start (more than 100ms after 100ms)

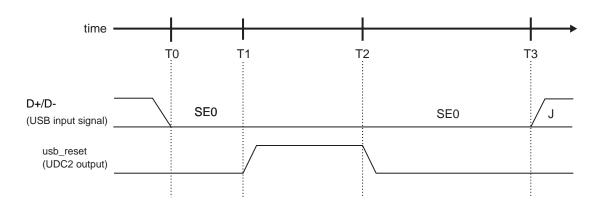

#### (2) Disconnect Operation

When a disconnected state is detected, it is recommended to apply a system reset to UDC2.

#### 13.9.1.2 Reset Operation

The "reset" here refers to the "Reset Signaling" defined in the USB 2.0 Specification, not the system reset (reset\_x) to UDC2.

#### (1) When Operation in FS Mode after Reset

• T0: Reset start

Upon recognizing SE0 from the host, UDC2 starts counting to recognize the reset.

• T1: Reset recognition (more than 2.5 µs after T0)

When UDC2 detects SE0 for more than approximately 68 µs after T0, it recognizes the reset from the host and drives usb\_reset "High".

• T2: deassert of USB reset

At this point, usb\_reset is driven "Low" more than 3.5ms from T1.

• T3: Reset end (more than 10ms after T0)

When SE0 from the host finishes and the device enters an idle state, it indicates the end of reset operation. The reset period from the host lasts a minimum of 10 ms.

#### (2) Notes on Reset Operation

· Initialization of registers after reset

When the reset from the host is completed (when usb\_reset changes from "High" to "Low"), all the internal registers of UDC2 are initialized (For the initial value of each register, refer to "13.4 Registers").

Note that registers that are set while usb\_reset is "High" are also initialized. Therefore, the UDC2 registers should be set after the reset period is completed.

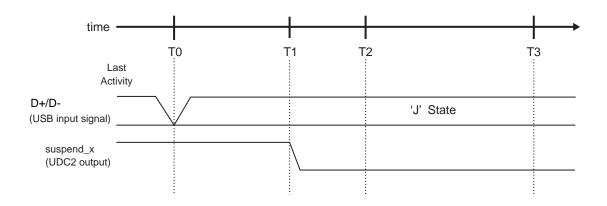

DMA transfer (EP-I/F access) after reset

When a reset from the host occurs during DMA transfer, the UDFS2EPxSTS is initialized and the bus access mode is set to "common bus access". Therefore, DMA transfer cannot be continued properly. When a reset occurs, the DMA controller must also be initialized.

In the enumeration operation after reset, configure each EP and then initialize the EPs by setting the EP\_Reset command in the UDFS2CMD.

#### 13.9.1.3 Suspend Operation

#### Figure 13-28 Suspend operation timing

• T0: End of bus activity

When the end of bus activity from the host (the end of packet) is detected, UDC2 starts counting to recognize suspend.

• T1: Recognition of suspend (3 ms after T0)

When the "FS-J" is detected for more than 3 ms after T0, UDC2 recognizes suspend and drives suspend\_x "Low".

• T2: Remote wakeup start enable (5 ms after T0)

Resume operation from the device (remote wakeup) is enabled 5 ms after T0.

T3: Transition to suspend state (10 ms after T0)

The device must enter the suspend state no later than 10 ms after T0. Processes required of the device system to enter the suspend state, such as stopping the CLK\_U, must be performed during this period.

It is necessary to control Clock /mode control circuit to stop the CLK\_U to UDC2.

#### (2) Notes on Suspend Operation

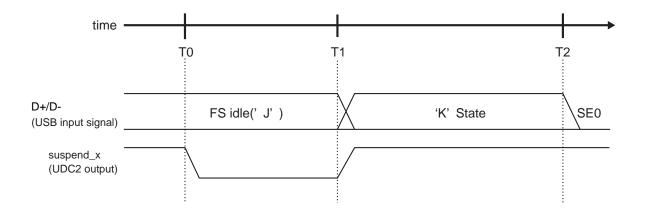

· Internal registers during the suspend state

During the suspend state, UDC2 retains the internal register values, the contents of FIFOs, and the state of each flag. These values and states are also retained after the suspend state is exited by resume operation.

When the CLK\_H to UDC2 is stopped, the internal registers in UDC2 cannot be accessed via PVC-I/F and EP-I/F.

#### 13.9.1.4 Resume Operation

(1) Resume Operation by the Host

- T0: suspend\_x output of UDC2 is "Low".
- T1: Start of host resume (No timing specifications)

The host starts resume operation ("FS-K") at arbitrary timing to wake up the device from the suspend state. At this point, UDC2 sets suspend\_x to "High". (Even if the CLK\_U to UDC2 is stopped, suspend\_x becomes "High").

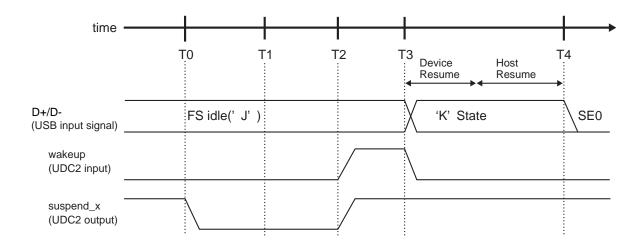

During suspend, when CLK\_H to UDC2 stops, resume the CLK\_H by controlling clock/ mode control circuit .

When CLK to UDC2 is stopped, it is necessary to control clk\_em.

• T2: End of host resume (more than 20 ms after T1)

The host resume operation ("FS-K") lasts for more than 20 ms, and completes after "SE0".

#### (2) Resume Operation by the Device (Remote Wakeup)

- T0: suspend x output of UDC2 is "Low".
- T1: Remote wakeup start enable (more than 2 ms after T0)

The device can be brought out of the suspend state by using the wakeup input of UDC2. Note that the USB specification prohibits remote wakeup for 5 ms after start of the suspend state. The wakeup signal should be set to "High" a minimum of 2 ms after T0 as 3 ms have already elapsed from the start of suspend operation to T0.

• T2: Wakeup input to UDC2 is "High" (after T1)

Set the wakeup signal to "High". No timing requirements are specified for this operation. At this point, UDC2 sets suspend\_x to "High". (Even if the CLK\_H input to UDC2 is stopped, suspend\_x becomes "High".) UDC2 requires the clock input to start resume operation ("FSK"). Then, keep wakeup at "High" until clock supply is resumed.

• T3: Start of device resume

When the CLK\_H input to UDC2 is resumed, UDC2 starts the device resume ("FS-K"). The device resume period is approximately 2 ms. After confirming the device resume, the host starts the host resume operation.

T4: End of host resume (more than 20 ms after T3)

The host resume operation ("FS-K") lasts for more than 20 ms, and completes after "SE0".

#### (3) Notes on Resume Operation

The restriction on use of remote wakeup are shown as follows.

To support remote wakeup as the device system, the device must notify the host in the Configuration descriptor that the remote wakeup function is enabled. Even if remote wakeup is supported, it is disabled by default. Remote wakeup can only be used after it is enabled by a request from the host. Use of remote wakeup using the wakeup input is allowed only when these conditions are satisfied.

When using this function, be sure to refer to 13.8 of the USB 2.0 Specification which offers detailed description.

### 13.9.2 Appendix B About Setting an Odd Number of Bytes as MaxPacketSize

#### 13.9.2.1 Setting an odd number in the UDFS2EPxMSZ

The USB specification allows MaxPacketSize (hereafter referred to as MPS) of each EP to be set as either an odd or even number of bytes for Isochronous and Interrupt transfers. (For Control and Bulk transfers, only an even number can be set.)

In UDC2, MPS is set through UDFS2EPxMSZ<max\_pkt>. The EP FIFOs of UDC2 only support even numbers of bytes. It is therefore recommended that MSP be set as an even number of bytes as a general rule.

When using MPS by odd bytes, it is possible to make <max\_pkt> into odd number. However, there are restrictions shown in Table 13-6 by the access method of a bus. In the case of EP direct access, an odd number cannot be set in <max\_pkt> for a transmit EP. In this case, an even number should be set in <max\_pkt> and write accesses to the EP FIFO should be controlled to implement an odd number of maximum write bytes. (For example, when MPS is 1023 bytes, <max\_pkt> should be set to 1024 bytes.)

#### Table 13-6 Restrictions on the setting of max\_pkt

	Receive EP	Transmit EP	
Common bus access (PVCI-IF)	An odd or even number can be set	An odd or even number can be set	
EP direct access (EP-I/F)	An odd or even number can be set	Only an even number can be set.	

Based on the above, the following pages describe how to set an odd number of bytes as MPS for each bus access method.

#### (1) Receive EP and common bus access

Either an odd or even number of bytes can be set in <max\_pkt>. The access method is the same for both cases.

#### (2) Transmit EP and common bus access

Either an odd or even number of bytes can be set in <max\_pkt>.

However, the following points must be observed in making common bus accesses for writing the maximum number of bytes with max\_pkt = odd number.

The following shows an example in which  $<\max_{pkt} = 5$  and the maximum number of bytes (5 bytes) are to be written.

- In the last access (5th byte), make sure that  $udc_be = 01$ .
- Because it is access of MPS, Do not issue the EP\_EOP command in the UDFS2CMD.

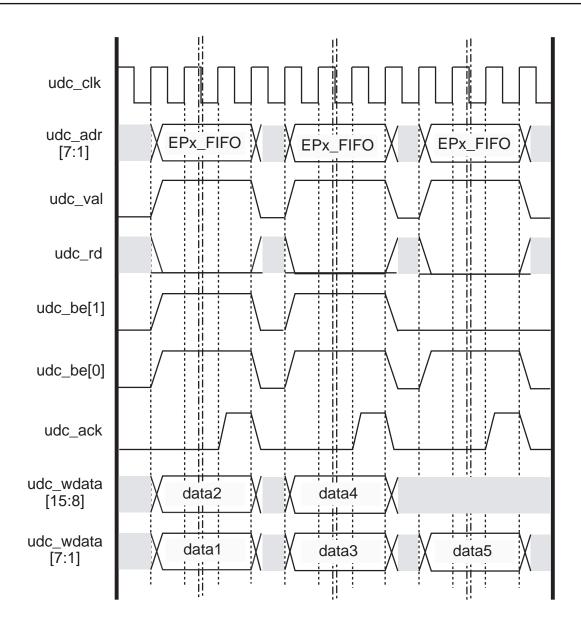

Figure 13-31 MPS write access with max\_pkt = odd number (common bus access)

(3) Receive EP and EP direct access

Either an odd or even number can be set in <max\_pkt>. The access method is the same for both cases.

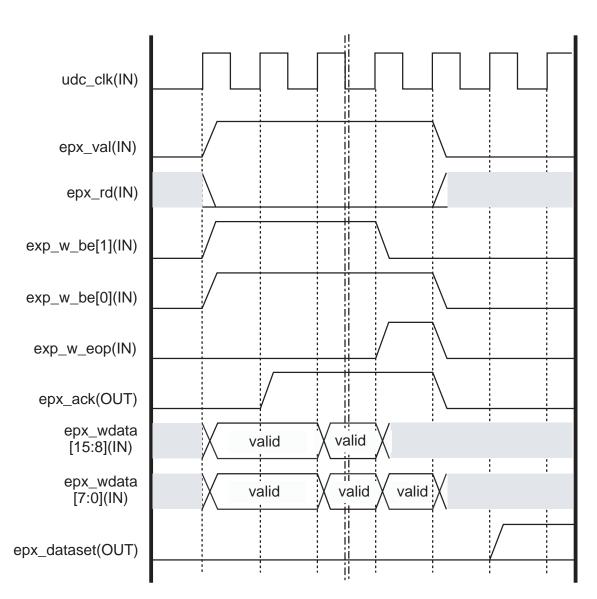

#### (4) Transmit EP and EP direst access

Only an even number of bytes can be set in <max\_pkt>. To use an odd number of bytes as MPS for a transmit EP, the following settings are required.

- When MPS is 1023
  - Set <max\_pkt> is 1024.
  - The maximum number of bytes that can be written to the EP is 1023 bytes. (It is not allowed to write the 1024th byte.)
  - "wMaxPacketSize" of the EP descriptor to be managed by firmware should be set to 1023. (This is the value to be sent to the USB host by the Get Descriptor request.)

The following shows an example in which  $max_pkt = 1024$  and the maximum number of bytes (1023 bytes) are to be written.

## TOSHIBA

- In the last access (1023rd byte), make sure that  $epx_w_be = 01$ .

Figure 13-32 MPS (odd number) write access with max\_pkt = even number (EP direct access)

#### 13.9.3 Appendix C Isochronous Translator

In Isochronous transfers, the isochronism of data is critical and transfers occur per frame. Therefore, accesses to an EP (FIFO) using Isochronous transfers require a certain level of performance (speed). In UDC2, the access method to each EP can be selected from PVCI-I/F and EP-I/F. The FIFO configuration can be selected from Single mode and Dual mode. However, for an EP using Isochronous transfers, it is recommended to use EP-IF and Dual mode.

#### 13.9.3.1 Accessing an EP using Isochronous transfer

The maximum data payload size is 1023 bytes in FS mode. To transfer 1023 bytes using Dual mode, 2048 bytes of RAM are required. Transfers are performed per frame (1 ms) in FS mode. In FS mode, One transactions can be made in one frame.

(Information such as the payload size and the number of transactions must be set in the relevant UDC2 register. This information must also be managed by software as the EP descriptor information to be sent to the host.)

#### 13.9.3.2 Restrictions on command usage to EP when using Isochronous transfer

Compared to other transfers, Isochronous transfers have certain restrictions on handshake, toggle, the number of transactions in a frame, etc., limiting the types of commands that can be used. As a general rule, commands must not be issued to EPs during Isochronous transfers. While a request is being processed, the EP\_Reset or EP\_Invalid command may be used as necessary.

(When using PVCI-I/F as the EP access method, use the EP\_EOP command.)

(About the Appendix)

For descriptions concerning the USB Specification, be sure to check the USB Specification (revision 2.0).

## TOSHIBA

## 14. Serial Channel (SIO/UART)

### 14.1 Overview

This device has two mode for the serial channel, one is the synchronous communication mode (I/O interface mode), and the other is the asynchronous communication mode (UART mode).

Their features are given in the following.

- Transfer Clock
  - Dividing by the prescaler, from the peripheral clock ( $\varphi$ T0) frequency into 1/2, 1/8, 1/32, 1/128.
  - Make it possible to divide from the prescaler output clock frequency into 1-16.
  - Make it possible to divide from the prescaler output clock frequency into 1, N+m/16 (N=2-15, m=1-15), 16. (only UART mode)
  - The usable system clock (only UART mode).
- Double Buffer /FIFO

The usable double buffer function, and the usable FIFO buffers of transmit and receive in all for maximum 4-byte.

- I/O Interface Mode
  - Transfer Mode: the half duplex (transmit/receive), the full duplex
  - Clock: Output (fixed rising edge) /Input (selectable rising/falling edge)
  - Make it possible to specify the interval time of continuous transmission.
- UART Mode
  - Data length: 7 bits, 8bits, 9bits
  - Add parity bit (to be against 9bits data length)
  - Serial links to use wake-up function
  - Handshaking function with  $\overline{\text{CTS}}$  pin

In the following explanation, "x" represents channel number.

### 14.2 Difference in the Specifications of SIO Modules

TMPM365FYXBG has two SIO channels.

Each channel functions independently. The used pins, interrupt, DMA request and UART source clock in each channel are collected in the following.

	Pin name			Inte	rrupt			
	TXD	RXD CTSx/ SCLKx		Receive Interrupt	Transmit Interrupt	DMA request	UART source clock	
Channel 0	PE0	PE1	PE2	INTRX0	INTTX0	Support	TB8OUT	
Channel 1	PC0	PC1	PC2	INTRX1	INTTX1	Support	TB8OUT	

### 14.3 Configuration

Figure 14-1 shows SIO block diagram.

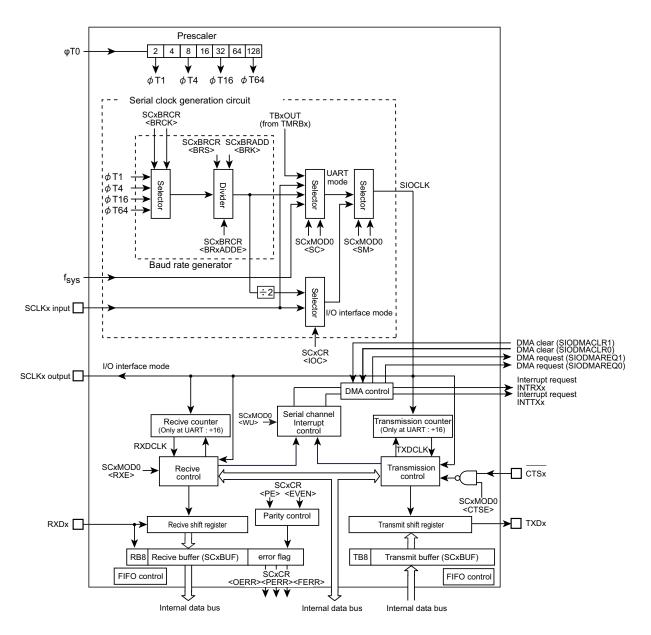

Figure 14-1 SIO Block Diagram

## TOSHIBA

### 14.4 Registers Description

### 14.4.1 Registers List in Each Channel

The each channel registers and addresses are shown below.

Channel x	Base Address		
Channel0	0x400E_1000		
Channel1	0x400E_1100		

Register name (x=0 to 1)		Address (Base+)			
Enable register	SCxEN	0x0000			
Buffer register	SCxBUF	0x0004			
Control register	SCxCR	0x0008			
Mode control register 0	SCxMOD0	0x000C			
Baud rate generator control register	SCxBRCR	0x0010			
Baud rate generator control register 2	SCxBRADD	0x0014			
Mode control register 1	SCxMOD1	0x0018			
Mode control register 2	SCxMOD2	0x001C			
RX FIFO configuration register	SCxRFC	0x0020			
TX FIFO configuration register	SCxTFC	0x0024			
RX FIFO status register	SCxRST	0x0028			
TX FIFO status register	SCxTST	0x002C			
FIFO configuration register	SCxFCNF	0x0030			
DMA request enable register	SCxDMA	0x0034			

Note 1: Do not modify any control register when data is being transmitted or received.

#### 14.4 Registers Description

	31	30	29	28	27	26	25	24
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	23	22	21	20	19	18	17	16
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	7	6	5	4	3	2	1	0
bit symbol	-	-	-	-	-	-	-	SIOE
After reset	0	0	0	0	0	0	0	0

### 14.4.2 SCxEN (Enable Register)

Bit	Bit Symbol	Туре	Function
31-1	-	R	Read as 0.
0	SIOE	R/W	SIO operation
			0: Disabled
			1: Enabled
			Specified the SIO operation.
			To use the SIO, set <sioe> = "1".</sioe>
			When the operation is disabled, no clock is supplied to the other registers in the SIO module. This can reduce the power consumption.
			If the SIO operation is executed and then disabled, the settings will be maintained in each register except for SCxTFC <til>.</til>

Note: In case that SCxEN<SIOE>="0" (Stop SIO operation) or the operation mode is changed to IDLE mode with SCxMOD1<I2SC>="0" (Stop SIO operation in IDLE mode), SCxTFC is initialized again.

### 14.4.3 SCxBUF (Buffer Register)

SCxBUF works as a transmit buffer or FIFO for write operation and as a receive buffer or FIFO for read operation.

	31	30	29	28	27	26	25	24	
bit symbol	-	-	-	-	-	-	-	-	
After reset	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	7	6	5	4	3	2	1	0
bit symbol	RB8	EVEN	PE	OERR	PERR	FERR	SCLKS	IOC
After reset	0	0	0	0	0	0	0	0

### 14.4.4 SCxCR (Control Register)

Bit	Bit Symbol	Туре	Function
31-8	-	R	Read as 0.
7	RB8	R	Receive data bit 8 (For UART) 9th bit of the received data in the 9 bits UART mode.
6	EVEN	R/W	Parity (For UART) 0: Odd 1: Even Selects even or odd parity. "0" : odd parity, "1" : even parity. The parity bit may be used only in the 7- or 8-bit UART mode.
5	PE	R/W	Add parity (For UART) 0: Disabled 1: Enabled Controls enabling/ disabling parity. The parity bit may be used only in the 7- or 8-bit UART mode.
4	OERR	R	Overrun error flag (Note) 0: Normal operation 1: Error
3	PERR	R	Parity / Under-run error flag (Note) 0: Normal operation 1: Error
2	FERR	R	Framing error flag (Note) 0: Normal operation 1: Error
1	SCLKS	R/W	<ul> <li>Selecting input clock edge (For I/O Interface)</li> <li>Set to "0" in the clock output mode.</li> <li>0: Data in the transmit buffer is sent to TXDx pin one bit at a time on the falling edge of SCLKx.</li> <li>Data from RXDx pin isrecieved in the recieve buffer one bit at a time on the rising edge of SCLKx.</li> <li>In this case, the SCLKx starts from high level.</li> <li>1: Data in the transmit buffer is sent to TXDx pin one bit at a time on the rising edge of SCLKx.</li> <li>Data from RXDx pin isrecieved in the recieve buffer one bit at a time on the rising edge of SCLKx.</li> <li>In this case, the SCLKx starts from high level.</li> <li>1: Data from RXDx pin isrecieved in the recieve buffer one bit at a time on the falling edge of SCLKx.</li> <li>Data from RXDx pin isrecieved in the recieve buffer one bit at a time on the falling edge of SCLKx.</li> <li>In this case, the SCLKx starts from low level.</li> </ul>
0	IOC	R/W	Selecting clock (For I/O Interface) 0: Baud rate generator 1: SCLK pin input

#### Note: Any error flag (OERR, PERR, FERR) is cleared to "0" when read.

	31	30	29	28	27	26	25	24
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	23	22	21	20	19	18	17	16
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8

	7	6	5	4	3	2	1	0
bit symbol	TB8	CTSE	RXE	WU	S	М	S	C
After reset	0	0	0	0	0	0	0	0

### 14.4.5 SCxMOD0 (Mode Control Register 0)

Bit	Bit Symbol	Туре	Function
31-8	-	R	Read as 0.
7	TB8	R/W	Transmit data bit 8 (For UART)
			Writes the 9th bit of transmit data in the 9 bits UART mode.
6	CTSE	R/W	Handshake function control (For UART)
			0: CTS disabled
			1: CTS enabled
			Controls handshake function.
			Setting "1" enables handshake function using CTS pin.
5	RXE	R/W	Receive control (Note)
			0: Disabled
			1: Enabled
4	WU	R/W	Wake-up function (For UART)
			0: Disabled
			1: Enabled
			This function is available only at 9-bit UART mode. In other mode, this function has no meaning.
			In it is Enabled, Interrupt only when RB9 = "1" at 9-bit UART mode.
3-2	SM[1:0]	R/W	Specifies transfer mode.
			00: I/O interface mode
			01: 7-bit length UART mode
			10: 8-bit length UART mode
			11: 9-bit length UART mode
1-0	SC[1:0]	R/W	Serial transfer clock (For UART)
			00: Timer TB8OUT
			01: Baud rate generator
			10: Internal clock fsys
			11: External clock (SCLK input)
			(As for the I/O interface mode, the serial transfer clock can be set in the control register (SCxCR).

Note:With <RXE> set to "0", set each mode register (SCxMOD0, SCxMOD1 and SCxMOD2). Then set <RXE> to "1".

Note:Do not stop the receive operation (by setting SCxMOD0<RXE> = "0") when data is being received.

14.4 Registers Description

	31	30	29	28	27	26	25	24
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	23	22	21	20	19	18	17	16
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0

After reset	0	0	0	0	0	0	0	0

### 14.4.6 SCxMOD1 (Mode Control Register 1)

Bit	Bit Symbol	Туре	Function
31-8	-	R	Read as 0.
7	I2SC	R/W	IDLE
			0: Stop
			1: Operate Specifies the IDLE mode operation.
6-5	FDPX[1:0]	R/W	Transfer mode setting
			00: Transfer prohibited
			01: Half duplex (Receive)
			10: Half duplex (Transmit)
			11: Full duplex
			Configures the transfer mode in the I/O interface mode. Also configures the FIFO if it is enabled.
			In the UART mode, it is used only to specify the FIFO configuration.
4	TXE	R/W	Transmit control (Note2)
			0 :Disabled
			1: Enabled
		ļ	This bit enables transmission and is valid for all the transfer modes.
3-1	SINT[2:0]	R/W	Interval time of continuous transmission (For I/O interface)
			000: None
			001: 1SCLK
			010: 2SCLK
			011: 4SCLK
			100: 8SCLK
			101: 16SCLK
			110: 32SCLK
			111: 64SCLK
			This parameter is valid only for the I/O interface mode when SCLK pin output is selected. In other modes, this function has no meaning.
			Specifies the interval time of continuous transmission when double buffering or FIFO is enabled in the I/O in- terface mode.
0	-	R/W	Write a "0".

Note 1: Specify the all mode first and then enable the <TXE> bit.

- Note 2: Do not stop the transmit operation (by setting <TXE> = "0") when data is being transmitted.
- Note 3: In case that SCxEN<SIOE>="0" (Stop SIO operation) or the operation mode is changed to IDLE mode with SCxMOD1<I2SC>="0" (Stop SIO operation in IDLE mode), SCxTFC is initialized again.

### 14.4.7 SCxMOD2 (Mode Control Register 2)

Bit	Bit Symbol	Туре			Function				
31-8	-	R	Read as 0.						
7	TBEMP	R	Transmit buffer empt	y flag.					
			0: Full						
			1: Empty If double buffering is disabled, this flag is insignificant.						
			, s						
					ble buffers are empty. When data in the transmit don't do the double buffers are empty, this bit is set to "1				
			Writing data again to	the double buffe	rs sets this bit to "0".				
6	RBFLL	R	Receive buffer full fla	ıg.					
			0: Empty						
			1: Full						
			This is a flag to show	v that the receive	double buffers are full.				
					d and received data is moved from the receive shi to "1" while reading this bit changes it to "0".	ft register to the re-			
			If double buffering is	disabled, this flag	g is insignificant.				
5	TXRUN	R	In transmission flag						
			0: Stop						
			1: Operate						
			This is a status flag	o show that data	transmission is in progress.				
			<txrun> and <tbe< td=""><td>MP&gt; bits indicate</td><td>the following status.</td><td></td></tbe<></txrun>	MP> bits indicate	the following status.				
			<txrun></txrun>	<tbemp></tbemp>	Status				
			1	-	Transmission in progress				
			0	1	Transmission completed				
			0	0	Wait state with data in Transmit buffer				
4	SBLEN	R/W	STOP bit (for UART)						
			0 : 1-bit						
			1 : 2-bit						
			· ·	•	on stop bit in the UART mode.				
			On the receive side,	the decision is m	ade using only a single bit regardless of the <sbl< td=""><td>EN&gt; setting.</td></sbl<>	EN> setting.			
3	DRCHG	R/W	Setting transfer direc	Setting transfer direction					
			0: LSB first						
			1: MSB first						
					in the I/O interface mode.				
			In the UART mode, s	set this bit to LSB	first.				

Bit	Bit Symbol	Туре		Function				
2	WBUF	R/W	Double-buffer 0: Disabled 1 : Enabled This parameter enables or disables the transmit/receive double buffers to transmit (in both SCLK output/in- put modes) and receive (in SCLK output mode) data in the I/O interface mode and to transmit data in the UART mode. When receiving data in the I/O interface mode (SCLK input) and UART mode, double buffering is enabled in both cases that 0 or 1 is set to <wbuf> bit.</wbuf>					
1-0	SWRST[1:0]	R/W		ace of "10" generates a software reset. When d and the transmit/receive circuit, the transmit s2).				
			Register	Bit				
			SCxMOD0	<rxe></rxe>				
			SCxMOD1	<txe></txe>				
			SCxMOD2 <tbemp>, <rbfll>, <txrun></txrun></rbfll></tbemp>					
			SCxCR <oerr>, <perr>, <ferr></ferr></perr></oerr>					
			SCxDMA (note2)	<dmaen1>, <dmaen0></dmaen0></dmaen1>				

Note 1: While data transmission is in progress, any software reset operation must be executed twice in succession.

Note 2: A software reset requires 2 clocks-duration at the time between the end of recognition and the start of execution of software reset instruction.

# 14.4.8 SCxBRCR (Baud Rate Generator Control Register), SCxBRADD (Baud Rate Generator Control Register 2)

The division ratio of the baud rate generator can be specified in the registers shown below.

SCxBRCR		-		-			-	
	31	30	29	28	27	26	25	24

Bit	Bit Symbol	Туре	Function
31-4	-	R	Read as 0.
3-0	BRK[3:0]	R/W	Specify K for the "N + (16 - K)/16" division (For UART) 0000: Prohibited 0001: K = 1 0010: K = 2  1111: K = 15

Table 14-2 lists the settings of baud rate generator division ratio.

#### Table 14-2 Setting division ratio

	<bradde> = "0"</bradde>	<bradde> = "1" (Note1) (Only UART mode)</bradde>
<brs></brs>	Specify "I	N" (Note2) (Note3)
<brk></brk>	No setting required	Specify "K" (Note4)
Division ratio	Divide by N	$N + \frac{(16 - K)}{16}$ division.

- Note 1: To use the "N + (16 K)/16" division function, be sure to set <BRADDE> to "1" after setting the K value to <BRK>. The "N + (16 K)/16" division function can only be used in the UART mode.
- Note 2: As a division ratio, 1 ("0001") or 16 ("0000") can not be applied to N when using the "N + (16 K)/ 16" division function in the UART mode.
- Note 3: The division ratio "1" of the baud rate generator can be specified only when the double buffering is used in the I/O interface mode.
- Note 4: Specifying "K = 0" is prohibited.

### 14.4.9 SCxFCNF (FIFO Configuration Register)

Bit	Bit Symbol	Туре		Function					
31-8	-	R	Read as 0						
7-5	-	R/W	Be sure to write "000"						
4	RFST	R/W	Bytes used in RX FIF	-0					
			0:Maximum						
			1:Same as FILL level	l of RX FIFO					
				abled, the number of RX FIFO bytes to					
				ber of bytes of the FIFO configured (see	·				
				vel for receive interrupt generation specif	fied by SCxRFC <ril[1:0]></ril[1:0]>				
3	TFIE	R/W	TX interrupt for TX F	IFO					
			0: Disabled						
			1:Enabled						
				abled, transmit interrupts are enabled or	disabled by this parameter.				
2	RFIE	R/W	RX interrupt for RX F	·IFO					
			0: Disabled						
				1:Enabled					
1	RXTXCNT	R/W		When RX FIFO is enabled, receive interrupts are enabled or disabled by this parameter. Automatic disable of RXE/TXE					
'		10.00	0: None						
			1: Auto disabled						
			Controls automatic di	isabling of transmission and reception.					
			Setting "1" enables to	o operate as follows					
			Half duplex RX	When receive shift register, the receive SCxMOD0 <rxe> is automatically set t</rxe>					
			Half duplex TX	When the TX FIFO, the transmit buffer SCxMOD1 <txe> is automatically set t</txe>	and the transmit shift register is empty, o "0" to inhibit further transmission.				
			Full duplex	When either of the above two condition ly set to "0" to inhibit further transmissi	ns is satisfied, TXE/RXE are automatical- on and reception.				
0	CNFG	R/W	Enables FIFO.						
			0: Disabled						
			1: Enabled						
			If enabled, the SCxMOD1 <fdpx[1:0]> setting automatically configures FIFO as follows:</fdpx[1:0]>						
				(The type of TX/RX can be specified in the mode control register 1 SCxMOD1 <fdpx[1:0]>).</fdpx[1:0]>					
			Half duplex RX	RX FIFO 4byte					
			Half duplex TX	TX FIFO 4byte					
			Full duplex	RX FIFO 2byte + TX FIFO 2byte					

Note 1: Regarding TX FIFO, the maximum number of bytes being configured is always available. The available number of bytes is the bytes already written to the TX FIFO.

Note 2: The FIFO can not use in 9bit UART mode.

### 14.4.11 SCxTFC (TX FIFO Configuration Register) (Note2)

Bit	Bit Symbol	Туре				Function						
31-8	-	R	Read as 0.	Read as 0.								
7	TFCS	w	TX FIFO cle	ear (Note 1)								
			1: Clears TX	k FIFO.								
				ST <tfcs> is set inter is initialized.</tfcs>	to "1", the transm	it FIFO is cleared and SCxTST <tlvl> is "000". And also</tlvl>						
6	TFIS	R/W	Selects inter	rrupt generation co	ondition.							
			0: An interru	upt is generated wh	hen the data reac	hes to the specified fill level.						
				upt is generated where the level at the time n		hes to the specified fill level or the data can not reach the						
5-2	-	R	Read as 0.									
1-0	TIL[1:0]	R/W	Selects FIF	O fill level.								
				Other than full duplex	Full duplex							
			00	Empty	Empty							
			01	1 byte	1 byte							
			10	2 byte	Empty							
			11	3 byte	1 byte							

Note 1: To use TX/RX FIFO buffer, TX/RX FIFO must be cleared after setting the SIO transfer mode (half duplex/ full duplex) and enabling FIFO (SCxFCNF<CNFG> = "1").

Note 2: After you perform the following operations, configure the SCxTFC register again.

SCxEN<SIOE> = "0" (SIO operation stop)

Conditions are as follows:SCxMOD1<I2SC> = "0" (operation is prohibited in IDLE mode) and releasing the low power consumption mode which started by the WFI (Wait For Interrupt) instruction.

#### 14.4 Registers Description

### 14.4.12 SCxRST (RX FIFO Status Register)

	0	0	0	0	0	0	0	0

### 14.4.14 SCxDMA (DMA request enable register)

Bit	Bit Symbol	Туре	Function
31-2	-	R	Read as 0.
1	DMAEN1	R/W	Enable DMA request. DMA request is generated by receive interrupt INTRX. 0: disable 1: enable
0	DMAEN0	R/W	Enable DMA request. DMA request is generated by receive interrupt INTTX. 0: disable 1: enable

Note 1: When DMA request is generated during DMA transfer is being, it is not kept and nesting.

### 14.5 Operation in Each Mode

Table 14-3 shows the modes and data formats.

#### Table 14-3 Mode and Data format

Mode	Mode type	Data length	Transfer direction	Specifies whether to use parity bits.	STOP bit length (transmit)	
Mode 0	Synchronous communication mode (IO interface mode)	8 bit	LSB first/MSB first	-	-	
Mode 1	Asynchronous communica-	7 bit		0		
Mode 2	tion mode	8 bit	LSB first	0	1 bit or 2 bit	
Mode 3	(UART mode)	9 bit		×		

Mode 0 is a synchronous communication and can be used to extend I/O. This mode transmits and receives data in synchronization with SCLK. SCLK can be used for both input and output.

The direction of data transfer can be selected from LSB first and MSB first. This mode is not allowed either to use parity bits or STOP bits.

The mode 1, mode 2 and mode 3 are asynchronous modes and the transfer direction is fixed to the LSB first.

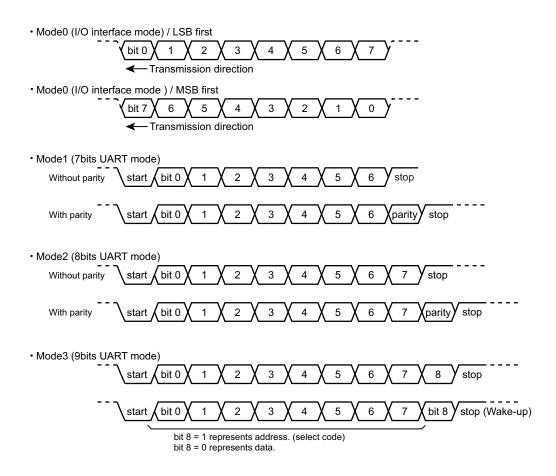

Parity bits can be added in the mode 1 and mode 2. The mode 3 has a wakeup function in which the master controller can start up slave controllers via the serial link (multi-controller system).

STOP bit in transmission can be selected from 1 bit and 2 bits. The STOP bit length in reception is fixed to a one bit.

### 14.6 Data Format

### 14.6.1 Data Format List

Figure 14-2 shows data format.

#### 14.6.2 Parity Control

The parity bit can be added only in the 7- or 8-bit UART mode.

Setting "1" to SCxCR<PE> enables the parity.

The <EVEN> bit of SCxCR selects either even or odd parity.

#### 14.6.2.1 Transmission

Upon data transmission, the parity control circuit automatically generates the parity with the data in the transmit buffer.

After data transmission is complete, the parity bit will be stored in SCxBUF<TB7> in the 7-bit UART mode and SCxMOD<TB8> in the 8-bit UART mode.

The <PE> and <EVEN> settings must be completed before data is written to the transmit buffer.

#### 14.6.2.2 Receiving Data

If the received data is moved from the receive shift register to the receive buffer, a parity is generated.

In the 7-bit UART mode, the generated parity is compared with the parity stored in SCxBUF<RB7>, while in the 8-bit UART mode, it is compared with the one in SCxCR<RB8>.

If there is any difference, a parity error occurs and the <PERR> of the SCxCR register is set to "1".

In use of the FIFO, <RERR> indicates that a parity error was generated in one of the received data.

#### 14.6.3 STOP Bit Length

The length of the STOP bit in the UART transmission mode can be selected from one bit or two bits by setting the SCxMOD2<SBLEN>. The length of the STOP bit data is determined as one-bit when it is received regardless of the setting of this bit.

### 14.7 Clock Control

#### 14.7.1 Prescaler

There is a 7-bit prescaler to divide a prescaler input clock  $\Phi$ T0 by 2, 8, 32 and 128.

Use the CGSYSCR register in the clock/mode control block to select the input clock  $\Phi$ T0 of the prescaler.

The prescaler becomes active only when the baud rate generator is selected as a transfer clock by SCxMOD0 < SC[1:0] > = "01".

The below tables show the resolution of the input clock to the baud rate generator.

Table 14-4 Clock Resolution to the Baud Rate Generator fc = 40 MHz

peripheral clock	Clock gear	Prescaler clock se-		Prescaler output	clock resolution

#### Table 14-5 Clock Resolution to the Baud Rate Generator fc = 48 MHz

Note 1: The prescaler output clock  $\phi$ Tn must be selected so that the relationship " $\phi$ Tn  $\leq$  fsys / 2" is satisfied (so that  $\phi$ Tn is slower than fsys / 2).

Note 2: Do not change the clock gear while SIO is operating.

Note 3: The dashes in the above table indicate that the setting is prohibited.

#### 14.7.2 Serial Clock Generation Circuit

The serial clock circuit is a block to generate transmit and receive clocks (SIOCLK) and consists of the circuits in which clocks can be selected by the settings of the baud rates generator and modes.

#### 14.7.2.1 Baud Rate Generator

The baud rate generator generates transmit and receive clocks to determine the serial channel transfer rate.

#### (1) Baud Rate Generator input clock

The input clock of the baud rate generator is selected from the prescaler outputs divided by 2, 8, 32 and 128.

This input clock is selected by setting the SCxBRCR<BRCK>.

#### (2) Baud Rate Generator output clock

The frequency division ratio of the output clock in the baud rate generator is set by SCxBRCR and SCxBRADD.

The following frequency divide ratios can be used; 1/N frequency division in the I/O interface mode ,either 1/N or N + (16-K)/16 in the UART mode.

The table below shows the frequency division ratio which can be selected.

Mode	Divide Function Setting SCxBRCR <bradde></bradde>	Divide by N SCxBRCR <brs></brs>	Divide by K SCxBRADD <brk></brk>
I/O interface	Divide by N	1 to 16 (Note)	-
LUNDT	Divide by N	1 to 16	-
UART	N + (16-K)/16 division	2 to 15	1 to 15

Note: 1/N (N=1)frequency division ratio can be used only when a double buffer is enabled.

#### 14.7.2.2 Clock Selection Circuit

A clock can be selected by setting the modes and the register.

Modes can be specified by setting the SCxMOD0<SM>.

The input clock in I/O interface mode is selected by setting SCxCR. The clock in UART mode is selected by setting SCxMOD0<SC>.

#### (1) Transfer Clock in I/O interface mode

Table 14-6 shows clock selection in I/O interface mode.

#### Table 14-6 Clock Selection in I/O Interface Mode

Mode SCxMOD0 <sm></sm>	Input/Output selection SCxCR <ioc></ioc>	Clock edge selection SCxCR <sclks></sclks>	Clock of use
	SCLK output	Set to "0". (Fixed to the rising edge)	Divided by 2 of the baud rate gen- erator output.
I/O interface mode		Rising edge	SCLK input rising edge
	SCLK input	Falling edge	SCLK input falling edge

To get the highest baud rate, the baud rate generator must be set as below.

Note: When deciding clock settings, make sure that AC electrical character is satisfied.

- <u>Clock/mode control block settings</u>
  - fc = 40MHz
  - fgear = 40MHz (CGSYSCR<GEAR[2:0]> = "000" : fc selected)
  - φT0 = 40MHz (CGSYSCR<PRCK[2:0]> = "000" : 1 division ratio)
- SIO settings (if double buffer is used)
  - Clock (SCxBRCR<BRCK[1:0]> = "00" : φT1 selected) = 20MHz
  - Divided clock frequency (SCxBRCR<BRS[3:0]> = "0001" : 1 division ratio) = 20MHz

1 division ratio can be selected if double buffer is used. In this case, baud rate is 10Mbps because 20MHz is divided by 2.

- <u>SIO settings (if double buffer is not used)</u>
  - Clock (SCxBRCR<BRCK[1:0]> = "00" :  $\phi$ T1 selected) = 20MHz
  - Divided clock frequency (SCxBRCR<BRS[3:0]> = "0010" : 2 division ratio) = 10MHz

2 division ratio is the highest if double buffer is not used. In this case, baud rate is 5Mbps because 10MHz is divided by 2.

To use SCLK input, the following conditions must be satisfied.

- If double buffer is used
  - SCLK cycle > 6/fsys

The highest baud rate is less than  $48 \div 6 = 8$  Mbps.

• If double buffer is not used

- SCLK cycle > 8/fsys

The highest baud rate is less than  $48 \div 8 = 6$  Mbps.

#### (2) Transfer clock in the UART mode

Table 14-7 shows the clock selection in the UART mode. In the UART mode, selected clock is divided by 16 in the receive counter or the transmit counter before use.

Mode SCxMOD0 <sm></sm>	Clock selection SCxMOD0 <sc></sc>
UART Mode	Timer output
	Baud rate generator
	fsys
	SCLK input

Table 14-7 Clock Selection in UART Mode

The examples of baud rate in each clock settings.

- If the baud rate generator is used
  - fc = 40MHz
  - fgear = 40MHz (CGSYSCR<GEAR[2:0]> = "000" : fc selected)
  - $\phi$ T0 = 40MHz (CGSYSCR<PRCK[2:0]> = "000" : 1 division ratio)
  - Clock =  $\Phi$ T1 = 20MHz (SCxBRCR<BRCK[1:0]> = "00" :  $\phi$ T1 selected)

The highest baud rate is 1.25Mbps because 20MHz is divided by 16.

Table 14-8 shows examples of baud rate when the baud rate generator is used with the following clock settings.

- fc = 9.8304 MHz
- fgear = 9.8304MHz (CGSYSCR<GEAR[2:0]> = "000" : fc selected)
- $\phi$ T0 = 4.9152MHz (CGSYSCR<PRCK[2:0]> = "001" : 2 division ratio)

Table 14-8 Example of UART Mode Baud Rate (Using the Baud Rate Generator)

fc [MHz]	Division ratio N (SCxBRCR <brs>)</brs>	φT1 (fc/4)	φT4 (fc/16)	φT16 (fc/64)	φT64 (fc/256)
9.830400	2	76.800	19.200	4.800	1.200
	4	38.400	9.600	2.400	0.600
	8	19.200	4.800	1.200	0.300
	16	9.600	2.400	0.600	0.150

Unit : kbps

If the SCLK input is used

To use SCLK input, the following conditions must be satisfied.

- SCLK cycle > 2/fsys

The highest baud rate must be less than  $48 \div 2 \div 16 = 1.5$  Mbps.

If fsys is used

Since the highest value of fsys is 48MHz, the highest baud rate is  $48 \div 16 = 3$ Mbps.

#### If timer output is used

To enable the timer output, the following condition must be set: a timer flip-flop output inverts when the value of the counter and that of TBxRG1 match. The SIOCLK clock frequency is "Setting value of TBxRG1  $\times$  2".

Baud rates can be obtained by using the following formula.

#### Baud rate calculation

•

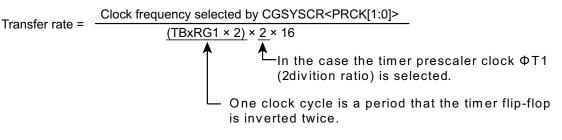

Table 14-9 shows the examples of baud rates when the timer output is used with the following clock settings.

- fc = 32MHz / 9.8304MHz / 8MHz
- fgear = 32MHz / 9.8304MHz / 8MHz (CGSYSCR<GEAR[2:0]> = "000" : fc selected)
- φT0 = 16MHz / 4.9152MHz / 4MHz (CGSYSCR<PRCK[2:0]> = "001" : 2 division ratio)
- Timer count clock = 4MHz / 1.2287MHz / 1MHz (TBxMOD<TBCLK[1:0]> = "01" : φT1 selected)

		fc				
TBxRG0 setting	32MHz	9.8304MHz	8MHz			
0x0001	250	76.8	62.5			
0x0002	125	38.4	31.25

### 14.8 Transmit/Receive Buffer and FIFO

#### 14.8.1 Configuration

Figure 14-3 shows the configuration of transmit buffer, receive buffer and FIFO.

Appropriate settings are required for using buffer and FIFO. The configuration may be predefined depending on the mode.

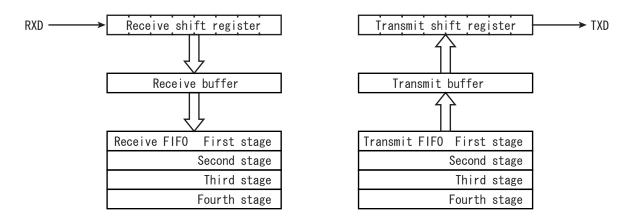

Figure 14-3 The Configuration of Buffer and FIFO

#### 14.8.2 Transmit/Receive Buffer

Transmit buffer and receive buffer are double-buffered. The buffer configuration is specified by SCxMOD2<WBUF>.

In the case of using a receive buffer, if SCLK input is set to generate clock output in the I/O interface mode or the UART mode is selected, it's double buffered despite the <WBUF> settings. In other modes, it's according to the <WBUF> settings.

Table 14-10 shows correlation between modes and buffers.

Mate	SCxMOD2 <wbuf></wbuf>		
Mode	"0"	"1"	
UART	Transmit	Single	Double
	Receive	Double	Double
I/O interface	Transmit	Single	Double
(SCLK input)	Receive	Double	Double
I/O interface	Transmit	Single	Double
(SCLK output)	Receive	Single	Double

Table 14-10 Mode and buffer Composition

#### 14.8.3 FIFO

In addition to the double buffer function above described, 4-byte FIFO can be used.

To enable FIFO, enable the double buffer by setting SCxMOD2<WBUF> to "1" and SCxFCNF<CNFG> to "1". The FIFO buffer configuration is specified by SCxMOD1<FDPX[1:0]>.

Note:To use TX/RX FIFO buffer, TX/RX FIFO must be cleared after setting the SIO transfer mode (half duplex/full duplex) and enabling FIFO (SCxFCNF<CNFG> = "1").

Table 14-11 shows correlation between modes and FIFO.

Table 14-11 Mode and FIFO Composition

	SCxMOD1 <fdpx[1:0]></fdpx[1:0]>	RX FIFO	TX FIFO
Half duplex RX	"01"	4byte	-
Half duplex TX	"10"	-	4byte
Full duplex	"11"	2byte	2byte

### 14.9 Status Flag

The SCxMOD2 register has two types of flag. This bit is significant only when the double buffer is enabled.

<RBFLL> is a flag to show that the receive buffer is full. When one frame of data is received and the data is moved from the receive shift register to the receive buffers, this bit changes to "1" while reading this bit changes it to "0".

<TBEMP> shows that the transmit buffers are empty. When data in the transmit buffers is moved to the transmit shift register, this bit is set to "1" When data is set to the transmit buffers, the bit is cleared to "0".

### 14.10 Error Flag

Three error flags are provided in the SCxCR register. The meaning of the flags is changed depending on the modes. The table below shows the meanings in each mode.

These flags are cleared to "0" after reading the SCxCR register.

Mode	Flag							
Mode	<oerr></oerr>	<perr></perr>	<ferr></ferr>					
UART	Overrun error	Parity error	Framing error					
I/O Interface	Overrun error	Underrun error (When using double buffer or FIFO)	Find to 0					
(SCLK input)	Ovenun enor	Fixed to 0 (When a double buffer and FIFO unused)	Fixed to 0					
I/O Interface (SCLK output)	Undefined	Undefined	Fixed to 0					

#### 14.10.1 OERR Flag

In both UART and I/O interface modes, this bit is set to "1" when an error is generated by completing the reception of the next frame of receive data before the receive buffer has been read. If the receive FIFO is enabled, the received data is automatically moved to the receive FIFO and no overrun error will be generated until the receive FIFO is full (or until the usable bytes are fully occupied).

In the I/O interface with SCLK output mode, the SCLK output stops upon setting the flag.

Note:To switch the I/O interface SCLK output mode to other modes, read the SCxCR register and clear the overrun flag.

#### 14.10.2 PERR Flag

This flag indicates a parity error in the UART mode and an under-run error in the I/O interface mode.

In the UART mode, <PERR> is set to "1" when the parity generated from the received data is different from the parity received.

In the I/O interface mode, <PERR> is set to "1" under the following conditions when a double buffer is enabled.

In the SCLK input mode, <PERR> is set to "1" when the SCLK is input after completing data output of the transmit shift register with no data in the transmit buffer.

In the SCLK output mode, <PERR> is set to "1" after completing output of all data and the SCLK output stops.

Note:To switch the I/O interface SCLK output mode to other modes, read the SCxCR register and clear the under-run flag.

#### 14.10.3 FERR Flag

A framing error is generated if the corresponding stop bit is determined to be "0" by sampling the bit at around the center. Regardless of the stop bit length settings in the SCxMOD2<SBLEN>register, the stop bit status is determined by only 1.

This bit is fixed to "0" in the I/O interface mode.

#### 14.11 Receive

#### 14.11.1 Receive Counter

The receive counter is a 4-bit binary counter and is up-counted by SIOCLK. In the UART mode, sixteen SIOCLK clock pulses are used in receiving a single data bit and the data symbol is sampled at the seventh, eighth, and ninth pulses. From these three samples, majority logic is applied to decide the received data.

#### 14.11.2 Receive Control Unit

#### 14.11.2.1 I/O interface mode

In the SCLK output mode with SCxCR <IOC> set to "0", the RXD pin is sampled on the rising edge of the shift clock outputted to the SCLK pin.

In the SCLK input mode with SCxCR <IOC> set to "1", the serial receive data RXD pin is sampled on the rising or falling edge of SCLK input signal depending on the SCxCR <SCLKS> setting.

#### 14.11.2.2 UART Mode

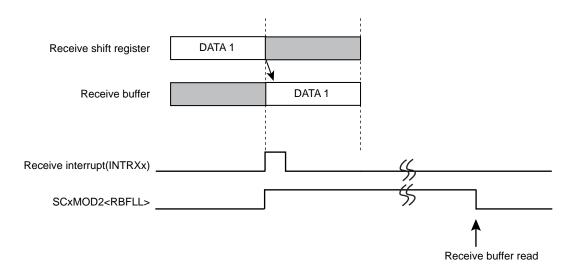

The receive control unit has a start bit detection circuit, which is used to initiate receive operation when a normal start bit is detected.

#### 14.11.3 Receive Operation

#### 14.11.3.1 Receive Buffer

The received data is stored by 1 bit in the receive shift register. When a complete set of bits has been stored, the interrupt INTRXx is generated.

When the double buffer is enabled, the data is moved to the receive buffer (SCxBUF) and the receive buffer full flag (SCxMOD2<RBFLL>) is set to "1". The receive buffer full flag is "0" cleared by reading the receive buffer.

#### Figure 14-4 Receive Buffer Operation

#### 14.11.3.2 Receive FIFO Operation

When FIFO is enabled, the received data is moved from receive buffer to receive FIFO and the receive buffer full flag is cleared immediately. An interrupt will be generated according to the SCxRFC<RIL> setting.

Note: When the data with parity bit are received in UART mode by using the FIFO, the parity error flag is shown the occurring the parity error in the received data.

The following describes configurations and operations in the half duplex RX mode.

SCxMOD1[6:5] =01	: Transfer mode is set to half duplex mode
SCxFCNF[4:0] = 10111	: Automatically inhibits continuous reception after reaching the fill level.
	: The number of bytes to be used in the receive FIFO is the same as the interrupt generation fill lev- el.
SCxRFC[1:0] = 00	: The fill level of FIFO in which generated receive interrupt is set to 4-byte.
SCxRFC[7:6] = 11	: Clears receive FIFO and sets the condition of interrupt generation.

After setting of the above FIFO configuration, the data reception is started by writing "1" to the SCxMOD0 <RXE>. When the data is stored all in the receive shift register, receive buffer and receive FIFO, SCxMOD0<RXE> is automatically cleared and the receive operation is finished.

In this above condition, if the continuous reception after reaching the fill level is enabled, and it is possible to receive a data continuously with and reading the data in the FIFO.

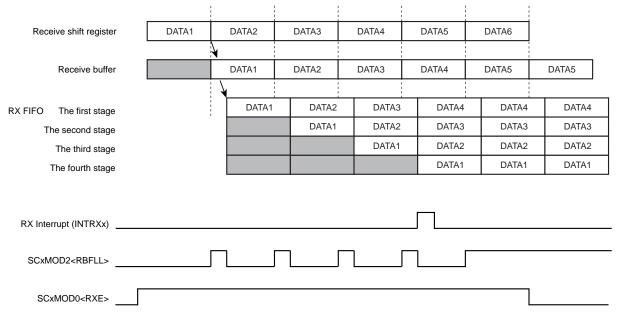

Figure 14-5 Receive FIFO Operation

## TOSHIBA

#### 14.11.3.3 I/O interface mode with SCLK output

In the I/O interface mode and SCLK output setting, SCLK output stops when all received data is stored in the receive buffer and FIFO. So, in this mode, the overrun error flag has no meaning.

The timing of SCLK output stop and re-output depends on receive buffer and FIFO.

#### (1) Case of single buffer

Stop SCLK output after receiving a data. In this mode, I/O interface can transfer each data with the transfer device by hand-shake.

When the data in a buffer is read, SCLK output is restarted.

#### (2) Case of double buffer

Stop SCLK output after receiving the data into a receive shift register and a receive buffer.

When the data is read, SCLK output is restarted.

#### (3) Case of FIFO

Stop SCLK output after receiving the data into a shift register, received buffer and FIFO.

When one byte data is read, the data in the received buffer is transferred into FIFO and the data in the receive shift register is transferred into received buffer and SCLK output is restarted.

And if SCxFCNF<RXTXCNT> is set to "1", SCLK stops and receive operation stops with clearing SCxMOD0<RXE> bit too.

#### 14.11.3.4 Read Received Data

In spite of enabling or disabling FIFO, read the received data from the receive buffer (SCxBUF).

When receive FIFO is disabled, the buffer full flag SCxMOD2<RBFLL> is cleared to "0" by this reading. In the case of the next data can be received in the receive shift register before reading a data from the receive buffer. The parity bit to be added in the 8-bit UART mode as well as the most significant bit in the 9-bit UART mode will be stored in SCxCR<RB8>.

When the receive FIFO is available, the 9-bit UART mode is prohibited because up to 8-bit data can be stored in FIFO. In the 8-bit UART mode, the parity bit is lost but parity error is determined and the result is stored in SCxCR<PERR>.

#### 14.11.3.5 Wake-up Function

In the 9-bit UART mode, the slave controller can be operated in the wake-up mode by setting the wake-up function SCxMOD0 < WU > to "1." In this case, the interrupt INTRXx will be generated only when SCxCR < RB8 > is set to "1."

#### 14.11.3.6 Overrun Error

When FIFO is disabled, the overrun error is occurred and set overrun flag without completing data read before receiving the next data. When overrun error is occurred, a content of receive buffer and SCxCR<RB8> is not lost, but a content of receive shift register is lost.

When FIFO is enabled, overrun error is occurred and set overrun flag by no reading the data before moving the next data into received buffer when FIFO is full. In this case, the content of FIFO are not lost.

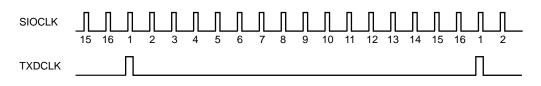

In the I/O interface mode with SCLK output setting, the clock output automatically stops, so this flag has no meaning.

Note: When the mode is changed from I/O interface SCLK output mode to the other mode, read SCxCR and clear overrun flag.

### 14.12 Transmission

#### 14.12.1 Transmission Counter

The transmit counter is a 4-bit binary counter and is counted by SIOCLK as in the case of the receive counter. In UART mode, it generates a transmit clock (TXDCLK) on every 16th clock pulse.

#### 14.12.2 Transmission Control

#### 14.12.2.1 I/O Interface Mode

In the SCLK output mode with SCxCR<IOC> set to "0", each bit of data in the transmit buffer is outputted to the TXD pin on the falling edge of the shift clock outputted from the SCLK pin.

In the SCLK input mode with SCxCR<IOC> set to "1", each bit of data in the transmit buffer is outputted to the TXD pin on the rising or falling edge of the SCLK input signal according to the SCxCR<SCLKS> setting.

#### 14.12.2.2 UART Mode

When the transmit data is written in the transmit buffer, data transmission is initiated on the rising edge of the next TXDCLK and the transmit shift clock signal is also generated.

#### 14.12.3 Transmit Operation

#### 14.12.3.1 Operation of Transmission Buffer

If double buffering is disabled, the CPU writes data only to Transmit shift Buffer and the transmit interrupt INTTXx is generated upon completion of data transmission.

If double buffering is enabled (including the case the transmit FIFO is enabled), data written to the transmit buffer is moved to the transmit shift register. The INTTXx interrupt is generated at the same time and the transmit buffer empty flag (SCxMOD2<TBEMP>) is set to "1". This flag indicates that the next transmit data can be written. When the next data is written to the transmit buffer, the <TBEMP> flag is cleared to "0".

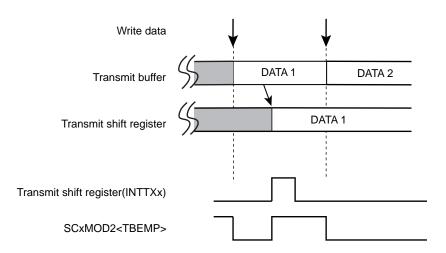

Figure 14-7 Operation of Transmission Buffer (Double-buffer is enabled)

#### 14.12.3.2 Transmit FIFO Operation

When FIFO is enabled, the maximum 5-byte data can be stored using the transmit buffer and FIFO. Once transmission is enabled, data is transferred to the transmit shift register from the transmit buffer and start transmission. If data exists in the FIFO, the data is moved to the transmit buffer immediately, and the <TBEMP> flag is cleared to "0".

#### Note:To use TX FIFO buffer, TX FIFO must be cleared after setting the SIO transfer mode (half duplex/full duplex) and enabling FIFO (SCxFCNF<CNFG> = "1").

Settings and operations to transmit 4-byte data stream by setting the transfer mode to half duplex are shown as below.

SCxMOD1[6:5] =10	: Transfer mode is set to half duplex.
SCxFCNF[4:0] = 11011	: Transmission is automatically disabled if FIFO becomes empty.
	The number of bytes to be used in the receive FIFO is the same as the interrupt
	generation fill level.
SCxTFC[1:0] = 00	: Sets the interrupt generation fill level to "0".
SCxTFC[7:6] = 11	: Clears receive FIFO and sets the condition of interrupt generation.
SCxFCNF[0] = 1	: Enable FIFO.

After above settings are configured, data transmission can be initiated by writing 5 bytes of data to the transmit buffer or FIFO, and setting the SCxMOD1<TXE> bit to "1". When the last transmit data is moved to the transmit buffer, the transmit FIFO interrupt is generated. When transmission of the last data is completed, the clock is stopped and the transmission sequence is terminated.

Once above settings are configured, if the transmission is not set as auto disabled, the transmission should lasts by writing transmit data.

Fransmit FIFO fourth stage	DATA 5					
Third stage	DATA 4	DATA 5				
Second stage	DATA 3	DATA 4	DATA 5			
First stage	DATA 2	DATA 3	DATA 4	DATA 5		
Transmit buffer	DATA 1	DATA 2	DATA 3	DATA 4	DATA 5	
Transmit shift register		DATA 1	DATA 2	DATA 3	DATA 4	DATA 5
SCxMOD1 <txe></txe>						
SCxMOD2 <tbemp></tbemp>	П	П	П			

#### 14.12.3.3 I/O interface Mode/Transmission by SCLK Output

If SCLK is set to generate clock the I/O interface mode, the SCLK output automatically stops when all data transmission is completed and underrun error will not occur.

The timing of suspension and resume of SCLK output is different depending on the buffer and FIFO usage.

#### (1) Single Buffer

TOSHIBA

The SCLK output stops each time one frame of data is transferred. Handshaking for each data with the other side of communication can be enabled. The SCLK output resumes when the next data is written in the buffer.

#### (2) Double Buffer

The SCLK output stops upon completion of data transmission of the transmit shift register and the transmit buffer. The SCLK output resumes when the next data is written in the buffer.

#### (3) FIFO

The transmission of all data stored in the transmit shift register, transmit buffer and FIFO is completed, the SCLK output stops. The next data is written, SCLK output resumes.

If SCxFCNF<RXTXCNT> is configured, SCxMOD0<TXE> bit is cleared at the same time as SCLK stop and the transmission stops.

#### 14.12.3.4 Under-run error

If the transmit FIFO is disabled in the I/O interface SCLK input mode and if no data is set in transmit buffer before the next frame clock input, which occurs upon completion of data transmission from transmit shift register, an under-run error occurs and SCxCR<PERR> is set to "1". In the I/O interface mode with SCLK output setting, the clock output automatically stops, so this flag has no meaning.

Note: Before switching the I/O interface SCLK output mode to other modes, read the SCxCR register and clear the underrun flag.

### 14.13 Handshake function

The function of the handshake is to enable frame-by-frame data transmission by using the CTS (Clear to send) pin and to prevent overrun errors. This function can be enabled or disabled by SCxMOD0<CTSE>.

When the  $\overline{\text{CTS}}$  pin is set to "High" level, the current data transmission can be completed but the next data transmission is suspended until the  $\overline{\text{CTS}}$  pin returns to the "Low" level. However in this case, the INTTXx interrupt is generated in the normal timing, the next transmit data is written in the transmit buffer, and it waits until it is ready to transmit data.

# Note: (1) If the CTS signal is set to "H" during transmission, the next data transmission is suspended after the current transmission is completed. (2) Data transmission starts on the first falling edge of the TXDCLK clock after CTS is set to "L".

Although no  $\overline{\text{RTS}}$  pin is provided, a handshake control function can easily implemented by assigning one bit of the port for the  $\overline{\text{RTS}}$  function. By setting the port to "High" level upon completion of data reception (in the receive interrupt routine), the transmit side can be requested to suspend data transmission.

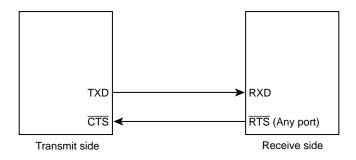

Figure 14-8 Handshake Function

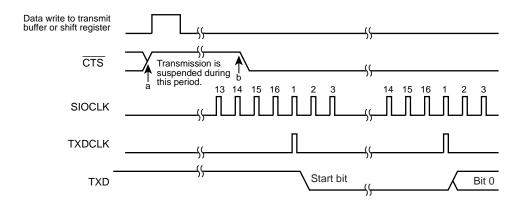

Figure 14-9 CTS Signal timing

### 14.14 Interrupt/Error Generation Timing

#### 14.14.1 RX Interrupts

Figure 14-10 shows the data flow of receive operation and the route of read.

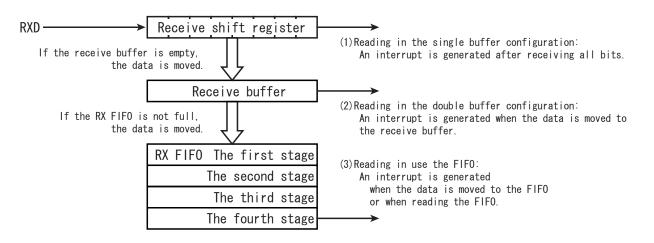

Figure 14-10 Receive Buffer/FIFO Configuration Diagram

#### 14.14.1.1 Single Buffer / Double Buffer

RX interrupts are generated at the time depends on the transfer mode and the buffer configurations, which are given as follows.

Buffer Configurations	UART modes	IO interface modes
Single Buffer	-	<ul> <li>Immediately after the raising / falling edge of the last SCLK (Rising or falling is determined according to SCxCR<sclks> setting.)</sclks></li> </ul>
Double Buffer	Around the center of the first stop bit	<ul> <li>Immediately after the raising / falling edge of the last SCLK (Rising or falling is determined according to SCxCR<sclks> setting.)</sclks></li> <li>On data transfer from the shift register to the buffer by reading buffer.</li> </ul>

Note: Interrupts are not generated when an overrun error is occurred.

#### 14.14.1.2 FIFO

In use of FIFO, receive interrupt is generated on the condition that the following either operation and SCxRFC<RFIS > setting are established.

- Reception completion of all bits of one frame.
- Reading FIFO

Interrupt conditions are decided by the SCxRFC<RFIS> settings as described in Table 14-12.

#### Table 14-12 Receive Interrupt conditions in use of FIFO

SCxRFC <rfis></rfis>	Interrupt conditions
"0"	"The fill level of FIFO" is equal to "the fill level of FIFO interruption generation."
"1"	"The fill level of FIFO" is greater than or equal to "the fill level of FIFO intrruption generation."

#### 14.14.2 TX interrupts

Figure 14-11 shows the data flow of transmit operation and the route of read.

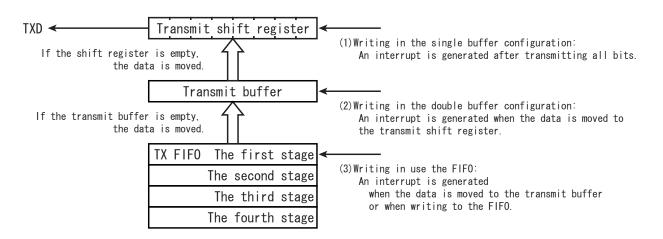

Figure 14-11 Transmit Buffer/FIFO Configuration Diagram

#### 14.14.2.1 Single Buffer / Double Buffer

TX interrupts are generated at the time depends on the transfer mode and the buffer configurations, which are given as follows.

Buffer Configurations	UART modes	IO interface modes				
Single Buffer	Just before the stop bit is sent	Immediately after the raising / falling edge of the last SCLK (Rising or falling is determined according to SCxCR <sclks> setting.)</sclks>				
Double Buffer	When a data is moved from the transmit buffet to the transmit shift register.					

Note: If double buffer is enabled, a interrupt is also generated when the data is moved from the buffer to the shift register by writing to the buffer.

#### 14.14.2.2 FIFO

In use of FIFO, transmit interrupt is generated on the condition that the following either operation and SCxTFC<TFIS> setting are established.

- Transmittion completion of all bits of one frame.
- Writing FIFO

Interrupt conditions are decided by the SCxTFC<TFIS> settings as described in Table 14-13.

Table 14-13 Transmit Interrupt conditions in use of FIFO

SCxTFC <tfis></tfis>	Interrupt conditions
"0"	"The fill level of FIFO" is equal to "the fill level of FIFO interruption generation."
"1"	"The fill level of FIFO" is smaller than or equal to "the fill level of FIFO interruption genera- tion."

#### 14.14.3 Error Generation

#### 14.14.3.1 UART Mode

modes	9 bits	7 bits 8 bits 7 bits+ Parity 8 bits + Parity		
Framing Error Overrun Error	Around the ce	nter of stop bit		
Parity Error	-	Around the center of parity bit		

#### 14.14.3.2 IO Interface Mode

Overrun Error	Immediately after the raising / falling edge of the last SCLK (Rising or falling is determined according to SCxCR <sclks> setting.)</sclks>
Underrun Error	Immediately after the rising or falling edge of the next SCLK. (Rising or falling is determined according to SCxCR <sclks> setting.)</sclks>

Note: Over-run error and Under-run error have no meaning in SCLK output mode.

### 14.15 Software Reset

Software reset is generated by writing SCxMOD2<SWRST[1:0]> as "10" followed by "01".

As a result, SCxMOD0<RXE>, SCxMOD1<TXE>, SCxMOD2<TBEMP><RBFLL><TXRUN>, SCxCR

<OERR><PERR><FERR> are initialized. And the receive circuit, the transmit circuit and the FIFO become initial state. Other states are maintained.

### 14.16 DMA request

DMA request to DMAC is generated at the timing of SIO/UART interrupt request (INTRXx, INTTXx). When DMA transfer is used, set SCxDMA (x=0, 1,).

### 14.17 Operation in Each Mode

#### 14.17.1 Mode 0 (I/O interface mode)

Mode 0 consists of two modes, the SCLK output mode to output synchronous clock and the SCLK input mode to accept synchronous clock from an external source.

The following operational descriptions are for the case use of FIFO is disabled. For details of FIFO operation, refer to the previous sections describing receive/transmit FIFO functions.

#### 14.17.1.1 Transmitting Data

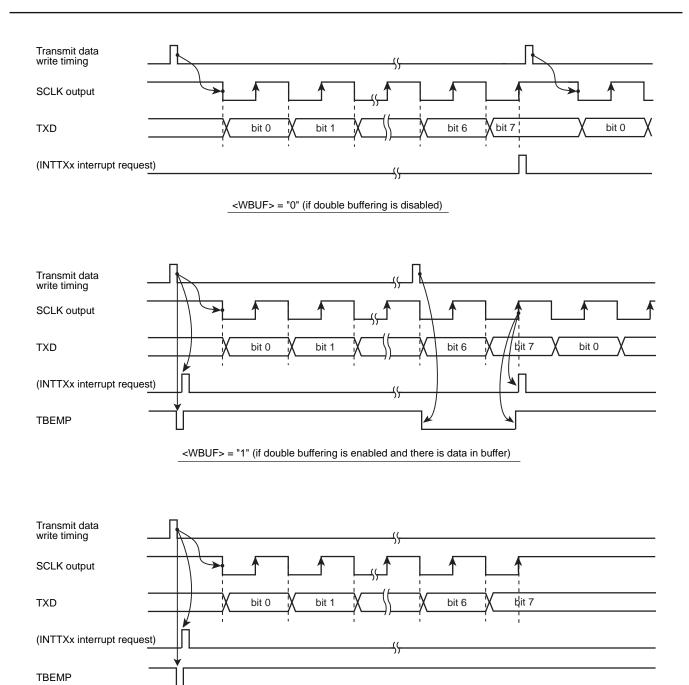

- (1) SCLK Output Mode
  - If the transmit double buffer is disabled (SCxMOD2<WBUF> = "0")

Data is output from the TXD pin and the clock is output from the SCLK pin each time the CPU writes data to the transmit buffer. When all data is output, an interrupt (INTTXx) is generated.

• If the transmit double buffer is enabled (SCxMOD2<WBUF> = "1")

Data is moved from the transmit buffer to the transmit shift register when the CPU writes data to the transmit buffer while data transmission is halted or when data transmission from the transmit buffer (shift register) is completed. Simultaneously, the transmit buffer empty flag SCxMOD2<TBEMP> is set to "1", and the INTTXx interrupt is generated.

When data is moved from the transmit buffer to the transmit shift register, if the transmit buffer has no data to be moved to the transmit shift register, INTTXx interrupt is not generated and the SCLK output stops.

<WBUF> = "1" (if double buffering is enabled and threre is no data in buffer)

#### (2) SCLK Input Mode

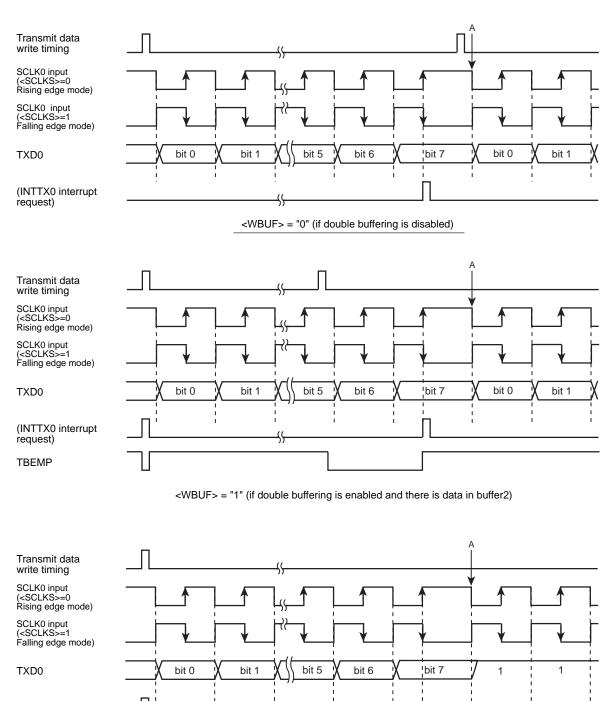

• If double buffering is disabled (SCxMOD2<WBUF> = "0")

If the SCLK is input in the condition where data is written in the transmit buffer, 8-bit data is outputted from the TXD pin. When all data is output, an interrupt INTTXx is generated. The next transmit data must be written before the timing point "A" as shown in Figure 14-13.

• If double buffer is enabled (SCxMOD2<WBUF> = "1")

Data is moved from the transmit buffer to the transmit shift register when the CPU writes data to the transmit buffer before the SCLK input becomes active or when data transmission from the transmit shift register is completed. Simultaneously, the transmit buffer empty flag SCxMOD2<TBEMP> is set to "1", and the INTTXx interrupt is generated.

If the SCLK input becomes active while no data is in the transmit buffer, although the internal bit counter is started, an under-run error occurs and 8-bit dummy data (0xFF) is sent.

(INTTX0 interrupt request)

TBEMP

PERR (Functions to detect under-run errors)

<WBUF> = "1" (if double buffering is enabled and there is no data in buffer2)

Figure 14-13 Transmit Operation in the I/O Interface Mode (SCLK Input Mode)

55

#### 14.17.1.2 Receive

#### (1) SCLK Output Mode

The SCLK output can be started by setting the receive enable bit SCxMOD0<RXE> to "1".

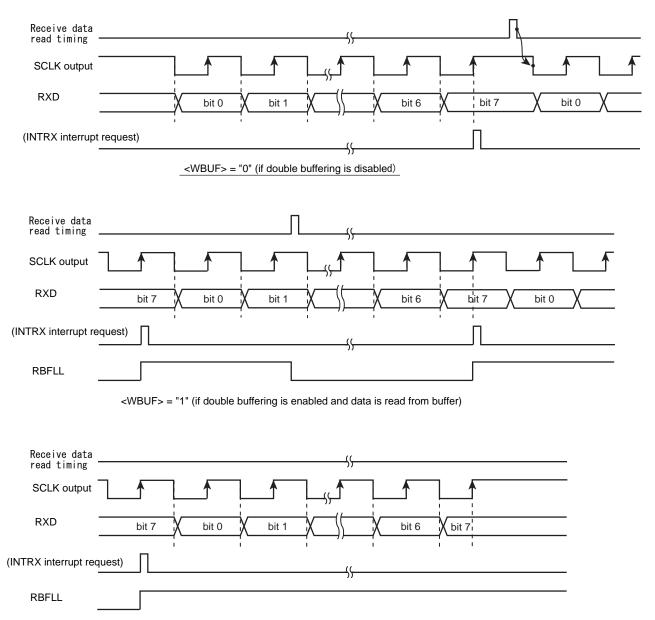

• If double buffer is disabled (SCxMOD2<WBUF> = "0")

A clock pulse is outputted from the SCLK pin and the next data is stored into the shift register each time the CPU reads received data. When all the 8 bits are received, the INTRXx interrupt is generated.

• If double buffer is enabled (SCxMOD2<WBUF> = "1")

Data stored in the shift register is moved to the receive buffer and the receive buffer can receive the next frame. A data is moved from the shift register to the receive buffer, the receive buffer full flag SCxMOD2<RBFLL> is set to "1" and the INTRXx is generated.

While data is in the receive buffer, if the data cannot be read from the receive buffer before completing reception of the next 8 bits, the INTRXx interrupt is not generated and the SCLK output stops. In this state, reading data from the receive buffer allows data in the shift register to move to the receive buffer and thus the INTRXx interrupt is generated and data reception resumes.

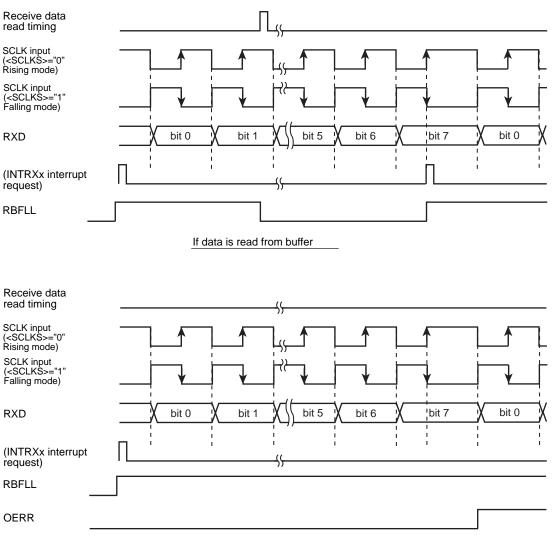

<WBUF> = "1" (if double buffering is enabled and data cannot be read from buffer)

Figure 14-14 Receive Operation in the I/O Interface Mode (SCLK Output Mode)

#### (2) SCLK Input Mode

In the SCLK input mode, receiving double buffering is always enabled, the received frame can be moved to the receive buffer from the shift register, and the receive buffer can receive the next frame successively.

The INTRx receive interrupt is generated each time received data is moved to the receive buffer.

#### 14.17.1.3 Transmit and Receive (Full-duplex)

- (1) SCLK Output Mode
  - If SCxMOD2<WBUF> is set to "0" and the double buffers are disabled

SCLK is outputted when the CPU writes data to the transmit buffer.

Subsequently, 8 bits of data are shifted into receive buffer and the INTRXx receive interrupt is generated. Concurrently, 8 bits of data written to the transmit buffer are outputted from the TXD pin, the INTTXx transmit interrupt is generated when transmission of all data bits has been completed. Then, the SCLK output stops.

The next round of data transmission and reception starts when the data is read from the receive buffer and the next transmit data is written to the transmit buffer by the CPU. The order of reading the receive buffer and writing to the transmit buffer can be freely determined. Data transmission is resumed only when both conditions are satisfied.

• If SCxMOD2<WBUF> is set to "1" and the double buffers are enabled

SCLK is outputted when the CPU writes data to the transmit buffer.

8 bits of data are shifted into the receive shift register, moved to the receive buffer, and the INTRXx interrupt is generated. While 8 bits of data is received, 8 bits of transmit data is outputted from the TXD pin. When all data bits are sent out, the INTTXx interrupt is generated and the next data is moved from the transmit buffer to the transmit shift register.

If the transmit buffer has no data to be moved to the transmit buffer (SCxMOD2 < TBEMP > = 1) or when the receive buffer is full (SCxMOD2 < RBFULL > = 1), the SCLK output is stopped. When both conditions, receive data is read and transmit data is written, are satisfied, the SCLK output is resumed and the next round of data transmission and reception is started.

# <u>TOSHIBA</u>

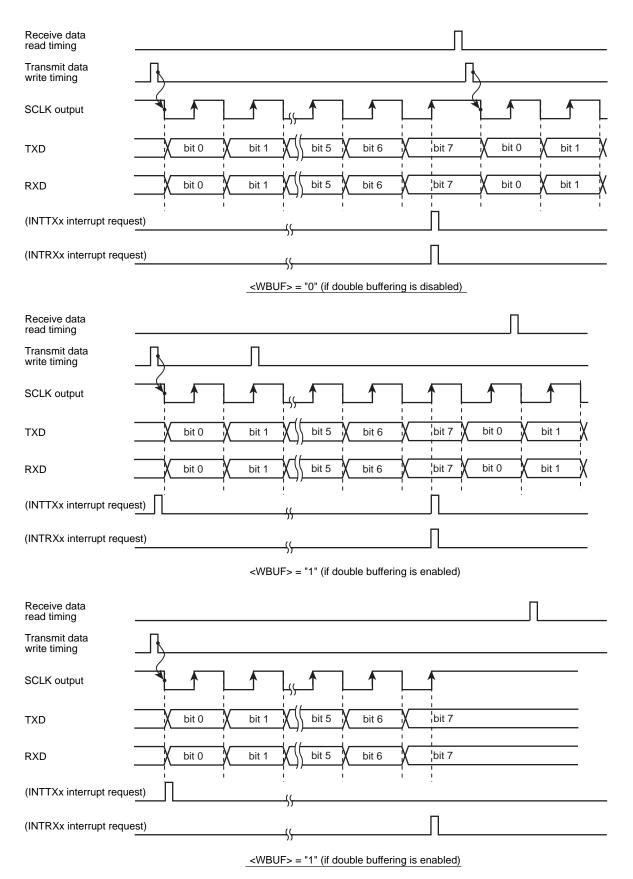

Figure 14-16 Transmit/Receive Operation in the I/O Interface Mode (SCLK Output Mode)

#### (2) SCLK Input Mode

#### • If SCxMOD2<WBUF> is set to "0" and the transmit double buffer is disabled

When receiving data, double buffer is always enabled regardless of the SCxMOD2  $<\!\!\text{WBUF}\!\!>$  settings.

8-bit data written in the transmit buffer is outputted from the TXD pin and 8 bit of data is shifted into the receive buffer when the SCLK input becomes active. The INTTXx interrupt is generated upon completion of data transmission. The INTTRXx interrupt is generated when the data is moved from shift register to receive buffer after completion of data reception.

Note that transmit data must be written into the transmit buffer before the SCLK input for the next frame (data must be written before the point A in Figure 14-17). Data must be read before completing reception of the next frame data.

• If SCxMOD2<WBUF> is set to "1" and the double buffer is enabled.

The interrupt INTRXx is generated at the timing the transmit buffer data is moved to the transmit shift register after completing data transmission from the transmit shift register. At the same time, data received is shifted to the shift register, it is moved to the receive buffer, and the INTRXx interrupt is generated.

Note that transmit data must be written into the transmit buffer before the SCLK input for the next frame (data must be written before the point A in Figure 14-17). Data must be read before completing reception of the next frame data.

Upon the SCLK input for the next frame, transmission from transmit shift register (in which data has been moved from transmit buffer) is started while receive data is shifted into receive shift register simultaneously.

If data in receive buffer has not been read when the last bit of the frame is received, an overrun error occurs. Similarly, if there is no data written to transmit buffer when SCLK for the next frame is input, an under-run error occurs.

# TOSHIBA

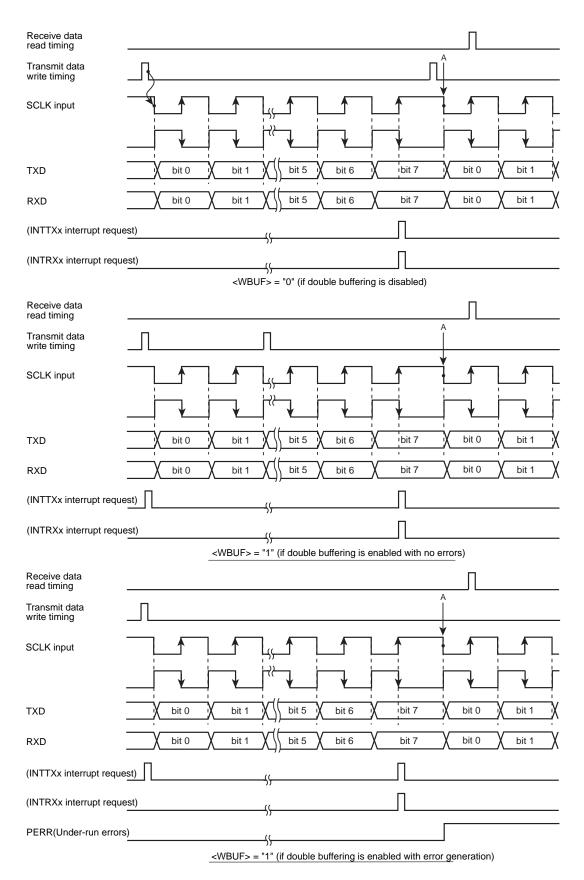

Figure 14-17 Transmit/Receive Operation in the I/O Interface Mode (SCLK Input Mode)

#### 14.17.2 Mode 1 (7-bit UART mode)

The 7-bit UART mode can be selected by setting the serial mode control register (SCxMOD<SM[1:0]>) to "01".

In this mode, parity bits can be added to the transmit data stream; the serial mode control register (SCxCR<PE>) controls the parity enable/disable setting.

When <PE> is set to "1" (enable), either even or odd parity may be selected using the SCxCR<EVEN> bit. The length of the stop bit can be specified using SCxMOD2<SBLEN>.

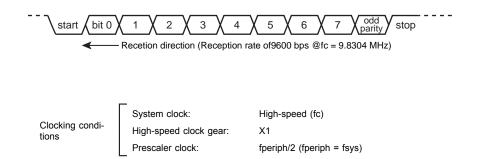

The following table shows the control register settings for transmitting in the following data format.

start bit 0 1 2 3 4 5 6 veven parity stop ✓ Transmission direction (Transmission rate of bps @fc = 9.8304 MHz)										
Clocking condi- tions	·Н	ligh-sp	clock eed cl er cloc	ock ge	ear:	X1	gh-spe (fc) eriph/2		bh = fsy	/s)
		7	6	5	4	3	2	1	0	
SCxMOD0	←	х	0	-	0	0	1	0	1	Set 7-bit UART mode
SCxCR	←	х	1	1	х	х	х	0	0	Even parity enabled
SCxBRCR	$\leftarrow$	0	0	1	0	0	1	0	0	Set 2400bps
SCxBUF	$\leftarrow$	*	*	*	*	*	*	*	*	Set transmit data
x : don't care - : no change										

#### 14.17.3 Mode 2 (8-bit UART mode)

The 8-bit UART mode can be selected by setting SCxMOD0 < SM[1:0] > to "10." In this mode, parity bits can be added and parity enable/disable is controlled using SCxCR < PE >. If < PE > = "1" (enabled), either even or odd parity can be selected using SCxCR < EVEN >.

The control register settings for receiving data in the following format are as follows:

		7	6	5	4	3	2	1	0	
SCxMOD0	$\leftarrow$	х	0	0	0	1	0	0	1	SEt 8-bit UART mode
SCxCR	←	х	0	1	х	х	х	0	0	Odd parity enabled
SCxBRCR	←	0	0	0	1	0	1	0	0	Set 9600bps
SCxMOD0	←	-	-	1	-	-	-	-	-	Reception enabled
x : don't care - :	no cha	inge								

## 14.17.4 Mode 3 (9-bit UART mode)

The 9-bit UART mode can be selected by setting SCxMOD0 < SM[1:0] > to "11." In this mode, parity bits must be disabled (SCxCR < PE > = "0").

The most significant bit (9th bit) is written to bit 7 <TB8> of the serial mode control register 0 (SCxMOD0) for transmitting data. The data is stored in bit 7 <RB8> of the serial control register SCxCR.

When writing or reading data to/from the buffers, the most significant bit must be written or read first before writing or reading to/from SCxBUF.

The stop bit length can be specified using SCxMOD2<SBLEN>.

#### 14.17.4.1 Wake up function

In the 9-bit UART mode, slave controllers can be operated in the wake-up mode by setting the wake-up function control bit SCxMOD0<WU> to "1."

In this case, the interrupt INTRXx will be generated only when SCxCR<RB8> is set to "1".

Note: The TXD pin of the slave controller must be set to the open drain output mode using the ODE register.

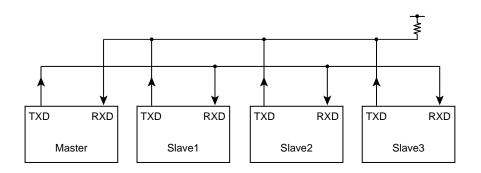

Figure 14-18 Serial Links to Use Wake-up Function

#### 14.17.4.2 Protocol

- 1. Select the 9-bit UART mode for the master and slave controllers.
- 2. Set SCxMOD<WU> to "1" for the slave controllers to make them ready to receive data.
- 3. The master controller is to transmit a single frame of data that includes the slave controller select code (8 bits). In this, the most significant bit (bit 8) <TB8> must be set to "1".

- 4. Each slave controller receives the above data frame; if the code received matches with the controller's own select code, it clears the WU bit to "0".
- 5. The master controller transmits data to the designated slave controller (the controller of which SCxMOD<WU> bit is cleared to "0"). In this, the most significant bit (bit 8) <TB8> must be set to "0".

$$\frac{1}{2 \times 3 \times 4 \times 5 \times 6 \times 7} \text{bit } 8 \text{stop}$$

6. The slave controllers with the <WU> bit set to "1" ignore the receive data because the most significant bit (bit 8) <RB8> is set to "0" and thus no interrupt (INTRXx) is generated. Also, the slave controller with the <WU> bit set to "0" can transmit data to the master controller to inform that the data has been successfully received.

# TOSHIBA

# 15. Serial Bus Interface (I2C/SIO)

The TMPM365FYXBG contains 2 Serial Bus Interface (I2C/SIO) channels, in which the following two operating modes are included:

- I2C bus mode (with multi-master capability)
- Clock-synchronous 8-bit SIO mode

In the I2C bus mode, the I2C/SIO is connected to external devices via SCL and SDA.

In the clock-synchronous 8-bit SIO mode, the I2C/SIO is connected to external devices via SCK, SI and SO.

The following table shows the programming required to put the I2C/SIO in each operating mode.

Table 15-1 Port settings for using serial bus interface

channel	Operating mode	pin	Port Function Reg- ister	Port Output Control Register	Port Input Control Register	Port Open Drain Output Control Register
	I2C bus mode	SCL0 :PG1 SDA0 :PG0	PGFR1[1:0] = 11	PGCR[1:0] = 11	PGIE[1:0] = 11	PGOD[1:0] = 11
SBI0	SIO mode	SCK0 :PG2 SI0 :PG1 SO0 :PG0	PGFR1[2:0] = 111	PGCR[2:0] = 101(SCK0 output) PGCR[2:0] = 001(SCK0 input)	PGIE[2:0] = 010(SCK0 output) PGIE[2:0] = 110(SCK0 input)	PGOD[2:0] = xxx
	I2C bus mode	SCL1 :PE5 SDA1 :PE4	PEFR1[5:4] = 11	PECR[5:4] = 11	PEIE[5:4] = 11	PEOD[5:4] = 11
SBI1	SIO mode	SCK1 :PE6 SI1 :PE5 SO1 :PE4	PEFR1[6:4] = 111	PECR[6:4] = 101(SCK1 output) PECR[6:4] = 001(SCK1 input)	PEIE[6:4] = 010(SCK1 output) PEIE[6:4] = 110(SCK1 input)	PEOD[6:4] = xxx

Note:x: Don't care

#### 15.1 Configuration

## 15.1 Configuration

The configuration is shown in Figure 15-1.

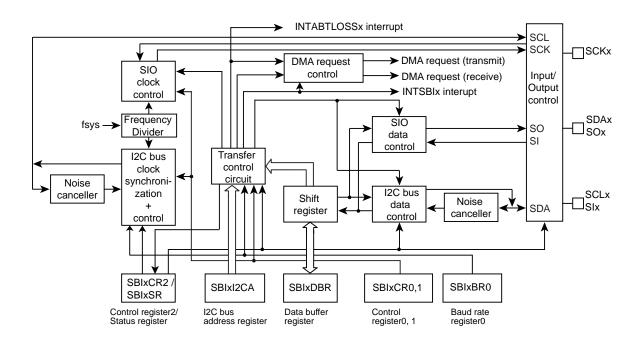

Figure 15-1 (I2C/SIO) Block Interface

## 15.2 Register

The following registers control the serial bus interface and provide its status information for monitoring.

The register below performs different functions depending on the mode. For details, refer to "15.4 Control Registers in the I2C Bus Mode" and "15.7 Control register of SIO mode".

## 15.2.1 Registers for each channel

The tables below show the registers and register addresses for each channel.

Channel x	Base Address
Channel0	0x400E_0000
Channel1	0x400E_0100

Register name(x=0,1,)	Register name(x=0,1,)						
Control register 0	SBIxCR0	0x0000					
Control register 1	SBIxCR1	0x0004					
Data buffer register	SBIxDBR	0x0008					
I2C bus address register	SBIxI2CAR	0x000C					
Control register 2	SBIxCR2 (writing)	0x0010					
Status register	SBIxSR (reading)						
Baud rate register 0	SBIxBR0	0x0014					

## 15.3 I2C Bus Mode Data Format

#### I2C Bus Mode Data Format 15.3

Figure 15-2 shows the data formats used in the I2C bus mode.

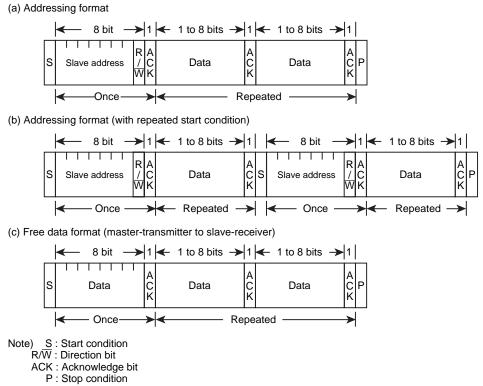

Figure 15-2 I2C Bus Mode Data Formats

## 15.4 Control Registers in the I2C Bus Mode

The following registers control the serial bus interface in the I2C bus mode and provide its status information for monitoring.

## 15.4.1 SBIxCR0(Control register 0)

	31	30	29	28	27	26	25	24
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	23	22	21	20	19	18	17	16

After reset	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	7	6	5	4	3	2	1	0
bit symbol	SBIEN	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0

Bit	Bit Symbol	Туре	Function
31-8	-	R	Read as 0.
7	SBIEN	R/W	Serial bus interface operation 0:Disable 1:Enable To use the serial bus interface, enable this bit first. For the first time in case of setting to enable, the relevant SBI registers can be read or written. Since all clocks except SBIxCR0 stop if this bit is disabled, power consumption can be reduced by disabling this bit.
			If this bit is disabled after it's been enabled once, the settings of each register are retained.
6-0	-	R	Read as 0.

Note: To use the serial bus interface, enable this bit first.

	31	30	29	28	27	26	25	24
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0

## 15.4.2 SBIxCR1(Control register 1)

Bit	Bit Symbol	Туре					Function		
31-8	-	R	Read a	s 0.					
7-5	BC[2:0]	R/W	Select t	he number of	bits per transf	er (Note 1)			
					When <a< td=""><td colspan="3">When <ack> = 0 When <ack> = 1</ack></ack></td><td>]</td></a<>	When <ack> = 0 When <ack> = 1</ack></ack>			]
				<bc></bc>	Number of clock cycles	Data length	Number of clock cycles	Data length	
				000	8	8	9	8	
				001	1	1	2	1	
				010	2	2	3	2	
				011	3	3	4	3	
				100	4	4	5	4	
				101	5	5	6	5	
				110	6	6	7	6	
				111	7	7	8	7	
	ACK		Master mode 0: Acknowledgement clock pulse is not generated. 1: Acknowledgement clock pulse is generated. Slave mode 0: Acknowledgement clock pulse is not counted. 1: Acknowledgement clock pulse is counted.						
3	-	R	Read a	s 1.					
2-1	SCK[2:1]	R/W	Select i	nternal SCL c	output clock fre	quency (Note	: 2).		
0	SCK[0]	w		000 001 010 011 100 101 110 111	n = 5 n = 6 n = 7 n = 8 n = 9 n = 10 n = 11	462 kHz 353 kHz 240 kHz 146 kHz 82 kHz 44 kHz 23 kHz reserved		n Clock: fsys ( gear : fc/1 ency = fsys 2 <sup>n</sup> + 7	= 48MHz ) 72 [Hz]
	SWRMON	R	0:Softw	are reset ope	DN>: Software ration is in prop ration is not in	gress.	monitor		

Note 1: Clear <BC[2:0]> to "000" before switching the operation mode to the SIO mode.

- Note 2: For details on the SCL line clock frequency, refer to "15.5.1 Serial Clock".
- Note 3: After a reset, the <SCK[0]/SWRMON> bit is read as "1". However, if the SIO mode is selected at the SBIxCR2 register, the initial value of the <SCK[0]> bit is "0".
- Note 4: The initial value for selecting a frequency is <SCK[2:0]>=000 and is independent of the read initial value.
- Note 5: When <BC[2:0]>="001" and <ACK>="0" in master mode, SCL line may be fixed to "L" by falling edge of SCL line after generation of STOP condition and the other devices can not use the bus. In the case of bus which is connected with several master devices, the bumber of bits per transfer should be set equal or more than 2 before generation of STOP condition.

15.4 Control Registers in the I2C Bus Mode

## 15.4.3 SBIxCR2(Control register 2)

This register serves as SBIxSR register by reading it.

	31	30	29	28	27	26	25	24
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	23	22	21	20	19	18	17	16
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	7	6	5	4	3	2	1	0
bit symbol	MST	TRX	BB	PIN	SE	BIM	SW	RST
After reset	0	0	0	1	0	0	0	0

Bit	Bit Symbol	Туре	Function
31-8	-	R	Read as 0.
7	MST	W	Select master/slave
			0: Slave mode
			1: Master mode
6	TRX	w	Select transmit/ receive
			0: Receive
			1: Transmit
5	вв	W	Start/stop condition generation
			0: Stop condition generated
			1: Start condition generated
4	PIN	W	Clear INTSBIx interrupt request
			0: -
			1: Clear interrupt request
3-2	SBIM[1:0]	W	Select serial bus interface operating mode (Note)
			00: Port mode (Disables a serial bus interface output)
			01: SIO mode
			10: I2C bus mode
			11: Reserved
1-0	SWRST[1:0]	w	Software reset generation
			Write "10" followed by "01" to generate a reset.

Note: Make sure that modes are not changed during a communication session. Ensure that the bus is free before switching the operating mode to the port mode. Ensure that the port is at the "High" level before switching the operating mode from the port mode to the I2C bus or clock-synchronous 8-bit SIO mode.

# TOSHIBA

## 15.4.4 SBIxSR (Status Register)

This register serves as SBIxCR2 by writing to it.

	31	30	29	28	27	26	25	24
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0

After reset	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	7	6	5	4	3	2	1	0
bit symbol				SA				ALS
After reset	0	0	0	0	0	0	0	0

## 15.4.7 SBIxI2CAR (I2Cbus address register)

Bit	Bit Symbol	Туре	Function
31-8	-	R	Read as 0.
7-1	SA[6:0]	R/W	Set the slave address when the SBI acts as a slave device.
0	ALS	R/W	Specify address recognition mode.
			0: Recognize its slave address.
			1: Do not recognize its slave address (free-data format).

Note 1: Please set the bit 0 <ALS> of I2C bus address register SBIxI2CAR to "0", except when you use a free data format. It operates as a free data format when setting it to "1". Selecting the master fixes to transmission. Selecting the slave fixes to reception.

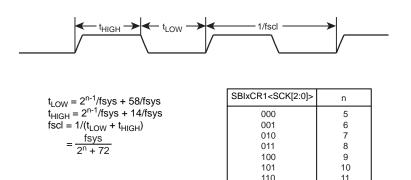

Note 2: Do not set SBIxI2CAR to "0x00" in slave mode. (If SBIxI2CAR is set to "0x00", it's recognized that the slave address matches the START byte ("0x01") of the I2C standard received in slave mode.)

## 15.5 Control in the I2C Bus Mode

#### 15.5.1 Serial Clock

#### 15.5.1.1 Clock source

SBIxCR1<SCK[2:0]> specifies the maximum frequency of the serial clock to be output from the SCL pin in the master mode.

## Figure 15-3 Clock source

Note: The maximum speeds in the standard and high-speed modes are specified to 100kHz and 400kHz respectively following the communications standards. Notice that the internal SCL clock frequency is determined by the fsys used and the calculation formula shown above.

#### 15.5.1.2 Clock Synchronization

The I2C bus is driven by using the wired-AND connection due to its pin structure. The first master that pulls its clock line to the "Low" level overrides other masters producing the "High" level on their clock lines. This must be detected and responded by the masters producing the "High" level.

Clock synchronization assures correct data transfer on a bus that has two or more master.

For example, the clock synchronization procedure for a bus with two masters is shown below.

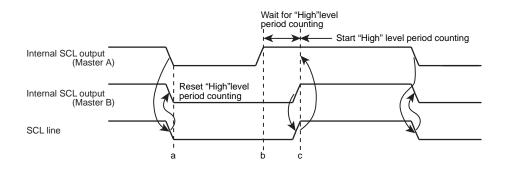

Figure 15-4 Example of Clock Synchronization

At the point a, Master A pulls its internal SCL output to the "Low" level, bringing the SCL bus line to the "Low" level. Master B detects this transition, resets its "High" level period counter, and pulls its internal SCL output level to the "Low" level.

Master A completes counting of its "Low" level period at the point b, and brings its internal SCL output to the "High" level. However, Master B still keeps the SCL bus line at the "Low" level, and Master A stops counting of its "High" level period counting. After Master A detects that Master B brings its internal SCL output to the "High" level and brings the SCL bus line to the "High" level at the point c, it starts counting of its "High" level period.

After that Master finishes counting the "High" level period, the Master pulls the SCL pin to "Low" and the SCL bus line becomes "Low".

This way, the clock on the bus is determined by the master with the shortest "High" level period and the master with the longest "Low" level period among those connected to the bus.

#### 15.5.2 Setting the Acknowledgement Mode

Setting SBIxCR1<ACK> to "1" selects the acknowledge mode. When operating as a master, the SBI adds one clock for acknowledgment signal. In slave mode, the clock for acknowledgement signals is counted. In transmitter mode, the SBI releases the SDAx pin during clock cycle to receive acknowledgement signals from the receiver. In receiver mode, the SBI pulls the SDAx pin to the "Low" level during the clock cycle and generates acknowledgement signals. Also in slave mode, if a general-call address is received, the SBI pulls the SDAx pin to the "Low" level during the clock cycle and generates acknowledgement signals.

By setting <ACK> to "0", the non-acknowledgment mode is activated. When operating as a master, the SBI does not generate clock for acknowledgement signals. In slave mode, the clock for acknowledgement signals is not counted.

#### 15.5.3 Setting the Number of Bits per Transfer

SBIxCR1<BC[2:0]> specifies the number of bits of the next data to be transmitted or received.

Under the start condition, <BC[2:0]> is set to "000", causing a slave address and the direction bit to be transferred in a packet of eight bits. At other times, <BC[2:0]> keeps a previously programmed value.

#### 15.5.4 Slave Addressing and Address Recognition Mode

Setting "0" to SBIxI2CAR<ALS> and a slave address in SBIxI2CAR<SA[6:0]> sets addressing format, and then the SBI recognizes a slave address transmitted by the master device and receives data in the address-ing format.

If <ALS> is set to "1", the SBI does not recognize a slave address and receives data in the free data format. In the case of free data format, a slave address and a direction bit are not recognized; they are recognized as data immediately after generation of the start condition.

#### 15.5.5 Operating mode

The setting of SBIxCR2<SBIM[1:0]> controls the operating mode. To operate in I2C mode, ensure that the serial bus interface pins are at "High" level before setting  $\langle SBIM[1:0] \rangle$  to "10". Also, ensure that the bus is free before switching the operating mode to the port mode.

## 15.5.6 Configuring the SBI as a Transmitter or a Receiver

Setting SBIxCR2<TRX> to "1" configures the SBI as a transmitter. Setting <TRX> to "0" configures the SBI as a receiver.

At the slave mode:

- when data is transmitted in the addressing format.
- when the received slave address matches the value specified at SBIxI2CAR.
- when a general-call address is received; i.e., the eight bits following the start condition are all zeros.

If the value of the direction bit  $(R/\overline{W})$  is "1",  $\langle TRX \rangle$  is set to "1" by the hardware. If the bit is "0",  $\langle TRX \rangle$  is set to "0".

As a master device, the SBI receives acknowledgement from a slave device. If the direction bit of "1" is transmitted, <TRX> is set to "0" by the hardware. If the direction bit is "0", <TRX> changes to "1". If the SBI does not receive acknowledgement, <TRX> retains the previous value.

 $\langle TRX \rangle$  is cleared to "0" by the hardware when it detects the stop condition on the bus or the arbitration lost.

If SBI is used in free data format, <TRX> is not changed by the hardware.

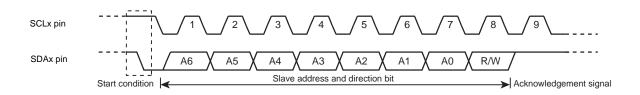

## 15.5.7 Configuring the SBI as a Master or a Slave

Setting SBIxCR2<MST> to "1" configures the SBI to operate as a master device.

Setting  $\langle MST \rangle$  to "0" configures the SBI as a slave device.  $\langle MST \rangle$  is cleared to "0" by the hardware when it detects the stop condition on the bus or the arbitration lost.

## 15.5.8 Generating Start and Stop Conditions

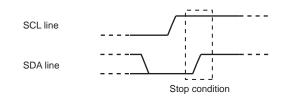

When SBIxSR<BB> is "0", writing "1" to SBIxCR2<MST, TRX, BB, PIN> causes the SBI to start a sequence for generating the start condition and to output the slave address and the direction bit prospectively written in the data buffer register. <ACK> must be set to "1" in advance.

When <BB> is "1", writing "1" to <MST, TRX, PIN> and "0" to <BB> causes the SBI to start a sequence for generating the stop condition on the bus. The contents of <MST, TRX, BB, PIN> should not be altered until the stop condition appears on the bus.

If SCL bus line is pulled "Low" by other devices when the stop condition is generated, the stop condition is generated after the SCL line is released.

#### Figure 15-6 Generating the Stop Condition

SBIxSR<BB> can be read to check the bus state. <BB> is set to "1" when the start condition is detected on the bus (the bus is busy), and cleared to "0" when the stop condition is detected (the bus is free).

#### 15.5.9 Interrupt Service Request and Release

In master mode, a serial bus interface request (INTSBIx) is generated when the transfer of the number of clock cycles set by <BC> and <ACK> is completed.

In slave mode, INTSBIx is generated under the following conditions.

- After output of the acknowledge signal which is generated when the received slave address matches the slave address set to SBIxI2CAR<SA[6:0]>.
- After the acknowledge signal is generated when a general-call address is received.
- When the slave address matches or a data transfer is completed after receiving a general-call address.

In the address recognition mode ( $\langle ALS \rangle = "0"$ ), INTSBIx is generated when the received slave address matches the values specified at SBIxI2CAR or when a general-call (eight bits data following the start condition is all "0") is received.

When an interrupt request (INTSBIx) is generated, SBIxCR2<PIN> is cleared to "0". While <PIN> is cleared to "0", the SBI pulls the SCL line to the "Low" level.

<PIN> is set to "1" when data is written to or read from SBIxDBR. It takes a period of t<sub>LOW</sub> for the SCL line to be released after <PIN> is set to "1". When the program writes "1" to <PIN>, it is set to "1". However, writing "0" does not clear this bit to "0".

Note:When arbitration is lost in master mode, <PIN> is not cleared to "0" if the slave address does not match (INTSBIx is generated).

Note: When the INTSBIx interrupt occurs, a DMA request occurs at the same time. If DMA is used, set the corresponding registers of the DMA controller.

#### 15.5.10 Arbitration Lost Detection Monitor

The I2C bus has the multi-master capability (there are two or more masters on a bus), and requires the bus arbitration procedure to ensure correct data transfer.

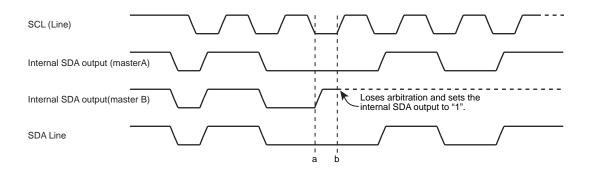

A master that attempts to generate the start condition while the bus is busy loses bus arbitration, with no start condition occurring on the SDA and SCL lines. The I2C-bus arbitration takes place on the SDA line. When a start condition is output under the bus busy state, a start condition is not output to SCL or SDA line, thus arbitration lost occurs.

The arbitration procedure for two masters on a bus is shown below.

Up until the point a, Master A and Master B output the same data. At the point a, Master A outputs the "Low" level and Master B outputs the "High" level.

Then Master A pulls the SDA bus line to the "Low" level because the line has the wired-AND connection. When the SCL line goes high at the point b, the slave device reads the SDA line data, i.e., data transmitted by Master A. At this time, data transmitted by Master B becomes invalid.

This condition of Master B is called "Arbitration Lost". Master B releases its SDA pin, so that it does not affect the data transfer initiated by another master. If two or more masters have transmitted exactly the same first data word, the arbitration procedure continues with the second data word.

A master compares the SDA bus line level and the internal SDA output level at the rising of the SCL line. If there is a difference between these two values, Arbitration Lost occurs and SBIxSR<AL> is set to "1" and the INTABLOSSx interrupt occurs.

When <AL> is set to "1", SBIxSR<MST, TRX> are cleared to "0", causing the SBI to operate as a slave receiver. Therefore, the serial bus interface circuit stops the clock output during data transfer after <AL> is set to "1".

<AL> is cleared to "0" when data is written to or read from SBIxDBR or data is written to SBIxCR2.

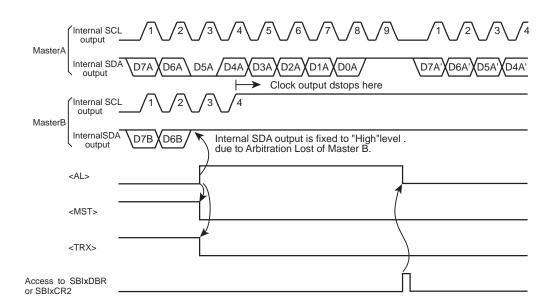

Figure 15-8 Example of Master B Lost Arbitration (D7A = D7B, D6A = D6B)

#### 15.5.11 Slave Address Match Detection Monitor

When the SBI operates as a slave device in the address recognition mode (SBIxI2CAR<ALS>="0"), SBIxSR<AAS> is set to "1" on receiving the general-call address or the slave address that matches the value specified at SBIxI2CAR.

When  $\langle ALS \rangle$  is "1",  $\langle AAS \rangle$  is set to "1" when the first data word has been received.  $\langle AAS \rangle$  is cleared to "0" when data is written to or read from SBIxDBR.

#### 15.5.12 General-call Detection Monitor

When the SBI operates as a slave device, SBIxSR<ADO> is set to "1" when it receives the general-call address; i.e., the eight bits following the start condition are all zeros.

<ADO> is cleared to "0" when the start or stop condition is detected on the bus.

#### 15.5.13 Last Received Bit Monitor

SBIxSR<LRB> is set to the SDA line value that was read at the rising of the SCL line.

In the acknowledgment mode, reading SBIxSR<LRB> immediately after generation of the INTSBIx interrupt request causes ACK signal to be read.

#### 15.5.14 Data Buffer Register (SBIxDBR)

Reading or writing SBIxDBR initiates reading received data or writing transmitted data.

When the SBI is acting as a master, setting a slave address and a direction bit to this register generates the start condition.

#### 15.5.15 Baud Rate Register (SBIxBR0)

The SBIxBR0<I2SBI> register determines if the SBI operates or not when it enters the IDLE mode.

This register must be programmed before executing an instruction to switch to the standby mode.

#### 15.5.16 Software Reset

If the serial bus interface circuit locks up due to external noise, it can be initialized by using a software reset.

If the serial bus interface circuit locks up due to external noise, it can be initialized by using a software reset.Writing "10" followed by "01" to SBIxCR2<SWRST[1:0]> generates a reset signal that initializes the serialbus interface circuit. When writing, set <SBIM[1:0]> to "10"; I2Cbus mode. After a reset, all control registers and status flags are initialized to their reset values. When the serial bus interface is initialized, <SWRST [1:0]> is automatically cleared to "0".

Note: A software reset causes the SBI operating mode to switch from the I2C mode to the port mode.

## 15.6 Data Transfer Procedure in the I2C Bus Model2C

#### 15.6.1 Device Initialization

First, program SBIxCR1<ACK, SCK[2:0]>. Writing "000" to SBIxCR1<BC[2:0]> at the time.

Next, program SBIxI2CAR by specifying a slave address at  $\langle SA[6:0] \rangle$  and an address recognition mode at  $\langle ALS \rangle$ . ( $\langle ALS \rangle$  must be cleared to "0" when using the addressing format).

To configure the Serial Bus Interface as a slave receiver, ensure that the serial bus interface pin is at "High" first. Then write "0" to SBIxCR2<MST, TRX, BB>, "1" to <PIN>, "10" to <SBIM[1:0]> and "0" to the bit 1 and 0.

Note: Initialization of the serial bus interface circuit must be completed within a period that any device does not generate start condition after all devices connected to the bus were initialized. If this rule is not followed, data may not be received correctly because other devices may start transfer before the initialization of the serial bus interface circuit is completed.

#### 15.6.2 Generating the Start Condition and a Slave Address

#### 15.6.2.1 Master mode

In the master mode, the following steps are required to generate the start condition and a slave address.

First, ensure that the bus is free ( $\langle BB \rangle = "0"$ ). Then, write "1" to SBIxCR1 $\langle ACK \rangle$  to select the acknowledgment mode. Write to SBIxDBR a slave address and a direction bit to be transmitted.

When  $\langle BB \rangle = "0"$ , writing "1111" to SBIxCR2 $\langle MST, TRX, BB, PIN \rangle$  generates the start condition on the bus. Following the start condition, the SBI generates nine clocks from the SCL pin. The SBI outputs the slave address and the direction bit specified at SBIxDBR with the first eight clocks, and releases the SDA line in the ninth clock to receive an acknowledgment signal from the slave device.

The INTSBIx interrupt request is generated on the falling of the ninth clock, and <PIN> is cleared to "0". In the master mode, the SBI holds the SCL line at the "Low" level while <PIN> is = "0".<TRX> changes its value according to the transmitted direction bit at generation of the INTSBIx interrupt request, provided that an acknowledgment signal has been returned from the slave device.

Note: To output slave address, check with software that the bus is free before writing to SBIxDBR. If this rule is not followed, data being output on the bus may get ruined.

#### 15.6.2.2 Slave mode

In the slave mode, the SBI receives the start condition and a slave address.

After receiving the start condition from the master device, the SBI receives a slave address and a direction bit from the master device during the first eight clocks on the SCL line.

If the received address matches its slave address specified at SBIxI2CAR or is equal to the general-call address, the SBI pulls the SDA line to the "Low" level during the ninth clock and outputs an acknowledgment signal.

The INTSBIx interrupt request is generated on the falling of the ninth clock, and <PIN> is cleared to "0". In the slave mode, the SBI holds the SCL line at the "Low" level while <PIN> is "0".

#### Figure 15-9 Generation of the Start Condition and a Slave Address

#### 15.6.3 Transferring a Data Word

At the end of a data word transfer, the INTSBIx interrupt is generated to test <MST> to determine whether the SBI is in the master or slave mode.

#### 15.6.3.1 Master mode (<MST> = "1")

Test <TRX> to determine whether the SBI is configured as a transmitter or a receiver.

#### (1) Transmitter mode (<TRX> = "1")

Test <LRB>. If <LRB> is "1", that means the receiver requires no further data.

The master then generates the stop condition as described later to stop transmission.

If <LRB> is "0", that means the receiver requires further data. If the next data to be transmitted has eight bits, the data is written into SBIxDBR. If the data has different length, <BC[2:0]> and <ACK> are programmed and the transmit data is written into SBIxDBR. Writing the data makes <PIN> to "1", causing the SCL pin to generate a serial clock for transferring a next data word, and the SDA pin to transfer the data word.

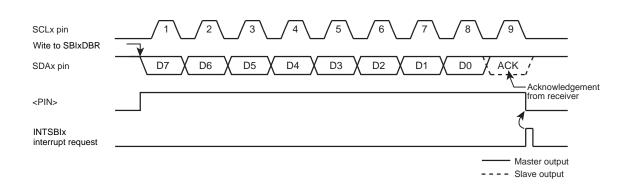

After the transfer is completed, the INTSBIx interrupt request is generated, <PIN> is cleared to "0", and the SCL pin is pulled to the "Low" level.

To transmit more data words, test <LRB> again and repeat the above procedure.

#### INTSBIx interrupt

if MST = 0 Then go to the slave-mode processing if TRX = 0 Then go to the receiver-mode processing. if LRB = 0 Then go to processing for generating the stop condition. Specifies the number of bits to be transmitted and SBIxCR1 х ххх 0 Х Х Х specify whether ACK is required. SBIxDBR Writes the transmit data. Х Х Х Х Х Х Х Х End of interrupt processing.

Note: X; Don't care

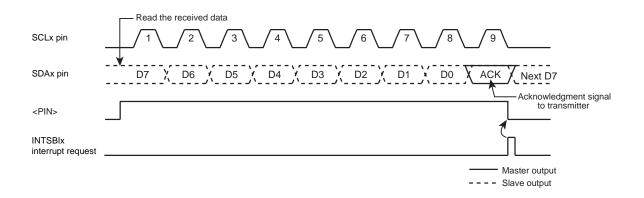

#### (2) Receiver mode (<TRX> = "0")

If the next data to be transmitted has eight bits, the transmit data is written into SBIxDBR.

If the data has different length, <BC[2:0]> and <ACK> are programmed and the received data is read from SBIxDBR to release the SCL line. (The data read immediately after transmission of a slave address is undefined.)On reading the data, <PIN> is set to "1", and the serial clock is output to the SCL pin to transfer the next data word.In the last bit, when the acknowledgment signal becomes the "Low" level, "0" is output to the SDA pin.

After that, the INTSBIx interrupt request is generated, and <PIN> is cleared to "0", pulling the SCL pin to the "Low" level.Each time the received data is read from SBIxDBR, one-word transfer clock and an acknowledgement signal are output.

## Figure 15-11 <BC[2:0]>= "000",<ACK>= "1" (Receiver Mode)

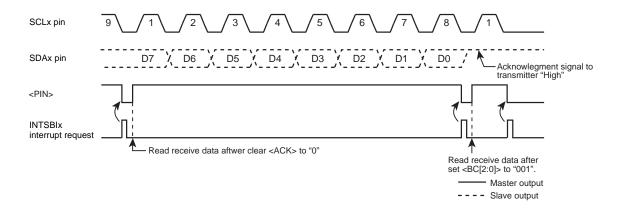

To terminate the data transmission from the transmitter, <ACK> must be cleared to "0" immediately before reading the data word second to last.

This disables generation of an acknowledgment clock for the last data word.

When the transfer is completed, an interrupt request is generated. After the interrupt processing, <BC[2:0]> must be set to "001" and the data must be read so that a clock is generated for 1-bit transfer.

At this time, the master receiver holds the SDA bus line at the "High" level, which signals the end of transfer to the transmitter as an acknowledgment signal.

In the interrupt processing for terminating the reception of 1-bit data, the stop condition is generated to terminate the data transfer.

#### Figure 15-12 Terminating Data Transmission in the Master Receiver Mode

Example: When receiving N data word

SBIxDBR Reads the Nth data word. ← End of interrupt INTSBlx interrupt (after completing data reception) Processing to generate the stop condition. Terminates the data transmission.

Note: X; Don't care

End of interrupt

#### 15.6.3.2 Slave mode (<MST> = "0")

In the slave mode, the SBI generates the INTSBIx interrupt request on four occasions:

1) when the SBI has received any slave address from the master.

2) when the SBI has received a general-call address.

3) when the received slave address matches its address.

4) when a data transfer has been completed in response to a general-call.

Also, if the SBI detects Arbitration Lost in the master mode, it switches to the slave mode.

Upon the completion of data word transfer in which Arbitration Lost is detected, the INTSBIx interrupt request is generated, <PIN> is cleared to "0", and the SCL pin is pulled to the "Low" level.

When data is written to or read from SBIxDBR or when  $\langle$ PIN $\rangle$  is set to "1", the SCLx pin is released after a period of t<sub>LOW</sub>.

In the slave mode, the normal slave mode processing or the processing as a result of Arbitration Lost is carried out.

SBIxSR<AL>, <TRX>, <AAS> and <ADO> are tested to determine the processing required.

"Table 15-2 Processing in Slave Mode" shows the slave mode states and required processing.

Example: When the received slave address matches the SBI's own address and the direction bit is "1" in the slave receiver mode.

#### INTSBIx interrupt

if TRX = 0 Then go to other processing. if AL = 0Then go to other processing. if AAS = 0 Then go to other processing. SBIxCR1 ← х Х х 1 0 Х Х Х Sets the number of bits to be transmitted. SBIxDBR х х х Х Sets the transmit data Х Х х Х

Note:X; Don't care

Table 15-2 Processing in Slave Mode

<trx></trx>	<al></al>	<aas></aas>	<ado></ado>	State	Processing
	1	1	0	Arbitration Lost is detected while the slave address was being transmitted and the SBI received a slave address with the direction bit "1" transmitted by an- other master.	Set the number of bits in a data word to <bc[2:0]></bc[2:0]>
1		1 0		In the slave receiver mode, the SBI received a slave address with the direction bit "1" transmitted by the master.	and write the transmit data into SBIxDBR.
	0	0	0	In the slave transmitter mode, the SBI has comple- ted a transmission of one data word.	Test LRB. If it has been set to "1", that means the receiver does not require further data. Set <pin> to 1 and reset <trx> to 0 to release the bus. If <lrb> has been reset to "0", that means the receiver requires further data. Set the number of bits in the data word to <bc[2:0]> and write the transmit data to the SBIxDBR.</bc[2:0]></lrb></trx></pin>
	1	1	1/0	Arbitration Lost is detected while a slave address is being transmitted, and the SBI receives either a slave address with the direction bit "0" or a general- call address transmitted by another master.	
0		0	0	Arbitration Lost is detected while a slave address or a data word is being transmitted, and the trans- fer is terminated.	Read the SBIxDBR (a dummy read) to set <pin> to 1, or write "1" to <pin>.</pin></pin>
	0	1	1/0	In the slave receiver mode, the SBI received either a slave address with the direction bit "0" or a general- call address transmitted by the master.	
		0	1/0	In the slave receiver mode, the SBI has completed a reception of a data word.	Set the number of bits in the data word to <bc[2:0]> and read the received data from SBIxDBR.</bc[2:0]>

#### 15.6.4 Generating the Stop Condition

When SBIxSR<BB> is "1", writing "1" to SBIxCR2<MST, TRX, PIN> and "0" to <BB> causes the SBI to start a sequence for generating the stop condition on the bus.

Do not alter the contents of <MST, TRX, BB, PIN> until the stop condition appears on the bus.

If another device is holding down the SCL bus line, the SBI waits until the SCL line is released.

After that, the SDA pin goes "High", causing the stop condition to be generated.

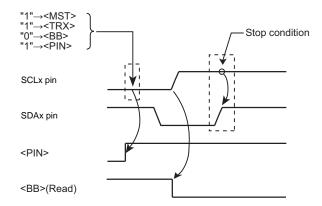

Figure 15-13 Generating the Stop Condition

#### 15.6.5 Restart Procedure

Restart is used when a master device changes the data transfer direction without terminating the transfer to a slave device. The procedure of generating a restart in the master mode is described below.

First, write SBIxCR2<MST, TRX, BB> to "0" and write "1" to <PIN> to release the bus. At this time, the SDAx pin is held at the "High" level and the SCLx pin is released. Because no stop condition is generated on the bus, other devices recognize that the bus is busy.

Then, test SBIxSR<BB> and wait until it becomes "0" to ensure that the SCLx pin is released.

Next, test <LRB> and wait until it becomes "1" to ensure that no other device is pulling the SCLx bus line to the "Low" level.

Once the bus is determined to be free by following the above procedures, follow the procedures described in "15.6.2 Generating the Start Condition and a Slave Address" to generate the start condition.

To satisfy the setup time of restart, at least  $4.7\mu$ s wait period (in the standard mode) must be created by the software after the bus is determined to be free.

Note 1: Do not write <MST> to "0" when it is "0". (Restart cannot be initiated.)

Note 2: When the master device is acting as a receiver, data transmission from the slave device which serves as a transmitter must be completed before generating a restart. To complete data transfer, slave device must receive a "High" level acknowledge signal. For this reason, <LBR> before generating a restart becomes "1", the rising edge of the SCL line is not detected even <LBR>=

"1" is confirmed by following the restart procedure. To check the status of the SCL line, read the port.

->			7	6	5	4	3	2	1	0	
	SBIxCR2	←	0	0	0	1	1	0	0	0	Releases the bus.

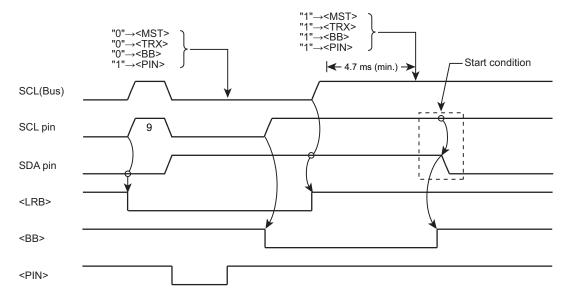

Figure 15-14 Timing Chart of Generating a Restart

## 15.6.6 Data Transfer using DMA

Data can be transfterred using DMA in I2C mode.But one master device and one slave device are connected to a bus line and the number of transfer data is decied beforehand.

Since a DMA request occurs at the same time when the INTSBIx request occurs in I2C mode, data can be transferred continuously by executing DMA transfer between SBIxDBR (data buffer) and the memory.

A DMA request for transmission and reception are separately executed.

Set enable or disable to the DMAC control register for transmission and reception before using the DMA.

To transfer data using DMA, the number of bytes to be transferred should be preliminarily specified on the both transmission and reception.

In the receive mode, data received for the last and the second-to-last reception should be read using software.

15

If arbitration lost occurs during I2C transfer, the INTABTLOSSx interrupt and the INTSBIx interrupt occurs, then the communication stops. A DMA request does not occur.

#### Note: DMA transfer cannot be performed in SIO mode.

#### 15.6.6.1 How to transfer data in master mode

- 1. Generate start condition and slave addres.
- 2. Check <LRB> and <TRX> in interrupt service ruoutine of INTSBIx after output slave adress.
- 3. When <LRB> is "1", output a stop condition and complete the transferring because no slave device which has the sent slave address is on the bus.
- 4. When <LRB> is "0", check <TRX> because slave device which has the sent slave address is on the bus. The proceeding is depended on <TRX>.
- (1) When <TRX> is "1" (Tramsmitter mode)
  - a. Set DMA such as transfer bit width, burst size and the total transferring number, etc. Subtract 1 from the number of data to be transmitted. And enable to receive DMA request of IN-TSBI.
  - b. Write the first data into SBIDBRx. Start tranmit the first data by this writing.
  - c. Start DMA transfer by the DMA request of INTSBIx which is after the completed transferring. And transmit the 2nd data and following data.
  - d. When the specified the number of DMA transfer (N-1 times) ends, a DMA transfer end interrupt occurs. Change the settings to ignore a DMA request reception in this interrupt service routine. (Configure the setting not to generate a DMA request before INTSBIx interrupt occurs.)
  - e. Generate stop condition to stop transmition at the interrupt service routine of INTSBIx.

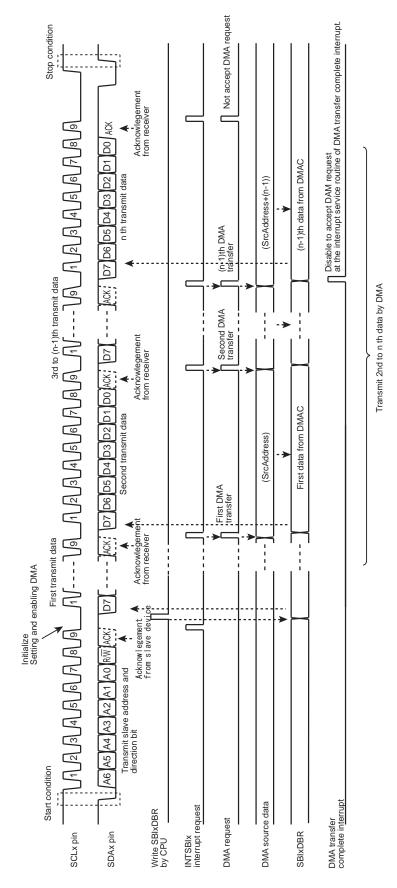

Figure 15-15 Master Transmit Mode

# TOSHIBA

- (2) When <TRX> is "0" (Receiver mode)
  - a. Set DMA such as transfer bit width, burst size and the total transferring number, etc. Subtract 2 from the number of data to be transmitted. And enable to receive DMA request of IN-TSBI.
  - b. Read dummy data from SBIDBRx. Start receive the first data by this reading.
  - c. Start DMA transfer by the DMA request of INTSBIx which is after the completed receiving. And receive the 2nd data and following data.
  - d. When the specified the number of DMA transfer (N-2 times) ends, a DMA transfer end interrupt occurs. Change the settings to ignore a DMA request reception in this interrupt service routine. (Configure the setting not to generate a DMA request before INTSBIx interrupt occurs.)
  - e. Clear <ACK> not to generate the clock for acknowlegement at the interrupt service routine of INTSBIx. Read received data from SBIDBRx.
  - f. Set <BC> to "001" and read received data at the interrupt service routine of INTSBIx. Receive one bit data with high level's SDA by this setting. Transmitter receives a negative ac-knowlegement.
  - g. Generate stop condition to stop transmition at the interrupt service routine of INTSBIx.

			0: Continue
			1: Forced termination
5-4	SIOM[1:0]	R/W	Select transfer mode
			00: Transmit mode
			01: Reserved
			10:Transmit/receive mode
			11:Receive mode
3	-	R	Read as 1.
2-0	SCK[2:0]	R/W	On writing <sck[2:0]>: Select serial clock frequency. (Note 1)</sck[2:0]>
			000 n = 3 3 MHz
			001 n = 4 1.5 MHz
			010 n = 5 750 kHz
			011 n = 6 375 kHz $\left( \begin{array}{c} \text{System clock: fsys} \\ (=48 \text{MHz}) \end{array} \right)$
			100 n = 7 187.5 kHz Clock gear: fc/1
			101 n = 8 93.8 kHz $\left( Frequency = \frac{fsys/2}{2^n} [Hz] \right)$
			110 n = 9 46.9 kHz
			111 – External clock

- Note 1: After a reset, the <SCK[0]> bit is read as "1". However, if the SIO mode is selected at the SBIxCR2 register, the initial value is read as "0". In this document, the value written in the column "after reset" is the value after setting the SIO mode in the initial state. The descriptions of the SBIxCR2 register and the SBIxSR register are the same.
- Note 2: Set <SIOS> to "0" and <SIOINH> to "1" before programming the transfer mode and the serial clock.
- Note 3: In the master mode, when <BC[2:0]>="001" and <ACK>="1" are set, the SCL line may be fixed to "L" on the falling edge of the SCL line after a stop condition occurs. So another bus master device cannot use the bus. If multiple master devices are connected to the bus, set two or more to the number of transfer bit before a stop condition occurs.

## 15.7.3 SBIxDBR (Data buffer register)

### 15.8 Control in SIO mode

### 15.8.1 Serial Clock

#### 15.8.1.1 Clock source

Internal or external clocks can be selected by programming SBIxCR1<SCK[2:0]>.

#### (1) Internal clocks

In the internal clock mode, one of the seven frequencies can be selected as a serial clock, which is output to the outside through the SCKx pin.

At the beginning of a transfer, the SCKx pin output becomes the "High" level.

If the program cannot keep up with this serial clock rate in writing the transmit data or reading the received data, the SBI automatically enters a wait period. During this period, the serial clock is stopped automatically and the next shift operation is suspended until the processing is completed.

	Autom	atic wait ──▶	
SCKx pin output			
SOx pin output	$a_0 \chi_{a_1} \chi_{a_2} a_5 \chi_{a_6} \chi_{a_7}$	$\chi_{b_0}\chi_{b_1}$ $b_4\chi_{b_5}\chi_{b_6}\chi_{b_7}\chi_{c_0}\chi_{c_1}\chi_{c_2}$	
Write the transmit data	a	b C	

#### (2) External clock (<SCK[2:0]> = "111")

The SBI uses an external clock supplied from the outside to the SCKx pin as a serial clock.

For proper shift operations, the serial clock at the "High" and "Low" levels must have the pulse widths as shown below.

### Figure 15-20 Maximum Transfer Frequency of External Clock Input

### 15.8.1.2 Shift Edge

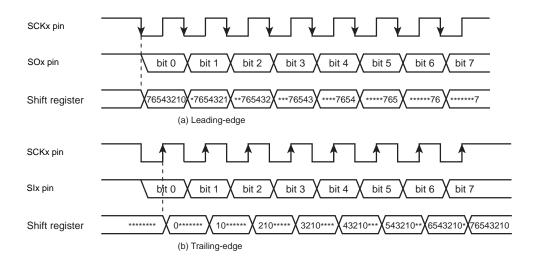

Leading-edge shift is used in transmission. Trailing-edge shift is used in reception.

- Leading-edge shift

Data is shifted at the leading edge of the serial clock (or the falling edge of the SCKx pin input/output).

- Trailing-edge shift

Data is shifted at the trailing edge of the serial clock (or the rising edge of the SCKx pin input/output).

### 15.8.2 Transfer Modes

The transmit mode, the receive mode or the transmit/receive mode can be selected by programming SBIxCR1<SIOM[1:0]>.

### 15.8.2.1 8-bit transmit mode

Set the control register to the transmit mode and write the transmit data to SBIxDBR.

After writing the transmit data, writing "1" to SBIxCR1<SIOS> starts the transmission. The transmit data is moved from SBIxDBR to a shift register and output to the SO pin, with the least-significant bit (LSB) first, in synchronization with the serial clock. Once the transmit data is transferred to the shift register, SBIxDBR becomes empty, and the INTSBIx (buffer-empty) interrupt is generated, requesting the next transmit data.

In the internal clock mode, the serial clock will be stopped and automatically enter the wait state, if next data is not loaded after the 8-bit data has been fully transmitted. The wait state will be cleared when SBIxDBR is loaded with the next transmit data.

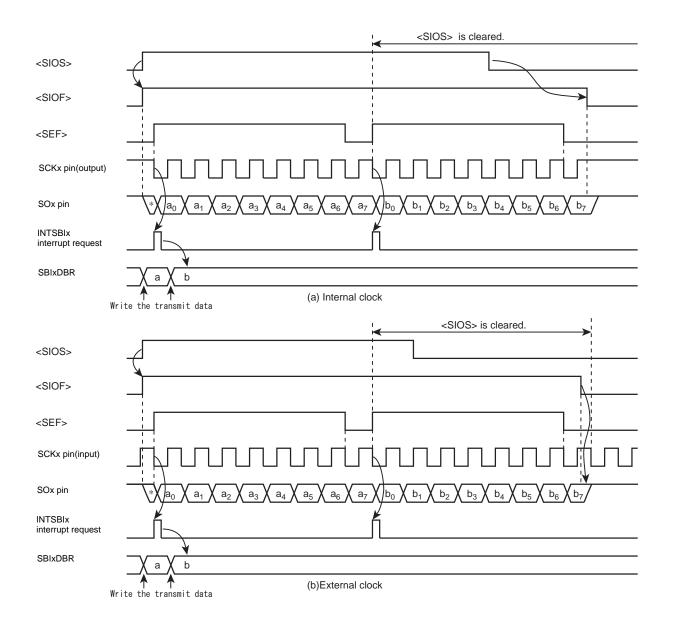

In the external clock mode, SBIxDBR must be loaded with data before the next data shift operation is started. Therefore, the data transfer rate varies depending on the maximum latency between when the interrupt request is generated and when SBIxDBR is loaded with data in the interrupt service program.

At the beginning of transmission, the same value as in the last bit of the previously transmitted data is output in a period from setting SBIxSR<SIOF> to "1" to the falling edge of SCK.

Transmission can be terminated by clearing <SIOS> to "0" or setting <SIOINH> to "1" in the IN-TSBIx interrupt service program. If <SIOS> is cleared, remaining data is output before transmission ends. The program checks SBIxSR<SIOF> to determine whether transmission has come to an end. <SIOF> is cleared to "0" at the end of transmission. If <SIOINH> is set to "1", the transmission is aborted immediately and <SIOF> is cleared to "0".

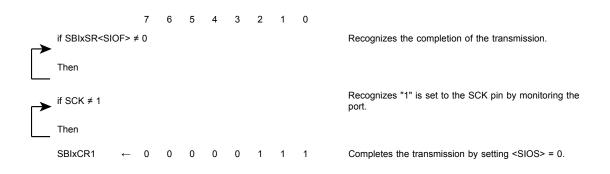

When in the external clock mode, <SIOS> must be cleared to "0" before next data shifting. If <SIOS> does not be cleared to "0" before next data shifting, SBI output dummy data and stopped.

		7	6	5	4	3	2	1	0	
SBIxCR1	←	0	1	0	0	0	Х	Х	Х	Selects the transmit mode.
SBIxDBR	$\leftarrow$	х	Х	Х	Х	Х	Х	Х	Х	Writes the transmit data.

INTSBIx in	terru	pt								
SBIxDBR	←	х	х	х	х	х	х	х	х	Writes the transmit data.

Example: Example of programming (external clock) to terminate transmission by <SIO>

#### 15.8.2.2 8-bit receive mode

Set the control register to the receive mode. Then writing "1" to SBIxCR1<SIOS> enables reception. Data is taken into the shift register from the SI pin, with the least-significant bit (LSB) first, in synchronization with the serial clock. Once the shift register is loaded with the 8-bit data, it transfers the received data to SBIxDBR and the INTSBIx (buffer-full) interrupt request is generated to request reading the received data. The interrupt service program then reads the received data from SBIxDBR.

In the internal clock mode, the serial clock will be stopped and automatically be in the wait state until the received data is read from SBIxDBR.

In the external clock mode, shift operations are executed in synchronization with the external clock. The maximum data transfer rate varies, depending on the maximum latency between generating the interrupt request and reading the received data

Reception can be terminated by clearing <SIOS> to "0" or setting <SIOINH> to "1" in the INTSBIx interrupt service program. If <SIOS> is cleared, reception continues until all the bits of received data are written to SBIxDBR. The program checks SBIxSR<SIOF> to determine whether reception has come to an end. <SIOF> is cleared to "0" at the end of reception. After confirming the completion of the reception, last received data is read. If <SIOINH> is set to "1", the reception is aborted immediately and <SIOF> is cleared to "0". (The received data becomes invalid, and there is no need to read it out.)

#### Note: The contents of SBIxDBR will not be retained after the transfer mode is changed. The ongoing reception must be completed by clearing <SIOS> to "0" and the last received data must be read before the transfer mode is changed.

		7	6	5	4	3	2	1	0	
SBIxCR1	$\leftarrow$	0	1	1	1	0	х	х	х	Selects the receive mode.
SBIxCR1	←	1	0	1	1	0	Х	Х	Х	Starts reception.
INTSBIx int	terru	pt								

Reg. ←

SBIxDBR

Reads the received data.

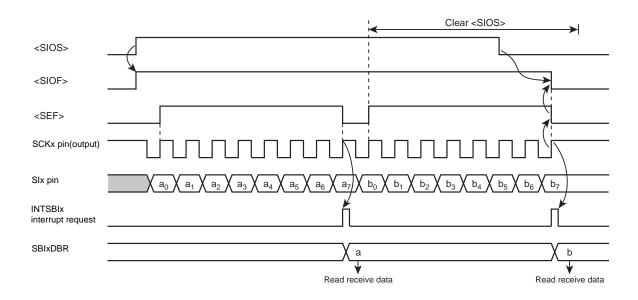

Figure 15-23 Receive Mode (Example: Internal Clock)

### 15.8.2.3 8-bit transmit/receive mode

Set the control register to the transfer/receive mode. Then writing the transmit data to SBIxDBR and setting SBIxCR1<SIOS> to "1" enables transmission and reception. The transmit data is output through the SOx pin at the falling of the serial clock, and the received data is taken in through the SI pin at the rising of the serial clock, with the least-significant bit (LSB) first. Once the shift register is loaded with the 8bit data, it transfers the received data to SBIxDBR and the INTSBIx interrupt request is generated. The interrupt service program reads the received data from the data buffer register and writes the next transmit data. Because SBIxDBR is shared between transmit and receive operations, the received data must be read before the next transmit data is written.

In the internal clock operation, the serial clock will be automatically in the wait state until the received data is read and the next transmit data is written.

In the external clock mode, shift operations are executed in synchronization with the external serial clock. Therefore, the received data must be read and the next transmit data must be written before the next shift operation is started. The maximum data transfer rate for the external clock operation varies depending on the maximum latency between when the interrupt request is generated and when the transmit data is written.

At the beginning of transmission, the same value as in the last bit of the previously transmitted data is output in a period from setting <SIOF> to "1" to the falling edge of SCK.

Transmission and reception can be terminated by clearing <SIOS> to "0" or setting SBIxCR1<SIOINH> to "1" in the INTSBIx interrupt service program. If <SIOS> is cleared, transmission and reception continue until the received data is fully transferred to SBIxDBR. The program checks SBIxSR<SIOF> to determine whether transmission and reception have come to an end. <SIOF> is cleared to "0" at the end of transmission and reception.If <SIOINH> is set to "1", the transmission and reception is aborted immediately and <SIOF> is cleared to "0".

Note: The contents of SBIxDBR will not be retained after the transfer mode is changed. The ongoing transmission and reception must be completed by clearing <SIOS> to "0" and the last received data must be read before the transfer mode is changed.

### 15.8.2.4 Data retention time of the last bit at the end of transmission

Under the condition SBIxCR1<SIOS>= "0", the last bit of the transmitted data retains the data of SCK rising edge as shown below. Transmit mode and transmit/receive mode are the same.

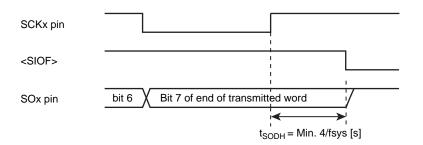

Figure 15-25 Data retention time of the last bit at the end of transmission

#### 15.8 Control in SIO mode

## 16. Analog/Digital Converter (ADC)

## 16.1 Outline

TMPM365FYXBG contains a 12-bit, sequential-conversion analog/digital converter (ADC) with 12 analog input channnels.

These 12 analog input channels (pins AIN00 through AIN11) are also used as input/output ports.

The 12-bit AD converter has the following features:

- · Starting normal AD conversion and highest-priority AD conversion
  - Software activation
  - Activation with the 16-bit timer (TMRB)
  - Hardware activation with an external trigger input (ADTRG pin)
- AD conversion
  - Fixed-channel singlel conversion mode
  - Channel scan single conversion mode
  - Fixed-channel repeat conversion mode
  - Channnel scan repeat conversion mode
- Highest-priority AD conversion
- · Normal AD conversion completion interrupt and highest-priority AD conversion completion interrupt
- Normal AD conversion and highest-priority AD conversion have the following status flags.

A flag indicating the AD conversion result data is valid, <ADRxRF>, and a flag indicating theAD conversion result data is overwritten, <OVRx>

Normal AD conversion completion flag and highest-priority AD conversion completion flag

Normal AD conversion busy flag and highest-priority AD conversion busy flag

AD Monitor Function

When the AD monitor function is enabled, an interrupt is generated if any comparison result is matched.

- AD conversion clock can be contorolled from 1/fc to 1/16fc.
- When AD conversion is completed, two types of DMA requests are supported.
- Standby mode is supported.

## 16.2 Configuration

Figure 16-1 shows the block diagram of the AD converter.

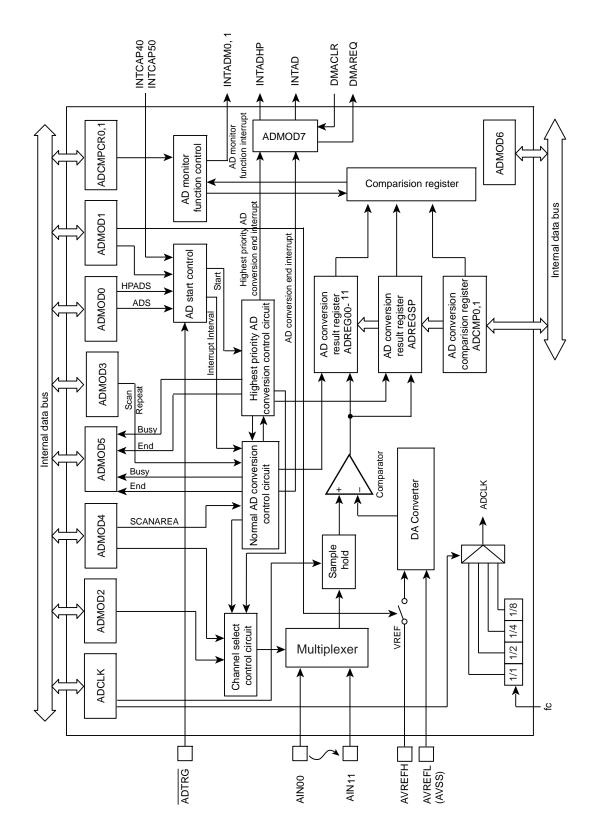

Figure 16-1 AD Converter Block Diagram

## 16.3 Registers

### 16.3.1 Register list

The control registers and addresses of the AD converter are as follows.

The AD converter is controlled by the AD mode control registers (ADMOD0 through ADMOD7). The result of AD conversion is stored in 12 AD conversion result registers, ADREG00 through ADREG11. The highest-priority conversion result is stored in the register ADREGSP.

## 16.3.3 ADMOD0 (Mode Control Register 0)

Bit	Bit Symbol	Туре	Function
31-2	-	R	Read as 0.
1	HPADS	W	Activate highest-priority AD conversion 0: Don't care 1: Start conversion
			"0" is always read.
0	ADS	w	Activate normal (software) AD conversion (Note 3) 0: Don't care 1: Start conversion "0" is always read.

- Note 1: In use ADC, write "1" to ADMOD1<VREFON> first, and then start AD conversion or external trigger by setting ADMOD0<ADS> or <HPADS>.
- Note 2: When both highest-priority AD conversion <HPADS> and normal AD conversion (software) are enabled and they are selected as ADTRG (external trigger input), highest-priority AD conversion is activated as a priority and normal AD conversion is not activated.

	31	30	29	28	27	26	25	24
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0

After reset	0	0	0	0	0	0	0	0

### 16.3.4 ADMOD1 (Mode Control Register 1)

Bit	Bit Symbol	Туре	Function
31-8	-	R	Read as 0.
7	VREFON	R/W	VREF application control (Note1 and Note2) 0: OFF 1: ON
6	I2AD	R/W	Specify operation mode in IDLE mode 0: Stop 1: Operation
5	RCUT	R/W	Control AVREFH-AVREFL current 0: Apply the current only in conversion. 1: Apply the current at any time except in RESET
4	-	R	Read as 0.
3	HPADHWS	R/W	Select hardware activation source of highest-priority AD conversion 0: External trigger 1: Interrupt of INTCAP40
2	HPADHWE	R/W	Activate highest-priority AD conversion triggered by hardware factors 0: Disable 1: Enable
1	ADHWS	R/W	Select hardware activation source of normal AD conversion (Note 3) 0: External trigger 1: Interrupt of INTCAP50
0	ADHWE	R/W	Activate normal AD conversion triggered by hardware factors 0: Disable 1: Enable

- Note 1: In use AD conversion, write "1" to the ADMOD<VREFON> bit, wait for 3µs during which time the internal reference voltage should stabilize, and then start AD conversion or external trigger by setting AD-MOD0<ADS> or <HPADS> to "1".
- Note 2: Set <VREFON> to "0" to go into standby mode upon completion of AD conversion.
- Note 3: The external trigger cannot be used for H/W activation of normal AD conversion when it is used for H/W activation of highest-priority AD conversion.
- Note 4: If it is necessary to reduce a power current with IDLE or STOP mode and if either case shown below is applicable, you must first suspend the AD converter and then execute the instruction to put into standby mode.
  - 1. In the case of putting into IDLE mode with ADMOD1 <I2AD> = "0".
  - 2. In the case of putting into STOP1 mode.

After reset	0	0	0	0	0	0	0	0

### 16.3.6 ADMOD3 (Mode Control Register 3)

Bit	Bit Symbol	Туре	Function
31-7	-	R	Read as 0.
6-4	ITM[2:0]	R/W	Specify interrupt in fixed channel repeat conversion mode. See Table 16-2.
3-2	-	R	Read as 0.
1	REPEAT	R/W	Specify repeat mode 0 : Single conversion mode 1 : Repeat conversion mode
0	SCAN	R/W	Specify scan mode 0 : Fixed channel mode 1 : Channel scan mode

# Table 16-2 AD conversion interrupt specification in fixed channel repeat conversion mode

<itm[2:0]></itm[2:0]>	Fixed channel repeat conversion mode <scan> = "0", <repeat> = "1"</repeat></scan>
000	Generate in interrupt once every single conversion.
001	Generate interrupt once every 2 conversions.
010	Generate interrupt once every 3 conversions.
011	Generate interrupt once every 4 conversions.
100	Generate interrupt once every 5 conversions.
101	Generate interrupt once every 6 conversions.
110	Generate interrupt once every 7 conversions.
111	Generate interrupt once every 8 conversions.

- Note 1: <ITM[2:0]> is valid only when it's specified in the fixed channel repeat mode, <REPEAT> ="1" and <SCAN> = "0".
- Note 2: When repeat conversion is aborted during repeat conversion (in <REPEAT>=1, fixed channel mode or channel scan mode), <REPEAT> is "0" cleared. In such case, do not change the setting except <RE-PEAT> bit.

	31	30	29	28	27	26	25	24	
bit symbol	-	-	-	-	-	-	-	-

After reset	0	0	0	0	0	0	0	0	

### 16.3.7 ADMOD4 (Mode Control Register 4)

Bit	Bit Symbol	Туре	Function
31-8	-	R	Read as 0.
7-4	SCANAREA [3:0]	R/W	Range of channel scan (prohibit 1100 to 1111)
3-0	SCANSTA[3:0]	R/W	Select the start channel to be scanned. (prohibit 1100 to 1111)

To specify channel scan single mode, set ADMOD3<SCAN> to "1" and <REPEAT> to "0". And, to specify channel scan repeat mode, set ADMOD3<SCAN> to "1" and <REPEAT> to "1".

At first, select the start channel to be scanned. Then select the number of channels to be scanned, starting on the specified start channel.

For example, when ADMOD4<SCANSTA> is set to "0001"(AIN01) and <SCANAREA> is set to "0010" (3ch scan), three channels from AIN01 to AIN03 are scanned.

The following shows the range of assignable value to <SCANAREA> in relation to setting of <SCANSTA>.

<scansta[3:0]></scansta[3:0]>	The start channel to be scanned	<scanarea[3:0]></scanarea[3:0]>	The range of as- signable channel scan value
0000	(AIN00)	0000 to 1011	(1ch to 12ch)
0001	(AIN01)	0000 to 1010	(1ch to 11ch)
0010	(AIN02)	0000 to 1001	(1ch to 10ch)
0011	(AIN03)	0000 to 1000	(1ch to 9ch)
0100	(AIN04)	0000 to 0111	(1ch to 8ch)
0101	(AIN05)	0000 to 0110	(1ch to 7ch)
0110	(AIN06)	0000 to 0101	(1ch to 6ch)
0111	(AIN07)	0000 to 0100	(1ch to 5ch)
1000	(AIN08)	0000 to 0011	(1ch to 4ch)
1001	(AIN09)	0000 to 0010	(1ch to 3ch)
1010	(AIN10)	0000 to 0001	(1ch to 2ch)
1011	(AIN11)	0000	(1ch)

Table 16-3 The range of assignable channel scan value

Note: In case of a setting other than listed above, AD conversion is not activated even if ADMOD0 register is set to activate AD conversion.

### 16.3 Registers

	31	30	29	28	27	26	25	24
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0

After reset	0	0	0	0	0	0	0	0

## 16.3.8 ADMOD5 (Mode Control Register 5)

Bit	Bit Symbol	Туре	Function
31-4	-	R	Read as 0.
3	HPEOCF	R	Highest-priority AD conversion completion flag (Note1) 0: Before or during conversion 1: Completion
2	HPADBF	R	Highest-priority AD conversion BUSY flag 0: During conversion halts 1: During conversion
1	EOCF	R	Normal AD conversion completion flag (Note1) 0: Before or during conversion 1: Completion
0	ADBF	R	Normal AD conversion BUSY flag 0: During conversion halts 1: During conversion

Note 1: This flag is "0" cleared by reading the ADMOD5 register.

- Note 2: If it is necessary to reduce a power current with IDLE or STOP mode and if either case shown below is applicable, you must first stop the AD converter and then execute the instruction to put into standby mode.
  - 1. In the case of putting into IDLE mode with ADMOD1<I2AD> = "0".
  - 2. In the case of putting into STOP1 mode.

## 16.3.9 ADMOD6 (Mode Control Register 6)

Bit	Bit Symbol	Туре	Function				
31-2	-	R	Read as 0.				
1-0	ADRST[1:0]	W	Overwriting 10 with 01 allows ADC to be software reset. A software reset initializes all the registers except for ADCLK <adclk>.</adclk>				

Note 1: When DMA transmission is executed by using AD conversion completion interrupt, software reset ADMOD6 <ADRST> first, and then operate DMAC(DMA request standby state) and configure (activate) the ADC.

Note 2: When executing the software reset, the bit of ADMOD1<VREFON> would be "1" is a valid.

Note 3: Initialization takes 3µs in case of the software reset.

## 16.3.11 ADCMPCR0 (Monitor Control Register 0)

Bit	Bit Symbol	Туре	Function						
31-12	-	R	Read as "0".						
11-8	CMPCNT0[3:0]	R/W	Number of comparison until the judgment is confirmed.						
			An interrupt is generated when the number of the counts is achieved.						
			0000 : each time 0110 : Over 7 times 1100 : Over 13 times						
			0001 : Over 2 times 0111 : Over 8 times 1101 : Over 14 times						
			0010 : Over 3 times 1000 : Over 9 times 1110 : Over 15 times						
			0011 : Over 4 times 1001 : Over 10 times 1111 : Over 16 times						
			0100 : Over 5 times 1010 : Over 11 times						
			0101 : Over 6 times 1011 : Over 12 times						
7	CMP0EN	R/W	AD monitor function 0						
			0: Disable						
			1: Enable						
			Setting the condition <cmp0en>="0" (disabled) clears the number of counts.</cmp0en>						
6	-	R	Read as "0".						
5	CMPCOND0	R/W	Sets the condition for judgement count.						
			0: Serial						
			1: Cumulative						
			Using serial method, an AD monitor interrupt occurs when the condition set to the <adbig0> continue- sand counts up to the number set to the <cmpcnt0>. After exceeding the setting value, an AD monitor in- terrupt occurs every time when the judgement condition is true. If the condition is different from the condition- set to the <adbig0>, the counter is cleared.</adbig0></cmpcnt0></adbig0>						
			Using cumulative method, an AD monitor interrupt occurs and the counter is cleared when the conditionset to the <adbig0> is accumulated and reaches the number set to the <cmpcnt0>. Even if the condition is different from the value set to the <adbig0>, the value of the counter is held.</adbig0></cmpcnt0></adbig0>						
4	ADBIG0	R/W	Set the AD monitor function interrupt 0 (INTADM0)						
			0: If the value of the conversion result register is bigger than the comparison register 0, an interrupt is gen- erated.						
			1: If the value of the conversion result register is smaller than the comparison register 0, an interrupt is gen- erated.						
			Every time when the AD conversion set to <ains0[3:0]> is completed, compare the size of conversion results.</ains0[3:0]>						
			If the result matches the settings of <adbig0>, the counter is incremented.</adbig0>						
3-0	AINS0[3:0]	R/W	Set analog inputs as a target for comparison.						
			0000 : AIN00 0101 : AIN05 1010 : AIN10						
			0001 : AIN01 0110 : AIN06 1011 : AIN11						
			0010 : AIN02 0111 : AIN07						
			0011 : AIN03 1000 : AIN08						
			0100 : AIN04 1001 : AIN09						
			1100 to 1111:						

Note: AD monitor function is used the fixed repeat mode and the scan repeat mode.

## 16.4 Description of Operations

### 16.4.1 Analog Reference Voltage

The "High" level of the analog reference voltage shall be applied to the AVRFEH pin, and the "Low" shall be applied to the AVREFL pin.

To start AD conversion, make sure that you first write "1" to the <VREFON> bit, wait for 3 µs during which time the internal reference voltage should stabilize, and then write "1" to the ADMOD0<ADS> bit.

By writing "0" to the ADMOD1<RCUT> bit, a switched-on state of AVREFH – AVREFL can be turned into a switched -off state.

### 16.4.2 AD Conversion Mode

Two types of AD conversion are supported: normal AD conversion and highest-priority AD conversion.

For normal AD conversion, the following four operation modes are supported.

### 16.4.2.1 Normal AD Conversion

For normal AD conversion, the following four operation modes are supported and the operation mode is selected with the ADMOD3<REPEAT, SCAN>.

- Fixed channel single conversion mode
- Channel scan single conversion mode
- Fixed channel repeat conversion mode
- Channel scan repeat conversion mode

### (1) Fixed channel single conversion mode

If ADMOD3<REPEAT, SCAN> is set to "00", AD conversion is performed in the fixed channel single conversion mode.

In this mode, AD conversion is performed once for one channel selected by ADMOD2 <ADCH>. After AD conversion is completed, ADMOD5<EOCF> is set to "1", ADMOD5<ADBF> is cleared to "0", and the AD conversion completion interrupt request (INTAD) is generated. <EOCF> is cleared to "0" upon read.

### (2) Channel scan single conversion mode

If ADMOD3 <REPEAT, SCAN> is set to "01," AD conversion is performed in the channel scan single conversion mode.

In this mode, AD conversion is performed once for the scan channel area selected by ADMOD4 <SCANAREA> from the start channel selected by ADMOD4 <SCANSTA>. After AD scan conversion is completed, ADMOD5<EOCF> is set to "1", ADMOD5<ADBF> is cleared to "0", and the conversion completion interrupt request (INTAD) is generated. <EOCF> is cleared to "0" upon read.

### (3) Fixed channel repeat conversion mode

If ADMOD3<REPEAT, SCAN> is set to "10", AD conversion is performed in fixed channel repeat conversation mode. In this mode, AD conversion is performed repeatedly for one channel selected by ADMOD2 <ADCH>. After AD conversion is completed, ADMOD5<EOCF> is set to "1". ADMOD5<ADBF> is not cleared to "0". It remains at "1". The timing with which the conversion completion interrupt request (INTAD) is generated can be selected by setting ADMOD3<ITM> to an appropriate setting. <EOCF> is set with the same timing as this interrupt INTAD is generated. <EOCF> is cleared to "0" upon read.

#### (4) Channel scan repeat conversion mode

If ADMOD3<REPEAT, SCAN> is set to "11", AD conversion is performed in the channel scan repeat conversion mode.

In this mode, AD conversion is performed repeatedly for the scan channel area selected by AD-MOD4 <SCANAREA> from the start channel selected by ADMOD4 <SCANSTA>. Each time one AD scan conversion is completed, ADMOD5 <EOCF> is set to "1", and the conversion completion interrupt request (INTAD) is generated. ADMOD5 <ADBF> is not cleared to "0" and remains at "1". <EOCF> is cleared to "0" upon read.

#### 16.4.2.2 Highest-priority AD conversion

By interrupting ongoing normal AD conversion, highest-priority AD conversion can be performed.

The fixed-channel single conversion is automatically selected, irrespective of the ADMOD3 <RE-PEAT, SCAN> setting. When conditions to start operation are met, a conversion is performed just once for a channel selected by ADMOD2<HPADCH>. When conversion is completed, the highest-priority AD conversion completion interrupt (INTADHP) is generated, and ADMOD5 <HPEOCF> showing the completion of AD conversion is set to "1". <HPADBF> returns to "0". <HPEOCF> flag is cleared to "0" upon read.

Highest-priority AD conversion activated while highest-priority AD conversion is under way is ignored.

### 16.4.3 AD monitor function

This function is used for configuring the fixed channel repeat mode and the scan repeat mode.

If ADCMPCR0<CMP0EN> and ADCMPCR1<CMP1EN> are set to "1", AD monitor function is enabled. Two monitor function can be enabled concurrently.

Here is an example of ADCMPCR0 (same as ADCMPCR1).

Analog input for comparison is set to ADACMPCR0/ADBCMPCR0<AINS0[3:0]>. Large or small judgement is set to <ADBIG0>. Conditions of this comparison count is set to <CMPCOND0>. The number of comparison count is set to <CMPCNT0[3:0]>.

Once AD conversion starts, the AD converter checks comparison conditions (smaller/larger than values of the compare register) for each AD conversion. If the result of the comparison meets the settings of <AD-BIG0>, the AD converter counts up the counter value.

There are two types of comparison condition: sequential method and cumulative method.

In the sequential method, an AD monitor interrupt (INTADM0) occurs if the condition set to <ADBIG0> continues and reaches the number of counts set to <CMPCNT0[3:0]>. An interrupt occurs without clearing the counter if the result of comparison meets the condition even after reaching the the number of counts set to <CMPCNT0[3:0]>. The value of the counter is zero cleared only when the condition does not meet the set condition of <ADBIG0>.

In the cumulative method, the counter is zero cleared when the total number of times that the condition set to <ADBIG0> meets reaches the number set to <CMPCNT0[3:0]>. An AD monitor interrupt (INTADM0) occurs at this time. The counter value is kept even if the result of the comparison is different from the set value

of the counter. If values of the Conversion Result Register configured by the ADCMPCR0 register are the same as those of the tar get register, the AD converter does not count up. An AD conversion interrupt (IN-TADM0) does not occur either.

This comparison operation is performed each time a result is stored in a corresponding conversion result register. An interrupt (INTADM0) occurs when conditions meet (including counting). Since the conversion result register assigned to perform the AD monitor function is usually not read by software, the conversion result storage flag ADREG<ADRF> and the overrun flag ADREG<ADOVRF> remain being set. Do not use the conversion result register when you use the AD monitor function.

- 1. AIN00 input is set to the fixed channel repeat conversion mode and compare values of the AD Conversion Result Compare Register (0x0888).
  - · ADMOD3=0x0002: fixed channel repeat conversion

AD conversion completion interrupt (INTAD) is disabled.

- ADCMPCR0 =0x0280: compare target channel: AIN00, size determination: larger than a value of the compare register. Compare counting condition: sequential method. AD monitor function: enabled. Size determination count: 3 counts.
  - ADCMP0=0x0888: AD Conversion Result Compare Register (compared value 0x0888)

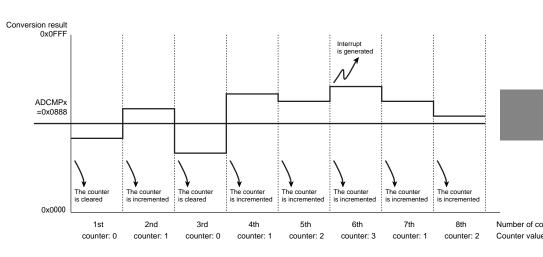

Figure 16-3 AD monitor function (fixed channel repeat and sequential method)

- 2. AIN00 is set to fixed channel repeat conversion and compare the value of the AD Conversion Result Compare Register (0x0888).
  - ADMOD3=0x0002: fixed channel repeat conversion

AD conversion completion interrupt (INTAD) is disabled.

- ADCMPCR0 =0x02A0: compare target channel: AINA00, size determination: larger than a value of the compare register. compare counting condition: cumulative method. AD monitor function: enabled. size determination count: 3 counts
- ADCMP0=0x0888: AD Conversion Result Compare Register (compared value 0x0888)

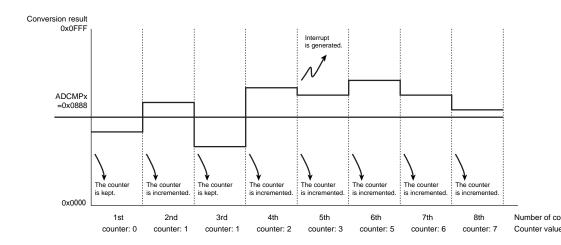

Figure 16-4 AD Monitor Function (fixed channel repeat and cumulative method)

### 16.4.4 Selecting the Input Channel

After reset, ADMOD3 <REPEAT, SCAN> is initialized to "00" and ADMOD2 <ADCH[3:0]> is initialized to "0000".

The channels to be converted are selected according to the operation mode of the AD converter as shown below.

- 1. Normal AD conversion mode
  - If the analog input channel is used in a fixed state (ADMOD3<SCAN> = "0")

One channel is selected from analog input pins AIN00 through AIN11 by setting AD-MOD2 <ADCH> to an appropriate setting

• If the analog input channel is used in a scan state (ADMOD3<SCAN> = "1")

The channel to be started can be specified by setting ADMOD4 <SCANSTA>. And, the number of channels to be scanned can be specified by setting ADMOD4 <SCANAREA>.

2. Highest-priority AD conversion mode

One channel is selected from analog input pins from AIN00 through AIN11 by setting AD-MOD2<HPADCH> to an appropriate setting. If highest-priority AD conversion has been activated during normal AD conversion, ongoing normal AD conversion is suspended, and restarts normal AD conversion after highest-priority AD conversion is completed.

# TOSHIBA

### 16.4.5 AD Conversion Details

### 16.4.5.1 Starting AD Conversion

Two types of AD conversion are supported: normal AD conversion and top-priority AD conversion. Normal AD conversion is activated by setting ADMOD0<ADS> to "1". Highest-priority AD conversion is activated by setting ADMOD0<HPADS> to "1".

Four operation modes are made available to normal AD conversion. In performing normal AD conversion, one of these operation modes must be selected by setting ADMOD3 <REPEAT, SCAN> to an appropriate setting. For highest-priority AD conversion, only one operation mode can be used: fixed channel single conversion mode.

Normal AD conversion can be activated using the H/W activation source selected by AD-MOD1<ADHWS>, and highest-priority AD conversion can be activated using the HW activation source selected by ADMOD1<HPADHWS>. If bits of <ADHWS> and <HPADHWS> are "0", normal and highestpriority AD conversions are activated in response to the input of a falling edge through the ADTRG pin. If these bits are "1", normal AD conversion is activated in response to INTCAP50 generated by the 16bit timer channel 5, and highest-priority AD conversion is activated in response to INTCAP40 generated by the 16-bit timer channel 4.

To permit H/W activation, set ADMOD1 <ADHWE> to "1" for normal AD conversion and set AD-MOD1<HPADHWE> to "1" for highest-priority AD conversion.

Software activation is still valid even after H/W activation has been permitted.

Note: When an external trigger is used for the HW activation source of a highest-priority AD conversion, an external trigger cannot be set for activating normal AD conversion H/W start.

### 16.4.5.2 AD Conversion

When normal AD conversion starts, the AD conversion Busy flag (ADMOD5 <ADBF>) showing that AD conversion is under way is set to "1".

When highest-priority AD conversion starts, the highest-priority AD conversion Busy flag (ADMOD5 <HPADBF>) showing that AD conversion is under way is set to "1".

At that time, the value of the Busy flag ADMOD5<ADBF> for normal AD conversion before the start of highest-priority AD conversion is retained.

The value of the conversion completion flag ADMOD5 <EOCF> for normal AD conversion before the start of highest-priority AD conversion is retained.

Note: Normal AD conversion must not be activated when highest-priority AD conversion is under way. If activated when highest-priority AD conversion is under way, the highest-priority AD conversion completion flag cannot be set, and the flag for previous normal AD conversion cannot be cleared.

### 16.4.5.3 Highest-priority AD conversion requests during normal AD conversion

If highest-priority AD conversion has been activated during normal AD conversion, ongoing normal AD conversion is suspended, and restarts normal AD conversion after highest-priority AD conversion is completed.

If ADMOD0<HPADS> is set to "1" during normal AD conversion, ongoing normal AD conversion is suspended, and the highest-priority AD conversion starts; specifically, AD conversion (fixed-channel single conversion) is executed for a channel designated by ADMOD2<HPADCH>. After the result of this highestpriority AD conversion is stored in the storage register ADREGSP, normal AD conversion is resumed.

If H/W activation of highest-priority AD conversion is authorized during normal AD conversion, ongoing AD conversion is discontinued when requirements for activation using a H/W activation resource are met, and highest-priority AD conversion (fixed-channel single conversion) starts for a channel designated by ADMOD2<HPADCH>. After the result of this highest-priority AD conversion is stored in the storage register ADREGSP, normal AD conversion is resumed.

For example, if channel repeat conversion is activated for channels AIN00 through AIN03 and if <HPADS> is set to "1" during AIN02 conversion, AIN02 conversion is suspended, and conversion is performed for a channel designated by <HPADCH> (AIN11 in the case shown below). After the result of conversion is stored in ADREGSP, channel repeat conversion is resumed, starting from AIN02.

Highest-priority A	D has beer	activated						
	(							
Conversion Ch	Ch0	Ch1	Ch2	Ch11	Ch2	Ch3	Ch0	

### 16.4.5.4 Stopping Repeat Conversion Mode

To stop the AD conversion operation in the repeat conversion mode (fixed-channel repeat conversion mode or channel scan conversion mode), write "0" to ADMOD3<REPEAT>. When ongoing AD conversion is completed, the repeat conversion mode terminates, and ADMOD5<ADBF> is set to "0".

### 16.4.5.5 Reactivating normal AD conversion

If ADMOD0 <ADS> is set to "1" during normal AD conversion, normal AD conversion is reactivated. Ongoing normal AD conversion is suspended at the time that it is reactivated. At that time, the normal AD conversion Busy flag ADMOD5 <ADBF>, the normal AD conversion completion flag ADMOD5 <EOCF> and the storage result flag ADREGm <ADOVRF>, <ADRF> are cleared to "0". (m=00-11)

If H/W activation of normal AD conversion is authorized during normal AD conversion, ongoing AD conversion is discontinued when requirements for activation using a H/W activation resource are met. Ongoing normal AD conversion is suspended at the time that it is reactivated. At that time, the normal AD conversion Busy flag ADMOD5 <ADBF>, the normal AD conversion completion flag ADMOD5 <EOCF> and the storage result flag ADREGm <ADOVRF>, <ADRF> are cleared to "0". (m=00-11)

### 16.4.5.6 Conversion completion

#### (1) Normal AD conversion completion

When normal AD conversion is completed, the AD conversion completion interrupt (INTAD) is generated. The result of AD conversion is stored in the storage register, and two registers change: the register ADMOD5<EOCF> which indicates the completion of AD conversion and the register AD-MOD5<ADBF>. The timing that interrupt request is generated and the timing that conversion result register <EOCF> <ADBF> changes vary according to a mode selected.

In mode other than fixed-channel repeat conversion mode, conversion results are stored in AD conversion result registers (ADREG00 through ADREG11) corresponding to a channel.

In fixed-channel repeat conversion mode, the conversion results are sequentially stored in storage registers ADREG00 through ADREG11. However, if interrupt setting on <ITM> is set to be generated each time one AD conversion is completed, the conversion result is stored only in ADREG00. If interrupt setting on <ITM> is set to be generated each time 8 AD conversions are completed, the conversion results are sequentially stored in ADREG00 through ADREG07.

Interrupt requests, flag changes and conversion result registers in each mode are as shown below.

Fixed-channel single conversion mode

After AD conversion is completed, ADMOD5 <EOCF> is set to "1", ADMOD5 <ADBF> is cleared to "0", and the interrupt request INTAD is generated.

Conversion results are stored a conversion result register correspond to a channel.

· Channel scan single conversion mode

After the channel scan conversion is completed, ADMOD5 <EOCF> is set to "1", AD-MOD5 <ADBF> is cleared to "0", and the interrupt request INTAD is generated.

Conversion results are stored a conversion result register correspond to a channel.

<u>Fixed-channel repeat conversion mode</u>

ADMOD5 <ADBF> is not cleared to "0". It remains at "1". The timing with which the interrupt request INTAD is generated can be selected by setting ADMOD3<ITM> to an appropriate setting. ADMOD5 <EOCF> is set with the same timing as this interrupt INTAD is generated.

a. One conversion

With ADMOD2 <ADCH[3:0]> set to "0000" (AIN00) and ADMOD3 <ITM[2:0]> set to "000", an interrupt request is generated each time one AD conversion is completed. In this case, the conversion results are always stored in the storage register ADREG00. After the conversion result is stored, <EOCF> is set to "1".

b. 8 conversions

With ADMOD2 <ADCH[3:0]> set to "1011" (AIN11) and ADMOD3 <ITM[2:0]> set to "111", an interrupt request is generated each time 8 AD conversions are completed. In this case, the conversion results are sequentially stored in the storage register ADREG00 through ADREG07. After the conversion result is stored in ADREG07, <EOCF> is set to "1", and the storage of subsequent conversion results starts from ADREG00.

• Channel scan repeat conversion mode

Each time one AD conversion is completed, ADMOD5<EOCF> is set to "1" and an interrupt request INTAD is generated. ADMOD5<ADBF> is not cleared to "0". It remains at "1".

If ADMOD4 <SCANSTA[3:0]> is set to "0001" (AIN01) and ADMOD4 <SCANAREA [7:4]> is set to "1110" (11Ch scan), each time one AD conversion is completed, AD-MOD5 <EOCF> is set to "1" and an interrupt request INTAD is generated. ADMOD5 <ADBF> is not cleared to "0" and remains at "1".

AD conversion results are stored in a AD conversion result register corresponding to a channel.

### (2) Highest-priority AD conversion completion

After the highest-priority AD conversion is completed, the highest-priority AD conversion completion interrupt (INTADHP) is generated, and ADMOD5<HPEOCF> which indicates the completion of highest-priority AD conversion is set to "1".

AD conversion results are stored in the AD conversion result register SP.

### (3) Data polling

To confirm the completion of AD conversion without using interrupts, data polling can be used. When AD conversion is completed, ADMOD5 <EOCF> is set to "1". To confirm the completion of AD conversion and to obtain the results, poll this bit.

AD conversion result storage register must be read by word access. If  $\langle ADOVRF \rangle = "0"$ ,  $\langle ADRF \rangle = "1"$  and  $\langle ADPOSWF \rangle = "0"$ , a correct conversion result has been obtained.

### (4) DMA request

After the normal AD conversion completion interrupt (INTAD) or the highest-priority AD conversion completion interrupt (INTADHP) is generated, DMA request is issued. DMA request after any interrupt is generated can be set to "disable" or "enable" by setting ADMOD7 register to an appropriate setting. A DMA request is issued in 2 system clocks (fsys) after AD conversion completion interrupt (INTAD or INTADHP) is generated.

### 16.4.5.7 Interrupt generation timings and AD conversion result storage register

Table 16-4 shows a relation in the following three items: AD conversion modes, interrupt generation timings and flag operations. Table 16-5 shows a relation between analog channel inputs and AD conversion result registers.

Table 16-4 Relations in conversion modes	, interrupt generation	timings and flag operations
--	------------------------	-----------------------------

		Scan/repeat mode setting (ADMOD3)				(ADMOD5)							
Conv	Conversion mode		<scan></scan>	<itm[2:0]></itm[2:0]>	Interrupt generation timing	<eocf>/ <hpeocf> set timing (See note1)</hpeocf></eocf>	<adbfn> (After the interrupt is generated)</adbfn>	<adbfhp> (After the interrupt is generated)</adbfhp>					
	Fixed-channel single conversion	0	0	-	After generation is completed.	After generation is completed.	0	-					
				000	Each time one conversion is completed.	After one conver- sion is completed.	1	-					
				001	Each time 2 con- version is com- pleted.	After 2 conver- sions are comple- ted.	1	-					
Normal conversion Channel scan single conversion				010	Each time 3 con- version is com- pleted.	After 3 conver- sions are comple- ted.	1	-					
	Fixed-channel	1	0	011	Each time 4 con- version is com- pleted.	After 4 conver- sions are comple- ted.	1	-

#### Table 16-5 Relations between analog channel inputs and AD conversion result registers

	Channel scan single mode / repeat mode (ex. ADREG03 to depend on the scan channel range.)							
ADMOD4 <scansta> (Starts channel)</scansta>	ADMOD4 <scanarea> (Scan channel range)</scanarea>	Storage register						
AIN00	12 channels	ADREG00 to ADRE11						
AIN01	11 channels	ADREG01 to ADRE11						
AIN02	10 channels	ADREG02 to ADRE11						
AIN03	9 channels	ADREG03 to ADRE11						
AIN04	8 channels	ADREG04 to ADRE11						
AIN05	7 channels	ADREG05 to ADRE11						
AIN06	6 channels	ADREG06 to ADRE11						
AIN07	5 channels	ADREG07 to ADRE11						
AIN08	4 channels	ADREG08 to ADRE11						
AIN09	3channels	ADREG09 to ADRE11						
AIN10	2 channels	ADREG10 to ADRE11						
AIN11	1 channels	ADREG11 to ADRE11						

Note: When the range of channel scan is set to out of the assignable value in channel scan mode, the AD conversion can not be activated even if ADMOD0 is set to activate AD conversion.

Notes on designing for AD converter inputs

<An output impedance of the external signal source which is connected with AIN pin>

An output impedance of the external signal source which is connected with AIN pin is equal or less than R<sub>EXAIN</sub> shown below formula.

- Calculating formula of allowable value of output impedance of the external signal source -

The maxmum value of an output impedance connected with AIN pin :  $R_{EXAIN} < T_{SCyc} + (ADCLK \times C_{ADC} \times In (2^{14})) - R_{AIN}$ 

MCU information	Symbol	Min	Тур	Max	Unit
ADC clock frequency	ADCLK	4	-	40	MHz
Total AIN input capacity in MCU	C <sub>ADC</sub>	-	-	12.2	pF
AIN resistance in MCU	R <sub>AIN</sub>	-	-	1	kΩ
Cycle number in the sample hold pe- riod	Тѕсус	10	-	80	Cycle

#### R<sub>EXAIN</sub> maximum value list ( ADCLK = 40MHz )

Tcsyc	R <sub>EXAIN</sub>	Unit
10	1.1	kΩ
20	3.2	kΩ
30	5.3	kΩ

Notes on	designing	for AD	converter inputs
110103 011	ucoigning		converter inputs

40	7.5	kΩ
80	15.9	kΩ

< Addition of stabilizing capacity >

If high-speed AD conversion is required and the sample hold period cannot meet the conditions of calculating formula of allowable values of output impedance of external signal source, add stabilizing capacity to the AIN pin. The additional capacity depends on external circuit. Although the capacity depended on the external circuit is different from the each board set, add the capacity from about 0.1µF to 1µF, appropriate amount for your circuit board.

Set the capacity to be added next to the AIN pin.

< Adjustment of sample hold period>

Generally, by setting the sample hold period long, you can make the input voltage of the comparator in the ADC circuit as same as the input voltage of the AIN pin can reduce the error of an AD conversion.

Although, in case that the sample hold period is too long, the error of an AD conversion may be increased because the voltage held in sample hold circuit is changed.

Because the suitable sample hold period is depended on the each board set, please decided the suitable sample hold period on your board set.

Notes of the use of the AD converter

The result value of AD conversion may vary depending on the fluctuation of the supply voltage, or may be affected by noise. When using analog input pins and ports alternately, do not read and write ports during conversion because the conversion accuracy may be reduced. Also the conversion accuracy may be reduced if the output ports current fluctuate during AD conversion. Please take counteractive measures with the program such as averaging the AD conversion results.

### 16.4 Description of Operations

# 17. Flash Memory Operation

This section describes the hardware configuration and operation of Flash memory. In this section, "1-word" means 32 bits.

# 17.1 Features

### 17.1.1 Memory Size and Configuration

Table 17-1 and Figure 17-1 show a built-in memory size and configuration of TMPM365FYXBG.

Table 17-1 Memory size and configuration

	Block configuration					Write	time	Erase	e time	
Memory size	128 KB	64 KB	32 KB	16 KB	# of words per page	# of pages 1	1 page	Total area	Block erase	Chip erase
256 KB	-	3	1	2	64	1024	1.25ms	1.28 sec	0.1sec	0.4 sec

Note: The above values are theoretical values not including data transfer time. The write time per chip depends on the write method used by a user.

User Boot Mode	Single Boot Mode		Page Configuration
0x0003_FFFF	0x3F83_FFFF	64K bytes (BLOCK0)	64 words × 256
0x0003_0000	0x3F83_0000		Į,
0x0002 0000	0x3F82_0000	64K bytes (BLOCK1)	64 words × 256
0x0002_0000	0,01 02_0000		11
		64K bytes (BLOCK2)	64 words × 256
0x0001_0000	0x3F81_0000		IJ
		32K bytes (BLOCK3)	≻64 words × 128
0x0000_8000	0x3F80_8000	16K huton (PLOCKE)	]   } 64 words × 64
0x0000_4000	0x3F80_4000	16K bytes (BLOCK5)	1
0x0000_0000	0x3F80_0000	16K bytes (BLOCK4)	64 words × 64

Figure 17-1 Block configuration

Flash memory configuration units are described as "block" and "page".

• Page

One page is 64 words. Same address [31:8] is used in a page. First address of the group is [7:0] = 0x00 and the last address of the group is [7:0] = 0xFF.

#### Block

There is size of 16 KB, 32 KB and 64 KB in a block, and a flash memory consists of blocks of some different sizes.

Write operation is performed per page. The write time per page is 1.25ms. (Typ.)

Erase is performed per block ( auto block erase command use ) or performed on entire flash memory (use of auto chip erase command). Erase time varies on commands. If auto block command is used, the erase time will be 0.1 sec per block (Typ.). If the auto chip erase command is used to erase entire area, the time will be 0.2 sec (Typ.).

In addition, the protect function can be used per block. For detail of the protect function, refer to "17.1.5 Protect/Security Function".

### 17.1.2 Function

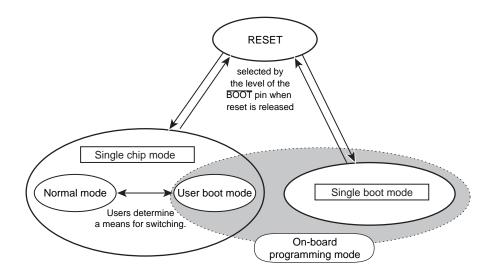

Flash memory built-in this device is generally compliant with the JEDEC standards except for some specific functions. Therefore, if a user is currently using a flash memory as an external memory, it is easy to implement the functions into this device. Furthermore, to provide easy write or erase operation, this product contains a dedicated circuit to perform write or chip erase automatically.

JEDEC compliant functions	Modified, added, or deleted functions
<ul> <li>Automatic programming</li> <li>Automatic chip erase</li> <li>Automatic block erase</li> <li>Data polling/toggle bit</li> </ul>	<modified> Block write/erase protect (only software protection is supported) <deleted> Erase resume - suspend function</deleted></modified>

### 17.1.3 Operation Mode

### 17.1.3.1 Mode Description

This device provides the single chip mode and single boot mode. The single chip mode contains the normal mode and user boot mode. Figure 17-2 shows the mode transition.

### Figure 17-2 Mode transition

### (1) Single chip mode

The single chip mode is a mode where the device can boot-up from Flash memory after reset. The mode contains two sub-modes in below.

Normal mode

The mode where user application program is executed.

• User boot mode

The mode where flash memory is re-programmed on the user's set.

Users can switch the normal mode to user boot mode freely. For example, a user can set if PA0 of port A is "1", the mode is the normal mode. If PA0 of port A is "0", the mode is the user boot mode. The user must prepare a routine program in the application program to determine the switching.

### (2) Single boot mode

The mode where flash memory can boot-up from the built-in BOOT ROM (Mask ROM) after reset.

The BOOT ROM contains the algorithm that can rewrite Flash memory via serial port of this device on the user's set. With connecting the serial port to external host, data transfer is performed in above-mentioned protocol and re-programed Flash memory.

### (3) On-board programming mode

The user boot mode and single boot mode are the modes where flash memory can be re-programmable on the user's set. These two modes are called "on-board programming mode".

### 17.1.3.2 Mode Determination

Either the single chip or single boot operation mode can be selected by the level of the BOOT pin when reset is released.

On another mode	Pin			
Operation mode	RESET	BOOT		
Single chip mode	$0 \rightarrow 1$	1		
Single boot mode	$0 \rightarrow 1$	0		

Table 17-2 Operation mode setting

### 17.1.4 Memory Map

Figure 17-3 shows a comparison of the memory map in the single chip mode and single boot mode. In the single boot mode, built-in Flash memory is mapped to 0x3F80\_0000 and subsequent addresses, and the built-in BOOT ROM is mapped to 0x0000\_0000 through 0x0000\_0FFF.

Flash memory and RAM addresses are shown below.

FLASH size	RAM size	FLASH address	RAM address
256 KB	24 KB	0x0000_0000 to 0x0003_FFFF(single mode) 0x3F80_0000 to 0x3F83_FFFF(single boot mode)	0x2000_0000 to 0x2000_5FFF

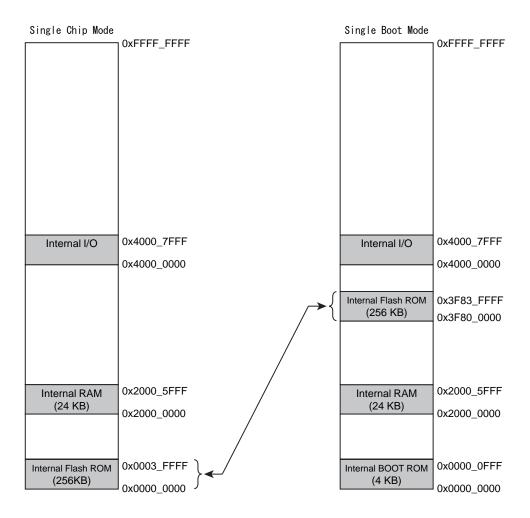

Figure 17-3 Comparison of memory map

### 17.1.5 Protect/Security Function

This device has the protect and security functions for Flash memory.

1. Protect function

The write/erase operation can be inhibited per block.

2. Security function

The read operation from a flash writer can be inhibited.

Usage restrictions on debug functions

### 17.1.5.1 Protect Function

This function inhibits the write/erase operation per block.

To enable the protect function, a protect bit corresponding to a block is set to "1" using the protect bit program command. If a protect bit is set to "0" using the protect bit erase command, a block protect can be canceled. The protect bit can be monitored with FCFLCS<BLPRO[3:0]>.

A program of protect bit can be programmed by 1-bit unit and can be erased by 4-bit unit. For detail of programming/erasing of protect bits, refer to "17.2.5 Command Description".

### 17.1.5.2 Security Function

Table 17-3 shows operations when the security function is enabled.

	<b>~</b>			· · ·	
Table 17-3	Operations	when t	he security	tunction is	senabled
	oporationo		no ocounty	Turiouori ie	, onabioa.

Item	Description	
Read flash memory	CPU can read flash memory.	
Debug port	JTAG, serial wire or trace communication is disabled.	
Command execution to Flash memory	Command write to flash memory is not accepted. If a user tries to erase a protect bit, chip erase is executed and all protect bits are erased.	

The security function is enabled under the following conditions;

- 1. FCSECBIT<SECBIT> is set to "1".
- 2. All protect bits (FCFLCS<BLPRO>) are set to "1".

FCSECBIT<SECBIT> is set to "1" by the cold reset. Rewriting of FCSECBIT <SECBIT> is described in below.

Note: Use a 32-bit transfer instruction when the following writing operations, item1 and 2.

1. Write the specified code (0xa74a9d23) to FCSECBIT

- ----

2. Write data within 16 clocks after the operation of item 1.

### 17.1.6 Register

### 17.1.6.1 Register List

		Base Address = 0x41FF_F000
Register name	Address(Base+)	
Security bit register	FCSECBIT	0x0010
Flash control register	FCFLCS	0x0014

Note:Do not access the address of 0x41FF\_F000 to 0x41 FF\_FFFF other than the above-mentioned address list.

### 17.1.6.2 FCFLCS (Flash control register)

	31	30	29	28	27	26	25	24
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	23	22	21	20	19	18	17	16
bit symbol	-	-	BLPRO5	BLPRO4	BLPRO3	BLPRO2	BLPRO1	BLPRO0
After reset	0	0	(Note 2)					
	15	14	13	12	11	10	9	8
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	7	6	5	4	3	2	1	0
bit symbol	-	-	-	-	-	-	-	RDY/BSY
After reset	0	0	0	0	0	0	0	1

Bit	Bit Symbol	Туре	Function
31-22	-	R	Read as "0".
19-21	BLPRO3- BLPRO0	R	Protection status of Block5 to 0 0: Not protected 1: Protected Protect bit values correspond to protect status of each block. If corresponding bit indicates "1", correspond- ing block is in the protection status.
15-1		R	A block in the protection status. Read as "0".
0	RDY/BSY	R	Ready/Busy (Note 1) 0: Busy (during auto operation) 1: Ready (auto operation ends) This bit is a function bit to monitor flash memory from CPU. While flash memory is in auto operation, this bit outputs "0" to indicate that flash memory is busy. Once auto operation is finished, this bit becomes ready state and outputs "1". Then next command is accepted. If a result of auto operation is failed, this bit outputs "0" continuously. The bit returns to "1" by hardware re- set.

Note 1: Make sure that flash memory is ready before commands are issued. If a command is issued during busy, not only the command is not sent but also subsequent commands may not be accepted. In that case, use hardware reset to return. Hardware reset needs 0.5 µs or more reset period regardless of system clock. At this time, it takes approximately 2 ms until enabling to read after reset.

Note 2: A value will correspond to the protection status.

	31	30	29	28	27	26	25	24
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	23	22	21	20	19	18	17	16
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8
bit symbol	-	-	-	-	-	-	-	-
After reset	0	0	0	0	0	0	0	0
	7	6	5	4	3	2	1	0
bit symbol	-	-	-	-	-	-	-	SECBIT
After reset	0	0	0	0	0	0	0	1

# 17.1.6.3 FCSECBIT (Security bit register)

Bit	Bit Symbol	Туре	Function				
31-1	-	R	Read as "0".				
0	SECBIT	R/W	Security bit 0: Security function setting is disabled. 1: Security function setting is enabled.				

Note: This register is initialized by cold reset.

# 17.2 Detail of Flash Memory

In on-board programming, the CPU executes commands for reprogramming or erasing Flash memory. This reprogramming/erase control program should be prepared by the user beforehand. Since Flash memory content cannot be read while Flash memory is being written or erased, it is necessary to run the reprogram/erase control program on the built-in RAM. Do not generate interrupt/fault except reset to avoid abnormal program termination.

### 17.2.1 Function

Flash memory is generally compliant with the JEDEC standards except for some specific functions. However; a method of address designation of operation command is different from standard commands.

If write/erase operation is executed, commands are input to flash memory using 32-bit (1-word) store instruction command. After command input, write or erase operation is automatically executed in inside.

Table 17-4 Flash memory function

Main function	Description
Automatic page program	Writes data automatically.
Automatic chip erase	Erases the entire area of Flash memory automatically.
Automatic block erase	Erases a selected block automatically.
Write/erase protect	The write or erase operation can be individually inhibited for each block.

### 17.2.2 Operation Mode of Flash Memory

Flash memory provides mainly two types of operation modes;

- The mode to read memory data (Read mode)
- The mode to erase or rewrite memory data automatically (Automatic operation mode)

After power-on, after rest or after automatic operation mode is finished normally, Flash memory becomes read mode. Instruction stored in Flash memory or data read is executed in the read mode.

If commands is input during the read mode, the operation mode becomes the automatic operation. If the command process is normally finished, the operation mode returns to the read mode except the ID-Read command. During the automatic operation, data read and instruction execution stored in Flash memory cannot be performed.

If command process is abnormally finished then the operation mode should forcibly return to read mode. In this case, use the read command, read/reset command or hardware reset.

### 17.2.3 Hardware Reset

A hardware reset means a cold reset or warm reset to use returning to the read mode when the automatic programming/erase operation is forced cancel, or automatic operation abnormally ends.

If the hardware reset occurs during the automatic operation, Flash memory stops the automatic operation and returns to the read mode. If a hardware reset is generated during Flash memory automatic program/erase operation, the hardware reset needs  $0.5 \ \mu$ s or more reset period regardless of system clock. At this time, it takes approximately 2 ms until enabling to read after reset. Note that if a hardware reset occurs during the automatic operation, data write operation is not executed properly. Set write operation again.

For detail of the reset operation, refer to "Reset". After a given reset input, CPU will read the reset vector data and then starts the routine after reset.

### 17.2.4 How to Execute Command

The command execution is performed by writing command sequences to Flash memory with a store instruction. Flash memory executes each automatic operation command according to the combination of input addresses and data. For detail of the command execution, refer to "17.2.5 Command Description".

An execution of store instruction to the Flash memory is called "bus write cycle". Each command consists of some bus write cycles. In Flash memory, when address and data of bus write cycle are performed in the specified order, the automatic command operation is performed. When the cycle is performed in non-specified order, Flash memory stops command execution and returns to the read mode.

If you cancel the command during the command sequence or input a different command sequence, execute the read command or read/reset command. Then Flash memory stops command execution and returns to the read mode. The read command and read/reset command are called "software reset".

When write command sequence ends, the automatic operation starts and FCFLCS<RDY/BSY> is set to "0". When the automatic operation normally ends, FCFLCS<RDY/BSY> = "1" is set and Flash memory returns to the read mode.

New command sequences are not accepted during the automatic operation. If you want to stop the command operation, use a hardware reset. In case that the automatic operation abnormally ends (FCFLCS<RDY/ BSY> remains "0"), Flash memory remains locked and will not return to the read mode. To returns to the read mode, use a hardware reset. If the hardware reset stops the command operation, commands are not normally executed.

Notes on the command execution;

- 1. To recognize command, command sequencer need to be in the read mode before command starting. Confirm FCFLCS<RDY/BSY> = 1 is set prior to the first bus write cycle of each command. Consecutively, it is recommended that the read command is executed.
- 2. Execute each command sequence from outside of Flash memory.
- 3. Execute sequentially each bus write cycle by data transfer instruction in 1-word (32-bit).
- 4. Do not access Flash memory during the each command sequence. Do not generate any interrupt or fault except reset.
- 5. Upon issuing a command, if any address or data is incorrectly written, make sure to return to the read mode by using software reset.

### 17.2.5 Command Description

This section explains each command content. For detail of specific command sequences, refer to "17.2.6 Command Sequence".

### 17.2.5.1 Automatic Page Program

### (1) Operation Description

The automatic page program writes data per page. When the program writes data to multiple pages, a page command need to be executed in page by page. Writing across pages is not possible.

Writing to Flash memory means that data cell of "1" becomes data of "0". It is not possible to become data cell of "1" from data of "0". To become data cell of "1" from "0", the erase operation is required.

The automatic page program is allowed only once to each page already erased. Either data cell of "1" or "0" cannot be written data twice or more. If rewriting to a page that has already been written once, the automatic page program is needed to be set again after the automatic block erase or automatic chip erase command is executed.

Note 1: Page program execution to the same page twice or more without erasing operation may damage the device.

Note 2: Writing to the protected block is not possible.

#### (2) How to Set

The 1st to 3rd bus write cycles indicate the automatic page program command.

In the 4th bus write cycle, the first address and data of the page are written. On and after 5th bus cycle, one page data will be written sequentially. Data is written in 1-word unit (32-bit).

If a part of the page is written, set "0xFFFFFFF" as data, which means not required to write, for entire one page.

No automatic verify operation is performed internally in the device. So, be sure to read the data programmed to confirm that it has been correctly written.

If the automatic page program is abnormally terminated, that page has been failed to write. It is recommended not to use the device or not to use the block including the failed address.

### 17.2.5.2 Automatic Chip Erase

### (1) Operation Description

The automatic chip erase is executed to the memory cell of all addresses. If protected blocks are contained, these blocks will not be erased. If all blocks are protected, the automatic chip erase operation will not performed and will return to the read mode after a command sequence is input.

### (2) How to Set

The 1st to 6th bus write cycles indicate the automatic chip erase command. After the command sequence is input, the automatic chip erase operation starts.

No automatic verify operation is performed internally in the device. So, be sure to read the data to confirm that it has been correctly erased.

If the automatic chip erase is abnormally terminated, specify the failed block with the block erase function. On and after it is recommended not to use the failed block.

### 17.2.5.3 Automatic Block Erase

### (1) Operation Description

The automatic erase command performs erase operation to the specified block. If the specified block is protected, erase operation is not executed.

### (2) How to Set

The 1st to 5th bus write cycles indicate the automatic block erase command. In the 6th bus write cycle, the block to be erased is specified. After the command sequence is input, the automatic block erase operation starts.

No automatic verify operation is performed internally in the device. So, be sure to read the data to confirm that it has been correctly erased.

If the automatic chip erase is abnormally terminated, on and after it is recommended not to use the faild block.

### 17.2.5.4 Automatic Protect Bit Program

#### (1) Operation Description

The automatic protect bit program writes "1" to a protect bit at a time. To set "0" to a protect bit, use the automatic protect bit erase command.

For detail of the protect function, refer to "17.1.5 Protect/Security Function".

### (2) How to Set

The 1st to 6th bus write cycles indicate the automatic protect bit program command. In the 7th bus write cycle, the protect bit to be written is specified. After the command sequence is input, the automatic protect bit program starts. Check whether write operation is normally terminated with FCFLCS<BLPRO>.

### 17.2.5.5 Auto Protect Bit Erase

### (1) Operation Description

The automatic protect bit erase command operation depends on the security status. For detail of security status, refer to "17.1.5 Protect/Security Function".

• Non-security status

Clear the specified protect bit to "0". Protect bit erase is performed in 4-bit unit.

Security status

Erase all protect bits after all addresses of Flash memory are erased.

### (2) How to Set

The 1st to 6th bus write cycles indicate the automatic protect bit erase command. In the 7th bus write cycle, the protect bit to be erased is specified. After the command sequence is input, the automatic protect bit erase operation starts.

In the non-security status, specified protect bit is erased. Check whether erase operation is normally terminated with FCFLCS<BLPRO>.

In the security status, all addresses and all protect of Flash memory bits are erased. Confirm if data and protect bits are erased normally. If necessary, execute the automatic protect bit erase, automatic chip erase or automatic block erase.

All cases are the same as other commands, FCFLCS<RDY/BSY> becomes "0" during the automatic protect bit erase command operation. After the operation is complete, FCFLCS<RDY/BSY> becomes "1" and Flash memory will return to the read mode. To abort the operation, a hardware reset is required.

#### 17.2.5.6 ID-Read

#### (1) Operation Description

The ID-Read command can read information including Flash memory type and three types of codes such as a maker code, device code and macro code.

### (2) How to Set

The 1st to 3rd bus write cycles indicate the ID-Read command. In the 4th bus write cycle, the code to be read is specified. After the 4th bus write cycle, read operation in the arbitrary flash area acquires codes.

The ID-Read can be executed successively. The 4th bus write cycle and reading ID value can be executed repeatedly.

The ID-Read command does not automatically return to the read mode. To return to the read mode, execute the read command, read/reset command or hardware reset.

#### 17.2.5.7 Read Command and Read/reset Command (Software Reset)

### (1) Operation Description

A command to return Flash memory to the read mode.

When the ID-Read command is executed, macro stops at the current status without automatically return to the read mode. To return to the read mode from this situation, use the read command or read/ reset command. It is also used to cancel the command when commands are input to the middle.

#### (2) How to Set

The 1st bus cycle indicates the read command. The 1st to 3rd bus write cycles indicate the read/reset command. After either command sequence is executed, Flash memory returns to the read mode.

### 17.2.6 Command Sequence

#### 17.2.6.1 Command Sequence List

Table 17-5 shows addresses and data of bus write cycle in each command.

All command cycles except the 5th bus cycle of ID-Read command are "bus write cycles". A bus write cycle is performed by 32-bit (1-word) data transfer instruction. (Following table shows only lower 8 bits of data.)

For detail of addresses, refer to Table 17-6. Use below values to "command" described in a column of Addr[15:9] in the Table 17-6.

Note 1) Always set to "0" to the address bit [1:0].

Note 2) Set below values to the address bit [19] according to Flash memory size. Memory size is 1MB or less : Always set to "0" Memory size is over 1MB : If bus write to 1MB area or less, the bit is set to "0". If bus write to over 1MB area, the bit is set to "1".

	1st bus cycle	2nd bus cycle	3rd bus cycle	4th bus cycle	5th bus cycle	6th bus cycle	7th bus cycle
Command	Addr.						
	Data						
Dead	0xXX	-	-	-	-	-	-
Read	0xF0	-	-	-	-	-	-

### Table 17-5 Command Sequence

Supplementary explanation

- IA: IDAddress
- ID: ID data
- PA: Program page address
- PD: Program data (32-bit data)

After the 4th bus cycle, input data in the order of the addresses per page

- BA: Block address (see Table 17-7)
- PBA: Protect bit address (see Table 17-8, Table 1-9)

### 17.2.6.2 Address Bit Configuration in the Bus Cycle

Table 17-6 is used in conjunction with "Table 17-5 Command Sequence".

Set the address setting according to the normal bus write cycle address configuration from the first bus cycle.

Table 17-6 Address	bit configuration	in the bus write cycle

Adress	Addr	Addr	Addr	Addr	Addr	Addr	Addr	Addr	Addr	Addr	Addr
Address	[31:19]	[18]	[17]	[16]	[15]	[14]	[13:11]	[10]	[9]	[8]	[7:0]

			Normal bus write	cycle address configuration						
Normal Command	Flash area	"0" is recommended.		Addr[1:0] = "0" (fixed) Other bits = "0" (recom- mended)						
		IA: ID addre	ss (Setting of the 4	th bus write cycle address for	ID-READ)					
ID-READ	Flash area	"0" is recommended.	ID Address	Addr[1:0] = "0" (fixed) Other bits= "0" (recommended)						
Diack aroos	BA: Block address(Setting of the 6th bus write cycle address for block erase)									
Block erase	E	Block address (Table 17-7)		Addr[1:0] = "0" (fixe	ed) Other bits= "0"	(recommended)				
	PA: Program page address (Setting of the 4th bus write cycle address for page program)									
Automatic page pro- gram		Addr[1:0] = "0" (fixed) Other bits= "0" (recom- mended)								
		PBA: Protect bit addre	ss (Setting of the 7	7th bus write cycle address for	protect bit progra	ım)				
Protect bit program	Flash area	Protect bit se- lection (Table 17-8)	Fix to "0"		Protect bit se- lection (Table 17-8)	Addr[1:0] = "0" (fixed) Other bits= "0" (recom- mended)				
		PBA: Protect bit address (Setting of the 7th bus write cycle address for protect bit erase)								
Protect bit erase	Flash area	Protect bit se- lection (Table 17-9)	Fix	to "0"	1:0] = "0" (fixed) - "0" (recommended)					

### 17.2.6.3 Block Address(BA)

Table 17-7 shows block addresses. Specify any address included in the block to be erased in the 6th bus write cycle of the automatic block erase command.

Block	Address (User boot mode)	Address (Single boot mode)	Size (Kbyte)
		-	
4	0x0000_0000 to 0x0000_3FFF	0x3F80_0000 to 0x3F80_3FFF	16
5	0x0000_4000 to 0x0000_7FFF	0x3F80_4000 to 0x3F80_7FFF	16
3	0x0000_8000 to 0x0000_FFFF	0x3F80_8000 to 0x3F80_FFFF	32
2	0x0001_0000 to 0x0001_FFFF	0x3F81_0000 to 0x3F81_FFFF	64
1	0x0002_0000 to 0x0002_FFFF	0x3F82_0000 to 0x3F82_FFFF	64
0	0x0003_0000 to 0x0003_FFFF	0x3F83_0000 to 0x3F83_FFFF	64

### 17.2.6.4 How to Specify Protect Bit (PBA)

The protect bit is specified in 1-bit unit in programming and in 4-bit unit in erasing.

Table 17-8 and Table 17-9 shows a protect bit selection table of the automatic protect bit program. The column of address example indicates an address described in upper side is used in the single mode and the lower side is used in the single boot mode.

Four protect bits are erased by the automatic protect bit erase command in all.

Table 17-8 Protect bit program address

			_	Address	of 7th bus w	rite cycle			
Block Protect bit		Address [18]	Address [17]	Address [16]	Address [15:11]	Address [10]	Address [9]	Address [8]	Address example [31:0]
				-					
Block0	<blpro[0]></blpro[0]>	0	0				0	0	0x0000_0000 0x3F80_0000

### 17.2.7.2 Automatic Erase

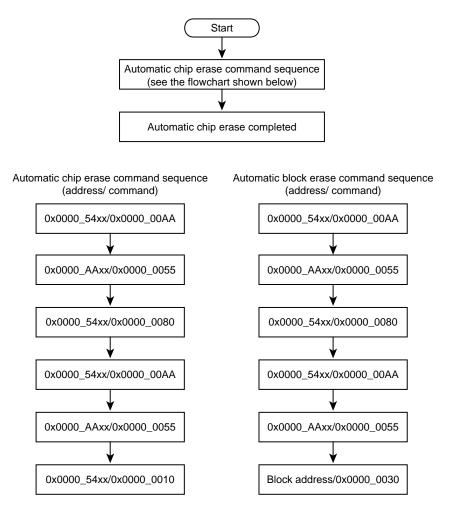

Figure 17-5 Flowchart of automatic erase

# 17.3 How to Reprogram Flash using Single Boot Mode

The single boot mode utilizes a program contained in built-in BOOT ROM for reprogrammig Flash memory. In this mode, BOOT ROM is mapped to the area containg interrupt vector tables and Flash memory is mapped to another address area other than BOOT ROM area.

In the boot mode, Flash memory is reprogrammed using serial command/data transfer. With connecting serial channel (SIO/UART) of this device to the external host, a reprogramming program is copied from the external host to the built-in RAM. A reprogramming routine in the RAM is executed to reprogram Flash memory. For details of communication with host, follow the protocol described later.

Even in the single boot mode, do not generate interrupt/fault except reset to avoid abnormal program termination.

To secure the contents of Flash memory in the single chip mode (normal operation mode), once re-programming is complete, it is recommended to protect relevant flash blocks against accidental erasure during subsequent single chip operations.

### 17.3.1 Mode Setting

In order to execute the on-board programming, this device is booted-up in the single boot mode. Below setting is for the single boot mode setting.

```
\overline{\text{BOOT}} = 0
\overline{\text{RESET}} = 0 \rightarrow 1
```

While  $\overline{\text{BOOT}}$  pin is set to the above in advance, set  $\overline{\text{RESET}}$  pin to "0". Then release  $\overline{\text{RESET}}$  pin, the device will boot-up in the single boot mode.

### 17.3.2 Interface Specification

This section describes SIO/UART communication format in the single boot mode. The serial operation supports both UART (asynchronous communication) and I/O interface modes. In order to execute the on-board programming, set the communication format of the programming controller as well.

UART communication

Communication channel: channel 0

Serial transfer mode: UART (asynchronous), half-duplex, LSB first

Data length: 8-bit

Parity bit: None

STOP bit: 1-bit

Baud rate: Arbitrary baud rate

• I/O interface mode

Communication channel: channel 0

Serial transfer mode: I/O interface, full-duplex, LSB first

Synchronous signal (SCLK0): Input mode, rising edge setting

Handshaking signal: PE4 (output mode)

Baud rate: Arbitrary baud rate

The boot program operates the clock/mode control block setting as an initial condition. For detail of the initial setting of the clock, refer to "Clock/Mode control".

As explained in the "17.3.5.1 Serial Operation Mode Determination", a baud rate is determined by the 16bit timer (TMRB). When determining the baud rate, communication is executed by 1/16 of a desired baud rate. Therefore, the communication baud rate must be within the measurable range. The timer count clock operates at  $\Phi$ T1 (fc/2).

A handshaking pin of I/O interface mode outputs "Low" waiting in receive state and outputs "High" in transmission state. Check the handshaking pin before communications and must follow the communication protocol.

Table 17-11 shows the pins used in the boot program. Other than these pins are not used by the boot program.

Pin		Interface				
Pir	1	UART	I/O interface mode			
Mode setting pin	BOOT	0	0			
Reset pin	RESET	0	0			
	TXD0 (PE0)	0	0			
Communication pin	RXD0 (PE1)	0	0			
	SCLK0 (PE2)	×	o (Input mode)			
	PE4	×	o (Output mode)			

Table 17-11 Pin connection

o:used ×:unused

### 17.3.3 Restrictions on Internal Memories

Note that the single boot mode places restrictions on the built-in RAM and built-in flash memory as shown in Table 17-12.

Table 17-12 Restrictions on the memories in the single boot mode	Table 17-12	Restrictions of	n the	memories in	the sin	ale boot mode
--	-------------	-----------------	-------	-------------	---------	---------------

Memory	Restrictions
Internal RAM	Boot program uses the memory as a work area through 0x2000_0000 to 0x2000_03FF. Store the program 0x2000_0400 through the end address of RAM.
Internal flash memory	The following addresses are assigned for storing software ID information and passo- werds. Storing program in below addresses is not recommendable. 0x3F83_FFF0 to 0x3F83_FFFF

Note: If a password is erased data (0xFF), it is difficult to protect data secure due to an easy-to-guess password. Even if the single boot mode is not used, it is recommended to set a unique value as a password.

## 17.3.4 Operation Command

The boot program provides the following operation commands.

Table 17-13 Opera	ion command data
-------------------	------------------

Operation command da- ta	Operation mode
0x10	RAM transfer
0x40	Flash memory chip erase and protect bit erase

### 17.3.4.1 RAM Transfer

The RAM transfer is to store data from the controller to the built-in RAM. When the transfer is complete normally, a user program starts. User program can use the memory address of 0x2000\_0400 or later except 0x2000\_0000 to 0x2000\_03FF for the boot program. CPU will start execution from RAM store start address.

This RAM transfer function enables user-specific on-board programming control. In order to execute the on-board programming by a user program, use Flash memory command sequence explained in 17.2.6.

### 17.3.4.2 Flash Memory Chip Erase and Protect Bit Erase

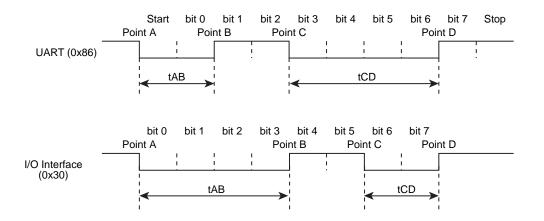

Flash memory chip erase and protect bit erase commands erase the entire blocks of Flash memory and write/erase protects of all blocks regardless of write/erase protect or security status. When the command is complete, the FCSECBIT<SECBIT> is set to "1".

### 17.3.5 Common Operation regardless of Command

This section describes common operation under the boot program execution.

### 17.3.5.1 Serial Operation Mode Determination

When the controller communicates via UART, set the 1st byte to 0x86 at the desired baud rate. When the controller communicate via I/O interface mode, set the 1st byte to 0x30 at 1/16 of the desired baud rate. Figure 17-6 shows waveforms in each case.

Figure 17-7 shows a flowchart of boot program. Using 16-bit timer (TMRB) with the time of tAB, tAC and tAD, the 1st byte of serial operation mode determination data (0x86, 0x30) after reset is provided. In Figure 17-7, the CPU monitors level of the receive pin, and obtains a timer value at the moment when the receive pin's level is changed. Consequently, the timer values of tAB, tAC and tAD have a margin of error. In addition, note that if the transfer goes at a high baud rate, the CPU may not be able to determine the level of receive pin. In particular, I/O Interface tends to generate this problem since its baud rate is generally much higher than those of UART. To avoid this, the controller should send data at 1/16 of the desired baud rate in the I/O interface mode.

The flowchart in Figure 17-8 shows the serial operation mode is determined that the time length of the receive pin is long or short. If the length is  $tAB \le tCD$ , the serial operation mode is determined as UART mode. The time of tAD is used whether the automatic baud rate setting is enable or not. If the length is tAB > tCD, the serial operation mode is determined as I/O Interface mode. Note that timer values of

tAB, tAC and tAD have a margin of error. If the baud rate is high and operation frequency is low, each timer value becomes small. This may generates unexpected determination occurs. (To prevent this problem, re-set UART within the programming routine.)

For example, the serial operation mode may be determined to be I/O Interface mode when the intended mode is UART mode. To avoid such a situation, when UART mode is utilized, the controller should allow for a time-out period where the time is expected to receive an echo-back (0x86) from the target board. The controller should give up the communication if it fails to get that echo-back within the allowed time. When I/O Interface mode is utilized, once the first serial byte has been transmitted, the controller should send the SCLK clock after a certain idle time to get an acknowledge response. If the received acknowledge response is not 0x30, the controller should give up further communications.

When the intended mode is I/O interface mode, it is not necessary that the first byte is 0x30 as long as tAB >tCD as shown above. 0x91, 0xA1 or 0xB1 can be sent as the first byte code to determine the falling edges of Point A and Point C and the rising edges of Point B and Point D. If tAB>tCD is established and SIO is selected by the resolution of the operation mode determination, the second byte code is 0x30 even though the transmitted code on the first byte is not 0x30 (The first byte code to determine I/O interface mode is described as 0x30).

- 17. Flash Memory Operation
- 17.3 How to Reprogram Flash using Single Boot Mode

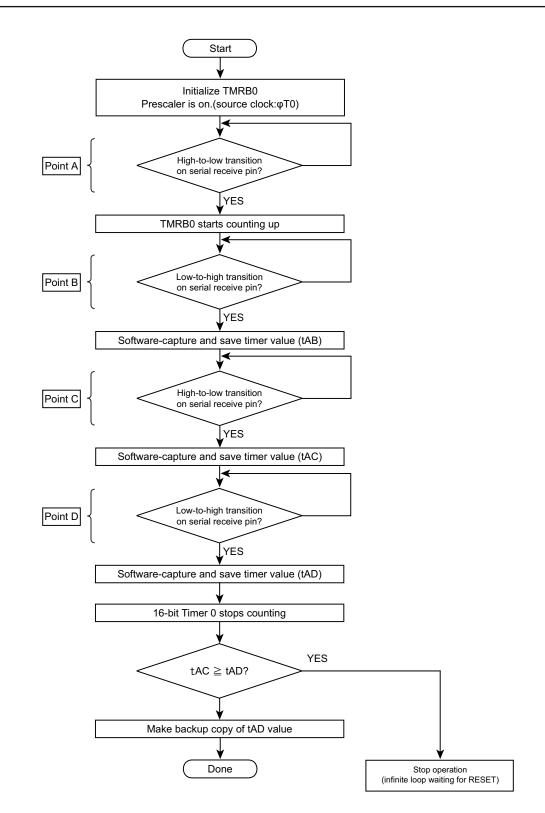

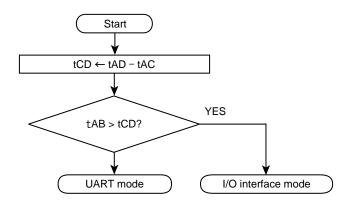

Figure 17-7 Serial operation mode receive flowchart

### 17.3.5.2 Acknowledge Response Data

The boot program represents processing states in specific codes and sends them to the controller. Table 17-14 to Table 17-17 show the values of acknowledge responses to each receive data.

In Table 17-15 to Table 17-17, the upper four bits of the acknowledge response are equal to those of the operation command data. The 3rd bit indicates a receive error. The 0th bit indicates an invalid operation command error, a checksum error or a password error. The 1st bit and 2nd bit are always "0". Receive error checking is not performed in I/O Interface mode.

#### Table 17-14 ACK response to the serial operation determination data

Transmit data	Description	
0x86	Determined that UART communication is possible. (Note)	
0x30	Determined that I/O interface communication is possible.	

Note: When the serial operation is determined as UART, if the baud rate setting is determined as unacceptable, the boot program aborts without sending back any response.

Transmit data	Description
0x?8 (Note)	A receive error occurrs in the operation command data
0x?1 (Note)	An undefined operation command data is received normally.
0x10	Determined as a RAM transfer command
0x20	Determined as a Flash Memory SUM command
0x30	Determined as a Device code read command
0x40	Determined as a flash memory chip erase command

Table 17-15 ACK response to the operation command data

Note: The upper 4 bits of the ACK response data are the same as those of the previous command data.

Table 17-16 ACK response to the CHECK SUM data

Transmit data	Description
0xN8 (Note)	A receive error occurs.
0xN1 (Note)	A CHECK SUM or a password error occurs.
0xN0 (Note)	The CHECK SUM value is correct.

Note: The upper 4 bits of the ACK response data are the same as those of the operation command data.

Transmit data	Description
0x54	Determined as a erase enable command
0x4F	Erase command is complete.
0x4C	Erase command is abnormally terminated.

Table 17-17 ACK response to Flash memory chip erase and protect bit erase operation

### 17.3.5.3 Password Determination

The boot program use the below area to determine whether a password is required or use as a password.

Area	Address		
Password requirement determination	0x3F83_FFF0 (1byte)		
Password area	0x3F83_FFF4 to 0x3F83_FFFF (12byte)		

The RAM Transfer command performs a password verification regardless of necessity judging data. Flash memory chip erase or protect bit erase command performs a password verification only when necessity judging is determined as "required".

Password requirement setting	Data		
Need password	Other than 0xFF		
No password	0xFF		

If a password is set to 0xFF (erased data), it is difficult to protect data securely due to an easy-to-guess password. Even if Single Boot mode is not used, it is recommended to set a unique value as a password.

#### (1) Password verification using RAM transfer command

If all these address locations contain the same bytes of data other than 0xFF, this condition is determined as a password area error as shown in Figure 17-9. In this case, the boot program returns an error acknowledge (0x11) in response to the 17th byte of checksum value regardless of the password verification.

The boot program verifies 5th byte to 16th byte of receive data (password data). A password error occurs if all 12 bytes do not match. If the password error is determined, an ACK response data to the 17th of CHECK SUM data is a password error.

The password verification is performed even if the security function is enabled.

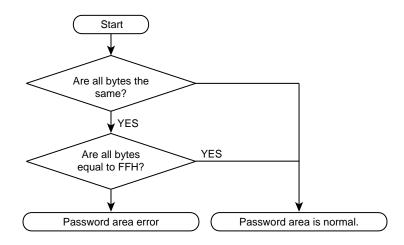

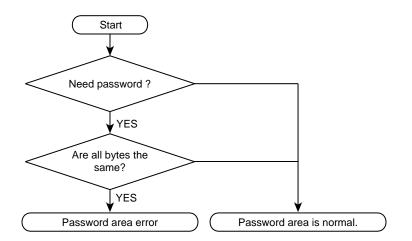

Figure 17-9 Password area check flowchart

(2) Password verification to Flash memory chip erase and protect bit erase command

When a password is enable in the erase password necessity determination area as shown in Figure 17-10 and the passwords are identical data, a password area error occurs. If a password area error is determined, an ACK response to the 17th byte of CHECK SUM sends 0x41 regardless of the password verification.

The boot program verifies 5th byte to 16th byte of receive data (password data). A password error occurs if all 12 bytes do not match. If the password error is determined, an ACK response data to the 17th of CHECK SUM data is a password error.

The password verification is performed even if the security function is enabled.

### 17.3.5.4 CHECK SUM Calculation

The checksum is calculated by 8-bit addition to transmit data, dropping the carries, and taking the two's complement of the total sum. The controller must perform the same checksum operation in transmitting checksum bytes.

Example of CHECK SUM

To calculate the checksum for a series of 0xE5 and 0xF6, perform 8-bit addition.

0xE5 + 0xF6 = 0x1DB

Take the two's complement of the sum to the lower 8-bit, and that is a checksum value. So the boot program sends 0x25 to the controller.

0 - 0xDB = 0x25

### 17.3.6 Transfer Format at RAM Transfer

This section shows a RAM transfer command format. Transfer directions in the table are indicated as follows: Transfer direction (C $\rightarrow$ T): Controller to TMPM365FYXBG Transfer direction (C $\leftarrow$ T): TMPM365FYXBG to Controller

Number of transfer bytes	Transfer direction	Transfer data	Description
		Serial operation mode and baud rate set- ting	Sends data to determine the serial operation mode. For detail of mode determina- tion, refer to "17.3.5.1 Serial Operation Mode Determination".
1	C→T	[UART mode] 0x86	Sends 0x86. If UART mode is determined, the program determines whether a baud setting is possible. If not, the program stops and communication is shutdown.
		[I/O interface mode] 0x30	Sends 0x30 at 1/6 of desired baud rate.The 2nd byte is also sent at 1/6 of desired baud rate. From the 3rd byte or later, you can send the data at a desirable baud rate.
		ACK response to serial operation mode	The 2nd byte of transmit data is a ACK response data to the 1st byte that corre- sponds to the serial operation setting mode data. If the setting is possible, sets SIO/ UART. A receive enable timing is set before transmit buffer is written to the data.
		[UART mode] Normal state: 0x86	If the setting is determined to be possible, sends 0x86. If not, the operation aborts without sending back any response.
2	C←T		When the controller finished to send the 1st byte of data, requires a time-out time (5 seconds). If data (0x86) is not normally received within a time-out time, communication is not possible.
		[I/O interface mode] Normal state:0x30	Writes data (0x30) to the transmit buffer and waits for SCLK0 clock. When the con- troller finished to send the 1st byte of data and several ms (idle time) later, out- puts SCLK clock. At this time, the baud rate is set to 1/16 of desired baud rate. If re- ceive data is 0x30, communications are possible. After the 3rd byte, sets a de- sired baud rate to communicate.
3	C→T	Operation command data (0x10)	Sends RAM transfer command data (0x10).
		ACK response to operation command	ACK response data to the operation command.
		Normal state: 0x10 Abnormal state: 0xX1 Communication error: 0xX8	First, checks if 3rd byte of receive data has errors. (UART mode only) If receive er- rors exist, sends a ACK response data 0xX8 that means abnormal communica- tions and waits for a next operation command (3rd byte). Upper 4 bits of transmit da- ta are undefined. (same as upper 4 bits of immediately before operation com- mand.) Note that in the I/O interface, receive error check is not performed.
4	C←T		Then, if the 3rd byte of receive data corresponds to either operation command da- ta in Table 17-13, receive data is echoed back. In the case of RAM transfer, 0x10 is echoed back and the transfer data branches to the RAM transfer service rou- tine. If the data does not correspond to the command in Table 17-13, sends a ACK response data 0xX1 that means operation command errors, and waits for next operation command (3rd byte). Upper 4 bits of transmit data are undefined. (same as upper 4 bits of immediately before operation command data.)
		Password data (12-byte) 0x3F83 FF04 to 0x3F83 FF0F	Checks data in the password area. For detail of password area checking, refer to "17.3.5.3 Password Determination".
5 to 16	C→T		Compares 5th to 16th byte of receive data with 0x3F83_FFF0 to 0x3F83_FFFF of data of Flash memory. If the data does not match the address, a password error flag is set.
17	C→T	5th to 16th byte of CHECK SUM values	Send 5th to 16th byte of CHECK SUM values.
			For detail of CHECK SUM calculation, refer to 17.3.5.4.

## TOSHIBA

Number of transfer bytes	Transfer direction	Transfer data	Description	
18	C←T	ACK response to CHECK SUM value Normal state: 0x10 Abnormal state: 0x11 Communication error: 0x18	<ul> <li>First, checks if 5th to 17th byte of receive data have errors.(UART mode only, ceive errors exist, sends a ACK response data 0x18 that means abnormal concations and waits for a next operation command (3rd byte).</li> <li>Then checks 17th byte of CHECK SUM data. If errors exist, sends 0x11 and for a next operation command (3rd byte).</li> <li>Finally, checks the result of password verification. If a password error exists, sends a ACK response data 0x11 that means a password error and waits for next operation command (3rd byte).</li> <li>If all procedure normally ends, sends a normal ACK response data 0x10.</li> </ul>	
19	C→T	RAM store start Address 31 to 24		
20	C→T	RAM store start Address 23 to 16	Sends a start address of block transfer for RAM store. The 19th byte corresponds to 31st to 24th bit of address. The 22nd byte corresponds to 7th to 0th bit of address.	
21	C→T	RAM store start Address 15 to 8	Specify the address to the address 0x2000 0400 through the last address of RAM.	
22	C→T	RAM store start Address 7 to 0	·····	
23	C→T	Number of RAM store bytes 15 to 8	Set the number of bytes to perform block transfer. The 23rd byte corresponds t	
24	C→T	Number of RAM store bytes 7 to 0	the15th bit to 8th bit of transfer bytes. The 24th byte corresponds to 7th bit to 0th bit of transfer bytes. Specify the data to be stored in the address from 0x2000_0400 through the last address of RAM.	
25	C→T	19th to 24th byte of CHECK SUM value	Send 19th byte to 24th byte of CHECK SUM values	
26	C←T	ACK response to CHECK SUM value Normal state: 0x10 Abnormal state: 0x11 Communication error: 0x18	First, checks if 19th byte to 25th byte of receive data have errors.(UART mode on- ly) If receive errors exist, sends a ACK response data 0x18 that means abnormal communications and waits for a next operation command (3rd byte). Then checks 25th byte of CHECK SUM data. If errors exist, sends 0x11 and waits for a next operation command (3rd byte). If all procedure normally ends, sends a normal ACK response data 0x10.	
27 to m	C→T	RAM stored data	Sends same bytes of data specified in 23th bytes to 24 byte for RAM stored data.	
m+1	C→T	27 to m byte of CHECK SUM value	Sends 27th byte to m byte of CHECK SUM value	
m+2	C←T	ACK response to CHECK SUM value Normal state:0x10 Abnormal state: 0x11 Communication error: 0x18	First, checks if 27th byte to m+1 byte of receive data have errors. (UART mode on- ly) If receive errors exist, sends a ACK response data 0xX8 that means abnormal communications and waits for a next operation command (3rd byte). Then checks m+1 byte of CHECK SUM data, if errors exist, sends 0x11 and waits for a next op- eration command (3rd byte). If all procedure normally ends, sends a normal ACK re- sponse data 0x10.	
-	-	-	If m + 2nd byte of ACK response data is normal ACK response data, the transfer da- ta branches to the address specified in 19th byte to 22 byte.	

### 17.3.7 Transfer Format of Flash memory Chip Erase and Protect Bit Erase

This section shows a transfer format of Flash memory chip erase and protect bit erase commands. Transfer directions in the table are indicated as follows:

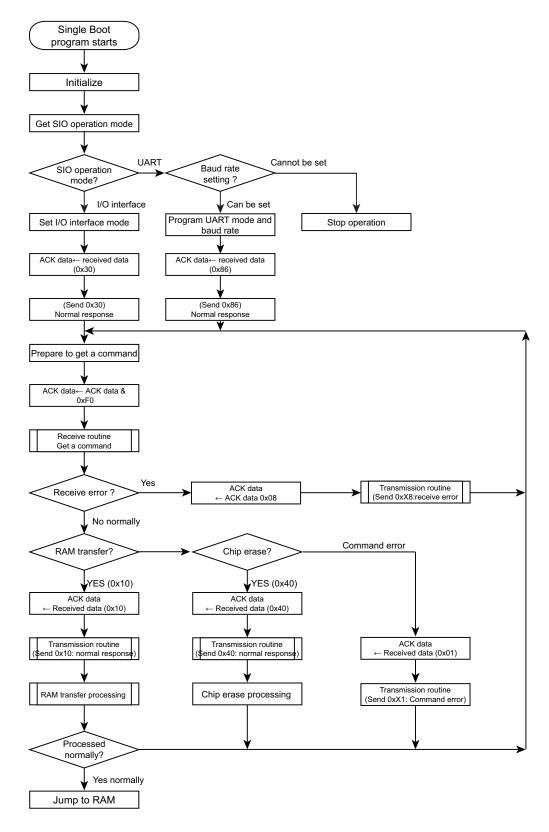

Transfer direction (C $\rightarrow$ T): Controller to TMPM365FYXBG

Transfer direction (C←T): TMPM365FYXBG to Controller

Number of transfer bytes	Transfer direction	Transfer data	Description
		Serial operation mode and baud rate set- ting	Sends data to determine the serial operation mode. For detail of mode determina- tion, refer to"17.3.5.1 Serial Operation Mode Determination".
1	C→T	[UART mode] 0x86	Sends 0x86. If UART mode is determined, checks if baud rate setting can be done. If not, operation stops communications.
		[I/O interface mode] 0x30	Sends 0x30 at 1/16 of desired baud rate. Same as the 1st byte, sends the 2nd byte at 1/16 of desired baud rate. Desired baud rate can be used after 3rd byte.
		ACK response to serial operation mode	The 2nd byte of transmit data is a ACK response data to the 1st byte that corre- sponds to the serial operation setting mode data. If the setting is possible, sets SIC UART. A receive enable timing is set before transmit buffer is written to the data.
		[UART mode] Normal state: 0x86	If the setting is determined to be possible, sends 0x86. If not, the operation aborts without sending back any response.
2	C←T		When the controller finished to send the 1st byte of data, requires a time-out time (5 seconds). If data (0x86) is not normally received within a time-out time, commun cation is not possible.
		[I/O interface mode] Normal state:0x30	Writes data (0x30) to the transmit buffer and waits for SCLK0 clock. When the cor troller finished to send the 1st byte of data and several ms (idle time) later, out- puts SCLK clock. At this time, the baud rate is set to 1/16 of desired baud rate. If re ceive data is 0x30, communications are possible. After the 3rd byte, sets a de- sired baud rate to communicate.
3	C→T	Operation command data (0x40)	Sends Flash memory chip erase and protect bit erase command data (0x40).
4	C←T	ACK response to the operation command Normal state: 0x40 Abnormal state: 0xX1 Communication error: 0xX8	ACK response data to the operation command. First, checks if 3rd byte of receive data has errors. (UART mode only) If receive e rors exist, sends a ACK response data 0xX8 that means abnormal communica- tions and waits for a next operation command (3rd byte). Upper 4 bits of transmit da ta are undefined. (same as upper 4 bits of immediately before operation comman data.) Note that in the I/O interface, receive error check is not performed. Then, if the 3rd byte of receive data corresponds to either operation command data
			ta in Table 17-13, receive data is echoed back. If the data does not correspond to the command in Table 17-13, sends a ACK response data 0xX1 that means operation command errors, and waits for next operation command. (3rd byte) Upper 4 bits of transmit data are undefined. (Upper 4 bits of immediate before operation command data are used.)
5 to 16	C→T	Password data (12-byte) 0x3F83_FF04 to 0x3F83_FF0F	If password necessity is set to "none", this data is dummy data. If password necessity is set to "necessary", checks data in the password area. For a method of password area data checking, refer to "17.3.5.3 Password Determina- tion". Compares 5th to 16th byte of receive data with 0x3F83_FFF0 to 0x3F83_FFFF o data of Flash memory in order. If the data does not match, a password error flag
			is set.
17	C→T	5 to 16 th byte CHECK SUMvalue	Sends 5th byte to 16 byte of CHECK SUM value. For a method of CHECK SUM calculation, refer to"17.3.5.4 CHECK SUM Calcula tion".
18	C←T	ACK response to the CHECK SUM value Normal state: 0x40 Abnormal state: 0x41 Communication error: 0x48	If password necessity is set to "none", sends a normal ACK response data 0x40. If password necessity is set to "necessary", first checks if receive errors exist in the 5th byte to 17th byte receive data. (UART mode only) If a receive error exists sends a ACK response data 0x48 that means abnormal communications and waits for next operation command. (3rd byte) Then checks 17th byte of CHECK SUM data. If error occurs, sends 0x41 and waits for a next operation command (3rd byte)
			Finally, checks the result of password verification. If a password error exists, sends a ACK response data 0x41that means a password error and waits for a next operation command (3rd byte) If all procedure normally ends, sends a normal ACK response data 0x40.
19	C→T	Erase enable command data (0x54)	Sends an enable command data (0x54).
20	C←T	ACK response to the erase enable com- mand Normal state: 0x54 Abnormal state: 0xX1 Communication error: 0x58	First, checks if 19th byte of receive data has errors. If receive errors exist, sends a ACK response data (bit 3) 0x58 that means abnormal communication and waits for next operation command (3rd byte). Then, if 19th byte of receive data corresponds to the erase enable command, re- ceive data is echoed back (normal ACK response data). In this case, 0x54 is ech oed back and the transfer data branches into Flash memory chip erase process rou
-			tine. If the data does not correspond to the erase enable command, sends a ACK re- sponse data (bit 0) 0xX1 and waits for next operation command. Upper 4 bits of transmit data are undefined. (Upper 4 bits of immediate before operation com- mand data are used.)
21	C→T	ACK response to the erase command Normal state: 0x4F Abnormal state: 0x4C	If the operation is normally complete, the end code (0x4F) is returned. If erase error occurs, an error code (0x4C) is returned.
			ሥቃite førናጽnext operation command.

### 17.3.8 Boot Program Whole Flowchart

This section shows a boot program whole flowchart.

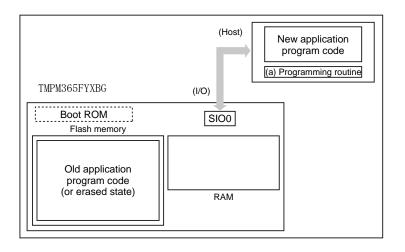

### 17.3.9 Reprogramming Procedure of Flash using reprogramming algorithm in the onchip BOOT ROM

This section describes the reprogramming procedure of the flash using reprogramming algorithm in the onchip boot ROM.

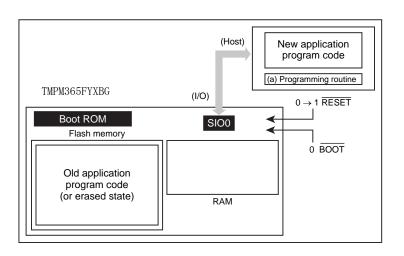

### 17.3.9.1 Step-1

The condition of Flash memory does not care whether a user program made of former versions has been written or erased. Since a programming routine and programming data are transferred via the SIO (SIO0), the SIO0 must be connected to an external host. A programming routine (a) is prepared on the host.

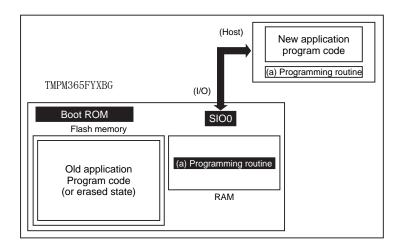

### 17.3.9.2 Step-2

Release the reset by pin condition setting in the boot mode and boot-up the BOOT ROM. According to the procedure of boot mode, transfer the programming routine (a) via SIO0 from the source (host). A password verification with the the password in the user application program is performed. (If Flash memory is erased, an erase data (0xFF) is dealt with a password.)

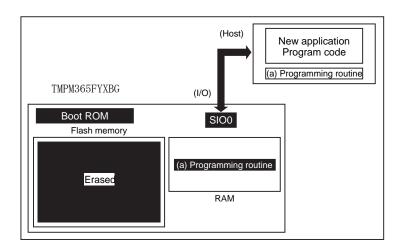

### 17.3.9.3 Step-3

If the password verification is complete, the boot program transfer a programming routine (a) from the host into the on-chip RAM. The programming routine must be stored in the range from 0x2000\_0400 to the end address of RAM.

#### 17.3.9.4 Step-4

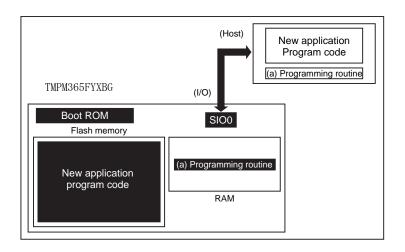

The boot program jumps to the programming routine (a) in the on-chip RAM to erase the flash block containing old application program codes. The Block Erase or Chip Erase command is be used.

### 17.3.9.5 Step-5

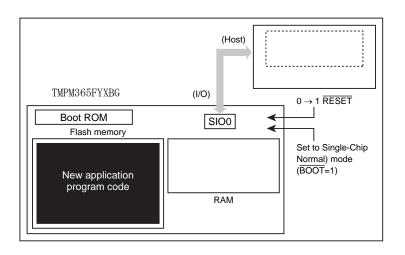

The boot program executes the programming routine (a) to download new application program codes from the host and programs it into the erased flash area. When the programming is complete, the writing or erase protection of that flash area in the user's program must be set.

In the example below, new program code comes from the same host via the same SIO0 channel as for the programming routine. However, once the programming routine has begun to execute, it is free to change the transfer path and the source of the transfer. Create a hardware board and programming routine to suit your particular needs.

#### 17.3.9.6 Step-6

When programming of Flash memory is complete, power off the board and disconnect the cable leading from the host to the target board. Turn on the power again so that the device re-boots in the singlechip (Normal) mode to execute the new program.

### 17.4 Programming in the User Boot Mode

A user Boot mode is to use flash memory programming routine defined by users. It is used when the data transfer buses for flash memory program code on the user application is different from the serial I/O. It operates in the single chip mode; therefore, a switch from normal mode in which user application is activated in the single chip mode to the user boot mode for programming flash is required. Specifically, add a mode judgment routine to the reset service routine in the user application program.

The condition to switch the modes needs to be set according to the user's system setup condition. Also, a flash memory programming routine that the user uniquely makes up needs to be set in the new application. This routine is used for programming after being switched to the user boot mode. The data in built-in Flash memory cannot be read out during erase/reprogramming mode. Thus, reprogramming routine must be take place while it is stored in the area outside of Flash memory area. Once re-programming is complete, it is recommended to protect relevant flash blocks from accidental reprogramming. Be sure not to generate interrupt/fault except reset to avoid abnormal termination during the user boot mode.

Taking examples from two cases such as the method that reprogramming routine stored in Flash memory (1-A) and transferred from the external device (1-B), the following section explains the procedure. For a detail of the program/erase to Flash memory, refer to "17.2 Detail of Flash Memory".

### 17.4.1 (1-A) Procedure that a Programming Routine Stored in Flash memory

### 17.4.1.1 Step-1

A user determines the conditions (e.g., pin status) to enter the user boot mode and the I/O bus to be used to transfer data. Then suitable circuit design and program are created. Before installing the device on a printed circuit board, write the following three program routines into an arbitrary flash block using programming equipment such as a flash writer.

gram Flash memory

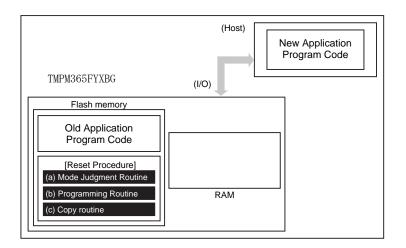

(a) Mode judgment routine: A program to determine to switch to user boot mode or not

(b) Flash programming routine:

A program to download new program from the host controller and re-pro-

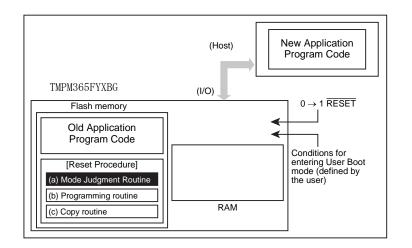

(c) Copy routine:

A program to copy the data described in (b) to the built-in RAM or external memory device

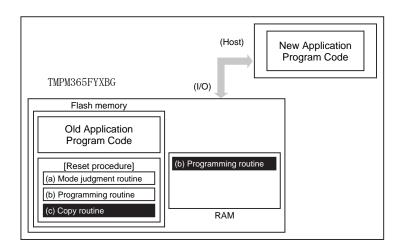

### 17.4.1.2 Step-2

This section explains the case that a programming routine storied in the reset routine. First, the reset routine determines to enter the user boot mode. If mode switching conditions are met, the device enters the user boot mode to reprogram data.

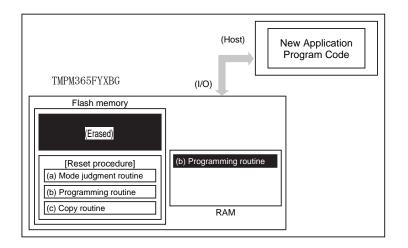

### 17.4.1.3 Step-3

Once the device enters the user boot mode, execute the copy routine (C) to download the flash programming routine (b) from the host controller to the built-in RAM.

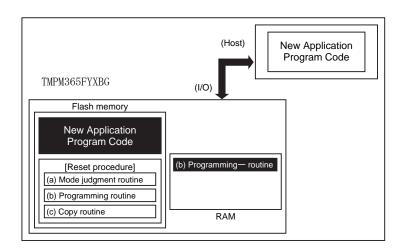

### 17.4.1.4 Step-4

Jump to the the reprogramming routine in the built-in RAM to release the write/erase protection for the old application program, and to erase a flash in block unit.

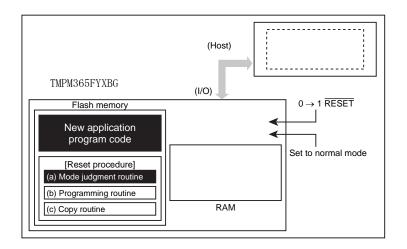

### 17.4.1.5 Step-5

Continue to execute the flash programming routine to download new program data from the host controller and program it into the erased flash block. When the programming is complete, the write/erase protection of that flash block in the user program area must be set.

### 17.4.1.6 Step-6

Set  $\overline{\text{RESET}}$  to "0". Upon reset, Flash memory is set to the normal mode. After reset, the CPU will start along with the new application program.

### 17.4.2 (1-B) Procedure that a Programming Routine is transferred from External Host

### 17.4.2.1 Step-1

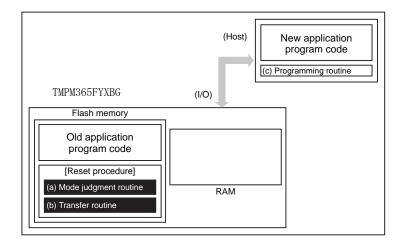

A user determines the conditions (e.g., pin status) to enter the user boot mode and the I/O bus to be used to transfer data. Then suitable circuit design and program are created. Before installing the device on a printed circuit board, write the following two program routines into an arbitrary flash block using programming equipment such as a flash writer.

(a) Mode judgment routine:	A program to determine to switch to reprogramming operation
(b) Transfer routine:	A program to obtain a reprogramming program from the external device.

In addition, prepare a reprogramming routine shown below must be stored on the host controller.

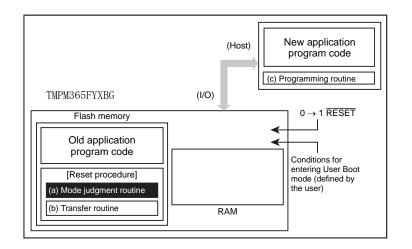

(c) Reprogramming routine:

A program to reprogram data

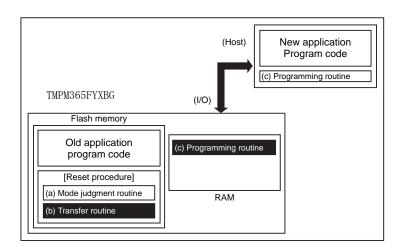

### 17.4.2.2 Step-2

This section explains the case that a programming routine stored in the reset routine. First, the reset routine determines to enter the user boot mode. If mode switching conditions are met, the device enters the user boot mode to reprogram data.

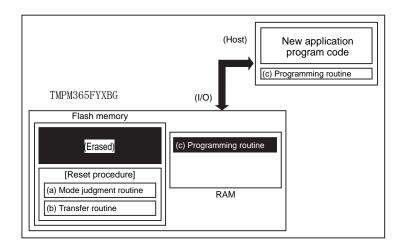

### 17.4.2.3 Step-3

Once the device enters the user boot mode, execute the transfer routine (b) to download the programming routine (c) from the host controller to the built-in RAM .

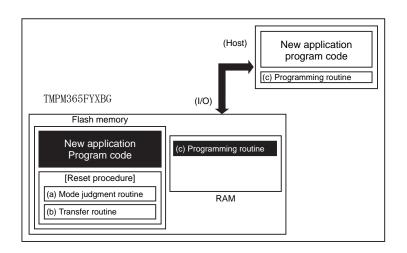

### 17.4.2.4 Step-4

Jump to the the reprogramming routine in the built-in RAM to release the write/erase protection for the old application program, and to erase a flash in block unit.

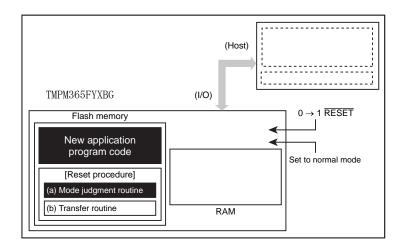

### 17.4.2.5 Step-5

Continue to execute the flash programming routine (c) to download new program data from the host controller and program it into the erased flash block. When the programming is complete, the write/erase protection of that flash block in the user program area must be set.

### 17.4.2.6 Step-6

Set  $\overline{\text{RESET}}$  to "0". Upon reset, Flash memory is set to the normal mode. After reset, the CPU will start along with the new application program.

### 17. Flash Memory Operation

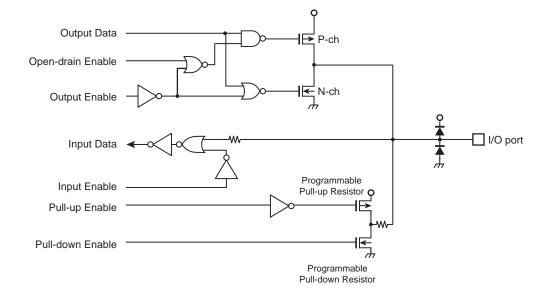

### 17.4 Programming in the User Boot Mode

## 18. Port Section Equivalent Circuit Schematic

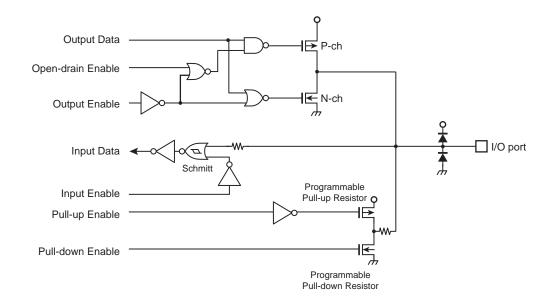

Basically, the gate symbols written are the same as those used for the standard CMOS logic IC [74HCXX] series.

The input protection resistance ranges from several tens of  $\Omega$  to several hundreds of  $\Omega$ . Feedback resistor and Damping resistor are shown with a typical value.

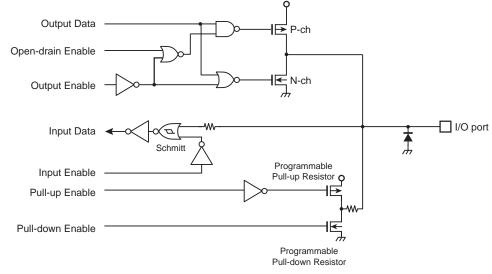

## 18.1 PA0 to 7,PB0 to 7

18.2 PC0 to 2, PD0 to 7, PE0 to 7, PF1 to 7, PG0 to 4, PH0 to 4, PI0 to 7

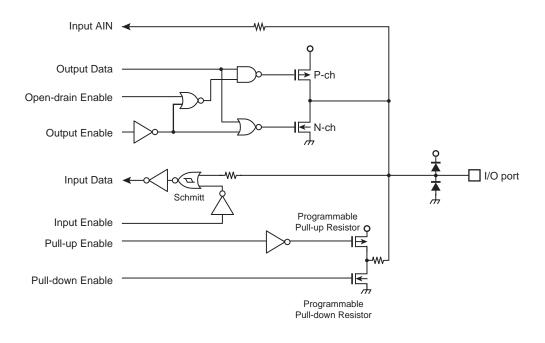

## 18.3 PG5

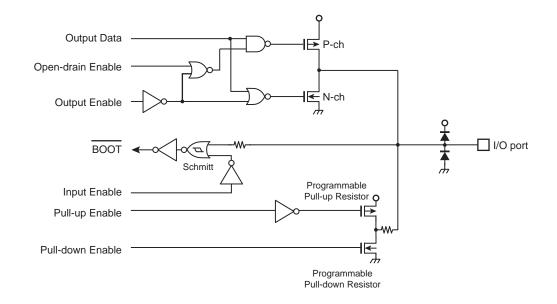

Note: Only when input is enabled, these pins tolerate 5V inputs.

## 18.4 PJ0 to 7,PK0 to 3

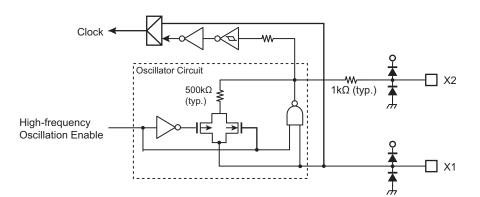

## TOSHIBA

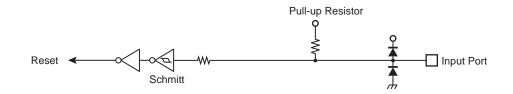

## 18.5 PF0

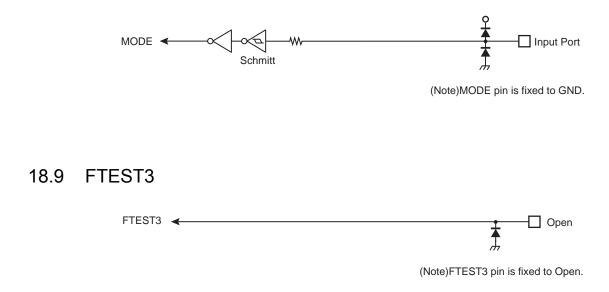

18.6 X1,X2

## 18.10 AVREFH, AVREFL

## **TOSHIBA**

## 19. Electrical Characteristics

### 19.1 Absolute Maximum Ratings

Parameter		Symbol	Rating	Unit	
		DVDD3A	-0.3 to 3.9		
Quarkunstana		DVDD3C	-0.3 to 3.9	V	
Supply voltage		AVDD3	-0.3 to 3.9		
		RVDD3	-0.3 to 3.9		
Input voltage	Except below port	V <sub>IN1</sub>	-0.3 to VDD + 0.3	+ 0.3 V	
Input voltage	PG5 (5V tolerant input) V <sub>IN2</sub>		-0.3 to 5.5	V	
Low-level	Per pin	I <sub>OL</sub>	5	mA	
output current	Total	ΣI <sub>OL</sub>	50		
High-level	Per pin	I <sub>OH</sub>	-5		
output current	Total	ΣI <sub>OH</sub>	-50		
Power consumption (Ta = 85 °C)		PD	600	mW	
Soldering temperature (10 s)		T <sub>SOLDER</sub>	260	°C	
Storage temperature		T <sub>STG</sub>	-40 to 125	°C	
Operating Temperature	Except during Flash W/E	т	-40 to 85		
Operating Temperature	During Flash W/E	T <sub>OPR</sub>	0 to 70	°C	

Note: Absolute maximum ratings are limiting values of operating and environmental conditions which should not be exceeded under the worst possible conditions. The equipment manufacturer should design so that no Absolute maximum rating value is exceeded with respect to current, voltage, power consumption, temperature, etc. Exposure to conditions beyond those listed above may cause permanent damage to the device or affect device reliability, which could increase potential risks of personal injury due to IC blowup and/or burning.

## 19.2 DC Electrical Characteristics (1/3)

DVSSA = DVSSB = AVSS = F	RVSS =	DVSSC =	0V
	Ta =	-40 to 85	°C

	Parameter	Symbol	Condition		Min.	Typ. (Note 1)	Max.	Unit
Supply volt- age	DVDD3A DVDD3C AVDD3 RVDD3 (Note 2)	DVDD3A AVDD3 RVDD3 DVDD3C	f <sub>OSC</sub> = 8 to 12 MHz fsys = 1 to 48 MHz	without USB	2.7 3.0	-	3.6 3.45	V V

DNL error			AIN resistance $\leq 600 \Omega$	-	2	8	
Offset error		-	AIN load capacitance $\ge 0.1 \ \mu F$ Conversion time $\ge 1.0 \ \mu s$	-	3	8	
Full-scale error				-	3	8	1.00
INL error				-	3	8	LSB
DNL error			AIN resistance $\leq 600 \Omega$	-	2	8	
Offset error		-	AIN load capacitance ≥33 pF Conversion time ≥ 1.66 µs	-	4	8	
Full-scale error				-	2	8	
Conversion time		Tconv	-	1.0	-	10	

DVDD3A = DVDD3C = AVDD3 = RVDD3 = AVREFH = 2.7 V to 3.6 V DVSSA = DVSS3C = AVSS = RVSS = DVSSC = 0 V

Note 1: 1LSB = (AVREFH - AVSS) / 4096 [V]

Note 2: All Peripheral functions except ADC are disabled.

Page 581

### 19.6 AC Electrical Characteristics

### 19.6.1 AC measurement condition

The AC characteristics data of this chapter is measured under the following conditions unless otherwise noted

- Output levels: High =  $0.8 \times \text{DVDD3A}$ ,  $0.8 \times \text{DVDD3C}$
- Output levels: Low =  $0.2 \times \text{DVDD3A}$ ,  $0.2 \times \text{DVDD3C}$
- Input levels: Refer to low-level input voltage and high-level input voltage in "DC Electrical Characteristics".
- Load capacity: CL = 30pF

### 19.6.2 Serial Channel (SIO/UART)

### 19.6.2.1 I/O Interface mode

In the table below, the letter x represents the SIO operation clock cycle time which is identical to the fsys cycle time. It varies depending on the programming of the clock gear function.

### (1) SCLK Input mode

[Data input]

Parameter	Cumbal	Equation		fsys = 40 MHz		48 MHz		Unit	
Parameter	Symbol	Min	Max.	Min	Max.	Min.	Max.	Unit	
SCLK Clock High width (input)	t <sub>SCH</sub>	4x	-	100	-	83.3	-		
SCLK Clock Low width (input)	t <sub>SCL</sub>	4x	-	100	-	83.3	-		
SCLK cycle	t <sub>SCY</sub>	t <sub>SCH</sub> + t <sub>SCL</sub>	-	200	-	166.6	-		
Valid Data input → SCLK rise / fall (Note1)	t <sub>SRD</sub>	30	-	30.0	-	30.0	-	ns	
SCLK rise / fall (Note1) → Input Data hold	t <sub>HSR</sub>	x + 30	-	55.0	-	50.8	-		

### [Data output]

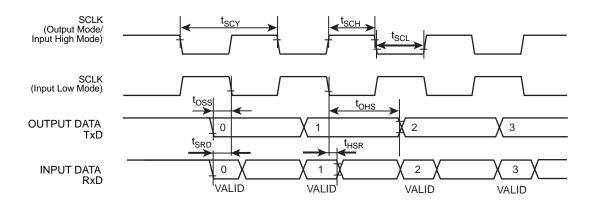

Parameter	Cumbal	Equation		fsys = 40 MHz		48 MHz		Unit	
Parameter	Symbol	Min	Max.	Min	Max.	Min.	Max.	Unit	
SCLK Clock High width (input)	t <sub>SCH</sub>	4x	-	120 (Note3)	-	107.5 (íç3)	-		
SCLK Clock Low width (input)	t <sub>SCL</sub>	4x	Ι	120 (Note3)	I	107.5 (íç3)	-		
SCLK cycle	t <sub>SCY</sub>	t <sub>SCH</sub> + t <sub>SCL</sub>	-	240	-	215	-	ns	
Output Data $\rightarrow$ SCLK rise / fall (Note1)	toss	t <sub>SCY</sub> /2 - 3x- 45	-	0.00 (Note2)	-	0.00 (íç2)	-		
SCLK rise / fall (Note1) $\rightarrow$ Output Data hold	toнs	t <sub>SCY</sub> /2	_	120	-	107.5	-		

- Note 1: SCLK rise/fall : SCLK rise mode uses the rise timing of SCLK. SCLK fall mode uses the fall timing of SCLK.
- Note 2: Use the frequency of SCLK in a range where the calculation value keeps positive.

Note 3: The value indicates a minimum value that enables  $t_{\mbox{OSS}}$  to be zero or more.

### (2) SCLK output mode

Parameter	Querra ha a l	Equation		40 MHz		48 MHz		Unit
Parameter	Symbol	Min.	Max.	Min.	Max.	Min.	Max.	Unit
SCLK cycle (programmable)	t <sub>SCY</sub>	4x	-	100	-	83.3	-	
Output Data ← SCLK rise	t <sub>oss</sub>	t <sub>SCY</sub> /2 - 30	-	20	-	11.7	-	
SCLK rise $\rightarrow$ Output hold Data hold	t <sub>OHS</sub>	t <sub>SCY</sub> /2 - 30	-	20	-	11.7	-	ns
Valid Data Input ← SCLK rise	t <sub>SRD</sub>	45	-	45	-	45	-	
SCLK rise $\rightarrow$ Input Data hold	t <sub>HSR</sub>	0	-	0	-	0	-	

### 19.6.3 Serial Bus Interface (I2C/SIO)

### 19.6.3.1 I2C Mode

In the table below, the letter x represents the I2C operation clock cycle time which is identical to the fsys cycle time. It varies depending on the programming of the clock gear function.

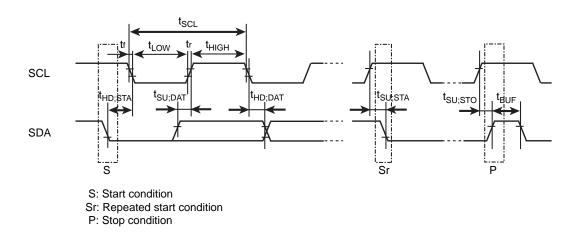

n denotes the value of n programmed into the SCK (SCL output frequency select) field in the SBIxCR.

Descender	0	Equ	ation	Standard Mode		Fast Mode		11.21
Parameter	Symbol	Min.	Max.	Min.	Max.	Min.	Max.	Unit
SCL clock frequency	t <sub>SCL</sub>	0	-	0	100	0	400	kHz
Hold time for START condition	t <sub>HD; STA</sub>	-	-	4.0	-	0.6	-	μs
SCL Low width (Input) (Note 1)	t <sub>LOW</sub>	-	-	4.7	-	1.3	-	μs
SCL High width (Input) (Note 2)	t <sub>HIGH</sub>	-	-	4.0	-	0.6	-	μs
Setup time for a repeated START condition	t <sub>SU; STA</sub>	(Note5)	-	4.7	-	0.6	-	μs
Data hold time (Input) (Note 3, 4)	t <sub>HD; DAT</sub>	-	-	0.0	-	0.0	-	μs
Data setup time	t <sub>SU; DAT</sub>	-	-	250	-	100	-	ns
Setup time for a STOP condition	t <sub>su; sто</sub>	-	-	4.0	-	0.6	-	μs
Bus free time between stop condition and start condition	t <sub>BUF</sub>	(Note5)	-	4.7	-	1.3	-	μs

Note 1: SCL clock Low width (output) =  $(2^{n-1} + 58)/x$ 

Note 2: SCL clock High width (output) = (2<sup>n-1</sup> + 14)/x On I2C-bus specification, Maximum Speed of Standard Mode is 100kHz, Fast mode is 400khz. Internal SCL Frequency setting should comply with Note1 & Note2 shown above.

- Note 3: The output data hold time is equal to 4x of internal SCL.
- Note 4: The Philips I2C-bus specification states that a device must internally provide a hold time of at least 300 ns for the SDA signal to bridge the undefined region of the falling edge of SCL. However, this SBI does not satisfy this requirement. Also, the output buffer for SCL does not incorporate slope control of the falling edges; therefore, the equipment manufacturer should design so that the input data hold time shown in the table is satisfied, including tr/tf of the SCL and SDA lines.
- Note 5: Software -dependent
- Note 6: The Philips I2C-bus specification instructs that if the power supply to a Fast-mode device is switched off, the SDA and SCL I/O pins must be floating so that they don't obstruct the bus lines. However, this SBI does not satisfy this requirement.

### 19.6.3.2 Clock-Synchronous 8-Bit SIO mode

In the table below, the letter x represents the I2C operation clock cycle time which is identical to the fsys cycle time. It varies depending on the programming of the clock gear function.

# (1) SCK Input mode(The electrical specifications below are for an SCK signal with a 50% duty cycle.)

[Data input]

Parameter	0	Equation		fsys = 40 MHz		48 MHz		Unit
Parameter	Symbol	Min	Max.	Min	Max.	Min.	Max.	Onic
SCK Clock High width (input)	t <sub>SCH</sub>	4x	-	100	-	83.3	-	
SCK Clock Low width (input)	t <sub>SCL</sub>	4x	-	100	-	83.3	-	
SCK cycle	t <sub>SCY</sub>	t <sub>SCH</sub> + t <sub>SCL</sub>	-	200	-	166	-	ns
Valid Data input $\rightarrow$ SCK rise	t <sub>SRD</sub>	30 - x	-	5	-	9	-	
SCK rise $\rightarrow$ Input Data hold	t <sub>HSR</sub>	2x + 30	-	80	-	71.7	-	

### [Data output]

Demmeter	Querra ha a l	Equation		fsys = 40 MHz		48 MHz		Unit
Parameter	Symbol	Min	Max.	Min	Max.	Min.	Max.	Unit
SCK Clock High width (input)	t <sub>SCH</sub>	4x	-	120 (Note2)	-	108 (Note2)	-	
SCK Clock Low width (input)	tscl	4x	-	120 (Note2)	-	108 (Note2)	-	
SCK cycle	t <sub>SCY</sub>	t <sub>SCH</sub> + t <sub>SCL</sub>	-	240	-	215	-	ns
Output Data $\rightarrow$ SCLK rise	toss	t <sub>SCY</sub> /2 - 3x - 45	-	0 (Note1)	-	0 (Note1)	_	
SCK rise $\rightarrow$ Output Data hold	t <sub>OHS</sub>	$t_{SCY}/2 + x$	-	145	-	128	_	

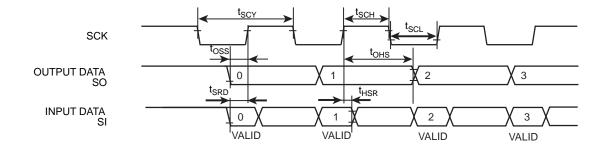

Note 1: Use the frequency of SCK in a range where the calculation value keeps positive. Note 2: The value indicates a minimum value that enables  $t_{OSS}$  to be zero or more.

(2) SCK Output Mode (The electrical specifications below are for an SCK signal with a 50% duty cycle.)

Parameter	Symbol	Equation		40 MHz		48 MHz		l la it
Parameter		Min.	Max.	Min.	Max.	Min.	Max.	Unit
SCK cycle (programmable)	t <sub>SCY</sub>	16x	-	400	-	333	-	
Output Data $\rightarrow$ SCK rise	toss	t <sub>SCY</sub> /2 - 20	-	180	-	147	-	
SCK rise $\rightarrow$ Output Data hold	t <sub>OHS</sub>	t <sub>SCY</sub> /2 - 20	-	180	-	147	-	ns
Valid Data input $\rightarrow$ SCK rise	t <sub>SRD</sub>	x + 45	-	70	-	65.8	-	
SCK rise $\rightarrow$ Input Data hold	t <sub>HSR</sub>	0	-	0	-	0	-	

Note 1: SCK cycle after automatic wait becomes 14x.

Note 2: toss after automatic wait may be tscy/2-x-20.

## 19.6.4 Event Counter

In the table below, the letter x represents the TMRB operation clock cycle time which is identical to the fsys cycle time. It varies depending on the programming of the clock gear function.

Parameter	Ourschal	Equ	ation	40	MHz	48	MHz	l la it
Parameter	Symbol	Min.	Max.	Min.	Max.	Min.	Max.	Unit
Clock Low pulse width	t <sub>VCKL</sub>	2x + 100	-	150	-	142	-	ns
Clock High pulse width	t <sub>VCKH</sub>	2x + 100	-	150	-	142	-	ns

#### 19.6.5 Capture

In the table below, the letter x represents the TMRB operation clock cycle time which is identical to the fsys cycle time. It varies depending on the programming of the clock gear function.

Parameter	Ourschal	Equ	ation	40	MHz	48	MHz	l la it
Parameter	Symbol	Min.	Max.	Min.	Max.	Min.	Max.	Unit
Low pulse width	t <sub>CPL</sub>	2x + 100	-	150	-	142	-	ns
High pulse width	t <sub>CPH</sub>	2x + 100	-	150	-	142	-	ns

## 19.6.6 External Interrupt

In the table below, the letter x represents the fsys cycle time.

1. Except STOP1 release interrupts

Deremeter	Ourschal	Equ	ation	40	MHz	48	MHz	l la it
Parameter	Symbol	Min.	Max.	Min.	Max	Min.	Max.	Unit
INT0 to 9 low level pulse width	t <sub>INTAL</sub>	x + 100	-	125	-	121	-	ns
INT0 to 9 high level pulse width	t <sub>INTAH</sub>	x + 100	-	125	-	121	-	ns

2. STOP1 release interrupts

Parameter	Symbol	Min.	Max.	Unit
INT0 to 9 low level pulse width	t <sub>INTBL</sub>	100	-	ns
INT0 to 9 high level pulse width	t <sub>INTBH</sub>	100	-	ns

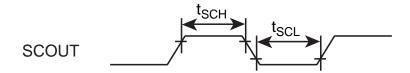

# 19.6.7 NMI

Parameter	Symbol	Min.	Max.	Unit
$\overline{\text{NIM}}$ low level pulse width	t <sub>INTCL</sub>	100	-	ns

# 19.6.8 SCOUT Pin AC Characteristic

Parameter	Cumbal	Equ	ation	40	MHz	48	MHz	Linit
Parameter	Symbol	Min.	Max.	Min.	Max.	Min.	Max.	Unit
High pulse width	t <sub>SCH</sub>	0.5T - 5	-	7.5	-	5.4	-	ns
Low pulse width	t <sub>SCL</sub>	0.5T - 5	-	7.5	-	5.4	-	ns

Note: In the above table, the letter T represents the cycle time of the SCOUT output clock.

# 19.6.9 ADTRG Tringger Input Pin AC Characteristic

In the table below, the letter x represents fsys cycle time. It varies depending on the programming of the clock gear function.

Parameter Symb	Ourschal	Equ	ation	401	ЛHz	481	MHz	l la it
Parameter	Symbol	Min.	Max.	Min.	Max.	Min.	Max.	Unit
Low level pulse width	T <sub>adl</sub>	2 x + 20	-	32.5	-	32.5	-	
High level pulse interval	T <sub>adh</sub>	2 x + 20	-	32.5	-	32.5	-	ns

# 19.6.10 USB Timing

Parameter	Symbol	Min.	Max.	Unit
D+,D-Supply rise time	t <sub>R</sub>	4	20	
D+,D-Supply withdraw time	t <sub>F</sub>	4	20	ns
Data Line crossover voltage	V <sub>CRS</sub>	1.3	2.0	V

# TOSHIBA

# 19.7 Recommended Oscillation Circuit

# Figure 19-1 High-frequency oscillation connection

Note: To obtain a stable oscillation, load capacity and the position of the oscillator must be configured properly. Since these factors are strongly affected by substratepatterns, please evaluate oscillation stability using the substrate you use.

The TX03 has been evaluated by the oscillator vender below. Please refer this information when selecting external parts

## 19.7.1 Ceramic oscillator

The TX03 recommends the high-frequency oscillator by Murata Manufacturing Co., Ltd.

Please refer to the following URL for details.

http://www.murata.co.jp

## 19.7.2 Crystal oscillator

The TX03 recommends the high-frequency oscillator by KYOCERA Crystal Device Corporation.

Please refer to the following URL for details

http://www.kinseki.co.jp

#### 19.7.2.1 Precautions for designing printed circuit board

Be sure to design printed circuit board patterns that connect a crystal unit with other oscillation elements so that the lenghts of such patterns become shortest possible to prevent deterioration of characteristics due to stray capacitances and wiring inductance. For multi-layer circuit boards, it is important not to wire the ground and other signal patterns right beneath the oscillation circuit.

For more information, please refer to the URL of the oscillator vendor .

# 19.8 Handling Precaution

## 19.8.1 Voltage level of power supply at power-on

The rising of power supply in power-on must be less than the value in below tabel. TMPM365FYXBG has some power supply pin. They must be supplied the power at same time. And the external reset pin (RESET) must be "Low" level at power-on.

Power supply pin = DVDD3A, DVDD3C, AVDD3, RVDD3

C = 0.1μF Ta = -40 ~ 85°C

				14	10 00 0
Parameter	condition	Min.	Тур.	Max.	unit
The rising of power supply in power-on	$0V \rightarrow 2.7~V$ to 3.6 $V$	-	-	10	mV/µs

## RESTRICTIONS ON PRODUCT USE

- Toshiba Corporation, and its subsidiaries and affiliates (collectively "TOSHIBA"), reserve the right to make changes to the information in this document, and related hardware, software and systems (collectively "Product") without notice.
- This document and any information herein may not be reproduced without prior written permission from TOSHIBA. Even with TOSHIBA's written permission, reproduction is permissible only if reproduction is without alteration/omission.
- Though TOSHIBA works continually to improve Product's quality and reliability, Product can malfunction or fail. Customers are responsible for complying with safety standards and for providing adequate designs and safeguards for their hardware, software and systems which minimize risk and avoid situations in which a malfunction or failure of Product could cause loss of human life, bodily injury or damage to property, including data loss or corruption. Before customers use the Product, create designs including the Product, or incorporate the Product into their own applications, customers must also refer to and comply with (a) the latest versions of all relevant TOSHIBA information, including without limitation, this document, the specifications, the data sheets and application notes for Product and the precautions and conditions set forth in the "TOSHIBA Semiconductor Reliability Handbook" and (b) the instructions for the application with which the Product will be used with or for. Customers are solely responsible for all aspects of their own product design or applications, including but not limited to (a) determining the appropriateness of the use of this Product in such design or applications; (b) evaluating and determining the applicability of any information contained in this document, or in charts, diagrams, programs, algorithms, sample application circuits, or any other referenced documents; and (c) validating all operating parameters for such designs and applications. TOSHIBA ASSUMES NO LIABILITY FOR CUSTOMERS' PRODUCT DESIGN OR APPLICATIONS.
- PRODUCT IS NEITHER INTENDED NOR WARRANTED FOR USE IN EQUIPMENTS OR SYSTEMS THAT REQUIRE EXTRAORDINARILY HIGH LEVELS OF QUALITY AND/OR RELIABILITY, AND/OR A MALFUNCTION OR FAILURE OF WHICH MAY CAUSE LOSS OF HUMAN LIFE, BODILY INJURY, SERIOUS PROPERTY DAMAGE AND/OR SERIOUS PUBLIC IMPACT ("UNINTENDED USE"). Except for specific applications as expressly stated in this document, Unintended Use includes, without limitation, equipment used in nuclear facilities, equipment used in the aerospace industry, medical equipment, equipment used for automobiles, trains, ships and other transportation, traffic signaling equipment, equipment used to control combustions or explosions, safety devices, elevators and escalators, devices related to electric power, and equipment used in finance-related fields. IF YOU USE PRODUCT FOR UNINTENDED USE, TOSHIBA ASSUMES NO LIABILITY FOR PRODUCT. For details, please contact your TOSHIBA sales representative.
- Do not disassemble, analyze, reverse-engineer, alter, modify, translate or copy Product, whether in whole or in part.
- Product shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable laws or regulations.
- The information contained herein is presented only as guidance for Product use. No responsibility is assumed by TOSHIBA for any infringement of patents or any other intellectual property rights of third parties that may result from the use of Product. No license to any intellectual property right is granted by this document, whether express or implied, by estoppel or otherwise.
- ABSENT A WRITTEN SIGNED AGREEMENT, EXCEPT AS PROVIDED IN THE RELEVANT TERMS AND CONDITIONS OF SALE FOR PRODUCT, AND TO THE MAXIMUM EXTENT ALLOWABLE BY LAW, TOSHIBA (1) ASSUMES NO LIABILITY WHATSOEVER, INCLUDING WITHOUT LIMITATION, INDIRECT, CONSEQUENTIAL, SPECIAL, OR INCIDENTAL DAMAGES OR LOSS, INCLUDING WITHOUT LIMITATION, LOSS OF PROFITS, LOSS OF OPPORTUNITIES, BUSINESS INTERRUPTION AND LOSS OF DATA, AND (2) DISCLAIMS ANY AND ALL EXPRESS OR IMPLIED WARRANTIES AND CONDITIONS RELATED TO SALE, USE OF PRODUCT, OR INFORMATION, INCLUDING WARRANTIES OR CONDITIONS OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, ACCURACY OF INFORMATION, OR NONINFRINGEMENT.
- Do not use or otherwise make available Product or related software or technology for any military purposes, including
  without limitation, for the design, development, use, stockpiling or manufacturing of nuclear, chemical, or biological
  weapons or missile technology products (mass destruction weapons). Product and related software and technology may be
  controlled under the applicable export laws and regulations including, without limitation, the Japanese Foreign Exchange
  and Foreign Trade Law and the U.S. Export Administration Regulations. Export and re-export of Product or related software
  or technology are strictly prohibited except in compliance with all applicable export laws and regulations.
- Please contact your TOSHIBA sales representative for details as to environmental matters such as the RoHS compatibility
  of Product. Please use Product in compliance with all applicable laws and regulations that regulate the inclusion or use of
  controlled substances, including without limitation, the EU RoHS Directive. TOSHIBA ASSUMES NO LIABILITY FOR
  DAMAGES OR LOSSES OCCURRING AS A RESULT OF NONCOMPLIANCE WITH APPLICABLE LAWS AND
  REGULATIONS.
