

# Si3473/72 Data Sheet

## Octal or Quad 2-pair 802.3bt Ethernet Port PoE PSE Controller

The Si3473 and Si3472 are fully programmable, 50 V to 57 V power sourcing equipment (PSE) controllers for IEEE 802.3bt 2-pair, Type 3 applications. As 2-pair, Type 3 PSE controllers, Si3473/72 are compatible with IEEE 802.3af and IEEE 802.3at powered device (PD) loads. Designed for use in PSE endspans (switches) and midspans (injectors), the Si3473/72 integrates eight (Si3473) or four (Si3472) independent ports, each with the IEEE-required detection and classification functionality.

In addition, the Si3473/72 features include powered device (PD) disconnect using dc-sense algorithms, a robust multipoint detection algorithm, software configurable per-port current and voltage monitoring, and programmable current limits to support the IEEE 802.3af, 802.3at, and 2-pair 802.3bt standards. Intelligent power protection circuitry includes input undervoltage detection, output power limit, and short-circuit protection. The Si3473/72 operates autonomously or by host processor control through a two wire,  $\rm I^2C$ -compatible serial interface. An interrupt pin is used to alert a host processor of various status and fault events.

## **Applications**

- IEEE 802.3af, 802.3at, and 2-pair 802.3bt Power Sourcing Equipment (PSE)
- · Power over Ethernet Switches
- · IP Phone Systems
- · Smartgrid Switches
- · Ruggedized and Industrial Switches
- Multiport PoE Injectors
- · Applications powering IEEE Type 1 & 2 PDs through Class 4 up to 30 W
- Applications powering legacy 2-pair Class 5 PDs to 45 W

#### **KEY FEATURES**

- Octal or Quad Port Power Sourcing Equipment (PSE) controller
- IEEE 802.3bt 2-pair, Type 3 compliant
- IEEE 802.3af and IEEE 802.3at compatible
- Autonomous or I<sup>2</sup>C host interface
- Emergency Shutdown support with port priority control
- Adds enhanced features for maximum design flexibility:
  - · Per-port current and voltage monitoring
  - · Multi-point detection
  - Programmable power MOSFET gate drive control
  - Configurable watchdog timer enables failsafe operation
- · Maskable interrupt pin
- Comprehensive fault protection circuitry includes:
- Power undervoltage lockout
- Output current limit and short-circuit protection
- · Thermal overload detection
- Extended operating temp range: –40 to +85 °C
- 38-pin 5 x 7 mm QFN package (Si3472)
- 56-pin, 8 x 8 mm QFN package (Si3473)

## 1. Ordering Guide

Table 1.1. Si3473/72 Ordering Guide

| Ordering<br>Part Number <sup>1</sup> | Product Revision | Current Sense<br>Resistor <sup>2</sup> | Package                                | Temperature Range (Ambient) |
|--------------------------------------|------------------|--|--|-----------------------------|
| Si3473A-A01-IM                       | A01              | 255 mΩ                                 | 56-pin, 8 x 8 mm QFN<br>RoHS-compliant | –40 to 85 °C                |
| Si3473B-A01-IM                       | A01              | 200 mΩ                                 | 56-pin, 8 x 8 mm QFN<br>RoHS-compliant | –40 to 85 °C                |
| Si3472A-A01-IM                       | A01              | 255 mΩ                                 | 38-pin, 5 x 7 mm QFN<br>RoHS-compliant | –40 to 85 °C                |
| Si3472B-A01-IM                       | A01              | 200 mΩ                                 | 38-pin, 5 x 7 mm QFN<br>RoHS-compliant | –40 to 85 °C                |

## Note:

- 1. Add an "R" to the end of the part number for tape and reel option (e.g., Si3473/72A or Si3473/72A-A01-IMR).
- 2. Options include industry-standard 255 m $\Omega$  or more thermally efficient 200 m $\Omega$  sense resistor.

## 2. Functional Description

#### 2.1 Overview

The Si3473/2 integrates a high-performance microcontroller with high-resolution A/D and D/A capabilities, and independent, high-voltage PSE port interfaces. External power FETs and sense resistors are used to power the PoE ports, communicate to a PD, and sense the current and voltage levels on the ports. The Si3473/72 enables an extremely flexible solution for virtually any PoE switch application. The Si3473/72 contains all PSE controller functions needed for an octal (Si3473) or quad (Si3472) port PoE design.

The Si3473/72 includes many additional features that can be individually enabled or disabled by programming the extended register set appropriately:

- · Per-port current / voltage monitoring and measurement
- · Multipoint detection algorithms
- · Programmable gate drive for external MOSFETs
- · Watchdog timer (WDT)

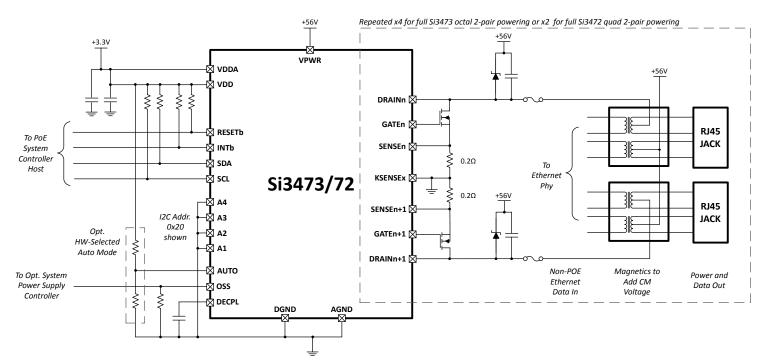

Figure 2.1. Si3473/72 Typical Application Circuit

#### 2.2 Functional Block Diagram

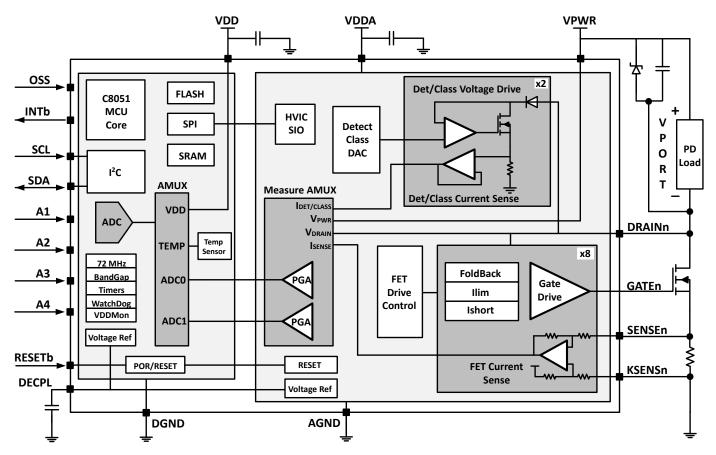

Figure 2.2. Si3473/72 Functional Block Diagram

## 2.3 Operational Modes

The Si3473/72 has three different operating modes: Autonomous, Semi-Autonomous, and Manual, plus one non-operating mode, Shutdown. The operating mode can be selected based on system requirements, such as whether the PSE system is power-constrained, whether the PSE system has a power manager host, or whether the PSE system must identify and power up non-compliant PD loads.

## 2.3.1 Autonomous Mode

Autonomous Mode should only be used in PSE systems where there is enough power to power all ports simultaneously to their total allocated power. Autonomous Mode can only be used in non-power constrained PSE systems. In Autonomous Mode, the Si3473/72 will automatically detect, classify and power on ports that present a valid PD signature without any external host interaction.

There are two methods to place the Si3473/72 into Autonomous Mode. One method is to power cycle the Si3473/72 while applying a voltage (other than VDD) on the AUTO pin. When using this method, the power allocation set by the AUTO pin applies to each port. The system must have sufficient VPWR current to handle the worst case where all ports are each supplying maximum PD current load. A requirement for AUTO pin Autonomous Mode is that each port must have the same Power Allocation setting.

The second method is to configure and start the Autonomous Mode through the  $I^2C$  registers. Use this method to configure and invoke the Autonomous Mode for systems that have ports with different power allocation settings or dynamic power allocation settings. Whether Autonomous Mode is invoked by the AUTO pin or by the  $I^2C$  interface, the  $I^2C$  register interface remains active so an external host processor can poll the event registers, for example, to control indicator LEDs.

For more details on autonomous operation, refer to 2.10.1 AUTO Pin Autonomous Mode and 2.10.2 I<sup>2</sup>C Autonomous Mode.

#### 2.3.2 Semi-Autonomous Mode

In PSE systems with high port counts, it is common to have more ports than the system power supply can power simultaneously. In Semi-Autonomous Mode, the Si3473/Si3472 I2C register interface allows a host processor to power or deny PD power requests as new PD loads are attached. In these systems, the Si3473/72 controller performs low level PoE protocols with PD power loads and provides real-time fault monitoring and power consumption measurements required by an external host processor to perform power management.

#### 2.3.3 Manual Mode

Manual Mode allows an external host processor to force a condition on the port(s) that bypasses the PoE protocol. For example, a host can use Manual Mode to force a port to power on a PD load immediately without exercising Detection and Classification protocol. Because of this behavior, Manual Mode should be used for diagnostic or debug purposes only.

#### 2.4 Host Interface

The Si3473/72 communicates with a host through an I<sup>2</sup>C interface using:

- · Registers
- Events
- · Pushbuttons

In this data sheet, register names, fields, and bits are listed in all capitals. Some have prefixes such as PORTn\_ or PORTnm\_. The PORTn\_ describes attributes that are associated with 2-pair (2P) ports. The Si3473 only supports 2-pair port configurations. The Si3474 can be configured for 4-pair port configurations. Some registers are associated with one set of four 2-pair ports (quad). The Si3473 has two quads and the second set of four 2-pair ports are accessed in the same register but through the alternate I<sup>2</sup>C address. The Si3472 has one quad. Refer to 3. Register Map for a complete listing of registers.

During operation, the Si3473/72 monitors global conditions such as temperature and supply voltage, and some conditions that are associated with the individual PoE ports. When an event occurs, the Si3473/72 will drive the INTb pin low. A host will then read the INTERRUPT register and decode what event has occurred. The Si3473/72 drives the INTb low until the appropriate Clear-on-Read (CoR) register is read by a host.

Some events cause the Si3473/72 to take immediate action without instructions from a host. Other events notify a host that a change has occurred and allow a host to determine how to handle the event. Once a host receives notification of an event, it is expected to act upon that event. The details and mechanics of event handling are described in 2.9 Event Handling.

A host can instruct the Si3473/72 to take certain actions through a Pushbutton (PB) command. All write-only registers are Pushbutton registers. A register designated as Pushbutton will always return zero when read.

Each Si3473/72 port can be in one of four operational Modes, controlled by the PORT\_MODE register. PORTn\_PORT\_MODE can be set to:

- SHUTDOWN
- MANUAL
- SEMI AUTO
- AUTO

The AUTO Mode is most applicable to a non-hosted PSE system. The MANUAL Mode is used primarily for diagnostic and debug purposes. For hosted PSE systems, SHUTDOWN and SEMI\_AUTO port Modes are the most important. When PORTn\_PORT\_MODE is set to SHUTDOWN, that port is in an idle state, ready to be configured by a host.

A port enters SHUTDOWN by:

- A hard reset (power on reset or by deasserting the RESETb pin)
- · Setting RESET QUAD in the PB RESET register to set all ports in that quad to SHUTDOWN
- · Setting individual PORTn\_RESET\_PORT bits in PB\_RESET register. Each port has a dedicated bit
- Any SUPPLY EVENT
- An I<sup>2</sup>C WATCHDOG event (equivalent to a RESET\_QUAD)

A port in SEMI\_AUTO Mode, when combined with PORTn\_DETECT\_ENABLE and PORTn\_CLASS\_ENABLE, instructs the Si3473/72 to actively look for connected PDs on a port. In a power-managed, hosted PSE system, the figure below describes the key interactions and events between a host and the PoE port conditions in the Si3473/72. The following sections describe the control flow of a Semi-Auto PSE.

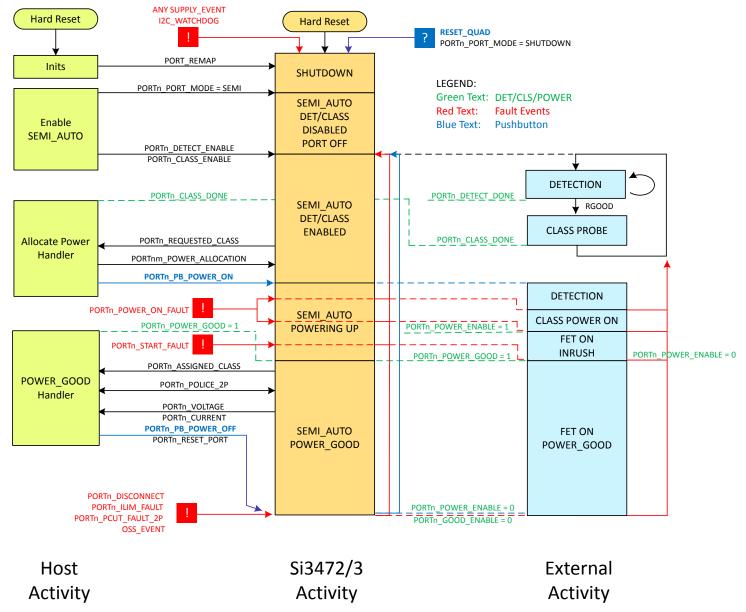

Figure 2.3. Semi-Auto System State Diagram

## 2.5 Reset and Initialization

Hard resets are invoked by either cycling power (Power on Reset or PoR) and/or deasserting the RESETb input. After a hard reset, all registers are set to default values. A PoR will always set all registers to default values. Invoking a hard reset by deasserting the RESETb input will set all registers to default values except the upper nibble of SUPPLY\_EVENT. The upper nibble is sticky until the condition that is causing the global event is cleared. For specific information, refer to 3.7 SUPPLY\_EVENT and SUPPLY\_EVENT COR (0x0A, 0x0B).

Immediately after a hard reset, a host must initialize the PORT\_REMAP register. For specifics, refer to 3.23 PORT\_REMAP (0x26). Once written to, this register is locked until a hard reset of the Si3473/72 unlocks it again.

During initialization, a host sets other global registers as needed.

Note that there is an important difference between the Si3472 and Si3473 pertaining to how RESETb affects powered ports. A powered port on the Si3473 powers down within 20 us after the FALLING edge of RESETb. On the other hand, a powered port on the Si3472 powers down within 300 us after the RISING edge of RESETb.

#### 2.6 Semi-Auto Detection and Class Probe

A host instructs the Si3473/72 to start detecting attached PDs by setting:

- PORTn PORT MODE = SEMI AUTO
- PORTn DETECT ENABLE and PORTn CLASS ENABLE in DETECT CLASS ENABLE

Prior to driving the Detection waveform, the Si3473/72 checks that the port's external FET is properly off and is not damaged. The first test is a current measurement across the external sense resistor and the second test is a voltage measurement at the DRAINx pin. If excessive current or an unexpected drain voltage is detected, PORTn\_DETECTION\_STATUS will indicate a MOSFET\_FAULT and Detection is aborted.

The Si3473/72 detects a PD by making a differential resistance measurement. To do this, the Si3473/72 drives 4 V ( $V_{det1}$ ) to 8 V ( $V_{det1}$ ) and back to 4 V on each enabled port through the DRAINx pin, while measuring current at each step. The results are used to calculate the Detection resistance, also known as the PD Signature Resistance, which is nominally 25 k $\Omega$ . The Si3473/72 reports the Detection results in the PORTn\_DETECTION\_STATUS field of the PORTn\_DETECT\_CLASS\_STATUS registers.

During Detection, the Si3473/72 monitors the voltage driven for evidence of contention with another PSE driving the same line. If the measured voltage deviates significantly from the driven voltage, PORTn\_DETECTION\_STATUS will report a PSE to PSE fault. The Si3473/72 also uses the voltage/current measurements taken during the Detection waveform to determine if the PD Signature Resistance is too capacitive and reports this in the PORTn\_DETECTION\_STATUS.

A DETECT\_DONE event will be reported to a host after the Detection sequence. If the Detection result is RGOOD, the Si3473/72 begins a Class Probe to determine the PD's Class Signature. A Class Probe will always consist of three class "fingers" to determine the PD requested power followed by a Class Reset. Three fingers are used to support Class 5 legacy PDs. The following figure shows the expected waveform with the aforementioned three fingers for a 2-pair powered PD.

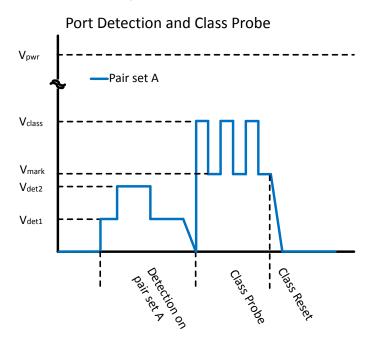

Figure 2.4. Port Voltage During Semi-Auto DET/CLASS 2-Pair Waveform

## 2.7 Powering Up

A port is ready to be powered on after PORTn\_CLASS\_DONE event is reported. A host can examine the results of PORTn\_CLASS\_STATUS to discover the PD's requested class. A host can then set or adjust PORTnm\_POWER\_ALLOCATION as needed, followed by setting the PORTn\_PB\_POWER\_ON for the port. The Si3473/72 goes through this sequence of events as described in the following subsections.

#### 2.7.1 Power Demotion

Before powering on a port, a host can determine how much power the PD has requested by reading the PD's requested class. If a host determines that it has the requested power available, it will typically set PORTnm\_POWER\_ALLOCATION so that the PD receives the power it has requested. If a host knows it does not have the full power available, it can choose to set the PORTnm\_POWER\_ALLOCATION such that the assigned class will be less than the requested class; this is known as Power Demotion.

A power-demoted PD can request more power at any time through the Ethernet Link Layer Discovery Protocol (LLDP). Through LLDP, if the PD requests additional power (and if the PSE has more power to spare at that time), it can then grant the additional power. A host communicates the allowable additional power to the Si3473/72 by updating the PORTn\_POLICE\_2P registers and need not put the port into SHUTDOWN or perform another PORTn\_PB\_POWER\_ON sequence.

When a Class 4 PD is only provided Class 3 power, the PSE will only send one Classification finger to the PD. In this case, the Si3473/72 will supply Class 3 power and report "Class 4 Type 1 Limited" in PORTn\_CLASS\_STATUS. PORTn\_ASSIGNED\_CLASS will show Class 3, and PORTn\_REQUESTED\_CLASS will show the result of the Class Probe, which will be Class 4.

It is important to note that Power Demotion can only occur from Class 4 to Class 3. There is no demotion strategy to lower classes.

#### 2.7.2 Final Detection and Class Probe

When a PORTn\_PB\_POWER\_ON command is received by the Si3473/72, it is likely to be performing a DET/CLASS PD discovery sequence that is unrelated to the port receiving the PB\_POWER\_ON pushbutton. The Si3473/72 allows those started sequences to complete before executing the Pushbutton command for the specified port. PB\_POWER\_ON performs a final set of Detection and "Class Power On" operations for the ports that a host wants to power on. The Class Power On sequence is described in the next section.

The PB\_POWER\_ON Detection sequence is similar to that performed by Semi-Auto Detection and Class Probe, with some slight differences. If the Detection results are anything other than RGOOD for the ports being powered up, the PORTn\_POWER\_ON\_FAULT event is set to INVALID. The Si3473/72 then performs another Class Probe to reconfirm the PD's requested class followed by a Class Reset.

#### 2.7.3 Class Power On

Unlike Class Probe, Class Power On sequence intends to power on the PD. With Class Power On, the number of Classification fingers is used to communicate to the PD how much power it was allocated by the PSE. For example, a Class 4 PD learns it has been power demoted and has been allocated only 15.5 W of power if the PSE presents a single Classification finger during Class Power On. If the PSE presents a Class 4 PD with two fingers during Class Power On, the PD learns it may draw the full 30 W.

If, during Class Power On, an overcurrent or an invalid Classification occurs, the PORTn\_POWER\_ON\_FAULT event is set to Classification Error.

Class Power On results are stored in PORTn\_ASSIGNED\_CLASS. However, PORTn\_CLASS\_STATUS can contain additional information. In the case of a Power Demotion where a Class 4 PD is demoted to Class 3, PORTn\_CLASS\_STATUS will report Class 4 Type 1 Limited, whereas PORTn\_ASSIGNED\_CLASS will report Class 3. Refer to Table 3.3 Classification Event Timing on page 64 in 3.34 CLASS\_RESULTS (0x4C - 0x4F) for a comprehensive list of class codes and when they are updated.

The Si3473/72 sends out a long class pulse on the first finger during Class Power On for two purposes. First, a long first Classification finger communicates to the PD that the Si3473/72 supports Short Maintain Power Signature (MPS) to save even more power when in standby. Second, with the initial long class pulse, it is possible to detect if the PD supports Autoclass. Refer to 2.8.5 Autoclass for details.

After Class Power On has completed, the FET controlling power to the port is turned on, and the Inrush period begins. The following figure shows the expected waveform for a PORTn PB POWER ON sequence powering a 2-pair PD.

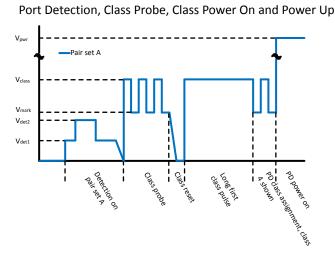

Figure 2.5. 2P Port Detection Waveform

#### 2.8 Powered States

There are two states for which the FET is ON:

- 1. Inrush Period
- 2. Power Good State

#### 2.8.1 FET On Status

Each pair set has the PORTn\_POWER\_ENABLE and PORTn\_POWER\_GOOD status information suitable for tracking the general state of the Si3473/72 after a PORTn\_PB\_POWER\_ON event, as shown in the following table.

**Table 2.1.** 

| PORTn_POWER_ENABLE | PORTn_POWER_GOOD | FET State | After PORTn_PB_POWER_ON |
|--------------------|------------------|-----------|-------------------------|
|                    |                  |           | Final Detection         |
| 0                  | 0                | OFF       | Class Probe             |
|                    |                  |           | Class Power             |
| 1                  | 0                | ON        | Inrush Period           |
| 1                  | 1                | ON        | Power Good              |
| 0                  | 1                | _         | Invalid                 |

The PORTn\_POWER\_ENABLE\_CHANGE and PORTn\_POWER\_GOOD\_CHANGE bits in the POWER\_EVENT register reflect the changes in the POWER\_ENABLE and the POWER\_GOOD fields of the POWER\_STATUS register. These events can be used by a host as a signal to check the POWER\_STATUS register and get the most up-to-date port status.

Once set, the PORTn\_POWER\_GOOD\_CHANGE and PORTn\_POWER\_ENABLE\_CHANGE bits are typically cleared by reading the POWER\_CHANGE COR register. In addition, PORTn\_POWER\_GOOD\_CHANGE and PORTn\_POWER\_ENABLE\_CHANGE bits are cleared when PORTn\_RESET\_PORT is set, PORTn\_PB\_POWER\_OFF is set, or when a port is turned off as a result of an OSS Event.

## 2.8.2 Inrush Period

Immediately after the external FET is turned on, the Si3473/72 enters the Inrush Period. The Inrush Period is a fixed time period defined by  $t_{\text{INRUSH}}$ , During the Inrush Period, the Si3473/72 performs a voltage-foldback function for currents higher than 425 mA in order to limit the current drawn from the VPWR rail (see ). The Si3473/72 also has a proprietary short-circuit FET protection circuit intended to protect the FET from damage.

The terms "start" and "inrush" are used interchangeably in this document. The Inrush Period is the initial part of a power-on in which the PSE is expected to supply current to the PD's bulk capacitors. During the Inrush Period, a port implements a 425 mA current limit, with a 30 V Foldback, during a t<sub>START</sub> or t<sub>INRUSH</sub> time period.

After t<sub>INRUSH</sub>, the port should no longer be in a current-limited state. If the port is still in a current-limited state, the port is powered off, and the PORTn\_START\_FAULT event is raised. Otherwise, the port reaches a POWER\_GOOD state, and the Si3473/72 begins monitoring the port.

See 2.8.4 Current Limit and Voltage Foldback for an illustration of how current limiting and voltage foldback work.

#### 2.8.3 Power Good State

When a port is in a POWER GOOD state, three things are monitored:

- 1. Disconnection
- 2. ILIM / Current Limit
- 3. PCUT / Power Overload Cutoff Point

Disconnection monitoring checks to see if the PD is drawing too little current.

For the next two items, the Si3473/72 is monitoring for "too much current". The difference between these two over-current monitors is the speed of the action taken.

ILIM events are considered to be fast, high current events. As such, the Si3473/72 aims to limit the current by reducing port voltage. Under extremely fast and high current conditions, the Si3473/72 implements a hardware control loop that aims to control the maximum port current by dynamically lowering the port voltage.

On the other hand, a PCUT does not involve FETs operating in a current-limited state. But rather, the Si3473/72 is monitoring the port voltage and port current, then comparing them against the POLICE register limits.

#### 2.8.3.1 Disconnection

While in the POWER\_GOOD state, the Si3473/72 checks whether or not the PD is still connected to the port. A connected PD is obligated to draw a minimum amount of current. To keep the PSE from declaring a disconnection, the PD must meet a defined "Maintain Power Signature" (MPS) for the time duration of  $t_{MPDO}$ . If the PD does not meet these MPS requirements, the PSE may choose to power down the port and set the PORTn DISCONNECTION bit.

#### 2.8.3.2 ILIM / Current Limit

Depending on the assigned PD Class, the Si3473/72 chooses a current-limit template designed to allow normal PD currents to flow, while also setting a peak current threshold to begin a voltage foldback. The Si3473/72 implements a number of current limit templates. A current limit template is a 2-dimensional function that defines a current limit based on a FET's drain voltage. At low drain voltages, the current limit is set at its maximum.

Whenever the measured port current exceeds these current limits, a feedback circuit then adjusts the gate voltage of the FET to fold-back the voltage. The speed at which the gate voltage is adjusted is a function of the difference between the current limit threshold at the drain voltage against the sensed port current.

As a simple example, if the Si3472/73 continuously detects overcurrent in excess of t<sub>LIM</sub>, it will be considered an ILIM fault and remove power from the port. Section 2.8.4 Current Limit and Voltage Foldback illustrates how this current limiting and voltage foldback works.

The foldback mechanism is done automatically, while the drain voltage is monitored to check for evidence of a current-limited state. The Si3473/72 implements a counter that counts up by 1 whenever the FET is in an over-current state. For every subsequent non-overcurrent event, the counter is decreased by 1/16. This allows current limited events to self-clear if only transient, and prevents nuisance disconnections while also allowing the disconnection of a port based on the severity of the event.

In addition to the programmable current-limit foldback voltage templates, the Si3473/72 also implements a separate short circuit monitor so that if the measured current exceeds two times the pre-set current limit threshold, the FET is turned off. This feature protects the FET in the case of an unexpected short-circuit.

Current Limit faults are reported through the PORTn\_ILIM\_FAULT bits in the ILIM\_START\_FAULT register.

#### 2.8.3.3 PCUT Faults

After Class Power On, the PSE is obligated to supply a certain amount of power to the PD based on the assigned class plus expected wire loss. If PSE senses that too much power is being drawn, the PSE disconnects the PD and issues a PCUT event to a host. Once the Port has reached a POWER\_GOOD state, the Si3473/72 enforces this mutual power agreement through the PORTn\_POLICE\_2P register.

Power values in the PORTn\_POLICE\_2P registers represent the minimum levels the PSE is obligated to supply and the maximum power the PD is allowed to draw before the PSE will disconnect. The majority of the PSE power budget is spent by the PD as useful power, but some of the PSE power budget is dissipated due to wire transmission losses.

The internal PCUT threshold is set at 15% above the power levels shown in PORTn\_POLICE\_2P. This 15% threshold was chosen to maximize the probability of powering up legacy PDs and to accommodate higher wire loss use cases.

It is important to note that a host always has the option of re-adjusting PORTn\_POLICE\_2P once the port has reached Power Good state to a lower PCUT level.

The expected PCUT behavior needs to take measurement error into consideration.

#### For Class 0, 1, 2 and 3:

- · Measurement Error is 10% max
- Class 1 PORTn POLICE 2P = 4 W
- Class 2 PORTn POLICE 2P = 7 W
- Class 0 or Class3 PORTn\_POLICE\_2P = 15.5 W
- Power is maintained if Measured V \* Measured I < 1.05 \* PORTn\_POLICE\_2P</li>
- Power is removed if Measured V \* Measured I > 1.25 \* PORTn\_POLICE\_2P
- Power may be maintained or removed if 1.05 \* PORTn POLICE 2P > Measured V \* Measured I > \* 1.25 PORTn POLICE 2P

#### For Class 4

- · Measurement Error is 5% max
- Class 4 PORTn\_POLICE 2P = 30W
- Power is maintained if Measured V \* Measured I < 1.10 \* PORTn POLICE 2P</li>
- Power is removed if Measured V \* Measured I > 1.20 \* PORTn POLICE 2P
- Power may be maintained or removed if 1.10 \* PORTn POLICE 2P > Measured V \* Measured I > 1.20 \* PORTn POLICE 2P

At the completion of Class Power On, the Assigned Class is determined based on the values in PORTnm\_POWER\_ALLOCATION and PORTn\_REQUESTED\_CLASS. PORTn\_ASSIGNED\_CLASS is converted into a minimum power threshold and stored in the applicable PORTn\_POLICE\_2P register.

After the Si3473/2 sets the police registers based on assigned class, a host can make adjustments to them once it has more accurately determined the actual usage of the PD either through long term checking of the pertinent PORTn\_VOLTAGE and PORTn\_CURRENT or through LLDP messaging.

PCUT faults are reported in PORTn PCUT FAULT 2P.

#### 2.8.4 Current Limit and Voltage Foldback

The figure below illustrates how current limiting works. Consider an initial condition where a FET is ON, with the PD appearing as a 167  $\Omega$  load. Suddenly, the load changes from 167  $\Omega$  to 62.5  $\Omega$ . The initial point condition is below the Green Line, which represents an ILIM Threshold vs VDRAIN template that the Si3473/72 is maintaining. Differences between the actual current and this threshold determine whether current flows into the gate of the FET or out of the gate. The magnitude of the gate current is proportional to the difference between the actual current through the sense resistor, relative to its set point.

When the load initially changes from 167  $\Omega$  to 62.5  $\Omega$ , the sensed current is higher than the ILIM Threshold at that VDRAIN voltage, and as such, current is removed from the gate, leading to the FET shutting down slightly, and an increase in VDRAIN.

Eventually, VDRAIN will increase enough that it meets the 62.5  $\Omega$  load line, where the gate drive becomes zero since the sensed current is at the green line. In this example, when the PD Load decreases from 167  $\Omega$  to 62.5  $\Omega$ , the port voltage folds back from 50 V to around 22 V.

Note that the example does not show the intermediate steps, only the starting points and end points. This is a feedback circuit and this illustration cannot show that the speed by which VDRAIN increases is in proportion to the magnitude difference between the sensed current and the ILIM curve.

Some things to note include:

- 1. The FET power in the current limited state is 28 V \* 350 mA = 9.8 W. To prevent damage, the Si3473/72 limits the time the FET spends in this condition.
- 2. The DRAIN Voltage is high. The Si3473/72 can measure this, and by taking the ILIM Template into account, the power level being experienced by the FET can be approximated.

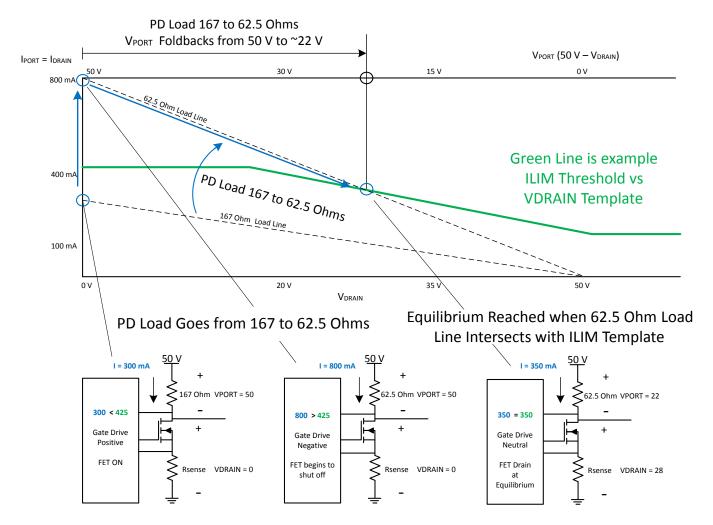

Figure 2.6. Current Limiting and Voltage Feedback

#### 2.8.5 Autoclass

When Automatic Autoclass is enabled, the Si3473/72 monitors the first long class finger of Class Power On to detect if the PD is Autoclass-capable. If the Si3473/72 detects the PD acknowledgement, the PORTn\_AUTOCLASS\_DETECTED bit is set on that port. The Si3473/72 then takes voltage and current measurements when the pair sets reach the POWER GOOD state. The PORTn\_POLICE\_2P registers will be initialized based on measured power plus margin. The margin depends on the measured power:

- 0 W to 25.9 W: margin = 1 W
- 26 W to 36.9 W: margin = 2 W
- 37 W to 44.9 W: margin = 3 W
- 45 W to 51.9 W: margin = 4 W

If PORTn\_AUTO\_AUTOCLASS is set, the corresponding PORTn\_POLICE\_2P register is updated using the information in PORTn\_AUTOCLASS\_POWER, plus some power margin. A host may also initiate a Manual Autoclass by setting PORTn\_MANUAL\_AUTOCLASS in the AUTOCLASS\_CONTROL register. The manual Autoclass feature is typically used in conjunction with the LLDP-initiated Autoclass procedure.

A host is expected to initiate a Manual Autoclass when the PD is drawing its maximum power. The Si3473/72 stores the computed Autoclass power results in PORTn\_AUTOCLASS\_POWER. Once the results are written into PORTn\_AUTOCLASS\_POWER fields, the Si3473/72 clears the PORTn\_MANUAL\_AUTOCLASS bits. When both PORTn\_MANUAL\_AUTOCLASS bits are cleared, a host can use this as an indication that information is ready. A host may then overwrite the results of the police register based on the power information supplied by the PORTn\_AUTOCLASS\_POWER field.

#### 2.9 Event Handling

As an I<sup>2</sup>C primary controller, a host can initiate communication with the Si3473/72 at any time. As events associated with PSE operations can happen at any time, the Si3473/72 signals a host by asserting the INTb pin and then waits for a host to respond.

A host may be busy when an event occurs and unable to service the interrupt until after the conditions that caused the event have passed. The Si3473/72 interface uses clear-on-read (COR) registers that retain event information until a host can read it.

When the Si3473/72 wants attention from a host, it does so by setting an event in the event register map. The event bits map into a corresponding bit in the INTERRUPT register. If the corresponding INTERRUPT\_MASK bit is also set, then the INTb pin will be asserted.

In a high port count system that has multiple Si3473 PSE controllers, all of the controllers' INTb open drain output pins must be tied together. Even with a single Si3473 PSE controller, there is just one INTb output for two quads that have separate I<sup>2</sup>C addresses. Therefore, when the INTb pin is asserted, a host must read the INTERRUPT register from every I<sup>2</sup>C address in the PSE system.

For speedy servicing of interrupts in a high port count system controlled by a single host, the INTERRUPT register is read first by a host. Each bit in the INTERRUPT register is mapped to another register where the details of the event are available to read. See Table 3.1 Si3473/72 Registers on page 27. The only way to clear the INTERRUPT register bit and associated INTb output is to have a host read these COR registers. For example, a host reads INTERRUPT and observes that the DISCONNECT bit is set. The color coding in the table below indicates that a host must read the DISCONNECT\_PCUT\_FAULT register to clear the DISCONNECT bit in the INTERRUPT register. In this case, a host would know to read DISCONNECT\_PCUT\_FAULT register as this is where the DISCONNECTION field is located.

When a host reads the appropriate COR register, the INTb pin is not guaranteed to negate since a new event may have occurred after the COR register was read to clear the event.

When a PORTn\_START\_FAULT event is reported, the corresponding PORTn\_POWER\_ON\_FAULT is updated with supplemental information about the fault. However, only the ILIM\_START\_FAULT register must be read to clear the START\_EVENT INTERRUPT bit.

In addition to reading a CoR register, PORTn\_CLASS\_DONE, PORTn\_DETECT\_DONE, PORTn\_DISCONNECTION, PORTn\_PCUT\_FAULT\_2P, PORTn\_ILIM\_FAULT, and PORTn\_START\_FAULT registers can also be cleared by:

- 1. Setting PORTn PORT MODE to SHUTDOWN
- 2. Setting PORTn PB POWER OFF in PB POWER ENABLE
- 3. Setting PORTn RESET PORT in PB RESET
- 4. An OSS EVENT in SUPPLY EVENT as a result of an emergency shutdown
- 5. Setting RESET QUAD
- Setting CLEAR\_ALL\_INTS

Table 2.2. Event Register Bits Associated with Interrupt Register

| Address  | Name                      | Access    | b7            | b6            | b5              | b4         | b3                                       | b2          | b2        | b0            |  |  |  |  |

#### 2.10 Autonomous Operation

If the total allocated PD load can be supplied by the system VPWR, one of the two Autonomous Modes may be used.

In auto mode, the Si3473/72 attempts to power on the port after every successful Detection/Classification. If a fault occurs at any time, the Si3473/72 will return to continuous Detection/Classification.

#### 2.10.1 AUTO Pin Autonomous Mode

To configure AUTO Pin Autonomous Mode, a voltage (other than VDD) must be applied to the AUTO pin input at time of Si3473/72 power up. The common way to achieve this is to use two resistors to create a voltage divider as shown inside the dashed box labeled "Opt. HW-Selected Auto Mode" in Figure 2.1 Si3473/72 Typical Application Circuit on page 6.

With a 15 k $\Omega$  resistor to VDD, the following resistors to GND can be used to configure the AUTO pin Autonomous Mode.

Table 2.3. AUTO Pin Autonomous Mode Configuration

|                   |                            | Aveilable                          |                                | Equivalent Registe | er Setting                                      |

| 5.1 kΩ            | Class 4                    | 30 W                               | Endspan                        | 0x33               | 0   |

The operation of AUTO Pin Autonomous Mode is identical to setting the following (in both Quads or the Si3473):

- 1. PORT REMAP = 0xE4 (no remapping)
- POWER\_ALLOCATION is described in the POWER\_ALLOCATION column of the above table.
- 3. INTERRUPT MASK = 0xE4 (faults enabled)
- 4. PORT MODE = 0xFF (all ports in AUTO Mode)
- 5. PORT\_DETECT\_CLASS\_ENABLE = 0xFF (all ports DETECT\_ENABLE = 1 and CLASS\_ENABLE = 1)
- 6. MIDSPAN is described in the MIDSPAN Bit column of the above table.

#### 2.10.2 I<sup>2</sup>C Autonomous Mode

A host can place a port in I<sup>2</sup>C Autonomous Mode at any time through the register interface by setting PORTn\_DETECT\_ENABLE, PORTn\_CLASS\_ENABLE, and PORTn\_MODE to AUTO.

Placing the Si3473/72 in I<sup>2</sup>C Autonomous Mode requires the following register settings to both Quads (only one quad for Si3472):

- 1. PORT\_REMAP = 0xE4 (no remapping)
- 2. POWER ALLOCATION = system-dependent
- 3. INTERRUPT MASK = 0xE4 (faults enabled)
- 4. PORT\_MODE = 0xFF (all ports in AUTO Mode)
- 5. PORT DETECT CLASS ENABLE = 0xFF (all ports DETECT ENABLE = 1 and CLASS ENABLE = 1)

POWER\_ALLOCATION refers to setting the PORTnm\_POWER\_ALLOCATION registers. Refer to 3.25 POWER\_ALLOCATION (0x29) for more details.

#### 2.11 OSS Operation

#### 2.11.1 Emergency Shutdown Feature

The Si3473/72 supports two kinds of Emergency Shutdown procedures, both of which are controlled by a host via the OSS pin. If MULTIBIT\_PRIORITY\_ENABLE = 0 (in MISC register), then 2.11.1.1 1-Bit Shutdown Priority describes the Emergency Shutdown behavior. Otherwise, if MULTIBIT\_PRIORITY\_ENABLE = 1 (in MISC register), then 2.11.1.2 Multi-Bit Shutdown Priority describes the Emergency Shutdown behavior.

The Emergency Shutdown Feature is useful in systems having multiple power supplies. When one of the power supplies fails, a host can use the Emergency Shutdown Feature to quickly turn off ports using the OSS pin. A host is expected to configure the priority level of each port so that the Si3473/72 knows which ports to power down in case of an emergency.

## 2.11.1.1 1-Bit Shutdown Priority

If MULTIBIT\_PRIORITY\_ENABLE = 0, then the PORTn\_PORT\_POWER\_PRIORITY bit in each port defines the port Shutdown priority. PORTn\_PORT\_POWER\_PRIORITY bits are found in the POWER\_PRIORITY\_PCUT\_DISABLE register. If PORTn\_PORT\_POWER\_PRIORITY is set, then the associated port is tagged as a "Low Priority" port. "High Priority" ports are unaffected by an OSS event.

A positive-going edge on the OSS pin will shut down powered lower priority ports. All powered lower priority ports will be shut down within 50 µs. Refer to the PORTn\_PB\_POWER\_OFF description for all event and register bits that are cleared. When a low priority port is shut down, the POWER\_GOOD\_CHANGE and POWER\_ENABLE\_CHANGE registers reflect the events and the POWER\_GOOD\_CHANGE bit and POWER\_ENABLE\_CHANGE bit in the INTERRUPT register are set. The OSS\_EVENT bit in the SUPPLY\_EVENT register is also set.

#### 2.11.1.2 Multi-Bit Shutdown Priority

If MULTIBIT PRIORITY ENABLE is set, then PORTn MULTIBIT PRIORITY defines the port priority and OSS action.

The figure below shows the operation and timing diagram of the OSS pin in multi-bit mode. Note that:

- · The priority of each port is defined by a 3-bit value in PORTn MULTIBIT PRIORITY for each port.
- · A port whose priority setting is "000" has the highest priority; priority setting of "111" has the lowest priority.
- When a host system wants certain priority ports to be shut down, it will transmit the "Shutdown code" over the OSS pin.
- Ports whose port priority settings are greater than or equal to the received Shutdown code will be turned off. For example, a received OSS Shutdown code of "101" will shut down ports whose port priority settings are "101", "110" or "111".

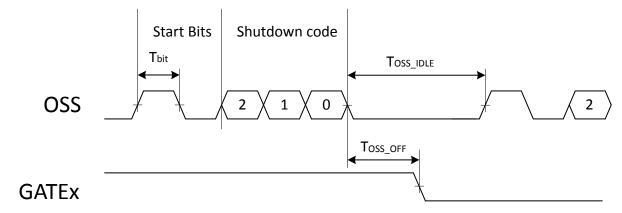

Figure 2.7. OSS Pin in Multi-Bit Mode

The following table describes the timing parameters associated with the OSS pin in multi-priority bit mode.

Table 2.4. Description of Timing Parameters Associated with the OSS Pin In Multi-Bit Mode

| Parameter             | Description   | Min | Тур | Max | Units |
|-----------------------|---|-----|-----|-----|-------|
| T <sub>bit</sub>      | Bit Period  | 24  | 25  | 26  | μs    |
| T <sub>OSS_OFF</sub>  | Maximum time between receiving Shut-<br>down code and shutting down of the<br>ports | _   | _   | 50  | μs    |
| T <sub>OSS_IDLE</sub> | Idle time between consecutive Shutdown code transmission in multi-bit mode          | 125 | _   | _   | μs    |

#### 2.12 I<sup>2</sup>C Interface

#### 2.12.1 I<sup>2</sup>C Protocol

Communicating with the Si3473/72 is accomplished through a 2-wire  $I^2C$  compatible serial interface. An  $I^2C$  transaction begins with a START condition and concludes with a STOP condition. The Si3473/72 registers are described in Table 3.1 Si3473/72 Registers on page 27. Note that the Register Map describes the operation of a quad (four ports). Each Si3473 has two quads. As such the Si3473 responds to two  $I^2C$  addresses, one for each quad. The Si3472 has only one quad and therefore responds only to the main  $I^2C$  addresses.

#### 2.12.1.1 Slave Address

The I<sup>2</sup>C Slave Addresses that the Si3473/72 responds to are dependent on the following:

- A1, A2, A3 and A4 pin strapping (the Si3472 does not have an A4 pin and is therefore limited to 3 bits of addresses.)
- Quad

As mentioned previously, each Si3473 responds to two I<sup>2</sup>C Addresses since there are two quads in each Si3473.

The 7-bit Slave Address is effectively constructed as this bit pattern:

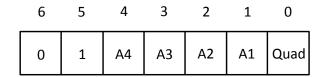

Figure 2.8. 7-bit I<sup>2</sup>C Address Bit Pattern

The following table outlines the I<sup>2</sup>C Addresses that the Si3473/72 will respond to, based on the A1, A2, A3 and A4 pin strapping as well as which quad a host intends to access:

Table 2.5. Si3473/72 I<sup>2</sup>C Slave Address

| A4 <sup>1</sup> | А3 | A2 | <b>A</b> 1 | Quad 0 l <sup>2</sup> C<br>Address | Quad 1 I <sup>2</sup> C<br>Address (Si3473 only) |
|-----------------|----|----|------------|------------------------------------|--|
| 0               | 0  | 0  | 0          | 0x20                               | 0x21   |
| 0               | 0  | 0  | 1          | 0x22                               | 0x23   |
| 0               | 0  | 1  | 0          | 0x24                               | 0x25   |
| 0               | 0  | 1  | 1          | 0x26                               | 0x27   |
| 0               | 1  | 0  | 0          | 0x28                               | 0x29   |
| 0               | 1  | 0  | 1          | 0x2A                               | 0x2B   |
| 0               | 1  | 1  | 0          | 0x2C                               | 0x2D   |
| 0               | 1  | 1  | 1          | 0x2E                               | 0x2F   |
| 1               | 0  | 0  | 0          | 0x30                               | 0x31   |
| 1               | 0  | 0  | 1          | 0x32                               | 0x33   |
| 1               | 0  | 1  | 0          | 0x34                               | 0x35   |
| 1               | 0  | 1  | 1          | 0x36                               | 0x37   |
| 1               | 1  | 0  | 0          | 0x38                               | 0x39   |
| 1               | 1  | 0  | 1          | 0x3A                               | 0x3B   |
| 1               | 1  | 1  | 0          | 0x3C                               | 0x3D   |
| 1               | 1  | 1  | 1          | 0x3E                               | 0x3F   |

## Note:

1. A4 is effectively tied low on the Si3472.

## 2.12.1.2 Available I<sup>2</sup>C Transfer Types

All Si3473/72 registers are accessible using 8-bit Writes and 8-bit Reads.

In addition, 16-bit Port Parametric Measurement Registers must be read using a 16-bit Read address in order to guarantee that the MSB and LSB of the Voltage or Current measurement belong to each other. The 16-bit Read Register Address should be pointing to the least significant byte so that the burst-read will end with the MSB. The following figures illustrate the bits of the possible read and write operations.

## Legend

Sr Repeated Start Bit

P Stop Bit

A1...A4 Si3473/72 A1, A2, A3, A4 pin strapping

Q Si3473/72 Quad Selection (virtual 'A0')

R0...R7 Si3473/72 Register Address

D0...D7 Si3473/72 Register Data LSB

D8...D15 Si3473/72 Register Data MSB

Wr Write Bit
Rd Read Bit
A ACK bit

N No ACK bit

#### 2.13 Updating the Si3473/72 FLASH Using the Bootloader

The Si3473/72 firmware can be updated through the  $I^2C$  interface. The Si3473/72 FLASH memory is separated into the "Application" space and the "Bootloader" space. To ensure that the flash loading process never results in a non-communicating device, only the "Application" part of the firmware is capable of being updated; the Bootloader cannot update itself.

The registers FLASH\_CONTROL, FLASH\_ERASE\_KEY\_FLASH\_ADDRESS\_LSB, FLASH\_ADDRESS\_MSB, and FLASH\_DATA work together to implement the flash update process. The figure below illustrates the flash loading sequence.

A good practice for a host is to check the FIRMWARE\_REVISION to see if the FLASH update is necessary.

Once it has been determined that the device needs to be updated, start the flash update procedure with a device reset. The following figure explains the steps to flash the Si3473 and Si3472 devices.

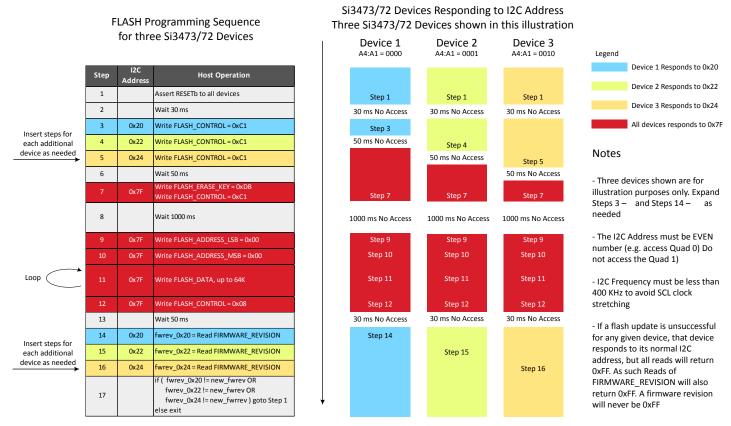

Figure 2.12. Si3473/72 Flash Updating Sequence

The chip reset is illustrated in Step 1. After a RESET, wait 30 ms before starting communication because the device is booting. After the 30 ms wait period, the devices should be able to communicate through I<sup>2</sup>C, via the standard I<sup>2</sup>C Address based on the A1-A4 pin strapping.

In Step 3, Step 4 and Step 5, a host should individually command each device to enter its bootload state (FLASH\_CONTROL=0xC1). Note that a host must access each device individually through its normal I<sup>2</sup>C address. It is also important to note that a host must access only the Quad 0. Quad 0 of each device has an even I<sup>2</sup>C Address. After each device receives its FLASH\_CONTROL=0xC1 command, each device will reset into a special state where the device responds to the Global Address 0x7F.

Once a host has sent FLASH\_CONTROL=0xC1 through each individual  $I^2C$  Address, it should delay an additional 50 ms to allow the last device to be ready. This 50 ms delay is illustrated in Step 6. After this final delay, a host can proceed to Step 7, where a host sends another FLASH\_CONTROL=0xC1 command. However, this time, a host will use the Global Address 0x7F. In addition, FLASH\_ERASE\_KEY=0xDB is sent prior to the FLASH\_CONTROL=0xC1. This is illustrated in Step 7.

Upon receiving the FLASH\_ERASE\_KEY=0xDB and FLASH\_CONTROL=0xC1 in Step 7, each device will begin to erase the Application FLASH area. This process takes 1000 ms, and a host should not initiate communication during this time. This is illustrated in Step 8.

After the 1000 ms delay, a host should then write 0x00 to both the FLASH\_ADDRESS\_LSB and FLASH\_ADDRESS\_MSB registers to indicate the starting address. This is illustrated in Steps 9 and 10.

A host then sends the contents of the new firmware by writing to the FLASH\_DATA continuously. For accessing FLASH\_DATA, in addition to the standard I<sup>2</sup>C Register Byte Write method, the Si3473/72 also supports burst writes in order to increase the throughput of the flash update. The burst write is illustrated in the figure below:

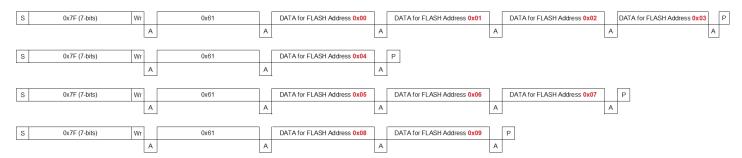

Figure 2.13. Burst Write

To complete the flash update, a host then writes FLASH\_CONTROL=0x08 using the Global Address 0x7F. This is illustrated in Step 12. When each Si3473/72 device receives the FLASH\_CONTROL=0x08 command, it completes the flash update process and computes the Flash CRC. The Si3473/72 will then reboot and the FIRMWARE\_REVISION register can be checked using the normal, non-global addresses to make sure the firmware revision has been updated.

The bootloader firmware is separate from the application firmware and unaware of the expected FIRMWARE\_REVISION value. A host should manually check the proper firmware revision in the FIRMWARE\_REVISION register using the normal, non-global, I<sup>2</sup>C address.

In the event something goes wrong with the flash update, a host will receive 0xFF in response to a FIRMWARE\_REVISION read. A host will receive 0xFF for all registers if the firmware update procedure fails. If this happens, a host should simply restart the entire process from the very beginning.

## 3. Register Map

Table 3.1. Si3473/72 Registers

| Addr      | Name  | Access | Reset State            | 7   | 6            | 5                                       | 4             | 3      | 2               | 1                 | 0          |  |

|     |                               | Masks the DETECT_DONE in the INTERRUPT register     |
| 3   | DETECT_DONE_MASK              | 0 = DETECT_DONE cannot assert INTb                  |
|     |                               | 1 = DETECT_DONE can assert INTb                     |
|     |                               | Masks DISCONNECT in the INTERRUPT register          |
| 2   | DISCONNECT_MASK               | 0 = DISCONNECT cannot assert INTb                   |
|     |                               | 1 = DISCONNECT can assert INTb                      |
|     |                               | Masks POWER_GOOD_CHANGE in the INTERRUPT register   |
| 1   | POW-<br>ER_GOOD_CHANGE_MASK   | 0 = POWER_GOOD_CHANGE cannot assert INTb            |
|     |                               | 1 = POWER_GOOD_CHANGE can assert INTb               |
|     |                               | Masks POWER_ENABLE_CHANGE in the INTERRUPT register |
| 0   | POWER_ENA-<br>BLE_CHANGE_MASK | 0 = POWER_ENABLE_CHANGE cannot assert INTb          |
|     |                               | 1 = POWER_ENABLE_CHANGE can assert INTb             |

The INTERRUPT and INTERRUPT\_MASK registers work together to influence the INTb pin logic for any given Quad. The Si3473 has two Quads, and either Quad can assert the INTb pin independently.

Quad\_0\_INT = INTERRUPT\_O0 AND INTERRUPT\_MASK\_O0

Quad\_1\_INT = INTERRUPTQ1 AND INTERRUPT\_MASKQ1

INTb = NOT (Quad 0 INT OR Quad 1 INT)

For the Si3472, which has a single quad:

INTb = NOT ( Quad\_0\_INT )

Bits in the in the INTERRUPT register can be cleared by a number of actions:

- 1. Reading CoR EVENT registers
- 2. Setting PORTn PORT MODE to SHUTDOWN
- 3. Setting PORTn PB POWER OFF
- 4. Setting RESET QUAD
- 5. Setting PORTn RESET PORT
- 6. Set CLEAR ALL INTS
- 7. OSS Emergency Shutdown

It is also possible to negate the INTb pin directly using the CLEAR\_INT\_PIN. This method does not clear any event register bits, nor does it clear bits in the INTERRUPT register.

## 3.3 POWER Event and POWER Event CoR (Address 0x02, 0x03)

|             |                   |       |                  | Register Addres        | s: 0x02          | Register Addres            | s: 0x03 |
|-------------|-------------------|-------|------------------|------------------------|------------------|----------------------------|---------|
| POWER_EVENT |                   |       |                  | Access Type: Read Only |                  | Access Type: Clear on Read |         |
|             |                   |       | Reset: 0000 0000 |                        | Reset: 0000 0000 |                            |         |
| 7           | 6                 | 5     | 4                | 3                      | 2                | 1                          | 0       |
|             | POWER_GOOD_CHANGE |       |                  | POWER_ENABLE_CHANGE    |                  |                            |         |
| PORT4       | PORT3             | PORT2 | PORT1            | PORT4                  | PORT3            | PORT2                      | PORT1   |

| Bit | Name                           | Description   |
|-----|--------------------------------|---|
| 7   | PORT4_POW-<br>ER_GOOD_CHANGE   | PORTn POWER GOOD CHANGE                             |
| 6   | PORT3_POW-<br>ER_GOOD_CHANGE   | PORTn_POWER_GOOD in POWER_STATUS register changed   |
| 5   | PORT2_POW-<br>ER_GOOD_CHANGE   | 0 = PORTn_POWER_GOOD did not change                 |
| 4   | PORT1_POW-<br>ER_GOOD_CHANGE   | 1 = PORTn_POWER_GOOD changed                        |
| 3   | PORT4_POWER_ENA-<br>BLE_CHANGE | PORTn POWER ENABLE CHANGE                           |
| 2   | PORT3_POWER_ENA-<br>BLE_CHANGE | PORTn_POWER_ENABLE in POWER_STATUS register changed |
| 1   | PORT2_POWER_ENA-<br>BLE_CHANGE | 0 = PORTn_POWER_ENABLE did not change               |
| 0   | PORT1_POWER_ENA-<br>BLE_CHANGE | 1 = PORTn_POWER_ENABLE changed                      |

For a description of what POWER\_GOOD and POWER\_ENABLE means, refer to the description in the POWER\_STATUS register.

PORTn\_POWER\_GOOD\_CHANGE indicates that PORTn\_POWER\_GOOD in the POWER\_STATUS register has changed. Any set PORTn POWER GOOD CHANGE bit will also set the POWER GOOD CHANGE bit in the INTERRUPT register.

PORTn\_POWER\_ENABLE\_CHANGE indicates that PORTn\_POWER\_ENABLE in the POWER\_STATUS register has changed. Any set PORTn\_POWER\_ENABLE\_CHANGE bit will also set the POWER\_ENABLE\_CHANGE bit in the INTERRUPT register.

## 3.4 CLASS\_DETECT\_EVENT and CLASS\_DETECT\_EVENT CoR (0x04, 0x05)

|       |            |       |       | Register Addres        | s: 0x04 | Register Address: 0x05     |       |

|       |            |       |       | Access Type: Read Only |         | Access Type: Clear on Read |       |
|       |            |       |       | Reset: 0000 0000       |         | Reset: 0000 0000           |       |
| 7     | 6          | 5     | 4     | 3                      | 2       | 1                          | 0     |
|       | CLASS_DONE |       |       | DETECT_DONE            |         |                            |       |
| PORT4 | PORT3      | PORT2 | PORT1 | PORT4                  | PORT3   | PORT2                      | PORT1 |

| Bit | Name              | Description  |  |  |  |
|-----|-------------------|--|--|--|--|
| 7   | PORT4_CLASS_DONE  | PORTn_CLASS_DONE   |  |  |  |
| 6   | PORT3_CLASS_DONE  | PORTn_CLASS_STATUS in PORTn_CLASS_DETECT_STATUS register was up-     |  |  |  |
| 5   | PORT2_CLASS_DONE  | dated or changed (see also CLASS_CHANGE in 3.16 MISC (0x17)).        |  |  |  |
| 4   | PORT1 CLASS DONE  | 0 = PORTn_CLASS_STATUS was not updated nor changed.                  |  |  |  |
| 4   | FORTI_CLASS_DONE  | 1 = PORTn_CLASS_STATUS was updated or changed.                       |  |  |  |
| 3   | PORT4_DETECT_DONE | PORTn_DETECT_DONE  |  |  |  |
| 2   | PORT3_DETECT_DONE | PORTN DETECTION STATUS in PORTN CLASS DETECT STATUS register         |  |  |  |
| 1   | PORT2_DETECT_DONE | was updated or changed (see also DETECT_CHANGE in 3.16 MISC (0x17)). |  |  |  |
| 0   | PORT1 DETECT DONE | 0 = PORTn_DETECTION_STATUS was not updated nor changed.              |  |  |  |
|     | FORTI_DETECT_DONE | 1 = PORTn_DETECTION_STATUS was updated or changed.                   |  |  |  |

PORTn\_DETECT\_DONE indicates whether the PORTn\_DETECTION\_STATUS in PORTn\_CLASS\_DETECT\_STATUS has valid results. Any set bits in the DETECT\_DONE field sets the DETECT\_DONE bit in the INTERRUPT register.

One common usability issue with enabling the DETECT\_DONE bit interrupt is that there tend to be many Detection events. One good way of reducing the number of interrupts is by also setting the DETECT\_CHANGE bit in the MISC register. When this bit is set, the PORTn\_DETECT\_DONE is only updated whenever there is a change in PORTn\_DETECTION\_STATUS, thereby reducing the number of interrupts to the system.

PORTn\_CLASS\_DONE indicates whether PORTn\_CLASS\_STATUS in PORTn\_CLASS\_DETECT\_STATUS register has valid results. The PORTn\_CLASS\_DETECT\_STATUS will always indicate RGOOD as Class Probe does not occur without RGOOD. Any set PORTn\_CLASS\_DONE bits also set the CLASS\_DONE bit in the INTERRUPT register.

# 3.5 DISCONNECT\_PCUT\_FAULT and DISCONNECT\_PCUT\_FAULT CoR (0x06, 0x07)

|                       |       |       |       | Register Addres        | s: 0x06 | Register Address: 0x07     |       |
|-----------------------|-------|-------|-------|------------------------|---------|----------------------------|-------|

| DISCONNECTION         |       |       |       | PCUT_FAULT_2P          |         |                            |       |
| PORT4                 | PORT3 | PORT2 | PORT1 | PORT4                  | PORT3   | PORT2                      | PORT1 |

| Bit | Name                | Description  |  |  |  |  |
|-----|---------------------|--|--|--|--|--|
| 7   | PORT4_DISCONNECTION | PORTn_DISCONNECTION  |  |  |  |  |
| 6   | PORT3_DISCONNECTION | A PORTh in POWER GOOD, did not detect sufficient current to meet MPS re-                                       |  |  |  |  |
| 5   | PORT2_DISCONNECTION | A PORTn in POWER_GOOD, did not detect sufficient current to meet MPS requirements, leading to a disconnection. |  |  |  |  |
| 4   | PORT1_DISCONNECTION | 0 = PORTn did not disconnect. 1 = PORTn disconnected.  |  |  |  |  |
| 3   | PORT4_PCUT_FAULT_2P | PORTn_PCUT_FAULT_2P  |  |  |  |  |
| 2   | PORT3_PCUT_FAULT_2P | PORTn in POWER GOOD state, was powered off because it exceeded the power                                       |  |  |  |  |
| 1   | PORT2_PCUT_FAULT_2P | threshold defined by the pertinent PORTn_POLICE_2P register.   |  |  |  |  |
| 0   | PORT1_PCUT_FAULT_2P | 0 = PORTn did not encounter a PCUT fault.  1 = PORTn encountered a PCUT fault.                                 |  |  |  |  |

PORTn\_DISCONNECTION indicates a powered port was formerly in a POWER\_GOOD state but is now unpowered because the PD drew too much current. Any set PORTn\_DISCONNECTION bits also set the DISCONNECT bit in the INTERRUPT register.

PORTn\_PCUT\_FAULT\_2P indicates a powered port, formerly in a POWER\_GOOD state, is now unpowered because the PD exceeded the power limits specified by the various POLICE registers. Any set PORTn\_PCUT\_FAULT\_2P bits will set the P\_I\_FAULT bit in the INTERRUPT register.

## 3.6 ILIM\_START\_FAULT and ILIM\_START\_FAULT CoR (0x08, 0x09)

|                  | ILIIM_FAULT |       |                  | START_FAULT            |                  |                            |         |
| PORT4            | PORT3       | PORT2 | PORT1            | PORT4                  | PORT3            | PORT2                      | PORT1   |

| Bit | Name              | Description  |  |  |  |
|-----|-------------------|--|--|--|--|
| 7   | PORT4_ILIM_FAULT  | PORTn_ILIM_FAULT   |  |  |  |
| 6   | PORT3_ILIM_FAULT  | PORTn previously in POWER GOOD state, encountered an overcurrent event, for            |  |  |  |
| 5   | PORT2_ILIM_FAULT  | longer than tLIM, leading to the port being powered down.                              |  |  |  |
| 4   | PORT1_ILIM_FAULT  | 0 = PORTn did not encounter an ILIM fault. 1 = PORTn encountered an ILIM fault.        |  |  |  |
| 3   | PORT4_START_FAULT | PORTn_START_FAULT  |  |  |  |
| 2   | PORT3_START_FAULT | PORTn was still powering up encountered an overcurrent condition, for longer than      |  |  |  |
| 1   | PORT2_START_FAULT | the t <sub>INRUSH</sub> . PORTn never achieved a POWER_GOOD status and is not powered. |  |  |  |
| 0   | PORT1_START_FAULT | 0 = PORTn did not encounter a start fault.  1 = PORTn encountered a start fault.       |  |  |  |

PORTn\_ILIM\_FAULT indicates that a powered port in POWER\_GOOD state is now unpowered because the port was in a current-limited state for longer than the t<sub>ILIM</sub> time limit. Any set PORTn\_ILIM\_FAULT bits will set the P\_I\_FAULT bit in the INTERRUPT register.

PORTn\_START\_FAULT indicates that a powering port did not reach POWER\_GOOD (POWER\_ENABLE is set but POWER\_GOOD is not set) because PORTn was in a current-limited state for longer than the t<sub>INRUSH</sub> time limit. Any set PORTn\_START\_FAULT bits will set the START\_FAULT bit in the INTERRUPT register.

# 3.7 SUPPLY\_EVENT and SUPPLY\_EVENT CoR (0x0A, 0x0B)

|              |                    |                    |                  | Register Addres        | s: 0x0A          | Register Addres            | s: 0x0B |

| 1111 | Class Mismatch <sup>3</sup>         | 1111 | MOSFET_FAULT            |

## Note:

- Class 4 Type 1 Limited is not emitted in Semi Auto Class Probe. It may occur during a Class Power On as a result of PB POWER\_ON
- 2. This status will only be reported if Class 5 Legacy power allocation is selected.
- The Si3473/72 automatically performs a Class Reset and repeats Classification.

#### Note:

- 1. Capacitive status is reported when the load capacitance is larger than 1.5  $\mu$ F (Cpd > 1.5  $\mu$ F).
- 2. The Si3473/72 is capable of detecting whether it is cross-connected to another PSE controller of a different type. In this case, the PSE to PSE Status is reported. Detection of another PSE is based on verifying the voltage level on the output (DRAINn pin) during Detection.

In SEMI\_AUTO mode, the Classification process is not initiated unless RGOOD is reported. When reading PORTn\_CLASS\_STATUS outside of an event handler servicing the PORTn\_CLASS\_DONE, the Classification status can be unknown, or it can be the last Classification status after the last RGOOD.

It is generally recommended to read PORTn\_CLASS\_STATUS only when PORTn\_CLASS\_DONE indicates that there is useful information available.

#### 3.10 PORT\_POWER\_STATUS Register (0x10)

|       |          |           |       | Register Addres        | s: 0x10 |       |       |
|-------|----------|-----------|-------|------------------------|---------|-------|-------|
|       | PORT_POW | ER_STATUS |       | Access Type: Read Only |         |       |       |
|       |          |           |       | Reset: 0000 0000       |         |       |       |
| 7     | 6        | 5         | 4     | 3                      | 2       | 1     | 0     |
|       | POWER    | R_GOOD    |       | POWER_ENABLE           |         |       |       |
| PORT4 | PORT3    | PORT2     | PORT1 | PORT4                  | PORT3   | PORT2 | PORT1 |

| Bit | Name               | Description   |
|-----|--------------------|---|
| 7   | PORT4_POWER_GOOD   | PORTn has passed through the initial inrush period and has successfully powered   |
| 6   | PORT3_POWER_GOOD   | up the port   |
| 5   | PORT2_POWER_GOOD   | 0 = OFF   |
| 4   | PORT1_POWER_GOOD   | 1 = PORTn is in POWER_GOOD state  PORTn is in POWER_GOOD state after the initial t <sub>INRUSH</sub> and that the PORTn  Drain is within 2 V of the Si3473/72 ground reference. |
| 3   | PORT4_POWER_ENABLE | PORTn_POWER_ENABLE correlates to PORTn FET ON / OFF Status.   |
| 2   | PORT3_POWER_ENABLE | 0 = FET is turned OFF.  |
| 1   | PORT2_POWER_ENABLE | 1 = FET is turned ON.   |
| 0   | PORT1_POWER_ENABLE | After a PORTn_PB_POWER_ON, the PORTn_POWER_ENABLE is set after the Detection and Class Power On.  |

The main difference between the POWER ENABLE and POWER GOOD concepts is rooted in time delays.

Assume for a moment that both PORTn\_POWER\_ENABLE and PORTn\_POWER\_GOOD are both OFF, as an initial condition of this illustration.

When a PORTn\_PB\_POWER\_ON is set, there is typically a delay from this pushbutton setting to when the Si3473/72 starts driving the GATE of the FET to turn it on. However, between PORTn\_PB\_POWER\_ON and the GATE drive, the Si3473/72 may need to complete servicing other ports before starting to service the PORTn\_PB\_POWER\_ON. Even if the Si3473/72 began servicing the PORTn\_PB\_POWER\_ON, the port will still need to go through Detection and Class Power On before turning on the FET.

The PORTn POWER ENABLE is declared when the Si3473/72 drives the FET.

At this point, PORTn\_POWER\_ENABLE is ON, but PORTn\_POWER\_GOOD is still OFF. This effectively defines an initial start-up period where the port is allowed to current-limit for a short t<sub>INRUSH</sub> duration in order to charge the PD capacitors. During this time, it is possible that the FET DRAIN would be folded-back to enforce this start-up current limit. Once the t<sub>INRUSH</sub> period is over, if the DRAIN voltage is less than 2 V, the POWER\_GOOD state is declared. Once in the POWER\_GOOD state, both PORTn\_POWER\_ENABLE and PORTn\_POWER\_GOOD are turned ON.

At this point, monitoring of ILIM, PCUT, and DISCONNECTION events begins. Throughout this document, the POWER\_GOOD state is sometimes used to distinguish between the initial  $t_{\text{INRUSH}}$  period and the long-term port monitoring of these events.

When a port is turned off, PORTn\_POWER\_ENABLE and PORTn\_POWER\_GOOD bits both change to OFF simultaneously.

POWER\_ENABLE\_CHANGE and POWER\_GOOD\_CHANGE are used to mark the transition time, as these transition times mark the status of the FET and the actions the Si3473/72 is performing to service the port.

## 3.11 PORT\_MODE (0x12)

|           |      |           |   | Register Addres           | s: 0x12 |           |   |
|-----------|------|-----------|---|---------------------------|---------|-----------|---|
| PORT_MODE |      |           |   | Access Type: Read / Write |         |           |   |
|           |      |           |   | Reset: 0000 0000          |         |           |   |
| 7         | 6    | 5         | 4 | 3                         | 2       | 1         | 0 |
| PORT_     | MODE | PORT_MODE |   | PORT_MODE                 |         | PORT_MODE |   |
|           | RT4  | PORT3     |   | PORT2                     |         | PORT1     |   |

| Bit | Name            | Description  |  |  |  |
|-----|-----------------|--|--|--|--|
| 7-6 | PORT4_PORT_MODE | PORTn_PORT_MODE  |  |  |  |
| 5-4 | PORT3_PORT_MODE | Sets the main port operating mode. SEMI_AUTO is used in managed power use                          |  |  |  |
| 3-2 | PORT2_PORT_MODE | case. AUTO mode is used in unmanaged power use case. MANUAL mode is used generally for debug only. |  |  |  |
|     |                 | 00 = Set PORTn to SHUTDOWN Mode.   |  |  |  |
|     |                 | 01 = Set PORTn to MANUAL Mode.   |  |  |  |
| 1-0 | PORT1_PORT_MODE | 10 = Set PORTn to SEMI_AUTO Mode.  |  |  |  |
|     |                 | 11 = Set PORTn to AUTO Mode.   |  |  |  |
|     |                 | See 3.13 DETECT_CLASS_ENABLE (0x14) and 3.18 PB_POWER_ENABLE (0x19).                               |  |  |  |

Setting PORTn\_PORT\_MODE to SHUTDOWN clears numerous port registers, and possibly the associated INTERRUPT bits. Refer to the description of PORTn\_PB\_POWER\_OFF in PB\_POWER\_ENABLE for a list.

A host can set PORTn\_PORT\_MODE, but it also can be set to SHUTDOWN when RESET\_QUAD is set.

After setting SEMI\_AUTO in PORTn\_PORT\_MODE, PORTn\_CLASS\_ENABLE, and PORTn\_DETECT\_ENABLE, DETECT\_ENABLE should also be set to begin continuous Detection and Class Probe. Refer to the DETECT\_CLASS\_ENABLE register for more details.

# 3.12 DISCONNECT\_ENABLE (0x13)

|   |          |           |   | Register Addres           | s: 0x13  |           |       |

|-------|------------------------|--------------------------|--|--|--|--|--|
| 7/3   | PORT4_CLASS_EN<br>ABLE | PORT4_DE-<br>TECT ENABLE | PORTn_CLASS_ENABLE / PORTn_DETECT_ENABLE   |  |  |  |  |
| 6/2   | PORT3_CLASS_EN<br>ABLE | PORT3_DE-<br>TECT_ENABLE | It is more useful to describe CLASS_ENABLE and DETECT_ENABLE together. CLASS_ENABLE is shown on the left; DETECT_ENABLE shown or the right.  |  |  |  |  |
| 5 / 1 | PORT2_CLASS_EN<br>ABLE | PORT2_DE-<br>TECT_ENABLE | If PORTn_MODE in SEMI_AUTO   |  |  |  |  |
|       |                        |                          | 00 = No Operation  |  |  |  |  |
|       |                        |                          | 01 = Continuous Detection  |  |  |  |  |
|       |                        |                          | 10 = Not supported   |  |  |  |  |
|       |                        |                          | 11 = Continuous Detection and Class Probe  |  |  |  |  |
|       |                        |                          | If PORTn_MODE in AUTO  |  |  |  |  |
|       |                        |                          | 00 = No Operation  |  |  |  |  |
|       |                        |                          | 01 = Not supported   |  |  |  |  |
| 4/0   | PORT1_CLASS_EN         | PORT1_DE-<br>TECT ENABLE | 10 = Not supported   |  |  |  |  |
|       | ABLE ABLE              | TECT_ENABLE              | 11 = Continuous Detection and Class Probe until a PD is detected. When a PD is detected, a Class Power On is initiated, followed by a turning on the port. In effect, it is as though the Si3473/72 received a PORTn_PB_POW-ER_ON. |  |  |  |  |
|       |                        |                          | If PORTn_MODE in MANUAL  |  |  |  |  |
|       |                        |                          | Use PB_DETECT_CLASS instead  |  |  |  |  |
|       |                        |                          | If PORTn_MODE in SHUTDOWN  |  |  |  |  |
|       |                        |                          | Set up PORTn_PORT_MODE first   |  |  |  |  |

PORTn\_CLASS\_ENABLE and PORTn\_DETECT\_ENABLE are cleared when the following occur:

- 1. PORTn PORT MODE is set to SHUTDOWN.
- 2. PORTn RESET PORT in PB RESET is set.
- 3. RESET\_QUAD is set.

The DETECT CLASS ENABLE register is intended for use only when PORT MODE is to SEMI AUTO or AUTO.

If PORTn\_PORT\_MODE is set to MANUAL, the corresponding bits in PB\_DETECT\_CLASS are set; refer to PB\_DETECT\_CLASS for an operational description.

If PORTn\_PORT\_MODE is set to SHUTDOWN, PORTn\_PORT\_MODE must be initialized first, as this is an invalid operation.

# 3.14 POWER\_PRIORITY\_PCUT\_DISABLE (0x15)

- PORTn\_REQUESTED\_CLASS
- PORTn AUTOCLASS POWER
- PORTn\_POLICE\_2P

If a host sets a PORTn\_PB\_POWER\_ON and PORTn\_PORT\_MODE is in SEMI\_AUTO, it is expected that PORTnm\_PORT\_ALLOCA-TION, PORTn\_CLASS\_ENABLE, and PORTn\_DETECT\_ENABLE are already initialized.

Detection and Class Probes that have already started are allowed to complete first. A new Detection and Classification are performed before the FET is finally turned on. If any faults occur prior to FET turn on, they are reported as PORTn POWER ON FAULT events.

Once the FET is turned on, PORTn\_POWER\_ENABLE is set. There is a short Inrush Period to allow the PD to charge its capacitors. After the Inrush Period, if the PORTn DRAIN voltage does not settle to under 2 V, the port is disconnected and a PORTn START FAULT is issued.

On the other hand, if the DRAIN voltage is under 2V, PORTn\_POWER\_GOOD is issued and the port reaches the POWER\_GOOD state.

PORTn\_POLICE\_2P is initialized automatically based on PORTn\_ASSIGNED\_CLASS. These registers are used later to check if the PD is exceeding its power budget. If the PD exceeds the negotiated power thresholds, PORTn\_PCUT\_FAULT\_2P events will occur.

If PORTn\_AUTO\_AUTOCLASS is set and if the PD is Autoclass-capable, PORTn\_POLICE\_2P is updated based on PORTn\_AUTO-CLASS\_POWER. At any time after the Si3473/72 updates the PORTn\_POLICE\_2P registers, a host can choose to manage power by overwriting these police registers. A host can compute actual PD power by monitoring PORTn\_CURRENT and PORTn\_VOLTAGE and may choose to increase or decrease port power as part of its power management scheme.

If a host chooses to decrease police registers, it may choose to also set the PORTn\_DISABLE\_PCUT so that it can be informed if a PD exceeds the police register thresholds without turning off power to the PD.

In addition, the Si3473/72 also monitors for disconnections (PORTn\_DISCONNECTION) and current limit events (PORTn\_ILIM\_FAULT).

Typically, it is expected that PORTn\_PB\_POWER\_ON is set in conjunction with PORTn\_CLASS\_ENABLE and PORTn\_DETECT\_ENABLE. However, there is a special use case in MANUAL mode that would allow Detection and Classification to be skipped. If a host sets PORTn\_PB\_POWER\_ON with PORTn\_PORT\_MODE in MANUAL mode, and if PORTn\_CLASS\_ENABLE = 0 and PORTn\_DETECT\_ENABLE = 0, then Detection and Classification are all skipped and the port is powered on immediately. Then PORTn\_POLICE\_2P and are initialized based on PORTnm\_POWER\_ALLOCATION instead of PORTn\_ASSIGNED\_CLASS.

# 3.19 PB\_RESET (0x1A)

| Register Address: 0x1A |                   |      |                   |                         |                  |       |       |  |  |
|------------------------|-------------------|------|-------------------|-------------------------|------------------|-------|-------|--|--|

| Reset: 0               |                   |      |                   |                         | reset: 0000 0000 |       |       |  |  |
| 7                      | 6                 | 5    | 4                 | 3 2 1 0                 |                  |       |       |  |  |
| CLEAR_ALL_I<br>NTS     | CLEAR_INT_P<br>IN |      | RESET_QUAD        | RESET_PORT              |                  |       |       |  |  |
| EIGHT PORTS            | NONE              |      | PORT1 to<br>PORT4 | PORT4                   | PORT3            | PORT2 | PORT1 |  |  |

| Bit | Name             | Description   |
|-----|------------------|---|
|     |                  | Clears the INTb pin by clearing all events on all Quads.  |
| 7   | CLEAR_ALL_INTS   | 0 = Do Nothing  |
|     |                  | 1 = Clear all events in all ports (all Quads) and negate INTb   |
|     |                  | Clears the INTb pin directly in hardware without affecting any event bits.  |
| 6   | CLEAR_INT_PIN    | 0 = Do Nothing  |
|     |                  | 1 = Clear INTb pin  |
|     | RESET_QUAD       | Registers in the current quad are initialized to Reset defaults. Registers in other quad are unaffected.  |
| 4   |                  | 0 = Do Nothing  |
|     |                  | 1 = Reset registers in the Quad to reset defaults   |
| 3   | PORT4_RESET_PORT | PORTn_RESET_PORT  |
| 2   | PORT3_RESET_PORT | Initiates Port Reset  |
| 1   | PORT2_RESET_PORT | 0 = Do Nothing  |
| 0   | PORT1_RESET_PORT | 1 = Associated PORTn Registers are set to Reset default values  Refer to PORTn_PB_POWER_OFF for a list of register Reset default values. If the port is powered, it will be shut off. |

PORTn\_RESET\_PORT clears event registers similar to that of PORTn\_PB\_POWER\_OFF. If PORTn is powered, the port will be shut off. Refer to PORTn\_PB\_POWER\_OFF for the list of registers set to Reset default values. The main difference between PORTn\_RESET\_PORT and PORTn\_PB\_POWER\_OFF is that PORTn\_RESET\_PORT may be used regardless of the PORTn\_PORT\_MODE setting.

| 1-0 | SENSE_RESISTOR   | 10 = 150 Ω                              |
|     |                  | 11 = 100 Ω                              |

The purpose of MANUFACTURER\_ID in the VENDOR\_ID register is to allow a host to determine the manufacturer of the device in the presence of a multi-source design. This allows a host to make adjustments to its software based on chip behavior across different vendors. The DEVICE\_ID defines the product as an Si347x-Class device. Together, the MANUFACTURER\_ID and the DEVICE\_ID is an overall identifier of a class of chips that may be similar to competitive offerings.

The VENDOR\_ID is therefore static and does not change across revisions in either hardware or firmware.

The CHIP\_REVISION tracks Si3473/72 hardware revisions.

The FIRMWARE\_REVISION tracks firmware revisions. The upper nibble is a "major" revision, while the lower nibble is a "minor" revision.

**Table 3.2.** 

| Ordering Part Number | Chip Revision       | DEVICE_ID | SENSE_RESISTOR |
|----------------------|---------------------|-----------|----------------|
| Si3472A-A01-IM       | 0x31                | 0011      | 01             |

| 6   | PORT3_AUTOCLASS_DETECTED | Indicates that the PD is Autoclass-capable and that the Classification occurred on PORTn |
| 5   | PORT2_AUTOCLASS_DETECTED | 0 = PD not Autoclass-capable   |
| 4   | PORT1_AUTOCLASS_DETECTED | 1 = PD is Autoclass-capable  |
| 3   |                          |  |
| 2   |                          | Reserved   |
| 1   |                          | Neserveu   |
| 0   |                          |  |

## 3.22 PORT1\_POLICE\_2P to PORT4\_POLICE\_2P (0x1E - 0x21)

| Name            | Address | Access Type | Reset     | 7  | 6 | 5 | 4 | 3 | 2 | 1 | 0     |
|-----------------|---------|-------------|-----------|--|---|---|---|---|---|---|-------|
| PORT1_POLICE_2P | 0x1E    | R/W         | 1111 1111 | PORTn_POLICE_2P  |   |   |   |   |   |   |       |
| PORT2_POLICE_2P | 0x1F    | R/W         | 1111 1111 |  |   |   |   |   |   |   |       |
| PORT3_POLICE_2P | 0x20    | R/W         | 1111 1111 | Minimum 2P PCUT Threshold (Watts) = PORTn_POLICE_2I  * 0.5 W |   |   |   |   |   |   | CE_2P |
| PORT4_POLICE_2P | 0x21    | R/W         | 1111 1111 | 0.5 W  |   |   |   |   |   |   |       |

PORTn\_POLICE\_2P registers are initialized by the Si3473/72 as part of PORTn\_PB\_POWER\_ON. PORTnm\_POWER\_ALLOCATION, in conjunction with the PD Requested Class, will negotiate to an ASSIGNED\_CLASS. The PCUT thresholds are then set by the Si3473/72.

Any of these police registers can be adjusted based on the actual power used by the port. Once the port has achieved a POW-ER\_GOOD state, the police registers can be written and the Si3473/72 will then evaluate power thresholds as set by these police registers.

It is important to note that the power values represented in the police register interfaces are the MINIMUM threshold. The actual internal thresholds are increased by 5%.

PORTn POLICE 2P are set to Reset default values when:

- 1. Setting PORTn\_PORT\_MODE = SHUTDOWN
- 2. Setting PORTn\_PB\_POWER\_OFF
- 3. Setting PORTn RESET PORT
- 4. Setting RESET\_QUAD
- 5. OSS Event

#### 3.23 PORT\_REMAP (0x26)

|             |       |       |             | Register Address: 0x26    |  |     |  |  |  |
|-------------|-------|-------|-------------|---------------------------|--|-----|--|--|--|
|             | PORT_ | REMAP |             | Access Type: Read / Write |  |     |  |  |  |
|             |       |       |             | Reset: 11 10 01 00        |  |     |  |  |  |
| 7           | 6     | 5     | 4           | 3 2 1 0                   |  |     |  |  |  |
| REMAP REMAP |       |       | REMAP REMAP |                           |  | ИАР |  |  |  |
| PORT4 PORT3 |       |       | PORT2 PORT1 |                           |  |     |  |  |  |

| Bit | Name        | Description  |
|-----|-------------|--|
| 7-6 | PORT4_REMAP | PORTn_REMAP  |
| 5-4 | PORT3_REMAP | PORTn REMAP defines the physical pins used when referencing the logical con-                               |
| 3-2 | PORT2_REMAP | cept called "PORTn"  |
|     |             | 00 = Use physical pins GATE1, DRAIN1, SENSE1   |
|     |             | 01 = Use physical pins GATE2, DRAIN2, SENSE2   |
|     |             | 10 = Use physical pins GATE3, DRAIN3, SENSE3   |
| 1-0 | PORT1_REMAP | 11 = Use physical pins GATE4, DRAIN4, SENSE4   |
|     |             | PORTn_REMAP must use a single write to PORT_REMAP, immediately after reset.                                |
|     |             | For example, the concept called "PORT4", by default, uses DRAIN4. The PORT4_REMAP field is therefore '11'. |

The port remapping feature allows a host to rearrange the sequencing of the Si3473/72 ports so that it better aligns to the end product's port alignment. Be aware that a Physical Port must appear, and may only appear, in one Logical Port.

Figure 3.1 RJ45 Example Layouts on page 57 shows a graphic illustration of how to create a logical-to-physical mapping by first starting with a sketch of how the DRAIN pins might line up to the RJ45 jacks. If the same physical pin code is assigned to more than one PORTn\_REMAP field, the Si3473/72 rejects the setting. It is best to confirm if the Si3473/72 accepted the remap setting by reading back the PORT\_REMAP register.

The PORT\_REMAP register is one of two registers that must be written once immediately after reset. Even if the intention is to use the default PORT\_REMAP, PORT\_REMAP must be written with 0xE4. Without this, the Si3473/72 will not function. Once PORT\_REMAP is written, ONLY a hardware reset can be used to allow PORT\_REMAP to be written again.

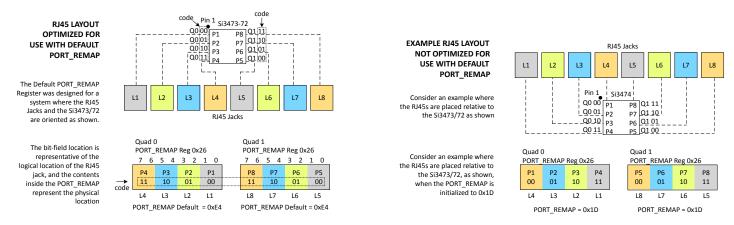

Figure 3.1. RJ45 Example Layouts

## 3.24 PORTn\_MULTIBIT\_PRIORITY (0x27, 0x28)

| Name                              | Address | Access Type | Reset     | 7                            | 6 | 5   | 4           | 3            | 2      | 1 | 0 |
|-----------------------------------|---------|-------------|-----------|------------------------------|---|---|-------------|--------------|--------|---|---|
| PORT1_PORT2_MUL<br>TIBIT_PRIORITY | 0x27    | R/W         | 0000 0000 | PORT2_MULTIBIT_PRIORI-<br>TY |   | PORT2_MULTIBIT_PRIORI- PORT1_MULTIBIT_PRIOR TY TY |             |              | RIORI- |   |   |
| PORT3_PORT4_MUL<br>TIBIT_PRIORITY | 0x28    | R/W         | 0000 0000 | PORT4_MULTIBIT_PRIORI-<br>TY |   | PORT  | 3_MULT<br>T | TBIT_PF<br>Y | RIORI- |   |   |

| Address | Bit | Name                    | Description   |
|---------|-----|-------------------------|---|
| 0x27    | 6-4 | PORT2_MULTIBIT_PRIORITY | PORTn_MULTIBIT_PRIORITY   |
| 0x27    | 2-0 | PORT1_MULTIBIT_PRIORITY | MULTIBIT_PRIORITY_ENABLE in MISC register must be set for   |
| 0x28    | 6-4 | PORT4_MULTIBIT_PRIORITY | PORTn_MULTIBIT_PRIORITY to take effect. PORTn_MULTIBIT_PRI-ORITY defines the OSS Code needed to turn PORTn off.   |
|         |     |                         | 111 = Receiving OSS Code 111 or lower shuts down PORTn (lowest priority).   |
|         |     |                         | 110 = Receiving OSS Code 110 or lower shuts down PORTn.   |
|         |     |                         | 101 = Receiving OSS Code 101 or lower shuts down PORTn.   |
|         |     |                         | 100 = Receiving OSS Code 100 or lower shuts down PORTn.   |
| 0x28    | 2-0 | PORT3_MULTIBIT_PRIORITY | 011 = Receiving OSS Code 011 or lower shuts down PORTn.   |
|         |     |                         | 010 = Receiving OSS Code 010 or lower shuts down PORTn.   |
|         |     |                         | 001 = Receiving OSS Code 001 or lower shuts down PORTn.   |
|         |     |                         | 000 = Receiving OSS Code 000 shuts down the port (highest priority).  |
|         |     |                         | Note that the higher the PORTn_MULTIBIT_PRIORITY setting, the more OSS Codes that can shut it down. As such, the lower the PORTn_MULTIBIT_PRIORITY is, the higher the priority of the port. |

If MULTIBIT\_PRIORITY\_ENABLE = 1, then PORT1\_PORT2\_MULTIBIT\_PRIORITY and PORT3\_PORT4\_MULTIBIT\_PRIORITY defines port power priority and governs OSS action. See 2.7.3 Class Power On for figures showing the operation and timing diagram of the OSS pin in multi-bit mode. The most significant bit is sent first. The priority for PORTn is defined with the three bits specified by PORTn\_MULTIBIT\_PRIORITY. A port whose priority setting is '000' has the highest priority; a priority setting of '111' has the lowest priority. When a host system wants certain priority ports shut down, it will transmit the "shutdown code" over the OSS pin. Ports whose port priority settings are greater than or equal to the received shutdown code will be turned off. For example, a received OSS shutdown code of '101' will shut down ports whose port priority settings are '101', '110' or '111'.

## 3.25 POWER\_ALLOCATION (0x29)

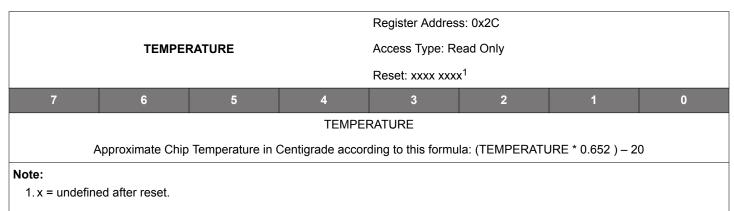

|                    |          |           |   | Register Addres           | s: 0x29 |      |   |  |
|--------------------|----------|-----------|---|---------------------------|---------|------|---|--|

## Note:

# 3.26 TEMPERATURE (0x2C)

<sup>1.</sup> The Class 5 Legacy setting allows the PSE to provide Class 5 power to a PD that presents a Classification current between 51 mA and 60 mA. This behavior is not defined in the IEEE 802.3bt specification.

#### 3.27 Parametric Measurement Registers (0x2E - 0x3F)

VPWR, PORTn VOLTAGE and PORTn CURRENT are each 14-bit registers straddled across two bytes.

A host must use an SMBus Burst Read of 16-bits, so with proper LSB / MSB pairing. Improper LSB / MSB pairing will result in a 256 code error if the measurement happens to be near a multiple of 256.

All of the 16-bit registers begin on even bytes. The SMBus Burst Read should therefore have an even Register Address. The first byte returned from the SMBus Read is the LSB, followed by the MSB.

VPWR can be read at any time.

PORTn\_VOLTAGE and PORTn\_CURRENT can be read as long as the port is in a POWER\_GOOD state. PORTn\_VOLTAGE and PORTn\_CURRENT are cleared when any of the following occur:

- 1. PORTn\_PORT\_MODE = SHUTDOWN
- 2. PORTn PB POWER OFF = 1
- 3. PORTn\_RESET\_PORT = 1
- 4. An OSS EVENT
- 5. RESET\_QUAD = 1

| Bit | Name              | Description                                     |
|-----|-------------------|---|
|     |                   | WATCHDOG_DISABLE                                |
| 4-1 | WATCHDOG DISABLE  | Enables the I <sup>2</sup> C Watchdog           |
| 7 1 | WATOTIBOO_BIOABLE | 1011 = Disable the I <sup>2</sup> C Watchdog    |
|     |                   | NOT 1011 = Enable the I <sup>2</sup> C Watchdog |
| 0   | WATCHDOG STATUS   | 0 = I <sup>2</sup> C Watchdog did not occur     |
|     | WATCHDOG_STATOS   | 1 = I <sup>2</sup> C Watchdog occurred          |

The Si3473/72 implements an  $I^2C$  transaction watchdog. The  $I^2C$  transaction watchdog is disabled by default and can be enabled by setting WATCHDOG\_DISABLE to any bit pattern except 0xB. When WATCHDOG\_DISABLE is set, the transaction watchdog will begin a 50 ms timer whenever an  $I^2C$  Start Bit is detected. If an  $I^2C$  Stop Bit is not detected within the 50 ms time period, the Si3473/72 restarts the  $I^2C$  subsystem and performs an action equivalent to RESET\_QUAD. This results in all ports being shut off.

Once the WATCHDOG\_STATUS bit is set, it remains set until a host sets it to 0.

The main benefit of enabling the  $I^2C$  WATCHDOG feature is to allow recovery if an  $I^2C$  miscommunication results in the Si3473/72 entering a "stuck" state where it continuously asserts the SDA pin.

Consider this condition as an example of how the Si3473/72 could end up asserting the SDA continuously:

Although an  $I^2C$  fault leads to the powering down of all ports, it places the Si3473/72 in a known state, ready for a host to reinitialize and start anew.

| PORT4 | PORT3     | PORT2     | PORT1 | PORT4 PORT3 PORT2 PORT1   |         |         |   |  |  |

| Bit | Name                        | Description   |
|-----|-----------------------------|---|
| 7   | PORT4_MANUAL_AUTO-<br>CLASS | PORTn_MANUAL_AUTOCLASS  |
| 6   | PORT3_MANUAL_AUTO-<br>CLASS | Initiates an Autoclass measurement.  0 = No Action  |
| 5   | PORT2_MANUAL_AUTO-<br>CLASS | 1 = Manually initiate an Autoclass power measurement.   |
| 4   | PORT1_MANUAL_AUTO-<br>CLASS | After being set, PORTn_MANUAL_AUTOCLASS will clear itself when the result in PORTn_AUTOCLASS_POWER is ready. It is recommended that a host make use of this auto-clearing behavior to determine that PORTn_AUTOCLASS_POWER is ready to be read. |
|     |                             | Once PORTn_AUTOCLASS_POWER is updated, a host may add some margin, then update the related PORTn_POLICE_2P register.  |
| 3   | PORT4_AUTO_AUTOCLASS        | PORTn_AUTO_AUTOCLASS  |
| 2   | PORT3_AUTO_AUTOCLASS        | PORTn AUTO AUTOCLASS Enable   |
| 1   | PORT2_AUTO_AUTOCLASS        | 0 = Disable AUTO Autoclass  |
|     |                             | 1 = Enables AUTO Autoclass  |
| 0   | PORT1_AUTO_AUTOCLASS        | PORTn_AUTO_AUTOCLASS must be initialized before initiating PORTn_PB_POWER_ON.   |
|     |                             | In the presence of an Autoclass-capable PD, the related PORTn_POLICE_2P register is updated based on some margin in addition to the measurement stored in PORTn_AUTOCLASS_POWER.  |

PORTn\_AUTO\_AUTOCLASS must be set prior to a PORTn\_PB\_POWER\_ON.

An Autoclass procedure is performed during Class Power On due to a PORTn\_PB\_POWER\_ON. If the Si3473/72 detects an Autoclass request from a PD, PORTn\_AUTOCLASS\_DETECTED is set.

Once the PORT has reached POWER\_GOOD, the PD is expected to draw its maximum power during the first few seconds after powering up. The Si3473/72 automatically measures the PD's power consumption and updates the police registers based on the measured power.

In the 802.3bt standard, it is possible to perform a manual Autoclass procedure between the PSE and PD through Data Link Layer messaging. A host can set the PORTn\_MANUAL\_AUTOCLASS when the PD is expected to be drawing full power as part of this Data Link Layer Autoclass protocol. Once PORTn\_MANUAL\_AUTOCLASS is set, the Si3473/72 performs a power measurement. Once the power measurement is ready, PORTn\_MANUAL\_AUTOCLASS is cleared as an indicator to a host that the PORTn\_AUTOCLASS\_POWER is ready.

If a manual autoclass measurement is made, the police registers are not updated, and it is a host's responsibility to set up the various police registers based on the PORTn AUTOCLASS POWER results.

| Junction Temperature                       | TJ                   |                             | -40 | _   | 125 | °C   |

## Note:

- 1. All specification voltages are referenced with respect to DGND. These specifications apply over the recommended operating voltage and temperature ranges of the device unless noted otherwise.
- 2. The Si3473/72 includes internal thermal shutdown above 125 °C.

#### **Table 4.2. Electrical Specifications**

These specifications apply over the recommended operating voltage and temperature ranges of the device specified in Table 4.1 Recommended Operating Conditions<sup>1</sup> on page 67 unless otherwise noted. Typical performance is for  $T_A = 25$  °C,  $V_{DD} = AGND + 3.3$  V, AGND and DGND = 0 V, and VPWR at 54 V.  $V_{PORTn}$ ,  $V_{CLASS}$ , and  $V_{MARK}$  voltages are referenced with respect to  $V_{DRAIN}$ . All other voltages are referenced with respect to GND.

## Note:

- 1. Positive values indicate currents flowing into the device. Negative currents indicate current flowing out of the device.
- 2. Current sense resistor,  $R_{SENSE}$ , is determined by part number to be either .255 or .200  $\Omega$  (see Top Marking section below).
- 3. An MPS signal is considered present on an alternative when the current on that alternative is above these thresholds.
- 4. See "AN1228: FET Selection Guide for Si347x PSE Families" for detailed information on FET selection.

Table 4.3. I<sup>2</sup>C Bus Timing Specifications<sup>1, 2, 3, 4</sup>

| Time from Hardware or Software Reset until Start of I <sup>2</sup> C Traffic |                  | Reset to start condition  | 5   | _   | _   | ms   |

#### Note:

- 1. All specification voltages are referenced with respect to AGND and DGND at ground.
- 2. Not production tested (guaranteed by design).
- 3. All timing references measured at  $V_{\text{IL}}$  and  $V_{\text{IH}}.$
- 4. SCL and SDA rise and fall times depend on bus pull-up resistance and bus capacitance.

#### Note:

- 1. All specification voltages are referenced with respect to DGND. These specifications apply over the recommended operating voltage and temperature ranges of the device unless noted otherwise.
- 2. SDA and INTb are open drain outputs. Tie each pin to VDD with a 1  $k\Omega$  resistor for normal operation
- 3. Note that VIL and VIH are shown as fractions of VDD. This is intended to allow the I<sup>2</sup>C interface to operate with CMOS voltage levels. These values will be higher than the standard TTL interface.

Table 4.5. Absolute Maximum Ratings<sup>1</sup>

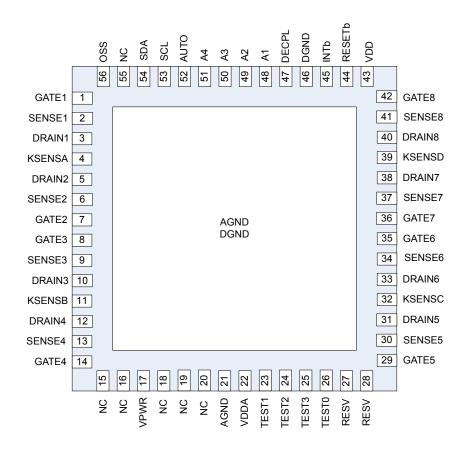

| Parameter                   | Range        | Unit |  |
|-----------------------------|--------------|------|--|
| Supply Voltage              |              |      |  |
| VDD                         | -0.3 to 4.0  | V    |  |
| VPWR                        | -0.3 to 80.0 | V    |  |
| DGND with Respect to AGND   | 0            | V    |  |
| Digital Signals             | ,            |      |  |
| All                         | -0.3 to 3.6  | V    |  |
| Analog Signals              | ,            |      |  |
| GATEn with Respect to AGND  | -0.3 to 20.0 | V    |  |
| SENSEn with Respect to AGND | -0.3 to 3.0  | V    |  |
| DRAINn with Respect to AGND | -3 to 80     | V    |  |
| Temperature                 | ,            |      |  |
| Junction                    | +150         | °C   |  |
| Storage                     | -55 to +150  | °C   |  |

#### Note:

1. Permanent device damage may occur if the maximum ratings are exceeded. Functional operation should be restricted to those conditions specified in the operational sections of this data sheet. Exposure to absolute maximum rating conditions for extended periods may adversely affect device reliability.

# 5. Pin Descriptions

## 5.1 Si3473 Pin Descriptions

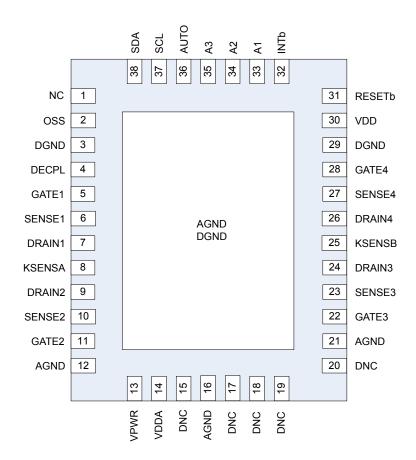

| Pin#              | Name              | Туре                                       | Description   |
|-------------------|-------------------|--|---|
| 44                | RESETb            | Digital input with 20 μA<br>pull-up to VDD | Active low device reset input. Generally, RESETb is used at initial power up. If RESETb is asserted (pulled to DGND), the MCU is disabled, all internal registers of the device are set to their default (power-up) state, and all output ports are shut off. Valid RESETb timing pulses must be >10 $\mu s$ . If RESETb is not used, RESETb should either be tied directly to VDD or through a 10 $k\Omega$ resistor to VDD. |
| 45                | INTb              | Digital output<br>(open drain)             | Interrupt output. This open drain output pin is asserted low (to DGND) if a fault condition occurs on any of the four ports. The state of INTb is updated for use by a host controller between valid $\rm I^2C$ commands. Refer to the "Interrupts" section of for more information. Tie INTb to VDD through a 10 k $\Omega$ resistor for normal operation.   |
| 53                | SCL               | Digital input                              | Serial clock input. This pin should be tied directly to the SCL (clock) connection on the I <sup>2</sup> C bus.   |
| 54                | SDA               | I <sup>2</sup> C input/output              | Bidirectional I <sup>2</sup> C input/output.  |
| 51, 50, 49,<br>48 | A4, A3, A2,<br>A1 | Digital input with 20 μA pull-up to VDD    | I <sup>2</sup> C address input. Used to set the base I <sup>2</sup> C address for the Si3473/72 in the following (binary) format: 010[A4][A3][A2][A1]b. The three MSB bits of the address are set to 010. Address values are latched after the deassertion of RESETB or when VDD ramps and VPWR exceeds the UVLO threshold voltage. Each address pin should be tied to either VDD or DGND.                                    |
| 46, ePAD          | DGND              | Digital ground                             | Ground connection for the 3.3 V digital supply (VDD). DGND and AGND are tied together inside the Si3473/72 package.   |

| Pin#     | Name   | Туре                    | Description  |  |
|----------|--------|-------------------------|--|--|
| 21, ePAD | AGND   | Analog ground           | Ground connection for the VPWR supply. DGND and AGND are tied together inside the Si3473/72 package  |  |
| 43       | VDD    | Digital power           | 3.3 V digital supply (relative to DGND). Bypass VDD with a 0.1 $\mu$ F capacitor to DGND as close as possible to the Si3473/72 power supply pins; tied to VDDA.  |  |
| 22       | VDDA   | Analog power            | 3.3 V supply to the analog components; tied to VDD at the PCB level.   |  |
| 17       | VPWR   | Analog power            | Positive PoE voltage (+44 to +56 V) relative to AGND.  |  |
| 41       | SENSE8 |                         |  |  |
| 37       | SENSE7 |                         | Current sense inputs for external MOSFETs. The SENSEn pin measures current through an external sense resistor tied between the AGND supply rail  |  |
| 34       | SENSE6 |                         | and the SENSEn input. If the I <sub>CUT</sub> limit (the overcurrent limit) is exceeded, the   |  |
| 30       | SENSE5 | Analog input            | current limit fault timer is incremented. If the voltage across the sense resistor subsequently triggers (the overcurrent limit), the voltage driven onto the GATEn  |  |
| 13       | SENSE4 | Analog input            | pin is modulated to provide constant current through the external MOSFET. Tie the SENSEn pin to AGND when the port is not used. To accommodate 802.3at   |  |
| 9        | SENSE3 |                         | (PoE Plus) classification, both the I <sub>CUT</sub> and Ilim values can be scaled. See  |  |
| 6        | SENSE2 |                         | 3.3 POWER Event and POWER Event CoR (Address 0x02, 0x03) for more information.   |  |
| 2        | SENSE1 |                         |  |  |
| 42       | GATE8  |                         |  |  |
| 36       | GATE7  |                         |  |  |
| 35       | GATE6  |                         | Gate drive outputs to external MOSFETs. Connect the GATEn outputs to the external MOSFET's gate node. A 50 µA pull-up current source is used to turn on the external MOSFET. When a current limit is detected, the GATEn voltage is reduced to maintain constant current through the external MOSFET. If the fault timer limit is reached, GATEn pulls down, shutting off the external MOSFET. GATEn will clamp to 11.5 V (typical) above AGND. If the port is unused, leave the GATEn pin disconnected or tie to AGND.  |  |
| 29       | GATE5  | Analog output           |  |  |
| 14       | GATE4  | Analog output           |  |  |
| 8        | GATE3  |                         |  |  |
| 7        | GATE2  |                         |  |  |
| 1        | GATE1  |                         |  |  |
| 40       | DRAIN8 |                         |  |  |
| 38       | DRAIN7 |                         |  |  |
| 33       | DRAIN6 |                         |  |  |
| 31       | DRAIN5 | Analog input with 25 μA | MOSFET drain output voltage sense. The Power Good bit is set on each port when the voltage between DRAINn and AGND drops below 2 V (typical). See  |  |
| 12       | DRAIN4 | pull-up to VPWR         | 3.3 POWER Event and POWER Event CoR (Address 0x02, 0x03) for further information. DRAINn pins should be left floating if the port is unused.   |  |
| 10       | DRAIN3 |                         | g a special section of the section o |  |

| 19, 18, 16,<br>15, 55, 20 | NC            | No Connect   | No connections or nets allowed. Leave floating.             |  |

# 5.2 Si3472 Pin Descriptions

| Pin#       | Name   | Туре                    | Description  |  |
|------------|--------|-------------------------|--|--|
| ePAD       | AGND   | Analog ground           | Ground connection for the 3.3 V digital supply (VDD). DGND and AGND are  |  |
| el AD      | DGND   | Digital ground          | tied together inside the Si3472 package.   |  |
| 21, 16, 12 | AGND   | Analog ground           | DGND and AGND are tied together inside the Si3472 package  |  |
| 27         | SENSE4 | Analog input            | Current sense inputs for external MOSFETs. The SENSEn pin measures cur-  |  |
| 23         | SENSE3 |                         | rent through an external sense resistor tied between the AGND supply rail and the SENSEn input. If the I <sub>CUT</sub> limit (the overcurrent limit) is exceeded, the   |  |
| 10         | SENSE2 |                         | current limit fault timer is incremented. If the voltage across the sense resistor subsequently triggers (the overcurrent limit), the voltage driven onto the GATEn  |  |
| 6          | SENSE1 |                         | pin is modulated to provide constant current through the external MOSFET. The the SENSEn pin to AGND when the port is not used. To accommodate 802.3a (PoE Plus) classification, both the I <sub>CUT</sub> and Ilim values can be scaled. See 3.23 PORT_REMAP (0x26) for more information. |  |
| 28         | GATE4  | Analog output           | Gate drive outputs to external MOSFETs. Connect the GATEn outputs to the   |  |
| 22         | GATE3  |                         | external MOSFET's gate node. A 50 µA pull-up current source is used to turn on the external MOSFET. When a current limit is detected, the GATEn voltage  |  |
| 11         | GATE2  |                         | is reduced to maintain constant current through the external MOSFET. If the fault timer limit is reached, GATEn pulls down, shutting off the external MOS-   |  |
| 5          | GATE1  |                         | FET. GATEn will clamp to 11.5 V (typical) above AGND. If the port is unused leave the GATEn pin disconnected or tie to AGND.   |  |
| 26         | DRAIN4 | Analog input with 25 µA | MOSFET drain output voltage sense. The Power Good bit is set on each port  |  |
| 24         | DRAIN3 | pull-up to VPWR         | when the voltage between DRAINn and AGND drops below 2 V (typical). See 3.3 POWER Event and POWER Event CoR (Address 0x02, 0x03) for further   |  |
| 9          | DRAIN2 |                         | information. DRAINn pins should be left floating if the port is unused.  |  |
| 7          | DRAIN1 |                         |  |  |

| Pin#                  | Name       | Туре                                       | Description  |  |
|-----------------------|------------|--|--|--|
| 38                    | SDA        | I <sup>2</sup> C input/output              | Bidirectional I <sup>2</sup> C input/output.   |  |
| 37                    | SCL        | Digital input                              | Serial clock input. This pin should be tied directly to the SCL (clock) connection on the I2C bus.   |  |
| 35, 34, 33            | A1, A2, A3 | Digital input with 20 μA<br>pull-up to VDD | I2C address input. Used to set the base I2C address for the Si3472 in the following (binary) format: 0100[A3][A2][A1]b. The three MSB bits of the address are set to 010. Address values are latched after the deassertion of RESETB or when VDD ramps and VPWR exceeds the UVLO threshold voltage. Each address pin should be tied to either VDD or DGND. |  |
| 29,3                  | DGND       | Digital ground                             | Ground connection for the 3.3 V digital supply (VDD). DGND and AGND are tied together inside the Si3472 package.   |  |
| 13                    | VPWR       | Analog power                               | Positive PoE voltage (+44 to +56 V) relative to AGND.  |  |
| 14                    | VDDA       | Analog power                               | 3.3 V supply to the analog components; tied to VDD at the PCB level.   |  |
| 30                    | VDD        | Digital Power                              | 3.3 V supply to the digital side; tied to VDDA at the PCB level.   |  |
| 25                    | KSENSB     | Input                                      | Kelvin points for accurate measurement of voltage across the sense resistor for ports 3 and 4.   |  |
| 8                     | KSENSA     | Input                                      | Kelvin points for accurate measurement of voltage across the sense resistor for ports 1 and 2.   |  |
| 2                     | oss        | Over supply signal                         | A positive going edge on this pin shuts down ports that have been identified as low priority by setting Register 0x15. This pin has a 20 $\mu$ A pull-up.  |  |
| 36                    | AUTO       | Automode                                   | Enables Automode.  |  |
| 31                    | RESETb     | Digital input with 20 μA<br>pull-up to VDD | Active low device reset input. Generally, RESETb is used at initial power up. If RESETb is asserted (pulled to DGND), the MCU is disabled, all internal registers of the device are set to their default (power-up) state, and all output ports are shut off. Valid RESETb timing pulses must be >10 μs.   |  |
|                       |            |  | If RESETb is not used, RESETb should either be tied directly to VDD or through a 10 $k\Omega$ resistor to VDD.   |  |
| 4                     | DECPL      | Decoupling                                 | Place a 0.1 μF capacitor between DECPL and GND.  |  |
| 32                    | INTb       | Digital output<br>(open drain)             | Interrupt output. This open drain output pin is asserted low (to DGND) if a fault condition occurs on any of the four ports. The state of INTb is updated for use by a host controller between valid $I^2C$ commands. Refer to the "Interrupts" section of for more information. Tie INTb to VDD through a 10 $k\Omega$ resistor for normal operation.     |  |
| 19, 18, 17,<br>15, 20 | DNC        | No Connect                                 | No connections or nets allowed. Leave floating.  |  |
| 1                     | NC         | No Connect                                 | No Connection. It is permitted to connect this pin to the neighboring pin SDA.   |  |

# 6. Package Outline

# 6.1 Package Outline: 56-Pin QFN

The figure below illustrates the package details for the Si3473. The table lists the values for the dimensions shown in the illustration. The Si3473 is packaged in an industry-standard, RoHS-compliant, 56-pin QFN package.

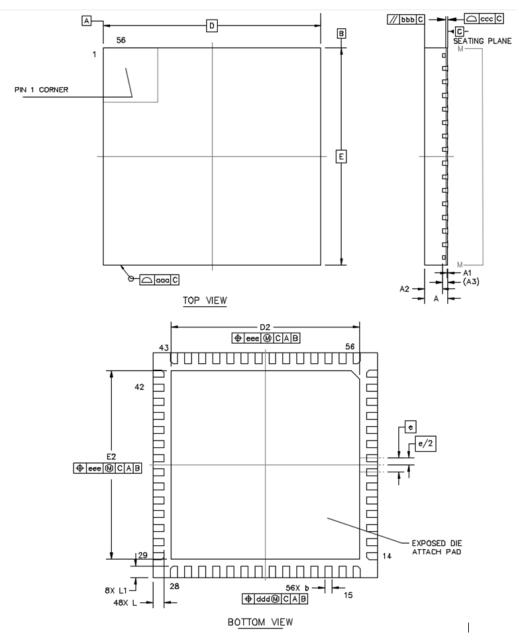

Figure 6.1. 56-Pin QFN Package

Table 6.1. Package Diagram Dimensions

| Dimension | Min      | Nom       | Max  |
|-----------|----------|-----------|------|
| A         | 0.80     | 0.85      | 0.90 |

## 7. Land Pattern

## 7.1 Si3473 Land Pattern

The following figure illustrates the land pattern details for the Si3473. The table lists the values for the dimensions shown in the illustration. The stencil design and notes are shared as recommendations only. A customer or user may find it necessary to use different parameters and fine-tune their SMT process as required for their application and tooling.

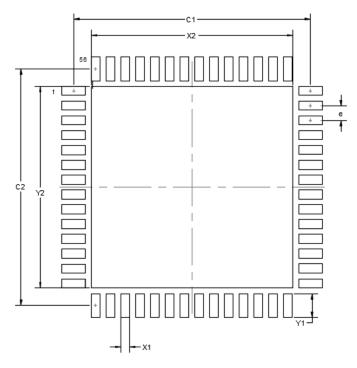

Figure 7.1. Si3473 Recommended Land Pattern

Table 7.1. PCB Land Pattern Dimensions

| Symbol | mm   |
|--------|------|
| C1     | 8.00 |
| C2     | 8.00 |
| е      | 0.50 |
| X1     | 0.30 |
| Y1     | 0.80 |
| X2     | 6.80 |
| Y2     | 6.80 |

## Notes:

#### General

- 1. All dimensions shown are at Maximum Material Condition (MMC). Least Material Condition (LMC) is calculated based on a Fabrication Allowance of 0.05 mm.
- 2. This Land Pattern Design is based on the IPC-7351 guidelines.

# Solder Mask Design

1. All metal pads are to be non-solder mask defined (NSMD). Clearance between the solder mask and the metal pad is to be 60 µm minimum, all the way around the pad.

## Stencil Design

- 1. A stainless steel, laser-cut and electro-polished stencil with trapezoidal walls should be used to assure good solder paste release.
- 2. The stencil thickness should be 0.125 mm (5 mils).
- 3. The ratio of stencil aperture to land pad size should be 1:1 for all perimeter pins.
- 4. A 3 x 3 array of 1.50 mm square openings on a 2.1 mm pitch should be used for the center ground pad.

## **Card Assembly**

- 1. A No-Clean, Type-3 solder paste is recommended.
- 2. The recommended card reflow profile is per the JEDEC/IPC J-STD-020 specification for Small Body Components.

## 7.2 Si3472 Land Pattern

The following figure illustrates the land pattern details for the Si3472. The table lists the values for the dimensions shown in the illustration. The stencil design and notes are shared as recommendations only. A customer or user may find it necessary to use different parameters and fine tune their SMT process as required for their application and tooling.

Information in this document is provided in connection with Skyworks Solutions, Inc. ("Skyworks") products or services. These materials, including the information contained herein, are provided by Skyworks as a service to its customers and may be used for informational purposes only by the customer. Skyworks assumes no responsibility for errors or omissions in these materials or the information contained herein. Skyworks may change its documentation, products, services, specifications or product descriptions at any time, without notice. Skyworks makes no commitment to update the materials or information and shall have no responsibility whatsoever for conflicts, incompatibilities, or other difficulties arising from any future changes.

No license, whether express, implied, by estoppel or otherwise, is granted to any intellectual property rights by this document. Skyworks assumes no liability for any materials, products or information provided hereunder, including the sale, distribution, reproduction or use of Skyworks products, information or materials, except as may be provided in Skyworks' Terms and Conditions of Sale.

THE MATERIALS, PRODUCTS AND INFORMATION ARE PROVIDED "AS IS" WITHOUT WARRANTY OF ANY KIND, WHETHER EXPRESS, IMPLIED, STATUTORY, OR OTHERWISE, INCLUDING FITNESS FOR A PARTICULAR PURPOSE OR USE, MERCHANTABILITY, PERFORMANCE, QUALITY OR NON-INFRINGEMENT OF ANY INTELLECTUAL PROPERTY RIGHT; ALL SUCH WARRANTIES ARE HEREBY EXPRESSLY DISCLAIMED. SKYWORKS DOES NOT WARRANT THE ACCURACY OR COMPLETENESS OF THE INFORMATION, TEXT, GRAPHICS OR OTHER ITEMS CONTAINED WITHIN THESE MATERIALS. SKYWORKS SHALL NOT BE LIABLE FOR ANY DAMAGES, INCLUDING BUT NOT LIMITED TO ANY SPECIAL, INDIRECT, INCIDENTAL, STATUTORY, OR CONSEQUENTIAL DAMAGES, INCLUDING WITHOUT LIMITATION, LOST REVENUES OR LOST PROFITS THAT MAY RESULT FROM THE USE OF THE MATERIALS OR INFORMATION, WHETHER OR NOT THE RECIPIENT OF MATERIALS HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

Skyworks products are not intended for use in medical, lifesaving or life-sustaining applications, or other equipment in which the failure of the Skyworks products could lead to personal injury, death, physical or environmental damage. Skyworks customers using or selling Skyworks products for use in such applications do so at their own risk and agree to fully indemnify Skyworks for any damages resulting from such improper use or sale.

Customers are responsible for their products and applications using Skyworks products, which may deviate from published specifications as a result of design defects, errors, or operation of products outside of published parameters or design specifications. Customers should include design and operating safeguards to minimize these and other risks. Skyworks assumes no liability for applications assistance, customer product design, or damage to any equipment resulting from the use of Skyworks products outside of Skyworks' published specifications or parameters.

Skyworks, the Skyworks symbol, Sky5®, SkyOne®, SkyBlue™, Skyworks Green™, Clockbuilder®, DSPLL®, ISOmodem®, ProSLIC®, and SiPHY® are trademarks or registered trademarks of Skyworks Solutions, Inc. or its subsidiaries in the United States and other countries. Third-party brands and names are for identification purposes only and are the property of their respective owners. Additional information, including relevant terms and conditions, posted at www.skyworksinc.com, are incorporated by reference.
