

Ultra Series[™] Crystal Oscillator (VCXO) Si565 Data Sheet

Ultra Low Jitter Any-Frequency VCXO (100 fs), 0.2 to 3000 MHz

The Si565 Ultra Series[™] voltage-controlled crystal oscillator utilizes Silicon Laboratories' advanced 4th generation DSPLL® technology to provide an ultra-low jitter, low phase noise clock at any output frequency. The device is factory-programmed to any frequency from 0.2 to 3000 MHz with <1 ppb resolution and maintains exceptionally low jitter for both integer and fractional frequencies across its operating range. On-chip power supply filtering provides industry-leading power supply noise rejection, simplifying the task of generating low jitter clocks in noisy systems that use switched-mode power supplies. Offered in industry-standard footprints, the Si565 has a dramatically simplified supply chain that enables Silicon Labs to ship custom frequency samples 1-2 weeks after receipt of order. Unlike a traditional XO, where a different crystal is required for each output frequency, the Si565 uses one simple crystal and a DSPLL IC-based approach to provide the desired output frequency. The Si565 is factory-configurable for a wide variety of user specifications, including frequency, output format, and OE pin location/polarity. Specific configurations are factory-programmed at time of shipment, eliminating the long lead times associated with custom oscillators.

1. Ordering Guide

The Si565 VCXO supports a variety of options including frequency, output format, and OE pin location/polarity, as shown in the chart below. Specific device configurations are programmed into the part at time of shipment, and samples are available in 1-2 weeks. Silicon Laboratories provides an online part number configuration utility to simplify this process. Refer to www.silabs.com/oscillators to access this tool and for further ordering instructions.

Notes:

- 1. Contact Silicon Labs for non-standard configurations.
- 2. Create custom part numbers at www.silabs.com/oscillators.
- 3. Min Absolute Pull Range (APR) includes temp stability, initial accuracy, load pulling, VDD variation, and 20 year aging at 70 °C.
 - a. For best jitter and phase noise performance, always choose the smallest Kv that meets the application's minimum APR requirements. Unlike SAW-based solutions which require higher Kv values to account for their higher temperature dependence, the Si56x series provides lower Kv options to minimize noise coupling and jitter in real-world PLL designs.
 - b. APR is the ability of a VCXO to track a signal over the product lifetime. A VCXO with an APR of ±20 ppm is able to lock to a clock with a ±20 ppm stability over 20 years over all operating conditions.
 - c. APR (\pm) = $(0.5 \times VDD \times tuning slope)$ (initial accuracy + temp stability + load pulling + VDD variation + aging).
 - d. Minimum APR values noted above include absolute worst case values for all parameters.
 - e. See application note, "AN266: VCXO Tuning Slope (Kv), Stability, and Absolute Pull Range (APR)" for more information.

- 4. R_{term} = 100 Ω (differential) (see Figure 4.2).
- 5. R_{term} = 50 Ω to GND (see Figure 4.2).
