

# Complete SO-8, 12-Bit, 200ksps ADC with Shutdown

## FEATURES

- **Complete 12-Bit ADC with Reference in SO-8**
- **Single Supply 3V Operation**
- **Sample Rate: 200ksps**
- Power Dissipation: 15mW (Typ)
- 68dB S/(N + D) and – 72dB THD at 50kHz
- No Missing Codes Over Temperature
- Nap Mode with Instant Wake-Up: 1.5mW
- Sleep Mode: 19.5μW
- Shutdown Mode: 13.5μW
- High Impedance Analog Input
- Input Range (0.5mV/LSB): 0V to 2.048V
- Internal Reference Can Be Overdriven Externally
- 3-Wire Interface to DSPs and Processors (SPI and MICROWIRE™ Compatible)

## APPLICATIONS

- Low Power and Battery-Operated Systems
- Handheld or Portable Instruments
- High Speed Data Acquisition
- Digital Signal Processing
- Multiplexed Data Acquisition Systems
- Telecommunication
- Digital Radio
- Spectrum Analysis

## DESCRIPTION

The LTC®1401 is a complete 200ksps, 12-bit A/D converter that converts 0V to 2.048V unipolar input and draws only 15mW from a single 3V supply. This easy-to-use device comes complete with a 315ns sample-and-hold and a precision reference. Maximum DC specifications include  $\pm 1$ LSB INL,  $\pm 1$ LSB DNL and 45ppm/°C full-scale drift over temperature.

The LTC1401 has three power saving modes: Nap and Sleep, through the serial interface and Shutdown by setting the SHDN pin to zero. In Nap mode, it consumes only 1.5mW of power and can wake up and convert immediately. In Sleep (Shutdown) mode, it consumes 19.5μW (13.5μW) of power typically. Upon power-up from Sleep or Shutdown mode, a reference ready (REFRDY) signal is available in the serial word to indicate that the reference has settled and the chip is ready to convert.

The 3-wire serial port allows compact and efficient data transfer to a wide range of microprocessors, microcontrollers and DSPs.

$t_{11}$	Minimum Time Between Nap/Sleep Request to Wake Up Request	(Notes 5 and 8) ●	50			ns

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** All voltage values are with respect to GND.

**Note 3:** When these pin voltages are taken below GND or above  $V_{CC}$ , they will be clamped by internal diodes. This product can handle input currents greater than 40mA without latch-up if the pin is driven below GND or above  $V_{CC}$ .

**Note 4:** When these pin voltages are taken below GND, they will be clamped by internal diodes. This product can handle input currents greater than 40mA without latch-up if the pin is driven below GND. These pins are not clamped to  $V_{CC}$ .

**Note 5:** Guaranteed by design, not subject to test.

**Note 6:** Integral nonlinearity is defined as the deviation of a code from a straight line passing through the actual endpoints of the transfer curve. The deviation is measured from the center of the quantization band.

**Note 7:** The rising edge of CONV starts a conversion. If CONV returns low at a bit decision point during the conversion, it can create small errors. For best performance, ensure that CONV returns low either within 120ns after the conversion starts (i.e., before the first bit decision) or after the 14 clock cycles. (Figure 13 Timing Diagram).

**Note 8:** If this timing specification is not met, the device may not respond to a request for a conversion. To recover from this condition a NAP request is required.

## PIN FUNCTIONS

**V<sub>CC</sub> (Pin 1):** Positive Supply, 3V. Bypass to GND (10 $\mu$ F tantalum in parallel with 0.1 $\mu$ F ceramic).

**A<sub>IN</sub> (Pin 2):** Analog Input. 0V to 2.048V.

**V<sub>REF</sub> (Pin 3):** 1.2V Reference Output. Bypass to GND (10 $\mu$ F tantalum in parallel with 0.1 $\mu$ F ceramic).

**GND (Pin 4):** Ground. GND should be tied directly to an analog ground plane.

**D<sub>OUT</sub> (Pin 5):** The A/D conversion result is shifted out from this pin.

**CLK (Pin 6):** Clock. This clock synchronizes the serial data transfer. A minimum CLK pulse of 60ns signals the ADC to wake up from Nap or Sleep mode.

**CONV (Pin 7):** Conversion Start Signal. This active high signal starts a conversion on its rising edge. Keeping CLK low and pulsing CONV two/four times will put the ADC into Nap/Sleep mode.

**SHDN (Pin 8):** Shutdown Input. Pull this pin Low to put the ADC in Shutdown mode and save power (REFRDY will go Low). The device will draw 4.5 $\mu$ A in this mode.

## TEST CIRCUITS

## APPLICATIONS INFORMATION

### Conversion Details

The LTC1401 uses a successive approximation algorithm and an internal sample-and-hold circuit to convert an analog signal to a 12-bit serial output based on a precision internal reference. The control logic provides an easy interface to microprocessors and DSPs through serial 3-wire connections.

A rising edge on the CONV input starts a conversion. At the start of a conversion the successive approximation register (SAR) is reset. Once a conversion cycle has begun, it cannot be restarted.

During conversion, the internal 12-bit capacitive DAC output is sequenced by the SAR from the most significant bit (MSB) to the least significant bit (LSB). Referring to Figure 1, the  $A_{IN}$  input connects to the sample-and-hold capacitor during the acquire phase and the comparator offset is nulled by the feedback switch. In this acquire phase, it typically takes 315ns for the sample-and-hold capacitor to acquire the analog signal. During the convert phase, the comparator feedback switch opens, putting the comparator into the compare mode. The input switches  $C_{SAMPLE}$  to ground, injecting the analog input charge onto the summing junction. This input charge is successively compared with the binary-weighted charges supplied by the capacitive DAC. Bit decisions are made by the high speed comparator. At the end of a conversion, the DAC

output balances the  $A_{IN}$  input charge. The SAR contents (a 12-bit data word) which represent the input voltage, are presented through the serial pin  $D_{OUT}$ .

### Dynamic Performance

The LTC1401 has excellent high speed sampling capability. FFT (Fast Fourier Transform) test techniques are used to test the ADC's frequency response, distortion and noise at the rated throughput. By applying a low distortion sine wave and analyzing the digital output using an FFT algorithm, the ADC's spectral content can be examined for frequencies outside the fundamental. Figure 2a shows a typical LTC1401 FFT plot.

Figure 2a. LTC1401 Nonaveraged, 4096 Point FFT Plot with 50kHz Input Frequency

Figure 1.  $A_{IN}$  Input

### Signal-to-Noise Ratio

The signal-to-noise plus distortion ratio  $[S/(N+D)]$  is the ratio between the RMS amplitude of the fundamental input frequency to the RMS amplitude of all other frequency components at the A/D output. The output is band limited to frequencies from DC to half the sampling frequency. Figure 2a shows a typical spectral content with a 200kHz sampling rate and a 50kHz input. The dynamic performance is excellent for input frequencies up to the Nyquist limit of 100kHz as shown in Figure 2b.

## APPLICATIONS INFORMATION

Figure 2b. LTC1401 Nonaveraged, 4096 Point FFT Plot with 100kHz Input Frequency

## Effective Number of Bits

The effective number of bits (ENOBs) is a measurement of the effective resolution of an ADC and is directly related to the  $S/(N + D)$  by the equation:

$$N = \frac{S/(N + D) - 1.76}{6.02}$$

where  $N$  is the effective number of bits of resolution and  $S/(N + D)$  is expressed in dB. Figure 3 shows ENOBs vs Input Frequency.

Figure 3. Effective Bits and Signal-to-Noise + Distortion vs Input Frequency

## Total Harmonic Distortion

Total harmonic distortion (THD) is the ratio of the RMS sum of all harmonics of the input signal to the fundamental itself. The out-of-band harmonics alias into the frequency band between DC and half of the sampling frequency. THD is expressed as:

$$THD = 20 \log \frac{\sqrt{V_2^2 + V_3^2 + \dots V_n^2}}{V_1}$$

Where  $V_1$  is the RMS amplitude of the fundamental frequency and  $V_2$  through  $V_n$  are the amplitudes of the second through  $n$ th harmonics. THD vs input frequency is shown in Figure 4. The LTC1401 has good distortion performance up to the Nyquist frequency and beyond.

Figure 4. Distortion vs Input Frequency

## Intermodulation Distortion

If the ADC input signal consists of more than one spectral component, the ADC transfer function nonlinearity can produce intermodulation distortion (IMD) in addition to THD. IMD is the change in one sinusoidal input caused by the presence of another sinusoidal input at a different frequency.

If two pure sine waves of frequencies  $f_a$  and  $f_b$  are applied to the ADC input, nonlinearities in the ADC transfer function can create distortion products at sum and differ-

## APPLICATIONS INFORMATION

ence frequencies of  $m f_a \pm n f_b$ , where  $m$  and  $n = 0, 1, 2, 3$ , etc. For example, the 2nd order IMD terms include  $(f_a + f_b)$  and  $(f_a - f_b)$  while 3rd order IMD terms includes  $(2f_a + f_b)$ ,  $(2f_a - f_b)$ ,  $(f_a + 2f_b)$  and  $(f_a - 2f_b)$ . If the two input sine waves are equal in magnitude, the value (in decibels) of the 2nd order IMD products can be expressed by the following formula.

$$\text{IMD}(f_a \pm f_b) = 20 \log \frac{\text{Amplitude at } (f_a \pm f_b)}{\text{Amplitude at } f_a}$$

Figure 5 shows the IMD performance at a 50kHz input.

Figure 5. Intermodulation Distortion Plot

### Peak Harmonic or Spurious Noise

The peak harmonic or spurious noise is the largest spectral component excluding the input signal and DC. This value is expressed in decibels relative to the RMS value of a full-scale input signal.

### Full Power and Full Linear Bandwidth

The full power bandwidth is the input frequency at which the amplitude of the reconstructed fundamental is reduced by 3dB for a full-scale input signal.

The full linear bandwidth is the input frequency at which the  $S/(N+D)$  has dropped to 68dB (11 effective bits).

### Driving the Analog Input

The analog input of the LTC1401 is easy to drive. It draws only one small current spike while charging the sample-and-hold capacitor at the end of a conversion. During conversion, the analog input draws only a small leakage current. The only requirement is that the amplifier driving the analog input must settle after the small current spike before the next conversion starts. Any op amp that settles in 315ns to small load current transients will allow maximum speed operation. If a slower op amp is used, more settling time can be provided by increasing the time between conversions. Suitable devices capable of driving the ADC's  $A_{IN}$  input include the LT<sup>®</sup>1498 and the LT1630 op amps.

The following list is a summary of the op amps that are suitable for driving the LTC1401, more detailed information is available in the Linear Technology databooks or the Linear Technology Web site.

**LT1215/LT1216:** Dual and quad 23MHz, 50V/ $\mu$ s single supply op amps. Single 5V to  $\pm 15$ V supplies, 6.6mA specifications, 90ns settling to 0.5LSB.

**LT1229/LT1230:** Dual and quad 100MHz current feedback amplifiers.  $\pm 2$ V to  $\pm 15$ V supplies, 6mA supply current each amplifier. Low noise. Good AC specs.

**LT1498/LT1499:** Dual or quad 10MHz, 6V/ $\mu$ s, single 2.2V to  $\pm 15$ V supplies, 1.7mA supply current per amplifier, input/output swings rail-to-rail. Excellent AC and DC specs.

**LT1630:** Dual or quad 30MHz, 10V/ $\mu$ s, single 2.7V to  $\pm 15$ V supplies, 3.5mA supply current per amplifier, input/output swings rail-to-rail. Good AC and DC specs.

### Internal Reference

The LTC1401 has an on-chip, temperature compensated, curvature corrected, bandgap reference, which is factory trimmed to 1.20V. It is internally connected to the DAC and

LinearView is a trademark of Linear Technology Corporation.

## APPLICATIONS INFORMATION

is available at Pin 3 to provide up to 1mA current to an external load. For minimum code transition noise, the reference output should be decoupled with a capacitor to filter wideband noise from the reference (10 $\mu$ F tantalum in parallel with a 0.1 $\mu$ F ceramic is recommended). The  $V_{REF}$  pin can be driven with a DAC or other means to provide input span adjustment. The  $V_{REF}$  pin must be driven to at least 1.25V to prevent conflict with the internal reference. The reference should not be driven to more than 3V.

Figure 6 shows an LT1360 op amp driving the reference pin. Figure 7 shows a typical reference (LT1634-1.25) connected to the LTC1401. This will provide improved drift (equal to the maximum 25ppm/ $^{\circ}$ C of the LT1634-1.25) and a 2.1338V full scale.

Figure 6. Driving the  $V_{REF}$  with the LT1360 Op Amp

Figure 7. Supplying a 2.5V Reference Voltage to the LTC1401 with the LT1634-1.25

## UNIPOLAR OPERATION AND ADJUSTMENT

Figure 8 shows the ideal input/output characteristics for the LTC1401. The code transitions occur midway between successive integer LSB values (i.e., 0.5LSB, 1.5LSB, 2.5LSB, ... FS – 1.5LSB). The output code is straight binary with 1LSB =  $2.048\text{V}/4096 = 0.5\text{mV}$ .

Figure 8. LTC1401 Unipolar Transfer Characteristics

## Unipolar Offset and Full-Scale Error Adjustments

In applications where absolute accuracy is important, the offset and full-scale errors can be adjusted to zero. Offset error must be adjusted before full-scale error. Figure 9a shows the extra components required for full scale error adjustment. If both offset and full-scale adjustments are needed, the circuit in Figure 9b can be used. For zero offset error, apply 0.25mV (i.e., 0.5LSB) at the input and adjust the offset trim until the LTC1401 output code flickers between 0000 0000 0000 and 0000 0000 0001. For zero full-scale error, apply an analog input of 2.04725V (FS – 1.5LSB or last code transition) at the input and adjust R5 until the LTC1401 output code flickers between 1111 1111 1110 and 1111 1111 1111.

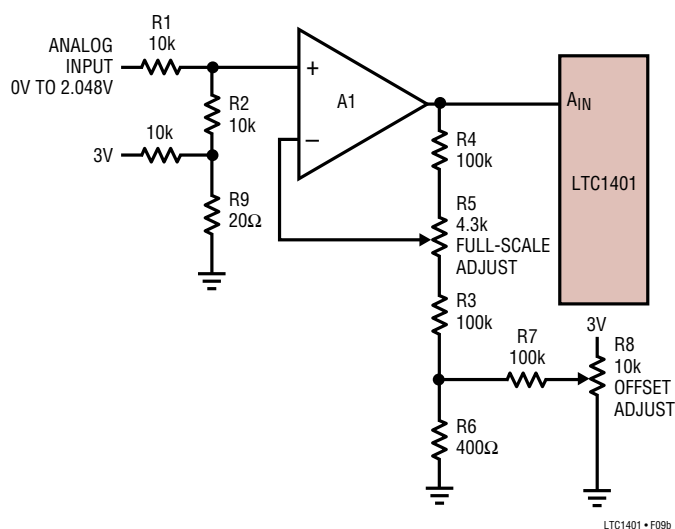

Figure 9b. LTC1401 Offset and Full-Scale Adjust Circuit

## BOARD LAYOUT AND BYPASSING

Wire wrap boards are not recommended for high resolution or high speed A/D converters. To obtain the best performance from the LTC1401, a printed circuit board is required. Layout for the printed circuit board should ensure that digital and analog signal lines are separated as much as possible. In particular, care should be taken not to run any digital traces alongside an analog signal trace or underneath the ADC. The analog input should be screened by GND.

High quality tantalum and ceramic bypass capacitors should be used at the  $V_{CC}$  and  $V_{REF}$  pins as shown in the Typical Application on the first page of this datasheet. For

optimum performance, a 10 $\mu$ F surface mount AVX capacitor in parallel with a 0.1 $\mu$ F ceramic is recommended for the  $V_{CC}$  and  $V_{REF}$  pins. The capacitors must be located as close to the pins as possible. The traces connecting the pins and the bypass capacitors must be kept short and should be made as wide as possible.

Input signal leads to  $A_{IN}$  and signal return leads from GND (Pin 4) should be kept as short as possible to minimize noise coupling. In applications where this is not possible, a shielded cable between the analog input signal and the ADC is recommended. Also, any potential difference in grounds between the analog signal and the ADC appears as an error voltage in series with the analog input signal. Attention should be paid to reducing the ground circuit impedance as much as possible.

Figure 10 shows the recommended system ground connections. All analog circuitry grounds should be terminated at the LTC1401 GND pin. The ground return to the power supply from Pin 4 should be low impedance for noise free operation. Digital circuitry grounds must be connected to the digital supply common.

Figure 10. Power Supply Connection

## Power-Down Mode

Upon power up, the LTC1401 is initialized to the active state and is ready for conversion. However, the chip can be easily placed into Nap or Sleep mode by exercising the right combination of CLK and CONV signals. In Nap mode, all power is off except the internal reference which remains active and provides 1.20V output voltage to the other

## APPLICATIONS INFORMATION

circuitry. In this mode, the ADC draws only 1.5mW of power instead of 15mW (for minimum power, the logic inputs must be within 500mV of the supply rails). The wake-up time from Nap mode to active mode is 350ns. In Sleep mode, power consumption is reduced to 19.5 $\mu$ W by cutting off the supply to the comparator and reference. Figure 11 illustrates power-down methods for the LTC1401. The chip enters Nap mode by keeping the CLK signal low and pulsing the CONV signal twice. For Sleep mode operation, CONV signal should be pulsed four times while CLK is kept low. NAP and SLEEP modes are activated on the falling edge of the CONV pulse. By pulling  $\overline{\text{SHDN}}$  low, the LTC1401 enters Shutdown mode and power consumption drops to 13.5 $\mu$ W.

Once  $\overline{\text{SHDN}}$  goes high, the LTC1401 returns to active mode or the LTC1401 returns to active mode by pulsing the CLK signal if the device has entered Nap/Sleep mode. During the transition from Sleep mode to active mode, the  $V_{\text{REF}}$  voltage ramp-up time is a function of its loading conditions. With a 10 $\mu$ F bypass capacitor, the wake-up time from Sleep mode is typically 3ms. A REFRDY signal is activated once the reference has settled and is ready for

an A/D conversion. This REFRDY bit is sent to the  $\text{D}_{\text{OUT}}$  pin as the first bit followed by the 12-bit data word (refer to Figure 12).

### DIGITAL INTERFACE

The digital interface requires only three digital lines. CLK and CONV are both inputs, and the  $\text{D}_{\text{OUT}}$  output provides the conversion result in serial form.

Figures 12 and 13 show the digital timing waveform of the LTC1401 during the Analog to Digital Conversion. The CONV rising edge starts the conversion. Once initiated, it can not be restarted until the conversion is completed. If the time from the CONV signal to the CLK rising edge is less than  $t_2$ , the digital output will be delayed by one clock cycle.

The digital output data is updated on the rising edge of the CLK line. The digital output data consists of a REFRDY bit followed by the valid 12-bit data word.  $\text{D}_{\text{OUT}}$  data should be captured by the receiving system on the rising CLK edge. Data remains valid for a minimum time of  $t_{10}$  after the rising CLK edge to allow capture to occur.

NOTE: NAP AND SLEEP ARE INTERNAL SIGNALS. REFRDY APPEARS AS THE FIRST BIT IN THE  $\text{D}_{\text{OUT}}$  WORD.

Figure 11. Nap Mode and Sleep Mode Waveforms
