

### FEATURES

- 3V to 40V Input Voltage Range
- 0.65A, 60V Integrated NPN Power Switch
- Boundary Mode Operation
- No Transformer Third Winding or Opto-Isolator Required for Regulation
- Improved Primary-Side Winding Feedback Load Regulation
- V<sub>OUT</sub> Set with Two External Resistors
- BIAS Pin for Internal Bias Supply and Power NPN Driver
- Programmable Soft-Start
- Programmable Power Switch Current Limit
- 16-Lead MSOP Package

## **APPLICATIONS**

 Industrial, Automotive and Medical Isolated Power Supplies

## Isolated Flyback Converter Without an Opto-Coupler

## DESCRIPTION

The LT<sup>®</sup>3574 is a monolithic switching regulator specifically designed for the isolated flyback topology. No third winding or opto-isolator is required for regulation. The part senses the isolated output voltage directly from the primary side flyback waveform. A 0.65A, 60V NPN power switch is integrated along with all control logic into a 16-lead MSOP package.

The LT3574 operates with input supply voltages from 3V to 40V, and can deliver output power up to 3W with no external power switch. The LT3574 utilizes boundary mode operation to provide a small magnetic solution with improved load regulation.

The output voltage is easily set with two external resistors and the transformer turns ratio. Off-the-shelf transformers are available for many applications.

## PIN FUNCTIONS

**BIAS**: Bias Voltage. This pin supplies current to the switch driver and internal circuitry of the LT3574. This pin must be locally bypassed with a capacitor. This pin may also be connected to V<sub>IN</sub> if a third winding is not used and if V<sub>IN</sub>  $\leq$  15V. If a third winding is used, the BIAS voltage should be lower than the input voltage for proper operation.

#### GND: Ground.

 $\mathbf{R_{FB}}$ : Input Pin for External Feedback Resistor. This pin is connected to the transformer primary (V<sub>SW</sub>). The ratio of this resistor to the R<sub>REF</sub> resistor, times the internal bandgap reference, determines the output voltage (plus the effect of any non-unity transformer turns ratio). The average current through this resistor during the flyback period should be approximately 200µA. For nonisolated applications, this pin should be connected to V<sub>IN</sub>.

 $\mathbf{R}_{\mathbf{ILIM}}$ : Maximum Current Limit Adjust Pin. A resistor should be tied to this pin to ground to set the current limit. Use a 10k resistor for the full current capabilities of the switch.

 $\mathbf{R}_{\mathbf{REF}}$ : Input Pin for External Ground-Referred Reference Resistor. This resistor should be in the range of 6k, but for convenience, need not be precisely this value. For nonisolated applications, a traditional resistor voltage divider may be connected to this pin.

**SHDN/UVLO**: Shutdown/Undervoltage Lockout. A resistor divider connected to  $V_{IN}$  is tied to this pin to program the minimum input voltage at which the LT3574 will operate. At a voltage below ~0.7V, the part draws no quiescent current. When below 1.22V and above ~0.7V, the part will draw 10µA of current, but internal circuitry will remain off. Above 1.22V, the internal circuitry will start and a 7µA current will be fed into the SS pin. When this pin falls below 1.22V, 2.5µA will be pulled from the pin to provide programmable hysteresis for UVLO.

**SS**: Soft-Start Pin. Place a soft-start capacitor here to limit start-up inrush current and output voltage ramp rate. Switching starts when the voltage at this pin reaches  $\sim 0.7$ V.

**SW**: Collector Node of the Output Switch. This pin has large currents flowing through it. Keep the traces to the switching components as short as possible to minimize electromagnetic radiation and voltage spikes.

 $\label{eq:transform} \begin{array}{l} \textbf{T}_{\textbf{C}} : \text{Output Voltage Temperature Compensation. Connect} \\ \text{a resistor to ground to produce a current proportional to} \\ \text{absolute temperature to be sourced into the } R_{REF} \text{ node.} \\ \textbf{I}_{TC} = 0.55 \text{V/R}_{TC}. \end{array}$ 

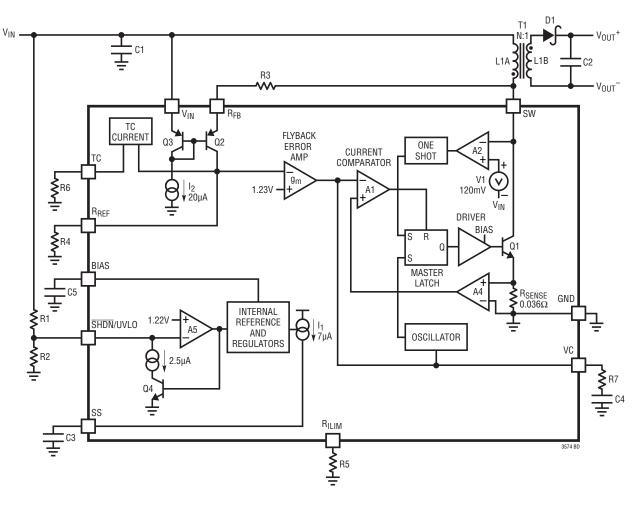

**TEST:** This pin is used for testing purposes only and must be connected to ground for the part to operate properly.

**VC**: Compensation Pin for Internal Error Amplifier. Connect a series RC from this pin to ground to compensate the switching regulator. A 100pF capacitor in parallel helps eliminate noise.

 $V_{IN}$ : Input Voltage. This pin supplies current to the internal start-up circuitry and as a reference voltage for the DCM comparator and feedback circuitry. This pin must be locally bypassed with a capacitor.

## **BLOCK DIAGRAM**

6

## OPERATION

The LT3574 is a current mode switching regulator IC designed specifically for the isolated flyback topology. The special problem normally encountered in such circuits is that information relating to the output voltage on the isolated secondary side of the transformer must be communicated to the primary side in order to maintain regulation. Historically, this has been done with opto-isolators or extra transformer windings. Opto-isolator circuits waste output power and the extra components increase the cost and physical size of the power supply. Optoisolators can also exhibit trouble due to limited dynamic response, nonlinearity, unit-to-unit variation and aging over life. Circuits employing extra transformer windings also exhibit deficiencies. Using an extra winding adds to the transformer's physical size and cost, and dynamic response is often mediocre.

The LT3574 derives its information about the isolated output voltage by examining the primary side flyback pulse waveform. In this manner, no opto-isolator nor extra transformer winding is required for regulation. The output voltage is easily programmed with two resistors. Since this IC operates in boundary control mode, the output voltage is calculated from the switch pin when the secondary current is almost zero. This method improves load regulation without external resistors and capacitors.

The Block Diagram shows an overall view of the system. Many of the blocks are similar to those found in traditional switching regulators including: internal bias regulator, oscillator, logic, current amplifier and comparator, driver, and output switch. The novel sections include a special flyback error amplifier and a temperature compensation circuit. In addition, the logic system contains additional logic for boundary mode operation, and the sampling error amplifier. The LT3574 features a boundary mode control method, where the part operates at the boundary between continuous conduction mode and discontinuous conduction mode. The VC pin controls the current level just as it does in normal current mode operation, but instead of turning the switch on at the start of the oscillator period, the part detects when the secondary-side winding current is zero.

#### **Boundary Mode Operation**

Boundary mode is a variable frequency, current mode switching scheme. The switch turns on and the inductor current increases until a VC pin controlled current limit. The voltage on the SW pin rises to the output voltage divided by the secondary-to-primary transformer turns ratio plus the input voltage. When the secondary current through the diode falls to zero, the SW pin voltage falls below  $V_{IN}$ . A discontinuous conduction mode (DCM) comparator detects this event and turns the switch back on.

Boundary mode returns the secondary current to zero every cycle, so the parasitic resistive voltage drops do not cause load regulation errors. Boundary mode also allows the use of a smaller transformer compared to continuous conduction mode and no subharmonic oscillation.

At low output currents the LT3574 delays turning on the switch, and thus operates in discontinuous mode. Unlike a traditional flyback converter, the switch has to turn on to update the output voltage information. Below 0.6V on the VC pin, the current comparator level decreases to its minimum value, and the internal oscillator frequency decreases in frequency. With the decrease of the internal oscillator, the part starts to operate in DCM. The output current is able to decrease while still allowing a minimum switch off-time for the error amp sampling circuitry. The typical minimum internal oscillator frequency with VC equal to 0V is 40kHz.

### ERROR AMPLIFIER—PSEUDO DC THEORY

In the Block Diagram, the  $R_{REF}$  (R4) and  $R_{FB}$  (R3) resistors can be found. They are external resistors used to program the output voltage. The LT3574 operates much the same way as traditional current mode switchers, the major difference being a different type of error amplifier which derives its feedback information from the flyback pulse.

Operation is as follows: when the output switch, Q1, turns off, its collector voltage rises above the V<sub>IN</sub> rail. The amplitude of this flyback pulse, i.e., the difference between it and V<sub>IN</sub>, is given as:

 $V_{FLBK} = (V_{OUT} + V_F + I_{SEC} \bullet ESR) \bullet N_{PS}$ 

 $V_F = D1$  forward voltage

I<sub>SEC</sub> = Transformer secondary current

ESR = Total impedance of secondary circuit

 $N_{\mbox{PS}}$  = Transformer effective primary-to-secondary turns ratio

The flyback voltage is then converted to a current by the action of  $R_{FB}$  and Q2. Nearly all of this current flows through resistor  $R_{REF}$  to form a ground-referred voltage. This voltage is fed into the flyback error amplifier. The flyback error amplifier samples this output voltage information when the secondary side winding current is zero. The error amplifier uses a bandgap voltage, 1.23V, as the reference voltage.

The relatively high gain in the overall loop will then cause the voltage at the  $R_{REF}$  resistor to be nearly equal to the bandgap reference voltage  $V_{BG}$ . The relationship between  $V_{FLBK}$  and  $V_{BG}$  may then be expressed as:

$$\alpha \left(\frac{V_{FLBK}}{R_{FB}}\right) = \frac{V_{BG}}{R_{REF}} \text{ or,}$$

$$V_{FLBK} = V_{BG} \left(\frac{R_{FB}}{R_{REF}}\right) \left(\frac{1}{\alpha}\right)$$

$$\alpha = \text{Ratio of Q1 } I_{C} \text{ to } I_{F}, \text{ typically} \approx 0.986$$

V<sub>BG</sub> = Internal bandgap reference

In combination with the previous  $V_{FLBK}$  expression yields an expression for  $V_{OUT}$ , in terms of the internal reference, programming resistors, transformer turns ratio and diode forward voltage drop:

$$V_{OUT} = V_{BG} \left( \frac{R_{FB}}{R_{REF}} \right) \left( \frac{1}{\alpha N_{PS}} \right) - V_{F} - I_{SEC} (ESR)$$

Additionally, it includes the effect of nonzero secondary output impedance (ESR). This term can be assumed to be zero in boundary control mode. More details will be discussed in the next section.

#### **Temperature Compensation**

The first term in the  $V_{OUT}$  equation does not have a temperature dependence, but the diode forward drop has a significant negative temperature coefficient. To compensate for this, a positive temperature coefficient current source is connected to the R<sub>REF</sub> pin. The current is set by a resistor to ground connected to the T<sub>C</sub> pin. To cancel the temperature coefficient, the following equation is used:

$$\frac{\delta V_{F}}{\delta T} = -\frac{R_{FB}}{R_{TC}} \bullet \frac{1}{N_{PS}} \bullet \frac{\delta V_{TC}}{\delta T} \text{ or,}$$
$$R_{TC} = \frac{-R_{FB}}{N_{PS}} \bullet \frac{1}{\delta V_{F} / \delta T} \bullet \frac{\delta V_{TC}}{\delta T} \approx \frac{R_{FB}}{N_{PS}}$$

 $(\delta V_F/\delta_T)$  = Diode's forward voltage temperature coefficient

$$(\delta V_{TC}/\delta T) = 2mV$$
  
 $V_{TC} = 0.55V$ 

The resistor value given by this equation should also be verified experimentally, and adjusted if necessary to achieve optimal regulation over temperature.

The revised output voltage is as follows:

$$V_{OUT} = V_{BG} \left( \frac{R_{FB}}{R_{REF}} \right) \left( \frac{1}{N_{PS} \alpha} \right) - V_{F}$$
$$- \left( \frac{V_{TC}}{R_{TC}} \right) \bullet \frac{R_{FB}}{N_{PS} \alpha} - I_{SEC} (ESR)$$

35741

#### ERROR AMPLIFIER—DYNAMIC THEORY

Due to the sampling nature of the feedback loop, there are several timing signals and other constraints that are required for proper LT3574 operation.

#### **Minimum Current Limit**

The LT3574 obtains output voltage information from the SW pin when the secondary winding conducts current. The sampling circuitry needs a minimum amount of time to sample the output voltage. To guarantee enough time, a minimum inductance value must be maintained. The primary side magnetizing inductance must be chosen above the following value:

$$L_{PRI} \ge V_{OUT} \bullet \frac{t_{MIN}}{I_{MIN}} \bullet N_{PS} = V_{OUT} \bullet N_{PS} \bullet \left(\frac{2\mu H}{V}\right)$$

t<sub>MIN</sub> = minimum off-time, 350ns

I<sub>MIN</sub> = minimum current limit, 175mA

The minimum current limit is higher than that on the Electrical Characteristics table due to the overshoot caused by the comparator delay.

#### Leakage Inductance Blanking

When the output switch first turns off, the flyback pulse appears. However, it takes a finite time until the transformer primary-side voltage waveform approximately represents the output voltage. This is partly due to the rise time on the SW node, but more importantly due to the transformer leakage inductance. The latter causes a very fast voltage spike on the primary side of the transformer that is not directly related to output voltage (some time is also required for internal settling of the feedback amplifier circuitry). The leakage inductance spike is largest when the power switch current is highest.

In order to maintain immunity to these phenomena, a fixed delay is introduced between the switch turn-off command and the beginning of the sampling. The blanking is internally set to 150ns. In certain cases, the leakage inductance may not be settled by the end of the blanking period, but will not significantly affect output regulation.

#### Selecting $R_{FB}$ and $R_{REF}$ Resistor Values

The expression for  $V_{\text{OUT},}$  developed in the Operation section, can be rearranged to yield the following expression for  $R_{\text{FB}}$ :

$$R_{FB} = \frac{R_{REF} \bullet N_{PS} \left[ \left( V_{OUT} + V_{F} \right) \alpha + V_{TC} \right]}{V_{BG}}$$

where,

V<sub>OUT</sub> = Output voltage

 $V_F$  = Switching diode forward voltage

 $\alpha$  = Ratio of Q1, IC to IE, typically 0.986

 $N_{PS}$  = Effective primary-to-secondary turns ratio  $V_{TC}$  = 0.55V

The equation assumes the temperature coefficients of the diode and  $V_{\text{TC}}$  are equal, which is a good first-order approximation.

Strictly speaking, the above equation defines  $R_{FB}$  not as an absolute value, but as a ratio of  $R_{REF}$ . So, the next question is, "What is the proper value for  $R_{REF}$ ?" The answer is that  $R_{REF}$  should be approximately 6.04k. The LT3574 is trimmed and specified using this value of  $R_{REF}$ . If the impedance of  $R_{REF}$  varies considerably from 6.04k, additional errors will result. However, a variation in  $R_{REF}$  of several percent is acceptable. This yields a bit of freedom in selecting standard 1% resistor values to yield nominal  $R_{FB}/R_{REF}$  ratios. The  $R_{FB}$  resistor given by this equation should also be verified experimentally, and adjusted if necessary for best output accuracy.

Tables 1-4 are useful for selecting the resistor values for  $R_{REF}$  and  $R_{FB}$  with no equations. The tables provide  $R_{FB}$ ,  $R_{REF}$  and  $R_{TC}$  values for common output voltages and common winding ratios.

Table 1. Common Resistor	Values for 1:1 Transformers

#### **Output Power**

A flyback converter has a complicated relationship between the input and output current compared to a buck or a boost. A boost has a relatively constant maximum input current regardless of input voltage and a buck has a relatively constant maximum output current regardless of input voltage. This is due to the continuous nonswitching behavior of the two currents. A flyback converter has both discontinuous input and output currents which makes it similar to a nonisolated buck-boost. The duty cycle will affect the input and output currents, making it hard to predict output power. In addition, the winding ratio can be changed to multiply the output current at the expense of a higher switch voltage.

The graphs in Figures 1-3 show the maximum output power possible for the output voltages 3.3V, 5V and 12V. The maximum power output curve is the calculated output power if the switch voltage is 50V during the off-time. To achieve this power level at a given input, a winding ratio value must be calculated to stress the switch to 50V, resulting in some odd ratio values. The curves below are examples of common winding ratio values and the amount of output power at given input voltages.

One design example would be a 5V output converter with a minimum input voltage of 20V and a maximum input voltage of 30V. A three-to-one winding ratio fits this design example perfectly and outputs close to 2.5W at 30V but lowers to 2W at 20V.

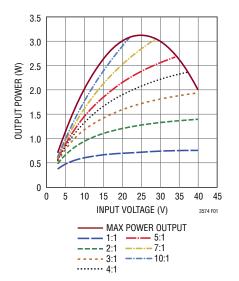

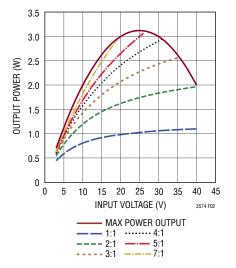

Figure 1. Output Power for 3.3V Output

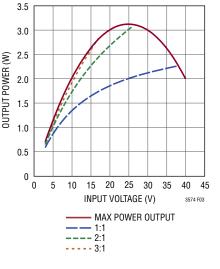

Figure 3. Output Power for 12V Output

#### TRANSFORMER DESIGN CONSIDERATIONS

Transformer specification and design is perhaps the most critical part of successfully applying the LT3574. In addition to the usual list of caveats dealing with high frequency isolated power supply transformer design, the following information should be carefully considered. Linear Technology has worked with several leading magnetic component manufacturers to produce pre-designed flyback transformers for use with the LT3574. Table 5 shows the details of several of these transformers.

TRANSFORMER Part Number	$\begin{array}{c} \text{SIZE} (W \times L \times H) \\ mm \end{array}$	L <sub>PRI</sub> (µH)	L <sub>LEAKAGE</sub> (nH)	NP:NS:NB	R <sub>PRI</sub> (mΩ)	R <sub>SEC</sub> (mΩ)	VENDOR	TARGET APPLICATIONS

#### Table 5. Predesigned Transformers—Typical Specifications Unless Otherwise Noted

#### Turns Ratio

Note that when using an  $R_{FB}/R_{REF}$  resistor ratio to set output voltage, the user has relative freedom in selecting a transformer turns ratio to suit a given application. In contrast, simpler ratios of small integers, e.g., 1:1, 2:1, 3:2, etc., can be employed to provide more freedom in setting total turns and mutual inductance.

Typically, the transformer turns ratio is chosen to maximize available output power. For low output voltages (3.3V or 5V), a N:1 turns ratio can be used with multiple primary windings relative to the secondary to maximize the transformer's current gain (and output power). However, remember that the SW pin sees a voltage that is equal to the maximum input supply voltage plus the output voltage multiplied by the turns ratio. This quantity needs to remain below the abs max rating of the SW pin to prevent breakdown of the internal power switch. Together these conditions place an upper limit on the turns ratio, N, for a given application. Choose a turns ratio low enough to ensure:

$$N < \frac{50V - V_{IN(MAX)}}{V_{OUT} + V_{F}}$$

For larger N:1 values, a transformer with a larger physical size is needed to deliver additional current and provide a large enough inductance value to ensure that the off-time is long enough to accurately measure the output voltage.

For lower output power levels, a 1:1 or 1:N transformer can be chosen for the absolute smallest transformer size. A 1:N transformer will minimize the magnetizing inductance (and minimize size), but will also limit the available output power. A higher 1:N turns ratio makes it possible to have very high output voltages without exceeding the breakdown voltage of the internal power switch.

#### Leakage Inductance

Transformer leakage inductance (on either the primary or secondary) causes a voltage spike to appear at the primary after the output switch turns off. This spike is increasingly prominent at higher load currents where more stored energy must be dissipated. In most cases, a snubber circuit will be required to avoid overvoltage breakdown at the output switch node. Transformer leakage inductance should be minimized.

An RCD (resistor capacitor diode) clamp, shown in Figure 4, is required for most designs to prevent the leakage inductance spike from exceeding the breakdown voltage of the power device. The flyback waveform is depicted in Figure 5. In most applications, there will be a very fast voltage spike caused by a slow clamp diode that may not exceed 60V. Once the diode clamps, the leakage inductance current is absorbed by the clamp capacitor. This period should not last longer than 150ns so as not to interfere with the output regulation, and the voltage during this clamp period must not exceed 55V. The clamp diode turns off after the leakage inductance energy is absorbed and the switch voltage is then equal to:

 $V_{SW(MAX)} = V_{IN(MAX)} + N(V_{OUT} + V_F)$ 

This voltage must not exceed 50V. This same equation also determines the maximum turns ratio.

When choosing the snubber network diode, careful attention must be paid to maximum voltage seen by the SW pin. Schottky diodes are typically the best choice to be used in the snubber, but some PN diodes can be used if they turn on fast enough to limit the leakage inductance spike. The leakage spike must always be kept below 60V. Figures 6 and 7 show the SW pin waveform for a  $24V_{IN}$ ,  $5V_{OUT}$  application at a 0.5A load current. Notice that the leakage spike is very high (more than 65V) with the *bad* diode, while the *good* diode effectively limits the spike to less than 55V.

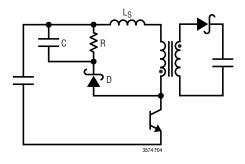

Figure 4. RCD Clamp

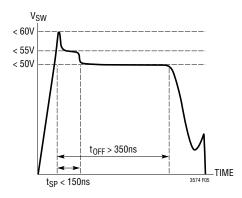

Figure 5. Maximum Voltages for SW Pin Flyback Waveform

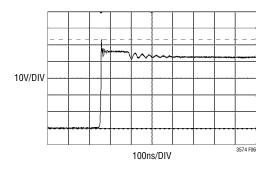

Figure 6. Good Snubber Diode Limits SW Pin Voltage

#### Secondary Leakage Inductance

In addition to the previously described effects of leakage inductance in general, leakage inductance on the secondary in particular exhibits an additional phenomenon. It forms an inductive divider on the transformer secondary that effectively reduces the size of the primary-referred flyback pulse used for feedback. This will increase the output voltage target by a similar percentage. Note that unlike leakage spike behavior, this phenomenon is load independent. To the extent that the secondary leakage inductance is a constant percentage of mutual inductance (over manufacturing variations), this can be accommodated by adjusting the  $R_{FB}/R_{REF}$  resistor ratio.

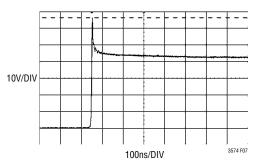

Figure 7. Bad Snubber Diode Does Not Limit SW Pin Voltage

#### Winding Resistance Effects

Resistance in either the primary or secondary will reduce overall efficiency ( $P_{OUT}/P_{IN}$ ). Good output voltage regulation will be maintained independent of winding resistance due to the boundary mode operation of the LT3574.

#### **Bifilar Winding**

A bifilar, or similar winding technique, is a good way to minimize troublesome leakage inductances. However, remember that this will also increase primary-to-secondary capacitance and limit the primary-to-secondary breakdown voltage, so, bifilar winding is not always practical. The Linear Technology applications group is available and extremely qualified to assist in the selection and/or design of the transformer.

#### Setting the Current Limit Resistor

The maximum current limit can be set by placing a resistor between the  $R_{ILIM}$  pin and ground. This provides some flexibility in picking standard off-the-shelf transformers that may be rated for less current than the LT3574's internal power switch current limit. If the maximum current limit is needed, use a 10k resistor. For lower current limits, the following equation sets the approximate current limit:

$$R_{ILIM} = 65 \bullet 10^3 (0.9 \text{A} - I_{LIM}) + 10 \text{k}$$

The Switch Current Limit vs  $\mathsf{R}_{\mathsf{ILIM}}$  plot in the Typical Performance Characteristics section depicts a more accurate current limit.

### Undervoltage Lockout (UVLO)

The SHDN/UVLO pin is connected to a resistive voltage divider connected to V<sub>IN</sub> as shown in Figure 8. The voltage threshold on the SHDN/UVLO pin for V<sub>IN</sub> rising is 1.22V. To introduce hysteresis, the LT3574 draws  $2.5\mu$ A from the SHDN/UVLO pin when the pin is below 1.22V. The hysteresis is therefore user-adjustable and depends on the value of R1. The UVLO threshold for V<sub>IN</sub> rising is:

$$V_{IN(UVLO,RISING)} = \frac{1.22V \bullet (R1 + R2)}{R2} + 2.5\mu A \bullet R1$$

The UVLO threshold for  $V_{IN}$  falling is:

$$V_{\text{IN}(\text{UVLO},\text{FALLING})} = \frac{1.22\text{V} \bullet (\text{R1} + \text{R2})}{\text{R2}}$$

To implement external run/stop control, connect a small NMOS to the UVLO pin, as shown in Figure 8. Turning the NMOS on grounds the UVLO pin and prevents the LT3574 from operating, and the part will draw less than a 1 $\mu$ A of quiescent current.

#### **Minimum Load Requirement**

The LT3574 obtains output voltage information through the transformer while the secondary winding is conducting current. During this time, the output voltage (multiplied times the turns ratio) is presented to the primary side of the transformer. The LT3574 uses this reflected signal to regulate the output voltage. This means that the LT3574 must turn on every so often to sample the output voltage, which delivers a small amount of energy to the output. This sampling places a minimum load requirement on the output of 1% to 2% of the maximum load.

#### **BIAS Pin Considerations**

For applications with an input voltage less than 15V, the BIAS pin is typically connected directly to the  $V_{IN}$  pin. For input voltages greater than 15V, it is preferred to leave the BIAS pin separate from the  $V_{IN}$  pin. In this condition, the BIAS pin is regulated with an internal LDO to a voltage of 3V. By keeping the BIAS pin separate from the input voltage at high input voltages, the physical size of the capacitors can be minimized (the BIAS pin can then use a 6.3V or 10V rated capacitor).

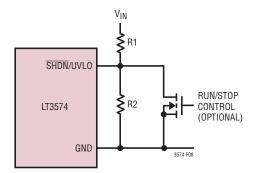

Figure 8. Undervoltage Lockout (UVLO)

#### Overdriving the BIAS Pin with a Third Winding

The LT3574 provides excellent output voltage regulation without the need for an opto-coupler, or third winding, but for some applications with higher input voltages (>20V), it may be desirable to add an additional winding (often called a third winding) to improve the system efficiency. For proper operation of the LT3574, if a winding is used as a supply for the BIAS pin, ensure that the BIAS pin voltage is at least 3.15V and always less than the input voltage. For a typical 24V<sub>IN</sub> application, overdriving the BIAS pin will improve the efficiency gain 4% to 5%.

#### Loop Compensation

The LT3574 is compensated using an external resistorcapacitor network on the VC pin. Typical values are in the range of  $R_C = 50k$  and  $C_C = 1nF$  (see the numerous schematics in the Typical Applications section for other possible values). If too large of an  $R_C$  value is used, the part will be more susceptible to high frequency noise and jitter. If too small of an  $R_C$  value is used, the transient performance will suffer. The value choice for  $C_C$  is somewhat the inverse of the  $R_C$  choice: if too small a  $C_C$  value is used, the loop may be unstable, and if too large a  $C_C$  value is used, the transient performance will also suffer. Transient response plays an important role for any DC/DC converter.

#### **Design Example**

The following example illustrates the converter design process using LT3574.

Given the input voltage of 20V to 28V, the required output is 5V, 0.5A.

 $V_{IN(MIN)}$  = 20V,  $V_{IN(MAX)}$  = 28V,  $V_{OUT}$  = 5V,  $V_F$  = 0.5V and  $I_{OUT}$  = 0.5A

## 1. Select the transformer turns ratio to accommodate the output.

The output voltage is reflected to the primary side by a factor of turns ratio N. The switch voltage stress  $V_{SW}$  is expressed as:

$$\begin{split} N &= \frac{N_P}{N_S} \\ V_{SW(MAX)} &= V_{IN} + N(V_{OUT} + V_F) < 50V \end{split}$$

or rearranged to:

$$N < \frac{50 - V_{IN(MAX)}}{(V_{OUT} + V_F)}$$

On the other hand, the primary-side current is multiplied by the same factor of N. The converter output capability is:

$$I_{OUT(MAX)} = 0.8 \bullet (1-D) \bullet \frac{1}{2} \text{ NI}_{PK}$$
$$D = \frac{N(V_{OUT} + V_F)}{V_{IN} + N(V_{OUT} + V_F)}$$

The transformer turns ratio is selected such that the converter has adequate current capability and a switch stress below 50V. Table 6 shows the switch voltage stress and output current capability at different transformer turns ratio.

Table 6. Switch Voltage Stress and Output Current Capability vs Turns Ratio

N	V <sub>SW(MAX)</sub> AT V <sub>IN(MAX)</sub> (V)	I <sub>out(max)</sub> at V <sub>in(min)</sub> (A)	DUTY CYCLE (%)
1:1	33.5	0.34	16~22
2:1	39	0.57	28~35
3:1	44.5	0.73	37~45
4:1	50	0.84	44~52

BIAS winding turns ratio is selected to program the BIAS voltage to 3~5V. The BIAS voltage shall not exceed the input voltage.

The turns ratio is then selected as primary: secondary: BIAS = 3:1:1.

## 2. Select the transformer primary inductance for target switching frequency.

The LT3574 requires a minimum amount of time to sample the output voltage during the off-time. This off-time,  $t_{OFF(MIN)}$ , shall be greater than 350ns over all operating conditions. The converter also has a minimum current limit,  $I_{MIN}$ , of 175mA to help create this off-time. This defines the minimum required inductance as defined as:

$$L_{MIN} = \frac{N(V_{OUT} + V_F)}{I_{MIN}} \bullet t_{OFF(MIN)}$$

The transformer primary inductance also affects the switching frequency which is related to the output ripple. If above the minimum inductance, the transformer's primary inductance may be selected for a target switching frequency range in order to minimize the output ripple.

The following equation estimates the switching frequency.

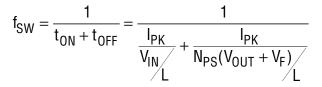

Table 7. Switching Frequency at Different Primary Inductance at  ${\sf I}_{\sf PK}$ 

L (µH)	f <sub>SW</sub> AT V <sub>IN(MIN)</sub> (kHz)	f <sub>SW</sub> AT V <sub>IN(MAX)</sub> (kHz)
30	317	373
60	159	187
120	79	93

Note: The switching frequency is calculated at maximum output.

In this design example, the minimum primary inductance is used to achieve a nominal switching frequency of 350kHz at full load. The PA2627NL from Pulse Engineering is chosen as the flyback transformer.

Given the turns ratio and primary inductance, a customized transformer can be designed by magnetic component manufacturer or a multi-winding transformer such as a Coiltronics Versa-Pac may be used.

#### 3. Select the output diodes and output capacitor.

The output diode voltage stress  $V_D$  is the summation of the output voltage and reflection of input voltage to the secondary side. The average diode current is the load current.

$$V_D = V_{OUT} + \frac{V_{IN}}{N}$$

The output capacitor should be chosen to minimize the output voltage ripple while considering the increase in size and cost of a larger capacitor. The following equation calculates the output voltage ripple.

$$\Delta V_{MAX} = \frac{LI^2 PK}{2CV_{OUT}}$$

# 4. Select the snubber circuit to clamp the switch voltage spike.

A flyback converter generates a voltage spike during switch turn-off due to the leakage inductance of the transformer. In order to clamp the voltage spike below the maximum rating of the switch, a snubber circuit is used. There are many types of snubber circuits, for example R-C, R-C-D and Zener clamps. Among them, RCD is widely used. Figure 9 shows the RCD snubber in a flyback converter.

A typical switch node waveform is shown in Figure 10.

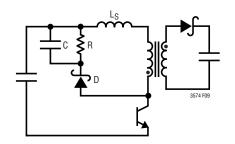

Figure 9. RCD Snubber in a Flyback Converter

During switch turn-off, the energy stored in the leakage inductance is transferred to the snubber capacitor, and eventually dissipated in the snubber resistor.

$$\frac{1}{2}L_{S}I_{PK}^{2}f_{SW} = \frac{V_{C}(V_{C} - N \bullet V_{OUT})}{R}$$

The snubber resistor affects the spike amplitude VC and duration  $t_{SP}$ , the snubber resistor is adjusted such that  $t_{SP}$  is about 150ns. Prolonged  $t_{SP}$  may cause distortion to the output voltage sensing.

The previous steps finish the flyback power stage design.

## 5. Select the feedback resistor for proper output voltage.

Using the resistor Tables 1-4, select the feedback resistor R<sub>FB</sub>, and program the output voltage to 5V. Adjust the R<sub>TC</sub> resistor for temperature compensation of the output voltage. R<sub>REF</sub> is selected as 6.04k.

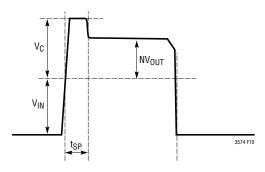

Figure 10. Typical Switch Node Waveform

A small capacitor in parallel with  $R_{REF}$  filters out the noise during the voltage spike, however, the capacitor should limit to 10pF. A large capacitor causes distortion on voltage sensing.

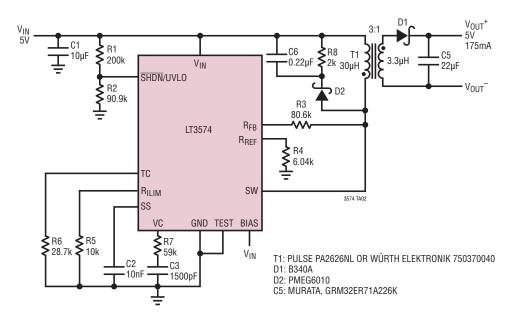

## 6. Optimize the compensation network to improve the transient performance.

The transient performance is optimized by adjusting the compensation network. For best ripple performance, select a compensation capacitor not less than 1nF, and select a compensation resistor not greater than 50k.

## 7. Current limit resistor, soft-start capacitor and UVLO resistor divider

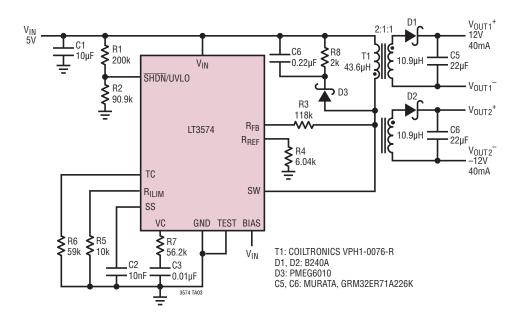

Use the current limit resistor  $R_{LIM}$  to lower the current limit if a compact transformer design is required. Soft-start capacitor helps during the start-up of the flyback converter. Select the UVLO resistor divider for intended input operation range. These equations are aforementioned.

### PACKAGE DESCRIPTION

#### **MS** Package **16-Lead Plastic MSOP** (Reference LTC DWG # 05-08-1669 Rev Ø)

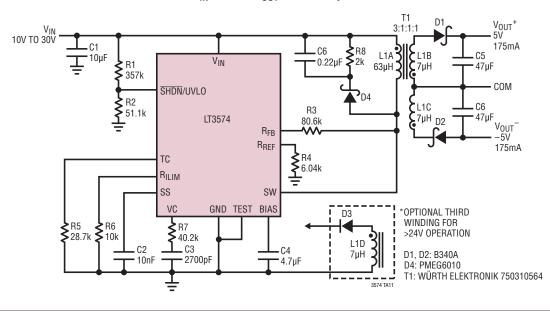

3. DIMENSION DOES NOT INCLUDE MOLD FLASH, PROTRUSIONS OR GATE BURRS.

MOLD FLASH, PROTRUSIONS OR GATE BURRS SHALL NOT EXCEED 0.152mm (.006") PER SIDE 4. DIMENSION DOES NOT INCLUDE INTERLEAD FLASH OR PROTRUSIONS.

INTERLEAD FLASH OR PROTRUSIONS SHALL NOT EXCEED 0.152mm (.006") PER SIDE

5. LEAD COPLANARITY (BOTTOM OF LEADS AFTER FORMING) SHALL BE 0.102mm (.004") MAX

10V to  $30V_{IN}$ , +5V/–5V<sub>OUT</sub> Isolated Flyback Converter

## **RELATED PARTS**

PART NUMBER	DESCRIPTION	COMMENTS
LT3573	Isolated Flyback Switching Regulator with 60V Integrated Switch	$3V \leq V_{IN} \leq$ 40V, No Opto-Isolator or "Third Winding" Required, Up to 7W, MSOP-16E
LT3757	Boost, Flyback, SEPIC and Inverting Controller	$2.9V \le V_{IN} \le 40V$ , Current Mode Control, 100kHz to 1MHz Programmable Operation Frequency, 3mm $\times$ 3mm DFN-10 and MSOP-10E Package
LT3758	Boost, Flyback, SEPIC and Inverting Controller	$5.5V \le V_{IN} \le 100V$ , Current Mode Control, 100kHz to 1MHz Programmable Operation Frequency, 3mm $\times$ 3mm DFN-10 and MSOP-10E Package
LT3837	Isolated No-Opto Synchronous Flyback Controller	Ideal for $V_{\text{IN}}$ from 4.5V to 36V Limited by External Components, Up to 60W, Current Mode Control
LT3825	Isolated No-Opto Synchronous Flyback Controller	V <sub>IN</sub> from 16V to 75V Limited by External Components, Up to 60W, Current Mode Control
LT1725	Isolated No-Opto Flyback Controller	$V_{\text{IN}}$ and $V_{\text{OUT}}$ Limited Only by External Components, Ideal for 48V Nominal Input Voltage
LT1737	Isolated No-Opto Flyback Controller	$V_{\text{IN}}$ and $V_{\text{OUT}}$ Limited Only by External Components, Ideal for 24V Nominal Input Voltage
LTC <sup>®</sup> 1871/LTC1871-1 LTC1871-7	No R <sub>SENSE</sub> ™ Low Quiescent Current Flyback, Boost and SEPIC Controllers	Adjustable Switching Frequency, $2.5V \le V_{IN} \le 36V$ , Burst Mode $^{\odot}$ Operation at Light Loads
LTC3803/LTC3803-3 LTC3803-5	200kHz or 300kHz Flyback DC/DC Controllers	V <sub>IN</sub> and V <sub>OUT</sub> Limited Only by External Components, 6-Pin ThinSOT™ Package
LTC3873/LTC3873-5	No R <sub>SENSE</sub> Constant Frequency Flyback, Boost, SEPIC Controllers	$V_{\text{IN}}$ and $V_{\text{OUT}}$ Limited Only by External Components, 2mm $\times$ 3mm DFN-8 or 8-Pin ThinSOT Packages
LTC3805/LTC3805-5	Adjustable Fixed 70kHz to 700kHz Operating Frequency Flyback Controllers	$V_{\text{IN}}$ and $V_{\text{OUT}}$ Limited Only by External Components, 3mm $\times$ 3mm DFN-10, MSOP-10E
