### MAX20011G Evaluation Kit

#### **General Description**

The MAX20011G EV kit is a fully assembled and tested PCB intended to demonstrate the capability of the MAX20011G step-down (buck) voltage regulator. The MAX20011G has an output current rating of 16A. The IC operates at 3V to 5.5V input supply voltage and can regulate to a voltage range of 0.5V to 1.275V.

The MAX20011G features a 2.2MHz fixed-frequency PWM mode for better noise immunity and load transient response. The 2.2MHz frequency operation allows for the use of all ceramic capacitors and minimizes external components. The spread-spectrum frequency modulation option minimizes radiated electromagnetic emissions. Integrated low  $R_{DS(ON)}$  switches improve efficiency at heavy loads and simplify the layout.

The MAX20011G is offered with factory-preset output voltage. The I<sup>2</sup>C interface supports dynamic voltage adjustment with programmable slew rates. Other features include programmable soft-start, over-current, and over-temperature protections.

#### **Features**

- High Efficiency DC-DC Converter
- Up to 16A Peak Output Current
- Differential Remote Voltage Sensing
- 3.0V to 5.5V Operating Supply Voltage
- I<sup>2</sup>C Controlled Output Voltage:
- 0.5V to 1.275V in 6.25mV Steps
- Excellent Load Transient Performance
- Programmable Compensation
- 2.2MHz or 1.1MHz Operation
- Loop Measurements Ready
- Proven PCB Layout
- Fully Assembled and Tested

#### **Quick Start**

#### **Required Equipment**

- MAX20011G EV kit
- 8V, 20A power supply
- Appropriate resistive load, or an electronic load
- Voltmeters
- Ammeter

#### Procedure

The EV kit comes fully assembled and tested. Follow the steps below to verify board operation:

- 1) Connect a 5V power supply to PV (TP1) and GND (TP2). Activate the supply.
- 2) Verify that RESET is at logic-low level (J8).
- 3) Populate jumper (J5) between EN and PV to activate the output.
- 4) Measure the output voltage at the sense point (J10).
- 5) Connect appropriate load between banana jacks TP3 (VOUT) and TP4 (GND).
- 6) Verify that the output voltage at the sense point (J10) remains within specification.
- 7) Verify that RESET is at logic-high level (J8).

Ordering Information appears at end of data sheet.

#### **Detailed Description of Hardware**

#### **EV Kit Interface**

The banana jacks TP1 (PV) and TP2 (GND) are the main input power supply points on the board. Connect a 5V power supply across these connectors. Use J32 (PV) as a test point for monitoring the input power supply. The banana jacks TP3 (VOUT) and TP4 (GND) serve as outputs to an external load. The MAX20011G's enable signal (EN) is activated (pulled up) by a jumper placed across the EN and PV pins on jumper J5. The enable signal (EN) is monitored at test point J2, and the power-good signal (RESETB) is monitored at test point J8. Connector J1 provides I2C communication connectivity. Use test points J27 (Bode+), J28 (Bode-) for loop measurements, and J10 for measuring output voltage at the sense point. (Use a differential probe for ripple and transient measurements.) During efficiency measurement, use test points J32 (PV) and J13 (GND) for measuring input voltage. The output test point (J12) and GND test points (J22, J29, J31) provide additional flexibility in monitoring the evaluation environment. For explicit information on how these jumpers and test points interact with the EV kit circuitry, see the MAX20011G EV Kit Schematic.

#### I<sup>2</sup>C Communication and PEC

The MAX20011G EV kit is designed to be used with an I<sup>2</sup>C interface such as the MINIQUSB or MAXPICO2MINIQ board and a PC software that can read and write to the

device like SimpleI2C. The IC has a packet error checking (PEC) feature. This option can be disabled through CONFIG register 0x05, bit 7 (PEC). In order to write to a register when the PEC is enabled, the I<sup>2</sup>C transaction must be followed by a PEC byte. The SimpleI2C software simplifies this process by providing a PEC enable setting.

#### **Evaluating IC Capabilities**

The default device on the board is the MAX20011G, a 16A device. Use the input and output connections described above to apply the input supply voltage and draw the appropriate current from the regulator while monitoring the output voltage at test point J10. The test point J10 provides a voltage readout at a remote sense point located at the output capacitor. This makes J10 suitable for taking output voltage ripple and transient measurements (using a differential probe) and for taking efficiency measurements (using a voltmeter). When measuring efficiency, connect a voltmeter to J32 for input voltage measurements. J4 allows an external synchronization pulse to be applied to the device's SYNC pin. Use the 50% duty cycle for the square wave. Loop measurements are made using J27 (bode+) and J28 (bode-). Inject the sinusoidal signal across the bode+ and bode- pins when measuring the gain and phase of the closed loop.

For  $I^2C$  communication specifics, please refer to the MAX20011G data sheet.

## Evaluates: MAX20011G

JUMPER	SIGNAL	DEFAULT POSITION	FUNCTION
J1	NA	NA	I <sup>2</sup> C communication connections
J2	EN	NA	Test point for monitoring the device enable (EN) signal
J3	SYNC	NA	Test point for monitoring the device sync (SYNC) signal
J4	SYNC	NA	Connection point for apply an external synchronization signal
J5	EN	OFF	Jumper for activating the device enable (EN) signal
J8	RESETB	NA	Test point for monitoring the device power-good (RESET) signal
J10	RS+	NA	Test point for measuring output voltage at the sense point
J12	VOUT	NA	Test point for output voltage
J13	GND	NA	Ground test point (see MAX20011G EV Kit Schematic)
J22	GND	NA	Ground test point (see MAX20011G EV Kit Schematic)
GND	GND	NA	Ground test point (see MAX20011G EV Kit Schematic)
