

## General Description

The MAX253 monolithic oscillator/power-driver is specifically designed to provide isolated power for an isolated RS-485 or RS-232 data interface. The device drives a center-tapped transformer primary from a 5V or 3.3V DC power supply. The secondary can be wound to provide any isolated voltage needed at power levels up to 1W.

The MAX253 consists of a CMOS oscillator driving a pair of N-channel power switches. The oscillator runs at double the output frequency, driving a toggle flip-flop to ensure 50% duty cycle to each of the switches. Internal delays are arranged to ensure break-before-make action between the two switches.

The SD pin puts the entire device into a low-power shutdown state, disabling both the power switches and oscillator.

## Applications

Isolated RS-485/RS-232 Power-Supply Transformer Driver  
High Noise-Immunity Communications Interface  
Isolated and/or High-Voltage Power Supplies  
Bridge Ground Differentials  
Medical Equipment  
Process Control

## Benefits and Features

- Simple Power-Supply Transformer Driver Design for Isolated RS-485/RS-232 Data-Interface Applications
  - Single 5V or 3.3V Supply
  - Low-Current Shutdown Mode: 0.4μA
  - Pin-Selectable Frequency: 350kHz or 200kHz
- 8-Pin DIP, SO, and μMAX® Packages Take Minimal Board Space

## Ordering Information

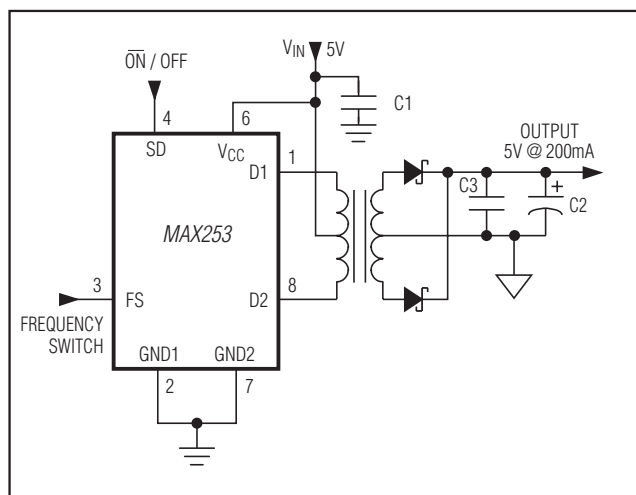

PART	TEMP RANGE	PIN-PACKAGE
MAX253CPA	0°C to +70°C	8 Plastic DIP
MAX253CSA	0°C to +70°C	8 SO
MAX253CUA	0°C to +70°C	8 μMAX
MAX253C/D	0°C to +70°C	Dice*
MAX253EPA	-40°C to +85°C	8 Plastic DIP
MAX253ESA	-40°C to +85°C	8 SO

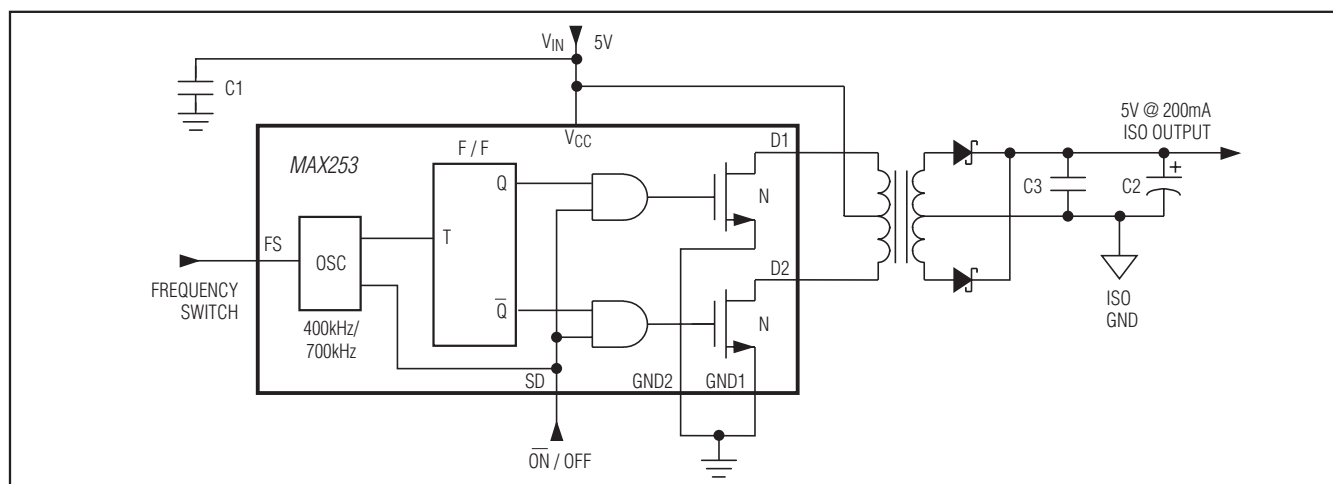

Figure 2. Block Diagram

## Detailed Description

The MAX253 is an isolated power-supply transformer driver specifically designed to form the heart of a fully isolated RS-485 data interface. Completely isolated communications are obtained by combining the MAX253 with a linear regulator, a center-tapped transformer, optocouplers, and the appropriate Maxim interface product (as described in the *Isolated RS-485/RS-232 Data Interface* section).

The MAX253 consists of an RC oscillator followed by a toggle flip-flop, which generates two 50% duty-cycle square waves, out-of-phase at half the oscillator fre-

quency (Figure 2). These two signals drive the ground-referenced output switches. Internal delays ensure break-before-make action between the two switches.

Ground SD for normal operation. When high, SD disables all internal circuitry, including the oscillator and both power switches.

Pulling FS low reduces the oscillator frequency and lowers the supply current (see Supply Current vs. Temperature in the *Typical Operating Characteristics*). FS includes a weak pull-up, so it will be set to the high-frequency state if not connected.

## Transformer Driver for Isolated RS-485 Interface

## Transformer Driver for Isolated RS-485 Interface

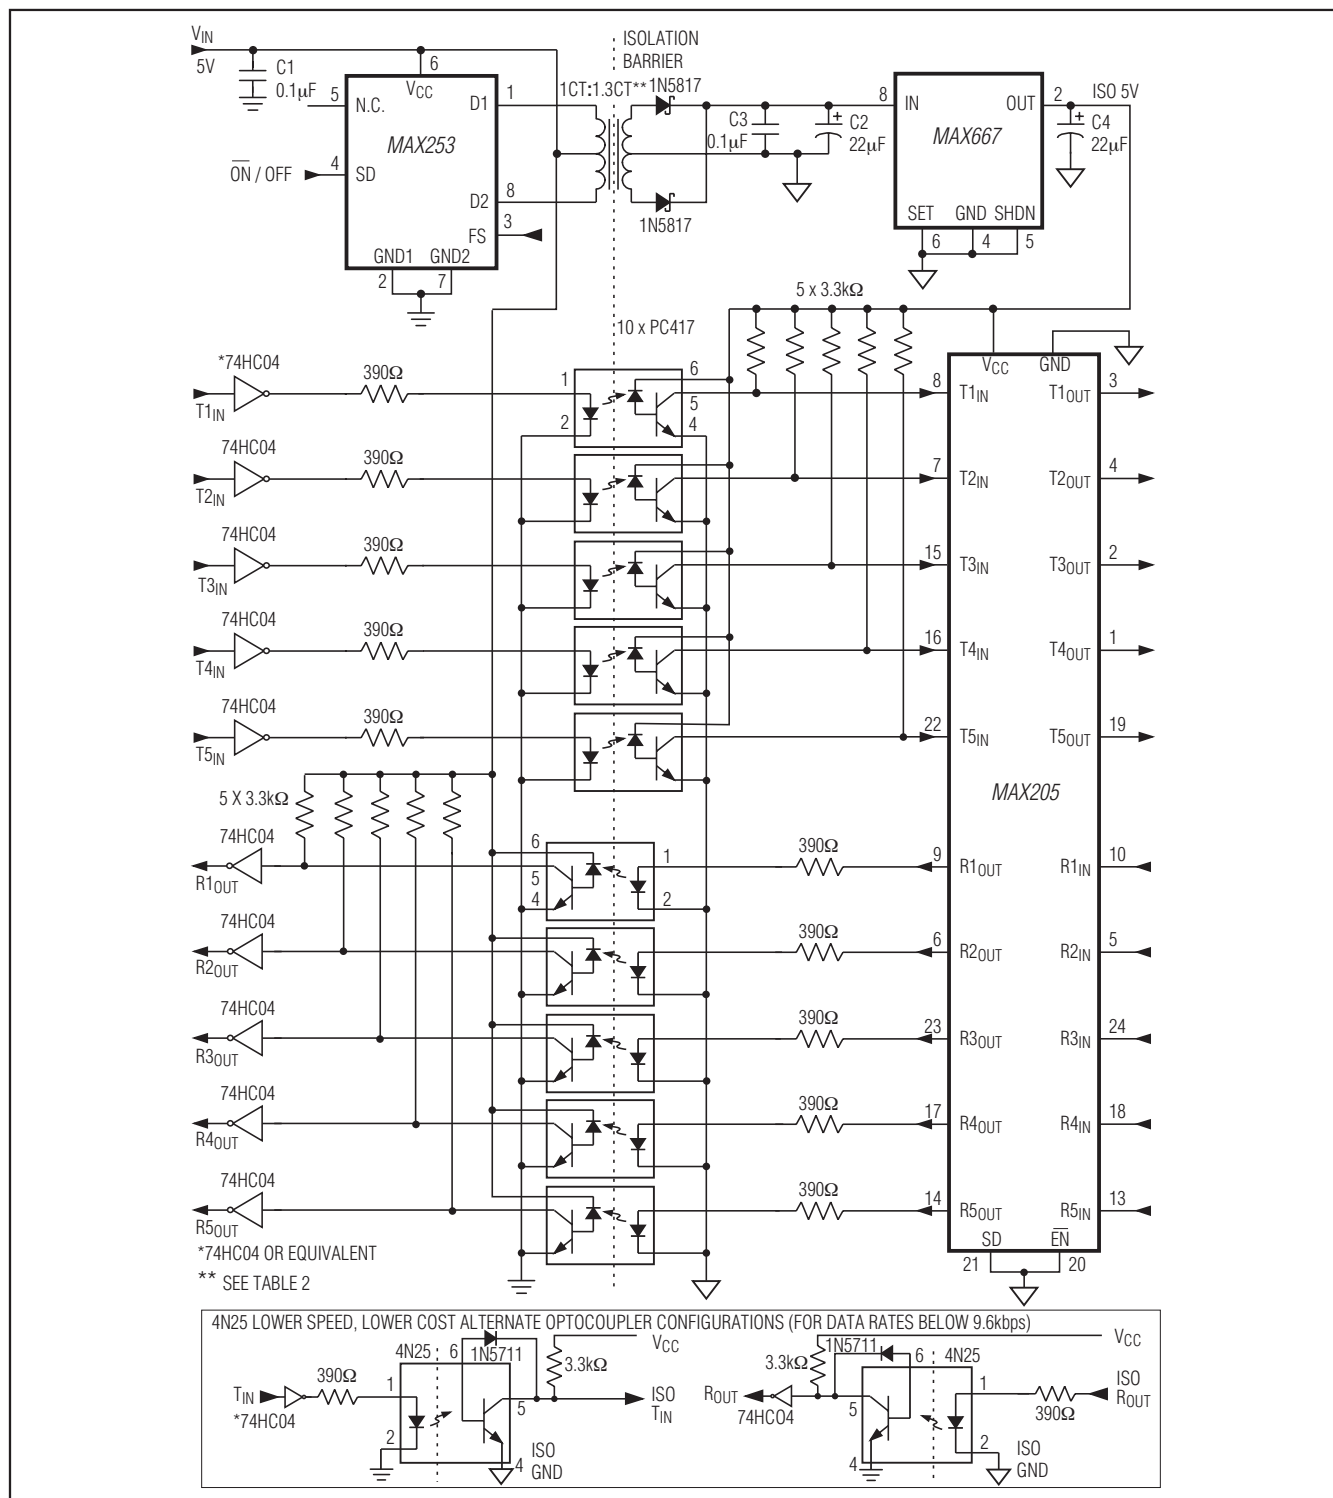

Figure 5. Typical RS-232 Application Circuit

## Applications Information

Figures 3–5 are typical isolated RS-485/RS-232 data-interface circuits. These circuits withstand 1800V<sub>RMS</sub> (1sec) and are intended for industrial communications and control applications where very high voltage transients, differential ground potentials, or high noise may be encountered.

Table 2 lists transformer characteristics for the applications of Figures 3–10. Some suggested manufacturers of transformers, transformer cores, and optocouplers are listed in Table 3, along with their respective phone and fax numbers.

Important layout considerations include:

- ◆ For maximum isolation, the “isolation barrier” should not be breached. Connections and components from one side should not be located near those of the other side.
- ◆ Since the optocoupler outputs are relatively high-impedance nodes, they should be located as close as possible to the Maxim interface IC. This minimizes stray capacitance and maximizes data rate.

Refer to the  $\mu$ MAX package information for pin spacing and physical dimensions.

### Isolated RS-485 Data Interface

The MAX253 power-supply transformer driver is designed specifically for isolated RS-485 data-interface applications. The application circuits of Figures 3 and 4 combine the MAX253 with a low-dropout linear regulator, a transformer, several high-speed optocouplers, and a Maxim RS-485 interface device. With a few modifications to these circuits, full-duplex communications can be implemented by substituting the MAX481/MAX485 with the MAX490/MAX491 (for data rates up to 2.5Mbps) or substituting the MAX483/MAX487 with the MAX488/MAX489 (for data rates up to 250kbps).

The data transfer rates of the application circuits in Figures 3 and 4 are critically limited by the optocouplers. Table 1 lists suggested optocouplers and the

appropriate Maxim interface device for data-transfer rates up to 2.5Mbps.

Refer to the MAX1480 data sheet for a complete isolated RS-485 solution in one package.

### Isolated RS-232 Data Interface

The MAX253 is ideal for isolated RS-232 data-interface applications requiring more than four transceivers. The 1W power output capability of the MAX253 enables it to drive more than 10 transceivers simultaneously. Figure 5 shows the typical application circuit for a complete 120kbps isolated RS-232 data interface. The figure also shows how the Sharp PC417 optocouplers can be replaced by the lower-cost 4N25 devices to achieve data-transfer rates up to 9.6kbps.

For 3.3V operation, substitute the primary portion of Figure 5 with the circuit of Figure 7.

For applications requiring two transceivers or fewer, refer to the MAX250/MAX251 or MAX252 data sheet.

### Isolated Power Supplies

The MAX253 is a versatile isolated power driver, capable of driving a center-tapped transformer primary from a 5V or a 3.3V DC power supply (Figures 6 and 7). The secondary can be wound to provide any isolated voltage needed at power levels up to 1W with a 5V supply, or 600mW with a 3.3V supply. Figure 6 shows a typical 5V to isolated 5V application circuit that delivers up to 200mA of isolated 5V power.

In Figure 7, the MAX253 is configured to operate from a 3.3V supply, deriving a “boost” V<sub>CC</sub> for the MAX253 by connecting diodes to both ends of the transformer primary. This produces nearly double the input supply, and may be useful for other applications, as shown in Figure 4. The average current in each MAX253 switch must still be limited to less than 200mA, so the total power available is approximately 600mW.

**Table 1. Optocouplers and RS-485 Interface ICs for Various Data Rates**

DATA RATE	FULL DUPLEX RS-485 IC	HALF DUPLEX RS-485 IC	OPTOCOUPLER FOR DI / RO	OPTOCOUPLER FOR DE

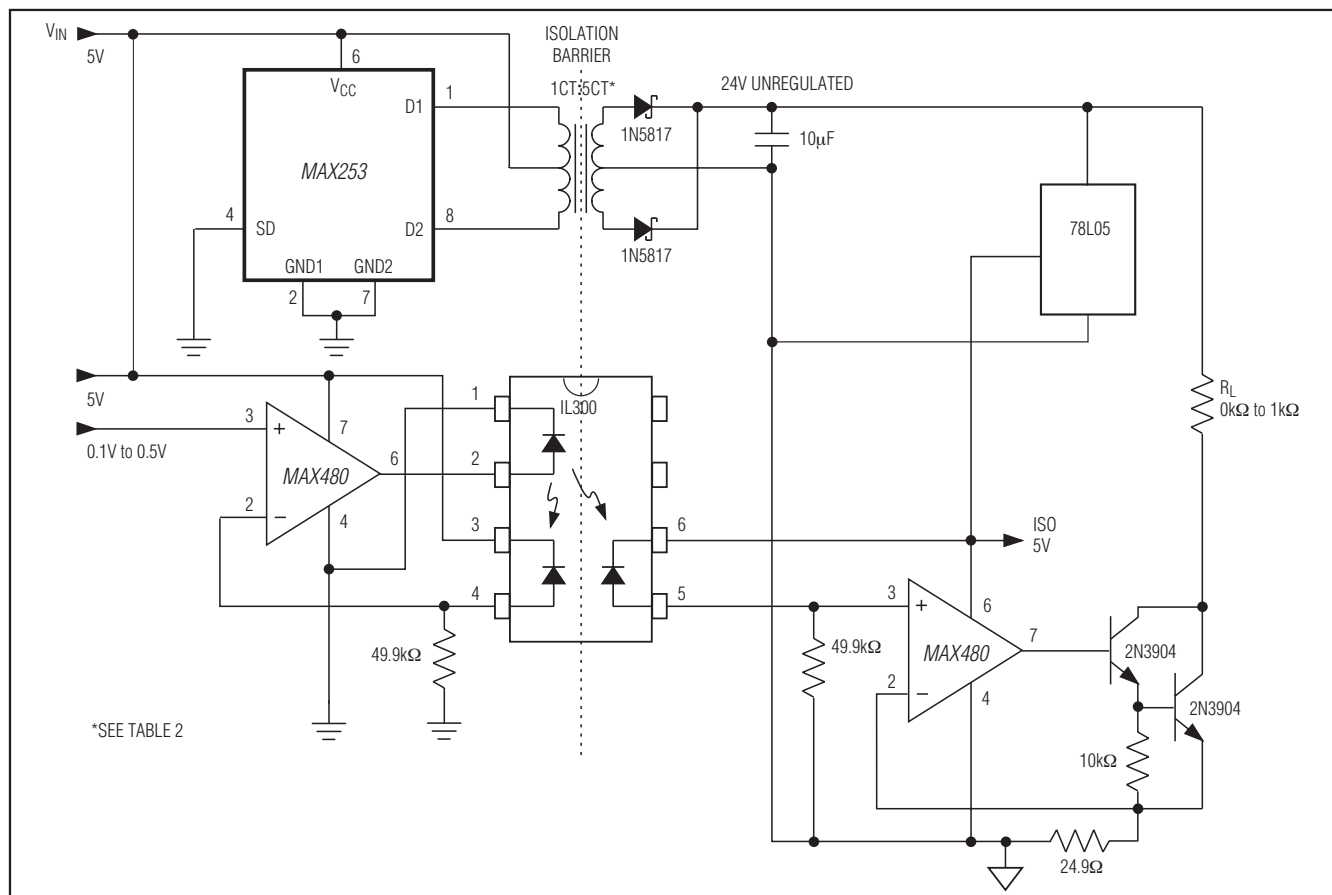

Figure 8. Typical 4mA to 20mA Application Circuit

### Output-Ripple Filtering

A simple lowpass pi-filter (Figures 6 and 7) can be added to the output to reduce output ripple noise to approximately 10mVp-p. The cutoff frequency shown is 21kHz. Since the filter inductor is in series with the circuit output, minimize its resistance so the voltage drop across it is not excessive.

### Isolated 4mA to 20mA Analog Interface

The 4mA to 20mA current loop is a standard analog signal range that is widely used in the process-control industry for transducer and actuator control signals. These signals are commonly referred to a distant ground that may be at a considerably higher voltage with respect to the local ground.

An analog signal in the range of 0.1V to 0.5V is applied to the first MAX480 to generate a signal current in the range of 20µA to 100µA. This low-level signal is transferred across the barrier by the Siemens IL300 linear optocoupler. This device is unique in that it corrects the dominant nonlinearity present in most optocou-

plers—the LED efficiency variation. The IL300 is really two optocouplers in the same package sharing the same LED; one detector is across the isolation barrier, the other is on the same side as the LED (Figure 8). The latter detector is used to generate a feedback signal identical to the signal on the isolated side of the barrier. The current signal transferred across the barrier is converted back to a voltage that matches the input in the 100mV to 500mV range. This voltage is then transformed to the final 4mA to 20mA current signal range by the second MAX480, Darlington stage, and the 20Ω resistor.

### Isolated ADC

Almost any serial-interface device is a candidate for operation across an isolation barrier; Figure 10 illustrates one example. The MAX176 analog-to-digital converter (ADC) operates from 5V and -12V supplies, provided by the multiple-tapped secondary and linear regulators. If some additional isolated power is needed for signal conditioning, multiplexing, or possibly for a

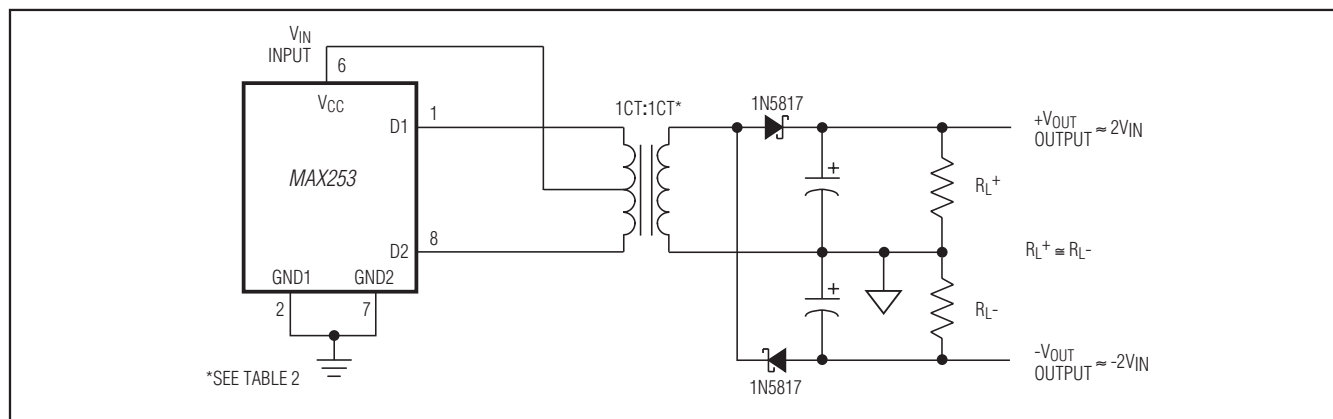

Figure 9a. Half-Wave Rectifier—Bipolar

Figure 9b. Full-Wave Rectifier—Bipolar

Figure 9c. Full-Wave Rectifier—Unipolar

sensor, an extra several hundred milliwatts could easily be supplied by the circuit, as shown. A 12V supply could be generated by adding two more diodes to the ends of the secondary, and a -5V supply could be generated by connecting additional diodes to the 1/4 and 3/4 tap points on the secondary. For 5V only applications, the MAX187 is recommended.

## Component Selection

### Transformer Selection

The transformer primary used with the MAX253 must be a center-tapped winding with sufficient ET product to prevent saturation at the worst-case lowest selected frequency. The MAX253's guaranteed minimum frequency with the FS pin held low is 150kHz, equating to a maximum period of 6.67μs. The required ET product

for half the primary is simply the product of the maximum supply voltage and half the maximum period. With FS connected high, the guaranteed minimum frequency is 250kHz, giving a maximum period of 4μs.

The secondary winding may or may not be center tapped, depending on the rectifier topology used. The phasing of the secondary winding is not critical. In some applications, multiple secondaries might be required. Half-wave rectification could be used, but is discouraged because it normally adds a DC imbalance to the magnetic flux in the core, reducing the ET product. If the DC load is imbalanced, full-wave rectification is recommended, as shown in Figure 9b.

The transformer turns ratio must be set to provide the minimum required output voltage at the maximum anticipated load with the minimum expected input volt-

age. In addition, include in the calculations an allowance for worst-case losses in the rectifiers. Since the turns ratio determined in this manner will ordinarily produce a much higher voltage at the secondary under conditions of high input voltage and/or light loading, be careful to prevent an overvoltage condition from occurring (see Output Voltage vs. Load Current in the *Typical Operating Characteristics*).

Transformers used with the MAX253 will ordinarily be wound on high-permeability magnetic material. To minimize radiated noise, use common closed-magnetic-path physical shapes (e.g., pot cores, toroids, E/I/U cores). A typical core is the Philips 213CT050-3B7, which is a toroid 0.190" in diameter and 0.05" thick. For operation with this core at 5.5V maximum supply voltage, the primary should have approximately 22 turns on each side of the center tap, or 44 turns total. This will result in a nominal primary inductance of approximately 832 $\mu$ H. The secondary can be scaled to produce the required DC output.

### Diode Selection

The MAX253's high switching frequency demands high-speed rectifiers. Schottky diodes are recommended. Ensure that the Schottky diode average current rating exceeds the load-current level. The 1N5817

is a good choice for through-hole applications, and the NIEC\* SB05W05C dual in an SOT-23 package is recommended for surface-mount applications. Use the higher frequency setting to reduce ripple.

### Output Filter Capacitor

In applications sensitive to output-ripple noise, the output filter capacitor C2 should have a low effective series resistance (ESR), and its capacitance should remain fairly constant over temperature. Sprague 595D surface-mount solid tantalum capacitors and Sanyo OS-CON through-hole capacitors are recommended due to their extremely low ESR. Capacitor ESR usually rises at low temperatures, but OS-CON capacitors provide very low ESR below 0°C.

In applications where output ripple is not critical, a 0.1 $\mu$ F chip or ceramic capacitor is sufficient. Refer to Table 4 for suggested capacitor suppliers. Use the higher frequency setting to reduce ripple.

### Input Bypass Capacitor

The input bypass capacitor C1 is not critical. Unlike switching regulators, the MAX253's supply current is fairly constant, and is therefore less dependent on the input bypass capacitor. A low-cost 0.1 $\mu$ F chip or ceramic capacitor is normally sufficient for input bypassing.
