

TMC2208/2 & TMC2224 family Datasheet

TMC2202, TMC2208, TMC2224 Step/Dir Drivers for Two-Phase Bipolar Stepper Motors up to 2A peak - StealthChop™ for Quiet Movement - UART Interface Option.

APPLICATIONS

Compatible Design Upgrade
3D Printers
Printers, POS
Office and home automation
Textile, Sewing Machines
CCTV, Security
ATM, Cash recycler
HVAC

FEATURES AND BENEFITS

2-phase stepper motors up to 2A coil current (peak)
STEP/DIR Interface with 2, 4, 8, 16 or 32 microstep pin setting
Smooth Running 256 microsteps by **MicroPlyer™** interpolation
StealthChop2™ silent motor operation
SpreadCycle™ highly dynamic motor control chopper
Low RDSon LS 280mΩ & HS 290mΩ (typ. at 25°C)
Voltage Range 4.75... 36V DC
Automatic Standby current reduction (option)
Internal Sense Resistor option (no sense resistors required)
Passive Braking and Freewheeling
Single Wire UART & OTP for advanced configuration options
Integrated Pulse Generator for standalone motion
Full Protection & Diagnostics
Choice of QFN and wettable QFN packages for best fit

DESCRIPTION

The TMC2202, TMC2208 and TMC2224 are ultra-silent motor driver ICs for two-phase stepper motors. Their pinning is compatible to a number of legacy drivers. TRINAMICs sophisticated StealthChop2 chopper ensures noiseless operation, maximum efficiency, and best motor torque. Its fast current regulation and optional combination with SpreadCycle allow for highly dynamic motion. Integrated power-MOSFETs handle motor current up to 1.4A RMS. Protection and diagnostic features support robust and reliable operation. A simple to use UART interface opens up more tuning and control options. Application specific tuning can be stored to OTP memory. Industries' most advanced STEP/DIR stepper motor driver family upgrades designs to noiseless and most precise operation for cost-effective and highly competitive solutions.

BLOCK DIAGRAM

APPLICATION EXAMPLES: SIMPLE SOLUTIONS – HIGHLY EFFECTIVE

The TMC22xx family scores with power density, integrated power MOSFETs, smooth and quiet operation, and a congenial simplicity. The TMC22xx covers a wide spectrum of applications from battery systems to embedded applications with up to 2A motor current per coil. TRINAMICs unique chopper modes SpreadCycle and StealthChop2 optimize drive performance. StealthChop reduces motor noise to the point of silence at low velocities. Standby current reduction keeps costs for power dissipation and cooling down. Extensive support enables rapid design cycles and fast time-to-market with competitive products.

STANDALONE REPLACEMENT FOR LEGACY STEPPER DRIVER

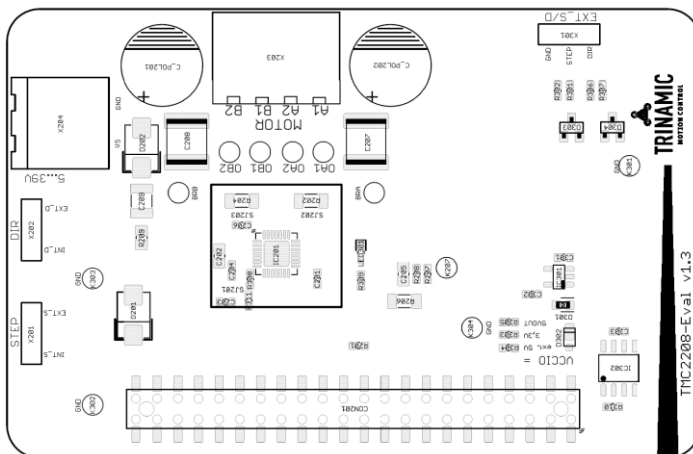

In this example, configuration is hard wired via pins. Software based motion control generates STEP and DIR (direction) signals, INDEX and ERROR signals report back status information.

UART INTERFACE FOR FULL DIAGNOSTICS AND CONTROL

A CPU operates the driver via step and direction signals. It accesses diagnostic information and configures the TMC22xx via the UART interface. The CPU manages motion control and the TMC22xx drives the motor and smoothens and optimizes drive performance.

TMC2208-EVAL EVALUATION BOARD

The TMC22xx-EVAL is part of TRINAMICs universal evaluation board system which provides a convenient handling of the hardware as well as a user-friendly software tool for evaluation. The TMC22xx evaluation board system consists of three parts: LANDUNGSBRÜCKE (base board), ESELSBRÜCKE (connector board with test points), and TMC22xx-EVAL.

ORDER CODES

Order code	Description	Size [mm²]
TMC2202-WA	Stepper Motor Driver/Controller IC, Step/Dir, UART, 4.75-36V, 1.4A, QFN32, Tray	5 x 5
TMC2202-WA-T	Stepper Motor Driver/Controller IC, Step/Dir, UART, 4.75-36V, 1.4A, QFN32, Tape & Reel	5 x 5
TMC2208-LA	Stepper Motor Driver IC, Step/Dir, UART, 4.75-36V Supply, 1.4A, QFN28, Tray	5 x 5
TMC2208-LA-T	Stepper Motor Driver IC, Step/Dir, UART, 4.75-36V Supply, 1.4A, QFN28, Tape & Reel	5 x 5
TMC2208-EVAL-KIT	Full Evaluation Kit for TMC2208	126 x 85
TMC2208-EVAL	Evaluation Board for TMC2208 (excl. Landungsbrücke and Eselsbrücke)	85 x 55
TMC2208 SilentStepStick	Step Direction Driver Board with TMC2208	20 x 15
TMC2224-LA	Stepper Motor Driver IC, Step/Dir, UART, 4.75-36V Supply, 1.4A, QFN28, Tray	5 x 5
TMC2224-LA-T	Stepper Motor Driver IC, Step/Dir, UART, 4.75-36V Supply, 1.4A, QFN28, Tape & Reel	5 x 5
TMC2224-EVAL-KIT	Full Evaluation Kit for TMC2224	126 x 85
TMC2224-EVAL	Evaluation Board for TMC2224 (excl. Landungsbrücke and Eselsbrücke)	85 x 55

1 Principles of Operation

The TMC22xx family of stepper drivers is intended as a drop-in upgrade for existing low-cost stepper driver applications. Its silent drive technology StealthChop enables non-bugging motion control for home and office applications. A highly efficient power stage enables high current from a tiny package. The TMC22xx requires just a few control pins on its tiny package. They allow selection of the most important setting: the desired microstep resolution. A choice of 2, 4, 8, 16 or 32 microsteps adapts the driver to the capabilities of the motion controller. Some package options also allow chopper mode selection by pin.

Even at low microstepping rate, the TMC22xx offers a number of unique enhancements over comparable products: TRINAMICs sophisticated StealthChop2 chopper plus the microstep enhancement MicroPlyer ensure noiseless operation, maximum efficiency and best motor torque. Its fast current regulation and optional combination with SpreadCycle allow for highly dynamic motion. Protection and diagnostic features support robust and reliable operation. A simple-to-use 8 bit UART interface opens up more tuning and control options. Application specific tuning can be stored to on-chip OTP memory. Industries' most advanced step & direction stepper motor driver family upgrades designs to noiseless and most precise operation for cost-effective and highly competitive solutions.

Figure 1.1 TMC22xx basic application block diagram

THREE MODES OF OPERATION:

OPTION 1: Standalone STEP/DIR Driver (Legacy Mode)

A CPU (μ C) generates step & direction signals synchronized to additional motors and other components within the system. The TMC22xx operates the motor as commanded by the configuration pins and STEP/DIR signals. Motor run current either is fixed or set by the CPU using the analog input VREF. The pin PDN_UART selects automatic standstill current reduction. Feedback from the driver to the CPU is granted by the INDEX and DIAG output signals. Enable or disable the motor using the ENN pin.

OPTION 2: Standalone STEP/DIR Driver with OTP pre-configuration

Additional options enabled by pre-programming OTP memory (label UART & OTP):

- + Tuning of the chopper to the application for application tailored performance
- + Cost reduction by switching the driver to internal sense resistor mode
- + Adapting the automatic power down level and timing for best application efficiency

Figure 1.2 Stand-alone driver with pre-configuration

To enable the additional options, either one-time program the driver's OTP memory, or store configuration in the CPU and transfer it to the on-chip registers following each power-up. Operation uses the same signals as Option 1. Programming does not need to be done within the application - it can be executed during testing of the PCB! Alternatively, use bit-banging by CPU firmware to configure the driver. Multiple drivers can be programmed at the same time using a single TXD line.

OPTION 3: STEP/DIR Driver with Full Diagnostics and Control

Similar to Option 2, but pin PDN_UART is connected to the CPU UART interface.

Additional options (label UART):

- + Detailed diagnostics and thermal management
- + Passive braking and freewheeling for flexible, lowest power stop modes
- + More options for microstep resolution setting (fullstep to 256 microstep)
- + Software controlled motor current setting and more chopper options

This mode allows replacing all control lines like ENN, DIAG, INDEX, MS1, MS2, and analog current setting VREF by a single interface line. This way, only three signals are required for full control: STEP, DIR and PDN_UART. Even motion without external STEP pulses is provided by an internal programmable step pulse generator: Just set the desired motor velocity. However, no ramping is provided by the TMC22xx. Access to multiple driver ICs is possible using an analog multiplexer IC.

1.1 Key Concepts

The TMC22xx implements advanced features which are exclusive to TRINAMIC products. These features contribute toward greater precision, greater energy efficiency, higher reliability, smoother motion, and cooler operation in many stepper motor applications.

StealthChop2™ No-noise, high-precision chopper algorithm for inaudible motion and inaudible standstill of the motor. Allows faster motor acceleration and deceleration than StealthChop™ and extends StealthChop to low stand still motor currents.

SpreadCycle™ High-precision cycle-by-cycle current control algorithm for highest dynamic movements.

MicroPlyer™ Microstep interpolator for obtaining full 256 microstep smoothness with lower resolution step inputs starting from fullstep

In addition to these performance enhancements, TRINAMIC motor drivers offer safeguards to detect and protect against shorted outputs, output open-circuit, overtemperature, and undervoltage conditions for enhancing safety and recovery from equipment malfunctions.

1.2 Control Interfaces

The TMC22xx supports both, discrete control lines for basic mode selection and a UART based single wire interface with CRC checking. The UART interface automatically becomes enabled when correct UART data is sent. When using UART, the pin selection may be disabled by control bits.

1.2.1 UART Interface

The single wire interface allows unidirectional operation (for parameter setting only), or bi-directional operation for full control and diagnostics. It can be driven by any standard microcontroller UART or even by bit banging in software. Baud rates from 9600 Baud to 500k Baud or even higher (when using an external clock) may be used. No baud rate configuration is required, as the TMC22xx automatically adapts to the masters' baud rate. The frame format is identical to the intelligent TRINAMIC controller & driver ICs TMC5130 and TMC5072. A CRC checksum allows data transmission over longer distance. For fixed initialization sequences, store the data including CRC into the μ C, thus consuming only a few 100 bytes of code for a full initialization. CRC may be ignored during read access, if not desired. This makes CRC use an optional feature! The IC has a fixed address. Multiple drivers can be programmed in parallel by tying together all interface pins, in case no read access is required. An optional addressing can be provided by analog multiplexers, like 74HC4066.

From a software point of view the TMC22xx is a peripheral with a number of control and status registers. Most of them can either be written only or are read only. Some of the registers allow both, read and write access. In case read-modify-write access is desired for a write only register, a shadow register can be realized in master software.

1.3 Moving and Controlling the Motor

1.3.1 STEP/DIR Interface

The motor is controlled by a step and direction input. Active edges on the STEP input can be rising edges or both rising and falling edges as controlled by a special mode bit (DEDGE). Using both edges cuts the toggle rate of the STEP signal in half, which is useful for communication over slow interfaces such as optically isolated interfaces. The state sampled from the DIR input upon an active STEP edge determines whether to step forward or back. Each step can be a fullstep or a microstep, in which there are 2, 4, 8, 16, 32, 64, 128, or 256 microsteps per fullstep. A step impulse with a low state on DIR increases the microstep counter and a high state decreases the counter by an amount controlled by the microstep resolution. An internal table translates the counter value into the sine and cosine values which control the motor current for microstepping.

1.3.2 Internal Step Pulse Generator

Some applications do not require a precisely co-ordinate motion – the motor just is required to move for a certain time and at a certain velocity. The TMC22xx comes with an internal pulse generator for these applications: Just provide the velocity via UART interface to move the motor. The velocity sign automatically controls the direction of the motion. However, the pulse generator does not integrate a ramping function. Motion at higher velocities will require ramping up and ramping down the velocity value via software.

STEP/DIR mode and internal pulse generator mode can be mixed in an application!

1.4 StealthChop2 & SpreadCycle Driver

StealthChop is a voltage chopper based principle. It especially guarantees that the motor is absolutely quiet in standstill and in slow motion, except for noise generated by ball bearings. Unlike other voltage mode choppers, StealthChop2 does not require any configuration. It automatically learns the best settings during the first motion after power up and further optimizes the settings in subsequent motions. An initial homing sequence is sufficient for learning. Optionally, initial learning parameters can be stored to OTP. StealthChop2 allows high motor dynamics, by reacting at once to a change of motor velocity.

For highest velocity applications, SpreadCycle is an option to StealthChop2. It can be enabled via input pin (TMC222x) or via UART and OTP. StealthChop2 and SpreadCycle may even be used in a combined configuration for the best of both worlds: StealthChop2 for no-noise stand still, silent and smooth performance, SpreadCycle at higher velocity for high dynamics and highest peak velocity at low vibration.

SpreadCycle is an advanced cycle-by-cycle chopper mode. It offers smooth operation and good resonance dampening over a wide range of speed and load. The SpreadCycle chopper scheme automatically integrates and tunes fast decay cycles to guarantee smooth zero crossing performance.

Benefits of using StealthChop2:

- Significantly improved microstepping with low-cost motors
- Motor runs smooth and quiet
- Absolutely no standby noise
- Reduced mechanical resonance yields improved torque

1.5 Precise clock generator and CLK input

The TMC22xx provides a factory trimmed internal clock generator for precise chopper frequency and performance. However, an optional external clock input is available for cases, where quartz precision is desired, or where a lower or higher frequency is required. For safety, the clock input features timeout detection, and switches back to internal clock upon fail of the external source.

1.6 Automatic Standstill Power Down

An automatic current reduction drastically reduces application power dissipation and cooling requirements. Per default, the stand still current reduction is enabled by pulling PDN_UART input to GND. It reduces standstill power dissipation to less than 33% by going to slightly more than half of the run current.

Modify stand still current, delay time and decay via UART, or pre-programmed via internal OTP. Automatic freewheeling and passive motor braking are provided as an option for stand still. Passive braking reduces motor standstill power consumption to zero, while still providing effective dampening and braking!

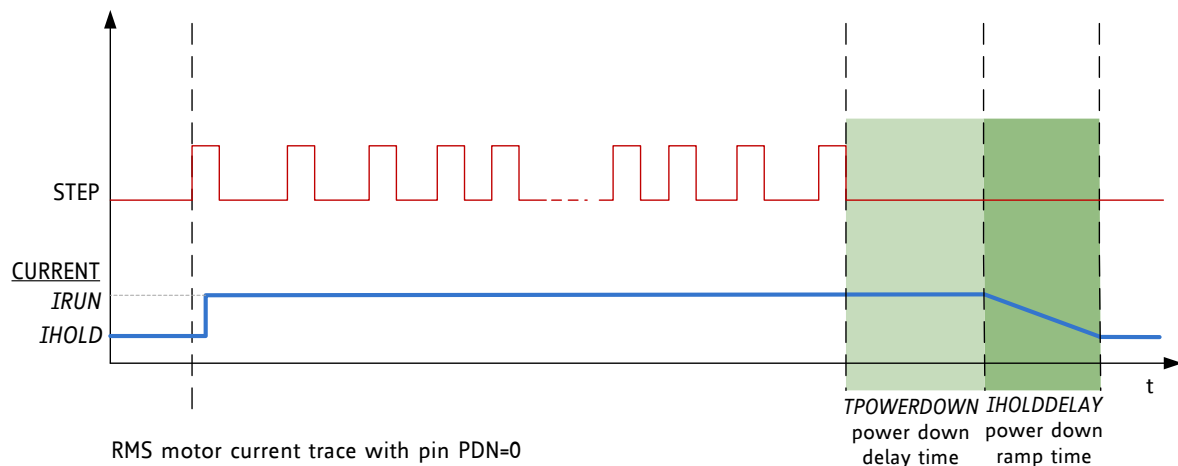

Figure 1.3 Automatic Motor Current Power Down

1.7 Index Output

The index output gives one pulse per electrical rotation, i.e. one pulse per each four fullsteps. It shows the internal sequencer microstep 0 position ($MSTEP$ near 0). This is the power on position. In combination with a mechanical home switch, a more precise homing is enabled.

2 Pin Assignments

The TMC22xx family comes in a number of package variants in order to fit different footprints. Please check for availability.

2.1 Package Outline TMC2208

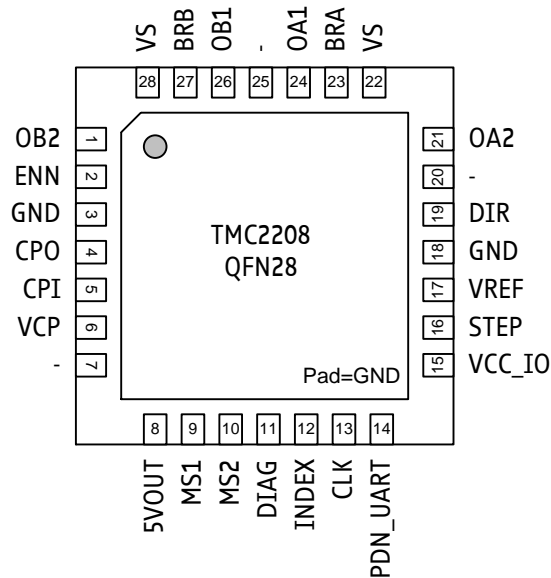

Figure 2.1 TMC2208 Pinning Top View – type: QFN28, 5x5mm², 0.5mm pitch

2.2 Signal Descriptions TMC2208

Pin	Number	Type	Function
OB2	1		Motor coil B output 2
ENN	2	DI	Enable not input. The power stage becomes switched off (all motor outputs floating) when this pin becomes driven to a high level.
GND	3, 18		GND. Connect to GND plane near pin.
CPO	4		Charge pump capacitor output.
CPI	5		Charge pump capacitor input. Tie to CPO using 22nF 50V capacitor.
VCP	6		Charge pump voltage. Tie to VS using 100nF capacitor.
N.C.	7, 20, 25		Unused pin, leave open or connect to GND for compatibility to future versions.
5VOUT	8		Output of internal 5V regulator. Attach 2.2μF to 4.7μF ceramic capacitor to GND near to pin for best performance. Provide the shortest possible loop to the GND pad.
MS1	9	DI (pd)	Microstep resolution configuration (internal pull-down resistors) MS2, MS1: 00: 1/8, 01: 1/2, 10: 1/4 11: 1/16
MS2	10	DI (pd)	
DIAG	11	DO	Diagnostic output. Hi level upon driver error. Reset by ENN=high.
INDEX	12	DO	Configurable index output. Provides index pulse.
CLK	13	DI	CLK input. Tie to GND using short wire for internal clock or supply external clock.
PDN_UART	14	DIO	Power down not control input (low = automatic standstill current reduction). Optional UART Input/Output. Power down function can be disabled in UART mode.
VCC_IO	15		3.3V to 5V IO supply voltage for all digital pins.

Pin	Number	Type	Function
STEP	16	DI	STEP input
VREF	17	AI	Analog reference voltage for current scaling or reference current for use of internal sense resistors (optional mode)
DIR	19	DI (pd)	DIR input (internal pull-down resistor)
VS	22, 28		Motor supply voltage. Provide filtering capacity near pin with shortest possible loop to GND pad.
OA2	21		Motor coil A output 2
BRA	23		Sense resistor connection for coil A. Place sense resistor to GND near pin. Tie to GND when using internal sense resistor.
OA1	24		Motor coil A output 1
OB1	26		Motor coil B output 1
BRB	27		Sense resistor connection for coil B. Place sense resistor to GND near pin. Tie to GND when using internal sense resistor.
Exposed die pad	-		Connect the exposed die pad to a GND plane. Provide as many as possible vias for heat transfer to GND plane. Serves as GND pin for power drivers and analogue circuitry.

2.3 Package Outline TMC2202

Figure 2.2 TMC2202 Pinning Top View – type: QFN32, 5x5mm², 0.5mm pitch

2.4 Signal Descriptions TMC2202

Pin	Number	Type	Function
OB2	1		Motor coil B output 2
N.C.	2, 4, 21, 23, 26, 28, 29, 31		Unused pin, leave open to provide for higher creeping voltage distances.
VS	3, 22		Motor supply voltage. Provide filtering capacity near pin with shortest possible loop to GND pad.
ENN	5	DI	Enable not input. The power stage becomes switched off (all motor outputs floating) when this pin becomes driven to a high level.

Pin	Number	Type	Function
GND	6, 19		GND. Connect to GND plane near pin.
CPO	7		Charge pump capacitor output.
CPI	8		Charge pump capacitor input. Tie to CPO using 22nF 50V capacitor.
VCP	9		Charge pump voltage. Tie to VS using 100nF capacitor.
5VOUT	10		Output of internal 5V regulator. Attach 2.2μF to 4.7μF ceramic capacitor to GND near to pin for best performance. Provide the shortest possible loop to the GND pad.
MS1	11	DI (pd)	Microstep resolution configuration (internal pull-down resistors) MS2, MS1: 00: 1/8, 01: 1/2, 10: 1/4 11: 1/16
MS2	12	DI (pd)	
DIAG	13	DO	Diagnostic output. Hi level upon driver error. Reset by ENN=high.
CLK	14	DI	CLK input. Tie to GND using short wire for internal clock or supply external clock.
PDN_UART	15	DIO	Power down not control input (low = automatic standstill current reduction). Optional UART Input/Output. Power down function can be disabled in UART mode.
VCC_IO	16		3.3V to 5V IO supply voltage for all digital pins.
STEP	17	DI	STEP input
VREF	18	AI	Analog reference voltage for current scaling or reference current for use of internal sense resistors (optional mode)
DIR	20	DI (pd)	DIR input (internal pull-down resistor)
OA2	24		Motor coil A output 2
BRA	25		Sense resistor connection for coil A. Place sense resistor to GND near pin. Tie to GND when using internal sense resistor.
OA1	27		Motor coil A output 1
OB1	30		Motor coil B output 1
BRB	32		Sense resistor connection for coil B. Place sense resistor to GND near pin. Tie to GND when using internal sense resistor.
Exposed die pad	-		Connect the exposed die pad to a GND plane. Provide as many as possible vias for heat transfer to GND plane. Serves as GND pin for power drivers and analogue circuitry.

2.5 Package Outline TMC2224

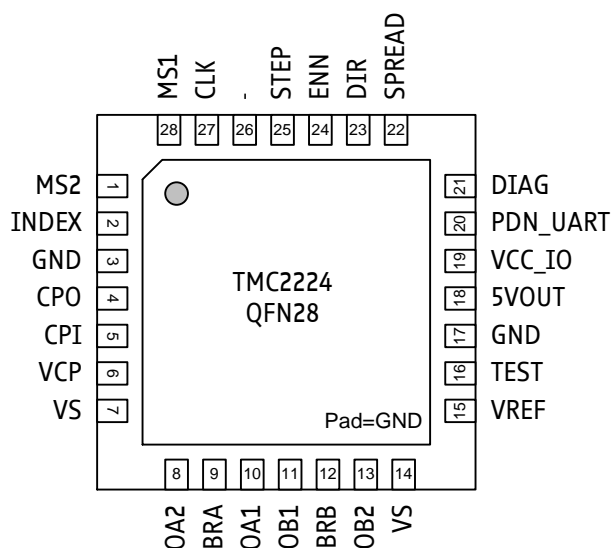

Figure 2.3 TMC2224 Pinning Top View – type: QFN28, 5x5mm², 0.5mm pitch

2.6 Signal Descriptions TMC2224

Pin	Number	Type	Function
MS1	28	DI (pd)	Microstep resolution configuration (internal pull-down resistors) MS2, MS1: 00: 1/4, 01: 1/8, 10: 1/16, 11: 1/32
MS2	1	DI (pd)	
INDEX	2	DO	Configurable index output. Provides index pulse.
GND	3, 17		GND. Connect to GND plane near pin.
CPO	4		Charge pump capacitor output.
CPI	5		Charge pump capacitor input. Tie to CPO using 22nF 50V capacitor.
VCP	6		Charge pump voltage. Tie to VS using 100nF capacitor.
VS	7, 14		Motor supply voltage. Provide filtering capacity near pin with shortest possible loop to GND pad.
OA2	8		Motor coil A output 2
BRA	9		Sense resistor connection for coil A. Place sense resistor to GND near pin. Tie to GND when using internal sense resistor.
OA1	10		Motor coil A output 1
OB1	11		Motor coil B output 1
BRB	12		Sense resistor connection for coil B. Place sense resistor to GND near pin. Tie to GND when using internal sense resistor.
OB2	13		Motor coil B output 2
VREF	15	AI	Analog reference voltage for current scaling or reference current for use of internal sense resistors (optional mode)
TEST	16		Connect to GND. May alternatively be left open or connected to VREF.
5VOUT	18		Output of internal 5V regulator. Attach 2.2µF to 4.7µF ceramic capacitor to GND near to pin for best performance. Provide the shortest possible loop to the GND pad.
VCC_IO	19		3.3V to 5V IO supply voltage for all digital pins (does not power logic block).
PDN_UART	20	DIO (pd)	Power down not control input (low = automatic standstill current reduction). (internal pull-down resistor) Optional UART Input/Output. Power down function can be disabled in UART mode.
DIAG	21	DO	Diagnostic output. Hi level upon driver error. Reset by ENN=high.
SPREAD	22	DI (pd)	Chopper mode selection: Low=StealthChop, High=SpreadCycle
DIR	23	DI (pd)	DIR input (internal pull-down resistor)
ENN	24	DI (pd)	Enable not input. The power stage becomes switched off (all motor outputs floating) when this pin becomes driven to a high level. (internal pull-down resistor)
STEP	25	DI (pd)	STEP input (internal pull-down resistor)
N.C.	26		Unused pin, leave open or connect to GND for compatibility to future versions.
CLK	27	DI	CLK input. Tie to GND using short wire for internal clock or supply external clock.
Exposed die pad	-		Connect the exposed die pad to a GND plane. Provide as many as possible vias for heat transfer to GND plane. Serves as GND pin for power drivers and analogue circuitry.

3 Sample Circuits

The sample circuits show the connection of external components in different operation and supply modes. The connection of the bus interface and further digital signals is left out for clarity.

3.1 Standard Application Circuit

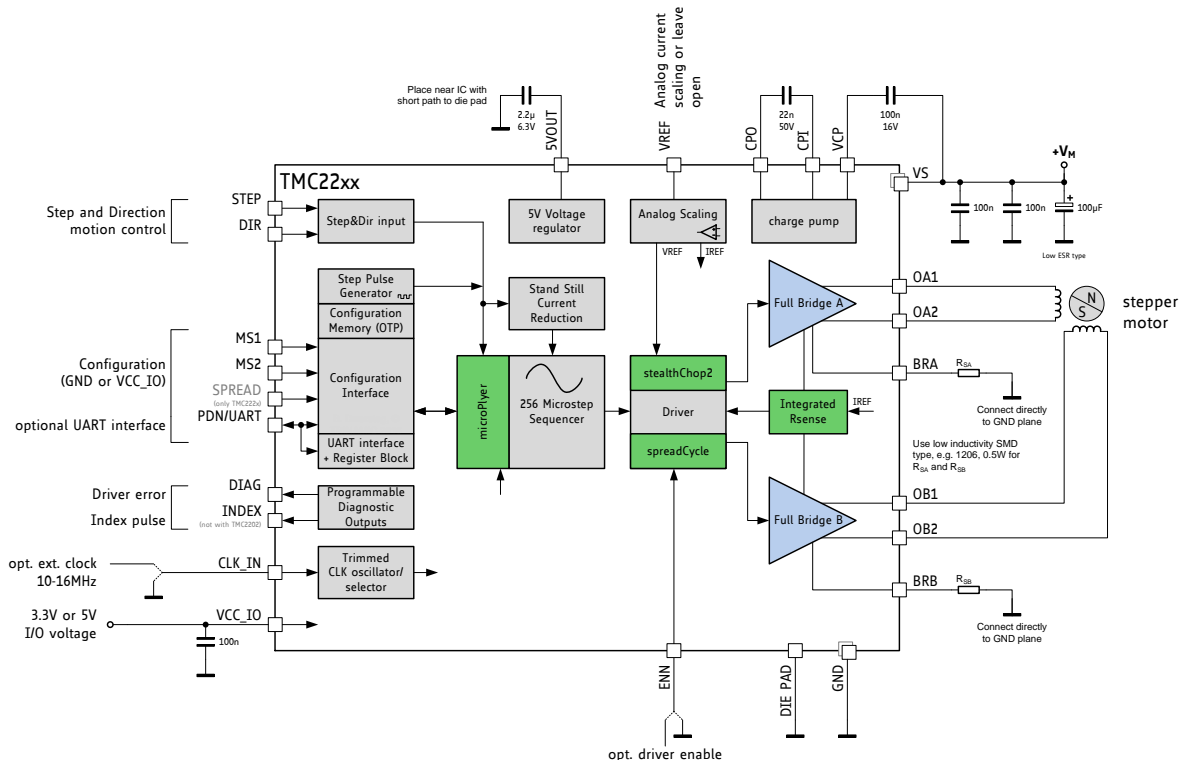

Figure 3.1 Standard application circuit

The standard application circuit uses a minimum set of additional components. Two sense resistors set the motor coil current. See chapter 8 to choose the right sense resistors. Use low ESR capacitors for filtering the power supply. The capacitors need to cope with the current ripple cause by chopper operation. A minimum capacity of 100 μ F near the driver is recommended for best performance. Current ripple in the supply capacitors also depends on the power supply internal resistance and cable length. VCC_IO can be supplied from 5VOUT, or from an external source, e.g. a 3.3V regulator.

Basic layout hints

Place sense resistors and all filter capacitors as close as possible to the related IC pins. Use a solid common GND for all GND connections, also for sense resistor GND. Connect 5VOUT filtering capacitor directly to 5VOUT and the die pad. See layout hints for more details. Low ESR electrolytic capacitors are recommended for VS filtering.

Attention

Ensure sufficient capacity on VS to limit supply ripple, and to keep power slopes below 1V/ μ s. Failure to do so could result in destructive currents via the charge pump capacitor. Provide overvoltage protection in case the motor could be manually turned at a high velocity, or in case the driver could become cut off from the main supply capacitors. Significant energy can be fed back from motor coils to the power supply in the event of quick deceleration, or when the driver becomes disabled.

3.2 Internal RDSon Sensing

For cost critical or space limited applications, sense resistors can be omitted. For internal current sensing, a reference current set by a tiny external resistor programs the output current. For calculation of the reference resistor, refer chapter 9.1.

Attention

Be sure to switch the IC to RDSon mode, before enabling drivers: Set `otp_internalRsense = 1`.

Figure 3.2 Application circuit using RDSon based sensing

3.4 Configuration Pins

The TMC22xx family members provide three or four configuration pins depending on the package option. These pins allow quick configuration for standalone operation. Several additional options can be set by OTP programming. In UART mode, the configuration pins can be disabled in order to set a different configuration via registers.

PDN_UART: CONFIGURATION OF STANDSTILL POWER DOWN	
PDN_UART	Current Setting
GND	Enable automatic power down in standstill periods
VCC_IO	Disable
UART interface	When using the UART interface, the configuration pin should be disabled via <i>GCONF.pdn_disable</i> = 1. Program <i>IHOLD</i> as desired for standstill periods.

OPTIONS FOR TMC220X DEVICES, ONLY:

MS1/MS2: CONFIGURATION OF MICROSTEP RESOLUTION FOR STEP INPUT (TMC220x)		
MS2	MS1	Microstep Setting
GND	GND	8 microsteps
GND	VCC_IO	2 microsteps (half step)
VCC_IO	GND	4 microsteps (quarter step)
VCC_IO	VCC_IO	16 microsteps

OPTIONS FOR TMC222X DEVICES, ONLY:

SPREAD (ONLY WITH TMC222X): SELECTION OF CHOPPER MODE	
SPREAD	Chopper Setting
GND or Pin open / not available	StealthChop is selected. Automatic switching to SpreadCycle in dependence of the step frequency can be programmed via OTP.
VCC_IO	SpreadCycle operation.

MS1/MS2: CONFIGURATION OF MICROSTEP RESOLUTION FOR STEP INPUT (TMC222x)		
MS2	MS1	Microstep Setting
GND	GND	4 microsteps (quarter step)
GND	VCC_IO	8 microsteps
VCC_IO	GND	16 microsteps
VCC_IO	VCC_IO	32 microsteps

3.5 High Motor Current

When operating at a high motor current, the driver power dissipation due to MOSFET switch on-resistance significantly heats up the driver. This power dissipation will significantly heat up the PCB cooling infrastructure, if operated at an increased duty cycle. This in turn leads to a further increase of driver temperature. An increase of temperature by about 100°C increases MOSFET resistance by roughly 50%. This is a typical behavior of MOSFET switches. Therefore, under high duty cycle, high load conditions, thermal characteristics have to be carefully taken into account, especially when increased environment temperatures are to be supported. Refer the thermal characteristics and the layout hints for more information. As a thumb rule, thermal properties of the PCB design become critical for the tiny QFN 5mm x 5mm package at or above 1A RMS motor current for increased periods of time. Keep in mind that resistive power dissipation raises with the square of the motor current. On the other hand, this means that a small reduction of motor current significantly saves heat dissipation and energy.

Pay special attention to good thermal properties of your PCB layout, when going for 1A RMS current or more.

An effect which might be perceived at medium motor velocities and motor sine wave peak currents above roughly 1.4A peak is a slight sine distortion of the current wave when using SpreadCycle. It results from an increasing negative impact of parasitic internal diode conduction, which in turn negatively influences the duration of the fast decay cycle of the SpreadCycle chopper. This is, because the current measurement does not see the full coil current during this phase of the sine wave, because an increasing part of the current flows directly from the power MOSFETs' drain to GND and does not flow through the sense resistor. This effect with most motors does not negatively influence the smoothness of operation, as it does not impact the critical current zero transition. The effect does not occur with StealthChop.

3.6 Driver Protection and EME Circuitry

Some applications have to cope with ESD events caused by motor operation or external influence. Despite ESD circuitry within the driver chips, ESD events occurring during operation can cause a reset or even a destruction of the motor driver, depending on their energy. Especially plastic housings and belt drive systems tend to cause ESD events of several kV. It is best practice to avoid ESD events by attaching all conductive parts, especially the motors themselves to PCB ground, or to apply electrically conductive plastic parts. In addition, the driver can be protected up to a certain degree against ESD events or live plugging / pulling the motor, which also causes high voltages and high currents into the motor connector terminals. A simple scheme uses capacitors at the driver outputs to reduce the dV/dt caused by ESD events. Larger capacitors will bring more benefit concerning ESD suppression, but cause additional current flow in each chopper cycle, and thus increase driver power dissipation, especially at high supply voltages. The values shown are example values – they may be varied between 100pF and 1nF. The capacitors also dampen high frequency noise injected from digital parts of the application PCB circuitry and thus reduce electromagnetic emission. A more elaborate scheme uses LC filters to de-couple the driver outputs from the motor connector. Varistors in between of the coil terminals eliminate coil overvoltage caused by live plugging. Optionally protect all outputs by a varistor to GND against ESD voltage.

Figure 3.4 Simple ESD enhancement and more elaborate motor output protection

4 UART Single Wire Interface

The UART single wire interface allows control of the TMC22xx with any microcontroller UART. It shares transmit and receive line like an RS485 based interface. Data transmission is secured using a cyclic redundancy check, so that increased interface distances (e.g. over cables between two PCBs) can be bridged without danger of wrong or missed commands even in the event of electro-magnetic disturbance. The automatic baud rate detection makes this interface easy to use.

4.1 Datagram Structure

4.1.1 Write Access

UART WRITE ACCESS DATAGRAM STRUCTURE																			
each byte is LSB...MSB, highest byte transmitted first																			
0 ... 63																			
sync + reserved								8 bit node address			RW + 7 bit register addr.			32 bit data			CRC		
0...7								8...15			16...23			24...55			56...63		
1	0	1	0	Reserved (don't cares but included in CRC)				NODEADDR=0			register address	1	data bytes 3, 2, 1, 0 (high to low byte)			CRC			
0	1	2	3	4	5	6	7	8	..	15	16	..	23	24	..	55	56	..	63

A sync nibble precedes each transmission to and from the TMC22xx and is embedded into the first transmitted byte, followed by an addressing byte (0 for TMC22xx). Each transmission allows a synchronization of the internal baud rate divider to the master clock. The actual baud rate is adapted and variations of the internal clock frequency are compensated. Thus, the baud rate can be freely chosen within the valid range. Each transmitted byte starts with a start bit (logic 0, low level on SWIOP) and ends with a stop bit (logic 1, high level on SWIOP). The bit time is calculated by measuring the time from the beginning of start bit (1 to 0 transition) to the end of the sync frame (1 to 0 transition from bit 2 to bit 3). All data is transmitted byte-wise. The 32 bit data words are transmitted with the highest byte first.

A minimum baud rate of 9000 baud is permissible, assuming 20 MHz clock (worst case for low baud rate). Maximum baud rate is $f_{CLK}/16$ due to the required stability of the baud clock.

The node address *NODEADDR* is always 0 for the TMC22xx.

The communication becomes reset if a pause time of longer than 63 bit times between the start bits of two successive bytes occurs. This timing is based on the last correctly received datagram. In this case, the transmission needs to be restarted after a failure recovery time of minimum 12 bit times of bus idle time. This scheme allows the master to reset communication in case of transmission errors. Any pulse on an idle data line below 16 clock cycles will be treated as a glitch and leads to a timeout of 12 bit times, for which the data line must be idle. Other errors like wrong CRC are also treated the same way. This allows a safe re-synchronization of the transmission after any error conditions. Remark, that due to this mechanism an abrupt reduction of the baud rate to less than 15 percent of the previous value is not possible.

Each accepted write datagram becomes acknowledged by the receiver by incrementing an internal cyclic datagram counter (8 bit). Reading out the datagram counter allows the master to check the success of an initialization sequence or single write accesses. Read accesses do not modify the counter.

The UART line must be logic high during idle state. Therefore, the power down function cannot be assigned by the pin PDN_UART in between of transmissions. In an application using the UART interface, set the desired power down function by register access and set *pdn_disable* in GCONF to disable the pin function.

4.1.2 Read Access

UART READ ACCESS REQUEST DATAGRAM STRUCTURE															
each byte is LSB...MSB, highest byte transmitted first															
sync + reserved								8 bit node address			RW + 7 bit register address				CRC
0...7								8...15			16...23				24...31
1	0	1	0	Reserved (don't cares but included in CRC)				NODEADDR=0			register address		0	CRC	
0	1	2	3	4	5	6	7	8	..	15	16	..	23	24	.. 31

The read access request datagram structure is identical to the write access datagram structure but uses a lower number of user bits. Its function is the addressing of the node and the transmission of the desired register address for the read access. The TMC22xx responds with the same baud rate as the master uses for the read request.

In order to ensure a clean bus transition from the master to the node, the TMC22xx does not immediately send the reply to a read access, but it uses a programmable delay time after which the first reply byte becomes sent following a read request. This delay time can be set in multiples of eight bit times using *SENDDelay* time setting (default=8 bit times) according to the needs of the master.

UART READ ACCESS REPLY DATAGRAM STRUCTURE															
each byte is LSB...MSB, highest byte transmitted first															
0 63															
sync + reserved								8 bit master address			RW + 7 bit register addr.		32 bit data		
0...7								8...15			16...23		24...55		
1	0	1	0	reserved (0)				0xFF			register address	0	data bytes 3, 2, 1, 0 (high to low byte)		CRC
0	1	2	3	4	5	6	7	8	..	15	16	..	23	24	.. 55 56 .. 63

The read response is sent to the master using address code %11111111. The transmitter becomes switched inactive four bit times after the last bit is sent.

Address %11111111 is reserved for read access replies going to the master.

4.2 CRC Calculation

An 8 bit CRC polynomial is used for checking both read and write access. It allows detection of up to eight single bit errors. The CRC8-ATM polynomial with an initial value of zero is applied LSB to MSB, including the sync- and addressing byte. The sync nibble is assumed to always be correct. The TMC22xx responds only to correctly transmitted datagrams containing its own node address. It increases its datagram counter for each correctly received write access datagram.

$$CRC = x^8 + x^2 + x^1 + x^0$$

SERIAL CALCULATION EXAMPLE

$CRC = (CRC \ll 1) \text{ OR } (CRC.7 \text{ XOR } CRC.1 \text{ XOR } CRC.0 \text{ XOR } [\text{new incoming bit}])$

C-CODE EXAMPLE FOR CRC CALCULATION

```
void swuart_calcCRC(UCHAR* datagram, UCHAR datagramLength)
{
    int i,j;
    UCHAR* crc = datagram + (datagramLength-1); // CRC located in last byte of message
    UCHAR currentByte;

    *crc = 0;
    for (i=0; i<(datagramLength-1); i++) {        // Execute for all bytes of a message
        currentByte = datagram[i];                // Retrieve a byte to be sent from Array
        for (j=0; j<8; j++) {
            if ((*crc >> 7) ^ (currentByte&0x01)) // update CRC based result of XOR operation
            {
                *crc = (*crc << 1) ^ 0x07;
            }
            else
            {
                *crc = (*crc << 1);
            }
            currentByte = currentByte >> 1;
        } // for CRC bit
    } // for message byte
}
```

4.3 UART Signals

The UART interface on the TMC22xx uses a single bi-direction pin:

UART INTERFACE SIGNAL	
PDN_UART	Non-inverted data input and output. I/O with Schmitt Trigger and VCC_IO level.

The IC checks PDN_UART for correctly received datagrams with its own address continuously. It adapts to the baud rate based on the sync nibble, as described before. In case of a read access, it switches on its output drivers and sends its response using the same baud rate. The output becomes switched off four bit times after transfer of the last stop bit.

Figure 4.1 Attaching the TMC22xx to a microcontroller UART

4.4 Addressing Multiple Nodes

WRITE ONLY ACCESS

If read access is not used, and all nodes are to be programmed with the same initialization values, no addressing is required. All nodes can be programmed in parallel like a single device (Figure 4.1.).

ADDRESSING MULTIPLE NODES

As the TMC22xx uses a fixed UART address, in principle only one IC can be accessed per UART interface channel. Adding analog switches allows separated access to individual ICs. This scheme is similar to an SPI bus with individual node select lines (Figure 4.2).

Figure 4.2 Addressing multiple TMC22xx via single wire interface using analog switches

PROCEED AS FOLLOWS TO CONTROL MULTIPLE NODES:

- Set the UART to 8 bits, no parity. Select a baud rate safely within the valid range. At 250kBaude, a write access transmission requires 320μs (=8 Bytes * (8+2) bits * 4μs).
- Before starting an access, activate the select pin going to the analog switch by setting it high. All other nodes select lines shall be off, unless a broadcast is desired.
- When using the optional buffer, set TMC22xx transmission send delay to an appropriate value allowing the μC to switch off the buffer before receiving reply data.
- To start a transmission, activate the TXD line buffer by setting the control pin low.
- When sending a read access request, switch off the buffer after transmission of the last stop bit is finished.
- Take into account, that all transmitted data also is received by the RXD input.

5 Register Map

This chapter gives an overview of the complete register set. Some of the registers bundling a number of single bits are detailed in extra tables. The functional practical application of the settings is detailed in dedicated chapters.

Note

- *Reset default:* All registers become reset to 0 upon power up, unless otherwise noted.
- Add 0x80 to the address **Addr** for write accesses!

NOTATION OF HEXADECIMAL AND BINARY NUMBERS

0x	precedes a hexadecimal number, e.g. 0x04
%	precedes a multi-bit binary number, e.g. %100

NOTATION OF R/W FIELD

R	Read only
W	Write only
R/W	Read- and writable register
R+C	Clear upon read

OVERVIEW REGISTER MAPPING

REGISTER	DESCRIPTION
General Configuration Registers	These registers contain <ul style="list-style-type: none"> - global configuration - global status flags - OTP read access and programming - interface configuration
Velocity Dependent Driver Feature Control Register Set	This register set offers registers for <ul style="list-style-type: none"> - driver current control, stand still reduction - setting thresholds for different chopper modes - internal pulse generator control
Chopper Register Set	This register set offers registers for <ul style="list-style-type: none"> - optimization of StealthChop2 and SpreadCycle and read out of internal values - passive braking and freewheeling options - driver diagnostics - driver enable / disable

5.1 General Registers

GENERAL CONFIGURATION REGISTERS (0x00...0x0F)				
R/W	Addr	n	Register	Description / bit names
RW	0x00	10	GCONF	Bit GCONF – Global configuration flags
				0 <i>I_scale_analog</i> (Reset default=1) 0: Use internal reference derived from 5VOUT 1: Use voltage supplied to VREF as current reference
				1 <i>internal_Rsense</i> (Reset default: OTP) 0: Operation with external sense resistors 1: Internal sense resistors. Use current supplied into VREF as reference for internal sense resistor. VREF pin internally is driven to GND in this mode.
				2 <i>en_SpreadCycle</i> (Reset default: OTP) 0: StealthChop PWM mode enabled (depending on velocity thresholds). Initially switch from off to on state while in stand still, only. 1: SpreadCycle mode enabled A high level on the pin SPREAD (TMC222x, only) inverts this flag to switch between both chopper modes.
				3 <i>shaft</i> 1: Inverse motor direction
				4 <i>index_otpw</i> 0: INDEX shows the first microstep position of sequencer 1: INDEX pin outputs overtemperature prewarning flag (<i>otpw</i>) instead
				5 <i>index_step</i> 0: INDEX output as selected by <i>index_otpw</i> 1: INDEX output shows step pulses from internal pulse generator (toggle upon each step)
				6 <i>pdn_disable</i> 0: PDN_UART controls standstill current reduction 1: PDN_UART input function disabled. Set this bit, when using the UART interface!
				7 <i>mstep_reg_select</i> 0: Microstep resolution selected by pins MS1, MS2 1: Microstep resolution selected by MSTEP register
				8 <i>multistep_filt</i> (Reset default=1) 0: No filtering of STEP pulses 1: Software pulse generator optimization enabled when fullstep frequency > 750Hz (roughly). <i>TSTEP</i> shows filtered step time values when active.
				9 <i>test_mode</i> 0: Normal operation 1: Enable analog test output on pin ENN (pull-down resistor off), ENN treated as enabled. <i>IHOLD</i> [1..0] selects the function of DCO: 0..2: T120, DAC, VDDH Attention: Not for user, set to 0 for normal operation!

GENERAL CONFIGURATION REGISTERS (0x00...0x0F)					
R/W	Addr	n	Register	Description / bit names	
R+ WC	0x01	3	GSTAT	Bit	GSTAT – Global status flags (Re-Write with '1' bit to clear respective flags)
				0	<i>reset</i> 1: Indicates that the IC has been reset since the last read access to GSTAT. All registers have been cleared to reset values.
				1	<i>drv_err</i> 1: Indicates, that the driver has been shut down due to overtemperature or short circuit detection since the last read access. Read DRV_STATUS for details. The flag can only be cleared when all error conditions are cleared.
				2	<i>uv_cp</i> 1: Indicates an undervoltage on the charge pump. The driver is disabled in this case. This flag is not latched and thus does not need to be cleared.
R	0x02	8	IFCNT		Interface transmission counter. This register becomes incremented with each successful UART interface write access. Read out to check the serial transmission for lost data. Read accesses do not change the content. The counter wraps around from 255 to 0.
W	0x03	4	NODECONF	Bit	NODECONF
				11..8	SENDDelay for read access (time until reply is sent): 0, 1: 8 bit times 2, 3: 3*8 bit times 4, 5: 5*8 bit times 6, 7: 7*8 bit times 8, 9: 9*8 bit times 10, 11: 11*8 bit times 12, 13: 13*8 bit times 14, 15: 15*8 bit times
W	0x04	16	OTP_PROG	Bit	OTP_PROGRAM – OTP programming Write access programs OTP memory (one bit at a time), Read access refreshes read data from OTP after a write
				2..0	<i>OTPBIT</i> Selection of OTP bit to be programmed to the selected byte location (n=0..7: programs bit n to a logic 1)
				5..4	<i>OTPBYTE</i> Selection of OTP programming location (0, 1 or 2)
				15..8	<i>OTPMAGIC</i> Set to 0xbd to enable programming. A programming time of minimum 10ms per bit is recommended (check by reading <i>OTP_READ</i>).
R	0x05	24	OTP_READ	Bit	OTP_READ (Access to OTP memory result and update) <i>See separate table!</i>
				7..0	<i>OTP0</i> byte 0 read data
				15..8	<i>OTP1</i> byte 1 read data
				23..16	<i>OTP2</i> byte 2 read data
R	0x06	10 + 8	IOIN	Bit	INPUT (Reads the state of all input pins available)
				0	ENN (TMC220x)
				1	PDN_UART (TMC222x)
				2	MS1 (TMC220x), SPREAD (TMC222x)
				3	MS2 (TMC220x), DIR (TMC222x)

GENERAL CONFIGURATION REGISTERS (0x00...0x0F)				
R/W	Addr	n	Register	Description / bit names
				4 DIAG (TMC220x), ENN (TMC222x)
				5 STEP (TMC222x)
				6 PDN_UART (TMC220x), MS1 (TMC222x)
				7 STEP (TMC220x), MS2 (TMC222x)
				8 SEL_A: Driver type 1: TMC220x 0: TMC222x
				9 DIR (TMC220x)
				31..24 <i>VERSION</i> : 0x20=first version of the IC Identical numbers mean full digital compatibility.
RW	0x07	5+2	FACTORY_ CONF	4..0 <i>FCLKTRIM</i> (Reset default: OTP) 0...31: Lowest to highest clock frequency. Check at charge pump output. The frequency span is not guaranteed, but it is tested, that tuning to 12MHz internal clock is possible. The devices come preset to 12MHz clock frequency by OTP programming.
				9..8 <i>OTTRIM</i> (Default: OTP) %00: OT=143°C, OTPW=120°C %01: OT=150°C, OTPW=120°C %10: OT=150°C, OTPW=143°C %11: OT=157°C, OTPW=143°C

5.1.1 OTP_READ – OTP configuration memory

The OTP memory holds power up defaults for certain registers. All OTP memory bits are cleared to 0 by default. Programming only can set bits, clearing bits is not possible. Factory tuning of the clock frequency affects *otp0.0* to *otp0.4*. The state of these bits therefore may differ between individual ICs.

0x05: OTP_READ – OTP MEMORY MAP			
Bit	Name	Function	Comment
23	<i>otp2.7</i>	<i>otp_en_SpreadCycle</i>	This flag determines if the driver defaults to <u>SpreadCycle</u> or to <u>StealthChop</u> . <div> <div>0</div> Default: StealthChop (<i>GCONF.en_SpreadCycle</i>=0) OTP 1.0 to 1.7 and 2.0 used for StealthChop SpreadCycle settings: <i>HEND</i>=0; <i>HSTART</i>=5; <i>TOFF</i>=3 <div>1</div> Default: SpreadCycle (<i>GCONF.en_SpreadCycle</i>=1) OTP 1.0 to 1.7 and 2.0 used for SpreadCycle StealthChop settings: <i>PWM_GRAD</i>=0; <i>TPWM_THRS</i>=0; <i>PWM_OFS</i>=36; <i>pwm_autograd</i>=1 </div>
22	<i>otp2.6</i>	<i>OTP_IHOLD</i>	Reset default for standstill current <i>IHOLD</i> (used only if current reduction enabled, e.g. pin PDN_UART low). %00: <i>IHOLD</i> = 16 (53% of <i>IRUN</i>) %01: <i>IHOLD</i> = 2 (9% of <i>IRUN</i>) %10: <i>IHOLD</i> = 8 (28% of <i>IRUN</i>) %11: <i>IHOLD</i> = 24 (78% of <i>IRUN</i>) (Reset default for run current <i>IRUN</i> =31)

5.2 Velocity Dependent Control

VELOCITY DEPENDENT DRIVER FEATURE CONTROL REGISTER SET (0x10...0x1F)					
R/W	Addr	n	Register	Description / bit names	
W	0x10	5 + 5 + 4	IHOLD_IRUN	Bit	IHOLD_IRUN – Driver current control
				4..0	IHOLD (Reset default: OTP) Standstill current (0=1/32 ... 31=32/32) In combination with StealthChop mode, setting IHOLD=0 allows to choose freewheeling or coil short circuit (passive braking) for motor stand still.
				12..8	IRUN (Reset default=31) Motor run current (0=1/32 ... 31=32/32) <i>Hint: Choose sense resistors in a way, that normal IRUN is 16 to 31 for best microstep performance.</i>
				19..16	IHOLDDELAY (Reset default: OTP) Controls the number of clock cycles for motor power down after standstill is detected (stst=1) and TPOWERDOWN has expired. The smooth transition avoids a motor jerk upon power down. 0: instant power down 1..15: Delay per current reduction step in multiple of 2 ¹⁸ clocks
W	0x11	8	TPOWERDOWN	TPOWERDOWN (Reset default=20) Sets the delay time from stand still (stst) detection to motor current power down. Time range is about 0 to 5.6 seconds. $0 \dots ((2^8)-1) * 2^{18} t_{CLK}$ <i>Attention: A minimum setting of 2 is required to allow automatic tuning of StealthChop PWM_OFFSET_AUTO.</i>	
R	0x12	20	TSTEP	Actual measured time between two 1/256 microsteps derived from the step input frequency in units of 1/fCLK. Measured value is (2 ²⁰)-1 in case of overflow or stand still. TSTEP always relates to 1/256 step, independent of the actual MRES. The TSTEP related threshold uses a hysteresis of 1/16 of the compare value to compensate for jitter in the clock or the step frequency: (Txx*15/16)-1 is the lower compare value for each TSTEP based comparison. This means, that the lower switching velocity equals the calculated setting, but the upper switching velocity is higher as defined by the hysteresis setting.	
W	0x13	20	TPWMTHRS	Sets the upper velocity for StealthChop voltage PWM mode. TSTEP ≥ TPWMTHRS - StealthChop PWM mode is enabled, if configured When the velocity exceeds the limit set by TPWMTHRS, the driver switches to SpreadCycle. 0: Disabled	
W	0x22	24	VACTUAL	VACTUAL allows moving the motor by UART control. It gives the motor velocity in $\pm(2^{23})-1$ [μsteps / t] 0: Normal operation. Driver reacts to STEP input. !=0: Motor moves with the velocity given by VACTUAL. Step pulses can be monitored via INDEX output. The motor direction is controlled by the sign of VACTUAL.	

5.3 Sequencer Registers

The sequencer registers have a pure informative character and are read-only. They help for special cases like storing the last motor position before power off in battery powered applications.

MICROSTEPPING CONTROL REGISTER SET (0x60...0x6B)					
R/W	Addr	n	Register	Description / bit names	Range [Unit]
R	0x6A	10	<i>MSCNT</i>	Microstep counter. Indicates actual position in the microstep table for <i>CUR_A</i> . <i>CUR_B</i> uses an offset of 256 into the table. Reading out <i>MSCNT</i> allows determination of the motor position within the electrical wave.	0...1023
R	0x6B	9 + 9	<i>MSCURACT</i>	bit 8... 0: <i>CUR_A</i> (signed): Actual microstep current for motor phase B (sine wave) as read from the internal sine wave table (not scaled by current setting) bit 24... 16: <i>CUR_A</i> (signed): Actual microstep current for motor phase A (co-sine wave) as read from the internal sine wave table (not scaled by current setting)	+/-0...255

5.4 Chopper Control Registers

DRIVER REGISTER SET (0x6C...0x7F)					
R/W	Addr	n	Register	Description / bit names	Range [Unit]
RW	0x6C	32	CHOPCONF	Chopper and driver configuration <i>See separate table!</i>	Reset default= 0x10000053
R	0x6F	32	DRV_STATUS	Driver status flags and current level read back <i>See separate table!</i>	
RW	0x70	22	PWMCONF	StealthChop PWM chopper configuration <i>See separate table!</i>	Reset default= 0xC10D0024
R	0x71	9+8	PWM_SCALE	Results of StealthChop amplitude regulator. These values can be used to monitor automatic PWM amplitude scaling (255=max. voltage).	
				bit 7... 0 PWM_SCALE_SUM: Actual PWM duty cycle. This value is used for scaling the values <i>CUR_A</i> and <i>CUR_B</i> read from the sine wave table.	0...255
				bit 24... 16 PWM_SCALE_AUTO: 9 Bit signed offset added to the calculated PWM duty cycle. This is the result of the automatic amplitude regulation based on current measurement.	signed -255...+255
R	0x72	8+8	PWM_AUTO	These automatically generated values can be read out in order to determine a default / power up setting for <i>PWM_GRAD</i> and <i>PWM_OFS</i> .	
				bit 7... 0 PWM_OFS_AUTO: Automatically determined offset value	0...255
				bit 23... 16 PWM_GRAD_AUTO: Automatically determined gradient value	0...255

6 StealthChop™

StealthChop is an extremely quiet mode of operation for stepper motors. It is based on a voltage mode PWM. In case of standstill and at low velocities, the motor is absolutely noiseless. Thus, StealthChop operated stepper motor applications are very suitable for indoor or home use. The motor operates absolutely free of vibration at low velocities.

With StealthChop, the motor current is applied by driving a certain effective voltage into the coil, using a voltage mode PWM. With the enhanced StealthChop2, the driver automatically adapts to the application for best performance. No more configurations are required. Optional configuration allows for tuning the setting in special cases, or for storing initial values for the automatic adaptation algorithm. For high velocity drives consider SpreadCycle in combination with StealthChop.

Figure 6.1 Motor coil sine wave current with StealthChop (measured with current probe)

6.1 Automatic Tuning

StealthChop2 integrates an automatic tuning procedure (AT), which adapts the most important operating parameters to the motor automatically. This way, StealthChop2 allows high motor dynamics and supports powering down the motor to very low currents. Just two steps have to be respected by the motion controller for best results: Start with the motor in standstill but powered with nominal run current (AT#1). Move the motor at a medium velocity, e.g., as part of a homing procedure (AT#2). Figure 6.2 shows the tuning procedure.

Border conditions in for AT#1 and AT#2 are shown in the following table:

AUTOMATIC TUNING TIMING AND BORDER CONDITIONS			
Step	Parameter	Conditions	Duration
AT#1	<code>PWM_OFS_AUTO</code>	<ul style="list-style-type: none"> - Motor in standstill and actual current scale (CS) is identical to run current (IRUN). - If standstill reduction is enabled (pin PDN_UART=0), provide an initial step pulse to switch the drive to run current. - Pins VS and VREF at operating level. 	$\leq 2^{20} + 2^{21} \cdot 18 \cdot t_{CLK}$ $\leq 130\text{ms}$ (with internal clock)
AT#2	<code>PWM_GRAD_AUTO</code>	<ul style="list-style-type: none"> - Motor must move at a velocity, where a significant amount of back EMF is generated and where the full run current can be reached. Conditions: <ul style="list-style-type: none"> - $1.5 \cdot PWM_OFS_AUTO \cdot (IRUN + 1) / 32 < PWM_SCALE_SUM$ - $PWM_SCALE_SUM < 4 \cdot PWM_OFS_AUTO \cdot (IRUN + 1) / 32$ - $PWM_SCALE_SUM < 255$. <p><i>Hint: A typical range is 60-300 RPM. Determine best conditions with the evaluation board and monitor PWM_SCALE_AUTO going down to zero during tuning.</i></p>	8 fullsteps are required for a change of +/-1. For a typical motor with <code>PWM_GRAD_AUTO</code> optimum at 64 or less, up to 400 fullsteps are required when starting from OTP default 14.

Determine best conditions for automatic tuning with the evaluation board.

Monitor *PWM_SCALE_AUTO* going down to zero during the constant velocity phase in AT#2 tuning. This indicates a successful tuning.

Attention:

Operating in StealthChop without proper tuning can lead to high motor currents during a deceleration ramp, especially with low resistive motors and fast deceleration settings. Follow the automatic tuning process and check optimum tuning conditions using the evaluation board. It is recommended to use an initial value for settings *PWM_OFS* and *PWM_GRAD* determined per motor type. Avoid hard stops from high velocities, even after tuning StealthChop settings. A deceleration ramp is required in each case.

When powering up in StealthChop, make sure that the supply voltage ramps to the final voltage. Powering up to a lower voltage (e.g. 5V) will lead to wrong tuning, in case the motor becomes enabled at the lower voltage. Alternatively disable the motor during power-up.

Known Limitations:

Successful completion of AT#1 tuning phase is not safely detected in all cases. It might require multiple motor start / stop events to safely detect completion.

Successful determination is mandatory for AT#2: Tuning of *PWM_GRAD* will not start when AT#1 has not completed.

Solution a):

Complete automatic tuning phase AT#1 process, by using a slow-motion sequence which leads to standstill detection in between of each two steps. Use a velocity of 8 (6 Hz) or lower and execute minimum 10 steps during AT#1 phase.

Solution b):

Complete automatic tuning phase AT#1 process, by a doing sequence of four or more initial motions (using reduced acceleration, to match the fact that AT#2 has not yet completed) after power up. Make sure, that the driver is at standstill more than 130ms in between of each two motions.

Solution c):

Store application specific *PWM_GRAD* to OTP memory.

Optionally store initial parameters for *PWM_GRAD_AUTO* for the application and initialize by UART interface.

Therefore, use the motor and operating conditions determined for the application and do a complete automatic tuning sequence (refer to *a*). Note the resulting *PWM_GRAD_AUTO* value and use it for initialization of *PWM_GRAD* or program the value to OTP memory. With this, tuning of AT#2 phase is not mandatory in the application and can be skipped. Automatic tuning will optimize settings during further operation. Combine with *a*) if desired.

Figure 6.2 StealthChop2 automatic tuning procedure

Attention

Modifying VREF or the supply voltage VS invalidates the result of the automatic tuning process. Motor current regulation cannot compensate significant changes until next AT#1 phase. Automatic tuning adapts to changed conditions whenever AT#1 and AT#2 conditions are fulfilled in the later operation.

6.2 StealthChop Options

In order to match the motor current to a certain level, the effective PWM voltage becomes scaled depending on the actual motor velocity. Several additional factors influence the required voltage level to drive the motor at the target current: The motor resistance, its back EMF (i.e. directly proportional to its velocity) as well as the actual level of the supply voltage. Two modes of PWM regulation are provided: The automatic tuning mode (AT) using current feedback (*pwm_autoscale* = 1, *pwm_autograd* = 1) and a feed forward velocity-controlled mode (*pwm_autoscale* = 0). The feed forward velocity-controlled mode will not react to a change of the supply voltage or to events like a motor stall, but it provides very stable amplitude. It does not use nor require any means of current measurement. This is perfect when motor type and supply voltage are well known. Therefore, we recommend the automatic mode, unless current regulation is not satisfying in the given operating conditions.

It is recommended to operate in automatic tuning mode for general use.

Half-automatic regulation (*pwm_autograd*=0), or velocity-based scaling (*pwm_autoscale*=0) should be considered only with fixed motor type and supply voltage. In this case, initializing *PWM_GRAD* resp. *PWM_OFs* and *PWM_OFs* via the UART interface is required. The operating parameters can be determined in automatic tuning mode initially. These modes offer reduced PWM amplitude jitter.

Hint: In non-automatic mode the power supply current directly reflects mechanical load on the motor.

The StealthChop PWM frequency can be chosen in four steps to adapt the frequency divider to the frequency of the clock source. A setting in the range of 20-50kHz is good for most applications. It balances low current ripple and good higher velocity performance vs. dynamic power dissipation.

CHOICE OF PWM FREQUENCY FOR STEALTHCHOP				
Clock frequency f_{CLK}	PWM_FREQ=%00 $f_{PWM}=2/1024 f_{CLK}$	PWM_FREQ=%01 $f_{PWM}=2/683 f_{CLK}$ (default)	PWM_FREQ=%10 $f_{PWM}=2/512 f_{CLK}$ (OTP option)	PWM_FREQ=%11 $f_{PWM}=2/410 f_{CLK}$
18MHz	35.2kHz	52.7kHz	70.3kHz	87.8kHz
16MHz	31.3kHz	46.9kHz	62.5kHz	78.0kHz
12MHz (internal)	23.4kHz	35.1kHz	46.9kHz	58.5kHz
10MHz	19.5kHz	29.3kHz	39.1kHz	48.8kHz
8MHz	15.6kHz	23.4kHz	31.2kHz	39.0kHz

Table 6.1 Choice of PWM frequency – green / light green: recommended

6.3 StealthChop Current Regulator

In StealthChop voltage PWM mode, the autoscaling function (*pwm_autoscale* = 1, *pwm_auto_grad* = 1) regulates the motor current to the desired current setting. Automatic scaling is used as part of the automatic tuning process (AT), and for subsequent tracking of changes within the motor parameters. The driver measures the motor current during the chopper on time and uses a proportional regulator to regulate *PWM_SCALE_AUTO* in order match the motor current to the target current. *PWM_REG* is the proportionality coefficient for this regulator. Basically, the proportionality coefficient should be as small as possible in order to get a stable and soft regulation behavior, but it must be large enough to allow the driver to quickly react to changes caused by variation of the motor target current (e.g. change of VREF). During initial tuning step AT#2, *PWM_REG* also compensates for the change of motor velocity. Therefore, a high acceleration during AT#2 will require a higher setting of *PWM_REG*. With careful selection of homing velocity and acceleration, a minimum setting of the regulation gradient often is sufficient (*PWM_REG*=1). *PWM_REG* setting should be optimized for the fastest required acceleration and deceleration ramp (compare Figure 6.3 and Figure 6.4). The quality of the setting *PWM_REG* in phase AT#2 and the finished automatic tuning procedure (or non-automatic settings for *PWM_OFs* and *PWM_GRAD*) can be examined when monitoring motor current during an acceleration phase Figure 6.5.

Figure 6.3 Scope shot: good setting for PWM_REG

Figure 6.4 Scope shot: too small setting for PWM_REG during AT#2

Figure 6.5 Successfully determined PWM_GRAD(AUTO) and PWM_OFS(AUTO)

Quick Start

For a quick start, see the Quick Configuration Guide in chapter 14.

6.3.1 Lower Current Limit

The StealthChop current regulator imposes a lower limit for motor current regulation. As the coil current can be measured in the shunt resistor during chopper on phase only, a minimum chopper duty cycle allowing coil current regulation is given by the blank time as set by *TBL* and by the chopper frequency setting. Therefore, the motor specific minimum coil current in StealthChop autoscaling mode rises with the supply voltage and with the chopper frequency. A lower blanking time allows a lower current limit. It is important for the correct determination of *PWM_OFS_AUTO*, that in AT#1 the run current set by the sense resistor, *VREF* and *IRUN* is well within the regulation range. Lower currents (e.g., for standstill power down) are automatically realized based on *PWM_OFS_AUTO* and *PWM_GRAD_AUTO* respectively based on *PWM_OFS* and *PWM_GRAD* with non-automatic current scaling. The freewheeling option allows going to zero motor current.

Lower motor coil current limit for StealthChop2 automatic tuning:

$$I_{Lower\ Limit} = t_{BLANK} * f_{PWM} * \frac{V_M}{R_{COIL}}$$

With V_M the motor supply voltage and R_{COIL} the motor coil resistance.

$I_{Lower\ Limit}$ can be treated as a thumb value for the minimum nominal *IRUN* motor current setting.

EXAMPLE:

A motor has a coil resistance of 5Ω, the supply voltage is 24V. With *TBL*=%01 and *PWM_FREQ*=%00, t_{BLANK} is 24 clock cycles, f_{PWM} is 2/(1024 clock cycles):

$$I_{Lower\ Limit} = 24 t_{CLK} * \frac{2}{1024 t_{CLK}} * \frac{24V}{5\Omega} = \frac{24}{512} * \frac{24V}{5\Omega} = 225mA$$

This means, the motor target current for automatic tuning must be 225mA or more, taking into account all relevant settings. This lower current limit also applies for modification of the motor current via the analog input *VREF*.

Attention

For automatic tuning, a lower coil current limit applies. The motor current in automatic tuning phase AT#1 must exceed this lower limit. $I_{LOWER\ LIMIT}$ can be calculated or measured using a current probe. Setting the motor run-current or hold-current below the lower current limit during operation by modifying *IRUN* and *IHOLD* is possible after successful automatic tuning.

The lower current limit also limits the capability of the driver to respond to changes of *VREF*.

Attention

For *pwm_autoscale* mode, *IRUN* must not be set below 6 to maintain correct current regulation.

6.4 Velocity Based Scaling

Velocity based scaling scales the StealthChop amplitude based on the time between each two steps (*TSTEP*) measured in clock cycles. This concept basically does not require a current measurement, because no regulation loop is necessary. A pure velocity-based scaling is available via UART programming, only, when setting *pwm_autoscale* = 0. The basic idea is to have a linear approximation of the voltage required to drive the target current into the motor. The stepper motor has a certain coil resistance and thus needs a certain voltage amplitude to yield a target current based on the basic

formula $I=U/R$. With R being the coil resistance, U the supply voltage scaled by the PWM value, the current I results. The initial value for PWM_AMPL can be calculated:

$$PWM_AMPL = \frac{374 * R_{COIL} * I_{COIL}}{V_M}$$

With V_M the motor supply voltage and I_{COIL} the target RMS current

The effective PWM voltage U_{PWM} ($1/\sqrt{2}$ x peak value) results considering the 8 bit resolution and 248 sine wave peak for the actual PWM amplitude shown as PWM_SCALE :

$$U_{PWM} = V_M * \frac{PWM_SCALE}{256} * \frac{248}{256} * \frac{1}{\sqrt{2}} = V_M * \frac{PWM_SCALE}{374}$$

With rising motor velocity, the motor generates an increasing back EMF voltage. The back EMF voltage is proportional to the motor velocity. It reduces the PWM voltage effective at the coil resistance and thus current decreases. The TMC22xx provides a second velocity dependent factor (PWM_GRAD) to compensate for this. The overall effective PWM amplitude (PWM_SCALE_SUM) in this mode automatically is calculated in dependence of the microstep frequency as:

$$PWM_SCALE_SUM = PWM_OFS * \frac{CS_ACTUAL + 1}{32} + PWM_GRAD * 256 * \frac{f_{STEP}}{f_{CLK}}$$

With f_{STEP} being the microstep frequency for 256 microstep resolution equivalent and f_{CLK} the clock frequency supplied to the driver or the actual internal frequency CS_ACTUAL takes into account the actual current scaling as defined by $IHOLD$ and $IRUN$

As a first approximation, the back EMF subtracts from the supply voltage and thus the effective current amplitude decreases. This way, a first approximation for PWM_GRAD setting can be calculated:

$$PWM_GRAD = C_{BEMF} \left[\frac{V}{\frac{rad}{s}} \right] * 2\pi * \frac{f_{CLK} * 1.46}{V_M * MSPR}$$

C_{BEMF} is the back EMF constant of the motor in Volts per radian/second.

$MSPR$ is the number of microsteps per rotation assuming a 256 microstep resolution, e.g., $51200 = 256\mu\text{steps}$ multiplied by 200 fullsteps for a 1.8° motor.

Figure 6.6 Velocity based PWM scaling (pwm_autoscale=0)

Hint

The values for *PWM_OFS* and *PWM_GRAD* can easily be optimized by tracing the motor current with a current probe on the oscilloscope. Alternatively, automatic tuning determines these values, and they can be read out from *PWM_OFS_AUTO* and *PWM_GRAD_AUTO*.

UNDERSTANDING THE BACK EMF CONSTANT OF A MOTOR

The back EMF constant is the voltage a motor generates when turned with a certain velocity. Often motor datasheets do not specify this value, as it can be deducted from motor torque and coil current rating. Within SI units, the numeric value of the back EMF constant C_{BEMF} has the same numeric value as the numeric value of the torque constant. For example, a motor with a torque constant of 1 Nm/A would have a C_{BEMF} of 1V/rad/s. Turning such a motor with 1 rps (1 rps = 1 revolution per second = 6.28 rad/s) generates a back EMF voltage of 6.28V. Thus, the back EMF constant can be calculated as:

$$C_{BEMF} \left[\frac{V}{rad/s} \right] = \frac{HoldingTorque[Nm]}{2 * I_{COILNOM}[A]}$$

$I_{COILNOM}$ is the motor's rated phase current for the specified holding torque

HoldingTorque is the motor specific holding torque, i.e. the torque reached at $I_{COILNOM}$ on both coils. The torque unit is [Nm] where 1Nm = 100Ncm = 1000mNm.

The voltage is valid as RMS voltage per coil, thus the nominal current is multiplied by 2 in this formula, since the nominal current assumes a full step position, with two coils operating.

6.5 Combining StealthChop and SpreadCycle

For applications requiring high velocity motion, SpreadCycle may bring more stable operation in the upper velocity range. To combine no-noise operation with highest dynamic performance, the TMC22xx allows combining StealthChop and SpreadCycle based on a velocity threshold (Figure 6.7). A velocity threshold (*TPWMTHRS*) can be preprogrammed to OTP to support this mode even in standalone operation. With this, StealthChop is only active at low velocities.

Figure 6.7 TPWMTHRS for optional switching to SpreadCycle

As a first step, both chopper principles should be parameterized and optimized individually (SpreadCycle settings may be programmed to OTP memory). In a next step, a transfer velocity has to be fixed. For example, StealthChop operation is used for precise low speed positioning, while SpreadCycle shall be used for highly dynamic motion. *TPWMTHRS* determines the transition velocity. Read out *TSTEP* when moving at the desired velocity and program the resulting value to *TPWMTHRS*. Use a low transfer velocity to avoid a jerk at the switching point.

A jerk occurs when switching at higher velocities, because the back-EMF of the motor (which rises with the velocity) causes a phase shift of up to 90° between motor voltage and motor current. So when switching at higher velocities between voltage PWM and current PWM mode, this jerk will occur with increased intensity. A high jerk may even produce a temporary overcurrent condition (depending on the motor coil resistance). At low velocities (e.g. 1 to a few 10 RPM), it can be completely neglected for most motors. Therefore, consider the switching jerk when choosing *TPWMTHRS*. Set *TPWMTHRS* zero if you want to work with StealthChop only.

When enabling the StealthChop mode the first time using automatic current regulation, the motor must be at stand still in order to allow a proper current regulation. When the drive switches to StealthChop at a higher velocity, StealthChop logic stores the last current regulation setting until the motor returns to a lower velocity again. This way, the regulation has a known starting point when returning to a lower velocity, where StealthChop becomes re-enabled. Therefore, neither the velocity threshold nor the supply voltage must be considerably changed during the phase while the chopper is switched to a different mode, because otherwise the motor might lose steps or the instantaneous current might be too high or too low.

A motor stall or a sudden change in the motor velocity may lead to the driver detecting a short circuit or to a state of automatic current regulation, from which it cannot recover. Clear the error flags and restart the motor from zero velocity to recover from this situation.

Hint

Start the motor from standstill when switching on StealthChop the first time and keep it stopped for at least 128 chopper periods to allow StealthChop to do initial standstill current control.

6.6 Flags in StealthChop

As StealthChop uses voltage mode driving, status flags based on current measurement respond slower, respectively the driver reacts delayed to sudden changes of back EMF, like on a motor stall.

Attention

A motor stall, or abrupt stop of the motion during operation in StealthChop can trigger an overcurrent condition. Depending on the previous motor velocity, and on the coil resistance of the motor, it significantly increases motor current for a time of several 10ms. With low velocities, where the back EMF is just a fraction of the supply voltage, there is no danger of triggering the short detection.

6.6.1 Open Load Flags

In StealthChop mode, status information is different from the cycle-by-cycle regulated SpreadCycle mode. OLA and OLB show if the current regulation sees that the nominal current can be reached on both coils. An active open load flag not necessarily signals an interrupted coil condition.

- A flickering OLA or OLB can result from asymmetries of the sense resistors or the motor coils.
- An interrupted motor coil leads to a continuously active open load flag for the coil.
- One or both flags become active, if the current regulation fails in scaling up to the full target current within a few fullsteps. This can result if the motor is not connected, or from a high velocity motion where the back EMF reaches the supply limit, or a too high motor resistance.
- Checking *PWM_SCALE_SUM* for a value determined during typical operation at slow motion may give a more reliable result.

With automatic scaling, the current regulation checks the current in a single coil at a time, only, measuring the coil with the higher target current. The other coil PWM duty cycle becomes scaled proportionally. In case a coil connection is interrupted, this behavior can lead to the PWM duty cycle increasing to its limit and staying undetected or triggering the overcurrent protection.

To prevent coil overheating or driver damage due to this behavior, do an on-demand open load test using the SpreadCycle chopper prior to operation in StealthChop, and do not enable StealthChop in case of open load failure, or check *PWM_SCALE_SUM* for a value in the expected range.

Attention

For *pwm_autoscale* mode, an open load situation on a single coil can lead to the current regulation algorithm scaling up the non-interrupted coil to too high current values. Therefore, it is recommended to test for open load prior to operation in StealthChop using SpreadCycle. Do not enable StealthChop in case of an open load situation.

6.6.2 PWM_SCALE_SUM Informs about the Motor State

Information about the motor state is available with automatic scaling by reading out *PWM_SCALE_SUM*. As this parameter reflects the actual voltage required to drive the target current into the motor, it depends on several factors: motor load, coil resistance, supply voltage, and current setting. Therefore, an evaluation of the *PWM_SCALE_SUM* value allows checking the motor operation point. When reaching the limit (255), the current regulator cannot sustain the full motor current, e.g. due to a drop in supply voltage.

6.7 Freewheeling and Passive Braking

StealthChop provides different options for motor standstill. These options can be enabled by setting the standstill current *IHOLD* to zero and choosing the desired option using the *FREEWHEEL* setting. The desired option becomes enabled after a time period specified by *TPOWERDOWN* and *IHOLD_DELAY*. Current regulation becomes frozen once the motor target current is at zero current in order to ensure a quick startup. With the freewheeling options, both freewheeling and passive braking can be realized. Passive braking is an effective eddy current motor braking, which consumes a minimum of energy, because no active current is driven into the coils. However, passive braking will allow slow turning of the motor when a continuous torque is applied.

Hint

Operate the motor within your application when exploring StealthChop. Motor performance often is better with a mechanical load, because it prevents the motor from stalling due mechanical oscillations which can occur without load.

PARAMETERS RELATED TO STEALTHCHOP			
Parameter	Description	Setting	Comment
<i>en_spread_cycle</i>	General disable for use of StealthChop (register <i>GCONF</i>). The input SPREAD is XORed to this flag.	1	Do not use StealthChop
		0	StealthChop enabled
<i>TPWMTHRS</i>	Specifies the upper velocity for operation in StealthChop. Entry the <i>TSTEP</i> reading (time between two 1/256 microsteps) when operating at the desired threshold velocity.	0 ... 1048575	StealthChop is disabled if <i>TSTEP</i> falls <i>TPWMTHRS</i>
<i>PWM_LIM</i>	Limiting value for limiting the current jerk when switching from SpreadCycle to StealthChop. Reduce the value to yield a lower current jerk.	0 ... 15	Upper four bits of 8 bit amplitude limit (Default=12)
<i>pwm_autoscale</i>	Enable automatic current scaling using current measurement or use forward controlled velocity based mode.	0	Forward controlled mode
		1	Automatic scaling with current regulator
<i>pwm_autograd</i>	Enable automatic tuning of <i>PWM_GRAD_AUTO</i>	0	disable, use <i>PWM_GRAD</i> from register instead
		1	enable
<i>PWM_FREQ</i>	PWM frequency selection. Use the lowest setting giving good results. The frequency measured at each of the chopper outputs is half of the effective chopper frequency f_{PWM} .	0	$f_{PWM}=2/1024 f_{CLK}$
		1	$f_{PWM}=2/683 f_{CLK}$
		2	$f_{PWM}=2/512 f_{CLK}$
		3	$f_{PWM}=2/410 f_{CLK}$
<i>PWM_REG</i>	User defined PWM amplitude (gradient) for velocity based scaling or regulation loop gradient when <i>pwm_autoscale</i> =1.	1 ... 15	Results in 0.5 to 7.5 steps for <i>PWM_SCALE_AUTO</i> regulator per fullstep
<i>PWM_OFS</i>	User defined PWM amplitude (offset) for velocity based scaling and initialization value for automatic tuning of <i>PWM_OFFS_AUTO</i> .	0 ... 255	<i>PWM_OFS</i> =0 disables linear current scaling based on current setting
<i>PWM_GRAD</i>	User defined PWM amplitude (gradient) for velocity based scaling and initialization value for automatic tuning of <i>PWM_GRAD_AUTO</i> .	0 ... 255	Reset value can be pre-programmed by OTP
<i>FREEWHEEL</i>	Stand still option when motor current setting is zero (<i>I_HOLD</i> =0). Only available with StealthChop enabled. The freewheeling option makes the motor easy movable, while both coil short options realize a passive brake.	0	Normal operation
		1	Freewheeling
		2	Coil short via LS drivers
		3	Coil short via HS drivers
<i>PWM_SCALE_AUTO</i>	Read back of the actual StealthChop voltage PWM scaling correction as determined by the current regulator. Should regulate to a value close to 0 during tuning procedure.	-255 ... 255	(read only) Scaling value becomes frozen when operating in SpreadCycle
<i>PWM_GRAD_AUTO</i> <i>PWM_OFFS_AUTO</i>	Allow monitoring of the automatic tuning and determination of initial values for <i>PWM_OFS</i> and <i>PWM_GRAD</i> . Set <i>pwm_autoscale</i> =0 resp. <i>pwm_autograd</i> =0 to initialize from <i>PWM_OFS</i> and <i>PWM_GRAD</i> .	0 ... 255	(read only)
<i>TOFF</i>	General enable for the motor driver, the actual value does not influence StealthChop	0	Driver off
		1 ... 15	Driver enabled
<i>TBL</i>	Comparator <i>blank time</i> . This time needs to safely cover the switching event and the duration of the ringing on the sense resistor. Choose a setting of 1 or 2 for typical applications. For higher capacitive loads, 3 may be required. Lower settings allow StealthChop to regulate down to lower coil current values.	0	16 t_{CLK}
		1	24 t_{CLK}
		2	32 t_{CLK}
		3	40 t_{CLK}

7 SpreadCycle Chopper

While StealthChop is a voltage mode PWM controlled chopper, SpreadCycle is a cycle-by-cycle current control. Therefore, it can react extremely fast to changes in motor velocity or motor load. SpreadCycle will give better performance in medium to high velocity range for motors and applications which tend to resonance. The currents through both motor coils are controlled using choppers. The choppers work independently of each other. In Figure 7.1 the different chopper phases are shown.

Figure 7.1 Chopper phases

Although the current could be regulated using only on phases and fast decay phases, insertion of the slow decay phase is important to reduce electrical losses and current ripple in the motor. The duration of the slow decay phase is specified in a control parameter and sets an upper limit on the chopper frequency. The current comparator can measure coil current during phases when the current flows through the sense resistor, but not during the slow decay phase, so the slow decay phase is terminated by a timer. The on phase is terminated by the comparator when the current through the coil reaches the target current. The fast decay phase may be terminated by either the comparator or another timer.

When the coil current is switched, spikes at the sense resistors occur due to charging and discharging parasitic capacitances. During this time, typically one or two microseconds, the current cannot be measured. Blanking is the time when the input to the comparator is masked to block these spikes.

The SpreadCycle chopper mode cycles through four phases: on, slow decay, fast decay, and a second slow decay.

The chopper frequency is an important parameter for a chopped motor driver. A too low frequency might generate audible noise. A higher frequency reduces current ripple in the motor, but with a too high frequency magnetic losses may rise. Also power dissipation in the driver rises with increasing frequency due to the increased influence of switching slopes causing dynamic dissipation. Therefore, a compromise needs to be found. Most motors are optimally working in a frequency range of 16 kHz to 30 kHz. The chopper frequency is influenced by a number of parameter settings as well as by the motor inductivity and supply voltage.

Hint

A chopper frequency in the range of 16 kHz to 30 kHz gives a good result for most motors when using SpreadCycle. A higher frequency leads to increased switching losses.

7.1 SpreadCycle Settings

The SpreadCycle (patented) chopper algorithm is a precise and simple to use chopper mode which automatically determines the optimum length for the fast-decay phase. The SpreadCycle will provide superior microstepping quality even with default settings. Several parameters are available to optimize the chopper to the application.

Each chopper cycle is comprised of an on phase, a slow decay phase, a fast decay phase and a second slow decay phase (see Figure 7.3). The two slow decay phases and the two blank times per chopper cycle put an upper limit to the chopper frequency. The slow decay phases typically make up for about 30%-70% of the chopper cycle in standstill and are important for low motor and driver power dissipation.

Calculation of a starting value for the slow decay time *TOFF*:

EXAMPLE:

Target Chopper frequency: 25kHz.

Assumption: Two slow decay cycles make up for 50% of overall chopper cycle time

$$t_{OFF} = \frac{1}{25kHz} * \frac{50}{100} * \frac{1}{2} = 10\mu s$$

For the *TOFF* setting this means:

$$TOFF = (t_{OFF} * f_{CLK} - 24)/32$$

With 12 MHz clock this gives a setting of *TOFF*=3.0, i.e. 3.

With 16 MHz clock this gives a setting of *TOFF*=4.25, i.e. 4 or 5.

The hysteresis start setting forces the driver to introduce a minimum amount of current ripple into the motor coils. The current ripple must be higher than the current ripple which is caused by resistive losses in the motor in order to give best microstepping results. This will allow the chopper to precisely regulate the current both for rising and for falling target current. The time required to introduce the current ripple into the motor coil also reduces the chopper frequency. Therefore, a higher hysteresis setting will lead to a lower chopper frequency. The motor inductance limits the ability of the chopper to follow a changing motor current. Further the duration of the on phase and the fast decay must be longer than the blanking time because the current comparator is disabled during blanking.

It is easiest to find the best setting by starting from a low hysteresis setting (e.g. *HSTRT*=0, *HEND*=0) and increasing *HSTRT*, until the motor runs smoothly at low velocity settings. This can best be checked when measuring the motor current either with a current probe or by probing the sense resistor voltages (see Figure 7.2). Checking the sine wave shape near zero transition will show a small ledge between both half waves in case the hysteresis setting is too small. At medium velocities (i.e. 100 to 400 fullsteps per second), a too low hysteresis setting will lead to increased humming and vibration of the motor.

Figure 7.2 No ledges in current wave with sufficient hysteresis (magenta: current A, yellow & blue: sense resistor voltages A and B)

A too high hysteresis setting will lead to reduced chopper frequency and increased chopper noise but will not yield any benefit for the wave shape.

Quick Start

For a quick start, see the Quick Configuration Guide in chapter 14.

For detail procedure see Application Note AN001 - *Parameterization of SpreadCycle*

As experiments show, the setting is quite independent of the motor, because higher current motors typically also have a lower coil resistance. Therefore, choosing a low to medium default value for the hysteresis (for example, effective hysteresis = 4) normally fits most applications. The setting can be optimized by experimenting with the motor: A too low setting will result in reduced microstep accuracy, while a too high setting will lead to more chopper noise and motor power dissipation. When measuring the sense resistor voltage in motor standstill at a medium coil current with an oscilloscope, a too low setting shows a fast decay phase not longer than the blanking time. When the fast decay time becomes slightly longer than the blanking time, the setting is optimum. You can reduce the off-time setting, if this is hard to reach.

The hysteresis principle could in some cases lead to the chopper frequency becoming too low, e.g. when the coil resistance is high when compared to the supply voltage. This is avoided by splitting the hysteresis setting into a start setting (*HSTRT+HEND*) and an end setting (*HEND*). An automatic hysteresis decremter (HDEC) interpolates between both settings, by decrementing the hysteresis value stepwise each 16 system clocks. At the beginning of each chopper cycle, the hysteresis begins with a value which is the sum of the start and the end values (*HSTRT+HEND*), and decrements during the cycle, until either the chopper cycle ends, or the hysteresis end value (*HEND*) is reached. This way, the chopper frequency is stabilized at high amplitudes and low supply voltage situations, if the frequency gets too low. This avoids the frequency reaching the audible range.

Hint

Highest motor velocities sometimes benefit from setting *TOFF* to 1 or 2 and a short *TBL* of 1 or 0.

Figure 7.3 SpreadCycle chopper scheme showing coil current during a chopper cycle

These parameters control SpreadCycle mode:

Parameter	Description	Setting	Comment
<i>TOFF</i>	Sets the slow decay time (<i>off time</i>). This setting also limits the maximum chopper frequency. For operation with StealthChop, this parameter is not used, but it is required to enable the motor. In case of operation with StealthChop only, any setting is OK. Setting this parameter to zero completely disables all driver transistors and the motor can free-wheel.	0	chopper off
		1...15	off time setting $N_{CLK} = 24 + 32 \cdot TOFF$ (1 will work with minimum blank time of 24 clocks)
<i>TBL</i>	Comparator <i>blank time</i> . This time needs to safely cover the switching event and the duration of the ringing on the sense resistor. For most applications, a setting of 1 or 2 is good. For highly capacitive loads, a setting of 2 or 3 will be required.	0	$16 t_{CLK}$
		1	$24 t_{CLK}$
		2	$32 t_{CLK}$
		3	$40 t_{CLK}$
<i>HSTRT</i>	<i>Hysteresis start</i> setting. This value is an offset from the hysteresis end value <i>HEND</i> .	0...7	$HSTRT=1...8$ This value adds to <i>HEND</i> .
<i>HEND</i>	<i>Hysteresis end</i> setting. Sets the hysteresis end value after a number of decrements. The sum $HSTRT+HEND$ must be ≤ 16 . At a current setting of max. 30 (amplitude reduced to 240), the sum is not limited.	0...2	-3...-1: negative <i>HEND</i>
		3	0: zero <i>HEND</i>
		4...15	1...12: positive <i>HEND</i>

Even at $HSTRT=0$ and $HEND=0$, the TMC22xx sets a minimum hysteresis via analog circuitry.

EXAMPLE:

A hysteresis of 4 has been chosen. You might decide to not use hysteresis decrement. In this case set:

$HEND=6$ (sets an effective end value of $6-3=3$)
 $HSTRT=0$ (sets minimum hysteresis, i.e. $1: 3+1=4$)

In order to take advantage of the variable hysteresis, we can set most of the value to the *HSTRT*, i.e., 4, and the remaining 1 to hysteresis end. The resulting configuration register values are as follows:

$HEND=0$ (sets an effective end value of -3)
 $HSTRT=6$ (sets an effective start value of hysteresis end +7: $7-3=4$)

8 Selecting Sense Resistors

Set the desired maximum motor current by selecting an appropriate value for the sense resistor. The following table shows the RMS current values which can be reached using standard resistors and motor types fitting without additional motor current scaling.

CHOICE OF R_{SENSE} AND RESULTING MAX. MOTOR CURRENT		
R_{SENSE} [Ω]	RMS current [A] VREF=2.5V (or open), IRUN=31, vsense=0 (standard)	Fitting motor type (examples)
1.00	0.22	300mA motor
0.82	0.27	
0.75	0.29	
0.68	0.32	
0.50	0.43	400mA motor
470m	0.46	
390m	0.55	
330m	0.64	
270m	0.77	500mA motor
220m	0.92	
180m	1.09	
150m	1.28	
120m	1.53*)	600mA motor
100m	1.77*)	
		1.5A motor

*) Value exceeds upper current rating, scaling down required, e.g. by reduced VREF.

Sense resistors should be carefully selected. The full motor current flows through the sense resistors. Due to chopper operation the sense resistors see pulsed current from the MOSFET bridges. Therefore, a low-inductance type such as film or composition resistors is required to prevent voltage spikes causing ringing on the sense voltage inputs leading to unstable measurement results. Also, a low-inductance, low-resistance PCB layout is essential. Any common GND path for the two sense resistors must be avoided, because this would lead to coupling between the two current sense signals. A massive ground plane is best. Please also refer to layout considerations in chapter 19.

The sense resistor needs to be able to conduct the peak motor coil current in motor standstill conditions unless standby power is reduced. Under normal conditions, the sense resistor conducts less than the coil RMS current, because no current flows through the sense resistor during the slow decay phases. A 0.5W type is sufficient for most applications up to 1.2A RMS current.

Attention

Properly select sense resistors especially for applications, where the ENN pin is fixed to an active level, because the full current for default setting IRUN=31 will flow through the motor right after power up for a short moment, until the driver goes to hold current reduction, or a lower setting has been issued via UART. Too low resistor values not matching the motor, thus lead to a significant increase in supply current, up to the current limit determined by the motor coil resistance.

Attention

Be sure to use a symmetrical sense resistor layout and short and straight sense resistor traces of identical length. Well matching sense resistors ensure best performance. A compact layout with massive ground plane is best to avoid parasitic resistance effects.

9 Motor Current Control

The basic motor current is set by the resistance of the sense resistors. Several possibilities allow scaling down motor current, e.g., to adapt for different motors, or to reduce motor current in standstill or low load situations.

METHODS FOR SCALING MOTOR CURRENT			
Method	Parameters	Range	Primary Use
Pin VREF voltage (chapter 9.1)	VREF input scales <i>IRUN</i> and <i>IHOLD</i> . Can be disabled by <i>GCONF.i_scale_analog</i>	2.5V: 100% ... 0.5V: 20% >2.5V or open: 100% <0.5V: not recommended	<ul style="list-style-type: none"> - Fine tuning of motor current to fit the motor type - Manual tuning via poti - Delayed or soft power-up - Standstill current reduction (preferred only with SpreadCycle)
Pin ENN	Disable / enable driver stage	0: Motor enable 1: Motor disable	<ul style="list-style-type: none"> - Disable motor to allow freewheeling
Pin PDN_UART	Disable / enable standstill current reduction to <i>IHOLD</i>	0: Standstill current reduction enabled. 1: Disable	<ul style="list-style-type: none"> - Enable current reduction to reduce heat up in stand still
OTP memory	<i>OTP_IHOLD</i> , <i>OTP_IHOLDDELAY</i>	9% to 78% standby current. Reduction in about 300ms to 2.5s	<ul style="list-style-type: none"> - Program current reduction to fit application for highest efficiency and lowest heat up
OTP memory	<i>otp_internalRsense</i>	0: Use sense resistors 1: Internal resistors	<ul style="list-style-type: none"> - Save two sense resistors on BOM, set current by single inexpensive 0603 resistor.
UART interface	<i>IHOLD_IRUN</i> <i>TPOWERDOWN</i> <i>OTP</i>	<i>IRUN</i> , <i>IHOLD</i> : 1/32 to 32/32 of full-scale current.	<ul style="list-style-type: none"> - Fine programming of run and hold (stand still) current - Change <i>IRUN</i> for situation specific motor current - Set OTP options
UART interface	<i>CHOPCONF.vsense</i> flag	0: Normal, most robust 1: Reduced voltage level	<ul style="list-style-type: none"> - Set <i>vsense</i> for half power dissipation in sense resistor to use smaller 0.25W resistors.

Select the sense resistor to deliver enough current for the motor at full current scale ($V_{REF}=2.5V$). This is the default current scaling ($IRUN = 31$).

STANDALONE MODE RMS RUN CURRENT CALCULATION:

$$I_{RMS} = \frac{325mV}{R_{SENSE} + 30m\Omega} * \frac{1}{\sqrt{2}} * \frac{V_{VREF}}{2.5V}$$

IRUN and *IHOLD* allow for scaling of the actual current scale (*CS*) from 1/32 to 32/32 when using UART interface, or via automatic standstill current reduction:

RMS CURRENT CALCULATION WITH UART CONTROL OPTIONS OR HOLD CURRENT SETTING:

$$I_{RMS} = \frac{CS + 1}{32} * \frac{V_{FS}}{R_{SENSE} + 30m\Omega} * \frac{1}{\sqrt{2}}$$

CS is the current scale setting as set by the *IHOLD* and *IRUN*.

V_{FS} is the full-scale voltage as determined by *vsense* control bit (please refer to electrical characteristics, V_{SRTL} and V_{SRTH}). Default is 325mV.

With analog scaling of V_{FS} (*I_scale_analog*=1, default), the resulting voltage V_{FS}' is calculated by:

$$V'_{FS} = V_{FS} * \frac{V_{VREF}}{2.5V}$$

with V_{VREF} the voltage on pin VREF in the range 0V to $V_{5VOUT}/2$

Hint

For best precision of current setting, measure and fine tune the current in the application.

PARAMETERS FOR MOTOR CURRENT CONTROL			
Parameter	Description	Setting	Comment
<i>IRUN</i>	Current scale when motor is running. Scales coil current values as taken from the internal sine wave table. For high precision motor operation, work with a current scaling factor in the range 16 to 31, because scaling down the current values reduces the effective microstep resolution by making microsteps coarser.	0 ... 31	scaling factor 1/32, 2/32, ... 32/32 <i>IRUN</i> is full scale (setting 31) in standalone mode.
<i>IHOLD</i>	Identical to <i>IRUN</i> , but for motor in stand still.		
<i>IHOLD DELAY</i>	Allows smooth current reduction from run current to hold current. <i>IHOLDDELAY</i> controls the number of clock cycles for motor power down after <i>TPOWERDOWN</i> in increments of 2^{18} clocks: 0=instant power down, 1..15: Current reduction delay per current step in multiple of 2^{18} clocks. <i>Example:</i> When using <i>IRUN</i> =31 and <i>IHOLD</i> =16, 15 current steps are required for hold current reduction. A <i>IHOLDDELAY</i> setting of 4 thus results in a power down time of $4*15*2^{18}$ clock cycles, i.e. roughly one second at 16MHz clock frequency.	0 1 ... 15	instant <i>IHOLD</i> $1*2^{18} \dots 15*2^{18}$ clocks per current decrement
<i>TPOWER DOWN</i>	Sets the delay time from stand still (<i>stst</i>) detection to motor current power down. Time range is about 0 to 5.6 seconds. Setting 0 is no delay, 1 a minimum delay. Further increment is in discrete steps of 2^{18} clock cycles.	0 ... 255	$0 \dots ((2^8)-1) * 2^{18} t_{CLK}$ A minimum setting of 2 is required to allow automatic tuning of <i>PWM_OFFS_AUTO</i>
<i>vsense</i>	Allows control of the sense resistor <i>voltage range</i> for full scale current. The low voltage range allows a reduction of sense resistor power dissipation.	0 1	$V_{FS} = 0.32V$ $V_{FS} = 0.18V$

9.1 Analog Current Scaling VREF

When a high flexibility of the output current scaling is desired, the analog input of the driver can be used for current control, rather than choosing a different set of sense resistors or scaling down the run current via the interface using *IRUN* or *IHOLD* parameters. This way, a simple voltage divider adapts a board to different motors.

VREF SCALES THE MOTOR CURRENT

The TMC22xx provides an internal reference voltage for current control, directly derived from the 5VOUT supply output. Alternatively, an external reference voltage can be used. This reference voltage becomes scaled down for the chopper comparators. The chopper comparators compare the voltages on BRA and BRB to the scaled reference voltage for current regulation. When *I_scale_analog* in *GCONF* is enabled (default), the external voltage on VREF is amplified and filtered and becomes used as reference voltage. A voltage of 2.5V (or any voltage between 2.5V and 5V) gives the same current

scaling as the internal reference voltage. A voltage between 0V and 2.5V linearly scales the current between 0 and the current scaling defined by the sense resistor setting. It is not advised to work with reference voltages below about 0.5V to 1V for full scale, because relative analog noise caused by digital circuitry and power supply ripple has an increased impact on the chopper precision at low VREF voltages. For best precision, choose the sense resistors in a way that the desired maximum current is reached with VREF in the range 2V to 2.4V. Be sure to optimize the chopper settings for the normal run current of the motor.

DRIVING VREF

The easiest way to provide a voltage to VREF is to use a voltage divider from a stable supply voltage or a microcontroller's DAC output. A PWM signal also allows current control. The PWM becomes transformed to an analog voltage using an additional R/C low-pass at the VREF pin. The PWM duty cycle controls the analog voltage. Choose the R and C values to form a low pass with a corner frequency of several milliseconds while using PWM frequencies well above 10 kHz. VREF additionally provides an internal low-pass filter with 3.5kHz bandwidth.

Hint

Using a low reference voltage (e.g. below 1V), for adaptation of a high current driver to a low current motor will lead to reduced analog performance. Adapt the sense resistors to fit the desired motor current for the best result.

Figure 9.1 Scaling the motor current using the analog input

10 Internal Sense Resistors

The TMC22xx provides the option to eliminate external sense resistors. In this mode the external sense resistors become omitted (shorted) and the internal on-resistance of the power MOSFETs is used for current measurement (see chapter 0). As MOSFETs are both, temperature dependent and subject to production stray, a tiny external resistor connected from +5VOUT to VREF provides a precise absolute current reference. This resistor converts the 5V voltage into a reference current. Be sure to directly attach BRA and BRB pins to GND in this mode near the IC package. The mode is enabled by setting *internal_Rsense* in *GCONF* (OTP option).

COMPARING INTERNAL SENSE RESISTORS VS. SENSE RESISTORS		
Item	Internal Sense Resistors	External Sense Resistors
Ease of use	Need to set OTP parameter first	(+) Default
Cost	(+) Save cost for sense resistors	
Current precision	Slightly reduced	(+) Good
Current Range Recommended	200mA RMS to 1.2A RMS	50mA to 1.4A RMS
Recommended chopper	StealthChop, SpreadCycle shows slightly reduced performance at >1A	StealthChop or SpreadCycle

While the RDSon based measurements bring benefits concerning cost and size of the driver, it gives slightly less precise coil current regulation when compared to external sense resistors. The internal sense resistors have a certain temperature dependence, which is automatically compensated by the driver IC. However, for high current motors, a temperature gradient between the ICs internal sense resistors and the compensation circuit will lead to an initial current overshoot of some 10% during driver IC heat up. While this phenomenon shows for roughly a second, it might even be beneficial to enable increased torque during initial motor acceleration.

PRINCIPLE OF OPERATION

A reference current into the VREF pin is used as reference for the motor current. In order to realize a certain current, a single resistor (R_{REF}) can be connected between 5VOUT and VREF (pls. refer the table for the choice of the resistor). VREF input resistance is about 0.7kOhm. An additional current of 40µA flows internally making up for an adder of roughly 120mA. The resulting current into VREF is amplified 3000 times. Thus, a current of 0.5mA yields a motor current of 1.5A peak. For calculation of the reference resistor, the internal resistance of VREF needs to be considered additionally.

CHOICE OF R_{REF} FOR OPERATION WITHOUT SENSE RESISTORS		
R_{REF} [Ω]	Peak current [A] (CS=31, vsense=0)	RMS current [A] (CS=31, vsense=0)
6k8	2.11	1.49
7k5	1.94	1.37
8k2	1.80	1.27
9k1	1.64	1.16
10k	1.51	1.07
12k	1.29	0.91
15k	1.07	0.75
18k	0.91	0.65
22k	0.77	0.55
27k	0.65	0.46
33k	0.56	0.39

vsense=1 allows a lower peak current setting of about 55% of the value yielded with *vsense=0* (as specified by V_{SRTH} / V_{SRTL}).

In RDSon measurement mode, connect the BRA and BRB pins to GND using the shortest possible path (i.e. lowest possible PCB resistance). RDSon based measurement gives best results when combined with StealthChop. When using SpreadCycle with RDSon based current measurement, slightly asymmetric current measurement for positive currents (on phase) and negative currents (fast decay phase) may result in chopper noise. This especially occurs at high die temperature and increased motor current.

Note

The absolute current levels achieved with RDSon based current sensing may depend on PCB layout exactly like with external sense resistors, because trace resistance on BR pins will add to the effective sense resistance. Therefore, we recommend to measure and calibrate the current setting within the application.

Thumb rule

RDSon based current sensing works best for motors with up to 1A RMS current. The best results are yielded with StealthChop operation in combination with RDSon based current sensing. For most precise current control and for best results with SpreadCycle, it is recommended to use external 1% sense resistors rather than RDSon based current control.

11 STEP/DIR Interface

The STEP and DIR inputs provide a simple, standard interface compatible with many existing motion controllers. The MicroPlyer step pulse interpolator brings the smooth motor operation of high-resolution microstepping to applications originally designed for coarser stepping.

11.1 Timing

Figure 11.1 shows the timing parameters for the STEP and DIR signals, and the table below gives their specifications. Only rising edges are active. STEP and DIR are sampled and synchronized to the system clock. An internal analog filter removes glitches on the signals, such as those caused by long PCB traces. If the signal source is far from the chip, and especially if the signals are carried on cables, the signals should be filtered or differentially transmitted.

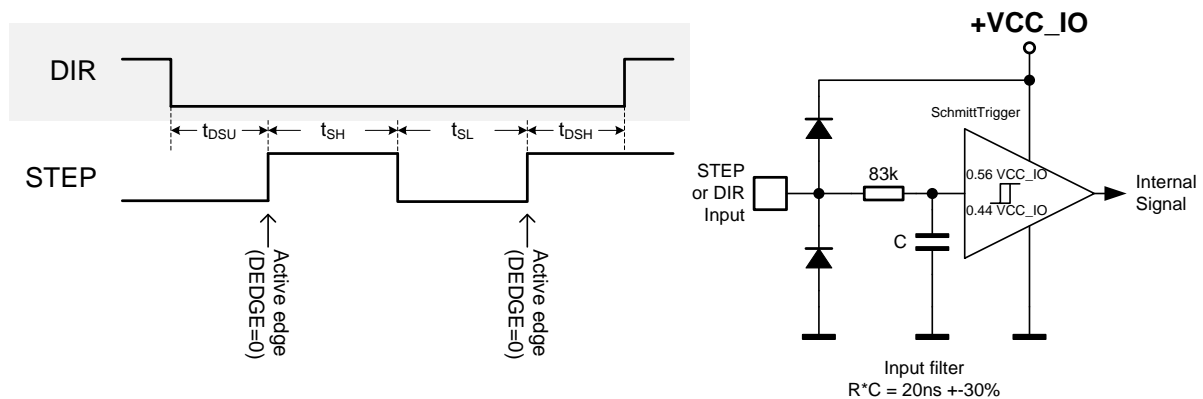

Figure 11.1 STEP and DIR timing, Input pin filter

STEP and DIR interface timing		AC-Characteristics				
		clock period is t_{CLK}				
Parameter	Symbol	Conditions	Min	Typ	Max	Unit
step frequency (at maximum microstep resolution)	f_{STEP}				$\frac{1}{2} f_{CLK}$	
fullstep frequency	f_{FS}				$f_{CLK}/512$	
STEP input minimum low time	t_{SL}		$\max(t_{FILTS}, t_{CLK}+20)$	100		ns
STEP input minimum high time	t_{SH}		$\max(t_{FILTS}, t_{CLK}+20)$	100		ns
DIR to STEP setup time	t_{DSU}		20			ns
DIR after STEP hold time	t_{DSH}		20			ns
STEP and DIR spike filtering time *)	t_{FILTS}	rising and falling edge	13	20	30	ns
STEP and DIR sampling relative to rising CLK input	t_{SDCLKH}	before rising edge of CLK input		t_{FILTS}		ns

*) These values are valid with full input logic level swing, only. Asymmetric logic levels will increase filtering delay t_{FILTS} , due to an internal input RC filter.

11.2 Changing Resolution

The TMC22xx includes an internal microstep table with 1024 sine wave entries to generate sinusoidal motor coil currents. These 1024 entries correspond to one electrical revolution or four fullsteps. The microstep resolution setting determines the step width taken within the table. Depending on the DIR input, the microstep counter is increased (DIR=0) or decreased (DIR=1) with each STEP pulse by the step width. The microstep resolution determines the increment respectively the decrement. At maximum resolution, the sequencer advances one step for each step pulse. At half resolution, it advances two steps. Increment is up to 256 steps for fullstepping. The sequencer has special provision to allow seamless switching between different microstep rates at any time. When switching to a lower microstep resolution, it calculates the nearest step within the target resolution and reads the current vector at that position. This behavior especially is important for low resolutions like fullstep and halfstep, because any failure in the step sequence would lead to asymmetrical run when comparing a motor running clockwise and counterclockwise.

EXAMPLES:

Fullstep: Cycles through table positions: 128, 384, 640 and 896 (45°, 135°, 225° and 315° electrical position, both coils on at identical current). The coil current in each position corresponds to the RMS-Value ($0.71 \cdot \text{amplitude}$). Step size is 256 (90° electrical)

Half step: The first table position is 64 (22.5° electrical), Step size is 128 (45° steps)

Quarter step: The first table position is 32 ($90^\circ/8=11.25^\circ$ electrical), Step size is 64 (22.5° steps)

This way equidistant steps result and they are identical in both rotation directions. Some older drivers also use zero current (table entry 0, 0°) as well as full current (90°) within the step tables. This kind of stepping is avoided because it provides less torque and has a worse power dissipation in driver and motor.

Step position	table position	current coil A	current coil B
Half step 0	64	38.3%	92.4%
Full step 0	128	70.7%	70.7%
Half step 1	192	92.4%	38.3%
Half step 2	320	92.4%	-38.3%
Full step 1	384	70.7%	-70.7%
Half step 3	448	38.3%	-92.4%
Half step 4	576	-38.3%	-92.4%
Full step 2	640	-70.7%	-70.7%
Half step 5	704	-92.4%	-38.3%
Half step 6	832	-92.4%	38.3%
Full step 3	896	-70.7%	70.7%
Half step 7	960	-38.3%	92.4%

See chapter 0 for resolution settings available in stand-alone mode.

11.3 MicroPlyer Step Interpolator and Stand Still Detection

For each active edge on STEP, MicroPlyer produces microsteps at 256x resolution, as shown in Figure 11.2. It interpolates the time in between of two step impulses at the step input based on the last step interval. This way, from 2 microsteps (128 microstep to 256 microstep interpolation) up to 256 microsteps (full step input to 256 microsteps) are driven for a single step pulse.

The step rate for the interpolated 2 to 256 microsteps is determined by measuring the time interval of the previous step period and dividing it into up to 256 equal parts. The maximum time between two microsteps corresponds to 2^{20} (roughly one million system clock cycles), for an even distribution of 256 microsteps. At 12 MHz system clock frequency, this results in a minimum step input frequency of roughly 12 Hz for MicroPlyer operation. A lower step rate causes a standstill event to be detected. At that frequency, microsteps occur at a rate of $(\text{system clock frequency})/2^{16} - 256 \text{ Hz}$. When a stand still is detected, the driver automatically begins standby current reduction if selected by pin PDN.

Attention

MicroPlyer only works perfectly with a jitter-free STEP frequency.

Figure 11.2 MicroPlyer microstep interpolation with rising STEP frequency (Example: 16 to 256)

In Figure 11.2, the first STEP cycle is long enough to set the *stst* bit standstill. Detection of standstill will enable the standby current reduction. This bit is cleared on the next STEP active edge. Then, the external STEP frequency increases. After one cycle at the higher rate MicroPlyer adapts the interpolated microstep rate to the higher frequency. During the last cycle at the slower rate, MicroPlyer did not generate all 16 microsteps, so there is a small jump in motor angle between the first and second cycles at the higher rate.

11.4 Index Output

An active INDEX output signals that the sine curve of motor coil B is at its positive zero transition. This correlates to the zero point of the microstep sequence. Usually, the cosine curve of coil A is at its maximum at the same time. Thus, the index signal is active once within each electrical period and corresponds to a defined position of the motor within a sequence of four fullsteps. The INDEX output this way allows the detection of a certain microstep pattern, and thus helps to detect a position with more precision than a stop switch can do.

Figure 11.3 Index signal at positive zero transition of the coil B sine curve

Hint

The index output allows precise detection of the microstep position within one electrical wave, i.e., within a range of four fullsteps. With this, homing accuracy and reproducibility can be enhanced to microstep accuracy, even when using an inexpensive home switch.

Hint

In StealthChop at high velocity, the current waves will appear shifted against the index pulse, due to the motor current lagging the voltage driven into the coil.

12 Internal Step Pulse Generator

The TMC22xx family integrates a high-resolution step pulse generator, allowing motor motion via the UART interface. However, no velocity ramping is provided. Ramping is not required, if the target motion velocity is smaller than the start & stop frequency of the motor. For higher velocities, ramp up the frequency in small steps to accelerate the motor, and ramp down again to decelerate the motor. Figure 12.1 shows an example motion profile ramping up the motion velocity in discrete steps. Choose the ramp velocity steps considerably smaller than the maximum start velocity of the motor, because motor torque drops at higher velocity, and motor load at higher velocity typically increases.

Figure 12.1 Software generated motion profile

PARAMETER VS. UNITS		
Parameter / Symbol	Unit	calculation / description / comment
$f_{CLK}[Hz]$	[Hz]	clock frequency of the TMC22xx in [Hz]
μ step velocity $v[Hz]$	μ steps / s	$v[Hz] = VACTUAL[22xx] * (f_{CLK}[Hz] / 2^{24})$ With internal oscillator: $v[Hz] = VACTUAL[22xx] * 0.715Hz$
USC microstep count	counts	microstep resolution in number of microsteps (i.e., the number of microsteps between two fullsteps – normally 256)
rotations per second $v[rps]$	rotations / s	$v[rps] = v[Hz] / USC / FSC$ FSC: motor fullsteps per rotation, e.g., 200
$TSTEP, TPWMTHRS$	-	$TSTEP = f_{CLK} / f_{256STEP} = f_{CLK} / (f_{STEP} * 256 / USC)$ $= 2^{24} / (VACTUAL * 256 / USC)$ The time reference for velocity threshold is referred to the actual 1/256 microstep frequency of the step input respectively velocity $v[Hz]$.
$VACTUAL$	Two's complement signed internal velocity	$VACTUAL[22xx] = v[Hz] / (f_{CLK}[Hz] / 2^{24})$ With internal oscillator: $VACTUAL[22xx] = v[Hz] / 0.715Hz$

Hint

To monitor internal step pulse execution, program the INDEX output to provide step pulses (*GCONF.index_step*). It toggles upon each step. Use a timer input on your CPU to count pulses. Alternatively, regularly poll *MSCNT* to grasp steps done in the previous polling interval. It wraps around from 1023 to 0.

13 Driver Diagnostic Flags

The TMC22xx drivers supply a complete set of diagnostic and protection capabilities, like short to GND protection, short to VS protection and undervoltage detection. A detection of an open load condition allows testing if a motor coil connection is interrupted. See the *DRV_STATUS* table for details.

13.1 Temperature Measurement

The driver integrates a four-level temperature sensor (pre-warning and thermal shutdown) for diagnostics and for protection of the IC against excess heat. The thresholds can be adapted by UART or OTP programming. Heat is mainly generated by the motor driver stages, and, at increased voltage, by the internal voltage regulator. Most critical situations, where the driver MOSFETs could be overheated, are avoided by the short to GND protection. For many applications, the overtemperature pre-warning will indicate an abnormal operation situation and can be used to initiate user warning or power reduction measures like motor current reduction. The thermal shutdown is just an emergency measure and temperature rising to the shutdown level should be prevented by design.

TEMPERATURE THRESHOLDS	
Overtemperature Setting	Comment
143°C (OTPW: 120°C)	Default setting. This setting is safest to switch off the driver stage before the IC can be destroyed by overheating. On a large PCB, the power MOSFETs reach roughly 150°C peak temperature when the temperature detector is triggered with this setting. This is a trip typical point for overtemperature shut down. The overtemperature pre-warning threshold of 120°C gives lots of headroom to react to high driver temperature, e.g. by reducing motor current.
150°C (OTPW: 120°C or 143°C)	Optional setting (OTP or UART). For small PCBs with high thermal resistance between PCB and environment, this setting provides some additional headroom. The small PCB shows less temperature difference between the MOSFETs and the sensor.
157°C (OTPW: 143°C)	Optional setting (UART). For applications, where a stop of the motor cannot be tolerated, this setting provides highest headroom, e.g. at high environment temperature ratings. Using the 143°C overtemperature pre-warning to reduce motor current ensures that the motor is not switched off by the thermal threshold.

Attention

Overtemperature protection cannot in all cases avoid thermal destruction of the IC. In case the rated motor current is exceeded, e.g. by operating a motor in StealthChop with wrong parameters, or with automatic tuning parameters not fitting the operating conditions, excess heat generation can quickly heat up the driver before the overtemperature sensor can react. This is due to a delay in heat conduction over the IC die.

After triggering the overtemperature sensor (*ot* flag), the driver remains switched off until the system temperature falls below the pre-warning level (*otpw*) to avoid continuous heating to the shutdown level.

13.2 Short Protection

The TMC22xx power stages are protected against a short circuit condition by an additional measurement of the current flowing through each of the power stage MOSFETs. This is important, as most short circuit conditions result from a motor cable insulation defect, e.g. when touching the conducting parts connected to the system ground. The short detection is protected against spurious triggering, e.g. by ESD discharges, by retrying three times before switching off the motor.

Once a short condition is safely detected, the corresponding driver bridge (A or B) becomes switched off, and the *s2ga* or *s2gb* flag, respectively *s2vsa* or *s2vsb* becomes set. In order to restart the motor, disable and re-enable the driver. Note, that short protection cannot protect the system and the power stages for all possible short events, as a short event is rather undefined and a complex network of external components may be involved. Therefore, short circuits should basically be avoided.

13.3 Open Load Diagnostics

Interrupted cables are a common cause for systems failing, e.g. when connectors are not firmly plugged. The TMC22xx detects open load conditions by checking if it can reach the desired motor coil current. This way, also undervoltage conditions, high motor velocity settings or short and overtemperature conditions may cause triggering of the open load flag, and inform the user, that motor torque may suffer. In motor stand still, open load cannot always be measured, as the coils might eventually have zero current.

Open load detection is provided for system debugging.

To safely detect an interrupted coil connection, operate in SpreadCycle, and check the open load flags following a motion of minimum four times the selected microstep resolution into a single direction using low or nominal motor velocity operation, only. However, the *ola* and *olb* flags have just informative character and do not cause any action of the driver.

13.4 Diagnostic Output

The diagnostic output DIAG and the index output INDEX provide important status information. An active DIAG output shows that the driver cannot work normally. The INDEX output signals the microstep counter zero position, to allow referencing (homing) a drive to a certain current pattern. The function set of the INDEX output can be modified by UART. Figure 13.1 shows the available signals and control bits.

Figure 13.1 DIAG and INDEX outputs

14 Quick Configuration Guide

This guide is meant as a practical tool to come to a first configuration. Do a minimum set of measurements and decisions for tuning the driver to determine UART settings or OTP parameters. The flow-charts concentrate on the basic function set to make a motor run smoothly. Once the motor runs, you may decide to explore additional features, e.g. freewheeling in more detail. A current probe on one motor coil is a good aid to find the best settings, but it is not a must.

Figure 14.1 Current Setting and first steps with StealthChop

Hint

Use the evaluation board to explore settings and to generate the required configuration datagrams.

Figure 14.2 Tuning StealthChop and SpreadCycle

Figure 14.3 OTP programming

15 External Reset

The chip is loaded with default values during power on via its internal power-on reset. Some of the registers are initialized from the OTP at power up. In order to reset the chip to power on defaults, any of the supply voltages monitored by internal reset circuitry (VS, +5VOUT or VCC_IO) must be cycled. As +5VOUT is the output of the internal voltage regulator, it cannot be cycled via an external source except by cycling VS. It is easiest and safest to cycle VCC_IO to completely reset the chip. Also, current consumed from VCC_IO is low and therefore it has simple driving requirements. Due to the input protection diodes not allowing the digital inputs to rise above VCC_IO level, all inputs must be driven low during this reset operation. When this is not possible, an input protection resistor may be used to limit current flowing into the related inputs.

16 Clock Oscillator and Input

The clock is the timing reference for all functions: the chopper frequency, the blank time, the standstill power down timing, and the internal step pulse generator etc. The on-chip clock oscillator is calibrated in order to provide timing precise enough for most operation cases.

USING THE INTERNAL CLOCK

Directly tie the CLK input to GND near to the IC if the internal clock oscillator is to be used. The internal clock frequency is factory-trimmed to 12MHz by OTP programming.

USING AN EXTERNAL CLOCK

When an external clock is available, a frequency of 10 MHz to 16 MHz is recommended for optimum performance. The duty cycle of the clock signal is uncritical, as long as minimum high or low input time for the pin is satisfied (refer to electrical characteristics). Up to 18 MHz can be used, when the clock duty cycle is 50%. Make sure, that the clock source supplies clean CMOS output logic levels and steep slopes when using a high clock frequency. The external clock input is enabled with the first positive polarity seen on the CLK input. Modifying the clock frequency is an easy way to adapt the StealthChop chopper frequency or to synchronize multiple drivers. Working with a very low clock frequency down to 4 MHz can help reducing power consumption and electromagnetic emissions, but it will sacrifice some performance.

Use an external clock source to synchronize multiple drivers, or to get precise motor operation with the internal pulse generator for motion. The external clock frequency selection also allows modifying the power down timing and the chopper frequency.

Hint

Switching off the external clock frequency would stop the chopper and could lead to an overcurrent condition. Therefore, TMC22xx has an internal timeout of 32 internal clocks. In case the external clock fails, it switches back to internal clock.

17 Absolute Maximum Ratings

The maximum ratings may not be exceeded under any circumstances. Operating the circuit at or near more than one maximum rating at a time for extended periods shall be avoided by application design.

Parameter	Symbol	Min	Max	Unit
Supply voltage operating with inductive load	V_{VS}	-0.5	39	V
Supply and bridge voltage max. *)	V_{VMAX}		40	V
I/O supply voltage	V_{VIO}	-0.5	5.5	V
5VOUT supply voltage (when using external supply)	V_{5VOUT}	-0.5	5.5	V
Logic input voltage	V_I	-0.5	$V_{VIO}+0.5$	V
VREF input voltage (Do not exceed both, VCC_IO and 5VOUT by more than 10%, as this enables a test mode)	V_{VREF}	-0.5	6	V
Maximum current to / from digital pins and analog low voltage I/Os	I_{IO}		+/-10	mA
5V regulator output current (internal plus external load)	I_{5VOUT}		25	mA
5V regulator continuous power dissipation ($V_{VM}-5V$) * I_{5VOUT}	P_{5VOUT}		0.5	W
Power bridge repetitive output current	I_{Ox}		2.5	A
Junction temperature	T_J	-50	150	°C
Storage temperature	T_{STG}	-55	150	°C
ESD-Protection for interface pins (Human body model, HBM)	V_{ESDAP}		4	kV
ESD-Protection for handling (Human body model, HBM)	V_{ESD}		1	kV

*) Stray inductivity of GND and VS connections will lead to ringing of the supply voltage when driving an inductive load. This ringing results from the fast switching slopes of the driver outputs in combination with reverse recovery of the body diodes of the output driver MOSFETs. Even small trace inductivities as well as stray inductivity of sense resistors can easily generate a few volts of ringing leading to temporary voltage overshoot. This should be considered when working near the maximum voltage.

18 Electrical Characteristics

18.1 Operational Range

Parameter	Symbol	Min	Max	Unit
Junction temperature	T_J	-40	125	°C
Supply voltage (using internal +5V regulator)	V_{VS}	5.5	36	V
Supply voltage (using internal +5V regulator) for OTP programming	V_{VS}	6	36	V
Supply voltage (internal +5V regulator bridged: $V_{5VOUT}=V_{VS}$)	V_{VS}	4.7	5.4	V
I/O supply voltage	V_{VIO}	3.00	5.25	V
RMS motor coil current per coil (value for design guideline)	I_{RMS}		1.2	A
RMS motor coil current per coil with duty cycle limit, e.g. 1s on, 1s standby (value for design guideline)	I_{RMS}		1.4	A
Peak output current per motor coil output (sine wave peak) using external or internal current sensing	I_{Ox}		2.0	A

18.2 DC and Timing Characteristics

DC characteristics contain the spread of values guaranteed within the specified supply voltage range unless otherwise specified. Typical values represent the average value of all parts measured at +25°C. Temperature variation also causes stray to some values. A device with typical values will not leave Min/Max range within the full temperature range.

Power supply current		DC-Characteristics

VREF input	DC-Characteristics					
Parameter	Symbol	Conditions	Min	Typ	Max	Unit
VREF input resistance to 2.5V (=5VOUT/2)	R_{AIN}	Measured to GND (<i>internalRsense=0</i>)	260	330	400	k Ω
VREF input voltage range for linear current scaling	V_{AIN}	Measured to GND (<i>IscaleAnalog=1</i>)	0	0.5-2.4	$V_{5VOUT}/2$	V
VREF open input voltage level	V_{AINO}	Open circuit voltage (<i>internalRsense=0</i>)		$V_{5VOUT}/2$		V
VREF input resistance to GND for reference current input	R_{IREF}	Measured to GND (<i>internalRsense=1</i>)	0.5	0.7	1.0	k Ω
VREF input reference offset current		Measured to GND (<i>internalRsense=1</i>)		38		μA
VREF current amplification for reference current to coil current at maximum setting	$I_{REFAMPL}$	$I_{IREF} = 0.25\text{mA}$		3000		Times
Motor current full scale tolerance -using RDSon measurement (value for design guideline to calculate reproduction of certain motor current & torque)	I_{COIL}	<i>Internal_Rsense=1, vsense=0, $I_{IREF} = 0.25\text{mA}$ (after reaching thermal balance)</i>	-10		+10	%

18.3 Thermal Characteristics

The following table shall give an idea on the thermal resistance of the package. The thermal resistance for a four-layer board will provide a good idea on a typical application. Actual thermal characteristics will depend on the PCB layout, PCB type and PCB size. The thermal resistance will benefit from thicker CU (inner) layers for spreading heat horizontally within the PCB. Also, air flow will reduce thermal resistance.

A thermal resistance of 30K/W for a typical board means, that the package is capable of continuously dissipating 3.3W at an ambient temperature of 25°C with the die temperature staying below 125°C. Note, that a thermally optimized layout is required.

Parameter	Symbol	Conditions	Typ	Unit
Typical power dissipation	P_D	StealthChop or SpreadCycle, 1A RMS in two phase motor, sinewave, 40 or 20kHz chopper, 24V, 110°C peak surface of package (motor QSH4218-035-10-027)	2.5	W
Typical power dissipation	P_D	StealthChop or SpreadCycle, 0.7A RMS in two phase motor, sinewave, 40 or 20kHz chopper, 24V, 68°C peak surface of package (motor QSH4218-035-10-027)	1.36	W
Thermal resistance junction to ambient on a multilayer board QFN28	R_{TMJA}	Dual signal and two internal power plane board (2s2p) as defined in JEDEC EIA JESD51-5 and JESD51-7 (FR4, 35µm CU, 70mm x 133mm, d=1.5mm)	30	K/W
Thermal resistance junction to case	R_{TJC}	Junction to heat slug of package	6	K/W

Table 18.1 Thermal characteristics TMC22xx

Note

A spread-sheet for calculating TMC22xx power dissipation is available on www.trinamic.com.

19 Layout Considerations

19.1 Exposed Die Pad

The TMC22xx uses its die attach pad to dissipate heat from the drivers and the linear regulator to the board. For best electrical and thermal performance, use a reasonable amount of solid, thermally conducting vias between the die attach pad and the ground plane. The printed circuit board should have a solid ground plane spreading heat into the board and providing for a stable GND reference.

19.2 Wiring GND

All signals of the TMC22xx are referenced to their respective GND. Directly connect all GND pins under the device to a common ground area (GND and die attach pad). The GND plane right below the die attach pad should be treated as a virtual star point. For thermal reasons, the PCB top layer shall be connected to a large PCB GND plane spreading heat within the PCB.

Attention

Especially the sense resistors are susceptible to GND differences and GND ripple voltage, as the microstep current steps make up for voltages down to 0.5 mV. No current other than the sense resistor current should flow on their connections to GND and to the TMC22xx. Optimally place them close to the IC, with one or more vias to the GND plane for each sense resistor. The two sense resistors for one coil should not share a common ground connection trace or vias, as also PCB traces have a certain resistance.

19.3 Supply Filtering

The 5VOUT output voltage ceramic filtering capacitor (2.2 to 4.7 μ F recommended) should be placed as close as possible to the 5VOUT pin, with its GND return going directly to the die pad or the nearest GND pin. This ground connection shall not be shared with other loads or additional vias to the GND plane. Use as short and as thick connections as possible.

The motor supply pins VS should be decoupled with an electrolytic capacitor (47 μ F or larger is recommended) and a ceramic capacitor, placed close to the device.

Take into account that the switching motor coil outputs have a high dV/dt . Thus capacitive stray into high resistive signals can occur, if the motor traces are near other traces over longer distances.

20.3 Package Codes

Type	Package	Temperature range	Code & marking
TMC2208-LA	QFN28 (RoHS)	-40°C ... +125°C	TMC2208-LA
TMC2224-LA	QFN28 (RoHS)	-40°C ... +125°C	TMC2224-LA
TMC2202-WA	QFN32 (RoHS)	-40°C ... +125°C	TMC2202-WA
TMC... -T	-T suffix denotes tape on reel packed products		

21 Designed for Sustainability

Sustainable growth is one of the most important and urgent challenges today. We at Trinamic try to contribute by designing highly efficient IC products, to minimize energy consumption, ensure best customer experience and long-term satisfaction by smooth and silent run, while minimizing the demand for external resources, e.g., for power supply, cooling infrastructure, reduced motor size and magnet material by intelligent control interfaces and advanced algorithms.

Please help and design efficient and durable products made for a sustainable world.

23 Revision History

Version	Date	Author	Description
		BD= Bernhard Dwersteg	
V1.00	2016-Nov-01	BD	Adapted min/max DC and Timing Characteristics (I_S , V_{CP_UV} , V_{UV_VS} , 25°C for clock calibration frequency) to fit test limits
V1.01	2016-Nov-16	BD	Corrected wording in DRV_STATUS
V1.02	2017-May-16	BD	Added QFN-32
V1.03	2017-May-31	BD	Hint on PWM_SCALE_AUTO during AT#2
V1.04	2018-May-17	BD	Minor corrections, Lead width missing in table
V1.05	2018-Jun-07	BD	Added errata / limitations for initial tuning of AT#1 / AT#2 phase Added precautions for power up with StealthChop
V1.06	2019-Feb-05	BD	Corrected timing requirements for CLK input (30ns for first pulse) / some minor fixes. Corrected calculation formula for sense resistor with 30mOhm internal resistance rather than 20mOhm.
V1.09	2019-Jul-17	BD	Minor fixes / added order codes, removed HTSSOP package
V1.10	2020-Jun-02	BD	Minor corrections, Logo
V1.11	2021-May-20	BD	Corrected position of CUR_A / CUR_B in register Improved description of StealthChop options
V1.12	2022-Jan-05	BD	p1: Changed logo & block diagram; p13: attention to avoid destructive conditions; p33: pwm_autoscale=0 wording; p33 & 36: Corrected condition for autotuning to include current setting p51: Caveat for selection of sense resistor w. ENN=0; p61: Corrected formula for VACTUAL; p63: Corrected open load detection preconditions; p68 & 69: Corrected pin name reference from VCC to 5VOUT; p79: Hint for sustainable design
V1.13	2022-May-25	BD	Minor corrections; P12: TMC2224 has pull-down on pin ENN; P52: Corrected formula for current calculation with 30mOhm; P60: Corrected position of index output pulse related to coil B rather than coil A
V1.14	2023-Feb-16	BD	P41: Added attention box for IRUN setting P42: Corrected formula for PWM_SCALE_SUM P45: Added attention box to test for open load before Stealth P55: Corrected calculation of external current reference resistor for better precision and matched table Replaced term "slave" against term "node"
