### 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

#### **General Description**

The MAX77801 is a high-efficiency, step-up/step-down (buck-boost) converter targeted for single-cell, Li-ion battery-powered applications. The device maintains a regulated output voltage from 2.6V to 4.18V across an input voltage range of 2.3V to 5.5V. The device supports up to 2A of output current in boost mode and up to 3A in buck mode.

The device seamlessly transitions between buck and boost modes. A unique control algorithm allows high-efficiency and outstanding load and line-transient response.

Dedicated enable and power-OK pins allow simple hardware control. An I<sup>2</sup>C serial interface is optionally used for dynamic voltage scaling, system power optimization, and fault read-back.

The MAX77801 is available in a 20-bump, 2.13mm x 1.83mm wafer-level package (WLP) and also 20-pin, 4mm x 4mm TQFN.

### **Applications**

• Single-Cell, Li-Ion Battery-Powered Devices

**Typical Application Circuit** 

- Handheld Scanners, Mobile Payment Terminals, Security Cameras
- AR/VR Headsets

#### Benefits and Features

- V<sub>IN</sub> Range: 2.30V to 5.5V
- V<sub>OUT</sub> Range: 2.60V to 4.18V (I<sup>2</sup>C Programmable in 12.5mV Steps)
- Up to 2A Output Current in Boost Mode (V<sub>IN</sub> = 3.0V, V<sub>OUT</sub> = 3.4V)
- Up to 3A Output Current in Buck Mode
- Up to 97% Peak Efficiency
- SKIP Mode for Optimal Light Load Efficiency
- 55µA (Typ) Low Quiescent Current
- 3.4MHz High-Speed I<sup>2</sup>C Serial Interface
- Dynamic Voltage Scaling (DVS) Function
- Power-OK Output
- 2.5MHz Switching Frequency
- Protection Features
- Soft-Start
- Thermal Shutdown
- Overvoltage Protection
- Overcurrent Protection
- 2.13mm x 1.83mm, 20-Bump WLP
- 4mm x 4mm, 20-Pin TQFN

Ordering Information appears at end of data sheet.

# 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

### **Absolute Maximum Ratings**

SYS, VIO to AGND	0.3V to +6.0V
IN, OUT to PGND	0.3V to +6.0V
PGND to AGND	0.3V to +0.3V
SCL, SDA to AGND	0.3V to (VIO + 0.3V)
EN, DVS, POK to AGND	0.3V to (V <sub>SYS</sub> + 0.3V)
FB to AGND	0.3V to (VOUT + 0.3V)
LX1 to PGND	0.3V to (VIN + 0.3V)

LX2 to PGND	0.3V to (V <sub>OUT</sub> + 0.3V)
LX1/LX2 Continuous RMS Current	3.3A
Operating Junction Temperature Range	e40°C to +125°C
Junction Temperature	+150°C
Storage Temperature Range	65°C to +150°C
Soldering Temperature (reflow)	+260°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### Package Thermal Characteristics (Note 1)

Junction-to-Ambient Thermal Resistance (0JA	)
20-Bump WLP	55.49°C/W
20-Pin TQFN	39°C/W

**Note 1:** Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to www.maximintegrated.com/thermal-tutorial.

### **Buck-Boost Electrical Characteristics**

 $(V_{SYS} = V_{IN} = +3.8V, V_{FB} = V_{OUT} = +3.3V, T_{J} = -40^{\circ}C$  to +125°C, typical values are at  $T_{A} \approx T_{J} = +25^{\circ}C$ , unless otherwise noted.) (Note 2)

# 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

#### **Detailed Description**

The MAX77801 is a synchronous step-up/step-down (buck-boost) DC-DC converter with integrated switches. The buck-boost operates on a supply voltage between 2.3V and 5.5V. Output voltage is configurable through I<sup>2</sup>C from 2.60V to 4.18V in 12.5mV steps. Factory-default startup voltage options of 3.3V, 3.4, and 3.75V are available (see the *Buck-Boost Electrical Characteristics* table).

#### **Buck-Boost Control Scheme**

The buck-boost converter operates using a 2.5MHz fixedfrequency pulse-width modulated (PWM) control scheme with current-mode compensation. The buck-boost utilizes an H-bridge topology using a single inductor and output capacitor.

The H-bridge topology has three switching phases. See Figure 1 for details.

- Φ1 switch period (Phase 1: HS1 = ON, LS2 = ON) stores energy in the inductor. Inductor current ramps up at a rate proportional to the input voltage divided by inductance: V<sub>IN</sub>/L.
- Φ2 switch period (Phase 2: HS1 = ON, HS2 = ON) ramps inductor current up or down depending on the differential voltage across the inductor: (V<sub>IN</sub> - V<sub>OUT</sub>)/L.
- Φ3 switch period (Phase 3: LS1 = ON, HS2 = ON) ramps inductor current down at a rate proportional to the output voltage divided by inductance: -V<sub>OUT</sub>/L.

Boost operation ( $V_{IN} < V_{OUT}$ ) utilizes phase 1 and phase 2 within a single clock period. See the representation of the inductor current waveform for boost mode operation in Figure 1.

Buck operation ( $V_{IN} > V_{OUT}$ ) utilizes phase 2 and phase 3 within a single clock period. See the representation of the inductor current waveform for buck mode operation in Figure 1.

Figure 1. Buck-Boost H-Bridge Topology

# 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

Figure 2. Buck-Boost Block Diagram

#### Enable Control (EN)

Raise the EN pin voltage above V<sub>IH</sub> threshold to enable the buck-boost output. Lower EN pin below the V<sub>IL</sub> threshold to disable it. EN pin has an internal 800k $\Omega$  (typ) pulldown resistor to AGND. Clear the EN\_PD bit using the I<sup>2</sup>C interface to disable the internal pulldown (making EN pin high-impedance). The EN\_PD bit reset value is 1 (pulldown enabled). Therefore, the internal pulldown resistor is present whenever the MAX77801 starts up. After the initial buck-boost startup, clear the EN bit through I<sup>2</sup>C to disable the buck-boost output. <u>Table 1</u> details the interaction between the EN pin and the EN bit. Provide a valid V<sub>IO</sub> and set the EN pin logic-high to enable the I<sup>2</sup>C serial interface. Serial reads and writes to the EN bit may happen only while V<sub>IO</sub> is valid and EN pin is logic-high. Setting EN pin to logic-low disables the buck-boost (regardless of EN bit) and causes all registers to reset to default values.

### Table 1. EN Logic

EN PIN	EN BIT	I <sup>2</sup> C SERIAL INTERFACE	BUCK-BOOST OUTPUT
Low	Х	Disabled	Disabled
High	0	Enabled	Disabled
High	1 (default)	Enabled	Enabled

# 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

#### **Dynamic Voltage Scaling (DVS)**

The MAX77801 includes a DVS feature that allows output voltage to change dynamically. The DVS pin status dictates whether the buck-boost regulates to  $V_{OUT}$ \_DVS\_L or  $V_{OUT}$ \_DVS\_H. When EN pin or EN bit goes high, the DVS pin status latches until soft-start completes, so changes on DVS are ignored. Internal logic sets  $V_{OUT}$  based on DVS input only after soft-start completion.

The buck-boost converter supports a programmable slew-rate control feature when increasing and decreasing the output voltage. The ramp-up slew rate can be set to  $12.5 \text{mV/}\mu\text{s}$  or  $25 \text{mV/}\mu\text{s}$  through RU\_SR bit. Also, the ramp-down slew rate can be set to  $3.125 \text{mV/}\mu\text{s}$  or  $6.25 \text{mV/}\mu\text{s}$  through RD\_SR bit.

#### Soft-Start

The IC implements a soft-start for a fixed time to control inrush current from the supply input ( $I_{IN}$ ) and prevents droop caused by upstream source impedance. The implementation of soft-start is different among variants. See <u>Table 2</u> for a summary. The soft-start time begins immediately after the startup delay ( $t_{ON}$  DLY).

MAX77801EWP+T and MAX77801ETP+T achieve softstart by reducing the peak inductor current limit ( $I_{LIM}_Lx$ ) for a fixed time  $t_{SS}_{LOW}_{ILIM}$  after the buck-boost enables through either the EN pin or EN bit (Figure 4).

Figure 3. DVS Functional Block Diagram

Figure 4. Startup Waveform (Reduce I<sub>LIM LX</sub> only)

PART	SOFT-START IMPLEMENTATION	<sup>t</sup> SS_RAMP_VREF SOFT- START TIME (μs)	<sup>t</sup> ss_Low_ILIM SOFT- START TIME (μs)	I <sub>LIM_LX_SS</sub> DURING t <sub>SS_LOW_</sub> ILIM (A)	I <sub>LIM_LX</sub> AFTER t <sub>SS_LOW_ILIM</sub> (A)	
MAX77801EWP+ T	Reduce Laws	NI/A				
MAX77801ETP+ T		IN/A	120	1.8	15	
MAX77801HEWP+ T	Ramp V <sub>REF</sub> and Reduce I <sub>LIM_LX</sub>	300	120	1.0	т.0	

### Table 2. Soft-Start Behavior

# 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

MAX77801HEWP+T achieves soft-start by slowly ramping internal reference (V<sub>REF</sub>) to the target value in a fixed time  $t_{SS\_RAMP\_VREF}$ , while also reducing the peak inductor current limit ( $I_{LIM\_LX}$ ) for a fixed time  $t_{SS\_LOW\_ILIM}$  after the buck-boost enables through either the EN pin or EN bit (Figure 5).

#### Burst Mode (Enhanced Load Response)

The device implements a burst mode to service shortduration heavy load transients (burst loads). A summary of burst mode operation follows:

- If a heavy load transient happens that requires peak inductor current > I<sub>LIM\_LX</sub> to maintain regulation, then the buck-boost temporarily increases the peak inductor current limit from I<sub>LIM\_LX</sub> to I<sub>LIM\_LX\_HIGH</sub>. (See <u>Table 3</u>.)
- If the heavy load causes a peak inductor current
   I<sub>LIM\_LX</sub> for longer than 800µs (typ), then burst mode deactivates and the peak inductor current limit returns to I<sub>LIM\_LX</sub>.

Figure 5. Startup Waveform (Ramp V<sub>REF</sub> and Reduce I<sub>LIM LX</sub>)

#### Table 3. ILIM Levels

INDUCTOR CURRENT	INDUCTOR CURRENT
LIMIT DURING NORMAL	LIMIT DURING BURST
OPERATION	MODE
I <sub>LIM_LX</sub> (A)	I <sub>LIM_LX_HIGH</sub> (A)
4.5	5.5

Figure 6. Short-Circuit Waveform

### 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

#### Power-OK (POK) Output

The device features an open-drain POK output to monitor the output voltage. POK requires an external pullup resistor (typically  $10k\Omega$  to  $100k\Omega$ ).

POK is active-high by default. Use the POK\_POL bit to change the POK polarity to active-low. See the <u>Register</u> <u>Map</u> for details.

While POK\_POL = 1 (active-high, default state), POK goes high (high-impedance) after the buck-boost output increases above 80% of the target regulation voltage. POK goes low when the output drops below 75% of the target or when the buck-boost is disabled.

# Output Voltage Selection and Slew-Rate Control

Write the VOUT\_DVS\_L[6:0] or VOUT\_DVS\_H[6:0] bit field through I<sup>2</sup>C to configure the target output voltage (V<sub>OUT</sub>) between 2.60V and 4.18V in 12.5mV steps. The default value of the bit fields is factory programmable. See the <u>Buck-Boost Electrical Characteristics</u> table for the default V<sub>OUT</sub> associated with each orderable part number. Overwriting the default value through I<sup>2</sup>C sets a new target V<sub>OUT</sub> until registers reset.

Changing the bit fields while the buck-boost output is enabled causes the device to respond in the following way:

- V<sub>OUT</sub> ramps up at a rate set by RU\_SR (12.5mV/µs or 25mV/µs) when the V<sub>OUT</sub> target is *increased*.
- V<sub>OUT</sub> ramps down at a rate set by RD\_SR (3.125mV/µs or 6.25mV/µs) when the V<sub>OUT</sub> target is *decreased*.

See the <u>Register Map</u> for details about the RU\_SR and RD\_SR bits.

#### **Output Overvoltage Protection (OVP)**

The device has an internal output overvoltage protection (OVP) circuit that monitors  $V_{OUT}$  for overvoltage faults. The buck-boost disables if the output exceeds the overvoltage threshold set by the OVP\_TH[1:0] bit field.

Disable OVP by programming OVP\_TH[1:0] to 0b00 using I<sup>2</sup>C. The default OVP threshold is 0b11 (120% of the target  $V_{OUT}$ ).

The OVP status bit continuously mirrors the status of the OVP circuit. See the *Register Map* for details.

#### **Thermal Shutdown**

The device has an internal thermal protection circuit that monitors die temperature. The buck-boost disables if the die temperature exceeds  $T_{SHDN}$  (+165°C typ). The buck-boost enables again after the die temperature cools by approximately 20°C.

The TSHDN status bit continuously mirrors the status of the thermal protection circuit. See the <u>*Register Map*</u> for details.

#### I<sup>2</sup>C Serial Interface

The device features a revision 3.0 I<sup>2</sup>C-compatible, 2-wire serial interface consisting of a bidirectional serial data line (SDA) and a serial clock line (SCL). The MAX77801 is a slave-only device that that relies on an external bus master to generate SCL. SCL clock rates from 0Hz to 3.4MHz are supported. I<sup>2</sup>C is an open-drain bus, and therefore, SDA and SCL require pullups (of 500 $\Omega$  or greater).

The device's I<sup>2</sup>C communication controller implements 7-bit slave addressing. An I<sup>2</sup>C bus master initiates communication with the slave by issuing a START condition followed by the slave address. The slave address of the device is shown in Table 4.

The device uses 8-bit registers with 8-bit register addressing. They support standard communication protocols:

- Writing to a single register
- Writing to multiple sequential registers with an automatically incrementing data pointer
- Reading from a single register
- Reading from multiple sequential registers with an automatically incrementing data pointer

For additional information on the I<sup>2</sup>C protocols, refer to the *Serial Interface* section.

### Table 4. I<sup>2</sup>C Slave Address

### **Applications Information**

#### **Inductor Selection**

Choose a 1 $\mu$ H inductor with a saturation current of 7A or higher. Table 5 recommends inductors for the MAX77801. Always choose the inductor carefully by consulting the manufacturer's latest released data sheet.

#### **Input Capacitor Selection**

Choose the input capacitor (C<sub>IN</sub>) to be a 10µF ceramic capacitor that maintains at least 2µF of effective capacitance at its working voltage. Larger values improve the decoupling of the buck-boost. C<sub>IN</sub> reduces the current peaks drawn from the battery or input power source and reduces switching noise in the device. Ceramic capacitors with X5R or X7R dielectric are highly recommended due to their small size, low ESR, and small temperature coefficients.

All ceramic capacitors derate with DC bias voltage (effective capacitance goes down as DC bias goes up). Generally, small case size capacitors derate heavily as compared to larger case sizes (0603 case size performs better than 0402). Consider the effective capacitance value carefully by consulting the manufacturer's data sheet.

#### **Output Capacitor Selection**

Sufficient output capacitance ( $C_{OUT}$ ) is required to keep the output-voltage ripple small and the regulation loop stable. Choose the effective  $C_{OUT}$  to be 16µF minimum. Considering the DC bias characteristic of ceramic capacitors, a 47µF 10V capacitor is recommended for most applications.

Effective  $C_{OUT}$  is the actual capacitance value seen by the buck-boost output during operation. Choose effective  $C_{OUT}$  carefully by considering the capacitor's initial tolerance, variation with temperature, and derating with DC bias.

Ceramic capacitors with X5R or X7R dielectric are highly recommended due to their small size, low ESR, and small temperature coefficients. All ceramic capacitors derate with DC bias voltage (effective capacitance goes down as DC bias goes up). Generally, small case size capacitors derate heavily as compared to larger case sizes (0603 case size performs better than 0402). Consider the effective capacitance value carefully by consulting the manufacturer's data sheet.

#### **PCB Layout Guidelines**

Careful circuit board layout is critical to achieve low switching power losses and clean, stable operation. For the WLP package, an HDI (high density interconnect) PCB is required. Figure 7 shows an example HDI PCB layout for the MAX77801 WLP package. Figure 9 shows an example PCB layout for the MAX77801 FC2QFN package.

When designing the PCB, follow these guidelines:

- Place the input capacitors (C<sub>IN</sub>) and output capacitors (C<sub>OUT</sub>) immediately next to the IN pin and OUT pin, respectively, of the IC. Since the IC operates at a high switching frequency, this placement is critical for minimizing parasitic inductance within the input and output current loops, which can cause high-voltage spikes and may damage the internal switching MOSFETs. See Figure 8 for an illustration.
- 2) Place the inductor next to the LX bumps/pins (as close as possible) and make the traces between the LX bumps/pins and the inductor short and wide to minimize PCB trace impedance. Excessive PCB impedance reduces converter efficiency. When routing LX traces on a separate layer (as in the examples), make sure to include enough vias to minimize trace impedance. Routing LX traces on multiple layers is recommended to further reduce trace impedance. Furthermore, do not make LX traces take up an excessive amount of area. The voltage on this node switches very quickly, and additional area creates more radiated emissions.

MFGR.	SERIES	NOMINAL INDUCTANCE (µH)	TYPICAL DC RESISTANCE (mΩ)	CURRENT RATING (A) -30% (ΔL/L)	CURRENT RATING (A) ΔT = 40°C RISE	DIMENSIONS L x W x H (mm)

#### Table 5. Suggested Inductors

# 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

- Prioritize the low-impedance ground plane of the PCB directly underneath the IC, C<sub>OUT</sub>, C<sub>IN</sub>, and inductor. Cutting this ground plane risks interrupting the switching current loops.
- AGND must carefully connect to PGND on the PCB's low-impedance ground plane. Connect AGND to the low-impedance ground plane on the PCB (the same net as PGND) away from any critical loops.
- 5) The IC requires a quiet supply input (SYS) which is often the same net as IN. Carefully bypass SYS to AGND with a dedicated capacitor (C<sub>SYS</sub>) as close as possible to the IC. Route a dedicated trace between

C<sub>SYS</sub> and the SYS bump/pin. Avoid connecting SYS directly to the nearest IN bumps/pins without dedicated bypassing.

- 6) Connect the FB bump/pin to the regulating point with a dedicated trace away from noisy nets such as LX1 and LX2.
- 7) Keep the power traces and load connections short and wide. This is essential for high converter efficiency.
- Do not neglect ceramic capacitor DC voltage derating. Choose capacitor values and case sizes carefully. See the <u>Output Capacitor Selection</u> section and refer to <u>Tutorial 5527</u> for more information.

# 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

Figure 8. Recommended Capacitor Placement

Figure 9. PCB Layout Example (TQFN)

### **Serial Interface**

The I<sup>2</sup>C-compatible, 2-wire serial interface is used for regulator on/off control, setting output voltages, and other functions. See the *Register Map* section for details.

The I<sup>2</sup>C serial bus consists of a bidirectional serial-data line (SDA) and a serial clock (SCL). I<sup>2</sup>C is an open-drain bus. SDA and SCL require pullup resistors (500 $\Omega$  or greater). Optional 24 $\Omega$  resistors in series with SDA and SCL help to protect the device inputs from high voltage spikes on the bus lines. Series resistors also minimize crosstalk and undershoot on bus lines.

#### **System Configuration**

The I<sup>2</sup>C bus is a multi-master bus. The maximum number of devices that can attach to the bus is only limited by bus capacitance.

Figure 10 shows an example of a typical I<sup>2</sup>C system. A device on I<sup>2</sup>C bus that sends data to the bus is called a "transmitter". A device that receives data from the bus is called a "receiver". The device that initiates a data transfer and generates SCL clock signals to control the data transfer

is called a "master". Any device that is being addressed by the master is called a "slave". When the MAX77801 I<sup>2</sup>C-compatible interface is operating, it is a slave on I<sup>2</sup>C bus, and it can be both a transmitter and a receiver.

#### **Bit Transfer**

One data bit is transferred for each SCL clock cycle. The data on SDA must remain stable during the high portion of SCL clock pulse. Changes in SDA while SCL is high are control signals (START and STOP conditions).

#### **START and STOP Conditions**

When the I<sup>2</sup>C serial interface is inactive, SDA and SCL idle high. A master device initiates communication by issuing a START condition (S). A START condition (S) is a high-to-low transition on SDA with SCL high. A STOP condition (P) is a low-to-high transition on SDA with SCL high.

A START condition (S) from the master signals the beginning of a transmission. The master terminates transmission by issuing a NOT-ACKNOWLEDGE (nA) followed by a STOP condition (P).

Figure 10. Functional Logic Diagram for Communications Controller

Figure 12. START and STOP Conditions

A STOP condition (P) frees the bus. To issue a series of commands to the slave, the master may issue REPEATED START (Sr) conditions instead of a STOP condition (P) in order to maintain control of the bus. In general, a REPEATED START (Sr) condition is functionally equivalent to a regular START condition (S).

When a STOP condition (P) or incorrect address is detected, the MAX77801 internally disconnects SCL from I<sup>2</sup>C serial interface until the next START condition (S), minimizing digital noise and feedthrough.

#### Acknowledge

Both the I<sup>2</sup>C bus master and the MAX77801 (slave) generate acknowledge bits when receiving data. The acknowledge bit is the last bit of each 9-bit data packet. To generate an ACKNOWLEDGE (A), the receiving device must pull SDA low before the rising edge of the acknowledge-related clock pulse (ninth pulse) and keep it low during the high portion of the clock pulse. To generate a NOT-ACKNOWLEDGE (nA), the receiving device allows SDA to be pulled high before the rising edge of the acknowledge-related clock pulse and leaves it high during the high portion of the clock pulse.

Monitoring the acknowledge bits allows for detection of unsuccessful data transfers. An unsuccessful data transfer occurs if a receiving device is busy or if a system fault has occurred. In the event of an unsuccessful data transfer, the bus master should reattempt communication at a later time.

#### **Slave Address**

The I<sup>2</sup>C slave address of the MAX77801 is shown in Table 6.

#### **Clock Stretching**

In general, the clock signal generation for the I<sup>2</sup>C bus is the responsibility of the master device. I<sup>2</sup>C specification allows slow slave devices to alter the clock signal by holding down the clock line. The process in which a slave device holds down the clock line is typically called clock stretching. The MAX77801 does not use any form of clock stretching to hold down the clock line.

#### **General Call Address**

The MAX77801 does not implement the I<sup>2</sup>C specification "General Call Address." If the MAX77801 detects a general call address (0000000b), it does not issue an ACKNOWLEDGE (A).

#### **Communication Speed**

The MAX77801 supports the following I<sup>2</sup>C revision 3.0-compatible communication speeds:

- 0Hz to 100kHz (standard mode)
- 0Hz to 400kHz (fast mode)
- 0Hz to 1MHz (fast mode plus)
- 0Hz to 3.4MHz (high-speed mode)

Operating in standard mode, fast mode, and fast mode plus does not require any special protocols. The main consideration when changing the bus speed through this range is the combination of the bus capacitance and pullup resistors. Higher time constants created by the bus capacitance and pullup resistance (C x R) slow the bus operation. Therefore, when increasing bus speeds, the pullup resistance must be decreased to maintain a reasonable time constant. Refer to the Pullup Resistor Sizing section of I<sup>2</sup>C revision 3.0 specification for detailed guidance on the pullup resistor selection. In general, for bus capacitances of 200pF, a 100kHz bus needs 5.6kΩ pullup resistors, a 400kHz bus needs about a 1.5kΩ pullup resistors, and a 1MHz bus needs 680Ω pullup resistors. Note that the pullup resistor is dissipating power when the open-drain bus is low. The lower the value of the pullup resistor, the higher the power dissipation  $(V^2/R)$ .

#### Table 6. I<sup>2</sup>C Slave Address

SLAVE AD-	SLAVE AD-	SLAVE AD-
DRESS (7 BIT)	DRESS (WRITE)	DRESS (READ)
0x18 (001 1000)	0x30 (0011 0000)	0x31 (0011 0001)

Figure 13. Slave Address Byte Example

### 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

Operating in high-speed mode requires some special considerations. For the full list of considerations, refer to the  $I^2C$  revision 3.0 specification. The major considerations with respect to the MAX77801 are:

- The master device shall use current source pullups to shorten the signal rise times.
- The slave device must use a different set of input filters on its SDA and SCL lines to accommodate for the higher bus speed.
- The communication protocols need to utilize the high-speed master code.

At power-up and after each STOP condition (P), the MAX77801 input filters are set for standard mode, fast mode, or fast mode plus (i.e., 0Hz to 1MHz). To switch the input filters for high-speed mode, use the protocol described in the *Engaging in High-Speed Mode* section.

#### **Communication Protocols**

The MAX77801 supports both writing and reading from its registers. The following sections show the  $I^2C$  communication protocols available.

#### Writing to a Single Register

Figure 14 shows the protocol for writing to a single register. This protocol is the same as SMBus specification's "Write Byte" protocol.

The "Write Byte" protocol is as follows:

- 1. The master sends a START condition (S).
- 2. The master sends the 7-bit slave address followed by a write bit (R/W = 0).
- The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 4. The master sends an 8-bit register pointer.
- 5. The slave acknowledges the register pointer.
- 6. The master sends a data byte.

- 7. The slave acknowledges the data byte. At the rising edge of SCL, the data byte is loaded into its target register and the data becomes active.
- The master sends a STOP condition (P) or a REPEATED START condition (Sr). Issuing a STOP condition (P) ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START condition (Sr) leaves the bus input filters in their current state.

#### Writing to Sequential Registers

Figure 15 shows the protocol for writing to sequential registers. This protocol is similar to the "Write Byte" protocol, except the master continues to write after the slave device receives the first byte of data. When the master is done writing, it issues a STOP condition (P) or a REPEATED START condition (Sr).

The "Writing to Sequential Registers" protocol is as follows:

- 1. The master sends a START condition (S).
- 2. The master sends the 7-bit slave address followed by a write bit (R/W = 0).
- The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 4. The master sends an 8-bit register pointer.
- 5. The slave acknowledges the register pointer.
- 6. The master sends a data byte.
- 7. The slave acknowledges the data byte. At the rising edge of SCL, the data byte is loaded into its target register and the data becomes active.
- 8. Steps 6 to 7 are repeated as many times as the master requires. During the last acknowledge related clock pulse, the slave issues an ACKNOWLEDGE (A).
- The master sends a STOP condition (P) or a REPEATED START condition (Sr). Issuing a STOP condition (P) ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START condition (Sr) leaves the bus input filters in their current state.

# 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

Figure 14. Writing to a Single Register

Figure 15. Writing to Sequential Registers

# 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

#### Reading from a Single Register

Figure 16 shows the protocol for reading from a single register. This protocol is the same as SMBus specification's "Read Byte" protocol.

The "Read Byte" protocol is as follows:

- 1. The master sends a START condition (S).
- 2. The master sends the 7-bit slave address followed by a write bit (R/W = 0).
- 3. The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 4. The master sends an 8-bit register pointer.
- 5. The slave acknowledges the register pointer.
- 6. The master sends a REPEATED START condition (Sr).

- 7. The master sends the 7-bit slave address followed by a read bit  $(R/\overline{W} = 1)$ .
- 8. The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 9. The addressed slave places 8 bits of data on the bus from the location specified by the register pointer.
- 10. The master issues a NOT-ACKNOWLEDGE (nA).
- 11. The master sends a STOP condition (P) or a REPEATED START condition (Sr). Issuing a STOP condition (P) ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START condition (Sr) leaves the bus input filters in their current state.

Figure 16. Reading from a Single Register

# 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

#### **Reading from Sequential Registers**

Figure 17 shows the protocol for reading from sequential registers. This protocol is similar to the "Read Byte" protocol, except the master issues an ACKNOWLEDGE (A) to signal the slave that it wants more data. When the master has all the data it requires, it issues a NOT-ACKNOWLEDGE (nA) and a STOP condition (P) to end the transmission.

The "Continuous Read from Sequential Registers" protocol is as follows:

- 1. The master sends a START condition (S).
- The master sends the 7-bit slave address followed by a write bit (R/W = 0).
- The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 4. The master sends an 8-bit register pointer.
- 5. The slave acknowledges the register pointer.
- 6. The master sends a REPEATED START condition (Sr).

- 7. The master sends the 7-bit slave address followed by a read bit  $(R/\overline{W} = 1)$ .
- 8. The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 9. The addressed slave places 8-bits of data on the bus from the location specified by the register pointer.
- 10. The master issues an ACKNOWLEDGE (A) signaling the slave that it wishes to receive more data.
- 11. Steps 9 to 10 are repeated as many times as the master requires. Following the last byte of data, the master must issue a NOT-ACKNOWLEDGE (nA) to signal that it wishes to stop receiving data.
- 12. The master sends a STOP condition (P) or a REPEATED START condition (Sr). Issuing a STOP condition (P) ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START condition (Sr) leaves the bus input filters in their current state.

Figure 17. Reading Continuously from Sequential Registers

# 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

#### Engaging in High-Speed Mode

Figure 18 shows the protocol for engaging in high-speed mode operation, which allows the bus to operate at speed up to 3.4MHz.

The "Engage in High-Speed Mode" protocol is as follows:

- 1. Begin the protocol while operating at a bus speed of 1MHz or lower
- 2. The master sends a START condition (S).

- 3. The master sends the 8-bit master code of 0000 1xxx where "xxx" are don't care bits.
- 4. The addressed slave issues a NOT-ACKNOWLEDGE (nA).
- 5. The master can now increase its bus speed up to 3.4MHz and issue any read/write operation.

The master may continue to issue high-speed read/write operations until a STOP condition (P) is issued. Issuing a STOP condition (P) ensures that the bus input filters are set for 1MHz or slower operation.

Figure 18. Engaging in High-Speed Mode

VOUT_DVS_L	6:0	Output Voltage Control (DVS Logic Low). Sets the V <sub>OUT</sub> target when DVS pin is logic low. Configurable in 12.5mV per LSB from 0x00 (2.60V) to 0x7F (4.1875V). The default value of this register is pre- set. See the <u>Ordering Information</u> table. Overwriting the default value sets a new target output voltage.	0x00 = 2.60V 0x01 = 2.6125V 0x02 = 2.6250V  0x38 = 3.30V  0x40 = 3.40V  0x7E = 4.1750V 0x7F = 4.1875V

# 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

### VOUT\_DVS\_H (0x05)

BIT	7	6	5	4	3	2	1	0

ACCESS	Read, Write	Read, Write						

BIT FIELD	BITS	DESCRIPTION	DECODE
RESERVED	7	Reserved. Bit is a <i>don't care</i> .	N/A
VOUT_DVS_H	6:0	Output Voltage Control (DVS Logic High). Sets the V <sub>OUT</sub> target when DVS pin is logic high. Configurable in 12.5mV per LSB from 0x00 (2.60V) to 0x7F (4.1875V). The default value of this register is pre- set. See the <u>Ordering Information</u> table. Overwriting the default value sets a new target output voltage.	0x00 = 2.60V 0x01 = 2.6125V 0x02 = 2.6250V  0x40 = 3.40V  0x5C = 3.75V  0x7E = 4.1750V 0x7F = 4.1875V

### **Ordering Information**

PART	DEFAULT V <sub>OUT</sub>	SOFT- START TIME <sup>1</sup>	PIN- PACKAGE
MAX77801EWP+T	3.3V/3.4V	120µs	20 WLP
MAX77801ETP+T	3.3V/3.75V	120µs	20 TQFN
MAX77801HEWP+T	3.3V/3.4V	300µs	20 WLP

<sup>1</sup>See the <u>Soft-Start</u> section for more information. +Denotes a lead(Pb)-free/RoHS-compliant package. T = Tape and reel.

### **Package Information**

For the latest package outline information and land patterns (footprints), go to <u>www.maximintegrated.com/packages</u>. Note that a "+", "#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

PACKAGE TYPE	PACKAGE CODE	OUTLINE NO.	LAND PATTERN NO.
20 WLP	W201F2+1	<u>21-0771</u>	Refer to Application Note 1891
20 TQFN	T2044-3C	<u>21-0139</u>	<u>90-0037</u>

# 5.5V Input, 2A, High-Efficiency Buck-Boost Converter

### **Revision History**

REVISION NUMBER	REVISION DATE	DESCRIPTION	PAGES CHANGED
0	2/15	Initial release	—
1	4/17	Added MAX77801ETP TQFN package information, updated <i>Benefits and Features</i> section, updated <i>Communication Protocals</i> sections, updated Figures 10–12, updated tables for <i>Package Thermal Characteristics</i> , <i>Buck-Boost Electrical Characteristics</i> , <i>Register Map</i> , <i>VOUT_DVS_H</i> , <i>Ordering Information</i> , and <i>Package Information</i>	1–3, 8, 14–19, 23, 24
2	2/18	Corrected a typo in Figure 5	11
3	3/18	Added MAX77801ETP default V <sub>OUT</sub> to <i>Electrical Characteristics</i> table	2
4	10/19	Updated front page, <i>Typical Operating Characteristics</i> , <i>Bump/Pin Configuration</i> , <i>Detailed Description</i> , <i>Applications Information</i> , <i>PCB Layout Guidelines</i> , Figures 1-8, <i>Register Map</i> , <i>Ordering Information</i> table, deleted original Note 1 and renumbered remaining Notes	1–3, 7–11, 19–24
5	11/19	Replaced <i>Typical Application Circuit</i> Figure, updated <i>Absolute Maximum Ratings</i> , updated EC Globals, <i>Buck-Boost Electrical Characteristics</i> table and <i>I</i> <sup>2</sup> <i>C Electrical</i> <i>Characteristics</i> table, updated Note 2, updated sub title for <i>Typical Operating</i> <i>Characteristics</i> , updated <i>Bump/Pin Configurations</i> figure and <i>Bump/Pin Description</i> table, updated Figure 2, replaced OUTS with FB in the <i>PCB Layout Guideline</i> section, updated Figures 6 and 8	1–10, 12, 17, 18
6	7/22	Updated Register Map	26–28
7	1/23	Updated General Description, Benefits and Features, Absolute Maximum Ratings, Buck-Boost Electrical Characteristics, Pin Configuration, Pin Description, Enable Control (EN), Table 1, Dynamic Voltage Scaling (DVS), Figure 5, Output Voltage Selection and Slew-Rate Control, Output Overvoltage Protection (OVP), Thermal Shutdown, I <sup>2</sup> C Serial Interface, Input Capacitor Selection, Output Capacitor Selection, PCB Layout Guidelines, Table 5, System Configuration, START and STOP Conditions, Acknowledge, Slave Address, General Call Address, Communication Speed, Table 6, Communication Protocols, Writing to a Single Register, Writing to Sequential Registers, Figures 13, 14, and 15, Reading from a Single Register, Reading from Sequential Registers, Figure 16, Engaging in High-Speed Mode, Figure 17, Register Map	1, 2, 4, 10, 12–17, 19–29
8	6/23	Updated <i>Buck-Boost Electrical Characteristics</i> table, TOC10, and <i>Soft-Start</i> section, renumbered Figures 5 to 17, updated <i>START</i> and <i>STOP</i> Conditions section, <i>Register Map</i> , and <i>Ordering Information</i> table	3, 8, 13, 14, 16–25, 28, 30
