| MAX77985/MAX77986 | 19VIN, 3.5/5.5A 1-Cell Li+ Battery Charger with Smart Power Selector and OTG for USBC PD |

General Description

The MAX77985/MAX77986 is a high-performance high input range 3.5/5.5A fast charger with Smart Power Selector™. The IC can operate as a reverse boost without an additional inductor, allowing the battery to share its power through the charging port with voltage programmable from 5V to 12V. The device features fully integrated low-loss power switches to provide a small solution size and high efficiency, even at high input voltage and high charging current. Its high switching frequency allows the use of a smaller sized inductor. Li-ion, Li-polymer, and LiFePO$_4$ battery chemistries are supported. The IC is compatible with USB Power Delivery sources with input current capability up to 5A. It can also provide fast unplug detection of 9V and 15V sources for dynamic management of system load. The IC also helps mitigate EMI with the spread spectrum feature. The IC features true load disconnection in reverse boost mode and has an adjustable output current protection limit. The device is highly flexible and programmable through I^{2}C configuration.

The battery charger includes a Smart Power Selector to accommodate a wide range of battery sizes and system loads. The Smart Power Selector allows the system to start up gracefully as soon as an input source is available, even when the battery is deeply discharged (dead battery) or missing. It can be configured so that when power is applied to the charger input, the battery charging can automatically start.

Applications

- Gaming Devices
- VR Applications
- mPOS
- Tablet PCs

Benefits and Features

- High-Efficiency Single-Cell Switching Charger
  - Up to 5.5A Charging with MAX77986
  - Up to 3.5A Charging with MAX77985
  - 92% Buck Efficiency at 4A, 12V Input
  - 92% Charging Efficiency at 3.5A, 9V Input
  - Optimized for High Voltage Input Operation
  - Accelerate Charge Time by Monitoring Kelvin Sensing Battery Voltage
  - Up to 5.5A Input Current Limit with AICL (MAX77986)
  - Up to 3.5A Input Current Limit with AICL (MAX77985)
- +28V Absolute Maximum Input Voltage Rating
- 4.7V to 19V Input Operating Voltage Range
- Reverse Boost with Programmable Output Voltage Options up to 12V
  - Up to 18W for MAX77986
  - Up to 12W for MAX77985
- Integrated Battery True-Disconnect FET
  - R$_{DSON}$ = 7.7mΩ
  - Programmable Discharge Current Limit up to 10A
  - Support Shipping Mode and Low Battery Leakage Current
  - 1.3MHz/2.6MHz Switching Frequency with 1µH/ 0.47µH Inductor
  - Disconnect Input (DISQBAT)
- Safety
  - Battery Temperature Sensing and Charge Safety Timer
  - JEITA Guideline Compliant
  - Thermal Regulation and Thermal Shutdown
  - System Voltage OVLO/UVLO
- Spread Spectrum for Noise Sensitive Applications
- Programmable Unplug Detection for 9V and 15V Sources
- Charge Status Output for LED
- Push-Button Input for Exiting from Ship Mode
- External Discharge FET Enable Output
- Dedicated Input for Suspend Mode (SUSPND)
- I^{2}C Interface
- 4mm x 4mm FC2QFN

Smart Power Selector is a trademark of Maxim Integrated Products, Inc.
USB Type-C is a registered trademark of USB Implementers Forum.
PowerPath is a trademark of Linear Technology Corporation.

Continuous Power Dissipation (Multilayer Board) (T_A = +70°C,
deration is 35.34mW/°C above +70°C)......... mW to 2826.86mW
Operating Temperature Range ....-40°C to +85°C
Junction Temperature ....+150°C
Storage Temperature Range ....-65°C to +150°C
Soldering Temperature (reflow) ....+260°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Package Information

FCQFN

Package Code	F234A4F+1
Outline Number	**21-100411**
Land Pattern Number	**90-100145**
Thermal Resistance, Four-Layer Board:	
Junction to Ambient (θ_{JA})	28.30°C/W
Junction to Case (θ_{JC})	6.65°C/W

IRQB Output High Leakage	I_{IRQB_H}	V_{IRQB} = 5.5V, T_A = +25°C	-1	0	+1	µA
		V_{IRQB} = 5.5V, T_A = +85°C		0.1		
CHGIN INPUT LIMITER						
CHGIN Operating Voltage Range	V_{CHGIN}	V_{CHGIN} must be less than V_{CHGIN_OVLO} and greater than both V_{CHGIN_UVLO} and (V_{SYS} + $V_{CHGIN2SYS\_TH}$) for the charger to turn-on	V_{CHGIN_UVLO}		V_{CHGIN_OVLO}	V
CHGIN Overvoltage Threshold	V_{CHGIN_OVLO}	V_{CHGIN} rising	19	19.5	20	V

Electrical Characteristics (continued)

(V_{SYS} = 3.8V, V_{BATT} = 3.8V, V_{VIO} = 1.8V, V_{CHGIN} = 5V, unless otherwise specified. Limits are production tested at T_A = +25°C. Limits over the operating temperature range and relevant supply voltage range are guaranteed by design and characterization.)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
CHGIN Overvoltage Threshold Hysteresis	$V_{CHGIN\_OVLO\_HYS}$			500		mV
CHGIN Undervoltage Threshold Setting Range	V_{CHGIN_UVLO}	V_{CHGIN} rising, 20% hysteresis, programmable at 4.7V, 4.8V, 4.9V, 5.05V	4.7		5.05	V
CHGIN Undervoltage Threshold Accuracy	$V_{CHGIN\_UVLO\_ACC}$	V_{CHGIN} rising, 4.7V setting	4.625	4.7	4.775	V
CHGIN to SYS Undervoltage Threshold Rising	$V_{CHGIN2SYS\_TH}$	V_{CHGIN} - V_{SYS}, rising	0.15	0.20	0.25	V
CHGIN Turn-On Threshold Validation Delay	t_{D-UVLO}	Delay from V_{CHGIN} > V_{CHGIN_UVLO} to Q_{CHGIN} FET enable		8		ms
CHGIN Switching Start Delay	t_{START}	Delay from Input Validation to LX switching (if charge or buck mode is selected and charger is not suspended); see the Input Validation section for input validation conditions		150		ms
CHGIN Adaptive Voltage Regulation Threshold Setting Range	V_{CHGIN_REG}	Programmable at 4.5V, 4.6V, 4.7V, 4.85V. The input voltage regulation loop decreases the input current to regulate V_{CHGIN} at V_{CHGIN_REG} under weak input source conditions. If the input current is decreased to I_{IULO_DET} and the input voltage is equal or below V_{CHGIN_REG}, then the charger input is turned off.	4.5		4.85	V
CHGIN Adaptive Voltage Regulation Threshold Accuracy	$V_{CHGIN\_REG\_ACC}$	4.5V setting	4.4	4.5	4.6	V
CHGIN Input Current Limit Setting Range	$I_{INLIMIT}$	Programmable, 500mA default, 50mA step, production tested at 5V (500mA, 2700mA), 9V (1500mA), 12V(1000mA), 15V(500mA) (MAX77985)	0.1		3.5	A
		Programmable, 500mA default, 50mA step, production tested at 5V (500mA, 2700mA, 5000mA), 9V (1500mA, 4000mA), 12V (1000mA, 3000mA), 15V (500mA, 2400mA) (MAX77986)	0.1		5.5	

Electrical Characteristics (continued)

(V_{SYS} = 3.8V, V_{BATT} = 3.8V, V_{VIO} = 1.8V, V_{CHGIN} = 5V, unless otherwise specified. Limits are production tested at T_A = +25°C. Limits over the operating temperature range and relevant supply voltage range are guaranteed by design and characterization.)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
CHGIN Input Current Limit Accuracy	$I_{INLIMIT}$	Charger enabled, CHGIN = 5V ±5%, input current limit setting ≤ 2.7A, T_A = -5°C to +85°C	-10		0	%
		Charger enabled, CHGIN = 5V ±5%, input current limit setting > 2.7A, T_A = -5°C to +85°C	-10		+5	
		Charger enabled, CHGIN = 9V ±5%, input current limit setting ≤ 1.5A, T_A = -5°C to +85°C	-10		0	
		Charger enabled, CHGIN = 9V ±5%, input current limit setting > 1.5A, T_A = -5°C to +85°C	-10		+5	
		Charger enabled, CHGIN = 12V ±5%, input current limit setting ≤ 1A, T_A = -5°C to +85°C	-10		+5	
		Charger enabled, CHGIN = 12V ±5%, input current limit setting > 1A, T_A = -5°C to +85°C	-10		+10	
		Charger enabled, CHGIN = 15V ±5%, input current limit setting ≤ 0.5A, T_A = -5°C to +85°C	-10		+5	
		Charger enabled, CHGIN = 15V ±5%, input current limit setting > 0.5A, T_A = -5°C to +85°C	-10		+10	
CHGIN Input Current Low Threshold	I_{IULO_DET}	Charger enabled, 3200mA input current limit setting		60		mA
CHGIN Unplug Detection Threshold Accuracy	$V_{CHGIN\_UNPLG\_ACC}$	V_{CHGIN} falling, UNPLUG_TH{1:0} = 0b10 (9V option)	7.30	7.45	7.60	V
		V_{CHGIN} falling, UNPLUG_TH{1:0} = 0b11 (15V option)	12.925	13.125	13.325	
CHGIN Unplug Detection Threshold Hysteresis	$V_{CHGIN\_UNPLG\_HYS}$			500		mV
SYSTEM BUCK						
Buck Output Voltage Setting Range (Tracking Disabled, MODE = 0x4, Variant A)	V_{SYSREG}	Programmable 4.15V to 4.5375V in 12.5mV steps (5-bits); production tested at 4.2V only	4.15		4.5375	V
Buck Output Voltage Setting Range (Tracking Disabled, MODE = 0x4, Variant B)	V_{SYSREG}	Programmable 3.50V to 4.275V in 25mV steps (5-bits); production tested at 4.2V only	3.50		4.275	V
Buck Output Voltage Setting Range (Tracking Disabled, MODE = 0x6, Variant A)	V_{SYSREG}	Programmable 4.65V to 5.00V in 50mV steps (3-bits); production tested at 5.0V only	4.65		5.00	V

Electrical Characteristics (continued)

(V_{SYS} = 3.8V, V_{BATT} = 3.8V, V_{VIO} = 1.8V, V_{CHGIN} = 5V, unless otherwise specified. Limits are production tested at T_A = +25°C. Limits over the operating temperature range and relevant supply voltage range are guaranteed by design and characterization.)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
Buck Output Voltage Setting Range (Tracking Disabled, MODE = 0x6, Variant B)	V_{SYSREG}	Programmable 4.50V to 5.00V in 100mV steps (3-bits); production tested at 5.0V only	4.50		5.00	V
Buck Output Voltage Accuracy (Tracking Disabled)	V_{SYSREG_ACC}	Buck only, charging disabled	-3		+3	%
Buck Output Voltage (Tracking Enabled)	$V_{SYSREG\_TRK\_MIN}$	MODE = 4, MINSYS setting = 3.60V, SYS Tracking mode enabled, V_{BATT} < V_{SYS_MIN}/1.04	3.48	3.60	3.72	V
	V_{SYSREG_TRK}	MODE = 4, SYS Tracking mode enabled, $V_{BATT} \geq V_{SYS\_MIN}$/1.04, V_{SYSREG_TRK} represented as a percentage of V_{BATT}		104		%
Buck Inductor Current Limit	I_{HSILIM}	For MAX77986	10.0	11.1	12.2	A
	I_{HSILIM}	For MAX77985	7.5	8.3	9.1	
Buck Minimum On Time	t_{ON-MIN}	Measured on LX		100		ns
Buck Minimum Off Time	$t_{OFF-MIN}$	Measured on LX		100		ns
System Power-Up Current (from BYP)	I_{SYSPU_BYP}	Charger present, V_{SYS} < $V_{SYS\_UVLO\_R}$	50	75	100	mA
System Power-Up Time-Out (from BYP)	t_{SYSPU_BYP}			150		ms
CHARGER						
Precharge Charge Current	I_{PRECHG}	V_{BATT} < V_{PRECHG}	40	55	80	mA
Precharge Voltage Threshold	V_{PRECHG}	V_{BATT} rising	2.425	2.5	2.575	V
Precharge Voltage Threshold Hysteresis	V_{PRECHG_HYS}			500		mV
Trickle Charge Current	$I_{TRICKLE}$	TKEN = 1 by default, V_{PRECHG} < V_{BATT} < $V_{TRICKLE}$	270	300	330	mA
Trickle Charge Voltage Threshold	$V_{TRICKLE}$	V_{BATT} rising, TKEN = 1 by default	3.0	3.1	3.2	V
Trickle Charge Voltage Threshold Hysteresis	$V_{TRICKLE\_HYS}$	TKEN = 1 by default		100		mV
Prequalification Time	t_{PQ}	Applies to the total time of precharge and trickle charge mode		30		min
Fast-Charge Current Setting Range	I_{FC}	100mA to 5500mA in 50mA steps; production tested at 500mA, 1000mA, 3000mA, and 5000mA settings (MAX77986 only)	0.1		5.5	A
		100mA to 3500mA in 50mA steps; production tested at 500mA, 1000mA, and 3000mA settings (MAX77985 only)	0.1		3.5	

Electrical Characteristics (continued)

(V_{SYS} = 3.8V, V_{BATT} = 3.8V, V_{VIO} = 1.8V, V_{CHGIN} = 5V, unless otherwise specified. Limits are production tested at T_A = +25°C. Limits over the operating temperature range and relevant supply voltage range are guaranteed by design and characterization.)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
Fast-Charge Current Accuracy	I_{FC_ACC}	Programmed I_{FC} ≥ 500mA, V_{BATT} > V_{SYSMIN}, T_A = +25°C	-3.5		+3.5	%
		Programmed I_{FC} ≥ 500mA, V_{BATT} > V_{SYSMIN}, T_A = 0°C to +85°C	-6		+6	
		Programmed I_{FC} ≥ 500mA, $V_{TRICKLE}$ < V_{BATT} < V_{SYSMIN} (LDO mode), T_A = -5°C to +85°C	-10		+10	
Fast-Charge Current Thermal Regulation Setting Range	T_{REG}	Junction temperature when charge current starts to reduce for thermal regulation; programmable from +85°C to +130°C in 5°C steps; the default value is +115°C	85		130	°C
Fast-Charge Current Thermal Regulation Gain	A_{TJREG}	The charge current is decreased by 5.73% of the fast-charge current full-scale for every degree that the junction temperature exceeds the thermal regulation temperature. This slope ensures that the full-scale current of 5.5A is reduced to 0A by the time the junction temperature is +17.5°C above the programmed loop set point. For lower programmed charge currents such as 480mA, this slope is valid for charge current reductions down to 80mA; below 100mA the slope becomes shallower but the charge current is reduced to 0A if the junction temperature is +20°C above the programmed loop set point.		-315		mA/°C
Fast-Charge Termination Voltage Setting Range (Variant A)	$V_{BATTREG}$	Programmable from 4.15V to 4.5375V in 12.5mV steps (5-bits); production tested at 4.2V and 4.35V only (MAX77985A and MAX77986A)	4.150		4.5375	V
Fast-Charge Termination Voltage Setting Range (Variant B)	$V_{BATTREG}$	Programmable from 3.500V to 4.275V in 25mV steps (5-bits); production tested at 3.6V and 4.2V only (MAX77985B and MAX77986B)	3.500		4.275	V
Fast-Charge Termination Voltage Accuracy at Room Temp (Variant A)	$V_{BATTREG\_ACC}$	$V_{BATTREG}$ = 4.35V setting, represented as percentage of $V_{BATTREG}$; T_A = +25°C	-0.6	-0.3	+0.0	%
Fast-Charge Termination Voltage Accuracy (Variant A)	$V_{BATTREG\_ACC}$	$V_{BATTREG}$ = 4.35V setting, represented as percentage of $V_{BATTREG}$; T_A = -5°C to +85°C	-0.8	-0.3	+0.2	%
Fast-Charge Termination Voltage Accuracy at Room Temp (Variant B)	$V_{BATTREG\_ACC}$	$V_{BATTREG}$ = 4.20V setting, represented as percentage of $V_{BATTREG}$; T_A = +25°C	-0.6	-0.3	+0.0	%
Fast-Charge Termination Voltage Accuracy (Variant B)	$V_{BATTREG\_ACC}$	$V_{BATTREG}$ = 4.20V setting, represented as percentage of $V_{BATTREG}$; T_A = -5°C to +85°C	-0.8	-0.3	+0.2	%

Electrical Characteristics (continued)

(V_{SYS} = 3.8V, V_{BATT} = 3.8V, V_{VIO} = 1.8V, V_{CHGIN} = 5V, unless otherwise specified. Limits are production tested at T_A = +25°C. Limits over the operating temperature range and relevant supply voltage range are guaranteed by design and characterization.)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
Fast-Charge Termination Debounce Time	t_{TERM}			30		ms
Fast-Charge Constant Current + Constant Voltage Safety Time	t_{FC}	Adjustable from 3hrs, 4hrs, 5hrs, 6hrs, 7hrs, 8hrs, and 10hrs including a disable setting; 5hrs default		5		hrs
Top-Off Current Setting Range	I_{TO}	Programmable from 150mA to 850mA with 50mA in 16 steps; production tested at 150mA, 200mA, 500mA, and 850mA settings	150		850	mA
Top-Off Current Accuracy	I_{TO_ACC}	150mA setting	122.5	150	177.5	mA
		200mA setting	170	200	230

FC2QFN (4mm x 4mm)
Pin Description

PIN	NAME	FUNCTION	TYPE
1	DISQBAT	Active-high to disable internal Q_{BATT} FET between SYS and BATT.	DI
2	THM	Thermistor Connection. Connect an external thermistor between THM and AGND.	A

Pin Description (continued)

PIN	NAME	FUNCTION	TYPE
3	VDD	Analog Voltage Level. The output of on-chip low voltage LDO used to power on-chip, low-noise circuits. Bypass with a 1µF (6.3V) ceramic capacitor to AGND. Powering external loads from VDD is not recommended, other than pullup resistors.	A
4	BATSN	Battery Negative Differential Sense Connection. Connect to the negative or ground terminal as close as possible.	A
5	BATSP	Battery Positive Differential Sense Pin. Connect to battery positive terminal as close as possible to eliminate errors due to trace/connector voltage drops.	A
6, 7, 8	BATT	Connection with Battery. Connect to the positive terminal of a single-cell Li-ion battery. Bypass with a 10µF (6.3V) ceramic capacitor from BATT to PGND.	P
9, 10, 11	SYS	Connection with System. Bypass with at least 2x22µF (6.3V) ceramic capacitors from SYS to PGND. This ensures that the minimum effective capacitance on the SYS node is 12µF (effective), for stability purposes. If Mode 0x6 is used, then it additionally requires more ceramic capacitors to give a total effective capacitance of at least 100µF on the SYS node. The SYS node capacitance can increase up to 350µF total (effective).	P
12	PVDD	Internal Bias Regulator High Current Output Bypass Pin. Supplies internal noisy and high current gate drive loads. Bypass with 1µF (6.3V) from PVDD to PGND. Powering external loads from PVDD is not recommended, other than pullup resistors.	P
13	DGND	Digital Ground	A
14, 15 ,16	PGND	Charger Power Ground	P
17, 18, 19	LX	Charger Switching Node. Connect the inductor between LX and SYS.	P
20	BST	High-Side FET Driver Supply. Bypass BST to LX with a 1x 100nF (6.3V) ceramic capacitor.	A
21	BYP	CHGIN Bypass Pin. This pin is the input for the switching charger and the output for the boost converter when the charger is operating in 'reverse-boost' mode. Bypass with 2x22µF (35V) + 100nF (35V) ceramic capacitor from BYP to PGND.	P
22, 23	CHGIN	Charger Input. Connect 2 x 10µF (35V) between CHGIN and PGND.	P
24	SCL	I2C Interface Clock Input	DI
25	SDA	I2C Interface Data Input	DI
26	EXTSM	Exit Ship Mode Input by Push-Button. Active-high input.	DI
27	VIO	I2C Supply Voltage Input. Bypass to AGND with a 0.1µF (6.3V) capacitor.	P
28	AGND	Analog Ground	A
29	STAT	LED Low-Side Driver Output for Indicating Charging Status	A
30	QBEXT/ PGOOD	When UNPLG_DET = 0x00, this pin is configured to QBEXT which is the external battery FET control output. Connect a pullup resistor to VIO, SYS, or BATT supply. When UNPLG_DET ≠ 0x00, this pin is configured to PGOOD which is the unplug detection comparator output.	DO
31	SUSPND	Active-High Input to Disable the DC-DC Between CHGIN Input and SYS Output	DI
32	IRQB	Interrupt Output. Connect a 100kΩ pullup resistor between IRQB and VIO.	DO

Functional Diagrams

Functional Diagram
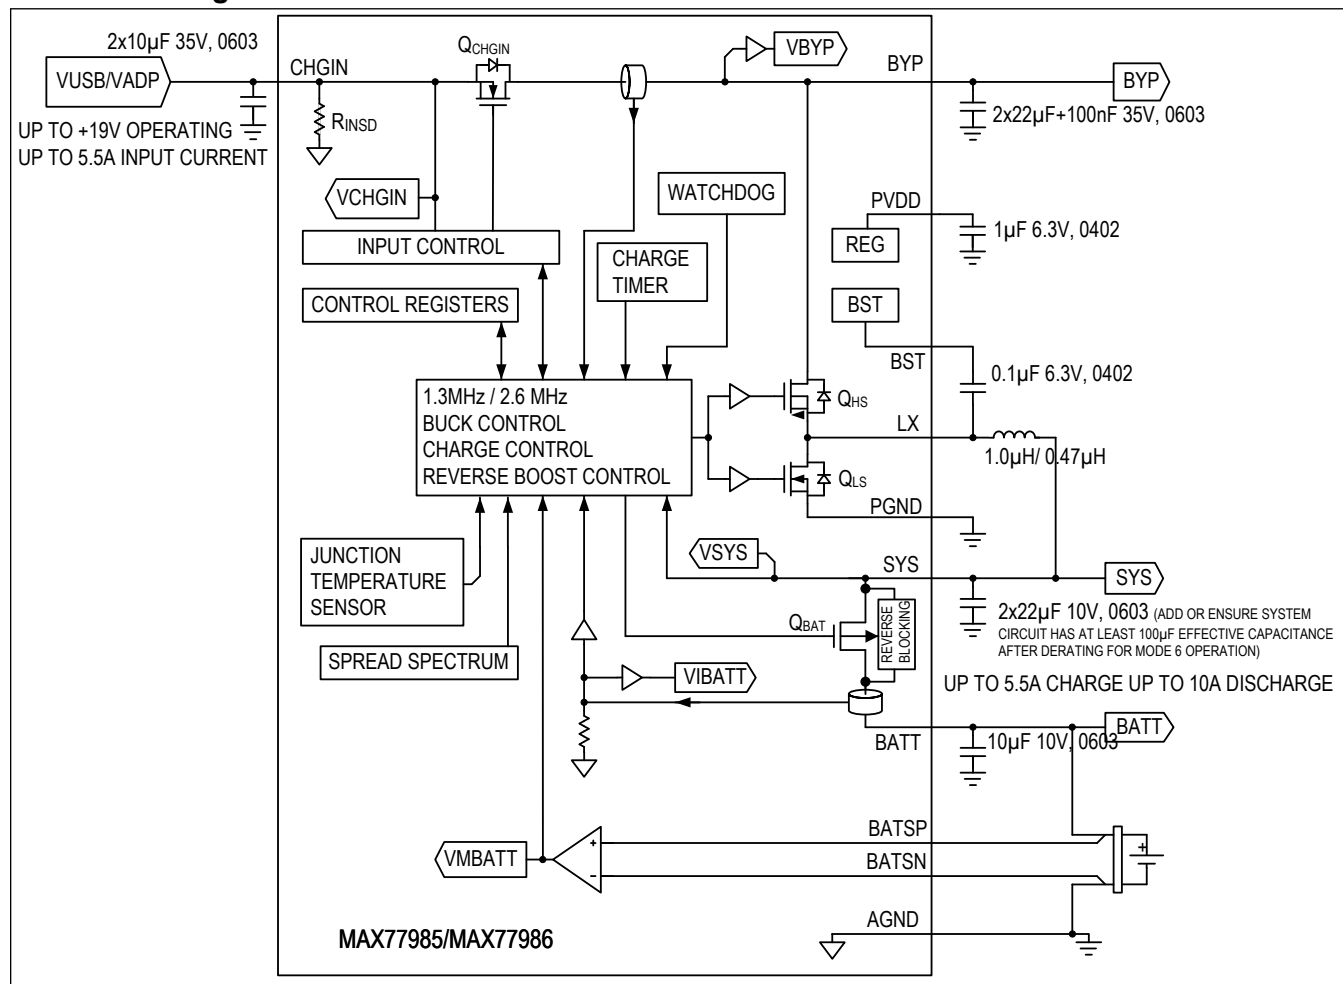

Detailed Description

Switching Mode Charger

Features

- Complete Li+/LiPoly Battery Charger
  - Prequalification, Constant Current, Constant Voltage
  - 55mA Precharge Current
  - 300mA Trickle Charge Current
  - Adjustable Constant Current Charge
    - 100mA to 5.5A in 50mA Steps (Limited to 3.5A for MAX77985)
  - Adjustable Charge-Termination Threshold
    - 150mA to 850mA in 50mA Steps
  - Adjustable Battery Regulation Voltage
    - 4.15V to 4.5375V in 12.5mV Steps for MAX7798xA
    - 3.50V to 4.275V in 25mV Steps for MAX7798xB
    - -0.8/+0.2% Accuracy from 0°C to +85°C
    - Remote Differential Sensing
- Synchronous Switch-Mode Based Design
- Smart Power Selector
  - Optimally distributes power between the charge adapter, system, and battery.
  - When powered by a charge adapter, the battery can provide supplemental current to the system.
  - The charge adapter can support the system with a dead battery or without a battery.
- No External MOSFETs Required for Switcher
- CHGIN Input
  - Adjustable Input Current Limit
    - 100mA to 5.5A in 50mA Steps (CHGIN_ILIM)
    - Default is set to 500mA
  - Supports AC-to-DC Wall Adapters
  - V_{CHGIN_OVLO} = 19.5V
  - Reverse-Leakage Protection Prevents the Battery Leaking Current to the Inputs
- Charge Safety Watchdog Timer
  - Selectable: 3hr to 8hr, plus a Disable Setting
- Die Temperature Monitor with Thermal Foldback Loop
  - Selectable Die-Temperature Thresholds (°C): +85°C to +130°C in +5°C Steps
- Input Voltage Dropout Control Allows Operation from High-Impedance Sources (AICL)
- BATT to SYS Switch is 7.7mΩ Typical
  - Capable of up to 10A Steady-State Operation from BATT to SYS
- Short-Circuit Protection
  - Programmable BATT to SYS Overcurrent Threshold from 3A to 10A, plus a Disable Setting
  - DISIBS Bit Allows the Host to Disable the Battery to System Discharge Path to Protect Against a Short-Circuit
  - SYS Short to Ground
    - Buck current is limited by switcher current limit and disabling of the synchronous rectifier.
    - BATT currents above the programmed by B2SOVRC threshold generate an interrupt. The host can then disable the battery to the system discharge path by setting DISIBS or asserting the DISQBAT pin high.
- Fast Unplug Detection of 9V and 15V Sources
- Spread Spectrum Modulation for Reduced EMI

Detailed Description

The MAX77985/MAX77986 includes a full-featured switch-mode charger for a one-cell lithium-ion (Li+) or lithium-polymer (Li-polymer) battery. The current limit for CHGIN input is independently programmable from 100mA to 3.2A in 50mA steps allowing the flexibility for connection to either an AC-to-DC wall charger or a USB port.

The synchronous switch-mode DC-DC converter utilizes a high 1.3MHz/2.6MHz switching frequency which is ideal for portable devices because it allows the use of small components while eliminating excessive heat generation. The DC-DC has both a buck and a boost mode of operation. When charging the main battery, the converter operates as a buck. The DC-DC buck operates from a 4.3V to 19.5V source. The battery charge current is programmable from 100mA to 5.5A.

As a boost converter, the DC-DC uses energy from the main battery to boost the voltage at BYP. The BYP supplies the USB OTG voltage (5.1V) and USB Type-C$^®$ PD Source Voltages (5V to 12V). The programmable boost output current limit range is from 0.5A to 3.1A with a 0.1A step.

The Smart Power Selector architecture makes the best use of the limited adapter power and the battery's power at all times to supply up to buck current limit from the buck to the system. (Additionally, supplement mode provides additional current from the battery to the system up to B2SOVRC.) Adapter power that is not used for the system goes to charging the battery. All power switches for charging and switching the system load between the battery and adapter power are included on-chip—no external MOSFETs are required.

A multitude of safety features ensures reliable charging. Features include a charge timer, watchdog, junction thermal regulation, over/under voltage protection, and short circuit protection.

The BATT to SYS switch has overcurrent protection (see the *Main-Battery Overcurrent Protection Due to Fault* section for more information).

Recommended buck output current range is as follows:

Table 1. Recommended Buck Output Current Range

	MINIMUM SYS CURRENT	MAXIMUM SYS CURRENT (A)

Smart Power Selector (SPS)

The SPS architecture is a network of internal switches and control loops that distribute energy between external power sources CHGIN, BYP, SYS, and BATT.

The *Functional Diagram* shows a more detailed arrangement of the Smart Power Selector switches and gives them the following names: Q_{CHGIN}, Q_{HS}, Q_{LS}, Q_{BATT}.

Switch and Control Loop Descriptions

- CHGIN Input Switch: The input switch is either completely on or completely off. As shown in the *Functional Diagram,* there are SPS control loops that monitor the current through the input switches as well as the input voltage.
- DC-DC Switches: Q_{HS} and Q_{LS} are the DC-DC switches that can operate as a buck (step-down) or a boost (step-up). When operating as a buck, energy is moved from BYP to SYS. When operating as a boost, energy is moved from SYS to BYP. SPS control loops monitor the DC-DC switch current, the SYS voltage, and the BYP voltage.
- Battery-to-System Switch: Q_{BATT} controls the battery charging and discharging. Additionally, Q_{BATT} allows the battery to be isolated from the system (SYS). An SPS control loop monitors the Q_{BATT} current.

Control Bits

- MODE configures the Smart Power Selector
- V_{BYPSET} sets the BYP regulation voltage target
- B2SOVRC configures the main-battery overcurrent protection

Energy Distribution Priority

- With a valid external power source:
  - The external power source is the primary source of energy
  - The main battery is the secondary source of energy
  - Energy delivery to BYP is the highest priority
  - Energy delivery to SYS is the second priority
  - Any energy that is not required by BYP or SYS is available to the main-battery charger

- With no power source available at CHGIN:
  - The main-battery is the primary source of energy
  - Energy delivery to BYP (if boost mode is selected) and SYS share the same priority
    - BYP includes CHGIN if boost OTG mode is selected, itself limited by OTG_ILIM threshold
  - Energy delivery to BYP (if boost mode is selected) and SYS is limited by B2SOVRC threshold

BYP Regulation Voltage

- When the DC-DC is off or in one of its buck modes and there is a valid power source at CHGIN, $V_{BYP} = V_{CHGIN} - I_{CHGIN} \times R_{CHGIN2BYP}$.
- When the DC-DC is off and there is no valid power source at CHGIN, BYP is connected to LX through the high-side switch's body diode.

SYS Regulation Voltage

- When the DC-DC is enabled as a buck and the charger is disabled, Q_{BATT} is off and V_{SYS} is regulated to $V_{SYSREG\_TRK\_MIN}$ when the $V_{BATT} < V_{SYSMIN}$ or V_{SYSREG_TRK} when the $V_{BATT} \geq V_{SYSMIN}$.
- When the DC-DC is enabled as a buck and the charger is enabled but in a non-charging state such as done, thermistor suspend, watchdog suspend, or timer fault, Q_{BATT} is off and V_{SYS} is regulated to $V_{SYSREG\_TRK\_MIN}$ when the $V_{BATT} < V_{SYSMIN}$ or V_{SYSREG_TRK} when the $V_{BATT} \geq V_{SYSMIN}$.
- When the DC-DC is enabled as a buck and charging in prequalification, fast-charge, or top-off modes, V_{SYS} is regulated to V_{SYSMIN} when the $V_{BATT} < V_{SYSMIN}$; in this mode, the Q_{BATT} switch acts as a linear regulator and dissipates power [$P = (V_{SYSMIN} - V_{BATT}) \times I_{BATT}$]. When $V_{BATT} > V_{SYSMIN}$, then $V_{SYS} = V_{BATT} + I_{BATT} \times R_{BAT2SYS}$; in this mode, the Q_{BATT} switch is closed.
- In all of the above modes, if the combined SYS and BYP loading exceeds the input current limit, then V_{SYS} drops to $V_{BATT} - V_{BSREG}$ and the battery provides supplemental current.
- When the DC-DC is enabled as a boost, then the Q_{BATT} switch is closed, and $V_{SYS} = V_{BATT} - I_{BATT} \times R_{BAT2SYS}$.

Input Validation

The charger input is compared with several voltage thresholds to determine if it is valid. A charger input must meet the following four characteristics to be valid:

- CHGIN must be above V_{CHGIN_UVLO} to be valid. Once CHGIN is above the UVLO threshold, the information (together with IN2SYS, described below) is latched and can only be reset when the charger is in an adaptive input current loop (AICL) and the input current is lower than the IULO_DET threshold.
- CHGIN must be below its overvoltage-lockout threshold (V_{CHGIN_OVLO}).
- CHGIN must be above the system voltage by IN2SYS drop out.
- CHGIN input generates a CHGIN_I interrupt when its status changes. The input status can be read with CHGIN_OK and CHGIN_DTLS. Interrupts can be masked with CHGIN_M.

Input Current Limit

The default settings of the CHGIN_ILIM and MODE control bits are such that when a charge source is applied to CHGIN, the IC turns its DC-DC converter on in BUCK mode, limits V_{SYS} to V_{SYSREG_TRK}, and limits the charge source current to $I_{INLIMIT}$. All control bits are reset on global shutdown.

Input Voltage Regulation Loop

An input voltage regulation loop allows the charger to be well behaved when it is attached to a poor-quality charge source. The loop improves performance with relatively high resistance charge sources that exist when long cables are used or devices are charged with non-compliant USB hub configurations. Additionally, this input voltage regulation loop improves performance with current limited adapters. If the ICs input current limit is programmed above the current-limit threshold of a given adapter, the input voltage loop allows the IC to regulate at the current limit of the adapter. Finally, the input-voltage regulation loop allows the IC to perform well with adapters that have poor transient load response times.

The input voltage regulation loop automatically reduces the inductor average current to keep the input voltage at V_{CHGIN_REG}. If the input current is reduced to I_{ULO_DET} and the input voltage is below V_{CHGIN_REG}, then the charger input is turned off. V_{CHGIN_REG} is programmable with $V_{CHGIN\_REG}[1:0]$.

After operating with the input voltage regulation loop active, an AICL_I interrupt is generated, and AICL_OK sets to 0. To optimize input power when working with a current limited charge source, monitor the AICL_OK status while decreasing the input current limit. When the input current limit is set below the limit of the adapter, the input voltage rises. Although the input current limit is lowered, more power can be extracted from the input source when the input voltage is allowed to rise.

Example 1. Optimum use of the Input Voltage Regulation Loop Along with a Current Limited Adapter.

Sequence of Events:

1. V_{BATT} = 3.2V, the system is operating normally.
2. MODE = 0x04, CHGIN_ILIM = 100mA, CHG_CV_PRM = 4.2V, V_{CHGIN_REG} = 4.5V, CHG_CC_TOT = 2.0A.
3. A 5.0V 1.2A current limited dedicated USB charger is applied to CHGIN.
4. The DC-DC buck regulator turns on, V_{SYS} is regulated to $V_{BATTREG}$ (4.2V) and the input is allowed to provide 100mA to the system.
5. The system detects that the charge source is a dedicated USB charger and enables the battery charger (MODE = 0x05) and programs an input current limit to 1.8A (CHGIN_ILIM = 1.8A).
6. The input current limit starts to ramp up from 100mA to 1.8A, but at the input current limit of the adapter (1.2A), the adapter voltage collapses. The ICs input voltage regulation loop prevents the adapter voltage from falling below 4.5V (V_{CHGIN_REG} = 4.5V). An AICL_I interrupt is generated and AICL_OK sets to 0.
7. With the input-voltage regulation loop active, the adapter provides 1.2A at 4.5V which is a total of 5.4W being delivered to the system.
8. The system software detects that the input voltage regulation loop is active and it begins to ramp down the programmed input current limit. When the current limit ramps down to 1.175A, the adapter is no longer in the current limit, and the adapter voltage increases from 4.5V to 5.0V.
9. With the adapter operating just below its current limit, it provides 1.175A at 5.0V which is a total of 5.88W to the system. This is 440mW more than when the adapter was in the current limit.

System Self-Discharge with No Power

To ensure a timely, complete, repeatable, and reliable reset behavior when the system has no power, the ICs actively discharge the SYS nodes when Q_{BATT} and switcher are disabled and V_{SYS} is less than $V_{SYSUVLO}$. As shown in Figure 1, the SYS discharge resistor is 600Ω.

Example 1. Basic System Self-Discharge

Initial Conditions: No charger adapter is present at CHGIN, the BAT-to-SYS switch is closed, C_{BAT} = 100μF, C_{SYS} = 200μF, V_{BATT} = 3.6V, and $V_{SYSUVLO}$ falling is SYS_UVLOB_F.

Sequence of Events:

1. With the system in its normal operating mode it is drawing 1A.
2. The main battery is removed.
3. The system continues to draw 1A until V_{SYS} falls below $V_{SYSUVLO}$. This takes 480μs ((3.6V-2.0V)/1A x 300μF).
4. When the system voltage falls below $V_{SYSUVLO}$, the system turns off the leakage current. To facilitate discharging C_{BAT} and C_{SYS} the IC engages its 600Ω discharge resistors.

Figure 1. System Self-Discharge Circuit
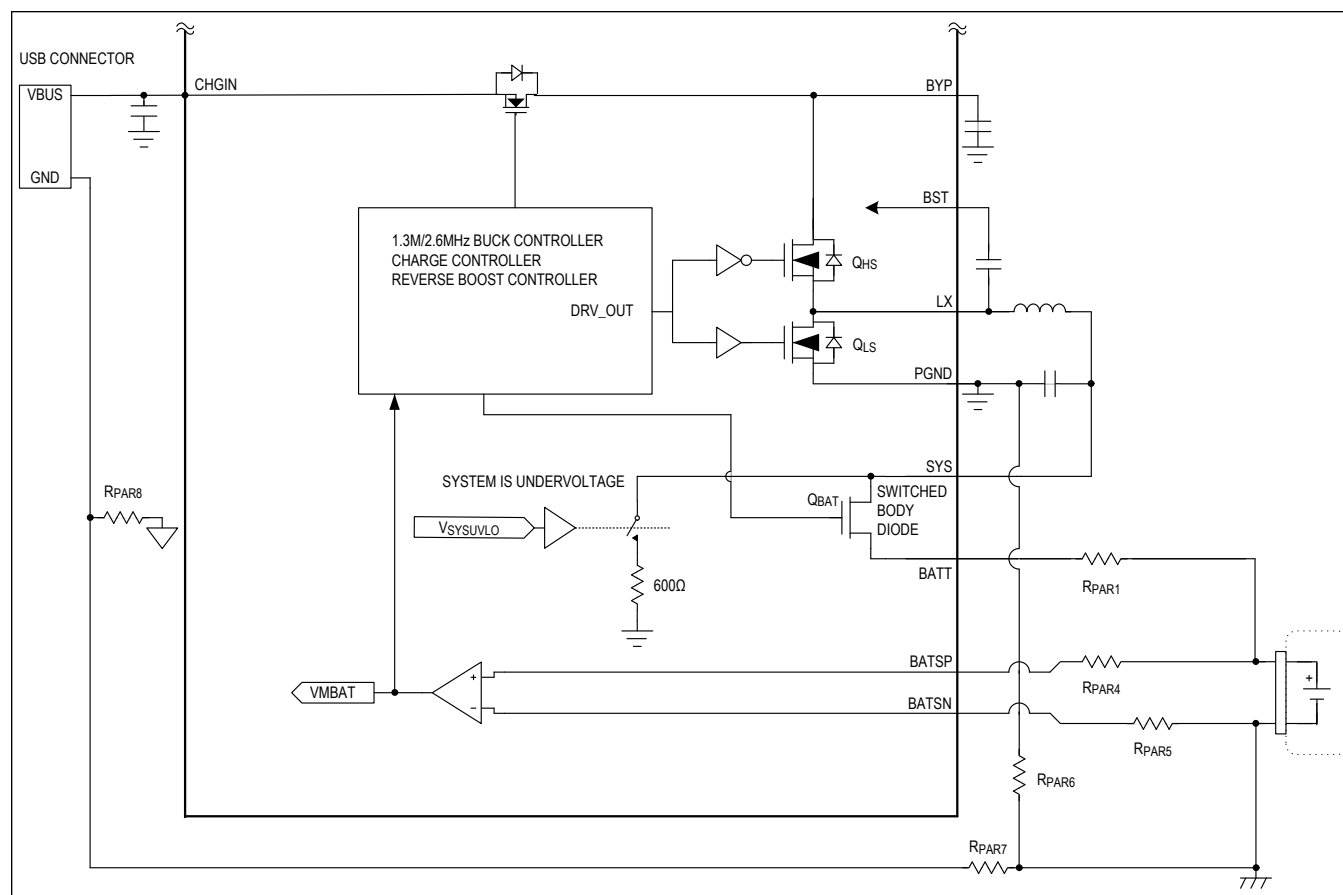

Power States

The MAX77985/MAX77986 transitions between power states as input/battery and load conditions dictate; see Figure 2.

Figure 2. Power State Diagram

The IC provides five (5) power modes and one (1) no power mode (MODE detailed description is at register CHG_CNFG_00 [3:0]). Under power limited conditions, the PowerPath^{TM} feature maintains SYS load at the expense of battery charge current. Also, the battery supplements the input power when required. As shown, transitions between power states are initiated by the detection/removal of valid power sources, OTG events, and under-voltage conditions. Details of the SYS voltage and BATT current are provided for each state. There are six main usage modes:

1. NO INPUT POWER, _MODE = undefined_: No input adapter or battery is detected. The charger and system are off. The battery is disconnected and the charger is off.

2. BATTERY-ONLY, _MODE = any modes_: The adapter is invalid and outside the input voltage operating range (Q_{CHGIN} = OFF). The battery is connected to power the SYS load (Q_{BATT} = ON).

3. NO CHARGE-BUCK, _MODE = 0x04_: The adapter is valid, buck supplies power to SYS. The battery is disconnected (Q_{BATT} = OFF) when SYS load is less than the power that the buck can supply.

When the SYS load is larger than the power that the buck can supply, the battery is reconnected (Q_{BATT} = ON) and supplements extra SYS load.

4. CHARGE-BUCK, _MODE = 0x05_: The adapter is valid, the buck supplies power to SYS, and charges the battery with I_{BATT}.

5. HIGH-VOLTAGE-BUCK, _MODE = 0x06_: Power path same as MODE = 0x04, except for the SYS regulation voltage when SYS tracking disabled is controlled by BCKSYS instead of CHG_CV_PRM.

6. BATTERY-BOOST (FLASH), _MODE = 0x09_: OTG is inactive (Q_{CHGIN} = OFF). The battery is connected to support SYS and BYP loads (Q_{BATT} = ON), and the charger is operating in boost mode (Boost = ON).

7. BATTERY-BOOST (OTG), _MODE = 0x0A_: OTG is active (Q_{CHGIN} = ON). The battery is connected to support SYS and OTG loads (Q_{BATT} = ON), and the charger is operating in boost mode (Boost = ON).

Charger States

The ICs utilize several charging states to safely and quickly charge batteries as shown in Figure 3. The figure shows an exaggerated view of a Li+/Li-Poly battery progressing through the following charge states when there is no system load and the die and battery are close to room temperature. It shows a complete charging state transition process with four states: prequalification, fast-charge, top-off, and done.
Figure 3. Li+/Li-Poly Charge Profile

No Input Power or Charge Idle State

While in the "no input power or charger idle" state, the charge current is 0mA, the watchdog and charge timers are forced to 0, and the power to the system is provided by either the battery or the adapter. When both battery and adapter power is available, the adapter provides primary power to the system and the battery contributes supplemental energy to the system if necessary.

To exit the "no input power or charger idle" state, the charger input must be valid and the charger has to be enabled.

Precharge State

As shown in [Figure 3](#), the precharge state occurs when the main-battery voltage is less than V_{PRECHG}. After being in this state for t_{SCIDG}, a CHG_I interrupt is generated only if CHG_OK was 0 previously, CHG_OK is set to 1, and CHG_DTLS is set to 0x00. In the precharge state, the charge current in the battery is I_{PRECHG}.

The following events cause the state machine to exit this state:

- Main battery voltage rises above V_{PRECHG} and the charger enters the next state in the charging cycle: "Trickle Charge".
- If the battery charger remains in this state for longer than t_{PQ}, the charger state machine transitions to the "Timer Fault" state.
- If the watchdog timer is not serviced (see the *[Watchdog Timer](#)* section), the charger state machine transitions to the "Watchdog Suspend" state.

Note that the precharge state works with battery voltages down to 0V. The low 0V operation typically allows this battery charger to recover batteries that have an "open" internal pack protector. Typically a pack internal protection circuit opens if the battery has seen an overcurrent, undervoltage, or overvoltage. When a battery with an "open" internal pack protector is used with this charger, the precharge mode current flows into the 0V battery—this current raises the pack's terminal voltage to the pointer where the internal pack protection switch closes.

Note that a normal battery typically stays in the precharge state for several minutes or less. Therefore a battery that stays in the precharge for longer than t_{PQ} may be experiencing a problem.

Trickle Charge State

As shown in [Figure 3](#), the trickle charge state occurs when $V_{BATT} > V_{PRECHG}$ and $V_{BATT} < V_{TRICKLE}$. After being in this state for t_{SCIDG}, a CHG_I interrupt is generated only if CHG_OK was 0 previously, CHG_OK is set to 1, and CHG_DTLS = 0x00.

With TKEN = 1 and the IC is in its trickle charge state, the current in the battery is less than or equal to ITRICKLE. When TKEN = 0, the battery current is less than or equal to I_{FC}.

Charge current may be less than ITRICKLE/I_{FC} for any of the following reasons:

- The charger input is in input current limit
- The charger input voltage is low
- The charger is in thermal foldback
- The system load is consuming adapter current. Note that the system load always gets priority over the battery charge current.

Typical systems operate with TKEN = 1. When operating with TKEN = 0, the system's software usually sets I_{FC} to a low value such as 450mA and then monitors the battery voltage. When the battery exceeds a relatively low voltage such as 3.1V, then the system's software usually increases I_{FC}.

The following events cause the state machine to exit this state:

- When the main battery voltage rises above VTRICKLE or the TKEN bit is cleared, the charger enters the next state in the charging cycle: "Fast Charge (CC)".
- If the battery charger remains in this state for longer than t_{PQ}, the charger state machine transitions to the "Timer Fault" state.
- If the watchdog timer is not serviced, the charger state machine transitions to the "Watchdog Suspend" state.

Note that a normal battery typically stays in the trickle charge state for several minutes or less. Therefore a battery that stays in trickle charge for longer than t_{PQ} may be experiencing a problem.

Fast-Charge Constant Current (CC) State

As shown in [Figure 3](#), the fast-charge CC state occurs when the main-battery voltage is greater than the low-battery prequalification threshold and less than the battery regulation threshold ($V_{TRICKLE} < V_{BATT} < V_{BATTREG}$). After being in the fast-charge CC state for t_{SCIDG}, a CHG_I interrupt is generated only if CHG_OK was 0 previously, CHG_OK is set to 1, and CHG_DTLS = 0x01.

In the fast-charge CC state, the current in the battery is less than or equal to I_{FC}. Charge current may be less than I_{FC} for any of the following reasons:

- The charger input is in input current limit
- The charger input voltage is low
- The charger is in thermal foldback
- The system load is consuming adapter current. Note that the system load always gets priority over the battery charge current.

The following events cause the state machine to exit this state:

- When the main battery voltage rises above $V_{BATTREG}$, the charger enters the next state in the charging cycle: "Fast Charge (CV)".
- If the battery charger remains in this state for longer than t_{FC}, the charger state machine transitions to the "Timer Fault" state.
- If the watchdog timer is not serviced, the charger state machine transitions to the "Watchdog Suspend" state.

The battery charger dissipates the most power in the fast-charge constant current state. This power dissipation causes the internal die temperature to rise. If the die temperature exceeds T_{REG}, I_{FC} is reduced. See the *[Thermal Foldback](#)* section for more information.

Fast-Charge Constant Voltage (CV) State

As shown in [Figure 3](#), the fast-charge CV state occurs when the battery voltage rises to $V_{BATTREG}$ from the fast-charge CC state. After being in the fast-charge CV state for t_{SCIDG}, a CHG_I interrupt is generated only if CHG_OK was 0 previously, CHG_OK is set to 1, and CHG_DTLS = 0x02.

In the fast-charge CV state, the battery charger maintains $V_{BATTREG}$ across the battery and the charge current is less than or equal to I_{FC}. As shown in [Figure 3](#), the charger current decreases exponentially in this state as the battery becomes fully charged.

The smart power selector control circuitry may reduce the charge current lower than the battery may otherwise consume for any of the following reasons:

- The charger input is in input current limit
- The charger input voltage is low
- The charger is in thermal foldback
- The system load is consuming adapter current. Note that the system load always gets priority over the battery charge current.

The following events causes the state machine to exit this state:

- When the charger current is below I_{TO} for t_{TERM}, the charger enters the next state in the charging cycle: the "TOP OFF" state.
- If the battery charger remains in this state for longer than t_{FC}, the charger state machine transitions to the "Timer Fault" state.
- If the watchdog timer is not serviced, the charger state machine transitions to the "Watchdog Suspend" state.

Top-Off State

As shown in Figure 3, the top-off state can only be entered from the fast-charge CV state when the charger current decreases below I_{TO} for t_{TERM}. After being in the top-off state for t_{SCIDG}, a CHG_I interrupt is generated only if CHG_OK was 0 previously, CHG_OK is set to 1, and CHG_DTLS = 0x03. In the top-off state, the battery charger tries to maintain $V_{BATTREG}$ across the battery and typically the charge current is less than or equal to I_{TO}.

The smart power selector control circuitry may reduce the charge current lower than the battery may otherwise consume for any of the following reasons:

- The charger input is in input current limit
- The charger input voltage is low
- The charger is in thermal foldback
- The system load is consuming adapter current. Note that the system load always gets priority over the battery charge current.

The following events cause the state machine to exit this state:

- After being in this state for the top-off time (t_{TO}), the charger enters the next state in the charging cycle: the "DONE" state.
- If $V_{BATT} < V_{BATTREG} - V_{RSTRT}$, the charger goes back to the "FAST CHARGE (CC)" state.
- If the watchdog timer is not serviced, the charger state machine transitions to the "Watchdog Suspend" state.

Done State

As shown in Figure 3, the battery charger enters its done state after the charger has been in the top-off state for t_{TO}. After being in this state for t_{SCIDG}, a CHG_I interrupt is generated only if CHG_OK was 0 previously, CHG_OK is set to 0, and CHG_DTLS = 0x04.

The following events cause the state machine to exit this state:

- If $V_{BATT} < V_{BATTREG} - V_{RSTRT}$, the charger goes back to the "FAST-CHARGE CC" state.
- If the watchdog timer is not serviced, the charger state machine transitions to the "Watchdog Suspend" state.

In the done state, the charge current into the battery (I_{CHG}) is 0A. In the done state, the charger presents a very low load (I_{MBDN}) to the battery. If the system load presented to the battery is low, then a typical system can remain in the done state for many days. If left in the done state long enough, the battery voltage decays below the restart threshold (V_{RSTRT}), and the charger state machine transitions back into the fast-charge CV state. There is no soft-start (di/dt limiting) during the done to a fast-charge state transition.

Timer Fault State

The battery charger provides both a charge timer and a watchdog timer to ensure safe charging. The charge timer prevents the battery from charging indefinitely. The time that the charger is allowed to remain in each of its prequalification states is t_{PQ}. The time that the charger is allowed to remain in the fast-charge CC & CV states is t_{FC} which is programmable with FCHGTIME. Finally, the time that the charger is in the top-off state is t_{TO} which is programmable with TO_TIME. Upon entering the timer fault state a CHG_I interrupt is generated without a delay, CHG_OK is cleared, and CHG_DTLS = 0x06.

In the timer fault state, the charger is off. The charger can exit the timer fault state by programming the charger to be off and then programming it to be on again through the MODE bits. Alternatively, the charger input can be removed and re-inserted to exit the timer fault state.

Watchdog Timer

The battery charger provides both a charge timer and a watchdog timer to ensure safe charging. The watchdog timer protects the battery from charging indefinitely if the host hangs or otherwise cannot communicate correctly. The watchdog timer is disabled by default with WDTEN = 0. To use the watchdog timer feature enable the feature by setting WDTEN. While enabled, the system controller must reset the watchdog timer within the timer period (t_{WD}) for the charger to operate normally. Reset the watchdog timer by programming WDTCLR = 0x01.

If WD_QBATTOFF bit is set to 0 and the watchdog timer expires while the charger is in dead-battery prequalification, low-battery prequalification, fast-charge CC or CV, top-off, done, or timer fault, the charging stops, a CHG_I interrupt is generated only if CHG_OK was 1 previously, CHG_OK is cleared, and CHG_DTLS indicates that the charger is off because the watchdog timer expired. Once the watchdog timer has expired, the charger may be restarted by programming WDTCLR = 0x01. The SYS node can be supported by the battery and/or the adapter through the DC-DC buck while the watchdog timer is expired.

If the WD_QBATTOFF bit is set to 1 and the watchdog timer expires, MAX77986 turns off the buck, charger, and Q_{BATT} switch for 150ms. And then V_{SYS} voltage collapses and it resets all I^{2}C registers. The IC restarts as the initial power-up condition.

Thermal Shutdown State

The thermal shutdown state occurs when the battery charger is in any state and the junction temperature (T_J) exceeds the device's thermal-shutdown threshold (T_{SHDN}). When T_J is close to T_{SHDN} the charger folds back the charge current to 0A (see the *Thermal Foldback* section). Upon entering this state, CHG_I interrupt is generated if CHG_OK was 1 previously, CHG_OK is cleared, and CHG_DTLS = 0x0A.

In the thermal shutdown state, the charger is off. MODE register (CHG_CNFG_00[3:0]) is reset to its default value as well as all O-type registers.

Charger Interrupt Debounce Time

Table 2. Charger Interrupt Debounce Time

	DEBOUNCE TIME RISING	DEBOUNCE TIME FALLING
INTERRUPT	Typ (ms)	Typ (ms)
AICL_I	30	30
CHGIN_I	7.5	—
INLIM_I	30	30
BAT_I (Overvoltage T_{BATOV})	7.5	—
BYP_I (T_{OTG_I})	20	—
BYP_I (BST_I_{LIM})	30	—
BYP_I (Buck Neg I_{LIM})	0.5	—

Accuracy of the timer is defined by T_{ACC}.

Main-Battery Differential Voltage Sense

BATSP and BATSN are differential remote sense lines for the main battery. To improve accuracy and decrease charging times, the battery charger voltage sense is based on the differential voltage between BATSP and BATSN. Similarly, the thermistor voltage is interpreted with respect to BATSN.

A Maxim battery charger without the remote sensing function would typically measure the battery voltage between BATT and GND. In case a charge current of 1A measuring from BATT to GND leads to a V_{BATT} that is 40mV higher than the real voltage because of R_{PAR1} and R_{PAR7} (I_{CHG} x (R_{PAR1} + R_{PAR7}) = 1A x 40mΩ = 40mV). Since the charger thinks the battery voltage is higher than it actually is, it enters its fast-charge CV state sooner and the effective charge time may be extended by 10 minutes (based on real lab measurements). This charger with differential remote sensing does not experience this type of problem because BATSP and BATSN sense the battery voltage directly. To get the maximum benefit from these sense lines, connect them as close as possible to the main-battery connector.

Reverse Boost Mode

The DC-DC converter topology of the IC allows it to operate as a forward buck converter or as a reverse boost converter. The modes of the DC-DC converter are controlled with MODE. When MODE = 0x09 or 0x0A, the DC-DC converter operates in reverse boost mode allowing it to source current to BYP. To allow current flow to CHGIN, set MODE = 0x0A. This mode allows current to be sourced from CHGIN and is commonly referred to as OTG mode.

When MODE = 0x0A, the DC-DC converter operates in reverse boost mode and regulates V_{BYP} to $V_{BYP.OTG}$ and the low ohmic ($R_{CHGIN2BYP}$) switch from BYP to CHGIN is closed. The current through the BYP to CHGIN switch is limited to the value programmed by OTG_ILIM. The programmable OTG_ILIM options allow for supplying from 500mA to 3100mA to an external load. When the OTG mode is selected, the unipolar CHGIN transfer function measures the current going out of CHGIN. When OTG mode is not selected, the unipolar CHGIN transfer function measures the current going into CHGIN.

If the external OTG load at CHGIN exceeds ICHGIN.OTG.ILIM current during a minimum time of T_{OTG_I} ms, then a BYP_I interrupt is generated. BYP_OK = 0 and BYP_DTLS[0] = 1. In response to an overload at CHGIN during OTG mode operation, the BYP to CHGIN switch is latched off T_{OTG_fault} after entering the OTG_ILIM condition. If the overload at CHGIN persists, BYP_DTLS keeps continuing to report OTG_ILIM fault through BYP_DTLS[0] = 1.

If OTG_REC_EN bit = '1: other functions remain unaffected, i.e., BYP is supplied by reverse boost, and the BYP to CHGIN switch automatically retries after T_{OTG_retry}. If the overload at CHGIN persists, then the CHGIN switch toggles ON and OFF with T_{OTG_fault} ON time and T_{OTG_retry} OFF time.

If OTG_REC_EN bit = '0: the BYP to CHGIN switch remains off and the switcher is turned off until MODE is toggled.

BYP_I exit interrupt is only generated on OTG load release such as IOTG < ICHGIN.OTG.ILIM or FET opening. At that time, the BYP_I interrupt is generated. BYP_OK = 1 and BYP_DTLS[0] = 0.

Note: On OTG_ILIM debounce time out, BYP_DTLS[0] is latched until the BYP_DTLS register is read by AP. BYP_OK is matching BYP_DTLS[0] behavior.

Main-Battery Overcurrent Protection During System Power-Up

The "main-battery overcurrent protection during system power-up" feature limits the main battery to system current to I_{SYSPU} as long as V_{SYS} is less than V_{SYSPU_BAT}. This feature limits the surge current that typically flows from the main battery to the device's low-impedance system bypass capacitors during a system power-up. System power-up is anytime that energy from the battery is supplied to SYS when $V_{SYS} < V_{SYSPU}$. This "system power-up" condition typically occurs when a battery is hot-inserted into an otherwise unpowered device. Similarly, the "system power-up" condition can occur when the DISIBS bit is driven low.

When "system power-up" occurs due to hot-insertion into an otherwise unpowered device, a small delay is required for this feature's control circuits to activate. A current spike over I_{SYSPU_BAT} can occur during this time.

Main-Battery Overcurrent Protection Due to Fault

The IC protects itself, the battery, and the system from potential damage due to excessive battery discharge current. Excessive battery discharge current can occur in a smartphone for several reasons such as exposure to moisture, a software problem, an IC failure, a component failure, or a mechanical failure that causes a short circuit. The main-battery overcurrent protection feature is enabled with B2SOVRC; disabling this feature reduces the main-battery current consumption by 2µA.

When the main battery (BATT) to system (SYS) discharge current (I_{BATT}) exceeds the programmed overcurrent threshold (I_{BOVRC}) for at least t_{BOVRC}, a BAT_I interrupt is generated, BAT_OK is cleared, and BAT_DTLS reports an overcurrent condition. Typically when the system's processor detects this overcurrent interrupt it executes a housekeeping routine that tries to mitigate the overcurrent situation. If the processor cannot correct the overcurrent within t_{OCP}, then the IC disables the BATT to SYS discharge path (Q_{BATT} switch) and turns off the Buck.

Under OCP fault condition, when SYS is low ($V_{SYS} < V_{SYSUP}$) for t_{OCP_RETRY}, the IC restarts on its own and attempts to pullup SYS again. If the fault condition remains, the whole cycle repeats until this fault condition is removed.

AP can also turn off the Q_{BATT} switch by driving the DISIBS bit to a logic-high or pulling the DISQBAT pin high.
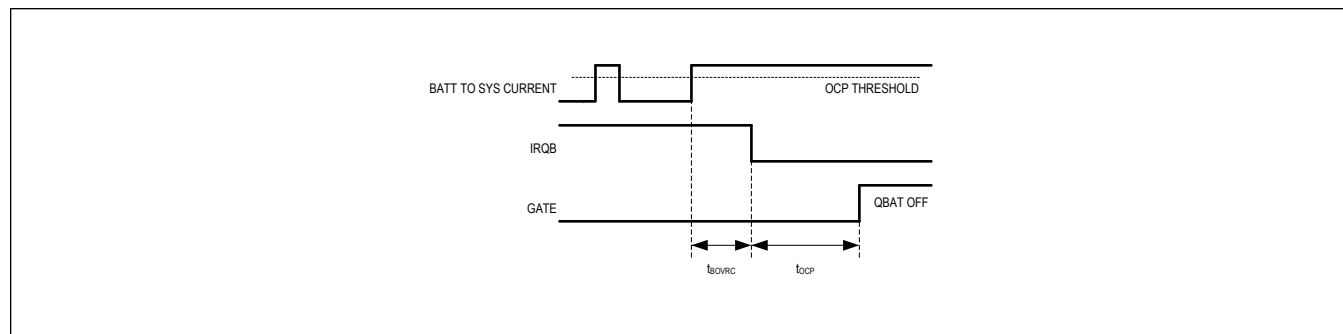

Figure 4. BATT to SYS Overcurrent Protection

There are different scenarios of how the ICs respond to the OCP event depending on the available power source and the state of the charger:

1) The IC is only powered by a battery, then the OCP event occurs:

    a. Q_{BATT} switch opens.

    b. SYS collapses and is allowed to go to 0V.

    c. If RECYCLE_EN = 1: After SYS is low ($V_{SYS} < V_{SYSUP}$) for t_{OCP}_RETRY, the IC restarts on its own and attempts to pull up SYS again. If the fault condition remains, the whole cycle repeats until this fault condition is removed. If RECYCLE_EN = 0: The Q_{BATT} switch remains open. When a valid charger input is inserted, the Buck and Q_{BATT} switch turns on.

2) The IC is powered from BATT and CHGIN, buck is switching, charge is ON, then an OCP event occurs:

    a. Buck is off and Q_{BATT} switch opens

    b. SYS collapses and is allowed to go to 0V

    c. Regardless of the RECYCLE_EN setting, the IC retries to bring up V_{SYS} above V_{SYSUP}

3) The IC is powered from CHGIN, the buck is switching, the charge is OFF, and then an OCP event occurs:

    a. Buck is off and Q_{BATT} switch opens

    b. SYS collapses and is allowed to go to 0V

    c. Regardless of the RECYCLE_EN setting, the IC retries to bring up V_{SYS} above V_{SYSUP}

Battery to SYS Q$_{BATT}$ Switch Control (DISIBS)

To protect the system from unexpected and critical events (e.g., excessive battery discharge current), the AP can control the MAX77985/MAX77986 Q$_{BATT}$ switch by driving the DISIBS bit to a logic-high.

There are different scenarios of how the IC responds to setting the DISIBS bit high depending on the available power source and the state of the charger:

1) The IC is only powered from BATT and DISIBS bit is set:

    a. Q$_{BATT}$ switch opens

    b. SYS collapses and is allowed to go to 0V

    c. If RECYCLE_EN = 1, the IC self-recovers and restarts after t$_{OCP\_RETRY}$. If RECYCLE_EN = 0, after t$_{OCP\_RETRY}$, the IC does not recycle until a valid charger input is inserted.

2) The IC is powered from BATT, CHGIN is present, the charger buck is not switching, and the DISIBS bit is set:

    a. Q$_{BATT}$ switch opens

    b. SYS collapses and is allowed to go to 0V

    a. Regardless of RECYCLE bit setting, the IC self-recovers and restarts after t$_{OCP\_RETRY}$.

3) The IC is powered from CHGIN, the buck is switching, the charge is OFF, and the DISIBS bit is set:

    a. Q$_{BATT}$ stays OFF (opened)

    b. Turn off Buck

    c. SYS collapses and is allowed to go to 0V

    d. Regardless of RECYCLE bit setting, the IC self-recovers and restarts after t$_{OCP\_RETRY}$.

4) The IC is powered from CHGIN, the buck is switching, the charge is ON, and the DISIBS bit is set:

    a. Charge is disabled

    b. Q$_{BATT}$ turns off (opened)

    c. Turn off Buck

    d. SYS collapses and is allowed to go to 0V

    e. Regardless of the RECYCLE bit setting, the IC self-recovers and restarts after t$_{OCP\_RETRY}$.

HW Control of Battery to SYS Q$_{BATT}$ Switch—DISQBAT

To protect the system from unexpected and critical events (e.g., excessive battery discharge current), the AP can control the IC's Q$_{BATT}$ switch by driving the DISQBAT hardware pin. This pin can also be driven during factory test modes.

On DISQBAT low-to-high assertion, Q$_{BATT}$ FET opens and any ongoing charge is disabled but buck keeps switching (if allowed by MODE setting).

The IC supports factory-boost mode to enter in boost mode (through CHG_CNFG_00.MODE setting) and keep Q$_{BATT}$ OFF even if boost mode is set.

This functionality is only enabled once functional register CHG_CNFG_07.QBEXT_CTRL_EN bit is set 1.

DISQBAT is an input control signal for Q$_{BATT}$ FET with an external logic signal. If DISQBAT is driven by high, Q$_{BATT}$ FET is truly disconnected. It has an internal 470kΩ pulldown resistor.

Thermal Management

The ICs charger uses several thermal management techniques to prevent excessive battery and die temperatures.

Thermal Foldback

Thermal foldback maximizes the battery charge current while regulating the ICs junction temperature. As shown in Figure 5, when the die temperature exceeds the value programmed by REGTEMP (T_{REG}), a thermal limiting circuit reduces the battery charger's target current by A_{TJREG}. The target charge current reduction is achieved with an analog control loop (i.e., not a digital reduction in the input current). When the thermal foldback loop changes state, a CHG_I interrupt is generated and the system's microprocessor may read the status of the thermal regulation loop through the T_{REG} status bit. Note that the thermal foldback loop being active is not considered to be an abnormal operation and the thermal foldback loop status does not affect the CHG_OK bit (only information contained within CHG_DTLS affects CHG_OK).

Figure 5. Charge Currents vs. Junction Temperature

Thermistor Input (THM)

The thermistor input can be utilized to achieve functions such as charge suspension, JEITA compliant charging, and battery removal detection. The thermistor monitoring feature can be disabled by connecting the THM pin to ground.

The THM input connects to an external negative temperature coefficient (NTC) thermistor to monitor battery or system temperature.

JEITA Compliant Charging

JEITA compliant charging is available with JEITA_EN = 1.

Charging stops when the thermistor temperature is out of range (T < T_{COLD} or T > T_{HOT}). The charge timers are reset and the CHG_DTLS[3:0], CHG_OK register bits report the charging suspension status, and CHG_I interrupt bit is set. When the thermistor comes back into range (T_{COLD} < T < T_{HOT}), charging resumes, and the charge timer restarts.

Battery Removal Detection

With pullup connected between PVDD and THM, if the battery is removed, the thermistor is disconnected from THM; this event is detected as THM is pulled up to PVDD. Battery removal event prevents charging.

Disable Thermistor Monitoring

Connecting THM to GND disables the thermistor monitoring function, and JEITA controlled charging is unavailable in this configuration. The IC detects an always-connected battery when THM is grounded, and charging starts automatically when a valid adapter is plugged in. In applications with removable batteries, do not connect THM to GND because the IC is not able to detect battery removal when THM is grounded. Instead, connecting THM to the thermistor pin in the battery pack is recommended.

Since the thermistor monitoring circuit employs an external bias resistor from THM to PVDD, the thermistor is not limited only to 10kΩ (at +25ºC). Any resistance thermistor can be used as long as the value is equivalent to the thermistor +25ºC resistance. For example, with a 10kΩ at RTB resistor, the charger enters a temperature suspend state when the thermistor resistance falls below 4.67kΩ (too hot) or rises above 30.3kΩ (too cold). This corresponds to 0ºC to +45ºC range when using a 10kΩ NTC thermistor with a beta of 3610. The general relation of thermistor resistance to temperature is defined by the following equation:

$$R_T = R_{25} \times e^{\left\{\beta\left\{\frac{1}{T+273°C} - \frac{1}{298°C}\right\}\right\}}$$

where:

R_T = The resistance in Ω of the thermistor at temperature T in Celsius

R_{25} = The resistance in Ω of the thermistor at +25ºC

β = The material constant of the thermistor, which typically ranges from 3000k to 5000k

T = The temperature of the thermistor in °C

Some designs might prefer other thermistor temperature limits. Threshold adjustment can be accommodated by changing R_{TB}, connecting a resistor in series and/or in parallel with the thermistor, or using a thermistor with different β. For example, a +45ºC hot threshold and 0°C cold threshold can be realized by using a thermistor with a β to 4250 and connecting 120kΩ in parallel. Since the thermistor resistance near 0ºC is much higher than it is near +50ºC, a large parallel resistance lowers the cold threshold while only slightly lowering the hot threshold. Conversely, a small series resistance raises the cold threshold, while only slightly raising the hot threshold. Raising R_{TB}, lowers both the hot and cold threshold, while lowering R_{TB} raises both thresholds.

Thermistor bias current flows whenever PVDD is enabled (CHGIN valid or BOOST enabled). When using a 10kΩ thermistor and a 10kΩ pullup to THM, this results in an additional 90µA load. This load can be reduced to 9µA by instead using a 100kΩ thermistor and 100kΩ pullup resistor.

Table 3. Trip Temperatures for Different Thermistors

Thermistor	R25 (Ω)	10000	10000	47000	100000
	Thermistor Beta (β)	3380	3610	4050	4250
	RTB (Ω)	10000	10000	47000	100000
	R15 (Ω)	14826	15223	75342	164083
	R45 (Ω)	4900	4671	19993	40781
Trip Temperatures	T_{COLD} (°C)	-1.3	0.2	2.7	3.7
	T_{COOL} (°C)	9.0	10.0	11.6	12.2
	T_{WARM} (°C)	46.2	44.8	42.5	41.7
	T_{HOT} (°C)	62.5	59.8	55.6	54.1

JEITA Controlled Charging

The IC safely charges Li+ batteries in accordance with JEITA specifications. The IC monitors the battery temperature with an NTC thermistor connected at the THM pin and automatically adjusts the fast-charge current and/or charge termination voltage as the battery temperature varies. JEITA controlled charging can be disabled by setting JEITA_EN to '0; if JEITA_EN = '0', thermistor input is not taken into account to determine charge state or charge current and voltage levels.

CHG_DTLS and THM_DTLS registers report JEITA controlled charging status.

The JEITA controlled fast-charging current (I_{CHGCC_JEITA}) for $T_{WARM} < T < T_{HOT}$ is programmable with I^2C bit CHG_CC_WARM.

The JEITA controlled charge termination voltage (V_{CHGCV_JEITA}) for $T_{COLD} < T < T_{COOL}$ is programmable with I^2C bit CHG_CV_COOL.

The JEITA controlled fast-charging current for $T_{COLD} < T < T_{COOL}$ is halved (to CHG_CC x 0.5) and the charge termination voltage for $T_{WARM} < T < T_{HOT}$ is reduced (CHG_CV_PRM - 187.5mV for MX77985A/MAX77986A, CHG_CV_PRM - 375mV for MAX77985B/MAX77986B) as shown in Figure 6.

The JEITA controlled charging is suspended when the battery temperature is too cold or too hot (T < T_{COLD} or $T_{HOT} <$ T).

Temperature thresholds T_{COLD}, T_{COOL}, T_{WARM}, and T_{HOT} depend on the thermistor selection. When JEITA controlled battery charge current is reduced by 50%, the charger timer is doubled.
Figure 6. JEITA Controlled Charging

Analog Low-Noise Power PVDD and VDD

VDD is the 1.8V LDO output for the charger's analog circuitry. VDD takes its power from the higher voltage of CHGIN, BATT, and SYS. VDD has a bypass capacitance of 1µF.

PVDD is the 1.8V LDO output for internal power circuitry. PVDD has a bypass capacitance of 1µF.

Factory-Ship Mode

The ICs support factory-ship mode.

Charger's CHG_CNFG_07 bit 0: FSHIP_MODE bit controls this mode.

When this bit is set to 1, the IC goes into factory-ship mode.

This mode can be exited by battery removal or on a valid charger input plug or by pulling EXTSM high longer than t_{EXTSM_DEB} (programmable with EXTSM_T bit).

Factory-ship mode can not be entered when a valid charger is present.

This feature minimizes battery leakage current when the factory ships battery-connected devices.

External Q$_{BATT}$ Control I/O

QBEXT is an open-drain output that is driven low in Battery mode and high-impedance (pulled-up externally) in non-battery mode.

The Q$_{BATT}$ in MAX77986 has a very low R$_{DSON}$ that equals 7.7mΩ. If the application requires a lower resistive discharging path then this output can be utilized to drive an external Q$_{BATT}$ FET driver in parallel with an internal Q$_{BATT}$. This output can be enabled or disabled by the QBEXT_CTRL bit.

Once this function is enabled, the BAT2SYS OCP detection is not valid and can be disabled by setting bits B2SOVRC = 0x0.

Table 4. QBEXT Output in Different System Modes

SYSTEM MODE	USE CASE DETAILS	QBEXT OUTPUT
Battery Mode	All use cases except non-battery mode	Low
Non-Battery Mode	Valid adapter is present, and buck is switching (whatever charge status is) or MODE = 0x09 (Boost) or MODE = 0x0A (Boost + OTG)	Hi-Z (pulled-up)

Unplug Detection

The QBEXT pin can also be configured to an alternative function called PGOOD. If a user writes UNPLUG_TH[1:0] with 0b10 or 0b11, then the QBEXT pin is working as a PGOOD which is the comparator output of VBUS unplug detection.

For the 9V and 15V unplug detection, the output goes high when V$_{CHGIN}$ voltage comes across the threshold of V$_{CHGIN\_UNPLUG}$ with a selectable debounce by the UNPLUG_DB bit.

The unplug detection does not apply to Mode 0, Mode 9, or Mode A.

The PGOOD output state follows the below table.

Table 5. PGOOD States Under Different Situations

VBUS	BATTERY	MODE	PGOOD
Plugged, > programmed threshold	Yes/No	Normal	Low
Plugged, < programmed threshold	Yes/No	Normal	Hi-Z
Not plugged	Yes	Normal	Hi-Z
Not plugged	Yes	Factory-ship mode	Hi-Z
Not plugged	No	No Power	Hi-Z
Plugged, > programmed threshold	Yes	Suspend	Low
Plugged, < programmed threshold	Yes	Suspend	Hi-Z
Don't care	Yes	Deep Suspend	Hi-Z
Don't care	Yes	OTG (reverse boost)	Hi-Z

Charge Status LED Indication

STAT is the LED current sink shown in the following tables based on the STAT_MODE bit.

The LED driving current can be programmed through I^{2}C STAT_CURR from 5mA to 20mA with a 5mA step.

Table 6. STAT_MODE = 0x0

CHG STATUS	LED	DUTY (%)
No DC input or Suspend or Buck operation	Off	0
Any Charging Timeout, Off by JEITA feature, Off by thermal shutdown	Blink in 2Hz	50
DBAT, Pre-Q, CC, CV	Blink in 1Hz	50
Top-off, Done, Restart	Solid on	100

Table 7. STAT_MODE = 0x1

CHG STATUS	LED	DUTY (%)
No DC input or Suspend or Buck operation	Off	0
Any Charging Timeout, Off by JEITA feature, Off by thermal shutdown	Off	0
DBAT, Pre-Q, CC, CV	Blink in 1Hz	50
Top-off, Done, Restart	Solid on	100

Audio Mode

When Audio Mode is enabled by writing AUDIO_MODE = 0b1, the switching frequency is limited to at least 64kHz so that the switching frequency is always higher than the audible frequency. Audio mode affects bootstrap refresh frequency and spread spectrum.

Spread Spectrum

The buck converter is capable of dithering its switching frequency for noise-sensitive applications. The dithering allows the buck converter to be operated not at a single fixed frequency but over a varying band of frequencies. This helps reduce the peak value of EMI emission. The spread-spectrum function is activated only in CCM (Continuous Conduction Mode) and it is automatically deactivated when the buck converter enters DCM (Discontinuous Conduction Mode). The spread-spectrum function can be disabled by the SS_ENV[1:0] bits.

Modulation envelope (ΔFSS) determines the maximum difference between the modulated switching frequency and the nominal switching frequency. The modulation envelope is programmable (±4%, ±8%, or ±16%) by the SS_ENV[1:0] bits and it controls 'how wide' the switching frequency dithers.

Two modulation patterns are determined by the SS_PAT bit. One is triangular and the other is pseudo-random.

The modulation frequency determines how often the switching frequency dithering cycle repeats. In a triangular pattern, the modulation frequency is fixed at 2.133kHz. In pseudo-random, it is 4.267kHz. When audio mode is enabled, then the modulation frequency is automatically changed to 133Hz for a triangular pattern and to 267Hz for a pseudo-random pattern.

Programmable Minimum System Voltage

MAX77985/MAX77986 supports programmable MINSYS (minimum system voltage) by MINSYS[2:1] value. It is recommended to position the Min SYS greater than the minimum system supply voltage for proper operation.

Table 8. Minimum System Voltage Values for Different Part Variants

VALUE	MAX77985A/MAX77986A (V)	MAX77985B/MAX77986B (V)
0b00	3.4	3.0
0b01	3.5	3.1
0b10	3.6	3.5
0b11	3.7	3.6

Top System Management

Overview

This section discusses the top system of the MAX77985/MAX77986 and how the IC manages its bias, system faults, and turn-on and off events.

Main Bias

The main bias includes voltage and current references for all circuitry that runs from the V_{SYS} node.

System Faults

V_{SYS} Fault

The system monitors the V_{SYS} node for undervoltage and overvoltage events. The following describes the IC behavior if any of these events are to occur.

V_{SYS} Undervoltage Lockout ($V_{SYSUVLO}$)

V_{SYS} undervoltage lockout prevents the regulators from being used when the input voltage is below the operating range. When the voltage from SYS to GND (V_{SYS}) is less than the undervoltage-lockout threshold ($V_{SYSUVLO}$), MAX77985/MAX77986 shuts down and resets the "O" Type I^{2}C registers.

V_{SYS} Overvoltage Lockout ($V_{SYSOVLO}$)

V_{SYS} overvoltage lockout is a fail-safe mechanism and prevents the regulators from being used when the input voltage is above the operating range. The absolute maximum ratings state that the SYS node withstands up to 6V. The SYS OVLO threshold is set to 5.35V (typ)—ideally, V_{SYS} should not exceed the battery charge termination threshold. Systems must be designed such that V_{SYS} never exceeds 5.2V (transient and steady-state). If the V_{SYS} exceeds $V_{SYS\_OVLO\_R}$, the ICs shuts down and resets the "O" Type I^{2}C registers.

V_{SYS} Power-Up Failure ($P_{WRUPFAIL}$)

V_{SYS} power-up failure is a hardware diagnostic mechanism to detect failures affecting the system and preventing the platform from powering up. When a **valid** power source (battery V_{BATT} > SYS_UVLOB_R or charger with V_{CHGIN} > $V_{CHGIN\_UVLO\_R}$) is plugged, the MAX77985/MAX77986 is expected to pull the SYS node up by utilizing one of the system power-up current sources (I_{SYSPU_BAT} or I_{SYSPU_BYP} respectively). If V_{SYS} does not rise above V_{SYSPU} due to a fault in the application (external to MAX77986), after a time-out elapses (t_{SYSPU_BAT} or t_{SYSPU_BYP} respectively) a power-up fault is asserted and an interrupt (PWRUP_FAIL_INT) is generated. Because the SYS node is down, the application software may not be able to service the interrupt; the interrupt can only be observed by pulling VIO up externally and serviced by taking control of the I^{2}C interface.

Thermal Fault

The ICs have one centralized thermal circuit which senses the temperature on the die. If the temperature increases >155°C (T_{SHDN}) this constitutes a thermal shutdown event and the MAX77986 shuts down and resets the "O" Type I^{2}C registers. There is a 15°C thermal hysteresis. After thermal shutdown, if the die temperature is reduced by 15°C, the thermal shutdown bus is deasserted and the IC can be enabled again. The main battery charger has an independent thermal control loop which does not cause a thermal shutdown event. If a charger thermal overload occurs, only the charger turns off.

S Type and O-Type Registers

S type registers include: TOP_FUNC registers 0x00, 0x01, 0x02, 0x03, 0x04, 0x05, 0x50, 0x51; I2C_FUNC register 0x40; CHARGER_FUNC registers 0x10, 0x12, 0x13, 0x14, 0x15.

O type registers include: CHARGER_FUNC registers 0x11, and all registers from 0x16 to 0x24.

Charger Register Write Protection

CHG_CNFG register 1, 2, 3, 4, 5, 7, 8 (CHARGER_FUNC register address 0x17, 0x18, 0x19, 0x1A, 0x1B, 0x1D, 0x1E) are protected by CHG_CNFG_06.CHGPROT bitfield. By default these configurations are not writable, and need unlock by writing bitfield CHGPROT = 0b11 first.

System Faults Debounce Time

Applicable in charge or buck mode.

Table 9. System Faults Debounce Time Summary

	EDGE TO I/T		I/T TO FAULT		ACTION ON FAULT
	t_{DEB} (Rising)	t_{DEB} (Falling)	t_{DEB} (Rising)	t_{DEB} (Falling)	
SYS UVLO	—	—	8ms	—	O-Type reset
SYS OVLO	*-/5ms by I^{2}C	—	—	—	O-Type reset
TSHDN	175µs	—	—	—	O-Type reset
BATT OCP	t_{BOVRC}	—	t_{OCP}	—	Q_{BATT} opens
OTG OCP	t_{OTG_ALARM}	—	t_{OTG_FAULT} - t_{OTG_ALARM}	—	RBFET opens

(*) Depending on I^{2}C bit SYSOVLO_DEB_EN

I^{2}C Interface Description

Main I^{2}C Interface

The IC acts as a Slave Transmitter/Receiver and has the following slave addresses:

Slave Address (7 bit)   0x6B   110 1011

Slave Address (Write)   0xD6   1101 0110

Slave Address (Read)   0xD7   1101 0111

I^{2}C Bit Transfer

One data bit is transferred for each clock pulse. The data on SDA must remain stable during the high portion of the clock pulse as changes in data during this time are interpreted as a control signal.
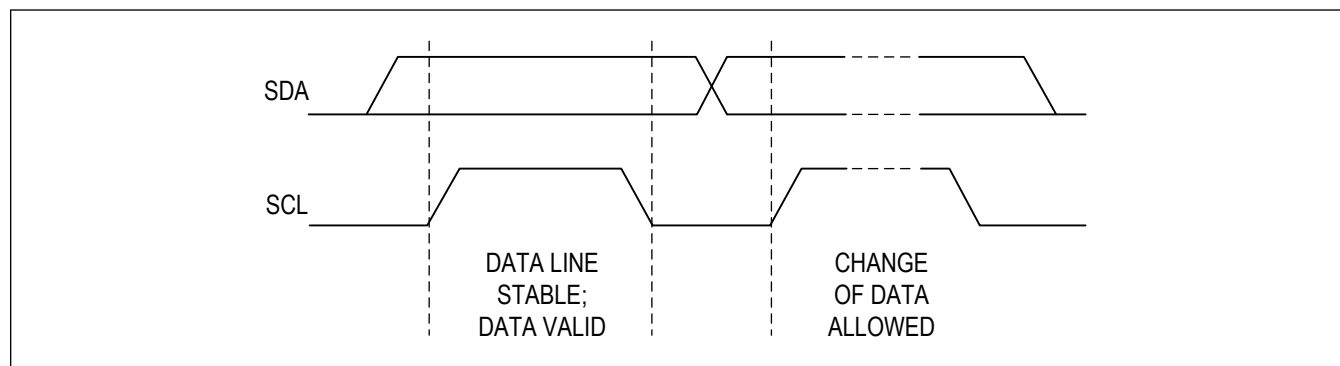

Figure 7. I^{2}C Bit Transfer

I²C Start and Stop Conditions

Both SDA and SCL remain High when the bus is not busy. The Start (S) condition is defined as a high-to-low transition of the SDA while the SCL is high. The Stop (P) condition is defined as a low-to-high transition of the SDA while the SCL is high.
Figure 8. I²C Start and Stop

I²C System Configuration

A device on the I²C bus that generates a "message" is called a "Transmitter" and a device that receives the message is a "Receiver". The device that controls the message is the "Master" and the devices that are controlled by the "Master" are called "Slaves".
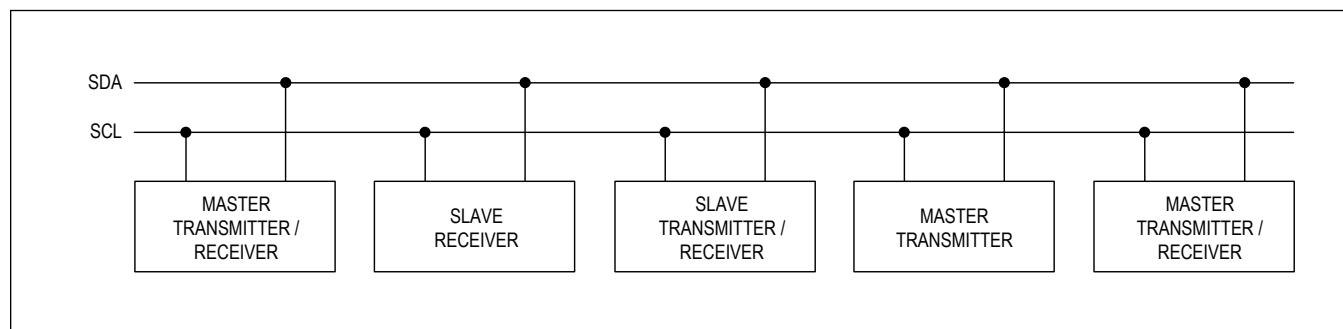

Figure 9. System Configurations

I²C Acknowledge

The number of data bytes between the start and stop conditions for the Transmitter and Receiver are unlimited.

Each 8-bit byte is followed by an Acknowledge bit. The Acknowledge bit is a high-level signal put on SDA by the transmitter during which time the master generates an extra acknowledge-related clock pulse. A slave receiver that is addressed must generate an acknowledge after each byte it receives. Also a master receiver must generate an acknowledge after each byte it receives that has been clocked out of the slave transmitter.

The device that acknowledges must pulldown the SDA line during the acknowledge-clock pulse so that the SDA line is stable and low during the high period of the acknowledge-clock pulse (setup and hold times must also be met). A master receiver must signal the end of data to the transmitter by not generating an acknowledge on the last byte that has been clocked out of the slave. In this case, the transmitter must leave SDA high to enable the master to generate a stop condition.
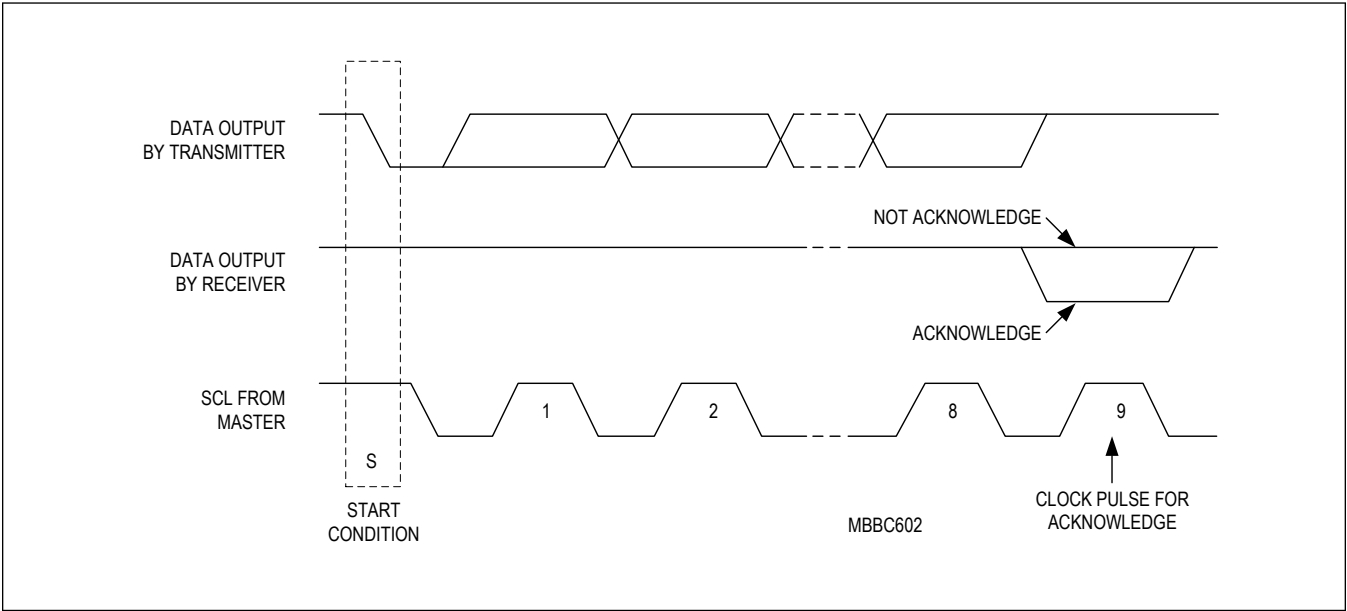

Figure 10. I²C Acknowledge

Master Transmits (Write Mode)

Use the following format when the master writes to the slave.
Figure 11. I²C Master Transmits

Master Reads after Setting Register Address (Write Register Address and Read Data)

Use the following format to read a specific register.
Figure 12. I^{2}C Master Reads After Setting Register Address

Master Reads Register Data Without Setting Register Address (Read Mode)

Use the following format to read registers continuously starting from first address.

TREG	7	Temperature Regulation Status	0b0: The junction temperature is less than the threshold set by REGTEMP and the full charge current limit is available. 0b1: The junction temperature is greater than the threshold set by REGTEMP and the charge current limit may be folding back to reduce power dissipation.

BITFIELD	BITS	DESCRIPTION	DECODE
BAT_DTLS	6:4	Battery Details	**0b000: Battery Removal** A valid adapter is present and the battery is detached, detected on the THM pin. **0b001: Battery Prequalification Voltage** A valid adapter is present and the battery voltage is low: $V_{BATT} < V_{TRICKLE}$. **Note:** This condition is also reported in the CHG_DTLS as 0x00. **0b010: Battery Timer Fault** A valid adapter is present and the battery has taken longer than expected to charge (exceeded t_{FC}). This could be due to high system currents, an old battery, a damaged battery, or something else. Charging has been suspended and the charger is in timer-fault mode. **Note:** This condition is also reported in the CHG_DTLS as 0x06. **0b011: Battery Regular Voltage** A valid adapter is present and the battery voltage is greater than the minimum system regulation level but lower than the overvoltage level: $V_{SYSMIN} < V_{BATT} < V_{BATTREG} + V_{COV}$ V_{SYS} is approximately equal to V_{BATT}. **0b100: Battery Low Voltage** A valid adapter is present and the battery voltage is lower than the minimum system regulation level but higher than the prequalification voltage: $V_{TRICKLE} < V_{BATT} < V_{SYSMIN}$ V_{SYS} is regulated at least equal to V_{SYSMIN}. **0b101: Battery Overvoltage** A valid adapter is present and the battery voltage is greater than the battery-overvoltage threshold ($V_{BATTREG} + V_{COV}$) for the last 30ms. **Note:** This flag is only generated when there is a valid input. **0b110: Battery Overcurrent** The battery current has exceeded the battery-overcurrent threshold (I_{BOVRC}) for at least 3ms since the last time this register was read. **0b111: Battery Only, No Overcurrent** No valid adapter is present and the battery current is lower than the battery-overcurrent threshold (I_{BOVRC}). The battery voltage and battery removal monitoring are not available. **Note:** In the case of deep suspend, it is considered that no valid adapter is present.

BITFIELD	BITS	DESCRIPTION	DECODE
CHG_DTLS	3:0	Charger Details	0x00: Charger is in dead-battery prequalification or low-battery prequalification mode. Access Type	Write, Read	Write, Read			Write, Read			

BITFIELD	BITS	DESCRIPTION	DECODE
SPR_7	7	Spare Bit	
TO_TIME	6:4	Top-Off Timer Setting (min)	0b000: 30sec 0b001: 10 0b010: 20 0b011: 30 0b100: 40 0b101: 50 0b110: 60 0b111: 70
TO_ITH	3:0	Top-Off Current Threshold (mA). The charger transitions from its fast-charge constant voltage mode to its top-off mode when the charger current decays to the value programmed by this register. This transition generates a CHG_I interrupt and causes the CHG_DTLS register to report top-off mode. This transition also starts the top-off time as programmed by TO_TIME.	0b0000: Disable 0b0001: 150mA 0b0010: 200mA 0b0011: 250mA 0b0100: 300mA 0b0101: 350mA 0b0110: 400mA 0b0111: 450mA 0b1000: 500mA 0b1001: 550mA 0b1010: 600mA 0b1011: 650mA 0b1100: 700mA 0b1101: 750mA 0b1110: 800mA 0b1111: 850mA

Typical Application Circuits

Layout Guidelines
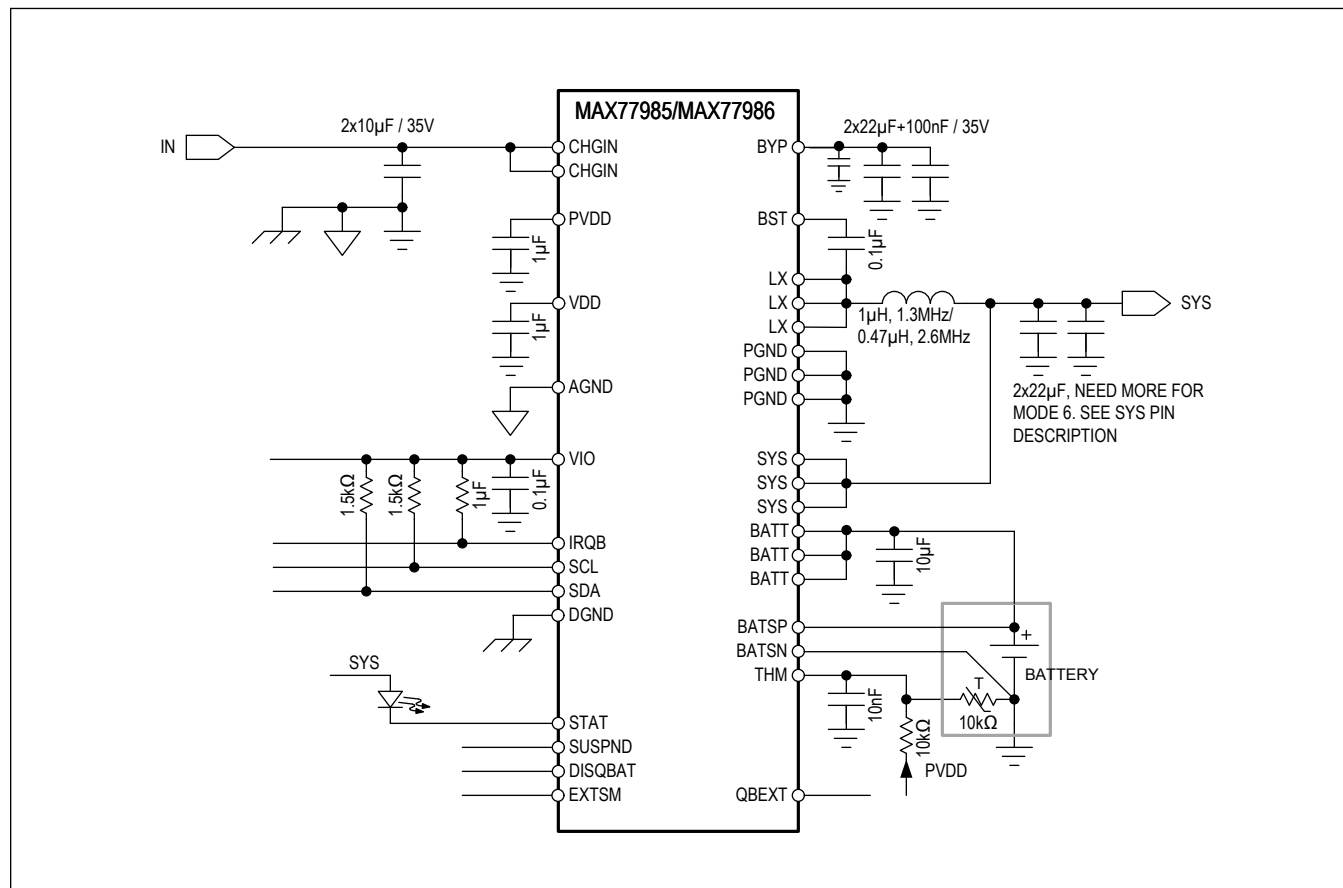

1. Connect the power ground plane to the analog ground plane with a star connection. Do not directly connect AGND with the top layer power ground. Instead, connect the AGND to stable inner ground plane through via.

2. Place CHGIN, BYP, SYS, and BATT bypass capacitors as close as possible to the IC pins and connect them to the power ground plane on the PCB top layer. Especially, make sure the connection between BYP cap ground and SYS cap ground is as direct, short, and wide as possible. If possible, reinforce the connection between BYP cap ground and SYS cap ground in other layers.

3. Place PVDD and AVDD bypass cap as close to IC as possible. Reduce the loop area between the bypass cap and the IC.

4. Use wide and short traces for high current connections such as CHGIN, BYP, SYS, and BATT.

5. BATSP and BATSN should have direct kelvin sensing connections to the interface of the battery. Connect as close to the battery terminal as possible, so that the battery voltage is sensed correctly.

6. The kelvin sensing traces should not be shared with other circuits and via on kelvin traces are not recommended.

Ordering Information

PART NUMBER	TEMP RANGE	MAX FAST-CHARGE CURRENT (A)	SUPPORTED BATTTERY TYPE	INDUCTOR CURRENT LIMIT (A)	REVERSE BOOST POWER CEILING (W)	PIN-PACKAGE
MAX77985AEFD+	-40°C to +85°C	3.5	General Li-ion	8.3	12	32-FC2QFN
MAX77985AEFD+T	-40°C to +85°C	3.5	General Li-ion	8.3	12	32-FC2QFN
