PFF3000-12-069RD 3000 W DC-DC Front-End Power Supply

PFF3000-12-069RD is a 3 kW DC/DC front-end converter that provides a main output 12.5 VDC from -40 to -72 VDC bus voltages to power Intermediate Bus Architectures (IBA) in high-performance and high-reliability servers, routers, and network switches.

Features include very high efficiency, high reliability, low output voltage noise, and excellent dynamic response to load / input changes.

Key Features & Benefits

- Best-in-class, platinum equivalent efficiency
- Input voltage range: -40 to -72 VDC
- Up to 3 kW output power 244 A output current
- Hot-plug capable
- Parallel operation with active analog current sharing
- 2 Status LEDs: DC input OK and warning / fault signaling
- High density design: 30.5 W/in³
- Form factor: 555 x 69 x 42 mm (21.85 x 2.72 x 1.65 in)
- Full digital controls for improved performance
- RoHS Compliant
- Reverse polarity, over temperature, output overvoltage, and overcurrent protections
- I2C communication interface for control, programming, and monitoring
 with Power Management Bus protocol

Applications

- High Performance Servers
- Routers
- Switches

2. OVERVIEW

PFF3000-12-069RD power supply is a fully digital controlled, highly efficient front-end converter. It incorporates state-of-the-art technology and uses an interleaved forward converter topology with active clamp and synchronous rectification to reduce component stresses, thus providing increased system reliability and very high efficiency.

With a wide DC input voltage range and minimal linear output power derating with ambient temperature, PFF3000-12-069RD maximizes power availability in demanding server, switch, and router applications. The frontend is fan cooled and ideally suited for server integration with a matching airflow path.

Active OR-ing devices on the main output ensure no reverse load current and render the supply ideally suited for operation in redundant power systems. The standby output (12V/2A) provides power to external power distribution and management controllers. Its protection with an active OR-ing device provides for maximum reliability.

Status information is provided with two front-panel LEDs. In addition, the power supply can be controlled via I2C bus. This allows full monitoring of the supply, including input and output voltage, current, power, and inside temperatures. Cooling is managed by a fan controlled by the DSP controller. The fan speed is adjusted automatically depending on the actual power demand and supply temperature and can be overridden through the I2C bus.

Figure 1. PFF3000-12-0069RD Block Diagram

3. ABSOLUTE MAXIMUM RATINGS

Stresses in excess of the absolute maximum ratings may cause performance degradation, adversely affect long-term reliability, and cause permanent damage to the supply.

| | | $V_{l \text{ nom}}, \qquad I_{1 \text{ nom}}, V_{1 \text{ nom}}, T_A = 25 ^\circ \text{C}$ | 91.0 | 93 | | % |

4.1 INPUT FUSE

Fast-acting 100 A input fuse in series on minus DC rail inside the PSU protects against severe defects. The fuse is not accessible from the outside and is not therefore a serviceable part.

4.2 INRUSH CURRENT & REVERSE POLARITY PROTECTION

Internal bulk capacitors will be charged through NTC resistors connected from bulk cap minus pin to the DC rail minus, thus limiting the inrush current. After the inrush phase, NTC resistors are then shorted with MOSFETs connected in parallel. Inrush control is managed by the digital controller (DSP).

Parallel connected MOSFETs in series to the DC minus rail input act as a reverse polarity blocking element (Fig. 1). In case of a short at the input voltage or input reverse polarity, these MOSFETs will open and prevent the bulk caps to be discharged via the input. Reverse polarity control is managed by a fast-acting analog circuit.

NOTE: In order to keep max inrush current below I₁ max, it is not recommended to repeat plug-in/-out operations within 20 s.

4.3 INPUT UNDER-VOLTAGE

If input voltage V_i is below the input under-voltage lockout threshold $V_{i,min}$, main output will be inhibited. Once the input voltage returns within the normal operating voltage range, main output voltage will be enabled again and converter returns into normal operation.

4.4 EFFICIENCY

High efficiency is achieved by using state-of-the-art silicon power devices, thus minimizing conduction and switching losses by an optimized design and layout. Synchronous rectifiers on the output stage reduce losses in the high current output path. Fan speed is digitally controlled in order to keep all components below critical operating temperature.

5.1 OUTPUT VOLTAGE RIPPLE

The internal output capacitance at the power supply output (behind OR-ing element) is minimized to prevent disturbances during hot plug. In order to provide low output ripple voltage in the application, external capacitors should be added close to the power supply output. The setup of Figure 3 has been used to evaluate suitable capacitor types. The capacitor combinations of Table 1 and Table 2 should be used to reduce the output ripple voltage.

The ripple voltage is measured with 20 MHz BWL, close to the external capacitors.

Figure 3. Output Ripple Test Setup

NOTE: Care must be taken when using ceramic capacitors with a total capacitance of 1 µF to 50 µF on output V1, due to their high quality factor the output ripple voltage may be increased in certain frequency ranges due to resonance effects.

| External Capacitor V1 | dV1max | Unit |
|--|--------|------|
| 2Pcs 47µF/16V/X5R/1210 | 160 | mVpp |
| 1Pcs 1000µF/16V/Low ESR Aluminum/ø10x20 | 160 | mVpp |

Unit

mVpp

The output ripple voltage on VSB is influenced by the main output V1. Evaluating VSB output ripple must be done when maximum load is applied to V1.

5.2 OUTPUT ISOLATION

Main and standby outputs and all signals are galvanic isolated from the chassis and protective earth connection, although the applied voltage V_I has not to exceed 75 V_{pk} in order to prevent catastrophic damage to the PSU.

¹ See *Figure 26* for linear power derating > 45°C

² Limit set don't include effects of main output capacitive discharge.

6.1 AUTOMATIC RETRY

Any fault condition on main output V_1 will shut down the main output and attempt to recover from the fault 5 times before latching off. The time between each restart attempt is 10 s. The fault latch and fault counter can be reset by disconnecting the input voltage or by toggling the PSON_L input. If the unit operates for more than 10 min with no failure, then the failure counter will be reset automatically. A failure on the standby output V_{SB} will shut down both outputs, whereas a failure on main output V1 will only shut down this output, while V_{SB} will continue to operate and communicate.

6.2 OVERVOLTAGE PROTECTION

The PSU provides a fixed threshold overvoltage (OV) protection, implemented with a hardware comparator. Once an overvoltage (OV) condition has been triggered, the supply will shut down and latch the fault condition.

6.3 UNDERVOLTAGE DETECTION

As both main and standby outputs are monitored, LEDs and the PWOK_L pin will warn if V_1 or V_{SB} exceed $\pm 7\%$ of its nominal voltage. Output undervoltage protection is provided on both outputs. When either V1 or VSB falls below 93% of its nominal voltage, the output is inhibited.

6.4 OUTPUT OVER-CURRENT PROTECTION

MAIN OUTPUT

Two different over current protection features are implemented on the main output.

The 1st protection - a static over current protection will shut down the output, if the output current does exceed $I_{v1 \text{ lim}}$ for more than 20 ms. If the output current is increased slowly this protection will shut down the supply. The main output current limitation level $I_{v1 \text{ lim}}$ will decrease if the ambient (inlet) temperature increases beyond 45 °C (see *Figure 26*).

The 2nd protection - a substantially rectangular output characteristic controlled by a software feedback loop. This protects the power supply and system during the 20 ms blanking time of the static over current protection. If the output current is rising fast and reaches $k_{1 \text{ ol lim}}$, the supply will immediately reduce its output voltage to prevent the output current from exceeding $k_{1 \text{ ol lim}}$. When the output current is reduced below $k_{1 \text{ ol lim}}$, the output voltage will return to its nominal value.

Figure 12. Current limitation on main output

STANDBY OUTPUT

On the standby output a hiccup type over current protection is implemented. This protection will shut down the standby output immediately when standby current reaches or exceeds $k_{\text{SB lim}}$. After an off-time of 1s the output automatically tries to restart. If the overload condition is removed the output voltage will reach again its nominal value $V_{\text{SB}} = V_{\text{SB nom}} \pm 1\%$. At continuous overload condition the output will repeatedly trying to restart with 1s intervals.

tech.support@psbel.com belfuse.com/power-solutions

8.2 INTERFACING WITH SIGNALS

A 15 V Zener diode is added on all signal pins versus signal ground SGND to protect internal circuits from negative and high positive voltage. Signal pins of several supplies running in parallel can be interconnected directly. A supply having no input power will not affect the signals of other PSUs running in parallel.

The current share bus pin (ISHR_BUS) must be interconnected without any additional components; as protection element, a 15 V Zener diode is connected to the signal reference SGND. The share bus is disconnected (analog switch) from internal circuits when the power supply is switched off.

8.3 LED STATUS - FRONT LEDs

The PSU has two front LEDs showing its status: DC Input LED is green colored and indicates DC power ON / OFF, DC Output LED is bi-colored green and yellow and shows DC output OK or a warning/fault status as listed in Table 1.

| OPERATING CONDITION | LED SIGNALING | |
|--|-----------------------------|--|
| IN: DC Input LED | | |
| DC line within range | Solid Green | _ |
| DC line UV / OV condition | OFF | |
| Bootload | Blinking green: OFF (1:1) | _ |
| OUT: DC Output LED | | |
| Normal Operation | Solid Green | |
| PSKILL_IN_L - Left open | | |
| PSON_L - High, PSKILL_L - High | Blinking Yellow (1:1) | |
| Power Management Bus Command OPERATION | 2 | |
| DC line UV / OV condition | | $\ \square \square$ |
| V1 or VSB out of regulation | | |
| Over temperature shutdown | | |
| Output over voltage shutdown (V ₁ or V_{SB}) | Solid Yellow | |
| Output under voltage shutdown (V $_1$ or V _{SB}) | | |
| Output over current shutdown $(V_1 \text{ or } V_{SB})$ | | |
| Both FANs blocked | | |
| Over temperature warning | Blinking Yellow/Green (2:1) | |
| Minor fan regulation error (> 5 %, < 15 %) | Blinking Yellow/Green (1.1) | |
| Or one of the FANs blocked | | |
| Bootload | Blinking Green (1:1) | |
| | | |

Table 3. LED Status

8.4 PRESENT_L

PRESENT_L is a trailing pin within the connector and will contact only once all other connector contacts. This active-low pin is used to indicate to a power distribution unit controller that a supply is plugged in. Maximum sink current on PRESENT_L pin should not exceed 10 mA.

8.5 PSKILL_L / PSKILL_IN_L INPUT

PSKILL_L input is an active-low trailing pin in the output connector and is used to disconnect the main output as soon as the power supply is being pulled out. This pin should be connected to SGND in the power distribution unit. Standby output will remain on, regardless of the PSKILL_L input state.

PSKILL_IN_L input is an active-low signal pin in the input connector and is used to disconnect the main output as soon as the input connector is plugged out. This pin should be connected to SGND on the input connector mating part. Standby output will remain on, regardless of the PSKILL_L input state.

8.6 DC TURN-ON / DROP-OUTS / INOK_L

The INOK_L signal indicates whether the DC input voltage is within the operating range and the power supply can turn on. The power supply will automatically turn-on when connected to the DC line within the operating voltage range under the condition that the PSON_L signal is pulled low. INOK_L is an active low open collector output that requires an external pullup voltage to maximum 12.0 V.

8.7 PSON_L INPUT

PSON_L is an internally pulled-up (3.3 V) input signal to enable / disable the main output V_1 . This active-low pin is also used to clear any latched fault condition. Timing parameters are listed in Table 2.

8.8 PWOK_L SIGNAL

PWOK_L is an open collector output that requires an external pull-up voltage to maximum 12 V, indicating whether both V_1 and V_{SB} outputs are within regulation. This pin is active-low; timing parameters are listed in Table 2.

8.9 SIGNAL TIMING

| OPERAT | ING CONDITION | MIN | MAX | UNIT |
|----------------------------------|---|-----|------|------|
| t _{V1_rise} | See table Output Parameter | | | |
| t _{VSB_rise} | See table Output Parameter | | | |
| t _{INOK_On} | INOK_L delay at dropout | 0 | 700 | ms |
| t _{INOK_On_Pwr_On} | INOK_L delay at coldstart | 500 | 1800 | ms |
| $t_{\text{INOK_to_VSB_rise}}$ | INOK_L to V _{SB} delay | 1 | 5 | ms |
| tvsB_Pwr_On | V _{in} to V _{SB} delay | 520 | 1805 | ms |
| tv1_Pwr_On | V _{in} to V ₁ delay | 700 | 3000 | ms |
| tpwok_on | V₁ in regulation to PWOK_L | 280 | 320 | ms |
| t _{V1_fall} | monotonic | | | |
| t _{VSB_fall} | monotonic | | | |
| t _{INOK_Off} | INOK_L delay | 0 | 1.8 | ms |
| t_{INOK_warn} | INOK_L to V_1 out of regulation (0.5 $I_1),V_I>48V$ | 1.0 | | ms |
| tv1_holdup | See table Output Parameter | | | |
| tvsB_holdup | See table Output Parameter | | | |
| tpwok_off | V1 out of regulation to PWOK_L | 0 | 5 | ms |
| tpson_on | PSON_L to V1 in regulation | 150 | 170 | ms |
| tpson_Off | PSON_L to V1 out of regulation | 0 | 5 | ms |
| t _{PSKILL(_IN)_On} | PSKILL(_IN)_L to V_1 in regulation | 150 | 170 | ms |
| t _{PSKILL(_IN)_Off} | PSKILL(_IN)_L to V₁ out of regulation | 0 | 5 | ms |

8.10 CURRENT SHARE

The PSU has an active current share scheme implemented for main output V₁. ISH_BUS current share pins of all units in parallel need to be interconnected in order to activate the sharing function. If a supply has an internal fault or is not turned on, it will disconnect its ISHR_BUS pin from the share bus: this will prevent dragging the output down (or up) in such cases. Master / Slave current share function implemented by the controller uses an analog bus: the power supply providing the largest current among the group is automatically the Master. The other supplies will operate as Slaves and increase their output current to a value close to the Master by slightly increasing their output voltage. The output voltage increase is limited to +250 mV. Standby output uses an analog passive current-share method (droop-output voltage characteristic). Maximum available main and stand-by power in (non)-redundant topology is listed in Table 5.

| No. of paralleled PSUs | Max available power on main output without redundancy | Max available power on main output with n+1 redundancy | Max available power on standby output |
|---------------------------|---|---|--|
| 1 | 3000 W | - | 24 W |
| 2 | 5850 W | 3000 W | 24 W |
| 3 | 8700 W | 5850 W | 24 W |
| 4 | 11550 W | 8700 W | 24 W |
| 5 | 14400 W | 11550 W | 24 W |
| 6 | 17250 W | 14400 W | 24 W |

Table 5. Available power when multiple PSUs are operating

8.11 SENSE INPUTS

Main output sense lines have been implemented in order to compensate voltage drops on the load wires: a maximum voltage drop of 200 mV on the positive rail and 100 mV on the PGND rail is allowed. If sense inputs are not connected (open), main output voltage will rise by 250 mV; therefore, if sense inputs are not used, they should be connected to the power output and SGND, close to the power supply connector. The sense inputs are protected against short circuit and reverse polarity. If the sense lines are shorted (or reverse polarized) at start-up condition, then V₁ will be regulated by 500 mV higher than the reference voltage for 100 ms and later the PSU will shut down reporting a sense fault error. If the sense lines are shorted (or reverse polarized) during operation, then the unit will shut down immediately.

8.12 I2C / POWER MANAGEMENT BUS COMMUNICATION

The PSU is a communication slave device only: it never initiates messages on the I2C / SMBus. It recognizes any time Start / Stop bus conditions and the interface driver in the supply is referred to the SGND. Communication bus voltage and timing are defined by:

- 100 kΩ internal pull-up resistors
- SDA / SCL IOs must be pull-up externally to 3.3 ± 0.3 V
- Pull-up resistor should be 2 kΩ to 5 kΩ to ensure SMBUS compliant signal rise times
- Full SMBus clock speed of 100 kbps
- Clock stretching limited to 1 ms
- SCL low time-out of > 25 ms with recovery time within 10 ms

Figure 20. Physical layer of communication interface

SMB_ALERT_L signal indicates that the power supply is experiencing a problem that the system agent should investigate: this is a logical OR of the shutdown and warning events. Communication to the DSP will be possible as long as the input voltage is provided. If no input voltage is present, communication to the unit is possible as long as it is connected to a live V_{SB} output (e.g. provided by a redundant unit); if only V_1 is provided, communication is not possible.

| PARAM | IETER | CONDITION | MIN | MAX | UNIT |
|--------------------|--|--|---------------------|---------------------------|------|
| ViL | Input low voltage | | -0.2 | 0.4 | V |
| ViH | Input high voltage | | 2.1 | 3.6 | V |
| V _{hys} | Input hysteresis | | 0.15 | | V |
| VoL | Output low voltage | 4 mA sink current | 0 | 0.4 | V |
| tr | Rise time for SDA and SCL | | $20 + R_b C_b^1$ | 300 | ns |
| t _{of} | Output fall time V _{iHmin} → V _{iLmax} | $10 \text{ pF} < C_b^1 < 400 \text{ pF}$ | $20 + R_b C_b^{-1}$ | 250 | ns |

8.13 ADDRESS

The unit supports the Power Management Bus communication protocol with a fixed address at 0x20. The EEPROM is at fixed address = 0xA0.

8.14 CONTROLLER ACCESS

The controller and the EEPROM in the power supply share the same I2C bus physical layer (see Figure 23). In order to write to the EEPROM, the write protection needs to be disabled by setting EEPROM_WP input correctly. EEPROM_WP=HIGH: write disabled; EEPROM_WP=LOW: write enabled.

Figure 22. I2C Bus to Controller and EEPROM

8.15 EEPROM PROTOCOL

The EEPROM follows the industry communication protocols used for this type of device. Even though page write / read commands are defined, it is recommended to use the single byte write / read commands.

WRITE

The write command follows the SMBus 1.1 Write Byte protocol. After the device address with the write bit cleared a first byte with the data address to write to is sent followed by the data byte and the STOP condition. A new START condition on the bus should only occur after 5ms of the last STOP condition to allow the EEPROM to write the data into its memory.

READ

The read command follows the SMBus 1.1 Read Byte protocol. After the device address with the write bit cleared the data address byte is sent followed by a repeated start, the device address and the read bit set. The EEPROM will respond with the data byte at the specified location.

8.16 **POWER MANAGEMENT BUS PROTOCOL**

The Power Management Bus is an open standard protocol that defines means of communicating with power conversion and other devices. For more information, please see the System Management Interface Forum web site at: www.powerSIG.org.

Power Management Bus command codes are not register addresses. They describe a specific command to be executed. PFF3000-12-069RD supply supports the following basic command structures:

- Clock stretching limited to 1 ms
- SCL low time-out of >25 ms with recovery within 10 ms
- Recognized any time Start/Stop bus conditions

WRITE

The write protocol is the SMBus 1.1 Write Byte/Word protocol. Note that the write protocol may end after the command byte or after the first data byte (Byte command) or then after sending 2 data bytes (Word command).

In addition, Block write commands are supported with a total maximum length of 255 bytes. See PFF3000-12-069RA Power Management Bus Communication Manual BCA.00070 for further information.

READ

The read protocol is the SMBus 1.1 Read Byte/Word protocol. Note that the read protocol may request a single byte or word.

In addition, Block read commands are supported with a total maximum length of 255 bytes. See PFF3000-12-069RD Power Management Bus Communication Manual BCA.00216 for further information.

8.17 GRAPHICAL USER INTERFACE

Bel Power Solutions provides its I2C Utility: a Windows® XP / Vista / Win7 compatible graphical user interface (GUI), allowing PFF3000-12-069RD programming and monitoring. This utility can be downloaded at <u>belfuse.com/power-solutions</u> and supports both the PSI and Power Management Bus protocols. The GUI allows automatic finding of connected units to the communication bus and will show them in the navigation tree. In, the monitoring view the power supply can be controlled and monitored.

Figure 23. Monitoring dialog of the I2C utility (example)

9. TEMPERATURE AND FAN CONTROL

In order to achieve best cooling results, sufficient airflow through the supply must be ensured; airflow shall not be blocked or obstructed by placing large objects close to the output connector at the rear of the supply. PFF3000-12-069RD is provided with a front-to-rear airflow, thus meaning the air enters through the power supply handle side (front) and leaves at the rear side. PFF3000-12-069RD has been designed for horizontal operation. The internal fan is controlled by a microprocessor: fan rpm is then adjusted to provide optimal cooling air and is a function of output power, inlet and internal MOSFETs temperature.

Figure 24. Airflow direction
