

MOSFET – N-Channel, UltraFET TRENCH

150 V, 0.047 mΩ 4.9 A

FDS2572

Description

UltraFET Devices Combine Characteristics that enable benchmark efficiency in power conversion applications. Optimized for $R_{DS(on)}$, low ESR, low total and Miller gate charge, these devices are ideal for high frequency DC–DC converters.

Features

- $R_{DS(on)} = 0.040 \text{ m}\Omega$ (Typ.), $V_{GS} = 10 \text{ V}$
- $Q_{g(TOT)} = 29 \text{ nC}$ (Typ.), $V_{GS} = 10 \text{ V}$
- Low Q_{RR} Body Diode
- Maximized Efficiency at High Frequencies
- UIS Rated
- These Device is Pb–Free and Halide Free

Typical Applications

- DC–DC Converters
- Telecom and Data–Com Distributed Power Architectures
- 48–volt I/P Half–Bridge/Full–Bridge
- 24–volt Forward and Push–Pull topologies

Product parametric performance is indicated in the Electrical Characteristics for the listed test conditions, unless otherwise noted. Product performance may not be indicated by the Electrical Characteristics if operated under different conditions.

NOTES:

- $R_{\theta JA}$ is the sum of the junction-to-case and case-to-ambient thermal resistance where the case thermal reference is defined as the solder mounting surface of the drain pins. $R_{\theta JC}$ is guaranteed by design while $R_{\theta CA}$ is determined by the user's board design.
- $R_{\theta JA}$ is measured with 1.0 in² copper on FR-4 board

THERMAL RESISTANCE VS. MOUNTING PAD AREA

The maximum rated junction temperature, T_{JM} , and the Thermal Resistance of the heat Dissipating Path Determines the Maximum Allowable Device Power Dissipation, PDM, in an application. Therefore the application's ambient

temperature, T_A ($^{\circ}\text{C}$), and thermal resistance $R_{\theta JA}$ ($^{\circ}\text{C}/\text{W}$) must be reviewed to ensure that T_{JM} is never exceeded. Equation 1 mathematically represents the relationship and serves as the basis for Establishing the rating of the Part.

$$P_{DM} = \frac{(T_{JM} - T_A)}{R_{\theta JA}} \quad (\text{eq.1})$$

In using surface mount devices such as the SO8 package, the environment in which it is applied will have a significant influence on the part's current and maximum power dissipation ratings. Precise determination of PDM is complex and influenced by many factors:

1. Mounting pad area onto which the device is attached and whether there is copper on one side or both sides of the board;
2. The number of copper layers and the thickness of the board.
3. The use of external heat sinks
4. The use of external heat sinks
5. Air flow and board orientation
6. For non steady state applications, the pulse width, the duty cycle and the transient thermal response of the part, the board and the environment they are in.

onsemi Provides Thermal Information to assist the Designer's Preliminary Application Evaluation. Figure 19 defines the $R_{\theta JA}$ for the device as a function of the top copper (component side) area. This is for a horizontally positioned FR-4 board with 1oz copper after 1000 seconds of steady state power with no air flow. This graph provides the necessary information for calculation of the steady state junction temperature or Power Dissipation. Pulse applications can be evaluated using the Fairchild Device Spice Thermal model or manually utilizing the normalized maximum transient thermal impedance curve.

Thermal resistances corresponding to other copper areas can be obtained from Figure 19 or by calculation using

Equation 2. The area, in square inches is the top copper area including the gate and source pads.

$$R_{\theta JA} = 64 + \frac{26}{0.23 + \text{Area}} \quad (\text{eq.2})$$

The transient thermal impedance ($Z_{\theta JA}$) is also effected by varied top copper board area. Figure 20 shows the effect of copper pad area on single pulse transient thermal impedance. Each trace represents a copper pad area in square inches corresponding to the descending list in the graph. Spice and SABER thermal models are provided for each of the listed pad areas.

Copper Pad area has no perceivable effect on transient thermal impedance for pulse widths less than 100 ms. For pulse widths less than 100 ms the transient thermal impedance is determined by the die and package. Therefore, C THERM1 through C THERM5 and R THERM1 through R THERM5 remain constant for each of the thermal models. A listing of the model component values is available in Table 1.
