Chapter 1

Addendum for Rev. 8 of MPC5777CRM

1.1 Introduction

This addendum describes corrections or updates to the MPC5777C Reference Manual. The currently-available version of the MPC5777C Reference Manual is Revision 8. In the table below, the page numbers in the Location column are relative to that version.

Navigation tip: When navigating this PDF file using the hyperlinks, pressing the ALT and "left arrow" keys simultaneously will return you to the previously viewed page.

Table 1-1. MPC5777CRM Rev. 8 addendum

Location	Description
Chapter 4, Memory Map, Interrupts, and DMA Requests	
Page 117	• In table "UTEST flash memory map", added the row for start addresses "0x004000E0" and "0x004002E0". • See Table 2-3.
Chapter 19, Clocking	
Page 794	• In "Operating frequencies" section, added table "Maximum system and peripheral clock frequencies 300 MHz". • See Operating frequencies.
Chapter 37, Enhanced Time Processing Unit (eTPU)	
Page 1473	• In "Chip-specific eTPU information" section, for ETPU_A, ETPU_B and ETPU_C added the the text "On devices with an operating frequency of 300 MHz, the eTPU has support for up to 240 MHz clock rate (provides 120 MHz instruction execution rate)". • See Chip-specific eTPU information.

NOTE

The section Appendix B: Release Notes describe the changes between the Rev. 7 and Rev. 8.

Chapter 2

RM Addendum

2.1 Memory Map, Interrupts, and DMA Requests

2.1.1 Memory map

All addresses in the device are identified in the following table. The addresses represent the physical addresses assigned to each block. Logical addresses are translated by the MMU into physical addresses.

Under software control of the Memory Management Unit (MMU), the logical addresses allocated to IP blocks may be changed on a minimum of a 1 KB boundary.

NOTE

Address ranges not declared in the memory map table must be considered reserved.

Table 2-1. Memory map

Address range	Module
Flash memory—see Table 2-2 for details	
0x0000_0000–0x0003_FFFF	Flash memory Low/Mid Blocks (256K)
0x0004_0000–0x003F_FFFF	Reserved
0x0040_0000–0x0040_3FFF	Flash memory UTEST (16K)—see Table 2-3 for details
0x0040_4000–0x005F_FFFF	Reserved
0x0060_0000–0x0060_7FFF	Flash memory High Blocks (32K)
0x0060_8000–0x007F_FFFF	Reserved
0x0080_0000–0x00FF_FFFF	Flash memory Large Blocks (8M)
0x0100_0000–0x0FFF_FFFF	Reserved
0x1000_0000–0x1FFF_FFFF	Emulation remapping of flash memory using MMU
External memory	
0x2000_0000–0x3FFF_FFFF	External Bus Memory

Table continues on the next page...

Table 2-1. Memory map (continued)

Address range	Module
System RAM	
0x4000_0000–0x4000_FFFF	Standby SRAM on XBAR Slave Port 2 (64 KB)
0x4001_0000–0x4003_FFFF	SRAM on XBAR Slave Port 2 (192 KB)
0x4004_0000–0x4007_FFFF	SRAM on XBAR Slave Port 4 (256 KB)
0x4008_0000–0xC3DF_FFFF	Reserved
Peripheral Bridge A (AIPS_1)

Clocking

1. Programmed by NXP during test. Contains the temperature sensor and bandgap ADC readings to be used by software to improve the accuracy of the temp sensor readings.
2. Programmed by NXP during test. In production devices, UTEST is sealed (one-time programmable) from the factory.
3. Programmed by the customer to select which blocks cannot be tested in Failure Analysis.
4. Secondary location that can be programmed by the customer to select which blocks cannot be tested in Failure Analysis.
5. Programmed by NXP to include ECC/EDC errors to allow testing of ECC/EDC hardware.
6. Programmed by NXP during test. The UID includes information on wafer lot, X/Y-position on the wafer, manufacturing data, test results, and company ID (65 for NXP).
7. The speed indicator is programmed in three locations. For devices with a maximum operating frequency of 300 MHz, addresses 0x0040_00B0 and 0x0040_00E0 will contain a value of 0xFFFF_300F. Address 0x0040_02E0 will contain a value of 0x0000_CFF0. For devices with a maximum operating frequency of 264 MHz, all three of these locations will contain a value of 0xFFFF_FFFF. The first location of the speed indicator is part of the UID.
8. Protected from read operations by flash memory BIU from OEM Production life cycle. Programmed by customer. Becomes unreadable (hidden) as soon as customer programs life cycle to OEM Production or later.
9. MCU Production life cycle slot. Programmed by NXP during test.
10. Customer Delivery life cycle slot. Programmed by NXP during test.
11. OEM Production life cycle slot. Programmed by customer during ECO module production/test.
12. In Field life cycle slot. Programmed by customer during ECO module production/test.
13. Failure Analysis life cycle slot. Programmed by the customer on returned modules.
14. DCF start record. Programmed by NXP during test. Contiguous list of DCF records start at this address.
15. Contiguous list of DCF records. Initial records programmed by NXP. Subsequent records added to the end of the list by the customer.
16. Programmed by the customer.

2.2 Clocking

2.2.1 Operating frequencies

On device with operating frequency of 264 MHz, the maximum supported operating frequencies are given in the following table.

Table 2-4. Maximum system and peripheral clock frequencies

Clock domain	Mode	Core (CORE_CLK)	eTPU (eTPU_CLK)	Platform (PLAT_CLK)	Peripherals memory mapped registers (FM_PER_CLK)	Peripherals protocol engines (PER_CLK)
Backwards compatible: one clock domain ¹	Double	264	132	132	132	132
	eTPU	200	200	100	100	100
Enhanced: dual clock domain ²	Normal	264	200	132	132	100

1. Clock selectors configured such that all clocks come from a single source, either PLL0 or PLL1.

2. Clock selectors configured such that both PLLs drive the clocks into two asynchronous domains.

On device with operating frequency of 300MHz, the maximum supported operating frequencies are given in the following table.

Table 2-5. Maximum system and peripheral clock frequencies for 300 MHz

Clock domain	Mode	Core (CORE_CLK)	eTPU (eTPU_CLK)	Platform (PLAT_CLK)	Peripherals memory mapped registers (FM_PER_CLK)	Peripherals protocol engines (PER_CLK)
Backwards compatible: one clock domain ¹	Double	300	150	150	150	150
	eTPU	240	240	120	120	120
Enhanced: dual clock domain ²	Normal	300	240	150	150	120

1. Clock selectors configured such that all clocks come from a single source, either PLL0 or PLL1.

2. Clock selectors configured such that both PLLs drive the clocks into two asynchronous domains.

NOTE

The essentially asynchronous clock domains of EVTO (eTPU_CLK) and NPC (CORE_CLK) require CORE_CLK to be set to a higher frequency than eTPU_CLK for guaranteed EVTO capture by NPC. Because CORE_CLK can be set to FM (2% intentional jitter), the frequency of CORE_CLK minus 2% must be greater than the frequency of eTPU_CLK.

2.3 Enhanced Time Processing Unit (eTPU)

2.3.1 Chip-specific eTPU information

This chip contains three eTPU modules with the following configuration:

- 32 channels per eTPU module
- 36 KB code RAM total
- 9 KB parameter RAM total
- ETPU_A and ETPU_B share the same program and data (parameter RAM) space in a dual-engine configuration
 - On devices with an operating frequency of 264 MHz, the eTPU has support for up to 200 MHz clock rate (provides 100 MHz instruction execution rate). On devices with an operating frequency of 300 MHz, the eTPU has support for up to 240 MHz clock rate (provides 120 MHz instruction execution rate).
 - ECC support on parameter RAM and program space
 - Sizes of shared eTPU_A and eTPU_B memories:

- SCM instruction memory address space: 24 KB code RAM
- SDM data memory address space: 6 KB parameter RAM
- No shared subsystem support and therefore no Shared Subsystem Integration registers (SSIRs)
- ETPU_C has private program and parameter RAM space in a single-engine configuration
 - On devices with an operating frequency of 264 MHz, the eTPU has support for up to 200 MHz clock rate (provides 100 MHz instruction execution rate). On devices with an operating frequency of 300 MHz, the eTPU has support for up to 240 MHz clock rate (provides 120 MHz instruction execution rate).
 - ECC support on parameter RAM and program space
 - Sizes of eTPU_C memories:
 - SCM instruction memory address space: 12 KB code RAM
 - SDM data memory address space: 3 KB parameter RAM
 - Supports REACM2 by [Shared Subsystems support](#)

14.4.5	Region Descriptor n, Word 1 (MPU_RGD _n _WORD1).....	544
14.4.6	Region Descriptor n, Word 2 (MPU_RGD _n _WORD2).....	544
14.4.7	Region Descriptor n, Word 3 (MPU_RGD _n _WORD3).....	547
14.4.8	Region Descriptor Alternate Access Control n (MPU_RGDAAC _n).....	548
14.5	Functional description.....	550
14.5.1	Access evaluation macro.....	550
14.5.2	Putting it all together and error terminations.....	552
14.5.3	Power management.....	553
14.6	Initialization information.....	553
14.7	Application information.....	553
Chapter 15		
Interrupt Controller (INTC)		
15.1	Chip-specific INTC information.....	557
15.2	Introduction.....	557
15.3	Block diagram.....	558

Section number	Title	Page
15.4	Features.....	560
15.5	Modes of operation.....	560
15.5.1	Software vector mode.....	560
15.5.2	Hardware vector mode.....	563
15.6	External signal description.....	564
15.7	Memory map and register definition.....	564
15.7.1	INTC Module Configuration Register (INTC_MCR).....	579
15.7.2	INTC Current Priority Register for Processor <i>n</i> (INTC_CPR_PRC <i>n</i>).....	580
15.7.3	INTC Interrupt Acknowledge Register for Processor <i>n</i> (INTC_IACKR_PRC <i>n</i>).....	581
15.7.4	INTC End Of Interrupt Register for Processor <i>n</i> (INTC_EOIR_PRC <i>n</i>).....	582
15.7.5	INTC Software Set/Clear Interrupt Register (INTC_SSCIR <i>n</i>).....	583
15.7.6	INTC Priority Select Register (INTC_PSR <i>n</i>).....	584
15.8	Functional description.....	584
15.8.1	Interrupt request sources.....	585
15.8.2	Priority management.....	586
15.8.3	Handshaking with processor.....	588
15.9	Initialization/application information.....	591
15.9.1	Initialization flow.....	591
15.9.2	Interrupt exception handler.....	592
15.9.3	ISR, RTOS, and task hierarchy.....	593
15.9.4	Order of execution.....	594
15.9.5	Priority ceiling protocol.....	595
15.9.6	Selecting priorities according to request rates and deadlines.....	598
15.9.7	Software-settable interrupt requests.....	599
15.9.8	Lowering priority within an ISR.....	600
15.9.9	Negating an interrupt request outside of its ISR.....	600
15.9.10	Examining LIFO contents.....	601
15.10	Interrupt sources.....	602

Chapter 16

Direct Memory Access Controller (eDMA)

16.1	Chip-specific eDMA information.....	603
16.2	Introduction.....	603
16.2.1	eDMA system block diagram.....	603
16.2.2	Block parts.....	604
16.2.3	Features.....	605
16.3	Modes of operation.....	607
16.4	Memory map/register definition.....	607
16.4.1	TCD memory.....	607
16.4.2	TCD initialization.....	608
16.4.3	TCD structure.....	608
16.4.4	Reserved memory and bit fields.....	609
16.4.5	Control Register (DMA_CR).....	660
16.4.6	Error Status Register (DMA_ES).....	663
16.4.7	Enable Request Register High (DMA_ERQH).....	666
16.4.8	Enable Request Register Low (DMA_ERQL).....	669
16.4.9	Enable Error Interrupt Register High (DMA_EEIH).....	673
16.4.10	Enable Error Interrupt Register Low (DMA_EEIL).....	676
16.4.11	Set Enable Request Register (DMA_SERQ).....	680
16.4.12	Clear Enable Request Register (DMA_CERQ).....	681
16.4.13	Set Enable Error Interrupt Register (DMA_SEEI).....	682
16.4.14	Clear Enable Error Interrupt Register (DMA_CEEI).....	683
16.4.15	Clear Interrupt Request Register (DMA_CINT).....	684
16.4.16	Clear Error Register (DMA_CERR).....	685
16.4.17	Set START Bit Register (DMA_SSRT).....	686
16.4.18	Clear DONE Status Bit Register (DMA_CDNE).....	687
16.4.19	Interrupt Request Register High (DMA_INTH).....	687
16.4.20	Interrupt Request Register Low (DMA_INTL).....	691

Section number	Title	Page
16.4.21	Error Register High (DMA_ERRH).....	695
16.4.22	Error Register Low (DMA_ERRL).....	699
16.4.23	Hardware Request Status Register High (DMA_HRSH).....	702
16.4.24	Hardware Request Status Register Low (DMA_HRSL).....	706
16.4.25	Global PCU Output Register (DMA_GPORn).....	710
16.4.26	Channel n Priority Register (DMA_DCHPRIn).....	711
16.4.27	TCD Source Address (DMA_TCDn_SADDR).....	712
16.4.28	TCD Transfer Attributes (DMA_TCDn_ATTR).....	712
16.4.29	TCD Signed Source Address Offset (DMA_TCDn_SOFF).....	713
16.4.30	TCD Minor Byte Count (Minor Loop Mapping Disabled) (DMA_TCDn_NBYTES_MLNO).....	713
16.4.31	TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (DMA_TCDn_NBYTES_MLOFFNO).....	714
16.4.32	TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (DMA_TCDn_NBYTES_MLOFFYES).....	715
16.4.33	TCD Last Source Address Adjustment (DMA_TCDn_SLAST).....	716
16.4.34	TCD Destination Address (DMA_TCDn_DADDR).....	717
16.4.35	TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCDn_CITER_ELINKYES).....	717
16.4.36	TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCDn_CITER_ELINKNO).....	718
16.4.37	TCD Signed Destination Address Offset (DMA_TCDn_DOFF).....	719
16.4.38	TCD Last Destination Address Adjustment/Scatter Gather Address (DMA_TCDn_DLASTSGA).....	720
16.4.39	TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCDn_BITER_ELINKYES).....	720
16.4.40	TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCDn_BITER_ELINKNO).....	721
16.4.41	TCD Control and Status (DMA_TCDn_CSR).....	722
16.5	Functional description.....	724
16.5.1	eDMA basic data flow.....	724
16.5.2	Fault reporting and handling.....	727

Section number	Title	Page
16.5.3	Channel preemption.....	730
16.5.4	Performance.....	730
16.6	Initialization/application information.....	735
16.6.1	eDMA initialization.....	735
16.6.2	Programming errors.....	737
16.6.3	Arbitration mode considerations.....	738
16.6.4	Performing DMA transfers.....	740
16.6.5	Monitoring transfer descriptor status.....	744
16.6.6	Channel Linking.....	746
16.6.7	Dynamic programming.....	747

Chapter 17 Error Injection Module (EIM)

17.1	Chip-specific EIM information.....	751
17.1.1	EIM channels.....	751
17.1.2	EIM channel assignments.....	751
17.1.3	EIM_EICHDN_Word register bit mapping.....	752
17.2	Introduction.....	752
17.2.1	Overview.....	753
17.2.2	Features.....	754
17.3	Memory map and register definition.....	754
17.3.1	Error Injection Module Configuration Register (EIM_EIMCR).....	756
17.3.2	Error Injection Channel Enable register (EIM_EICHEN).....	757
17.3.3	Error Injection Channel Descriptor, Word0 (EIM_EICHDN_WORD0).....	759
17.3.4	Error Injection Channel Descriptor, Word1 (EIM_EICHDN_WORD1).....	760
17.3.5	Error Injection Channel Descriptor, Word2 (EIM_EICHDN_WORD2).....	760
17.4	Functional description.....	761

Section number	Title	Page
Chapter 18		
Error Reporting Module (ERM)		
18.1	Chip-specific ERM information.....	763
18.1.1	ERM memory channels.....	763
18.1.2	Sources of memory error events.....	763
18.1.3	Managing single-bit faults of TCD RAM for eDMA_A.....	764
18.2	Introduction.....	764
18.2.1	Overview.....	764
18.2.2	Features.....	765
18.3	Memory map and register definition.....	765
18.3.1	ERM Configuration Register (ERM_CR0).....	767
18.3.2	ERM Configuration Register (ERM_CR1).....	770
18.3.3	ERM Configuration Register (ERM_CR2).....	773
18.3.4	ERM Status Register (ERM_SR0).....	776
18.3.5	ERM Status Register (ERM_SR1).....	780
18.3.6	ERM Status Register (ERM_SR2).....	784
18.3.7	ERM Memory <i>n</i> Error Address Register (ERM_EAR _{<i>n</i>}).....	786
18.3.8	ERM Memory <i>n</i> Syndrome Register (ERM_SYN _{<i>n</i>}).....	787
18.4	Functional description.....	787
18.4.1	Single-bit correction events.....	787
18.4.2	Non-correctable error events.....	788
18.5	Initialization.....	789
Chapter 19		
Clocking		
19.1	Introduction.....	791
19.2	Clock generation.....	792
19.3	SIU registers.....	793
19.4	Operating frequencies.....	794
19.5	Default clock configuration.....	795

Section number	Title	Page
19.6	Clock sources.....	796
19.6.1	16 MHz RC oscillator (IRC).....	796
19.6.2	External oscillator (XOSC).....	796
19.6.3	PLL.....	798
19.7	Clock gating.....	800
19.8	Core and on-platform clocking.....	801
19.9	Peripheral clocks.....	802
19.9.1	eTPU clocking.....	803
19.9.2	FlexCAN and MCAN clocking.....	804
19.9.3	LFAST clocking.....	804
19.9.4	PSI5 clocking.....	805
19.9.5	Ethernet clocking.....	805
19.9.6	SDADC clocking.....	805
19.10	Serial boot clocking.....	805
19.11	MCKO.....	806
19.12	CLKOUT / ENGCLK.....	806
19.13	Clock monitoring.....	806
19.13.1	CMU-monitored clocks.....	806
19.13.2	CMU_0 configuration.....	807
19.13.3	CMU_1 to CMU_8 configuration.....	808
19.13.4	CMU output signals to FCCU and INTC.....	809
19.13.5	CMU register and field availability	810
19.13.6	CMU_0_CSR reset value.....	810
19.13.7	CMU use restrictions.....	810
19.13.8	Loss-of-clock behavior.....	811
19.14	PLL loss of lock interrupt.....	811
19.15	Debug mode.....	812

Section number	Title	Page
Chapter 20		
Progressive Clock Switch (PCS)		
20.1	Introduction.....	813
20.2	Block diagram.....	813
20.3	Features.....	813
20.4	Memory map and register definition.....	814
20.4.1	PCS Switch Duration Register (PCS_SDUR).....	815
20.4.2	PCS Divider Change Register for XOSC (PCS_DIVC1).....	815
20.4.3	PCS Divider End Register for XOSC (PCS_DIVE1).....	816
20.4.4	PCS Divider Start Register for XOSC (PCS_DIVS1).....	816
20.4.5	PCS Divider Change Register for PLL1 (PCS_DIVC2).....	817
20.4.6	PCS Divider End Register for PLL1 (PCS_DIVE2).....	818
20.4.7	PCS Divider Start Register for PLL1 (PCS_DIVS2).....	818
20.4.8	PCS Divider Change Register for PLL0 (PCS_DIVC3).....	819
20.4.9	PCS Divider End Register for PLL0 (PCS_DIVE3).....	819
20.4.10	PCS Divider Start Register for PLL0 (PCS_DIVS3).....	820
20.5	Functional description.....	821
20.5.1	Generic clock change requirements.....	822
20.5.2	Configuration of PCS_SDUR.....	822
20.5.3	Configuration of PCS_DIVCn[RATE].....	822
20.5.4	Generic clock change properties.....	823
20.5.5	Clock ramp-down.....	823
20.5.6	Clock ramp-up.....	824
Chapter 21		
Dual PLL Digital Interface (PLLDIG)		
21.1	Chip-specific PLLDIG information.....	827
21.2	Introduction.....	827
21.3	Acronyms and Abbreviations.....	827
21.4	Block Diagram.....	828

Section number	Title	Page
21.5	Features.....	828
21.6	Modes of operation.....	828
21.6.1	Normal mode with reference, PLL0 or both PLLs enabled.....	828
21.7	Memory map and register definition.....	829
21.7.1	PLLDIG PLL0 Control Register (PLLDIG_PLL0CR).....	830
21.7.2	PLLDIG PLL0 Status Register (PLLDIG_PLL0SR).....	831
21.7.3	PLLDIG PLL0 Divider Register (PLLDIG_PLL0DV).....	832
21.7.4	PLLDIG PLL1 Control Register (PLLDIG_PLL1CR).....	834
21.7.5	PLLDIG PLL1 Status Register (PLLDIG_PLL1SR).....	835
21.7.6	PLLDIG PLL1 Divider Register (PLLDIG_PLL1DV).....	836
21.7.7	PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM).....	837
21.7.8	PLLDIG PLL1 Fractional Divide Register (PLLDIG_PLL1FD).....	838
21.8	Functional description.....	839
21.8.1	Input clock frequency.....	839
21.8.2	Clock configuration.....	840
21.8.3	Loss of lock.....	842
21.8.4	Frequency modulation.....	842
21.9	Maximum lock time.....	845
21.10	Initialization information.....	845

Chapter 22

Clock Monitor Unit (CMU)

22.1	Chip-specific CMU information.....	847
22.2	Introduction.....	847
22.2.1	Main features.....	848
22.3	Block diagram.....	848
22.4	Signals.....	848
22.5	Register description and memory map.....	849
22.5.1	CMU Control Status Register (CMU_CSR).....	850
22.5.2	CMU Frequency Display Register (CMU_FDR).....	851

Section number	Title	Page
22.5.3	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR).....	852
22.5.4	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR).....	852
22.5.5	CMU Interrupt Status Register (CMU_ISR).....	853
22.5.6	CMU Measurement Duration Register (CMU_MDR).....	854
22.6	Functional description.....	855
22.6.1	Frequency meter.....	855
22.6.2	CLKMN0_RMT supervisor.....	855
22.6.3	CLKMN1 supervisor.....	856

Chapter 23 Embedded Memories

23.1	Overview.....	859
23.2	End-to-end Error Correction Code (e2eECC).....	859

Chapter 24 RAM Controller (PRAMC)

24.1	Chip-specific PRAM information.....	863
24.1.1	PRAM optional read wait states.....	863
24.1.2	Reset effects on System RAM accesses.....	863
24.2	Introduction.....	864
24.3	SRAM controller memory map and register definition.....	866
24.3.1	Platform RAM Configuration Register 1 (PRAMC_PRCR1).....	866
24.4	Functional description.....	868
24.4.1	Read and Write operations.....	868
24.4.2	Writes.....	869
24.5	Initialization/application information.....	871
24.6	Reliability considerations.....	871
24.6.1	Hsiao ECC algorithm.....	871
24.6.2	Transaction monitor.....	874

Chapter 25 Flash Memory Controller (PFLASH)

25.1	Chip-specific PFLASH information.....	877

Section number	Title	Page
25.2	Introduction.....	877
25.3	Features.....	878
25.4	Block diagrams.....	878
25.5	Flash memory controller memory map.....	879
25.5.1	Platform Flash Configuration Register 1 (PFLASH_PFCR1).....	881
25.5.2	Platform Flash Configuration Register 2 (PFLASH_PFCR2).....	884
25.5.3	Platform Flash Configuration Register 3 (PFLASH_PFCR3).....	887
25.5.4	Platform Flash Access Protection Register (PFLASH_PFAPR).....	889
25.6	Functional description.....	892
25.6.1	Basic interface protocol.....	892
25.6.2	Access protections.....	892
25.6.3	Access pipelining.....	893
25.6.4	Line read buffers and prefetch operation.....	894
25.6.5	Instruction/Data prefetch triggering.....	895
25.6.6	Per-Master prefetch triggering.....	895
25.6.7	Buffer allocation.....	895
25.6.8	Reliability considerations.....	896
25.6.9	ECC on data flash accesses.....	898
25.6.10	Array integrity considerations.....	898

Chapter 26

Embedded Flash Memory (C55FMC)

26.1	Chip-specific C55FMC information.....	901
26.1.1	C55FMC register reset values.....	901
26.1.2	Access to and configuration of blocks mapped to C55FMC_LOCK1 register.....	901
26.1.3	C55FMC_LOCKn register bit mapping.....	902
26.1.4	C55FMC_SELn register bit mapping.....	905
26.1.5	C55FMC_OPpn register bit mapping.....	909
26.2	Introduction.....	912
26.2.1	Overview.....	913

Section number	Title	Page
26.2.2	Features.....	913
26.2.3	Modes of operation.....	913
26.3	UTest NVM block.....	914
26.4	Test mode disable seal.....	914
26.5	Memory map and register definition.....	916
26.5.1	Module Configuration Register (C55FMC_MCR).....	918
26.5.2	Extended Module Configuration Register (C55FMC_MCRE).....	923
26.5.3	Lock 0 register (C55FMC_LOCK0).....	926
26.5.4	Lock 1 register (C55FMC_LOCK1).....	928
26.5.5	Lock 2 register (C55FMC_LOCK2).....	928
26.5.6	Lock 3 register (C55FMC_LOCK3).....	929
26.5.7	Select 0 register (C55FMC_SEL0).....	930
26.5.8	Select 1 register (C55FMC_SEL1).....	931
26.5.9	Select 2 register (C55FMC_SEL2).....	932
26.5.10	Select 3 register (C55FMC_SEL3).....	933
26.5.11	Address register (C55FMC_ADR).....	934
26.5.12	UTest 0 register (C55FMC_UT0).....	936
26.5.13	UMISR register (C55FMC_UM n).....	939
26.5.14	UMISR register (C55FMC_UM9).....	940
26.5.15	Over-Program Protection 0 register (C55FMC_OPP0).....	941
26.5.16	Over-Program Protection 1 register (C55FMC_OPP1).....	942
26.5.17	Over-Program Protection 2 register (C55FMC_OPP2).....	943
26.5.18	Over-Program Protection 3 register (C55FMC_OPP3).....	943
26.5.19	Test Mode Disable Password Check register (C55FMC_TMD).....	944
26.6	Functional Description.....	945
26.6.1	User Mode.....	946
26.6.2	UTest mode.....	954
26.7	Initialization information.....	958

Section number	Title	Page
Chapter 27		
External Bus Interface (EBI)		
27.1	Chip-specific EBI information.....	961
27.1.1	EBI use cases.....	961
27.1.2	EBI signal names.....	961
27.1.3	EBI supported configurations.....	962
27.1.4	EBI CLKOUT division for slower-speed modes.....	963
27.1.5	EBI register reset values.....	963
27.1.6	EBI_TESR in Module Disable mode.....	963
27.2	Introduction.....	963
27.2.1	Overview.....	963
27.2.2	Features.....	964
27.2.3	Modes of Operation.....	964
27.3	External Signal Description.....	967
27.3.1	Overview.....	967
27.3.2	Detailed Signal Descriptions.....	968
27.3.3	Signal Output Buffer Enable Logic by Mode.....	971
27.4	Memory map and register definition.....	972
27.4.1	EBI Module Configuration Register (EBI_MCR).....	973
27.4.2	EBI Transfer Error Status Register (EBI_TESR).....	975
27.4.3	EBI Bus Monitor Control Register (EBI_BMCR).....	976
27.4.4	EBI Calibration Base Register (EBI_CAL_BR _n).....	977
27.4.5	EBI Calibration Option Register (EBI_CAL_OR _n).....	980
27.5	Functional Description.....	982
27.5.1	External Bus Interface Features.....	982
27.5.2	External Bus Operations.....	988
27.6	Initialization/Application Information.....	1037
27.6.1	Booting from External Memory.....	1037
27.6.2	Running with SDR (Single Data Rate) Burst Memories.....	1037

Section number	Title	Page
27.6.3	Running with Asynchronous Memories.....	1038
27.6.4	Connecting an MCU to Multiple Memories.....	1041
27.6.5	EBI Operation with Reduced Pinout MCUs.....	1042
27.6.6	Summary of Differences from MPC5xx.....	1043

Chapter 28 Analog Modules Overview

28.1	Introduction	1047
28.2	EQADC subsystem.....	1047
28.3	SDADC connections to other modules.....	1049

Chapter 29 Sigma Delta Analog-to-Digital Converter (SDADC) Digital Interface

29.1	Chip-specific SDADC information.....	1051
29.1.1	SDADC triggers and synchronous start.....	1051
29.1.2	Connections among SDADCs and eTPUs.....	1053
29.2	Introduction.....	1053
29.3	Overview.....	1053
29.4	Features.....	1054
29.5	Modes of operation.....	1055
29.5.1	Differential input mode.....	1055
29.5.2	Single-ended input mode.....	1055
29.6	External signal description.....	1056
29.7	Memory map and register definition.....	1056
29.7.1	Module Configuration Register (SDADC_MCR).....	1057
29.7.2	Channel Selection Register (SDADC_CSR).....	1060
29.7.3	Reset Key Register (SDADC_RKR).....	1062
29.7.4	Status Flag Register (SDADC_SFR).....	1063
29.7.5	Request Select and Enable Register (SDADC_RSER).....	1065
29.7.6	Output Settling Delay Register (SDADC_OSDR).....	1067
29.7.7	FIFO Control Register (SDADC_FCR).....	1068

Section number	Title	Page
29.7.8	Software Trigger Key Register (SDADC_STKR).....	1070
29.7.9	Converted Data Register (SDADC_CDR).....	1070
29.7.10	WDG Threshold Register (SDADC_WTHHLR).....	1071
29.8	Functional description.....	1071
29.8.1	Differential input mode.....	1072
29.8.2	Single-ended input mode.....	1072
29.8.3	Low consumption mode.....	1072
29.8.4	Analog input multiplexing and bias support.....	1072
29.8.5	Programmable gain and decimation rate.....	1073
29.8.6	High-pass filter support.....	1073
29.8.7	Data conversion.....	1073
29.8.8	Hardware triggering.....	1075
29.8.9	Interrupt/DMA request support.....	1076
29.8.10	Gain calibration support.....	1076
29.8.11	Offset calibration support.....	1077
29.9	Initialization information.....	1078
29.9.1	Data conversion step.....	1079

Chapter 30

Enhanced Queued Analog-to-Digital Converter (EQADC)

30.1	Chip-specific EQADC information.....	1081
30.1.1	EQADC connections to other modules.....	1082
30.1.2	EQADC Stop mode entry.....	1085
30.1.3	EQADC pre-gain control.....	1085
30.1.4	CFIFO and RFIFO depth.....	1085
30.1.5	EQADC pin pullup/pulldown control.....	1085
30.1.6	EQADC pin-to-channel mapping.....	1085
30.2	Introduction.....	1087
30.2.1	Module overview.....	1087
30.2.2	Block diagram.....	1088

Section number	Title	Page
30.2.3	Features.....	1090
30.3	Modes of operation.....	1091
30.3.1	Normal Mode.....	1091
30.3.2	Debug Mode.....	1092
30.3.3	Stop Mode.....	1093
30.4	External signal description.....	1094
30.4.1	Overview.....	1094
30.4.2	Detailed signal descriptions.....	1096
30.5	Memory map and register definition.....	1101
30.5.1	EQADC Module Configuration Register (EQADC_MCR).....	1106
30.5.2	EQADC Test Register (EQADC_TST).....	1107
30.5.3	EQADC External Trigger Digital Filter Register (EQADC_ETDFR).....	1108
30.5.4	EQADC CFIFO Push Register (EQADC_CFPRn).....	1109
30.5.5	EQADC Result FIFO Pop Register (EQADC_RFPRn).....	1110
30.5.6	EQADC CFIFO Control Register 0 (EQADC_CFCR0).....	1111
30.5.7	EQADC CFIFO Control Register 1 (EQADC_CFCR1).....	1115
30.5.8	EQADC CFIFO Control Register 2 (EQADC_CFCR2).....	1118
30.5.9	EQADC Interrupt and DMA Control Register 0 (EQADC_IDCR0).....	1121
30.5.10	EQADC Interrupt and DMA Control Register 1 (EQADC_IDCR1).....	1125
30.5.11	EQADC Interrupt and DMA Control Register 2 (EQADC_IDCR2).....	1130
30.5.12	EQADC FIFO and Interrupt Status Register (EQADC_FISRn).....	1135
30.5.13	EQADC CFIFO Transfer Counter Register 0 (EQADC_CFTCR0).....	1139
30.5.14	EQADC CFIFO Transfer Counter Register 1 (EQADC_CFTCR1).....	1140
30.5.15	EQADC CFIFO Transfer Counter Register 2 (EQADC_CFTCR2).....	1141
30.5.16	EQADC CFIFO Status Snapshot Register 0 (EQADC_CFSSR0).....	1142
30.5.17	EQADC CFIFO Status Snapshot Register 1 (EQADC_CFSSR1).....	1144
30.5.18	EQADC CFIFO Status Register (EQADC_CFSR).....	1146
30.5.19	EQADC STAC Bus Client Configuration Register (EQADC_STACCCR).....	1147
30.5.20	EQADC CFIFO0 Register (EQADC_CF0Rn).....	1148

Section number	Title	Page
30.5.21	EQADC CFIFO0 Extension Register (EQADC_CF0ERn).....	1149
30.5.22	EQADC CFIFO1 Register (EQADC_CF1Rn).....	1149
30.5.23	EQADC CFIFO2 Register (EQADC_CF2Rn).....	1150
30.5.24	EQADC CFIFO3 Register (EQADC_CF3Rn).....	1151
30.5.25	EQADC CFIFO4 Register (EQADC_CF4Rn).....	1151
30.5.26	EQADC CFIFO5 Register (EQADC_CF5Rn).....	1152
30.5.27	EQADC RFIFO0 Register (EQADC_RF0Rn).....	1153
30.5.28	EQADC RFIFO1 Register (EQADC_RF1Rn).....	1153
30.5.29	EQADC RFIFO2 Register (EQADC_RF2Rn).....	1154
30.5.30	EQADC RFIFO3 Register (EQADC_RF3Rn).....	1155
30.5.31	EQADC RFIFO4 Register (EQADC_RF4Rn).....	1155
30.5.32	EQADC RFIFO5 Register (EQADC_RF5Rn).....	1156
30.5.33	On-chip ADC registers.....	1156
30.6	Functional description.....	1181
30.6.1	Overview.....	1181
30.6.2	Data flow in EQADC.....	1182
30.6.3	Command/result queues.....	1195
30.6.4	EQADC command FIFOs.....	1195
30.6.5	EQADC result FIFOs.....	1223
30.6.6	On-chip ADC configuration and control.....	1227
30.6.7	Internal/external multiplexing.....	1240
30.6.8	EQADC DMA/interrupt request.....	1244
30.6.9	EQADC Parallel Side Interface (PSI) sub-block.....	1247
30.6.10	Analog sub-block.....	1252
30.7	Initialization/application information.....	1255
30.7.1	Multiple queues control setup example.....	1255
30.7.2	EQADC/DMAC interface.....	1260
30.7.3	Sending immediate command setup example.....	1262
30.7.4	Modifying queues.....	1263

Section number	Title	Page
30.7.5	CQueue and RQueues usage.....	1264
30.7.6	ADC Result Calibration.....	1266
30.7.7	EQADC versus QADC.....	1269

Chapter 31 Decimation Filter (DECFILTER)

31.1	Chip-specific DECFILTER information.....	1273
31.1.1	DECFILTER instance interconnections.....	1273
31.1.2	DECFILTER connections to other modules.....	1274
31.2	Introduction.....	1275
31.2.1	Overview.....	1276
31.2.2	Features.....	1279
31.2.3	Modes of operation.....	1279
31.3	External signal description.....	1282
31.3.1	Decimation trigger signal	1282
31.3.2	Integrator enable signal	1282
31.3.3	Integrator halt signal	1282
31.3.4	Integrator reset signal	1282
31.3.5	Integrator output request signal	1282
31.4	Memory map and register definition.....	1283
31.4.1	Module Configuration Register (DECFILTER_MCR).....	1284
31.4.2	Module Status Register (DECFILTER_MSR).....	1290
31.4.3	Module Extended Config Register (DECFILTER_MXCR).....	1294
31.4.4	Module Extended Status Register (DECFILTER_MXSR).....	1297
31.4.5	Interface Input Buffer (DECFILTER_IB).....	1300
31.4.6	Interface Output Buffer (DECFILTER_OB).....	1302
31.4.7	Filter Coefficient (DECFILTER_COEF _n).....	1303
31.4.8	Filter TAP (DECFILTER_TAP _n).....	1303
31.4.9	Enhanced Debug Input Data (DECFILTER_EDID).....	1304
31.4.10	Final Integer Value Register (DECFILTER_FINTVAL).....	1305

Section number	Title	Page
31.4.11	Final Integer Count Register (DECFILTER_FINTCNT).....	1305
31.4.12	Current Integer Value Register (DECFILTER_CINTVAL).....	1306
31.4.13	Current Integer Count Register (DECFILTER_CINTCNT).....	1306
31.5	Functional Description.....	1307
31.5.1	Overview.....	1307
31.5.2	Parallel Side Interface (PSI) sub-block description.....	1307
31.5.3	Input Buffer Description.....	1308
31.5.4	Output Buffer Description.....	1309
31.5.5	Bypass Configuration Description.....	1312
31.5.6	IIR and FIR Filter.....	1313
31.5.7	Filter Prefill Control Description.....	1316
31.5.8	Timestamp Data Transmission.....	1317
31.5.9	Flush Command Description.....	1318
31.5.10	Soft-Reset Command Description.....	1319
31.5.11	Interrupts Requests Description.....	1320
31.5.12	DMA Requests Description.....	1322
31.5.13	Freeze Mode Description.....	1323
31.5.14	Enhanced Debug Monitor Description.....	1324
31.5.15	Integrator.....	1324
31.5.16	Cascade mode description.....	1329
31.5.17	Return PSI (RPSI) and PSI Output Selector (PSIOSEL).....	1334
31.6	Initialization Information.....	1334
31.6.1	Initialization Procedure.....	1334
31.7	Application Information.....	1335
31.7.1	eQADC IP as the PSI Master Block.....	1335
31.8	Filter Example Simulation.....	1336
31.8.1	Coefficients Calculation.....	1336
31.8.2	Input Data Calculation.....	1338
31.8.3	Filter Results.....	1338

Section number	Title	Page
Chapter 32		
Temperature Sensor (TSENS)		
32.1	Chip-specific Temperature Sensor information.....	1339
32.1.1	Temperature Sensor programming control.....	1339
32.1.2	Accessing TSC parameters.....	1339
32.1.3	Temperature name alignment.....	1339
32.2	Introduction.....	1340
32.3	Functional Description.....	1340
32.3.1	Temperature threshold detection (digital output generation).....	1340
32.3.2	Linear temperature sensor (analog output generation).....	1341
32.4	Temperature formula.....	1342
32.5	Calculating device temperature.....	1343
Chapter 33		
System Timer Module (STM)		
33.1	Chip-specific STM information.....	1345
33.2	Introduction.....	1345
33.2.1	Overview.....	1345
33.2.2	Features.....	1345
33.2.3	Modes of operation.....	1346
33.3	External signal description.....	1346
33.4	Memory map and registers.....	1346
33.4.1	STM Control Register (STM_CR).....	1347
33.4.2	STM Count Register (STM_CNT).....	1348
33.4.3	STM Channel Control Register (STM_CCR _n).....	1348
33.4.4	STM Channel Interrupt Register (STM_CIR _n).....	1349
33.4.5	STM Channel Compare Register (STM_CMP _n).....	1349
33.5	Functional description.....	1350

Chapter 34

Software Watchdog Timer (SWT)

34.1	Chip-specific SWT information.....	1351
34.1.1	SWT register reset values.....	1351
34.1.2	SWT time-out events and invalid accesses: configuring reset and interrupt requests.....	1351
34.2	Introduction.....	1352
34.2.1	Overview.....	1352
34.2.2	Features.....	1353
34.2.3	Modes of operation.....	1353
34.3	External signal description.....	1354
34.4	Memory Map and Registers.....	1354
34.4.1	SWT Control Register (SWT_CR).....	1355
34.4.2	SWT Interrupt Register (SWT_IR).....	1358
34.4.3	SWT Time-out Register (SWT_TO).....	1359
34.4.4	SWT Window Register (SWT_WN).....	1359
34.4.5	SWT Service Register (SWT_SR).....	1360
34.4.6	SWT Counter Output Register (SWT_CO).....	1360
34.4.7	SWT Service Key Register (SWT_SK).....	1361
34.5	Functional description.....	1361
34.5.1	Introduction.....	1361
34.5.2	Configuration locking.....	1362
34.5.3	Unlock sequence.....	1363
34.5.4	Servicing operations.....	1363
34.5.5	Time-out.....	1364
34.5.6	Initialization.....	1365

Chapter 35

Periodic Interrupt Timer (PIT-RTI)

35.1	Chip-specific PIT information.....	1367

Section number	Title	Page
35.2	Introduction.....	1367
35.2.1	Block diagram.....	1367
35.2.2	Features.....	1368
35.3	Signal description.....	1369
35.4	Memory map/register description.....	1369
35.4.1	PIT Module Control Register (PIT_MCR).....	1370
35.4.2	PIT Upper Lifetime Timer Register (PIT_LTMR64H).....	1371
35.4.3	PIT Lower Lifetime Timer Register (PIT_LTMR64L).....	1372
35.4.4	Timer Load Value Register (PIT_RTI_LDVAL).....	1372
35.4.5	Current Timer Value Register (PIT_RTI_CVAL).....	1373
35.4.6	Timer Control Register (PIT_RTI_TCTRL).....	1373
35.4.7	Timer Flag Register (PIT_RTI_TFLG).....	1374
35.4.8	Timer Load Value Register (PIT_LDVAL _n).....	1375
35.4.9	Current Timer Value Register (PIT_CVAL _n).....	1375
35.4.10	Timer Control Register (PIT_TCTRL _n).....	1376
35.4.11	Timer Flag Register (PIT_TFLG _n).....	1377
35.5	Functional description.....	1377
35.5.1	General operation.....	1377
35.5.2	Interrupts.....	1379
35.5.3	Chained timers.....	1379
35.6	Initialization and application information.....	1380
35.7	Example configuration for chained timers.....	1381
35.8	Example configuration for the lifetime timer.....	1382

Chapter 36

Enhanced Modular IO Subsystem (eMIOS)

36.1	Chip-specific eMIOS information.....	1383
36.1.1	eMIOS channels and counter buses.....	1383
36.1.2	eMIOS unimplemented channels.....	1383

Section number	Title	Page
36.1.3	eMIOS interaction with other modules.....	1384
36.2	Introduction.....	1386
36.2.1	Overview.....	1386
36.2.2	Features.....	1387
36.2.3	Modes of operation.....	1388
36.3	Memory map / register definition.....	1389
36.3.1	Memory map.....	1389
36.4	Control Memory Map and Registers.....	1390
36.4.1	eMIOS Module Configuration Register (eMIOS_MCR).....	1391
36.4.2	eMIOS Global FLAG Register (eMIOS_GFLAG).....	1393
36.4.3	eMIOS Output Update Disable register (eMIOS_OUDIS).....	1393
36.5	Unified Channels Memory Map and Registers.....	1394
36.5.1	eMIOS UC A register n (eMIOS_An).....	1397
36.5.2	eMIOS UC B register n (eMIOS_Bn).....	1398
36.5.3	eMIOS CNT register n (eMIOS_CNTn).....	1399
36.5.4	eMIOS UC Control register n (eMIOS_Cn).....	1400
36.5.5	eMIOS UC Status register n (eMIOS_Sn).....	1406
36.5.6	eMIOS Alternate Address register n (eMIOS_ALTAn).....	1408
36.5.7	eMIOS UC A register n (eMIOS_An).....	1409
36.5.8	eMIOS UC B register n (eMIOS_Bn).....	1409
36.5.9	eMIOS CNT register n (eMIOS_CNTn).....	1410
36.5.10	eMIOS UC Control register n (eMIOS_Cn).....	1411
36.5.11	eMIOS UC Status register n (eMIOS_Sn).....	1416
36.5.12	eMIOS Alternate Address register n (eMIOS_ALTAn).....	1418

Section number	Title	Page
36.6	Functional Description.....	1418
36.6.1	Unified Channel (UC).....	1420
36.6.2	IP Bus Interface Unit (BIU).....	1465
36.6.3	STAC Bus Client submodule.....	1466
36.6.4	Global Clock Prescaler Submodule (GCP).....	1467
36.7	Initialization/Application Information.....	1467
36.7.1	Considerations.....	1467
36.7.2	Application Information.....	1468

Chapter 37

Enhanced Time Processing Unit (eTPU)

37.1	Chip-specific eTPU information.....	1473
37.1.1	eTPU register field reset values.....	1474
37.1.2	Access to eTPU registers in chip-level Stop mode.....	1474
37.1.3	STAC server IDs.....	1474
37.1.4	eTPU inputs with Glitch Filters.....	1475
37.1.5	eMIOS and eTPU signal passthrough from pins via IGFs.....	1475
37.1.6	eTPU output disable channel groups.....	1476
37.1.7	Control of the eTPU Output Buffer Enable signal.....	1476
37.2	Device-specific Information.....	1476
37.3	Introduction.....	1477
37.3.1	Overview.....	1478
37.3.2	Features.....	1485
37.3.3	Modes of operation.....	1492
37.4	Detailed signal descriptions.....	1494
37.4.1	eTPU channel output signals.....	1494
37.4.2	eTPU channel input signals.....	1494
37.4.3	Time Base Clock Signal — TCRCLK.....	1495
37.4.4	eTPU channel output disable signals.....	1495
37.5	Memory map/register definition.....	1496

Section number	Title	Page
37.6	Memory map.....	1496
37.7	System Configuration memory map and registers.....	1501
37.7.1	eTPU Module Configuration Register (eTPU_SCR_MCR).....	1502
37.7.2	eTPU Coherent Dual-Parameter Controller Register (eTPU_SCR_CDCR).....	1506
37.7.3	eTPU MISC Compare Register (eTPU_SCR_MISCCMPR).....	1508
37.7.4	eTPU SCM Off-range Data Register (eTPU_SCR_SCMOFFDATAR).....	1508
37.7.5	eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1).....	1509
37.7.6	eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2).....	1513
37.8	Timebase memory map and registers.....	1517
37.8.1	eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1).....	1518
37.8.2	eTPU Engine 1 Time Base 1 (TCR1) Visibility Register (eTPU_TBR_TB1R_ENG1).....	1522
37.8.3	eTPU Engine 1 Time Base 2 (TCR2) Visibility Register (eTPU_TBR_TB2R_ENG1).....	1522
37.8.4	eTPU Engine 1 STAC Configuration Register (eTPU_TBR_STAC_ENG1).....	1523
37.8.5	eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2).....	1525
37.8.6	eTPU Engine 2 Time Base 1 (TCR1) Visibility Register (eTPU_TBR_TB1R_ENG2).....	1529
37.8.7	eTPU Engine 2 Time Base 2 (TCR2) Visibility Register (eTPU_TBR_TB2R_ENG2).....	1529
37.8.8	eTPU Engine 2 STAC Configuration Register (eTPU_TBR_STAC_ENG2).....	1530
37.9	Engine memory map and registers.....	1532
37.9.1	eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1).....	1532
37.9.2	eTPU Idle Register for Engine 1 (eTPU_ER_IDLER_ENG1).....	1534
37.9.3	eTPU Watchdog Timer Register for Engine 2 (eTPU_ER_WDTR_ENG2).....	1535
37.9.4	eTPU Idle Register for Engine 2 (eTPU_ER_IDLER_ENG2).....	1536
37.10	Latency Monitor memory map and registers.....	1537
37.10.1	eTPU Latency Monitor Configuration Register for Engine 1 (eTPU_LMR_LMnCR_ENG1).....	1538
37.10.2	eTPU Latency Monitor Measure Register for Engine 1 (eTPU_LMR_LMnMR_ENG1).....	1540
37.10.3	eTPU Latency Monitor Configuration Register for Engine 2 (eTPU_LMR_LMnCR_ENG2).....	1541
37.10.4	eTPU Latency Monitor Measure Register for Engine 2 (eTPU_LMR_LMnMR_ENG2).....	1542
37.11	Memory Error Support memory map and registers.....	1543
37.11.1	eTPU Memory Error Control Register (eTPU_MESR_MECR).....	1544

Section number	Title	Page
37.11.2	eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR).....	1547
37.11.3	eTPU Data Error Injection Data Pattern Register (eTPU_MESR_DEIDPR).....	1548
37.11.4	eTPU Data Error Injection Parity Pattern Register (eTPU_MESR_DEIPPR).....	1548
37.11.5	eTPU Data Error Report Address Register (eTPU_MESR_DERAR).....	1550
37.11.6	eTPU Data Error Report Data Register (eTPU_MESR_DERDR).....	1551
37.11.7	eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR).....	1552
37.11.8	eTPU Memory Error Status Register (eTPU_MESR_MESR).....	1554
37.11.9	eTPU Code Error Injection Address Register (eTPU_MESR_CEIAR).....	1557
37.11.10	eTPU Code Error Injection Data Pattern Register (eTPU_MESR_CEIDPR).....	1558
37.11.11	eTPU Code Error Injection Parity Pattern Register (eTPU_MESR_CEIPPR).....	1558
37.11.12	eTPU Code Error Report Address Register (eTPU_MESR_CERAR).....	1559
37.11.13	eTPU Code Error Report Data Register (eTPU_MESR_CERDR).....	1560
37.11.14	eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR).....	1561
37.11.15	eTPU Code Error Fix Register (eTPU_MESR_CEFR).....	1562
37.12	Global Channel memory map and registers.....	1563
37.12.1	eTPU Channel Interrupt Status Register for Engine 1 (eTPU_GCR_CISR_ENG1).....	1564
37.12.2	eTPU Channel Interrupt Status Register for Engine 2 (eTPU_GCR_CISR_ENG2).....	1564
37.12.3	eTPU Channel Data Transfer Request Status Register for Engine 1 (eTPU_GCR_CDTRSR_ENG1).....	1565
37.12.4	eTPU Channel Data Transfer Request Status Register for Engine 2 (eTPU_GCR_CDTRSR_ENG2).....	1566
37.12.5	eTPU Channel Interrupt Overflow Status Register for Engine 1 (eTPU_GCR_CIOSR_ENG1).....	1566
37.12.6	eTPU Channel Interrupt Overflow Status Register for Engine 2 (eTPU_GCR_CIOSR_ENG2).....	1567
37.12.7	eTPU Channel Data Transfer Request Overflow Status Register for Engine 1 (eTPU_GCR_CDTROSR_ENG1).....	1568
37.12.8	eTPU Channel Data Transfer Request Overflow Status Register for Engine 2 (eTPU_GCR_CDTROSR_ENG2).....	1568
37.12.9	eTPU Channel Interrupt Enable Register for Engine 1 (eTPU_GCR_CIER_ENG1).....	1569
37.12.10	eTPU Channel Interrupt Enable Register for Engine 2 (eTPU_GCR_CIER_ENG2).....	1569
37.12.11	eTPU Channel Data Transfer Request Enable Register for Engine 1 (eTPU_GCR_CDTRER_ENG1)....	1570
37.12.12	eTPU Channel Data Transfer Request Enable Register for Engine 2 (eTPU_GCR_CDTRER_ENG2)....	1570

Section number	Title	Page
37.12.13	eTPU Watchdog Status Register for Engine 1 (eTPU_GCR_WDSR_ENG1).....	1571
37.12.14	eTPU Watchdog Status Register for Engine 2 (eTPU_GCR_WDSR_ENG2).....	1572
37.12.15	eTPU Channel Pending Service Status Register for Engine 1 (eTPU_GCR_CPSSR_ENG1).....	1572
37.12.16	eTPU Channel Pending Service Status Register for Engine 2 (eTPU_GCR_CPSSR_ENG2).....	1573
37.12.17	eTPU Channel Service Status Register for Engine 1 (eTPU_GCR_CSSR_ENG1).....	1574
37.12.18	eTPU Channel Service Status Register for Engine 2 (eTPU_GCR_CSSR_ENG2).....	1574
37.13	Channel Configuration Control memory map and registers.....	1575
37.13.1	eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_CnCR_ENG1).....	1585
37.13.2	eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_CnSCR_ENG1).....	1588
37.13.3	eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_CnHSRR_ENG1).....	1590
37.13.4	eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_CnCR_ENG2).....	1591
37.13.5	eTPU Channel n Status Control Register for Engine 2 (eTPU_CCCR_CnSCR_ENG2).....	1594
37.13.6	eTPU Channel n Host Service Request Register for Engine 2 (eTPU_CCCR_CnHSRR_ENG2).....	1596
37.14	Shared Subsystem Integration memory map and registers.....	1597
37.14.1	eTPU Shared Subsystem n Integration Register (eTPU_SSIR_ETPUSSSIRn).....	1598
37.15	Functional description.....	1598
37.15.1	Functions and threads.....	1599
37.15.2	Host interface.....	1614
37.15.3	Scheduler.....	1623
37.15.4	Parameter sharing and coherency.....	1631
37.15.5	Enhanced Channels.....	1637
37.15.6	Time bases.....	1691
37.15.7	EAC - eTPU Angle Counter.....	1700
37.15.8	Microengine.....	1723
37.15.9	Microinstruction Set.....	1742
37.15.10	Shared Subsystems support.....	1776
37.15.11	Development support features.....	1780
37.15.12	SCM Emulation.....	1788

Section number	Title	Page
37.15.13	Safety features.....	1788
37.15.14	Performance monitoring features.....	1796
37.16	Initialization/application information.....	1800
37.16.1	Configuration sequence.....	1800
37.16.2	Reset options.....	1802
37.16.3	Multiple parameter coherency methods.....	1802
37.16.4	Programming Hints and Caveats.....	1803
37.16.5	Estimating Worst Case Latency.....	1805
37.16.6	Endianness.....	1823
37.16.7	Memory Error Service Procedures.....	1824
37.17	Appendices.....	1827
37.17.1	Microcycle and I/O timing.....	1827
37.17.2	Channel Mode Summary.....	1832
37.17.3	MISC Algorithm.....	1835

Chapter 38

Reaction Module 2 (REACM2)

38.1	Chip-specific REACM2 information.....	1837
38.1.1	REACM2 interaction with other modules.....	1837
38.1.2	Timer inputs.....	1838
38.1.3	REACM2 buffer overflow prevention.....	1838
38.2	Introduction.....	1839
38.2.1	Features.....	1839
38.2.2	Modes of Operation.....	1839
38.2.3	Block Diagram.....	1842
38.3	Signal Description.....	1846
38.3.1	REACM2_RCHn — REACM Channel (n) Output Pin a, b and c.....	1846
38.4	Memory Map and Register Definition.....	1847
38.4.1	Module Configuration (REACM2_MCR).....	1852
38.4.2	Timer Configuration (REACM2_TCR).....	1854

Section number	Title	Page
38.4.3	Threshold Router Register (REACM2_THRR).....	1854
38.4.4	ADC Sensor Input Register (REACM2_SINR).....	1856
38.4.5	Period Generator Configuration Register (REACM2_PCR).....	1857
38.4.6	Period Shift Delay Configuration Register (REACM2_PSCR).....	1857
38.4.7	Global Error Flag Register (REACM2_GEFR).....	1858
38.4.8	Channel n Configuration Register (REACM2_CHCR _n).....	1860
38.4.9	Channel n Status Register (REACM2_CHSR _n).....	1863
38.4.10	Channel n Router Register (REACM2_CHRR _n).....	1866
38.4.11	Shared Timer Bank (REACM2_STBK _n).....	1867
38.4.12	Hold Timer Bank (REACM2_HOTBK _n).....	1867
38.4.13	Threshold Bank (REACM2_THBK _n).....	1868
38.4.14	ADC Result Maximum Limit Check (REACM2_ADCMAX).....	1869
38.4.15	Modulation Range Pulse Width (REACM2_RANGE_PWD).....	1869
38.4.16	Modulation Minimum Pulse Width (REACM2_MIN_PWD).....	1870
38.4.17	Modulation Control Word Bank (REACM2_MWBK _n).....	1871
38.5	Functional Description.....	1873
38.5.1	Reaction Channel.....	1874
38.5.2	Modulation Control Words Bank.....	1876
38.5.3	Shared Timer Bank.....	1877
38.5.4	Hold Time Bank.....	1879
38.5.5	Threshold Bank and Comparator.....	1879
38.5.6	ADC Interface.....	1880
38.5.7	Prescalers.....	1883
38.5.8	Period / Delay Generator.....	1883
38.5.9	Banked Mode Support.....	1884
38.6	Modulation Modes.....	1885
38.6.1	Threshold/Threshold Mode.....	1885
38.6.2	Threshold/Hold-off Mode.....	1886
38.6.3	Threshold/Hold-on Mode.....	1887

Section number	Title	Page
38.6.4	Threshold low/Period Mode.....	1888
38.6.5	Threshold high/Period Mode.....	1889
38.6.6	Limitations on the Modulation Process.....	1890
38.7	Monitored Modulation.....	1894
38.7.1	Monitoring the ON Pulse Width.....	1894
38.7.2	Monitoring the OFF State Width and the ADC Maximum Value.....	1898
38.8	Reset Overview.....	1900
38.9	Reaction Module Interrupts.....	1901
38.9.1	Interrupt sources.....	1901
38.9.2	Global Interrupt and Channel Interrupt.....	1901
38.10	Use cases.....	1902
38.10.1	Advancing Modulation Phase on a Threshold level.....	1909
38.10.2	Controlling the LOOP function.....	1910
38.10.3	Banked Mode.....	1911

Chapter 39

Input Glitch Filter (IGF)

39.1	Chip-specific IGF information.....	1913
39.1.1	IGF channels and internal prescalers.....	1913
39.1.2	IGF internal prescaler selection.....	1913
39.1.3	IGF interaction with other modules.....	1914
39.1.4	STOP mode system requests for IGF_0 and IGF_1.....	1915
39.2	Introduction.....	1915
39.3	Block Diagram.....	1916
39.4	Input Glitch Filter overview.....	1916
39.4.1	Interaction with other peripherals.....	1917
39.4.2	Mode of operation.....	1917
39.5	Memory map.....	1919
39.5.1	Module Configuration Register (IGF_MCR _n).....	1924
39.5.2	Module Status Register (IGF_MSR _n).....	1927

Section number	Title	Page
39.5.3	Prescaler Register (IGF_PRESR _n).....	1928
39.5.4	Rising edge Threshold Register (IGF_RTHR _n).....	1929
39.5.5	Falling edge Threshold Register (IGF_FTHR).....	1929
39.6	Functional description.....	1929
39.6.1	Input double sampling.....	1930
39.6.2	Filter types.....	1930
39.6.3	Application.....	1934
39.6.4	Programming guidelines.....	1937
39.6.5	On-the-fly filter reconfiguration.....	1937
39.7	Power saving mode.....	1938
39.7.1	STOP mode.....	1938

Chapter 40 FlexCAN (CAN)

40.1	Chip-specific FlexCAN information.....	1941
40.1.1	FlexCAN RAM.....	1941
40.1.2	FlexCAN reset.....	1941
40.1.3	CAN_MCR[SUPV] and access to FlexCAN registers.....	1941
40.2	Introduction.....	1941
40.2.1	Overview.....	1942
40.2.2	FlexCAN module features.....	1943
40.2.3	Modes of operation.....	1945
40.3	FlexCAN signal descriptions.....	1946
40.3.1	CAN Rx	1946
40.3.2	CAN Tx	1947
40.4	Memory map/register definition.....	1947
40.4.1	FlexCAN memory mapping.....	1947
40.4.2	Module Configuration Register (CAN_MCR).....	1953
40.4.3	Control 1 register (CAN_CTRL1).....	1958
40.4.4	Free Running Timer (CAN_TIMER).....	1961

Section number	Title	Page
40.4.5	Rx Mailboxes Global Mask Register (CAN_RXMGMASK).....	1962
40.4.6	Rx 14 Mask register (CAN_RX14MASK).....	1963
40.4.7	Rx 15 Mask register (CAN_RX15MASK).....	1964
40.4.8	Error Counter (CAN_ECR).....	1964
40.4.9	Error and Status 1 register (CAN_ESR1).....	1966
40.4.10	Interrupt Masks 2 register (CAN_IMASK2).....	1970
40.4.11	Interrupt Masks 1 register (CAN_IMASK1).....	1970
40.4.12	Interrupt Flags 2 register (CAN_IFLAG2).....	1971
40.4.13	Interrupt Flags 1 register (CAN_IFLAG1).....	1972
40.4.14	Control 2 register (CAN_CTRL2).....	1974
40.4.15	Error and Status 2 register (CAN_ESR2).....	1978
40.4.16	CRC Register (CAN_CRCR).....	1979
40.4.17	Rx FIFO Global Mask register (CAN_RXFGMASK).....	1980
40.4.18	Rx FIFO Information Register (CAN_RXFIR).....	1981
40.4.19	Rx Individual Mask Registers (CAN_RXIMR _n).....	1981
40.4.20	Memory Error Control Register (CAN_MECR).....	1982
40.4.21	Error Injection Address Register (CAN_ERRIAR).....	1984
40.4.22	Error Injection Data Pattern Register (CAN_ERRIDPR).....	1986
40.4.23	Error Injection Parity Pattern Register (CAN_ERRIPPR).....	1986
40.4.24	Error Report Address Register (CAN_RERRAR).....	1987
40.4.25	Error Report Data Register (CAN_RERRDR).....	1988
40.4.26	Error Report Syndrome Register (CAN_RERRSYNR).....	1989
40.4.27	Error Status Register (CAN_ERRSR).....	1991
40.4.28	Message buffer structure.....	1992
40.4.29	Rx FIFO structure.....	1998
40.5	Functional description.....	2000
40.5.1	Transmit process.....	2001
40.5.2	Arbitration process.....	2002
40.5.3	Receive process.....	2005

Section number	Title	Page
40.5.4	Matching process.....	2007
40.5.5	Move process.....	2012
40.5.6	Data coherence.....	2014
40.5.7	Rx FIFO.....	2017
40.5.8	CAN protocol related features.....	2019
40.5.9	Clock domains and restrictions.....	2025
40.5.10	Modes of operation details.....	2026
40.5.11	Interrupts.....	2030
40.5.12	Bus interface.....	2031
40.5.13	Detection and Correction of Memory Errors.....	2031
40.6	Initialization/application information.....	2035
40.6.1	FlexCAN initialization sequence.....	2035

Chapter 41 Modular CAN (M_CAN)

41.1	Chip-specific M_CAN information.....	2039
41.1.1	M_CAN Message RAM allocation.....	2039
41.1.2	Introduction.....	2039
41.1.3	Functional Description.....	2040
41.1.4	External Signals.....	2042
41.2	Overview.....	2043
41.2.1	Features.....	2043
41.2.2	Block Diagram.....	2044
41.2.3	Dual Clock Sources.....	2046
41.2.4	Dual Interrupt Lines.....	2046
41.3	Memory Map and Register Description.....	2047
41.3.1	Core Release Register (M_CAN_CREL).....	2049
41.3.2	Endian Register (M_CAN_ENDN).....	2050
41.3.3	Data Bit Timing and Prescaler Register (M_CAN_DBTP).....	2051
41.3.4	Test Register (M_CAN_TEST).....	2052

Section number	Title	Page
41.3.5	RAM Watchdog Register (M_CAN_RWD).....	2054
41.3.6	CC Control Register (M_CAN_CCCR).....	2055
41.3.7	Nominal Bit Timing and Prescaler Register (M_CAN_NBTP).....	2057
41.3.8	Timestamp Counter Configuration Register (M_CAN_TSCC).....	2059
41.3.9	Timestamp Counter Value Register (M_CAN_TSCV).....	2060
41.3.10	Timeout Counter Configuration Register (M_CAN_TOCC).....	2060
41.3.11	Timeout Counter Value Register (M_CAN_TOCV).....	2061
41.3.12	Error Counter Register (M_CAN_ECR).....	2062
41.3.13	Protocol Status Register (M_CAN_PSR).....	2063
41.3.14	Transmitter Delay Compensation Register (M_CAN_TDCR).....	2066
41.3.15	Interrupt Register (M_CAN_IR).....	2067
41.3.16	Interrupt Enable Register (M_CAN_IE).....	2070
41.3.17	Interrupt Line Select Register (M_CAN_ILS).....	2073
41.3.18	Interrupt Line Enable Register (M_CAN_ILE).....	2077
41.3.19	Global Filter Configuration Register (M_CAN_GFC).....	2078
41.3.20	Standard ID Filter Configuration Register (M_CAN_SIDFC).....	2079
41.3.21	Extended ID Filter Configuration Register (M_CAN_XIDFC).....	2080
41.3.22	Extended ID and Mask Register (M_CAN_XIDAM).....	2080
41.3.23	High Priority Message Status Register (M_CAN_HPMS).....	2081
41.3.24	New Data 1 Register (M_CAN_NDAT1).....	2082
41.3.25	New Data 2 Register (M_CAN_NDAT2).....	2082
41.3.26	Rx FIFO 0 Configuration Register (M_CAN_RXF0C).....	2083
41.3.27	Rx FIFO 0 Status Register (M_CAN_RXF0S).....	2084
41.3.28	Rx FIFO 0 Acknowledge Register (M_CAN_RXF0A).....	2085
41.3.29	Rx Buffer Configuration Register (M_CAN_RXBC).....	2085
41.3.30	Rx FIFO 1 Configuration Register (M_CAN_RXF1C).....	2086
41.3.31	Rx FIFO 1 Status Register (M_CAN_RXF1S).....	2087
41.3.32	Rx FIFO 1 Acknowledge Register (M_CAN_RXF1A).....	2088
41.3.33	Rx Buffer / FIFO Element Size Configuration Register (M_CAN_RXESC).....	2089

Section number	Title	Page
41.3.34	Tx Buffer Configuration Register (M_CAN_TXBC).....	2091
41.3.35	Tx FIFO/Queue Status Register (M_CAN_TXFQS).....	2092
41.3.36	Tx Buffer Element Size Configuration (M_CAN_TXESC).....	2093
41.3.37	Tx Buffer Request Pending Register (M_CAN_TXBRP).....	2094
41.3.38	Tx Buffer Add Request Register (M_CAN_TXBAR).....	2095
41.3.39	Tx Buffer Cancellation Request Register (M_CAN_TXBCR).....	2095
41.3.40	Tx Buffer Transmission Occurred Register (M_CAN_TXBTO).....	2096
41.3.41	Tx Buffer Cancellation Finished Register (M_CAN_TXBCF).....	2096
41.3.42	Tx Buffer Transmission Interrupt Enable Register (M_CAN_TXBTIE).....	2097
41.3.43	Tx Buffer Cancellation Finished Interrupt Enable Register (M_CAN_TXBCIE).....	2097
41.3.44	Tx Event FIFO Configuration Register (M_CAN_TXEFC).....	2098
41.3.45	Tx Event FIFO Status Register (M_CAN_TXEFS).....	2099
41.3.46	Tx Event FIFO Acknowledge Register (M_CAN_TXEFA).....	2100
41.4	Message RAM.....	2100
41.4.1	Rx Buffer and FIFO Element.....	2101
41.4.2	Tx Buffer Element.....	2103
41.4.3	Tx Event FIFO Element.....	2105
41.4.4	Standard Message ID Filter Element.....	2106
41.4.5	Extended Message ID Filter Element.....	2108
41.5	Functional Description.....	2110
41.5.1	Operating Modes.....	2110
41.5.2	Timestamp Generation.....	2119
41.5.3	Timeout Counter.....	2120
41.5.4	Rx Handling.....	2120
41.5.5	Tx Handling.....	2131
41.5.6	FIFO Acknowledge Handling.....	2137

Section number	Title	Page
Chapter 42		
Deserial Serial Peripheral Interface (DSPI)		
42.1	Chip-specific DSPI information.....	2139
42.1.1	DSPI and eMIOS direct connections.....	2139
42.1.2	DSPI connections with SIU, eTPU, and eMIOS modules.....	2140
42.2	Introduction.....	2141
42.2.1	Block Diagram.....	2141
42.2.2	Features.....	2142
42.2.3	Interface configurations.....	2145
42.2.4	Modes of Operation.....	2146
42.3	Module signal descriptions.....	2147
42.3.1	HT—Hardware Trigger.....	2148
42.3.2	PCS0/SS—Peripheral Chip Select/Slave Select.....	2148
42.3.3	PCS1—PCS3—Peripheral Chip Selects 1–3.....	2148
42.3.4	PCS4—Peripheral Chip Select 4.....	2149
42.3.5	PCS5/PCSS—Peripheral Chip Select 5/Peripheral Chip Select Strobe.....	2149
42.3.6	SCK—Serial Clock.....	2149
42.3.7	SIN—Serial Input.....	2149
42.3.8	SOUT—Serial Output.....	2149
42.4	Memory Map/Register Definition.....	2150
42.4.1	Module Configuration Register (DSPI_MCR).....	2152
42.4.2	Transfer Count Register (DSPI_TCR).....	2155
42.4.3	Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTAR _n).....	2156
42.4.4	Clock and Transfer Attributes Register (In Slave Mode) (DSPI_CTAR _n _SLAVE).....	2161
42.4.5	Status Register (DSPI_SR).....	2163
42.4.6	DMA/Interrupt Request Select and Enable Register (DSPI_RSER).....	2166
42.4.7	PUSH TX FIFO Register In Master Mode (DSPI_PUSHHR).....	2168
42.4.8	PUSH TX FIFO Register In Slave Mode (DSPI_PUSHHR_SLAVE).....	2170
42.4.9	POP RX FIFO Register (DSPI_POPR).....	2171

Section number	Title	Page
42.4.10	Transmit FIFO Registers (DSPI_TXFR n).....	2171
42.4.11	Receive FIFO Registers (DSPI_RXFR n).....	2172
42.4.12	DSI Configuration Register 0 (DSPI_DSICR0).....	2173
42.4.13	DSI Serialization Data Register 0 (DSPI_SDR0).....	2175
42.4.14	DSI Alternate Serialization Data Register 0 (DSPI_ASDR0).....	2176
42.4.15	DSI Transmit Comparison Register 0 (DSPI_COMPR0).....	2176
42.4.16	DSI Deserialization Data Register 0 (DSPI_DDR0).....	2177
42.4.17	DSI Configuration Register 1 (DSPI_DSICR1).....	2177
42.4.18	DSI Serialization Source Select Register 0 (DSPI_SSR0).....	2179
42.4.19	DSI Parallel Input Select Register 0 (DSPI_PISR0).....	2179
42.4.20	DSI Parallel Input Select Register 1 (DSPI_PISR1).....	2180
42.4.21	DSI Parallel Input Select Register 2 (DSPI_PISR2).....	2181
42.4.22	DSI Parallel Input Select Register 3 (DSPI_PISR3).....	2182
42.4.23	DSI Deserialized Data Interrupt Mask Register 0 (DSPI_DIMR0).....	2183
42.4.24	DSI Deserialized Data Polarity Interrupt Register 0 (DSPI_DPIR0).....	2183
42.5	Functional description.....	2184
42.5.1	Start and Stop of module transfers.....	2185
42.5.2	Serial Peripheral Interface (SPI) configuration.....	2186
42.5.3	Deserial Serial Interface (DSI) Configuration.....	2190
42.5.4	Combined Serial Interface (CSI) Configuration.....	2195
42.5.5	Module baud rate and clock delay generation.....	2197
42.5.6	Transfer formats.....	2200
42.5.7	Continuous Serial Communications Clock.....	2210
42.5.8	Slave Mode Operation Constraints.....	2212

Section number	Title	Page
42.5.9	Timed Serial Bus (TSB).....	2212
42.5.10	Parity Generation and Check.....	2215
42.5.11	Interrupts/DMA requests.....	2217
42.5.12	Power saving features.....	2220
42.6	Initialization/application information.....	2221
42.6.1	How to manage queues.....	2221
42.6.2	Switching Master and Slave mode.....	2222
42.6.3	Initializing Module in Master/Slave Modes.....	2222
42.6.4	Baud rate settings.....	2222
42.6.5	Delay settings.....	2223
42.6.6	Calculation of FIFO pointer addresses.....	2224

Chapter 43 Zipwire

43.1	Chip-specific Zipwire information.....	2227
43.2	Overview.....	2227
43.3	Introduction.....	2228
43.4	Zipwire Block Diagram.....	2228
43.5	Architecture.....	2229
43.6	Zipwire interconnections.....	2230
43.7	Zipwire performance.....	2231
43.7.1	Read performance.....	2231
43.7.2	Write performance.....	2233

Chapter 44 Serial Interprocessor Interface (SIPI)

44.1	Chip-specific SIPI information.....	2237
44.1.1	SIPI Chip ID.....	2237
44.2	Introduction.....	2237
44.2.1	Scalability.....	2237
44.3	Overview.....	2238

Section number	Title	Page
44.4	SIPI block diagram.....	2240
44.5	Feature description.....	2240
44.5.1	Main features.....	2240
44.5.2	Standard features.....	2241
44.6	SIPI operation from reset.....	2241
44.7	Functional description.....	2241
44.7.1	External signals.....	2241
44.7.2	Frame format.....	2242
44.8	Transfer types.....	2248
44.8.1	Read transfer.....	2248
44.8.2	Register read answer transfer.....	2249
44.8.3	Register Write transfer.....	2250
44.8.4	Write Acknowledge transfer.....	2253
44.8.5	ID request response.....	2253
44.9	Transfer API and flow charts.....	2255
44.10	DMA programming sequence.....	2262
44.11	Modes of operation.....	2263
44.11.1	Initialization mode.....	2263
44.11.2	Normal mode.....	2263
44.11.3	Module Disable (MD).....	2263
44.12	Errors.....	2264
44.12.1	Timeout error.....	2264
44.12.2	CRC error.....	2264
44.12.3	Maximum count reached error.....	2265
44.12.4	Transaction ID error.....	2265
44.12.5	Acknowledge error.....	2265
44.13	CRC calculation.....	2265
44.14	Interrupt logic.....	2266
44.15	SIPI control and status overview.....	2267

Section number	Title	Page
44.16	Memory map and register definition.....	2268
44.16.1	SIPI Channel Control Register 0 (SIPI_CCR0).....	2271
44.16.2	SIPI Channel Status Register 0 (SIPI_CSR0).....	2274
44.16.3	SIPI Channel Interrupt Register 0 (SIPI_CIR0).....	2275
44.16.4	SIPI Channel Timeout Register 0 (SIPI_CTOR0).....	2276
44.16.5	SIPI Channel CRC Register 0 (SIPI_CCRC0).....	2277
44.16.6	SIPI Channel Address Register 0 (SIPI_CAR0).....	2277
44.16.7	SIPI Channel Data Register 0 (SIPI_CDR0).....	2278
44.16.8	SIPI Channel Control Register 1 (SIPI_CCR1).....	2278
44.16.9	SIPI Channel Status Register 1 (SIPI_CSR1).....	2281
44.16.10	SIPI Channel Interrupt Register 1 (SIPI_CIR1).....	2283
44.16.11	SIPI Channel Timeout Register 1 (SIPI_CTOR1).....	2284
44.16.12	SIPI Channel CRC Register 1 (SIPI_CCRC1).....	2285
44.16.13	SIPI Channel Address Register 1 (SIPI_CAR1).....	2285
44.16.14	SIPI Channel Data Register 1 (SIPI_CDR1).....	2286
44.16.15	SIPI Channel Control Register 2 (SIPI_CCR2).....	2286
44.16.16	SIPI Channel Status Register 2 (SIPI_CSR2).....	2289
44.16.17	SIPI Channel Interrupt Register 2 (SIPI_CIR2).....	2291
44.16.18	SIPI Channel Timeout Register 2 (SIPI_CTOR2).....	2292
44.16.19	SIPI Channel CRC Register 2 (SIPI_CCRC2).....	2293
44.16.20	SIPI Channel Address Register 2 (SIPI_CAR2).....	2293
44.16.21	SIPI Channel Data Register 2 (SIPI_CDR2_n).....	2294
44.16.22	SIPI Channel Control Register 3 (SIPI_CCR3).....	2294
44.16.23	SIPI Channel Status Register 3 (SIPI_CSR3).....	2297
44.16.24	SIPI Channel Interrupt Register 3 (SIPI_CIR3).....	2299
44.16.25	SIPI Channel Timeout Register 3 (SIPI_CTOR3).....	2300
44.16.26	SIPI Channel CRC Register 3 (SIPI_CCRC3).....	2301
44.16.27	SIPI Channel Address Register 3 (SIPI_CAR3).....	2301
44.16.28	SIPI Channel Data Register 3 (SIPI_CDR3).....	2302

44.16.33	SIPI Address Count Register (SIPI_ACR).....	2308
44.16.34	SIPI Error Register (SIPI_ERR).....	2309

Chapter 45

LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications

45.1	Chip-specific LFAST information.....	2313
45.2	Introduction.....	2313
45.3	Block diagram	2313
45.4	External signals.....	2314
45.4.1	LFAST operating data rates.....	2314
45.5	LFAST frame structure.....	2315
45.6	Features.....	2318
45.7	Memory map and register definition.....	2319
45.7.1	LFAST Mode Configuration Register (LFAST_MCR).....	2321
45.7.2	LFAST Speed Control Register (LFAST_SCR).....	2323
45.7.3	LFAST Correlator Control Register (LFAST_COCR).....	2324
45.7.4	LFAST Test Mode Control Register (LFAST_TMCR).....	2326
45.7.5	LFAST Auto Loopback Control Register (LFAST_ALCR).....	2327
45.7.6	LFAST Rate Change Delay Control Register (LFAST_RCDCR).....	2328
45.7.7	LFAST Wakeup Delay Control Register (LFAST_SLCR).....	2328
45.7.8	LFAST ICLC Control Register (LFAST_ICR).....	2330
45.7.9	LFAST Ping Control Register (LFAST_PICR).....	2331
45.7.10	LFAST Rx FIFO CTS Control Register (LFAST_RFCR).....	2332
45.7.11	LFAST Tx Interrupt Enable Register (LFAST_TIER).....	2332
45.7.12	LFAST Rx Interrupt Enable Register (LFAST_RIER).....	2333
45.7.13	LFAST Rx ICLC Interrupt Enable Register (LFAST_RIIER).....	2335

Section number	Title	Page
45.7.14	LFAST PLL Control Register (LFAST_PLLCR).....	2337
45.7.15	LFAST LVDS Control Register (LFAST_LCR).....	2339
45.7.16	LFAST Unsolicited Tx Control Register (LFAST_UNSTCR).....	2342
45.7.17	LFAST Unsolicited Tx Data Registers (LFAST_UNSTDR _n).....	2342
45.7.18	LFAST Global Status Register (LFAST_GSR).....	2343
45.7.19	LFAST Ping Status Register (LFAST_PISR).....	2345
45.7.20	LFAST Data Frame Status Register (LFAST_DFSR).....	2345
45.7.21	LFAST Tx Interrupt Status Register (LFAST_TISR).....	2346
45.7.22	LFAST Rx Interrupt Status Register (LFAST_RISR).....	2347
45.7.23	LFAST Rx ICLC Interrupt Status Register (LFAST_RIISR).....	2349
45.7.24	LFAST PLL and LVDS Status Register (LFAST_PLLLSR).....	2351
45.7.25	LFAST Unsolicited Rx Status Register (LFAST_UNSRSR).....	2352
45.7.26	LFAST Unsolicited Rx Data Register (LFAST_UNSRDR _n).....	2353
45.8	Functional description.....	2353
45.8.1	Startup procedure.....	2353
45.8.2	Line Receiver.....	2357
45.8.3	Transmit Controller.....	2366
45.8.4	CTS mode support.....	2371
45.8.5	Frames supported.....	2372
45.8.6	Frame flow.....	2373
45.8.7	Test and Debug Support.....	2380
45.8.8	Interrupts.....	2389
45.9	Packet memory.....	2392
45.10	Resets.....	2393
45.11	Clocks.....	2394
45.11.1	Clocking strategy.....	2394
45.11.2	Slow speed clock.....	2395
45.11.3	Rx Controller Clocks.....	2398
45.11.4	Clocking Module Requirements for High Speed Phases.....	2398

Section number	Title	Page
45.11.5	Clock module requirements for low speed phases.....	2399
45.11.6	Tx Controller Clocks.....	2400

Chapter 46 Fast Ethernet Controller (FEC)

46.1	Chip-specific FEC information.....	2403
46.1.1	FEC interface selection.....	2403
46.1.2	FEC clocking.....	2403
46.2	Introduction.....	2403
46.2.1	Block diagram.....	2403
46.2.2	Features.....	2405
46.2.3	Clocking requirements.....	2406
46.3	Modes of operation.....	2406
46.3.1	Full and half duplex operation.....	2407
46.3.2	Interface options.....	2407
46.3.3	Address recognition options.....	2409
46.3.4	Internal loopback.....	2409
46.4	External signal description.....	2409
46.5	Memory map and register definition.....	2410
46.5.1	Interrupt Event Register (FEC_EIR).....	2415
46.5.2	Interrupt Mask Register (FEC_EIMR).....	2417
46.5.3	Receive Descriptor Active Register (FEC_RDAR).....	2419
46.5.4	Transmit Descriptor Active Register (FEC_TDAR).....	2420
46.5.5	Ethernet Control Register (FEC_ECR).....	2421
46.5.6	MII Management Frame Register (FEC_MMFR).....	2422
46.5.7	MII Speed Control Register (FEC_MSCR).....	2423
46.5.8	MIB Control Register (FEC_MIBC).....	2424
46.5.9	Receive Control Register (FEC_RCR).....	2426
46.5.10	Transmit Control Register (FEC_TCR).....	2428
46.5.11	Physical Address Low Register (FEC_PALR).....	2429

Section number	Title	Page
46.5.12	Physical Address High Register and Type Field (FEC_PAUR).....	2430
46.5.13	Opcode/Pause Duration (FEC_OPD).....	2430
46.5.14	Descriptor Individual Upper Address Register (FEC_IAUR).....	2431
46.5.15	Descriptor Individual Lower Address Register (FEC_IALR).....	2431
46.5.16	Descriptor Group Upper Address Register (FEC_GAUR).....	2432
46.5.17	Descriptor Group Lower Address Register (FEC_GALR).....	2432
46.5.18	Transmit FIFO Watermark (FEC_TFWR).....	2433
46.5.19	FIFO Receive Bound Register (FEC_FRBR).....	2434
46.5.20	FIFO Receive Start Register (FEC_FRSR).....	2434
46.5.21	Receive Descriptor Ring Start Register (FEC_ERDSR).....	2435
46.5.22	Transmit Buffer Descriptor Ring Start Register (FEC_ETDSR).....	2436
46.5.23	Receive Buffer Size Register (FEC_EMRBR).....	2436
46.5.24	Count of frames not counted correctly (FEC_RMON_T_DROP).....	2437
46.5.25	RMON Tx packet count (FEC_RMON_T_PACKETS).....	2438
46.5.26	RMON Tx broadcast packets (FEC_RMON_T_BC_PKT).....	2438
46.5.27	RMON Tx multicast packets (FEC_RMON_T_MC_PKT).....	2439
46.5.28	RMON Tx packets with CRC/align error (FEC_RMON_T_CRC_ALIGN).....	2439
46.5.29	RMON Tx packets < 64 bytes, good CRC (FEC_RMON_T_UNDERSIZE).....	2440
46.5.30	RMON Tx packets > MAX_FL bytes, good CRC (FEC_RMON_T_OVERSIZE).....	2440
46.5.31	RMON Tx packets < 64 bytes, bad CRC (FEC_RMON_T_FRAG).....	2441
46.5.32	RMON Tx packets > MAX_FL bytes, bad CRC (FEC_RMON_T_JAB).....	2441
46.5.33	RMON Tx collision count (FEC_RMON_T_COL).....	2442
46.5.34	RMON Tx 64 byte packets (FEC_RMON_T_P64).....	2442
46.5.35	RMON Tx 65 to 127 byte packets (FEC_RMON_T_P65TO127).....	2443
46.5.36	RMON Tx 128 to 255 byte packets (FEC_RMON_T_P128TO255).....	2443
46.5.37	RMON Tx 256 to 511 byte packets (FEC_RMON_T_P256TO511).....	2444
46.5.38	RMON Tx 512 to 1023 byte packets (FEC_RMON_T_P512TO1023).....	2444
46.5.39	RMON Tx 1024 to 2047 byte packets (FEC_RMON_T_P1024TO2047).....	2445
46.5.40	RMON Tx packets with > 2048 bytes (FEC_RMON_T_P_GTE2048).....	2445

Section number	Title	Page
46.5.41	RMON Tx Octets (FEC_RMON_T_OCTETS).....	2446
46.5.42	Count of transmitted frames not counted correctly (FEC_IEEE_T_DROP).....	2446
46.5.43	Frames transmitted OK (FEC_IEEE_T_FRAME_OK).....	2447
46.5.44	Frames transmitted with single collision (FEC_IEEE_T_ICOL).....	2447
46.5.45	Frames transmitted with multiple collisions (FEC_IEEE_T_MCOL).....	2448
46.5.46	Frames transmitted after deferral delay (FEC_IEEE_T_DEF).....	2448
46.5.47	Frames transmitted with late collision (FEC_IEEE_T_LCOL).....	2449
46.5.48	Frames transmitted with excessive collisions (FEC_IEEE_T_EXCOL).....	2449
46.5.49	Frames transmitted with Tx FIFO underrun (FEC_IEEE_T_MACERR).....	2450
46.5.50	Frames transmitted with carrier sense error (FEC_IEEE_T_CSERR).....	2450
46.5.51	Frames transmitted with SQE error (FEC_IEEE_T_SQE).....	2451
46.5.52	Flow control pause frames transmitted (FEC_IEEE_T_FDXFC).....	2451
46.5.53	Octet count for frames transmitted without error (FEC_IEEE_T_OCTETS_OK).....	2452
46.5.54	Count of received frames not counted correctly (FEC_RMON_R_DROP).....	2452
46.5.55	RMON Rx packet count (FEC_RMON_R_PACKETS).....	2453
46.5.56	RMON Rx broadcast packets (FEC_RMON_R_BC_PKT).....	2453
46.5.57	RMON Rx multicast packets (FEC_RMON_R_MC_PKT).....	2454
46.5.58	RMON Rx packets with CRC/Align error (FEC_RMON_R_CRC_ALIGN).....	2454
46.5.59	RMON Rx packets < 64 bytes, good CRC (FEC_RMON_R_UNDERSIZE).....	2455
46.5.60	RMON Rx packets > MAX_FL bytes, good CRC (FEC_RMON_R_OVERSIZE).....	2455
46.5.61	RMON Rx packets < 64 bytes, bad CRC (FEC_RMON_R_FRAG).....	2456
46.5.62	RMON Rx packets > MAX_FL bytes, bad CRC (FEC_RMON_R_JAB).....	2456
46.5.63	Reserved (FEC_RMON_R_RESVD_0).....	2457
46.5.64	RMON Rx 64 byte packets (FEC_RMON_R_P64).....	2457
46.5.65	RMON Rx 65 to 127 byte packets (FEC_RMON_R_P65TO127).....	2458
46.5.66	RMON Rx 128 to 255 byte packets (FEC_RMON_R_P128TO255).....	2458
46.5.67	RMON Rx 256 to 511 byte packets (FEC_RMON_R_P256TO511).....	2459
46.5.68	RMON Rx 512 to 1023 byte packets (FEC_RMON_R_P512TO1023).....	2459
46.5.69	RMON Rx 1024 to 2047 byte packets (FEC_RMON_R_P1024TO2047).....	2460

Section number	Title	Page
46.5.70	RMON Rx packets with > 2048 bytes (FEC_RMON_R_P_GTE2048).....	2460
46.5.71	RMON Rx octets (FEC_RMON_R_OCTETS).....	2461
46.5.72	Count of received frames not counted correctly (FEC_IEEE_R_DROP).....	2461
46.5.73	Frames received OK (FEC_IEEE_R_FRAME_OK).....	2462
46.5.74	Frames received with CRC error (FEC_IEEE_R_CRC).....	2462
46.5.75	Frames received with alignment error (FEC_IEEE_R_ALIGN).....	2463
46.5.76	Receive FIFO overflow count (FEC_IEEE_R_MACERR).....	2463
46.5.77	Flow control pause frames received (FEC_IEEE_R_FDXFC).....	2464
46.5.78	Octet count for frames received without error (FEC_IEEE_R_OCTETS_OK).....	2464
46.5.79	Using the RMON and IEEE registers.....	2464
46.6	Functional description.....	2465
46.6.1	MII data frame.....	2465
46.6.2	MII management frame structure.....	2466
46.6.3	Buffer descriptors.....	2467
46.6.4	Initialization sequence.....	2473
46.6.5	User initialization (Prior to Setting ECR[ETHER_EN]).....	2473
46.6.6	Microcontroller initialization.....	2474
46.6.7	User initialization (after setting ECR[ETHER_EN]).....	2475
46.6.8	Network interface options.....	2475
46.6.9	FEC frame transmission.....	2476
46.6.10	FEC frame reception.....	2478
46.6.11	Ethernet address recognition.....	2479
46.6.12	Hash algorithm.....	2482
46.6.13	Full duplex flow control.....	2485
46.6.14	Inter-Packet Gap (IPG) time.....	2486
46.6.15	Collision managing.....	2486
46.6.16	MII internal and external loopback.....	2486
46.6.17	RMII loopback.....	2487
46.6.18	RMII echo.....	2487

Section number	Title	Page
46.6.19	Ethernet error-managing procedure.....	2487

Chapter 47

Peripheral Sensor Interface (PSI5)

47.1	Chip-specific PSI5 information.....	2491
47.1.1	PSI5 GTM interface.....	2491
47.1.2	Detection of PSI5 SMC messages.....	2491
47.2	Introduction.....	2492
47.2.1	Overview.....	2492
47.2.2	Features.....	2493
47.2.3	Modes of operation.....	2495
47.3	External signal description.....	2499
47.4	Memory map and register description.....	2499
47.4.1	Global Control Register (PSI5_GCR).....	2505
47.4.2	PSI5 Channel Control Register (PSI5_CH0_PCCR).....	2507
47.4.3	DMA Control Register (PSI5_CH0_DCR).....	2513
47.4.4	DMA Status Register (PSI5_CH0_DSR).....	2517
47.4.5	General Interrupt Control Register (PSI5_CH0_GICR).....	2519
47.4.6	New Data Interrupt Control Register (PSI5_CH0_NDICR).....	2521
47.4.7	Overwrite Interrupt Control Register (PSI5_CH0_OWICR).....	2521
47.4.8	Error Interrupt Control Register (PSI5_CH0_EICR).....	2522
47.4.9	General Interrupt Status Register (PSI5_CH0_GISR).....	2523
47.4.10	DMA PSI5 Message Register (PSI5_CH0_DPMR).....	2525
47.4.11	DMA SMC Frame Register (PSI5_CH0_DSFR).....	2526
47.4.12	DMA Diagnostic Status Register (PSI5_CH0_DDSDR).....	2526
47.4.13	PSI5 Message Receive Register Low (PSI5_CH0_PMRRL).....	2527
47.4.14	PSI5 Message Receive Register High (PSI5_CH0_PMRRH).....	2527
47.4.15	PSI5 Message Register Low i (PSI5_CH0_PMRL _n).....	2529
47.4.16	PSI5 Message Register High i (PSI5_CH0_PMRH _n).....	2530
47.4.17	SMC Frame Register n (PSI5_CH0_SFR _n).....	2531

Section number	Title	Page
47.4.18	New Data Status Register (PSI5_CH0_NDSR).....	2533
47.4.19	Overwrite Status Register (PSI5_CH0_OWSR).....	2533
47.4.20	Error Indication Status Register (PSI5_CH0_EISR).....	2534
47.4.21	Set New Data Status Register (PSI5_CH0_SNDSR).....	2534
47.4.22	Set Overwrite Status Register (PSI5_CH0_SOWSR).....	2535
47.4.23	Set Error Status Register (PSI5_CH0_SEISR).....	2535
47.4.24	Set SMC Error Status Register (PSI5_CH0_SSESr).....	2536
47.4.25	Sync Time Stamp Read Register (PSI5_CH0_STSRR).....	2537
47.4.26	Data Time Stamp Read Register (PSI5_CH0_DTSRR).....	2537
47.4.27	Slot n Frame Configuration Register (PSI5_CH0_SnFCR).....	2538
47.4.28	Slot 1 Start Boundary Register (PSI5_CH0_S1SBR).....	2540
47.4.29	Slot 2 Start Boundary Register (PSI5_CH0_S2SBR).....	2540
47.4.30	Slot 3 Start Boundary Register (PSI5_CH0_S3SBR).....	2541
47.4.31	Slot 4 Start Boundary Register (PSI5_CH0_S4SBR).....	2541
47.4.32	Slot 5 Start Boundary Register (PSI5_CH0_S5SBR).....	2542
47.4.33	Slot 6 Start Boundary Register (PSI5_CH0_S6SBR).....	2542
47.4.34	Slot n End Boundary Register (PSI5_CH0_SnEBR).....	2543
47.4.35	Data Output Block Configuration Register (PSI5_CH0_DOBCR).....	2544
47.4.36	Manchester Decoder Disable Offset (PSI5_CH0_MDDIS_OFF).....	2547
47.4.37	Pulse Width for Data Bit Value 0 (PSI5_CH0_PW0D).....	2548
47.4.38	Pulse Width for Data Bit Value 1 (PSI5_CH0_PW1D).....	2548
47.4.39	Counter Target Pulse Register (PSI5_CH0_CTPR).....	2549
47.4.40	Counter Initialize Pulse Register (PSI5_CH0_CIPR).....	2550
47.4.41	Data Preparation Register Low (PSI5_CH0_DPRL).....	2550
47.4.42	Data Preparation Register High (PSI5_CH0_DPRH).....	2551
47.4.43	Data Buffer Register Low (PSI5_CH0_DBRL).....	2552
47.4.44	Data Buffer Register High (PSI5_CH0_DBRH).....	2554
47.4.45	Data Shift Register Low (PSI5_CH0_DSRL).....	2556
47.4.46	Data Shift Register High (PSI5_CH0_DSRH).....	2557

Section number	Title	Page
47.4.47	Device modes and Register bit accesses.....	2557
47.5	Functional description.....	2559
47.5.1	Sensor-to-ECU communication.....	2559
47.5.2	Data Link Layer.....	2560
47.5.3	ECU-to-sensor communication.....	2582
47.5.4	Tx/Rx scenario.....	2594
47.5.5	Interrupt handling.....	2594
47.5.6	DMA support.....	2597
47.5.7	Message read through interrupt generation.....	2600
47.6	Initialization information.....	2600
47.6.1	Initialization.....	2600
47.7	Design Assumptions and Limitations.....	2601
47.7.1	Assumptions.....	2601
47.7.2	Limitations.....	2602
47.8	Miscellaneous descriptions.....	2602
47.8.1	Internal SYNC Pulse generation and coordination across PSI5 channels.....	2602
47.8.2	Valid states for integrated sync pulse generator.....	2606
47.8.3	Implementation of EI Diagnostic Register.....	2609

Chapter 48 SENT Receiver (SRX)

48.1	Chip-specific SRX information.....	2611
48.2	Introduction.....	2611
48.2.1	Features.....	2612
48.2.2	Modes of operation.....	2613
48.2.3	Block diagram.....	2615
48.2.4	Design overview.....	2617
48.3	External signal description.....	2618
48.3.1	SENT_RX [(CH-1):0].....	2618

Section number	Title	Page
48.4	Memory map and register definition.....	2619
48.4.1	Global Control Register (SRX_GBL_CTRL).....	2623
48.4.2	Channel Enable Register (SRX_CHNL_EN).....	2625
48.4.3	Global Status Register (SRX_GBL_STATUS).....	2626
48.4.4	Fast Message Ready Status Register (SRX_FMSG_RDY).....	2627
48.4.5	Slow Serial Message Ready Status Register (SRX_SMSG_RDY).....	2628
48.4.6	Data Control Register 1 (SRX_DATA_CTRL1).....	2629
48.4.7	Fast Message DMA Control Register (SRX_FDMA_CTRL).....	2631
48.4.8	Slow Serial Message DMA Control Register (SRX_SDMA_CTRL).....	2631
48.4.9	Fast Message Ready Interrupt Control Register (SRX_FRDY_IE).....	2632
48.4.10	Slow Serial Message Ready Interrupt Enable Register (SRX_SRDY_IE).....	2633
48.4.11	DMA Fast Message Data Read Register (SRX_DMA_FMSG_DATA).....	2633
48.4.12	DMA Fast Message CRC Read Register (SRX_DMA_FMSG_CRC).....	2634
48.4.13	DMA Fast Message Time Stamp Read Register (SRX_DMA_FMSG_TS).....	2635
48.4.14	DMA Slow Serial Message Bit3 Read Register (SRX_DMA_SMSG_BIT3).....	2635
48.4.15	DMA Slow Serial Message Bit2 Read Register (SRX_DMA_SMSG_BIT2).....	2637
48.4.16	DMA Slow Serial Message Time Stamp Read Register (SRX_DMA_SMSG_TS).....	2637
48.4.17	Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX_CHn_CLK_CTRL).....	2638
48.4.18	Channel 'n' Status Register (n=0 to (CH-1)) (SRX_CHn_STATUS).....	2640
48.4.19	Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CHn_CONFIG).....	2643
48.4.20	Channel 'n' Fast Message Data Read Register (n=0 to (CH-1)) (SRX_CHn_FMSG_DATA).....	2646
48.4.21	Channel 'n' Fast Message CRC Read Register (n=0 to (CH-1)) (SRX_CHn_FMSG_CRC).....	2647
48.4.22	Channel 'n' Fast Message Time Stamp Read Register (n=0 to (CH-1)) (SRX_CHn_FMSG_TS).....	2647
48.4.23	Channel 'n' Serial Message Read Register (Bit 3) (n=0 to (CH-1)) (SRX_CHn_SMSG_BIT3).....	2648
48.4.24	Channel 'n' Serial Message Read Register (Bit 2)(n=0 to (CH-1)) (SRX_CHn_SMSG_BIT2).....	2649
48.4.25	Channel 'n' Serial Message Time Stamp Read Register (n=0 to (CH-1)) (SRX_CHn_SMSG_TS).....	2650
48.5	Functional description.....	2650
48.5.1	Initialization sequence.....	2650

Section number	Title	Page
48.5.2	DMA read logic.....	2651
48.5.3	Message reading via interrupts.....	2659
48.5.4	Overflow behavior.....	2661
48.5.5	Adjustment for variation in sensor (Tx) clock.....	2662
48.5.6	Input programmable filter.....	2663
48.5.7	Receiver diagnostics.....	2663
48.5.8	Time stamp logic.....	2669
48.5.9	Bus Idle Diagnostic.....	2670
48.6	Clocks and resets.....	2670
48.6.1	Clocking strategy.....	2670
48.6.2	System bus clock requirements.....	2671
48.6.3	High frequency receiver clock (protocol clock) requirements.....	2672

Chapter 49

Enhanced Serial Communication Interface (eSCI)

49.1	Chip-specific eSCI information.....	2675
49.1.1	eSCI clocking.....	2675
49.1.2	eSCI registers: core access in supervisor mode.....	2675
49.2	Introduction.....	2676
49.2.1	Bibliography.....	2676
49.2.2	Acronyms and Abbreviations.....	2676
49.2.3	Glossary.....	2676
49.2.4	Overview.....	2677
49.2.5	Features.....	2678
49.2.6	Modes of Operation.....	2680
49.3	External Signal Description.....	2681
49.3.1	Detailed Signal Descriptions.....	2681
49.4	Memory Map and Register Definition.....	2681
49.4.1	Baud Rate Register (eSCI_BRR).....	2682
49.4.2	Control Register 1 (eSCI_CR1).....	2683

Section number	Title	Page
49.4.3	Control Register 2 (eSCI_CR2).....	2685
49.4.4	SCI Data Register (eSCI_SDR).....	2687
49.4.5	Interrupt Flag and Status Register 1 (eSCI_IFSR1).....	2689
49.4.6	Interrupt Flag and Status Register 2 (eSCI_IFSR2).....	2691
49.4.7	LIN Control Register 1 (eSCI_LCR1).....	2692
49.4.8	LIN Control Register 2 (eSCI_LCR2).....	2694
49.4.9	LIN Transmit Register (eSCI_LTR).....	2694
49.4.10	LIN Receive Register (eSCI_LRR).....	2696
49.4.11	LIN CRC Polynomial Register (eSCI_LPR).....	2697
49.4.12	Control Register 3 (eSCI_CR3).....	2697
49.5	Functional Description.....	2698
49.5.1	Module Control.....	2698
49.5.2	Frame Formats.....	2698
49.5.3	Baud Rate and Clock Generation.....	2702
49.5.4	Baud Rate Tolerance.....	2704
49.5.5	SCI Mode.....	2706
49.5.6	LIN Mode.....	2723
49.5.7	Interrupts.....	2734
49.6	Application Information.....	2735
49.6.1	SCI Data Frames Separated by Preamble.....	2735

Chapter 50 Resets

50.1	Overview.....	2737
50.2	Reset sequence.....	2738
50.3	Reset pins.....	2741
50.3.1	RESET.....	2741
50.3.2	RSTOUT.....	2741

Section number	Title	Page
50.4	Reset sources.....	2742
50.4.1	Power-on reset.....	2742
50.4.2	External reset.....	2744
50.4.3	FCCU reset.....	2744
50.4.4	FOSU reset.....	2745
50.4.5	Dual core reset.....	2745
50.4.6	JTAG reset.....	2745
50.4.7	Software system reset.....	2746
50.4.8	Software external reset.....	2746
50.4.9	STCU reset.....	2746
50.4.10	Life cycle manipulation reset.....	2747
50.5	Reset configuration.....	2747
50.5.1	Weak pull up/down configuration.....	2747
50.5.2	Boot configuration.....	2748
50.6	Boot sequence.....	2748

Chapter 51 System Boot

51.1	Overview.....	2751
51.2	Features.....	2751
51.3	Modes of operation.....	2752
51.3.1	Normal boot.....	2752
51.3.2	Parallel secure boot.....	2752
51.3.3	Debug mode.....	2752
51.3.4	Internal boot mode.....	2752
51.3.5	Serial boot mode.....	2753
51.3.6	Development bus boot mode.....	2753
51.4	Memory Map.....	2753
51.5	Functional Description.....	2754
51.5.1	BAM program flow chart.....	2754

Section number	Title	Page
51.5.2	BAM program operation.....	2754
51.5.3	Reset Configuration Half Word (RCHW).....	2756
51.5.4	Internal boot mode.....	2758
51.5.5	Serial boot mode.....	2759
51.5.6	Booting from the development bus.....	2768

Chapter 52

System Status and Configuration Module (SSCM)

52.1	Chip-specific SSCM information.....	2771
52.1.1	SSCM and UTEST flash memory.....	2771
52.1.2	SSCM security reset and LC state.....	2772
52.1.3	SSCM_ERROR[PAE] and abort responses to illegal accesses.....	2773
52.2	Introduction.....	2773
52.2.1	Overview.....	2773
52.2.2	Glossary.....	2774
52.2.3	Features.....	2774
52.2.4	Modes of operation.....	2775
52.3	External signal description.....	2775
52.4	Memory map and register definition.....	2775
52.4.1	SSCM System Status (SSCM_STATUS).....	2776
52.4.2	SSCM Error Configuration Register (SSCM_ERROR).....	2778
52.4.3	Life Cycle Status Register (SSCM_LCSTAT).....	2779
52.5	Functional description.....	2779
52.5.1	DCF mechanism.....	2780
52.5.2	Life Cycle.....	2782
52.6	Initialization and application information.....	2784
52.6.1	Reset.....	2784
52.7	Additional safety measures.....	2784
52.7.1	Spurious reset protection.....	2784

Section number	Title	Page
Chapter 53		
Power Management		
53.1	Overview.....	2785
53.2	Functional description.....	2786
53.3	Power modes.....	2786
53.4	External supply.....	2786
53.5	Power management supply description.....	2786
53.6	Voltage monitoring.....	2787

Chapter 54

Power Management Controller (PMC)

54.1	Introduction.....	2789
54.1.1	Features.....	2789
54.2	Memory Map and Registers.....	2791
54.2.1	Temperature Sensor Interrupt Enable Register (PMC_TS_IER).....	2792
54.2.2	Temperature Event Status Register (PMC_ESR_TD).....	2794
54.2.3	Temperature Reset Event Enable register (PMC_REE_TD).....	2796
54.2.4	Temperature Reset Event Selection Register (PMC_RES_TD).....	2798
54.2.5	Temperature Detector Configuration Register (PMC_CTL_TD).....	2799
54.2.6	Temperature Sensor Fault Injection Register (PMC_TS_FIR).....	2800
54.2.7	Voltage Detect User Mode Test Register (PMC_SELF_TEST_UM_VD_REG).....	2801
54.2.8	FCCU Fault Injection Register (PMC_FIR).....	2804
54.2.9	LVD/HVD Interrupt Enable Control Register (PMC_LVD_HVD_INTR_ENB).....	2805
54.2.10	LVD/HVD Event Status Register (PMC_LVD_HVD_EVENT_STATUS).....	2808
54.2.11	ADC Channel Select Register (PMC_ADC_CS).....	2810
54.2.12	Reset Event Enable Register (PMC_REE).....	2812
54.3	Functional description.....	2814
54.3.1	Analog PMC interface.....	2814
54.3.2	Temperature Sensor interface logic.....	2814
54.3.3	POR phase gates.....	2814

Section number	Title	Page
54.3.4	Flash memory interface to DCF.....	2814
54.3.5	FCCU interface.....	2815
54.3.6	LVD/HVD self test mechanism.....	2815

Chapter 55 JTAG Controller (JTAGC)

55.1	Chip-specific JTAGC information.....	2819
55.1.1	JTAG ID.....	2819
55.2	Introduction.....	2819
55.2.1	Block diagram.....	2819
55.2.2	Features.....	2820
55.2.3	Modes of operation.....	2821
55.3	External signal description.....	2822
55.3.1	TCK—Test clock input.....	2822
55.3.2	TDI—Test data input.....	2822
55.3.3	TDO—Test data output.....	2823
55.3.4	TMS—Test mode select.....	2823
55.3.5	JCOMP—JTAG compliancy.....	2823
55.4	Register description.....	2823
55.4.1	Instruction register.....	2823
55.4.2	Bypass register.....	2824
55.4.3	Device identification register.....	2824
55.4.4	JTAG_PASSWORD register.....	2825
55.4.5	Boundary scan register.....	2825
55.5	Functional description.....	2826
55.5.1	JTAGC reset configuration.....	2826
55.5.2	IEEE 1149.1-2001 (JTAG) Test Access Port.....	2826
55.5.3	TAP controller state machine.....	2826
55.5.4	JTAGC block instructions.....	2829
55.5.5	Boundary scan.....	2832

Section number	Title	Page
55.6	Initialization/Application information.....	2833
Chapter 56 IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG)		
56.1	References.....	2835
56.2	Abbreviations.....	2835
56.3	Introduction.....	2836
56.3.1	Types of operation.....	2837
56.3.2	Deployment by class.....	2837
56.3.3	1149.7 TAP signals.....	2838
56.3.4	TAP.7 architecture.....	2839
56.3.5	Protocols.....	2840
56.4	Operating models.....	2842
56.5	CJTAG implementation summary.....	2842
56.5.1	T0 functions.....	2842
56.5.2	T1 functions.....	2843
56.5.3	T2 functions.....	2843
56.5.4	T3 functions.....	2843
56.5.5	T4 functions.....	2843
56.6	Ancillary services.....	2843
56.6.1	Overview.....	2843
56.6.2	Resets.....	2844
56.6.3	Start-up Options.....	2847
56.6.4	RSU operation.....	2848
56.6.5	TAPC State Machine.....	2850
56.7	EPU (Extended Protocol Unit) Operation.....	2851
56.7.1	EPU Operation.....	2851
56.7.2	EPU Registers.....	2854
56.7.3	EPU Commands.....	2866
56.7.4	EPU operating states.....	2874

Section number	Title	Page
56.7.5	System and EPU Paths.....	2875
56.8	APU (Advanced Protocol Unit) Operation.....	2875
56.8.1	Overview.....	2875
56.8.2	Operation.....	2878
56.8.3	Escape sequences.....	2880
56.8.4	Signal behaviors.....	2880
56.8.5	APU Functions.....	2881
56.8.6	Configuration Change Packets (CP).....	2887
56.8.7	Scan Packet.....	2888
56.8.8	SP Format.....	2888
56.9	Functional Description.....	2895
56.9.1	Switching from Standard Protocol to Advanced Protocol.....	2895

Chapter 57 JTAG Data Communication (JDC)

57.1	Introduction.....	2897
57.2	Overview.....	2897
57.3	Memory mapped registers.....	2898
57.3.1	Module Configuration Register (JDC_MCR).....	2899
57.3.2	Module Status Register (JDC_MSR).....	2900
57.3.3	JTAG Output Data Register (JDC_JOUT_IPS).....	2901
57.3.4	JTAG Input Data Register (JDC_JIN_IPS).....	2902
57.4	Non-Memory mapped register definition.....	2902
57.4.1	JTAG output data register (JOUT).....	2902
57.4.2	JTAG input data register (JIN).....	2903
57.5	Functional description.....	2903
57.5.1	JTAG register access.....	2904

Chapter 58 Nexus Development Interface (NDI)

58.1	Overview.....	2905

Section number	Title	Page
58.2	Nexus clients for TAP access.....	2906
58.3	Debug break and cross-triggering.....	2906
58.3.1	Break control.....	2907
58.3.2	Cross-triggering control.....	2907
58.3.3	Synchronous restart control.....	2907
58.4	Nexus eDMA Interface (NXDM) and Nexus SIPI Interface (NXSI).....	2908
58.4.1	Introduction.....	2908
58.4.2	External Signal Description.....	2910
58.4.3	NXDM and NXSI Programmers Model.....	2910
58.4.4	Functional Description.....	2921

Chapter 59 Nexus Port Controller (NPC)

59.1	Chip-specific NPC information.....	2931
59.1.1	DID register reset value.....	2931
59.1.2	NPC MDO pins.....	2931
59.2	Introduction.....	2932
59.2.1	Overview.....	2932
59.2.2	Features.....	2932
59.2.3	Modes of operation.....	2933
59.3	External signal description.....	2935
59.3.1	Overview.....	2935
59.3.2	Detailed signal descriptions.....	2935
59.4	Register definition.....	2937
59.4.1	Register descriptions.....	2937
59.5	Functional Description.....	2942
59.5.1	NPC reset configuration.....	2942
59.5.2	Auxiliary Output Port.....	2942
59.5.3	IEEE 1149.1-2001 (JTAG) TAP.....	2945
59.5.4	Nexus JTAG Port Sharing.....	2950

Section number	Title	Page
59.5.5	MCKO Control	2950
59.5.6	EVTO Sharing.....	2951
59.5.7	Nexus Reset Control.....	2951
59.5.8	System Clock Locked Indication.....	2951
59.6	Initialization/Application Information.....	2952
59.6.1	Accessing NPC tool-mapped registers.....	2952

Chapter 60

Nexus eTPU Development Interface (NDEDI)

60.1	Chip-specific NDEDI information.....	2953
60.1.1	NDEDI/NSEDI device-specific parameters.....	2953
60.2	Introduction.....	2954
60.3	Features.....	2955
60.4	Modes of operation.....	2957
60.4.1	Reset.....	2957
60.4.2	Disabled-port mode.....	2957
60.4.3	Full-port mode.....	2957
60.4.4	Reduced-port mode.....	2958
60.4.5	Stop mode.....	2958
60.5	External signal description.....	2958
60.5.1	Overview.....	2958
60.5.2	Detailed signal descriptions.....	2959
60.6	Register definition.....	2961
60.6.1	Register descriptions.....	2963
60.6.2	Unimplemented Registers.....	2996
60.7	Functional description.....	2997
60.7.1	NDEDI reset configuration.....	2997
60.7.2	Auxiliary output port.....	2997
60.7.3	IEEE 1149.1 (JTAG) Input Port.....	3007
60.7.4	Microcode Development Support.....	3012

Section number	Title	Page
60.7.5	Debug Status.....	3013
60.7.6	Ownership Trace.....	3015
60.7.7	Program Trace.....	3016
60.7.8	Data Trace.....	3031
60.7.9	Watchpoint Trace.....	3038
60.7.10	ETPU Message Queue.....	3040
60.8	Initialization/Application Information.....	3044
60.8.1	Accessing NDEDI tool-mapped registers.....	3044
60.8.2	Program Trace Reconstruction.....	3045
60.8.3	Microcode Development Support.....	3049

Chapter 61 Development Trigger Semaphore (DTS)

61.1	Introduction.....	3053
61.2	Overview.....	3053
61.3	DTS device connections.....	3055
61.3.1	DTS register access.....	3056
61.4	Memory mapped registers.....	3057
61.4.1	Output Enable Register (DTS_ENABLE).....	3057
61.4.2	Startup Register (DTS_STARTUP).....	3058
61.4.3	Semaphore Register (DTS_SEMAPHORE).....	3059
61.4.4	Semaphore Extension (DTS_SEMAPHORE_B).....	3060
61.5	Example application.....	3060

Chapter 62 Fault Collection and Control Unit (FCCU)

62.1	Chip-specific FCCU information.....	3063
62.1.1	FCCU register default values.....	3063
62.1.2	FOSU_COUNT value.....	3063
62.1.3	FCCU fault inputs.....	3064
62.1.4	Error signal flow diagram.....	3068

Section number	Title	Page
62.1.5	Restriction on configuring RESET and NMI reactions on same FCCU channel.....	3069
62.1.6	FCCU_CFG register event bit values by source (N and C).....	3070
62.2	Introduction.....	3071
62.2.1	Acronyms and abbreviations.....	3072
62.3	Main features.....	3073
62.4	Block diagram.....	3073
62.5	Signal description.....	3075
62.5.1	Signals.....	3075
62.6	Put FCCU in Configuration or Normal state.....	3077
62.6.1	Introduction.....	3077
62.6.2	About changing states.....	3077
62.6.3	Put FCCU in Configuration state.....	3077
62.6.4	Put FCCU in Normal state.....	3078
62.7	Run operations.....	3078
62.7.1	Introduction.....	3078
62.7.2	About running operations.....	3079
62.7.3	Run an operation.....	3079
62.8	Lock and unlock the configuration.....	3079
62.8.1	Introduction.....	3079
62.8.2	About locking the configuration.....	3080
62.8.3	Temporarily lock the configuration.....	3080
62.8.4	Temporarily unlock the configuration.....	3080
62.8.5	Permanently lock the configuration.....	3080
62.9	Functional description.....	3080
62.9.1	Definitions.....	3080
62.9.2	FSM description.....	3081
62.9.3	Fault priority scheme and nesting.....	3083
62.9.4	STCU interface.....	3084
62.9.5	Nonvolatile memory interface.....	3085

Section number	Title	Page
62.9.6	EOUT interface.....	3086
62.9.7	Error signal flow.....	3093
62.10	Register descriptions.....	3093
62.10.1	Control (FCCU_CTRL).....	3096
62.10.2	Control Key (FCCU_CTRLK).....	3098
62.10.3	Configuration (FCCU_CFG).....	3099
62.10.4	Noncritical Fault Configuration (FCCU_NCF_CFGn).....	3102
62.10.5	Noncritical Fault State Configuration (FCCU_NCFS_CFGn).....	3103
62.10.6	Noncritical Fault Status (FCCU_NCF_Sn).....	3104
62.10.7	Noncritical Fault Key (FCCU_NCFK).....	3106
62.10.8	Noncritical Fault Enable (FCCU_NCF_En).....	3107
62.10.9	Noncritical Fault Timeout Enable (FCCU_NCF_TOEn).....	3108
62.10.10	Noncritical Fault Timeout (FCCU_NCF_TO).....	3109
62.10.11	Configuration-State Timer Interval (FCCU_CFG_TO).....	3109
62.10.12	IO Control (FCCU_EINOUT).....	3110
62.10.13	Status (FCCU_STAT).....	3112
62.10.14	NA Freeze Status (FCCU_N2AF_STATUS).....	3114
62.10.15	AF Freeze Status (FCCU_A2FF_STATUS).....	3115
62.10.16	NF Freeze Status (FCCU_N2FF_STATUS).....	3116
62.10.17	FA Freeze Status (FCCU_F2A_STATUS).....	3117
62.10.18	Noncritical Fault Fake (FCCU_NCFF).....	3118
62.10.19	IRQ Status (FCCU_IRQ_STAT).....	3119
62.10.20	IRQ Enable (FCCU_IRQ_EN).....	3120
62.10.21	XTMR (FCCU_XTMR).....	3121
62.10.22	Transient Configuration Lock (FCCU_TRANS_LOCK).....	3122
62.10.23	Permanent Configuration Lock (FCCU_PERMNT_LOCK).....	3123
62.10.24	Delta T (FCCU_DELTA_T).....	3123
62.10.25	IRQ Alarm Enable (FCCU_IRQ_ALARM_ENn).....	3124
62.10.26	NMI Enable (FCCU_NMI_ENn).....	3125

Section number	Title	Page
62.10.27	Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN n).....	3126
62.10.28	Configuration registers.....	3127
62.10.29	FCCU_CFG register bit value sources (N and C) by event.....	3128
62.11	FCCU Output Supervision Unit.....	3129
62.12	Use cases and limitations.....	3131
62.12.1	Configuration guidelines.....	3131
62.12.2	Recommendations to configure FCCU.....	3132

Chapter 63

Self-Test Control Unit (STCU2)

63.1	Chip-specific STCU information.....	3135
63.1.1	Supported BIST sequences.....	3135
63.1.2	Configure or bypass STCU2 off-line self-tests.....	3136
63.1.3	STCU interfaces to other modules.....	3136
63.1.4	On-line LBIST and MBIST clock configuration.....	3137
63.1.5	STCU2_PLL_CFG configuration of PLLDIG_PLL0DV.....	3138
63.1.6	Wait time for writing to the on-line registers.....	3138
63.1.7	On-line MBIST.....	3138
63.1.8	LBIST scenarios.....	3141
63.1.9	STCU register default values.....	3145
63.1.10	AUTOLOCK_VALUE for register write access and DCF_COMPLETION value for DCF write completion.....	3146
63.2	Introduction.....	3146
63.3	Main features.....	3147
63.4	Block diagram.....	3149
63.5	IPS bus interface.....	3150
63.6	BISTs and BIST partitions.....	3151
63.6.1	Definition: BIST.....	3151
63.6.2	Definition: BIST partition.....	3151
63.6.3	Example: BIST partitions on a chip.....	3152

Section number	Title	Page
63.6.4	Types of BIST partitions.....	3152
63.7	BIST sequences.....	3152
63.7.1	Definition: BIST sequence.....	3152
63.7.2	STCU2 executes MBISTs before LBISTs.....	3152
63.7.3	Example: Single-phase BIST sequence.....	3153
63.7.4	Example: Multiphase BIST sequence.....	3153
63.7.5	Types of BIST sequences.....	3153
63.7.6	Supported BIST sequences.....	3154
63.7.7	Definition: Default offline BIST sequence.....	3154

66.4.4	CSE Error Code Register (CSE_ECR).....	3272
66.4.5	CSE Command Register (CSE_CMD).....	3273
66.4.6	CSE Parameter Register (CSE_Pn).....	3274
66.5	CSE functional description.....	3274
66.5.1	Host interface.....	3274
66.5.2	Command processing.....	3275
66.5.3	Secure storage.....	3276
66.5.4	Encryption and decryption.....	3278
66.5.5	Message authentication.....	3278
66.5.6	Secure boot.....	3279

Section number	Title	Page
66.5.7	Random number generation.....	3280
66.5.8	Error handling.....	3280
66.6	CSE commands.....	3282
66.6.1	Encrypt ECB.....	3282
66.6.2	Encrypt CBC.....	3283
66.6.3	Decrypt ECB.....	3283
66.6.4	Decrypt CBC.....	3283
66.6.5	Generate MAC.....	3284
66.6.6	Verify MAC.....	3284
66.6.7	Load Key.....	3285
66.6.8	Load Plain Key.....	3286
66.6.9	Export RAM Key.....	3286
66.6.10	Initialize RNG.....	3286
66.6.11	Extend PRNG Seed.....	3287
66.6.12	Generate Random Number.....	3287
66.6.13	Secure Boot.....	3288
66.6.14	Boot Failure.....	3288
66.6.15	Boot OK.....	3288
66.6.16	Get ID.....	3289
66.6.17	Cancel.....	3289
66.6.18	Debug Challenge.....	3289
66.6.19	Debug Authorization.....	3290
66.6.20	Generate TRNG Random Number.....	3290
66.6.21	Initialize CSE.....	3291
66.6.22	Miyaguchi-Preneel (MP) Compression.....	3291

Chapter 67

Password and Device Security Module (PASS)

67.1	Chip-specific PASS information.....	3293
67.1.1	Accesses to unimplemented PASS registers.....	3293

Section number	Title	Page
67.1.2	PASS_LOCKm_PGn register bit mapping.....	3293
67.1.3	PASS chip select (client select).....	3297
67.1.4	Flash memory read protection scenarios.....	3297
67.1.5	Debug Interface Access.....	3298
67.1.6	Duration of Debug Interface Access via JTAG password.....	3299
67.1.7	Production Disable enablement.....	3299
67.1.8	PASS_LCSTAT[LIFE] value source.....	3300
67.2	Introduction.....	3300
67.2.1	Overview.....	3300
67.2.2	Features.....	3301
67.2.3	Modes of operation.....	3301
67.3	Memory map and register definition.....	3301
67.3.1	Life Cycle Status Register (PASS_LCSTAT).....	3303
67.3.2	Challenge Selector Register (PASS_CHSEL).....	3304
67.3.3	Challenge Status Register (PASS_CSTAT).....	3305
67.3.4	Challenge Input Register (PASS_CINn).....	3305
67.3.5	Password Group <i>n</i> - Lock 0 Status Register (PASS_LOCK0_PGn).....	3306
67.3.6	Password Group <i>n</i> - Lock 1 Status Register (PASS_LOCK1_PGn).....	3308
67.3.7	Password Group <i>n</i> - Lock 2 Status Register (PASS_LOCK2_PGn).....	3309
67.3.8	Password Group <i>n</i> - Lock 3 Status Register (PASS_LOCK3_PGn).....	3310
67.4	DCF clients.....	3313
67.4.1	Censorship.....	3314
67.4.2	Production Disable.....	3314
67.5	Functional description.....	3316
67.5.1	Censorship.....	3316
67.5.2	Debug Interface Access.....	3316
67.5.3	Flash Memory Read Protection.....	3317

Section number	Title	Page
67.5.4	Production Disable.....	3317
67.6	Initialization/application information.....	3318
67.6.1	Reset.....	3318
67.6.2	Setting lock bits in a password group.....	3318

Chapter 68 Tamper Detection Module (TDM)

68.1	Chip-specific TDM information.....	3321
68.1.1	Disabling the override of tamper detection.....	3321
68.1.2	TDRn_LOCKm DCF client bit mapping.....	3322
68.1.3	OTPENn DCF client bit mapping.....	3325
68.2	Overview.....	3328
68.3	Features.....	3329
68.4	External signal description.....	3329
68.5	DCF clients.....	3330
68.5.1	Diary Base Address (DBA) DCF client.....	3330
68.5.2	Tamper Region Override (TO) DCF client.....	3331
68.5.3	Software Tamper Region Override Disable (STO_DIS) DCF client.....	3332
68.5.4	One Time Programmable Enable (OTPEN0) DCF client.....	3333
68.5.5	One Time Programmable Enable (OTPEN1) DCF client.....	3334
68.5.6	One Time Programmable Enable (OTPEN2) DCF client.....	3334
68.5.7	One Time Programmable Enable (OTPEN3) DCF client.....	3335
68.5.8	Tamper Region Assignment DCF client (TDRn_LOCK0).....	3336
68.5.9	Tamper Region Assignment DCF client (TDRn_LOCK1).....	3337
68.5.10	Tamper Region Assignment DCF client (TDRn_LOCK2).....	3338
68.5.11	Tamper Region Assignment DCF client (TDRn_LOCK3).....	3339
68.6	Memory Map/Register Definition.....	3339
68.6.1	TDR Status Register (TDM_TDRSR).....	3340
68.6.2	Last Flash Programmed Address Register (TDM_LFPAR).....	3342
68.6.3	Diary Base Address (TDM_DBA).....	3343

Section number	Title	Page
68.6.4	Software Tamper Override Key Region (TDM_STO_KEY _n).....	3343
68.7	Functional description.....	3344
68.7.1	Flash erase counter and tamper detection.....	3344
68.7.2	Assigning blocks to Tamper Detect Regions (TDR).....	3346
68.7.3	Diary.....	3346
68.7.4	Specifying the diary base address.....	3347
68.7.5	TDR lock status.....	3348
68.7.6	TDR override.....	3348
68.7.7	One time programmable (OTP).....	3349

Chapter 1

Preface

1.1 Overview

The primary objective of this document is to define the functionality of the MPC5777C Qorivva microcontroller for use by software and hardware developers. The MPC5777C is based on the Power Architecture® developed by Freescale/NXP.

The information in this document is preliminary and subject to change. As with any technical documentation, it is the reader's responsibility to ensure he or she is using the most recent version of the documentation.

To locate any published errata or updates for this document, visit <http://www.nxp.com>.

1.2 Device versions

This release of this document describes the functionality and programming model of maskset 3N45H.

With some exceptions, this document also describes maskset 2N45H. For information about 2N45H's differences from 3N45H, see the MPC5777C Reference Manual Addendum (document number MPC5777CRMAD).

1.3 Audience

This manual is intended for system software and hardware developers and applications programmers who want to develop products with the MPC5777C. It is assumed that the reader understands operating systems, microprocessor system design, basic principles of software and hardware, and basic details of the Power Architecture.

1.4 Document organization

This document includes two major sets of chapters.

Table 1-1. Chapter sets

Chapters or chapter groups	Description
Introduction Signal Description ¹ Memory Map, Interrupts, and DMA Requests Device Configuration Format (DCF) Records	Contain information that applies to all components on the chip
Core and system modules Clocking Memories and memory interfaces Analog measurement modules Timers Communication interfaces Reset and boot Power management Debug Safety modules Security modules	Detail particular areas of functionality, including individual modules on the chip

1. Details about external signal functions, their static electrical characteristics, and pad configuration settings for this chip appear in the spreadsheet that is embedded within this document: `MPC5777C_System_IO_Definition.xlsx`. To access this spreadsheet, view the document's list of attachments.

1.5 Conventions

1.5.1 Numbering systems

The following suffixes identify different numbering systems:

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is written 101b. In some cases, binary numbers are shown with the prefix <i>0b</i> .
d	Decimal number. Decimal numbers are followed by this suffix only when the possibility of confusion exists. In general, decimal numbers are shown without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is written 3Ch. In some cases, hexadecimal numbers are shown with the prefix <i>0x</i> .

1.5.2 Typographic notation

The following typographic notation is used throughout this document:

Example	Description
<i>placeholder, x</i>	Items in italics are placeholders for information that you provide. Italicized text is also used for the titles of publications and for emphasis. Plain lowercase letters are also used as placeholders for single letters and numbers.
code	Fixed-width type indicates text that must be typed exactly as shown. It is used for instruction mnemonics, directives, symbols, subcommands, parameters, and operators. Fixed-width type is also used for example code. Instruction mnemonics and directives in text and tables are shown in all caps; for example, BSR.
SR[SCM]	A mnemonic in brackets represents a named field in a register. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets and separated by a colon represent either: • A subset of a register's named field For example, REVNO[6:4] refers to bits 6–4 that are part of the COREREV field that occupies bits 6–0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7–0 of the XAD bus.

1.5.3 Special terms

The following terms have special meanings:

Term	Meaning
asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as <i>negated</i>.
reserved	Refers to a memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior. • Do not modify the default value of a reserved programming setting, such as the reset value of a reserved register field. • Consider undefined locations in memory to be reserved.
w1c	Write 1 to clear: Refers to a register bitfield that must be written as 1 to be "cleared."

1.6 References

In addition to this reference manual, the following documents provide information about the operation of the MPC5777C:

- MPC5777C Reference Manual Addendum (document number MPC5777CRMAD)
- MPC5777C Data Sheet (document number MPC5777C)
- *e200z759n3 Core Reference Manual* (document number e200z759n3CRM)
- *Safety Manual for MPC5777C* (document number MPC5777CSM)

Chapter 2

Introduction

2.1 Overview

The MPC5700 family of devices is closely compatible with the MPC5600 families, while introducing new features coupled with high performance CMOS technology to provide substantial cost reduction per feature and significant performance improvement. This document summarizes features and critical performance parameters of the MPC5777C.

The two e200z7 host processor cores of the MPC5777C are compatible with the Power Architecture Book E architecture. They are 100% user-mode compatible (with floating point library) with the classic PowerPC instruction set. The Book E architecture has enhancements that improve the architecture's fit in embedded applications. In addition to the standard and VLE Power Architecture instruction sets, the cores of the MPC5777C have instruction support for digital signal processing (DSP).

The MPC5777C has two levels of memory hierarchy: separate 16 KB instruction and 16 KB data caches for each of two cores and 512 KB of on-chip SRAM as well as 8 MB of internal flash memory. An external bus interface is also available for special packaged parts to support application development and calibration.

2.2 Device Description

2.2.1 Family comparison

The following table summarizes major features of the family of devices defined in this document and compares the family with predecessor families of similar devices. The feature column represents a combination of module names and capabilities of certain modules.

Table 2-1. Family comparison

Feature	MPC5565	MPC5567	MPC5566	MPC5674F	MPC5676R	MPC5777C
Process	130 nm	130 nm	130 nm	90 nm	90 nm	55 nm
Core	z6	z6	z6	z7	z7 ¹	z7 ¹

Low power modes	No	No	No	Stop mode Slow mode	Stop mode Slow mode	Stop mode Slow mode

1. There are two cores on the MPC5777C and MPC5676R. Both cores have identical features.
2. External Bus Interface (EBI) is not available on 416 PBGA
3. Calibration bus is combined with EBI.
4. External 3.3V may be needed for external 3.3V pins.

2.2.2 Block diagram

The following figure shows a top-level block diagram of the MPC5777C. The purpose of the block diagram is to show the general interconnection of functional modules through the crossbar switch.

Figure 2-1. MPC5777C block diagram

2.2.3 Packages

The MPC5777C is offered in the following package types:

- 416-ball MAPBGA, 1 mm ball pitch, 27 mm × 27 mm outline, without EBI
- 516-ball MAPBGA, 1 mm ball pitch, 27 mm × 27 mm outline, with EBI
- VertiCal Calibration System, which includes EBI

2.2.4 Features summary

On-chip modules available within the family include the following features:

- Three dual issue, 32-bit CPU core complexes (e200z7), two of which run in lockstep
 - Power Architecture embedded specification compliance
 - Instruction set enhancement allowing variable length encoding (VLE), optional encoding of mixed 16-bit and 32-bit instructions, for code size footprint reduction
 - On the two computational cores: Signal processing extension (SPE1.1) instruction support for digital signal processing (DSP)
 - Single-precision floating point operations
 - On the two computational cores: 16 KB I-Cache and 16 KB D-Cache
 - Hardware cache coherency between cores
- 16 hardware semaphores
- 3-channel CRC module
- 8 MB on-chip flash memory
 - Supports read during program and erase operations, and multiple blocks allowing EEPROM emulation
- 512 KB on-chip general-purpose SRAM including 64 KB standby RAM
- Two multichannel direct memory access controllers (eDMA)
 - 64 channels per eDMA
- Dual core Interrupt Controller (INTC)
- Dual phase-locked loops (PLLs) with stable clock domain for peripherals and frequency modulation (FM) domain for computational shell
- Crossbar Switch architecture for concurrent access to peripherals, flash memory, or RAM from multiple bus masters with End-To-End ECC
- External Bus Interface (EBI) for calibration and application use
- System Integration Unit (SIU)
- Error Injection Module (EIM) and Error Reporting Module (ERM)
- Four protected port output (PPO) pins
- Boot Assist Module (BAM) supports serial bootload via CAN or SCI
- Three second-generation Enhanced Time Processor Units (eTPUs)
 - 32 channels per eTPU
 - Total of 36 KB code RAM
 - Total of 9 KB parameter RAM
- Enhanced Modular Input/Output System (eMIOS) supporting 32 unified channels with each channel capable of single action, double action, pulse width modulation (PWM) and modulus counter operation
- Two Enhanced Queued Analog-to-Digital Converter (eQADC) modules with:
 - Two separate analog converters per eQADC module
 - Support for a total of 70 analog input pins, expandable to 182 inputs with off-chip multiplexers

- Interface to twelve hardware Decimation Filters
- Enhanced "Tap" command to route any conversion to two separate Decimation Filters
- Four independent 16-bit Sigma-Delta ADCs (SDADCs)
- 10-channel Reaction Module
- Ethernet (FEC)
- Two PSI5 modules
- Two SENT Receiver (SRX) modules supporting 12 channels
- Zipwire: SIPI and LFAST modules
- Five Deserial Serial Peripheral Interface (DSPI) modules
- Five Enhanced Serial Communication Interface (eSCI) modules
- Four Controller Area Network (FlexCAN) modules
- Two M_CAN modules that support FD
- Fault Collection and Control Unit (FCCU)
- Clock Monitor Units (CMUs)
- Tamper Detection Module (TDM)
- Cryptographic Services Engine (CSE)
 - Complies with *Secure Hardware Extension (SHE) Functional Specification Version 1.1* security functions
 - Includes software selectable enhancement to key usage flag for MAC verification and increase in number of memory slots for security keys
- PASS module to support security features
- Nexus development interface (NDI) per IEEE-ISTO 5001-2003 standard, with some support for 2010 standard
- Device and board test support per Joint Test Action Group (JTAG) IEEE 1149.1 and 1149.7
- On-chip voltage regulator controller (VRC) that derives the core logic supply voltage from the high-voltage supply
- On-chip voltage regulator for flash memory
- Self Test capability

Chapter 3

Signal Description

3.1 Production packages

The following production packages are available for the MPC5777C:

- BGA416
- BGA516

The 516 BGA is a superset of the 416 BGA. Compared to the BGA416, BGA516 contains the EBI, additional GPIO and analog inputs, and added multiplexing options.

Case number and outline drawings for each package are provided in the MPC5777C data sheet.

3.2 Emulation packages

The following emulation packages are available for the MPC5777C:

- BGA552

The case outline drawing for the emulation packages is provided in the MPC5777C data sheet.

3.3 Pad ring and ball maps

Refer to the MPC5777C data sheet for ball-map figures.

3.4 Pin function selection

3.4.1 Pad output multiplexing

Most pins on the package support more than one output function. The selection of which function is driven to the pin is done by a set of Port Control Registers (SIU_PCR) within the SIU module. These registers also configure electrical attributes such as drive strength and pull up/down selection. Refer to the SIU_PCR section of the SIU chapter for more information.

3.4.2 Pin input multiplexing

Some modules in this device are allowed to receive input signals from multiple package pins. The selection of which pin drives the function is done by a set of Input Multiplexing Registers (SIU_IMUX) within the SIU module. Refer to the SIU_IMUX section of the SIU chapter for more information.

3.4.3 LVDS signal selection

A pin that is driven by a signal from a 5V pad or from an LVDS pad has a single PCR controlling both signals. Different values of PA select either the 5V signal or the LVDS signal. Note that a single LVDS pad supplies two signals: a "true" and a "complement" output. This means that one LVDS pad drives two balls, but each ball has a separate PCR (and PA field). The two LVDS signals are enabled only when the PA values in both PCRs are set to select LVDS operation. Both LVDS signals are deselected when either PA is set to a value that deselects its LVDS signal. The ball that has its PA field still set to LVDS will go to an undriven state until its PA field is updated to a non-LVDS value.

The following table is an example of the options for PA on two balls, where LVDS "true" and LVDS "complement" LVDS outputs are multiplexed with SCK_C and SINC.

Table 3-1. LVDS example

PCR235 ¹ PA selection	PCR236 ² PA selection	SCKC ball function	SINC ball function
SCKC	SINC	SCKC	SINC
LVDS	LVDS	SCK_C_LVDS_P	SCK_C_LVDS_N
SCKC	LVDS	SCKC	undriven
LVDS	SINC	undriven	SINC

1. SCKC_SCK_C_LVDS_P_GPIO235

2. SINC_SCK_C_LVDS_N_GPIO236

Table 3-2 lists all LVDS pads available on the MPC5777C and respective SIU PCR configuration registers and PA values. When LVDS TX functions are enabled on the balls, they can be configured to operate in LFAST mode or Micro-Second Bus mode. Also, LVDS RX pads can be configured to increase bias current and enhance timing performance. **Table 3-3** lists the register bits used to configure LVDS pad operating modes.

NOTE

Differential signal output swing can be configured on MPC5776R LVDS pads. This feature is not available on MPC5777C LVDS pads.

Table 3-2. LVDS function selection

LVDS function	Pin polarity	Description	SIU_PCR[PA] configuration
SIPI_TX	–	SIPI Transmit LVDS Neg Terminal	PCR208[PA]=100b AND PCR209[PA]=100b
	+	SIPI Transmit LVDS Pos Terminal	
SIPI_RX	+	SIPI Receive LVDS Pos Terminal	PCR212[PA]=100b AND PCR213[PA]=100b
	–	SIPI Receive LVDS Neg Terminal	
SCK_C_LVDS	+	MSC LVDS+ downstream signal positive output clock	PCR235[PA]=10b AND PCR236[PA]=10b
	–	MSC LVDS– downstream signal negative output clock	
SOUT_C_LVDS	+	MSC LVDS+ downstream signal positive output data	PCR237[PA]=10b AND PCR238[PA]=10b
	–	MSC LVDS– downstream signal negative output data	
SCK_D_LVDS	+	MSC LVDS+ downstream signal positive output clock	PCR240[PA]=10b AND PCR241[PA]=10b
	–	MSC LVDS– downstream signal negative output clock	
SOUT_D_LVDS	+	MSC LVDS+ downstream signal positive output data	PCR242[PA]=011b AND PCR243[PA]=011b
	–	MSC LVDS– downstream signal negative output data	

Table 3-3. LVDS pad operating modes

LVDS function	Configuration register/bit	Value	Pad effect
SIPI_TX	LFAST LCR/LVTXOP	0	Micro-Second Bus mode
		1	LFAST mode
SIPI_RX	LFAST LCR/LVRXOP[0]	0	Normal I _{bias} current to RX comp block
		1	Increased I _{bias} current to RX comp block. Improves timing performance
SCK_C_LVDS	SIU PCR235/SRC[0]	0	Micro-Second Bus mode
		1	LFAST mode
SOUT_C_LVDS	SIU PCR237/SRC[0]	0	Micro-Second Bus mode
		1	LFAST mode
SCK_D_LVDS	SIU PCR240/SRC[0]	0	Micro-Second Bus mode
		1	LFAST mode

Table continues on the next page...

Table 3-3. LVDS pad operating modes (continued)

LVDS function	Configuration register/bit	Value	Pad effect
SOUT_D_LVDS	SIU PCR242/SRC[0]	0	Micro-Second Bus mode
		1	LFAST mode

3.5 External signal descriptions, multiplexing, and attributes

Details about external signal functions, their static electrical characteristics, and pad configuration settings for this chip appear in the spreadsheet that is embedded within this document:

MPC5777C_System_IO_Definition.xlsx

To access this spreadsheet, view the document's list of attachments.

The signal properties and their electrical characteristics are set in the SIU's Pad Configuration Registers (PCRs).

3.5.1 IBE and OBE control special cases

The "input buffer enable" and/or "output buffer enable" of some signals are not controlled by the IBE/OBE bits of the corresponding SIU_PCR. The following tables list these special-case signals:

- IBE always ON: [Table 3-4](#)
- OBE always ON: [Table 3-5](#)
- IBE and OBE always ON: [Table 3-6](#)
- IBE and/ or OBE controlled by a peripheral or controller: [Table 3-7](#)

1. ERROR0 and ERROR1 IBE are forced ON when DCF client is set to lock ERROR0/1 functions on respective pads. See [FCCU signals](#). When function is not locked, IBE control depends on FCCU control.
2. PLLCFG0 and PLLCFG1 have no function on MPC5777C. These pin names exist only for compatibility with MPC5676R.

3.5.2 FCCU signals

A DCF client, as defined in the DCF Records chapter, is used to enable ERROR0, ERROR1, and ERRORIN functions on each pin independently. If one of the ERROR functions is disabled by the DCF client at power-on reset (POR), the associated pin resets as GPIO.

If the ERROR0, ERROR1, or ERRORIN function is enabled on the pin by the DCF client bits E0E, E1E, or EINE, respectively, the ERROR function and its attributes are locked on the pin until the next POR. A reset of the device that is not a POR will not disrupt the ERROR pins' function or state.

When the ERROR function is enabled by the DCF client at POR, the following applies to the ERROR0 and ERROR1 pins:

- POR state of the pins is Hi-Z
- Input to the FCCU is enabled
- FCCU drives the output data on the pin and no muxing change can occur on the pin, but software can read the pin state via GPIO if it enables the input buffer in the corresponding PCR
- Bits in the DCF client select the open-drain or push-pull output configuration (see the DCF Records chapter for details):
 - E1OD (ERROR1)
 - E0OD (ERROR0)
- The slew rate of the ERROR0/1 pins is set to the maximum
- Weak pull up/down is disabled, which overrides the weak pull up/down configuration for the GPIO pins determined by the WKPCFG pin or WKPCFG DCF client

When the ERROR function is enabled by the DCF client at POR, the following applies to the ERRORIN pin:

- POR state of the pins is Hi-Z
- Input to the FCCU is enabled
- Weak pull up/down is disabled, which overrides the weak pull up/down configuration for the GPIO pins determined by the WKPCFG pin or WKPCFG DCF client

Chapter 4

Memory Map, Interrupts, and DMA Requests

4.1 Memory map

All addresses in the device are identified in the following table. The addresses represent the physical addresses assigned to each block. Logical addresses are translated by the MMU into physical addresses.

Under software control of the Memory Management Unit (MMU), the logical addresses allocated to IP blocks may be changed on a minimum of a 1 KB boundary.

NOTE

Address ranges not declared in the memory map table must be considered reserved.

Table 4-1. Memory map

Address range	Module
Flash memory—see Table 4-2 for details	
0x0000_0000–0x0003_FFFF	Flash memory Low/Mid Blocks (256K)
0x0004_0000–0x003F_FFFF	Reserved
0x0040_0000–0x0040_3FFF	Flash memory UTEST (16K)—see Table 4-3 for details
0x0040_4000–0x005F_FFFF	Reserved
0x0060_0000–0x0060_7FFF	Flash memory High Blocks (32K)
0x0060_8000–0x007F_FFFF	Reserved
0x0080_0000–0x00FF_FFFF	Flash memory Large Blocks (8M)
0x0100_0000–0x0FFF_FFFF	Reserved
0x1000_0000–0x1FFF_FFFF	Emulation remapping of flash memory using MMU
External memory	
0x2000_0000–0x3FFF_FFFF	External Bus Memory
System RAM	
0x4000_0000–0x4000_FFFF	Standby SRAM on XBAR Slave Port 2 (64 KB)
0x4001_0000–0x4003_FFFF	SRAM on XBAR Slave Port 2 (192 KB)

Table continues on the next page...

Table 4-1. Memory map (continued)

Address range	Module
0x4004_0000–0x4007_FFFF	SRAM on XBAR Slave Port 4 (256 KB)

1. Programmed by NXP during test. Contains the temperature sensor and bandgap ADC readings to be used by software to improve the accuracy of the temp sensor readings.
2. Programmed by NXP during test. In production devices, UTEST is sealed (one-time programmable) from the factory.
3. Programmed by the customer to select which blocks cannot be tested in Failure Analysis.
4. Secondary location that can be programmed by the customer to select which blocks cannot be tested in Failure Analysis.
5. Programmed by NXP to include ECC/EDC errors to allow testing of ECC/EDC hardware.

Interrupt vector assignments

6. Programmed by NXP during test. The UID includes information on wafer lot, X/Y-position on the wafer, manufacturing data, test results, and company ID (65 for NXP).
7. Protected from read operations by flash memory BIU from OEM Production life cycle. Programmed by customer. Becomes unreadable (hidden) as soon as customer programs life cycle to OEM Production or later.
8. MCU Production life cycle slot. Programmed by NXP during test.
9. Customer Delivery life cycle slot. Programmed by NXP during test.
10. OEM Production life cycle slot. Programmed by customer during ECO module production/test.
11. In Field life cycle slot. Programmed by customer during ECO module production/test.
12. Failure Analysis life cycle slot. Programmed by the customer on returned modules.
13. DCF start record. Programmed by NXP during test. Contiguous list of DCF records start at this address.
14. Contiguous list of DCF records. Initial records programmed by NXP. Subsequent records added to the end of the list by the customer.
15. Programmed by the customer.

4.2 Interrupt vector assignments

NOTE

The following table shows the mapping between interrupt sources and interrupt vectors. Some interrupt sources have a separate mechanism for enabling the interrupt, such as an interrupt enable register field. To support the mapping between a source and a vector, any such separate mechanism must be set to enable the interrupt source.

Table 4-4. Interrupt vectors and request sources

Offset	Vector	Source	Module	Description
0x0000	0	INTC_SSCIR0[CLR0]	Software	INTC software settable Clear flag 0
0x0010	1	INTC_SSCIR1[CLR1]	Software	INTC software settable Clear flag 1

4.3 DMA request mapping

This chip has two separate eDMA controllers: eDMA_A and eDMA_B. Each has 64 channels.

The following tables show the sources of DMA requests for each controller.

Table 4-5. eDMA_A channel request allocation

Channel	Requesting source	Description
0	EQADC_A_FISR0[CFFF0]	EQADC_A Command FIFO 0 Fill Flag
1	EQADC_A_FISR0[RFDF0]	EQADC_A Receive FIFO 0 Drain Flag
2	EQADC_A_FISR1[CFFF1]	EQADC_A Command FIFO 1 Fill Flag
3	EQADC_A_FISR1[RFDF1]	EQADC_A Receive FIFO 1 Drain Flag

Chapter 5

Device Configuration Format (DCF) Records

5.1 Overview

Device Configuration Format (DCF) records are used by the System Status and Configuration Module (SSCM) to configure certain registers in the device during system boot while the reset signal is asserted.

There are two kinds of DCF records:

- Factory-written DCF records: written to UTEST flash memory by the factory.
- User-supplied DCF records: written to UTEST flash memory by the user.

The following figure is a high-level conceptual representation of the functionality of DCF records.

Figure 5-1. Conceptual representation of DCF record functionality

5.2 DCF records in boot sequence

The following is a high-level summary of the boot sequence leading to the use of DCF records:

1. When power is applied to a properly programmed device, the Power Management Controller (PMC) takes control of the device.
2. After the system power supplies have reached predefined levels, the flash memory array is initialized and the SSCM is enabled.
3. The SSCM reads the DCF records.
4. The SSCM writes the configuration information to the specified registers.
5. After registers are initialized: If the STCU2 is enabled by DCF record information, it begins executing the tasks enabled by its DCF record configuration.

5.3 DCF records location

Factory-written DCF records start at the first address allocated to the DCF records in the UTEST flash memory area. See the UTEST flash memory map.

User-supplied UTEST DCF records may be added at the next location in the UTEST memory map immediately following the factory-written UTEST DCF records.

5.4 DCF record structure

A DCF record is a contiguous double-word (64-bit) entry consisting of the following:

- Control word: Information to locate the corresponding DCF client internal to the device (pointer to the location of a register internal to the device)
- Data word: Data to be written to that client

Figure 5-2. DCF record structure

Table 5-1. DCF record field descriptions

Field	Name	Description
0-31	Data[0:31]	32 bits of data to be written to the DCF client
32-46	CS _n	Chip Select <i>n</i> For each DCF record, one Chip Select bit is asserted (1b) to select the target module for the DCF client. All other Chip Select bits per DCF record should be negated (0b).
47-61	Address[16:2]	Address of the DCF client within the selected module NOTE: Address decoding for DCF clients may not match the standard software address map decoding. Details of DCF client addresses are defined in each applicable module chapter.
62	Parity	Parity bit for the DCF record
63	Stop	Stop bit Indicates the end of the list of DCF records. 0 indicates the DCF record is not the end of the list 1 indicates the DCF record is the end of the list NOTE: The erased state of flash memory is 0xFFFF_FFFF_FFFF_FFFF. As a result, the list ends with the first unprogrammed double word. This location can be programmed with a new record to extend the list.

5.5 DCF records sequence

DCF records must appear as contiguous series of entries programmed from the beginning of the UTEST flash memory area in the following order.

DCF records sequence

1. **Start DCF record:** The first DCF record must be a start record. This record must be found at the beginning of a DCF area in flash memory to indicate to the device that the following records must be processed.
2. **DCF records containing configuration data:** DCF records containing configuration data must immediately follow the start record with no blank records in between.
3. **Stop DCF record:** The end of the configuration records is indicated by the stop record. A record with the stop bit set is a stop record. All other bits are ignored. No DCF records following the stop record are processed.

SSCM recognizes the following record as a start record.

Table 5-2. DCF start record

0x00 (0:31)	0x04 (32:63)
0x05AA_55AF	0x0000_0000

The start bit is set by the factory at the beginning of the UTEST flash memory area.

SSCM recognizes the following record as a stop record.

Table 5-3. DCF stop record

0:31	32:62	63
Ignored	Ignored	1

The stop bit is never set by the factory, since this would not allow the user to add DCF records. The flash memory location following the last factory-written UTEST DCF record is unprogrammed, with the content of 0xFFFF_FFFF. This is interpreted as the stop record, since the stop bit is set.

User-supplied DCF records may be added in a contiguous manner immediately following the factory-written DCF records. There must never be an unprogrammed record in the series of DCF records as it will be interpreted as a stop record.

The following table shows the series of DCF records when *n* data records are stored in the UTEST flash.

Table 5-4. Series of DCF records in UTEST flash memory

Record type	ADDR offset	DATA	
Start record	0x00	0x05AA_55AF	
	0x04	0x0000_0000	STOP=0

Table continues on the next page...

Table 5-4. Series of DCF records in UTEST flash memory (continued)

Record type	ADDR offset	DATA			
Data records	0x08	WDATA[31:0]			
	0x0C	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
	0x10	WDATA[31:0]			
	0x14	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
	...	...			
Stop record	$8n-1 + 0x0$	Reserved			
	$8n-1 + 0x4$	Reserved			1
	$8n + 0x0$				
	$8n + 0x4$				

It is possible for more than one DCF Record to write to the same DCF client. In this case the later record usually overrides a DCF client value set by a previous record. However, not all DCF clients allow overwrites; this depends on the DCF client implementation.

**Figure 5-3. Appending DCF records**

5.6 DCF client Chip Select module assignments

The following table shows the Chip Select (CS) for each group of DCF clients. A CS can be assigned to one module or multiple modules, as indicated. CSs not listed are reserved.

Table 5-5. DCF client CS module assignments

CS	DCF client target module(s)
CS[0]	Reserved
CS[1]	SSCM (Reserved)

CS[4]	Tamper Detect (TDM)
CS[5]	Reserved
CS[6]	Reserved
CS[7]	Miscellaneous CSE Secure Boot Configurations Analog Oscillator Configurations ERROR Functions Pads Configuration Reset Escalation PMC Trimming

5.7 DCF clients

DCF clients are 32-bit-wide hardware registers inside a module that receive and store the data from a DCF record. This stored data is used to initialize registers and to configure features. Their characteristics include:

- DCF clients have a default value before any DCF records are written.
- DCF clients are not required to implement all 32 bits.

The following table below shows the DCF clients that are available in this chip's UTEST area of flash memory. The following list of terms defines the meaning of the table's column headings.

DCF CS: Chip Select

The CS field is a 15-bit field with each bit in the field assigned to a particular module. These bits act as module select signals for the internal modules. Only one bit in this field should be set in a DCF record.

DCF Address[10:2]

The Address[16:2] field of a DCF record specifies an internal address for a DCF client. The following table provides the Address[10:2] portion of the field. The address is used only by the SSCM when interpreting DCF records and writing the data to specified modules.

DCF client description

This entry contains the name of the DCF client.

DCF client reset value

This field contains one of the following:

- the reset value of the DCF client before the SSCM writes the client with the associated DCF record
- a factory-programmed value

DCF client target module

This entry identifies the module that uses the DCF client information.

DCF client special strategy

Special requirements apply to how some DCF clients are written. The SSCM examines the DCF client to determine any correct special strategy to use and then appropriately writes a DCF record to that client.

None

No special DCF strategy is used.

Parity

On this chip, parity is implemented only for PMC DCF clients.

Triple Voted

DCF clients that use the Triple Voted strategy have three copies of the register. The SSCM writes to all three registers in a single write cycle. The outputs of the three registers are majority voted together to determine the correct data value. Triple voting allows a bit-flip error to occur without changing the DCF client output data.

write_once

A register using the Write Once strategy can only be written once. The DCF client ignores subsequent writes.

CAUTION

Plan carefully before writing write-once DCF clients. Any DCF client that has a write-once attribute cannot be reprogrammed by user software until the next reset or by more than one DCF record. Subsequent DCF records are ignored.

wr0_only: Write 0 only

A bit in a DCF client can be written only from a logic 1 to a logic 0. An attempt to write a bit with this attribute to a logic 1 is ignored.

wr1_only: Write 1 only

A bit in a DCF client can be written only from a logic 0 to a logic 1. An attempt to write a bit with this attribute to a logic 0 is ignored.

Any UTEST DCF client can be programmed as UTEST non-differential.

Table 5-6. UTEST DCF clients

DCF CS[14:0]	DCF Address[10:2]	DCF client description	DCF client reset value (hex)	DCF client target module	DCF client special strategy

1. See Miscellaneous DCF client description

2. Be careful when programming the UTEST Miscellaneous, XOSC ANA, and VREG Enable DCF clients. DCF records are processed sequentially in the order they are read from flash memory. DCF records that control actions such as enabling/disabling voltage regulators or detectors should not be programmed more than once with different values.

5.7.1 UTEST Miscellaneous DCF client

This is a 32-bit Triple-Voting DCF Client that implements a variety of settings related to different modules and functionalities, such as boot settings on SIU, oscillator trimming, oscillator enable/disable, and lockstep mode selection. The reset value indicated below is the value when no DCF record has been read or written.

NOTE

Be careful when programming the UTEST Miscellaneous, XOSC ANA, and VREG Enable DCF clients. DCF records are processed sequentially in the order they are read from flash

memory. DCF records that control actions such as enabling/disabling voltage regulators or detectors should not be programmed more than once with different values.

Figure 5-4. UTEST Miscellaneous DCF client

Table 5-7. UTEST Miscellaneous DCF client field descriptions

Field	Description
0 LEG	Legacy Mode. This bit indicates whether the WKPCFG, ABR, and BOOTCFG settings should come from package pins or from the Miscellaneous DCF client. 0 Settings come from this DCF client 1 Settings driven from pins
1-7 XOSC_CNT	Oscillator Stabilization Counter. These seven bits are used to pre-load a counter clocked by the crystal oscillator. Upon reset negation, the counter runs for 512 x XOSC_CNT clock cycles, then sets the XOSC flag in the SIU_RSR register.
8-11 Reserved	Reserved
12 WKPCFG	Weak Pull Configuration. SIU_RSR stores this configuration during reset. This information is then used to configure pull up/down of external pins. 0 Weak pulldown is selected 1 Weak pullup is selected
13 ABR	Auto Baud Rate. SIU_RSR stores this configuration during reset. This information is then used by the Boot Code to configure the Auto Baud Rate feature. 0 Auto Baud Rate disabled 1 Auto Baud Rate enabled

Table continues on the next page...

Table 5-7. UTEST Miscellaneous DCF client field descriptions (continued)

Field	Description
14-15 BOOTCFG	Boot Mode Selection. SIU_RSR stores this configuration during reset. This information is then used to by the Boot Code to configure the boot sequence. 00 Internal boot mode 01 Serial boot mode 10 Non-Muxed EBI boot mode (16-bit data, non-muxed address bus) 11 Muxed EBI boot mode (16-bit data, muxed address bus)
16 Reserved	Reserved
17 XOSC_ALC_DIS	Oscillator Automatic Level Controller 0 Automatic level controller enabled 1 Automatic level controller disabled
18 XOSC_LF_EN	Oscillator Low Setting Selection Set this bit to 1 only when XOSC_EN_HIGH is 0. Setting this bit to 1 when XOSC_EN_HIGH is 1 selects a high setting, but this combination is not recommended.¹ 0 Oscillator is used for medium or high setting 1 Oscillator is used for low setting
19-20 Reserved	Reserved
21 XOSC_EN_HIGH	Oscillator Medium or High Setting Selection If the LEG bit is 0, this field is loaded by the SSCM during reset into the XOSCHIGH bit of SIU_RSR. This bit determines whether the oscillator operates at medium or high setting. Use this bit to select between medium or high setting when XOSC_LF_EN is 0. Setting this bit to 1 when XOSC_LF_EN is 1 selects a high setting, but this combination is not recommended.¹ 0 Oscillator at medium setting 1 Oscillator at high setting
22 Reserved	Reserved
23 LOCKSTEP_EN	Lockstep Mode. This bit is used to enable the Safety Core to be in lockstep with the Core1. 0 Lockstep disabled 1 Lockstep enabled
24 XOSCEN	Crystal Oscillator Enable. This bit is used to enable the crystal oscillator. If disabled, an external clock source can be connected to the EXTAL pin, with the oscillator working in bypass mode. 0 Crystal oscillator disabled, bypass mode with clock sourced from EXTAL pin. 1 Oscillator enabled, crystal connected.
25 XOSC_EXT_CLOAD	Oscillator External Cap 0 Selects oscillator internal cap: acceptable for oscillators that require load capacitance of 10 pF or less 1 Selects oscillator external cap: required for oscillators that have load capacitance of 10 pF or greater

Table continues on the next page...

Table 5-7. UTEST Miscellaneous DCF client field descriptions (continued)

Field	Description
26-30 XOSC_LOAD_CAP_SEL	Oscillator Load Capacitance Selection. Five bits to program the load capacitance. Load capacitor values are determined by the crystal manufacturer data sheet.

1. "Low" is the setting commonly used for crystals at 8 MHz, "medium" is commonly used for crystals greater than 8 MHz to 20 MHz, and "high" is commonly used for crystals greater than 20 MHz to 40 MHz. However, the user must characterize carefully to determine the best g_m setting for the intended application because crystal load capacitance, board layout, and other factors affect the g_m value that is needed. See the Data Sheet for additional information.

5.7.2 UTEST Secure Boot Configurations DCF client

This DCF client, in conjunction with the UTEST Secure Boot Code Address and UTEST Secure Boot Code Length clients, configures the CSE security module to carry out a secure boot in the device. This 32-bit write-once DCF client selects:

- whether the CSE module is enabled
- whether the secure boot is to be executed
- the mode (sequential or parallel) in which the secure boot runs
- whether CSE must be disabled in the Failure Analysis (FA) life cycle

The CSE module must be enabled for the secure boot to execute.

When this client selects to execute the secure boot, the boot occurs during reset on the memory space defined by the Secure Boot Code Address and Code Length DCF clients.

NOTE

This write-once DCF client is programmed at the factory with the value 0000_000Dh. This value cannot be overwritten. This configuration:

- enables CSE
- enables CSE to execute the secure boot during reset
- configures the secure boot to occur in parallel mode
- disables CSE when the life cycle advances to FA

**Figure 5-5. UTEST Secure Boot Configurations DCF client**

Table 5-8. UTEST Secure Boot Configurations DCF client field descriptions

Field	Description
0-27 Reserved	Reserved
28 FAD	CSE FA Disable Set this field to 1 to disable the CSE module when the chip's life cycle matures to Failure Analysis (FA). When CSE boots, security information such as the Security Keys is always loaded into RAM. This bit is meant to provide some protection against an MBIST-based attack to extract that security information from the RAM. 0 CSE module will not be disabled when device is matured to FA. 1 CSE module will be disabled when device is matured to FA. NOTE: If the MEN bit is set to 1, the CSE module will be disabled in FA when FAD is 1, but in FA the CSE will still maintain exclusive access to the flash memory blocks mapped to the C55FMC_LOCK1 register, PASS_LOCK1_PGn registers, and TDRn_LOCK1 DCF client.
29 SBE	Secure Boot Enable 0 Secure boot disabled. CSE will not execute the secure boot during reset. 1 Secure boot enabled. CSE will execute the secure boot during reset in parallel or serial mode as per SBM settings.
30 SBM	Secure Boot Mode 0 Secure boot runs in parallel mode. In this mode, CSE executes the secure boot in parallel with the user boot code. 1 Secure boot runs in sequential mode. In this mode, the user boot mode starts only after CSE finishes the secure boot.
31 MEN	CSE Module Enable This bit indicates that the CSE module will be used in the part. 0 CSE is not used. The CSE clock is disabled, and accesses to the registers generate a bus error. 1 CSE is enabled. NOTE: The secure boot functionality works only if MEN is set to 1. The secure boot functionality does not work if CSE is disabled.

5.7.3 UTEST Secure Boot Code Address DCF client

This DCF client, in conjunction with the UTEST Secure Boot Configurations and UTEST Secure Boot Code Length clients, configures the CSE security module to carry out a secure boot in the device. This 32-bit DCF client provides CSE with the location in memory of the boot code to be verified.

DCF clients

Figure 5-6. UTEST Secure Boot Code Address DCF client

Table 5-9. UTEST Secure Boot Code Address DCF client field descriptions

Field	Description
0-31	Secure Boot Code Address
SBCA	This 32-bit field indicates the start address of the secure boot code.

5.7.4 UTEST Secure Boot Code Length DCF client

This DCF client, in conjunction with the UTEST Secure Boot Configurations and UTEST Secure Boot Code Address clients, configures the CSE security module to carry out a secure boot in the device. This 32-bit DCF client provides CSE with the length of the secure boot code.

NOTE

Users whose applications do not use the CSE module, which is automatically enabled, should ensure that the Secure Boot Code Length DCF client has the value 0000_0000h (its default value).

Figure 5-7. UTEST Secure Boot Code Length DCF client

Table 5-10. UTEST Secure Boot Code Length DCF client field descriptions

Field	Description
0-31	Secure Boot Code Length
SBCL	This 32-bit field indicates the size in bytes of the secure boot code.

5.7.5 UTEST Analog External Oscillator (XOSC ANA) DCF client

This 32-bit DCF client is used to apply settings to the analog external oscillator. The internal current control setting is the only feature available and is used to boot the current. This setting is accessible in functional mode for test and debug purposes.

NOTE

Be careful when programming the UTEST Miscellaneous, XOSC ANA, and VREG Enable DCF clients. DCF records are processed sequentially in the order they are read from flash memory. DCF records that control actions such as enabling/disabling voltage regulators or detectors should not be programmed more than once with different values.

Figure 5-8. UTEST Analog External Oscillator DCF client

Table 5-11. UTEST Analog External Oscillator DCF client field descriptions

Field	Description
0-28 Reserved	Reserved
29-31 ICC	Internal Current Control These bits allow the internal current to be disabled (no current flowing, so the oscillator does not work), decreased, and increased. 000 No (0x) current 001 0.25x: decrease current by 25% of default current 010 0.5x: decrease current by 50% of default current 100 1x: default current, which is 10 mA 101 1.25x: increase current by 25% of default current 110 1.5x: increase current by 50% of default current 111 1.75x: increase current by 75% of default current

5.7.6 UTEST Error Functions Pads Configuration DCF client

This 32-bit Triple-Voting DCF client enables the ERROR function on the ERROR0, ERROR1, and ERRORIN pins independently.

CAUTION

The ERROR function is disabled by the DCF at power-on reset (POR). After it is enabled, the ERROR function is locked on the pin until the next POR. Any other type of reset has no effect on these settings.

Field	Description
31 E0E	ERROR0 Enable Selects multiplexing of ETPUA3 pin. 0 ETPUA3 pin function depends on PCR117 settings 1 Enables and locks ERROR0 function on ETPUA3 pin

5.7.7 UTEST Reset Escalation Configuration DCF client

This 32-bit Triple-Voting DCF client enables the Reset Escalation function on the reset sequence of the device. See the Reset chapter for further details on this feature.

CAUTION

The Reset Escalation function is disabled by the DCF at power-on reset (POR). After it is enabled, the Reset Escalation function is locked until the next POR. Any other type of reset has no effect on these settings.

**Figure 5-10. UTEST Reset Escalation Configuration DCF client****Table 5-13. UTEST Reset Escalation Configuration DCF client field descriptions**

Field	Description
0-30 Reserved	Reserved
31 REE	Reset Escalation Enable Enables a reset escalation counter that is incremented at the end of every reset cycle. If the counter exceeds the number programmed in SIU_RCR[RET], the device is locked into a reset state that can be undone only by a power-up cycle. NOTE: LVD/HVD and temperature events that are enabled in the PMC to trigger a reset cause a POR. In these cases, the reset escalation counter resets. 0 Reset Escalation disabled 1 Reset Escalation enabled

5.7.8 UTEST PMC Reset Enable Control (REE CTRL) DCF client

This DCF client trims the PMC_REE register. See the PMC chapter for details about this register.

Offset: 0000_0000_0001_1111

5.7.9 UTEST PMC Temperature Sensor Reset Event Enable Control (REE TMPSNS) DCF client

This DCF client trims the PMC_REE_TD register. See the PMC chapter for details about this register.

Figure 5-11. UTEST PMC Temperature Sensor Reset Event Enable Control DCF client

Field	Description
0-24 Reserved	Reserved
25 LDPLS	Load pulse to latch Temperature Sensor REE values 0 Load the PMC_REE_TD register with IPS bus data. 1 Load the PMC_REE_TD register with the data in this DCF client.
26-27 Reserved	Reserved
28-29 TMPSNS2	For both Temperature Sensor modules 0 and 1, REE control of temperature 2: 150°C
30-31 TMPSNS0	For both Temperature Sensor modules 0 and 1, REE control of temperature 0: -40°C

5.7.10 UTEST PMC Voltage Regulator Enable (VREG ENB) DCF client

This 32-bit DCF client implements the active low enables for three PMC voltage regulators.

NOTE

Be careful when programming the UTEST Miscellaneous, XOSC ANA, and VREG Enable DCF clients. DCF records are processed sequentially in the order they are read from flash memory. DCF records that control actions such as enabling/disabling voltage regulators or detectors should not be programmed more than once with different values.

Chapter 6

e200z7 Core Complex Overview

6.1 Core complex

The following table summarizes the cores on this chip.

Table 6-1. Core complex overview

Core identifier	Core type	Brief description
Core0	e200z759n3	Main boot computational core
Core1	e200z759n3	Duplicated computational core
Checker core	e200z758	Operates in delayed lockstep with Core1, executing exactly the same instructions to confirm correct execution

6.2 Core0 and Core1 overview

The two e200z759n3 cores are identical.

For a comprehensive core description, see the *e200z759n3 Core Reference Manual* (document number e200z759n3CRM).

See [End-to-end Error Correction Code \(e2eECC\)](#) for any limitations of the cores due to the implementation of e2eECC.

6.3 Checker core overview

The e200z758 core does not have these features of the e200z759n3 computational cores:

- Instruction cache and data cache
- Nexus 3+ module

Otherwise, the e200z758 checker core has the same features as the e200z759n3 cores.

Chapter 7

Platform Coherency Unit (PCU)

7.1 Introduction

The Platform Coherency Unit is a hardware mechanism for maintaining memory coherency between multiple bus masters. It supports cache coherency between the two cores, including writes via the Nexus read-write access block. In addition, DMA writes to system memory may be configured to provide cache coherency.

For writes originating from either core, the MMU for the core must be configured with Memory Coherence (M bit) and Write Through (W bit) set for the address spaces to be accessed. For writes originating from either DMA module, use the [Global PCU Output Register \(DMA_GPOR_n\)](#) to enable coherency on a channel-by-channel basis. Finally, set the Master Write Monitor Enable bits for each master, requiring coherency for its writes, and the global enable bit (ENB) in the PCU's configuration register.

NOTE

On predecessor devices, the Platform Coherency Unit (PCU) was named the Cache Coherency Unit (CCU).

7.2 Memory map and register descriptions

The programming model contains control and status registers. It can be referenced using only 32-bit (word) accesses. Writes to the configuration fields can be performed only in supervisor mode. Attempted accesses using non-32-bit data sizes, accesses to undefined or reserved addresses, or accesses with a non-supported access type result in a bus error termination.

PCU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	PCU Configuration and Error Status Register (PCU_CESR)	32	R/W	0300_0000h	7.2.1/172

PCU_CESR field descriptions

Field	Description
0–1 CP1ERR[1:0]	Core Processor 1 Error This field represents a flag maintained by the PCU for signaling the presence of a captured snoop error or the occurrence of a queue overflow. The error details are contained in PCU_EAR1 and PCU_EDR1. CP1ERR[1] is set when the snoop queue for Core1 has overflowed; the address and attributes of the global write that caused the queue overflow are recorded in PCU_EAR1 and PCU_EDR1. CP1ERR[0] is set when the hardware detects a snoop error and records the faulting address and attributes. This field is cleared when the corresponding bits are written as 1. If another Core1 error occurs before the CP1ERR bit is cleared, CP1ERR remains set while PCU_EAR1 and PCU_EDR1 capture address and attributes for the most recent error event. 00 PCU_EAR1/PCU_EDR1 do not contain a captured snoop error. 01 PCU_EAR1/PCU_EDR1 contain a captured snoop error. 10 PCU_EAR1/PCU_EDR1 contain a queue overflow occurrence. 11 A snoop error event occurred, followed by a queue overflow event. Because the PCU_EAR1/PCU_EDR1 registers capture the most recent error event, PCU_EAR1/PCU_EDR1 contain the queue overflow occurrence.
2–3 CP0ERR[1:0]	Core Processor 0 Error This field represents a flag maintained by the PCU for signaling the presence of a captured snoop error or the occurrence of a queue overflow. The error details are contained in PCU_EAR0 and PCU_EDR0. CP0ERR[1] is set when the snoop queue for Core0 has overflowed; the address and attributes of the global write that caused the queue overflow are recorded in PCU_EAR0 and PCU_EDR0. CP0ERR[0] is set when the hardware detects a snoop error and records the faulting address and attributes. This field is cleared when the corresponding bits are written as 1. If another Core0 error occurs before the CP0ERR bit is cleared, CP0ERR remains set while PCU_EAR0 and PCU_EDR0 capture address and attributes for the most recent error event. 00 PCU_EAR0/PCU_EDR0 do not contain a captured snoop error. 01 PCU_EAR0/PCU_EDR0 contain a captured snoop error. 10 PCU_EAR0/PCU_EDR0 contain a queue overflow occurrence. 11 A snoop error event occurred, followed by a queue overflow event. Because the PCU_EAR0/PCU_EDR0 registers capture the most recent error event, PCU_EAR0/PCU_EDR0 contain the queue overflow occurrence.
4 SRST_FLAG	Software Reset Flag This field represents a flag maintained by the PCU to indicate that a software reset event has occurred. A software reset of the PCU is invoked by programming the PCU_CESR[SRST_EN] field.

Table continues on the next page...

PCU_CESR field descriptions (continued)

Field	Description
	0 The last PCU reset event was a hardware reset event. 1 The last PCU reset event was a software-invoked reset event.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 CP1IDLE	Core Processor 1 Idle This read-only status flag indicates when the Core1 snoop queue is empty. 0 Core1 snoop queue is not empty; Core1 snoop queue is busy processing valid snoop requests to Core1. 1 Core1 snoop queue is empty.
7 CP0IDLE	Core Processor 0 Idle This read-only status flag indicates when the Core0 snoop queue is empty. 0 Core0 snoop queue is not empty; Core0 snoop queue is busy processing valid snoop requests to Core0. 1 Core0 snoop queue is empty.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 CP1IEN	Core Processor 1 Interrupt Enable This bit enables interrupt generation upon detection of a Core1 snoop request that results in an error. 0 PCU generates an interrupt request upon detection of a Core1 snoop that terminated with error. 1 PCU does not generate an interrupt request upon detection of a Core1 snoop request that terminated with error.
11 CP0IEN	Core Processor 0 Interrupt Enable This bit enables interrupt generation upon detection of a Core0 snoop request that results in an error. 0 PCU generates an interrupt request upon detection of a Core0 snoop that terminated with error. 1 PCU does not generate an interrupt request upon detection of a Core0 snoop request that terminated with error.
12–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 M3WMEN	Master 3 Write Monitor Enable This bit enables monitoring of eDMA_B for global writes. 0 Disable eDMA_B monitoring. Global writes from eDMA_B do not initiate any snoop requests. 1 Enable eDMA_B monitoring for global writes.
17 M2WMEN	Master 2 Write Monitor Enable This bit enables monitoring of eDMA_A for global writes. 0 Disable eDMA_A monitoring. Global writes from eDMA_A do not initiate any snoop requests. 1 Enable eDMA_A monitoring for global writes.
18 M1WMEN	Master 1 Write Monitor Enable This bit enables monitoring of Core1 for global writes.

Table continues on the next page...

PCU_CESR field descriptions (continued)

Field	Description
	0 Disable Core1 monitoring. Global writes from Core1 do not initiate any snoop requests. 1 Enable Core1 monitoring for global writes.
19 M0WMEN	Master 0 Write Monitor Enable This bit enables monitoring of Core0 for global writes. 0 Disable Core0 monitoring. Global writes from Core0 do not initiate any snoop requests. 1 Enable Core0 monitoring for global writes.
20–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–24 CP1DS	Core1 Disable Snoop This field allows the suspension of snooping activity targeting Core1. Snooping can be disabled universally for Core1, upon detection of a Core1 snoop termination with error or queue overflow occurrence, or upon detection of an overflow of the Core0 snoop queue. 000 Core1 snooping disabled upon detection of an overflow of the Core1 snoop queue, as flagged in PCU_CESR[CP1ERR]. When PCU_CESR[CP1ERR] is cleared, Core1 snooping activity can resume. 001 Core1 snooping disabled upon detection of an overflow of the Core1 snoop queue or upon a Core1 snoop termination with error, as flagged in PCU_CESR[CP1ERR]. Any valid entries in the Core1 snoop queue will be invalidated and will not be processed. When PCU_CESR[CP1ERR] is cleared, Core1 snooping activity can resume. 010 Core1 snooping disabled upon detection of an overflow of the Core1 snoop queue or upon detection of an overflow of the Core0 snoop queue, as flagged in PCU_CESR[CP1ERR] or PCU_CESR[CP0ERR]. Any valid entries in the Core1 snoop queue will be invalidated and will not be processed. When PCU_CESR[CP1ERR] or PCU_CESR[CP0ERR] (as applicable) is cleared, Core1 snooping activity can resume. 011 Core1 snooping disabled upon a Core1 snoop termination with error or upon detection of an overflow of either the Core1 snoop queue or the Core0 snoop queue, as flagged in PCU_CESR[CP1ERR] or PCU_CESR[CP0ERR]. Any valid entries in the Core1 snoop queue will be invalidated and will not be processed. When PCU_CESR[CP1ERR] or PCU_CESR[CP0ERR] (as applicable) is cleared, Core1 snooping activity can resume. 1xx Core1 snooping entirely disabled. Any valid entries in the Core1 snoop queue will be invalidated and will not be processed.
25–27 CP0DS	Core0 Disable Snoop This field allows the suspension of snooping activity targeting Core0. Snooping can be disabled universally for Core0, upon detection of a Core0 snoop termination with error or queue overflow occurrence, or upon detection of an overflow of the Core1 snoop queue. 000 Core0 snooping disabled upon detection of an overflow of the Core0 snoop queue, as flagged in PCU_CESR[CP0ERR]. When PCU_CESR[CP0ERR] is cleared, Core0 snooping activity can resume. 001 Core0 snooping disabled upon detection of an overflow of the Core0 snoop queue or upon a Core0 snoop termination with error, as flagged in PCU_CESR[CP0ERR]. Any valid entries in the Core0 snoop queue will be invalidated and will not be processed. When PCU_CESR[CP0ERR] is cleared, Core0 snooping activity can resume. 010 Core0 snooping disabled upon detection of an overflow of the Core0 snoop queue or upon detection of an overflow of the Core1 snoop queue, as flagged in PCU_CESR[CP0ERR] or PCU_CESR[CP1ERR]. Any valid entries in the Core0 snoop queue will be invalidated and will not be processed. When PCU_CESR[CP0ERR] or PCU_CESR[CP1ERR] (as applicable) is cleared, Core0 snooping activity can resume.

Table continues on the next page...

PCU_CESR field descriptions (continued)

Field	Description
011	Core0 snooping disabled upon a Core0 snoop termination with error or upon detection of an overflow of either the Core0 snoop queue or the Core1 snoop queue, as flagged in PCU_CESR[CP0ERR] or PCU_CESR[CP1ERR]. Any valid entries in the Core0 snoop queue will be invalidated and will not be processed. When PCU_CESR[CP0ERR] or PCU_CESR[CP1ERR] (as applicable) is cleared, Core0 snooping activity can resume.
1xx	Core0 snooping entirely disabled. Any valid entries in the Core0 snoop queue will be invalidated and will not be processed.
28–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 SRST_EN	Software Reset Enable Writing 1 to this bit invokes a software-driven reset of the PCU. On the next cycle following the programming of PCU_CESR[SRST_EN], all programming model registers in the PCU are reset, and all snoop queue entries are invalidated. Then PCU_CESR[SRST_FLAG] is set to 1 to indicate that a software-driven reset of the PCU has occurred. Writing 0 to this bit has no effect. Reading this bit returns 0. 0 No software-driven reset is requested. Writing 0 to this field has no effect. Reading this bit always returns 0. 1 Invoke software-driven reset.
31 ENB	PCU Enable This bit provides a global enable/disable for the PCU. While the PCU is disabled, hardware coherency checking is not performed. 0 The PCU is disabled. 1 The PCU is enabled.

7.2.2 PCU Error Address Register, Core n (PCU_EAR_n)

This register can be read in all modes.

Address: 0h base + 10h offset + (16d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	EADDR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PCU_EAR_n field descriptions

Field	Description
0–31 EADDR	Error Address This read-only field is the reference address associated with the global write that resulted in a snoop error or overflow event.

7.2.3 PCU Error Detail Register, Core n (PCU_EDRn)

This register can be read in all modes.

Address: 0h base + 14h offset + (16d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	EMSTR				EPTR				ESTAMP								0		EPROT				ERESP				0					
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

PCU_EDRn field descriptions

Field	Description
0–3 EMSTR	Error Master This read-only field holds the AHB master ID associated with the global write that resulted in a snoop error or overflow event.
4–7 EPTR	Error Pointer This read-only field holds the value of the queue pointer associated with the global write that resulted in a snoop error or overflow event. Upon a snoop error event, this field describes the relative position of the corresponding entry in the 16-entry queue for the global write that resulted in a snoop error. Upon a queue overflow event, this field describes the relative position of the corresponding entry in the 16-entry queue for the global write that resulted in an overflow event.
8–15 ESTAMP	Error Time Stamp This read-only field holds the time stamp value associated with the snoop error or overflow event. The time stamp value is based on a free-running 8-bit timer that begins counting upon assertion of PCU_CESR[ENB]. Upon a snoop error event, this field captures the value of the time stamp at the time the snoop request was loaded into the queue. Upon a queue overflow event, this field captures the value of the time stamp at the time the overflow condition is detected.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 EPROT	Error Protection Attribute This read-only field holds the AHB protection attributes that resulted in a snoop error or overflow event.
24–28 ERESP	Error Snoop Response This read-only field holds the snoop response associated with the snoop that terminated with error. This field is cleared when PCU_EDRn is loaded on an overflow event. Upon a queue overflow event, this field reads as all zeroes. In the field-setting descriptions, cc designates the number of collapsed requests: 00: no collapsing 01: two requests combined 10: three requests combined 11: four requests combined

Table continues on the next page...

PCU_EDR_n field descriptions (continued)

Field	Description
000cc	NULL: no operation performed or no matching cache entry
001cc	AutoInv: AutoInvalidation performed on clean unlocked lines with tag parity errors
010cc	ERROR: Error in processing a snoop request due to tag parity error
011cc	SYNC: Sync completed, snoop queue synchronized
100cc	Hit Clean: matching unlocked clean cache entry found
101cc	Hit Dirty: matching unlocked dirty cache entry found
110cc	Hit Locked: matching locked clean cache entry found
111cc	Hit Dirty Locked: matching locked clean cache entry found
29–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

7.2.4 PCU Interrupt Register, Core n (PCU_IR_n)

Access by mode:

- Read: all modes
- Write: Supervisor mode

Address: 0h base + 30h offset + (4d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0														OIF	EIF
W															w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PCU_IR_n field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 OIF	Overflow Interrupt Flag This field indicates an outstanding interrupt request as a result of a queue overflow. The flag and interrupt are cleared by writing 1 to this bit. Writing 0 to this bit has no effect. 0 No interrupt request 1 Interrupt request due to snoop termination with error
31 EIF	Error Interrupt Flag

Table continues on the next page...

PCU_IRn field descriptions (continued)

Field	Description
	This field indicates an outstanding interrupt request as a result of a snoop that terminated with error if PCU_CESR[CPnIEN]. The flag and interrupt are cleared by writing 1 to this bit. Writing 0 to this bit has no effect.
0	No interrupt request
1	Interrupt request due to snoop termination with error

Chapter 8

System Integration Unit (SIU, SIU_B)

8.1 Introduction

This chapter describes the device system integration units (SIU, and SIU_B) that configure and initialize the following features in the SIU:

- MCU reset configuration
- System reset operation
- Pad configuration
- External interrupts
- General-purpose I/O (GPIO)
- Internal peripheral multiplexing
- GPDI and GPDO I/Os of the DSPI modules
- TLB Entry Selector

as well as the following feature in SIU_B:

- Mirrored pad configuration and GPIO registers for Protected Port Output mode

8.1.1 Block diagram

The figure below is a block diagram of the SIU. The Power-on Reset Detection, Pad Ring/Pad Interface, and the Peripheral I/O Channels are external to the SIU.

Figure 8-1. SIU block diagram

8.1.2 Overview

The following table lists the features that the SIU configures.

Table 8-1. SIU features

Feature	Description
MCU reset operations	Controls the external pin boot logic
System reset operations	Monitors internal and external reset sources, and drives the $\overline{\text{RSTOUT}}$ signal • Power-on reset support • Reset status register providing last reset source to software • Glitch detection on reset input • Software controlled reset assertion
Pad configuration registers	Enables the configuration and initialization of the I/O pin electrical characteristics using software to select the following: • Active function from the set of multiplexed functions • Pullup and pulldown characteristics of the pin • Slew rate for slow and medium pads • Open drain mode for output pins • Hysteresis for input pins • Drive strength of bus signals for fast pads
External interrupt operations	16 interrupt requests Rising- or falling-edge event detection Programmable digital filter for glitch rejection NMI and critical interrupt control
General purpose I/O (GPIO)	Provides uniform and discrete I/O control of MCU general-purpose I/O pins, where each GPIO signal has an input register and an output register.
Internal peripheral multiplexing	Provides flexibility to customize signal/pin assignments for application development that allows: • Flexible selection of eQADC trigger inputs • Assignment of interrupt requests (IRQs) between external pins and DSPI
TLB entry selector	Allows an external tool to non-intrusively change the TLB entry that is used by the cores to access memory.
Protected Port Output	Allows up to four GPIO pins to be reserved by any one of the two cores.

8.1.3 Modes of operation

8.1.3.1 Normal mode

In normal mode, the SIU provides the register interface and logic that controls the device and system configuration, the reset controller, and GPIO.

8.1.3.2 Debug mode

SIU operation in debug mode is identical to operation in normal mode.

8.2 Memory Map and Register Definition

Register offsets are relative to SIU's base address.

Pad Configuration Register (PCR) details

[Pad Configuration Register \(SIU_PCR_n\)](#) provides a general description of the PCRs. The following tables provide details about individual PCRs. Gaps exist in the memory map where registers correspond to GPIO pins that are not implemented in the package.

[Table 8-2](#) defines the symbols for PCR_n fields' reset values that appear in [Table 8-3](#).

Table 8-2. SIU_PCR_n field reset-value symbols

Symbol	Meaning
—	Not implemented in the PCR. Software should write a default value of 0.
0 or 1	Function is implemented. For its definition, see the applicable field's description.
U	Function is implemented and is defined by the WKPCFG bit of the Miscellaneous DCF client (or, in legacy mode, by the value of the WKPCFG pin at reset).

Table 8-3. SIU_PCR_n settings

1. The choice between MDO and GPIO functions is based on Nexus programming. If Nexus is enabled, this pin takes the role of MDO, otherwise it is GPIO. The OBE and IBE fields only apply when the pin is working as GPIO, otherwise it is an output-only MDO pin.
2. This input function is also present in other pins, but only one pin can be selected at any given time. Select the pin to drive the function using the SIU_IMUX registers.

Memory Map and Register Definition

- NMI function is not selected by the PA settings. It is enabled by write-once bits in the SIU_IREER and SIU_IFEER registers. Once NMI is enabled by one of these registers, the PA settings are ignored.
- The choice between MDO and GPIO functions is based on Nexus programming. If Nexus is enabled and configured to use Full Port Mode, then this pin takes the role of MDO. If Nexus is not enabled or it is enabled but configured to use Reduced Port Mode, then this pin takes the role of GPIO. The OBE and IBE fields only apply when the pin is working as GPIO, otherwise it is an output-only MDO pin.

8.2.1 MCU Identification Register (SIU_MIDR)

The SIU_MIDR contains the part number and mask number revisions specific to the device. The part number is a read-only field that is mask programmed with the part number of the device on which the SIU resides. It is intended to help factory test and user code which are sensitive to part changes. The part number is changed if a new module is added to the device or a memory size is changed, for example. It is not changed for bug fixes or process changes.

The mask number is a read-only field that is mask programmed with the specific mask revision level of the device. It is intended to help factory test and user code which is sensitive to mask changes.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- MASKNUM_MINOR field: 1N45H = 0001b, 2N45H = 0010b, 3N45H = 0000b
- MASKNUM_MAJOR field: 1N45H = 0000b, 2N45H = 0000b, 3N45H = 0001b
- PKG field: 416 = 0110b, 516 = 1110b, 552 = 1100b

SIU_MIDR field descriptions

Field	Description
0–15 PARTNUM	MCU Part Number. Read-only, mask programmed part number of the MCU. MPC5777 reads 0x5777.
16–19 PKG	Package settings. Read-only, package information. 0110: 416-pin package. 1110: 516-pin package.

Table continues on the next page...

SIU_MIDR field descriptions (continued)

Field	Description
	1100: 552-pin package. All other settings reserved.
20–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–27 MASKNUM_ MAJOR	Major revision of MCU Mask. Read-only, mask programmed mask number of the MCU. Reads 0x0 for the initial mask set of the device, and changes sequentially for each mask set.
28–31 MASKNUM_ MINOR	Minor revision MCU Mask. Read-only, mask programmed mask number of the MCU. Reads 0x0 for the initial mask set of the device, and changes sequentially for each mask set.

8.2.2 Reset Status Register (SIU_RSR)

The Reset Status Register contains the sources of the most recent reset as well as a number of configuration bits defined by the Miscellaneous DCF record, which the SSCM reads from flash memory during reset. Alternatively, if the LEG bit of the Miscellaneous DCF record is set to 1, then the reset controller assumes that a backwards compatible legacy mode must be used. In this case, the values of the configuration bits are latched from package pins at the end of the reset cycle instead of coming from the DCF record.

The reset values of status bits are applied at POR. The reset value of the configuration bits (WKPCFG, XOSCHIGH, ABR, BOOTCFG) are loaded from the Miscellaneous DCF record or from external pins.

Address: 0h base + Ch offset = Ch

* Notes:

- The reset values of status bits are applied at POR.
- BOOTCFG field: The reset value of this configuration field is loaded from the Miscellaneous DCF record or from external pins.
- ABR field: The reset value of this configuration field is loaded from the Miscellaneous DCF record or from external pins.
- XOSCHIGH field: The reset value of this configuration field is loaded from the Miscellaneous DCF record or from external pins.
- WKPCFG field: The reset value of this configuration field is loaded from the Miscellaneous DCF record or from external pins.

SIU_RSR field descriptions

Field	Description
0 PORS	Power-on reset status. 0 Another reset source has been acknowledged by the reset controller since the last assertion of the power-on reset input. 1 The power-on reset input to the reset controller was asserted and no other reset source was acknowledged since that assertion of the power-on reset input, except an external reset.
1 ERS	External reset status. 0 The last reset source acknowledged by the reset controller was not a valid assertion of the RESET pin. 1 The last reset source acknowledged by the reset controller was a valid assertion of the RESET pin.
2–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 CPURS	Simultaneous Core 0 and Core 1 reset status. 0 The last reset source acknowledged by the reset controller was not a simultaneous reset attempt of both cores. 1 The last reset source acknowledged by the reset controller was a simultaneous reset attempt of both cores.
10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

SIU_RSR field descriptions (continued)

Field	Description
11 FOSURS	FCCU Output Supervision Unit (FOSU) reset status. 0 The last reset source acknowledged by the reset controller was not a reset from the FOSU. 1 The last reset source acknowledged by the reset controller was a reset from the FOSU.
12 FCCURS	Failure Collection and Control Unit (FCCU) reset status. 0 The last reset source acknowledged by the reset controller was not a reset from the FCCU. 1 The last reset source acknowledged by the reset controller was a reset from the FCCU.
13 STCURS	Self Test Control Unit (STCU) reset status. 0 The last reset source acknowledged by the reset controller was not a reset from the STCU. 1 The last reset source acknowledged by the reset controller was a reset from the STCU.
14 SSRS	Software system reset status. 0 The last reset source acknowledged by the reset controller was not a software system reset. 1 The last reset source acknowledged by the reset controller was a software system reset.
15 SERF	Software external reset flag. 0 The software external reset input to the reset controller was not asserted, or this bit has been cleared by writing a 1 to it. 1 The software external reset input to the reset controller was asserted while this bit was zero.
16 WKPCFG	Weak pull-up configuration. The value of this bit is loaded from bit 12 of the Miscellaneous DCF record by the SSCM during reset. If the MSB bit of the DCF record (Legacy Bit) is set to '1', then the value of this bit is latched from the WKPCFG pin upon negation of reset, instead of being loaded from the DCF record. 0 Weak pulldown is the default setting. 1 Weak pullup is the default setting.
17–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 XOSC	External oscillator status. This is a set-once bit that is set after an internal counter (clocked by XOSC) finishes counting to 512 times the XOSC_CNT field of the Miscellaneous DCF record. When set, this flag indicates that the XOSC clock is stable and can be used as clock source for system and peripherals. 0 XOSC clock not stable yet. 1 XOSC clock is stable.
25–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 XOSCHIGH	XOSC at High Setting. The value of this bit is loaded from bit 21 of the Miscellaneous DCF record by the SSCM during reset. However, if the MSB of the DCF record (Legacy bit) is set to 1, then the value of this bit is latched from the PLLCFG[2] pin upon negation of reset instead of being loaded from the DCF record. NOTE: "Low" is the setting commonly used for crystals at 8 MHz, "medium" is commonly used for crystals greater than 8 MHz to 20 MHz, and "high" is commonly used for crystals greater than 20 MHz to 40 MHz. However, the user must characterize carefully to determine the best g_m setting for the intended application because crystal load capacitance, board layout, and other factors affect the g_m value that is needed. See the Data Sheet for additional information. 0 Crystal in the range of low to medium setting. 1 Crystal is at high setting.
28 ABR	Auto baud rate configuration. The value of this bit is loaded from bit 13 of the Miscellaneous DCF record by the SSCM during reset. If the MSB bit of the DCF record (Legacy Bit) is set to '1', then the value of this

Table continues on the next page...

SIU_RSR field descriptions (continued)

Field	Description
	bit is determined by the value of the EVTO pin upon negation of reset as follows. If no debug tool is attached to the device and EVTO is held at low logic level during reset, the ABR bit reset state is logic one. Otherwise it is zero. 0 Auto Baud Rate Disabled. 1 Auto Baud Rate Enabled.
29–30 BOOTCFG	Boot configuration. BOOTCFG[0:1] is used by the Boot Assist Module (BAM) to configure the boot mode. If the component life cycle is "in field", then the value of BOOTCFG is fixed to 0b00 (internal boot). For all other life cycles, the value of BOOTCFG is loaded from bits 14-15 of the Miscellaneous DCF record by the SSCM during reset. Alternatively, if the MSB bit of the Miscellaneous DCF record (Legacy Bit) is set to '1', then the value of this field is latched from the BOOTCFG pins upon negation of reset, instead of being loaded from the DCF record. 00 Internal boot mode. 01 Serial boot mode. 10 Non-muxed EBI boot mode (16-bit data, non-muxed address bus). 11 Muxed EBI boot mode (16-bit data, muxed address bus).
31 RGF	Reset glitch flag. Set by the reset controller when a glitch is detected on the RESET pin. This bit is cleared by the assertion of the power-on reset or a write of one to the RGF bit. 0 No glitch has been detected on the RESET pin. 1 A glitch has been detected on the RESET pin.

8.2.3 System Reset Control Register (SIU_SRCR)

The system reset control register configures whether a software system reset or a software external reset is generated. A software system reset uses an internal system reset. A software external reset asserts $\overline{\text{RSTOUT}}$.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W	SSR	SER														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R																
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIU_SRCR field descriptions

Field	Description
0 SSR	Software system reset. The software system reset is processed as a synchronous reset. Except for a software external reset, the bit automatically clears if any other reset source asserts. NOTE: The SSR bit always reads as zero. A write of zero to this bit has no effect. 0 No software system reset. 1 Generate a software internal system reset.
1 SER	Software external reset. Used to generate a Software External Reset. Writing 1 to this bit asserts RSTOUT for 2480 clock cycles, but the internal reset is not asserted. The bit is automatically cleared when the software external reset completes or any other reset source is asserted. After a software external reset has been initiated, RSTOUT negates if this bit is cleared before the 2480 clock cycles period expires. NOTE: Write 1 to the SER bit to generate a software external reset. A write of 0 to this bit has no effect. When reset completes, the SER bit is cleared to 0. 0 Do not generate a software external reset. 1 Generate a software external reset.
2–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

8.2.4 External IRQ Status Register (SIU_EISR)

The external interrupt status register is used to record edge-triggered events on the $\overline{\text{IRQ}}[0]-\overline{\text{IRQ}}[15]$ inputs to the SIU and record the critical interrupts NMI and SWT. When an edge-detect enable bit is set in the SIU_IREER or SIU_IFEER registers for an IRQ and an IRQ edge-event is detected, the flag bit is set in the SIU_EISR. The flag bits are cleared by writing 1 to the bit. Writing 0 has no effect.

The flag bit is set regardless of the state of the DMA or interrupt request enable bit in SIU_DIRER. The flag bit remains set until cleared by software or through the servicing of a DMA or interrupt request.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SIU_EISR field descriptions

Field	Description
0 NMI0	Core0 non-maskable interrupt flag. This bit is set when a NMI interrupt occurs on the NMI input pin of Core0. 0 No NMI event has occurred on the NMI input of Core0. 1 An NMI event has occurred on the NMI input of Core0.
1 NMI1	Core1 non-maskable interrupt flag. This bit is set when a NMI interrupt occurs on the NMI input pin of Core1. 0 No NMI event has occurred on the NMI input of Core1. 1 An NMI event has occurred on the NMI input of Core1.
2–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 EIF15	External interrupt request flag 15. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[15]$ input. Cleared by writing 1. 0 No edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin. 1 An edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin.
17 EIF14	External interrupt request flag 14. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[14]$ input. Cleared by writing 1. 0 No edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin. 1 An edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin.
18 EIF13	External interrupt request flag 13. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[13]$ input. Cleared by writing 1. 0 No edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin. 1 An edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin.
19 EIF12	External interrupt request flag 12. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[12]$ input. Cleared by writing 1. 0 No edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin. 1 An edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin.
20 EIF11	External interrupt request flag 11. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[11]$ input. Cleared by writing 1. 0 No edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin. 1 An edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin.
21 EIF10	External interrupt request flag 10. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[10]$ input. Cleared by writing 1.

Table continues on the next page...

SIU_EISR field descriptions (continued)

Field	Description
	0 No edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin. 1 An edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin.
22 EIF9	External interrupt request flag 9. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[9]$ input. Cleared by writing 1. 0 No edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin. 1 An edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin.
23 EIF8	External interrupt request flag 8. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[8]$ input. Cleared by writing 1. 0 No edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin. 1 An edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin.
24 EIF7	External interrupt request flag 7. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[7]$ input. Cleared by writing 1. 0 No edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin. 1 An edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin.
25 EIF6	External interrupt request flag 6. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[6]$ input. Cleared by writing 1. 0 No edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin. 1 An edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin.
26 EIF5	External interrupt request flag 5. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[5]$ input. Cleared by writing 1. 0 No edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin. 1 An edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin.
27 EIF4	External interrupt request flag 4. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[4]$ input. Cleared by writing 1. 0 No edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin. 1 An edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin.
28 EIF3	External interrupt request flag 3. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[3]$ input. Cleared by writing 1. 0 No edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin. 1 An edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin.
29 EIF2	External interrupt request flag 2. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[2]$ input. Cleared by writing 1. 0 No edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin. 1 An edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin.
30 EIF1	External interrupt request flag 1. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[1]$ input. Cleared by writing 1. 0 No edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin. 1 An edge triggered event has occurred on the corresponding $\overline{\text{IRQ}}$ pin.
31 EIF0	External interrupt request flag 0. This bit is set when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[0]$ input. Cleared by writing 1.

Table continues on the next page...

SIU_EISR field descriptions (continued)

Field	Description
0	No edge triggered event has occurred on the corresponding IRQ pin.
1	An edge triggered event has occurred on the corresponding IRQ pin.

8.2.5 DMA/Interrupt Request Enable Register (SIU_DIRER)

The SIU_DIRER enables external signals on selected pins to generate DMA or interrupt requests, and the SWT modules to generate interrupt requests. The EIRE[0:3] bits enable requests to either the DMA or INTC modules, based on the value of the DIRSn bits in the SIU_DIRSR register. The EIRE[4:15] bits enable requests only to the INTC module. The NMISELn bits enable requests to either the critical or non-maskable interrupt inputs of the cores. For a pin to generate an interrupt, the appropriate bit in either SIU_IREER or SIU_IFEER registers must additionally be set.

Address: 0h base + 18h offset = 18h

SIU_DIRER field descriptions

Field	Description
0 NMISEL8	Core0 non-maskable/critical interrupt selection (NMI comes from external pin). The NMI external pin can be routed to Core0 either as critical interrupt or as non-maskable interrupt (NMI). The NMISEL8 bit selects which of them is driven by the NMI pin. This bit is write-once. NOTE: NMISEL8 is a write-once bit. 0 Core0 NMI interrupt receives the signal from the NMI pin (IVOR1 core exception). 1 Core0 critical interrupt receives the signal from the NMI pin (IVOR0 core exception).
1 NMISEL7	Core1 non-maskable/critical interrupt selection (NMI comes from external pin). The NMI external pin can be routed to Core1 either as critical interrupt or as non-maskable interrupt (NMI). The NMISEL7 bit selects which of them is driven by the NMI pin. This bit is write-once.

Table continues on the next page...

SIU_DIRER field descriptions (continued)

Field	Description
	NOTE: NMISEL7 is a write-once bit. 0 Core1 NMI interrupt receives the signal from the NMI pin (IVOR1 core exception). 1 Core1 critical interrupt receives the signal from the NMI pin (IVOR0 core exception).
2–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 NMISEL0	Core0 non-maskable/critical interrupt selection (NMI comes from SWT_A). The Software Watchdog Timer A (SWT_A) interrupt output can be routed to Core0 either as critical interrupt or as non-maskable interrupt (NMI). The NMISEL0 bit selects which of them is driven by SWT_A. This bit is write-once. NOTE: NMISEL0 is a write-once bit. 0 Core0 NMI interrupt receives the signal from SWT_A (IVOR1 core exception). 1 Core0 critical interrupt receives the signal from SWT_A (IVOR0 core exception).
9 NMISEL1	Core1 non-maskable/critical interrupt selection (NMI comes from SWT_B). The Software Watchdog Timer B (SWT_B) interrupt output can be routed to Core1 either as critical interrupt or as non-maskable interrupt (NMI). The NMISEL1 bit selects which of them is driven by SWT_B. This bit is write-once. NOTE: NMISEL1 is a write-once bit. 0 Core1 NMI interrupt receives the signal from SWT_B (IVOR1 core exception). 1 Core1 critical interrupt receives the signal from SWT_B (IVOR0 core exception).
10–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 EIRE15	Interrupt request enable 15. This bit enables the assertion of an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[15]$ pin. 0 Interrupt request is disabled. 1 Interrupt request is enabled.
17 EIRE14	Interrupt request enable 14. This bit enables the assertion of an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[14]$ pin. 0 Interrupt request is disabled. 1 Interrupt request is enabled.
18 EIRE13	Interrupt request enable 13. This bit enables the assertion of an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[13]$ pin. 0 Interrupt request is disabled. 1 Interrupt request is enabled.
19 EIRE12	Interrupt request enable 12. This bit enables the assertion of an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[12]$ pin. 0 Interrupt request is disabled. 1 Interrupt request is enabled.
20 EIRE11	Interrupt request enable 11. This bit enables the assertion of an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[11]$ pin. 0 Interrupt request is disabled. 1 Interrupt request is enabled.
21 EIRE10	Interrupt request enable 10. This bit enables the assertion of an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[10]$ pin.

SIU_DIRER field descriptions (continued)

Field	Description
	0 Interrupt request is disabled. 1 Interrupt request is enabled.
22 EIRE9	Interrupt request enable 9. This bit enables the assertion of an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[9]$ pin. 0 Interrupt request is disabled. 1 Interrupt request is enabled.
23 EIRE8	Interrupt request enable 8. This bit enables the assertion of an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[8]$ pin. 0 Interrupt request is disabled. 1 Interrupt request is enabled.
24 EIRE7	Interrupt request enable 7. This bit enables the assertion of an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[7]$ pin. 0 Interrupt request is disabled. 1 Interrupt request is enabled.
25 EIRE6	Interrupt request enable 6. This bit enables the assertion of an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[6]$ pin. 0 Interrupt request is disabled. 1 Interrupt request is enabled.
26 EIRE5	Interrupt request enable 5. This bit enables the assertion of an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[5]$ pin. 0 Interrupt request is disabled. 1 Interrupt request is enabled.
27 EIRE4	Interrupt request enable 4. This bit enables the assertion of an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[4]$ pin. 0 Interrupt request is disabled. 1 Interrupt request is enabled.
28 EIRE3	DMA/interrupt request enable 3. This bit enables the assertion of a DMA request or an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[3]$ pin. NOTE: EIRE[0:3] can optionally enable DMA requests instead of IRQs. 0 DMA and interrupt requests are disabled. 1 DMA or interrupt request is enabled.
29 EIRE2	DMA/interrupt request enable 2. This bit enables the assertion of a DMA request or an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[2]$ pin. NOTE: EIRE[0:3] can optionally enable DMA requests instead of IRQs. 0 DMA and interrupt requests are disabled. 1 DMA or interrupt request is enabled.
30 EIRE1	DMA/interrupt request enable 1. This bit enables the assertion of a DMA request or an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[1]$ pin. NOTE: EIRE[0:3] can optionally enable DMA requests instead of IRQs.

Table continues on the next page...

SIU_DIRER field descriptions (continued)

Field	Description
	0 DMA and interrupt requests are disabled. 1 DMA or interrupt request is enabled.
31 EIRE0	DMA/interrupt request enable 0. This bit enables the assertion of a DMA request or an interrupt request when an edge-triggered event occurs on the $\overline{\text{IRQ}}[0]$ pin. NOTE: EIRE[0:3] can optionally enable DMA requests instead of IRQs. 0 DMA and interrupt requests are disabled. 1 DMA or interrupt request is enabled.

8.2.6 DMA/Interrupt Request Select Register (SIU_DIRSR)

The SIU_DIRSR selects between DMA and interrupt requests for events on the $\overline{\text{IRQ}}[0]$ - $\overline{\text{IRQ}}[3]$. If the corresponding bits are set in SIU_EISR and SIU_DIRER, then the DMA/Interrupt Request Select bit (DIRS n) determines whether a DMA or interrupt request is asserted.

SIU_DIRSR field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 DIRS3	DMA/interrupt select 3. Selects between a DMA or external interrupt request when an edge-triggered event occurs on $\overline{\text{IRQ}}[3]$ pin. 0 Interrupt request is selected. 1 DMA request to eDMA_A channel 51 is selected.

Table continues on the next page...

SIU_DIRSR field descriptions (continued)

Field	Description
29 DIRS2	DMA/interrupt select 2. Selects between a DMA or external interrupt request when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[2]$ pin. 0 Interrupt request is selected. 1 DMA request to eDMA_A channel 50 is selected.
30 DIRS1	DMA/interrupt select 1. Selects between a DMA or external interrupt request when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[1]$ pin. 0 Interrupt request is selected. 1 DMA request to eDMA_A channel 49 is selected.
31 DIRS0	DMA/interrupt select 0. Selects between a DMA or external interrupt request when an edge-triggered event occurs on the corresponding $\overline{\text{IRQ}}[0]$ pin. 0 Interrupt request is selected. 1 DMA request to eDMA_A channel 48 is selected.

8.2.7 Overrun Status Register (SIU_OSR)

The SIU_OSR flag bits indicate that an overrun has occurred. An overrun is generated if an event on an $\overline{\text{IRQ}}$ pin occurs while the corresponding flag bit is set in SIU_EISR. The overrun flag bit is set regardless of the state of the corresponding DMA/Interrupt Request Enable bit in SIU_DIRER or the corresponding Overrun Request Enable bit in SIU_ORER. The numbering of the Overrun Flag bits correspond to the numbering of the flag bits in SIU_EISR. The Overrun Flag bit remains set until cleared by software. Each Overrun Flag bit is cleared by writing 1. Writing 0 has no effect.

SIU_OSR field descriptions (continued)

Field	Description
	0 No overrun occurred. 1 An overrun occurred.
18 OVF13	Overrun flag 13. This bit is set when an interrupt overrun occurs on $\overline{\text{IRQ}}[13]$. Bit 31 (OVF0) is the overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (OVF15) is overrun flag for $\overline{\text{IRQ}}[15]$. 0 No overrun occurred. 1 An overrun occurred.
19 OVF12	Overrun flag 12. This bit is set when an interrupt overrun occurs on $\overline{\text{IRQ}}[12]$. Bit 31 (OVF0) is the overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (OVF15) is overrun flag for $\overline{\text{IRQ}}[15]$. 0 No overrun occurred. 1 An overrun occurred.
20 OVF11	Overrun flag 11. This bit is set when an interrupt overrun occurs on $\overline{\text{IRQ}}[11]$. Bit 31 (OVF0) is the overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (OVF15) is overrun flag for $\overline{\text{IRQ}}[15]$. 0 No overrun occurred. 1 An overrun occurred.
21 OVF10	Overrun flag 10. This bit is set when an interrupt overrun occurs on $\overline{\text{IRQ}}[10]$. Bit 31 (OVF0) is the overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (OVF15) is overrun flag for $\overline{\text{IRQ}}[15]$. 0 No overrun occurred. 1 An overrun occurred.
22 OVF9	Overrun flag 9. This bit is set when an interrupt overrun occurs on $\overline{\text{IRQ}}[9]$. Bit 31 (OVF0) is the overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (OVF15) is overrun flag for $\overline{\text{IRQ}}[15]$. 0 No overrun occurred. 1 An overrun occurred.
23 OVF8	Overrun flag 8. This bit is set when an interrupt overrun occurs on $\overline{\text{IRQ}}[8]$. Bit 31 (OVF0) is the overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (OVF15) is overrun flag for $\overline{\text{IRQ}}[15]$. 0 No overrun occurred. 1 An overrun occurred.
24 OVF7	Overrun flag 7. This bit is set when an interrupt overrun occurs on $\overline{\text{IRQ}}[7]$. Bit 31 (OVF0) is the overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (OVF15) is overrun flag for $\overline{\text{IRQ}}[15]$. 0 No overrun occurred. 1 An overrun occurred.
25 OVF6	Overrun flag 6. This bit is set when an interrupt overrun occurs on $\overline{\text{IRQ}}[6]$. Bit 31 (OVF0) is the overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (OVF15) is overrun flag for $\overline{\text{IRQ}}[15]$. 0 No overrun occurred. 1 An overrun occurred.
26 OVF5	Overrun flag 5. This bit is set when an interrupt overrun occurs on $\overline{\text{IRQ}}[5]$. Bit 31 (OVF0) is the overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (OVF15) is overrun flag for $\overline{\text{IRQ}}[15]$. 0 No overrun occurred. 1 An overrun occurred.
27 OVF4	Overrun flag 4. This bit is set when an interrupt overrun occurs on $\overline{\text{IRQ}}[4]$. Bit 31 (OVF0) is the overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (OVF15) is overrun flag for $\overline{\text{IRQ}}[15]$.

Table continues on the next page...

SIU_OSR field descriptions (continued)

Field	Description
	0 No overrun occurred. 1 An overrun occurred.
28 OVF3	Overrun flag 3. This bit is set when a DMA or interrupt overrun occurs on $\overline{\text{IRQ}}[3]$. Bit 31 (OVF0) is the overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (OVF15) is overrun flag for $\overline{\text{IRQ}}[15]$. 0 No overrun occurred. 1 An overrun occurred.
29 OVF2	Overrun flag 2. This bit is set when a DMA or interrupt overrun occurs on $\overline{\text{IRQ}}[2]$. Bit 31 (OVF0) is the overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (OVF15) is overrun flag for $\overline{\text{IRQ}}[15]$. 0 No overrun occurred. 1 An overrun occurred.
30 OVF1	Overrun flag 1. This bit is set when a DMA or interrupt overrun occurs on $\overline{\text{IRQ}}[1]$. Bit 31 (OVF0) is the overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (OVF15) is overrun flag for $\overline{\text{IRQ}}[15]$. 0 No overrun occurred. 1 An overrun occurred.
31 OVF0	Overrun flag 0. This bit is set when a DMA or interrupt overrun occurs on $\overline{\text{IRQ}}[0]$. Bit 31 (OVF0) is the overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (OVF15) is overrun flag for $\overline{\text{IRQ}}[15]$. 0 No overrun occurred. 1 An overrun occurred.

8.2.8 Overrun Request Enable Register (SIU_ORER)

The SIU_ORER contains bits to enable an overrun if the corresponding flag bit is set in the SIU_OSR. If the overrun request enable bit and the flag bit are set, the single combined overrun request from the SIU to the interrupt controller is asserted.

SIU_ORER field descriptions (continued)

Field	Description
	0 Overrun request is disabled. 1 Overrun request is enabled.
26 ORE5	Overrun request enable 5. Enables the overrun request when an overrun occurs in the $\overline{\text{IRQ}}[5]$ pin. Bit 31 (ORE0) is the enable overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (ORE15) is the overrun flag for $\overline{\text{IRQ}}[15]$. 0 Overrun request is disabled. 1 Overrun request is enabled.
27 ORE4	Overrun request enable 4. Enables the overrun request when an overrun occurs in the $\overline{\text{IRQ}}[4]$ pin. Bit 31 (ORE0) is the enable overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (ORE15) is the overrun flag for $\overline{\text{IRQ}}[15]$. 0 Overrun request is disabled. 1 Overrun request is enabled.
28 ORE3	Overrun request enable 3. Enables the overrun request when an overrun occurs in the $\overline{\text{IRQ}}[3]$ pin. Bit 31 (ORE0) is the enable overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (ORE15) is the overrun flag for $\overline{\text{IRQ}}[15]$. 0 Overrun request is disabled. 1 Overrun request is enabled.
29 ORE2	Overrun request enable 2. Enables the overrun request when an overrun occurs in the $\overline{\text{IRQ}}[2]$ pin. Bit 31 (ORE0) is the enable overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (ORE15) is the overrun flag for $\overline{\text{IRQ}}[15]$. 0 Overrun request is disabled. 1 Overrun request is enabled.
30 ORE1	Overrun request enable 1. Enables the overrun request when an overrun occurs in the $\overline{\text{IRQ}}[1]$ pin. Bit 31 (ORE0) is the enable overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (ORE15) is the overrun flag for $\overline{\text{IRQ}}[15]$. 0 Overrun request is disabled. 1 Overrun request is enabled.
31 ORE0	Overrun request enable 0. Enables the overrun request when an overrun occurs in the $\overline{\text{IRQ}}[0]$ pin. Bit 31 (ORE0) is the enable overrun flag for $\overline{\text{IRQ}}[0]$; bit 16 (ORE15) is the overrun flag for $\overline{\text{IRQ}}[15]$. 0 Overrun request is disabled. 1 Overrun request is enabled.

8.2.9 IRQ Rising-Edge Event Enable Register (SIU_IREER)

The SIU_IREER enables rising edge-triggered events on $\overline{\text{IRQ}}[n]$. Rising- and falling-edge events are enabled by setting the bits in SIU_IREER and SIU_IFEER.

SIU_IREER bits used for NMI events are write once after a reset.

SIU_IFEER field descriptions (continued)

Field	Description
21 IFEEN10	IRQ falling-edge event enable 10. Enables falling edge triggered events on the external $\overline{\text{IRQ}}[10]$ pin. 0 Falling edge event is disabled. 1 Falling edge event is enabled.
22 IFEEN9	IRQ falling-edge event enable 9. Enables falling edge triggered events on the external $\overline{\text{IRQ}}[9]$ pin. 0 Falling edge event is disabled. 1 Falling edge event is enabled.
23 IFEEN8	IRQ falling-edge event enable 8. Enables falling edge triggered events on the external $\overline{\text{IRQ}}[8]$ pin. 0 Falling edge event is disabled. 1 Falling edge event is enabled.
24 IFEEN7	IRQ falling-edge event enable 7. Enables falling edge triggered events on the external $\overline{\text{IRQ}}[7]$ pin. 0 Falling edge event is disabled. 1 Falling edge event is enabled.
25 IFEEN6	IRQ falling-edge event enable 6. Enables falling edge triggered events on the external $\overline{\text{IRQ}}[6]$ pin. 0 Falling edge event is disabled. 1 Falling edge event is enabled.
26 IFEEN5	IRQ falling-edge event enable 5. Enables falling edge triggered events on the external $\overline{\text{IRQ}}[5]$ pin. 0 Falling edge event is disabled. 1 Falling edge event is enabled.
27 IFEEN4	IRQ falling-edge event enable 4. Enables falling edge triggered events on the external $\overline{\text{IRQ}}[4]$ pin. 0 Falling edge event is disabled. 1 Falling edge event is enabled.
28 IFEEN3	IRQ falling-edge event enable 3. Enables falling edge triggered events on the external $\overline{\text{IRQ}}[3]$ pin. 0 Falling edge event is disabled. 1 Falling edge event is enabled.
29 IFEEN2	IRQ falling-edge event enable 2. Enables falling edge triggered events on the external $\overline{\text{IRQ}}[2]$ pin. 0 Falling edge event is disabled. 1 Falling edge event is enabled.
30 IFEEN1	IRQ falling-edge event enable 1. Enables falling edge triggered events on the external $\overline{\text{IRQ}}[1]$ pin. 0 Falling edge event is disabled. 1 Falling edge event is enabled.
31 IFEEN0	IRQ falling-edge event enable 0. Enables falling edge triggered events on the external $\overline{\text{IRQ}}[0]$ pin. 0 Falling edge event is disabled. 1 Falling edge event is enabled.

8.2.11 IRQ Digital Filter Register (SIU_IDFR)

The SIU_IDFR specifies the amount of digital filtering on $\overline{\text{IRQ}}[0]-\overline{\text{IRQ}}[15]$ and NMI. The digital filter length field specifies the number of system clocks that define the period of the digital filter and the minimum time an IRQ or NMI signal must hold the active state to qualify as an edge-triggered event.

Address: 0h base + 30h offset = 30h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SIU_IDFR field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 DFL	Digital filter length. Defines the digital filter period on the $\overline{\text{IRQ}}[n]$ and NMI inputs according to the following equation: $\text{FilterPeriod} = (\text{PeripheralClockPeriod} \times 2^{\text{DFL}}) + 1(\text{PeripheralClockPeriod})$ For a 100 MHz peripheral clock, this gives a range of 20 ns to 328 ns. The minimum time of two system clocks accounts for synchronization of the $\overline{\text{IRQ}}$ and NMI input pins with the system clock.

8.2.12 IRQ Filtered Input Register (SIU_IFIR)

The SIU_IFIR is a read only register where the filtered values of the NMI and $\overline{\text{IRQ}}[0]-\overline{\text{IRQ}}[15]$ pins are captured.

Address: 0h base + 34h offset = 34h

Field	Description
	0 A logic one has passed through the digital filter of the corresponding $\overline{\text{IRQ}}$ pin. 1 A logic zero has passed through the digital filter of the corresponding $\overline{\text{IRQ}}$ pin.
26 IFI5	Filtered Input 5. This bit is set/cleared for the corresponding filtered $\overline{\text{IRQ}}$ pin. 0 A logic one has passed through the digital filter of the corresponding $\overline{\text{IRQ}}$ pin. 1 A logic zero has passed through the digital filter of the corresponding $\overline{\text{IRQ}}$ pin.
27 IFI4	Filtered Input 4. This bit is set/cleared for the corresponding filtered $\overline{\text{IRQ}}$ pin. 0 A logic one has passed through the digital filter of the corresponding $\overline{\text{IRQ}}$ pin. 1 A logic zero has passed through the digital filter of the corresponding $\overline{\text{IRQ}}$ pin.
28 IFI3	Filtered Input 3. This bit is set/cleared for the corresponding filtered $\overline{\text{IRQ}}$ pin. 0 A logic one has passed through the digital filter of the corresponding $\overline{\text{IRQ}}$ pin. 1 A logic zero has passed through the digital filter of the corresponding $\overline{\text{IRQ}}$ pin.
29 IFI2	Filtered Input 2. This bit is set/cleared for the corresponding filtered $\overline{\text{IRQ}}$ pin. 0 A logic one has passed through the digital filter of the corresponding $\overline{\text{IRQ}}$ pin. 1 A logic zero has passed through the digital filter of the corresponding $\overline{\text{IRQ}}$ pin.
30 IFI1	Filtered Input 1. This bit is set/cleared for the corresponding filtered $\overline{\text{IRQ}}$ pin. 0 A logic one has passed through the digital filter of the corresponding $\overline{\text{IRQ}}$ pin. 1 A logic zero has passed through the digital filter of the corresponding $\overline{\text{IRQ}}$ pin.
31 IFI0	Filtered Input 0. This bit is set/cleared for the corresponding filtered $\overline{\text{IRQ}}$ pin. 0 A logic one has passed through the digital filter of the corresponding $\overline{\text{IRQ}}$ pin. 1 A logic zero has passed through the digital filter of the corresponding $\overline{\text{IRQ}}$ pin.

8.2.13 Pad Configuration Register (SIU_PCRn)

These registers define the pad configuration for all configurable device pins by specifying the active function, direction, and electrical attributes for the pin. PCR information includes the register fields that are active for a given pin or group of pins and the reset state of the register.

The reset states of SIU_PCRs reflect the values before the BAM program executes. The BAM program can change some pad configuration registers based on the reset configuration. Refer to the System Boot chapter for more information.

The SIU_PCRs are 16-bit registers that are read from or written to as:

- 16-bit values aligned on 16-bit boundaries, or
- 32-bit values aligned on 32-bit address boundaries.

The PCR registers allow software to control the following range of electrical characteristics of the external pads:

- Weak pullup/down enable/disable
- Weak pullup/down selection
- Slew-rate selection for outputs
- Drive strength selection for outputs
- Input buffer enable (when direction is configured for output)
- Input hysteresis enable/disable
- Open drain/push-pull output selection
- Multiplexed function selection
- Data direction selection

NOTE

The actual characteristics available in any SIU_PCR depend on the type of pad it controls.

All device pin names begin with the primary function, followed by the alternate function, and then GPIO. In some cases, the third function can be a secondary alternate, which supersedes the GPIO. Those exceptions are noted. For example, SIU_PCR85 configures the CNTXB_PCSC[3]_GPIO[85] muxed signal, where CNTXB is the primary function and PCSC[3] is the alternate function. See [External signal descriptions, multiplexing, and attributes](#) for how to identify the source module for primary and alternate functions and the description of these signals. For an additional signal description, see the chapter for the module that uses this signal.

A number of input signals on the device have multiple external pins as input sources. Only one input source can be active at any time for these pins. A set of multiplexers controlled by the SIU_IMUX0 to SIU_IMUX12 registers selects which input drives the function.

For information about implemented fields and reset states of individual PCRs, see [Pad Configuration Register \(PCR\) details](#).

Address: 0h base + D6h offset + (2d × i), where i=0d to 416d

SIU_PCR_n field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

SIU_PCR_n field descriptions (continued)

Field	Description
3–5 PA	Pin assignment. Selects the function of a multiplexed pad. A separate port enable output signal from the SIU is asserted for each value of this register. The size of the field can be from 1 to 3 bits, depending on the amount of multiplexing on the pad. NOTE: For any SIU_PCR that does not comply with these rules, the PA definition is given explicitly with the SIU_PCR definition. 000 GPIO. 001 Primary function. 010 Alternate 1. 011 Alternate 2. 100 Alternate 3. 101 Invalid value. 110 Invalid value. 111 Invalid value.
6 OBE	Output buffer enable. Enables the pad as an output and drives the output buffer enable signal. 0 Disable output buffer for the pad. 1 Enable output buffer for the pad.
7 IBE	Input buffer enable. Enables the pad as an input and drives the input buffer enable signal. 0 Disable input buffer for the pad. 1 Enable input buffer for the pad.
8–9 DSC	Drive strength control. Controls the pad drive strength. Actual drive strength depends on the pad type and load. See the electrical specifications in the Data Sheet for this information. 00 Minimum drive strength. 01 Medium drive strength. 10 Medium-high drive strength. 11 Maximum drive strength.
10 ODE	Open drain output enable. Controls output driver configuration for the pads. Either open drain or push/pull driver configurations can be selected. This feature applies to output pins only. 0 Disable open drain for the pad (push/pull driver enabled). 1 Enable open drain for the pad.
11 HYS	Input hysteresis. Controls whether hysteresis is enabled for the pad. 0 Disable hysteresis for the pad. 1 Enable hysteresis for the pad.
12–13 SRC	Slew rate control. Controls slew rate for the pad. Slew rate control pertains to pins with slow or medium I/O pad types, and the output signals are driven according to the value of this field. Actual slew rate depends on the pad type and load. See the electrical specifications in the Data Sheet for this information. 00 Half drive strength with slew control enabled. 01 Full drive strength with slew control enabled. 10 Half drive strength with slew control disabled. 11 Full drive strength with slew control disabled.
14 WPE	Weak pull up/down enable. Controls whether the weak pullup/down devices are enabled/disabled for the pad. Pullup/down devices are enabled by default.

Table continues on the next page...

SIU_PCR_n field descriptions (continued)

Field	Description
	0 Disable weak pull device for the pad. 1 Enable weak pull device for the pad.
15 WPS	Weak pull up/down select. Controls whether weak pullup or weak pulldown devices are used for the pad when weak pullup/down devices are enabled. During reset, the weak pull up/down behavior is controlled by the WKPCFG bit of the Miscellaneous DCF client, or by the WKPCFG pin when operating in legacy mode ((LEG=1 in the Miscellaneous DCF client). The WPS bit determines whether weak pullup or pulldown devices are used after reset, or for pads in which the WKPCFG pin does not determine the reset weak pullup/down state. 0 Pulldown is enabled for the pad. 1 Pullup is enabled for the pad.

8.2.14 GPIO Pin Data Output Register (SIU_GPDO_n)

Each SIU_GPDO_n register specifies the output data for the function assigned to the GPIO[*n*] pin. The *n* notation in the SIU_GPDO_n register name relate to the [*n*] in GPIO[*n*] signal name. For example, SIU_GPDO246 contains the PDO246 bit for CNTXD_GPIO246. The address for a GPDO pin is the GPIO number plus an offset of SIU_BASE + 0600h. Gaps exist in the memory map where registers correspond to GPIO pins that are not implemented in the package.

Software writes to the SIU_GPDO_n registers to drive data out on the external pin. Each register drives one external pin, which allows independent control of the pin. Writes to the SIU_GPDO_n register will not be reflected to the pin when a primary or alternate function is assigned, or when an input function is assigned to the pin.

If the direction of a GPIO signal changes from input to output, the SIU_GPDO_n register value is automatically driven out to the external pin without the need for a software update.

Writes to an SIU_GPDO_n register have no effect when a primary or alternate function is assigned.

Address: 0h base + 64Bh offset + (1d × *i*), where *i*=0d to 416d

Bit	0	1	2	3	4	5	6	7
Read	0						PDO _n	
Write								
Reset	0	0	0	0	0	0	0	0

SIU_GPDO_n field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

SIU_GPDO_n field descriptions (continued)

Field	Description
7 PDO _n	Pin Data Out. This bit stores the data to be driven out on the external GPIO. If the register is read, it returns the value written. 0 Logic low value is driven to the external GPIO pin when the pin is configured as an output. 1 Logic high value is driven to the external GPIO pin when the pin is configured as an output.

8.2.15 GPIO Pin Data Input Register (legacy) (SIU_GPDInL)**NOTE**

These registers are implemented for legacy purposes and are limited to 256 general purpose input registers. The GPDI address for a particular pin is the GPIO number plus an offset of SIU_BASE + 0800h. For full access to all 512 general purpose input registers, the SIU_GPDIn registers starting at address offset 0E00h should be used.

Each SIU_GPDIn register specifies the input state for the GPDI[*n*] pin. The *n* notation in the SIU_GPDIn register name relates to the [*n*] in GPIO[*n*] signal name. For example, SIU_GPDI246 contains the PDI246 bit for CNTXD_GPIO246. Gaps exist in the memory map where registers correspond to GPIO pins that are not implemented in the package.

Software reads the SIU_GPDIn registers to get the input state of the external GPIO pin. Each GPDI register contains the input state of one external GPIO pin. If a GPDI register is configured as output, and the input buffer enable bit is set to one in the PCR register, the SIU_GPDIn register reflects the state of the output pin.

Address: 0h base + 84Bh offset + (1d × i), where i=0d to 178d

Bit	0	1	2	3	4	5	6	7
Read	0						PDI _n	
Write

Field	Description
20–21 SCKSELC	DSPI C clock input select. Specifies the source of the DSPI C clock input when in slave mode. 00 PCSB[4]_SCKC_GPIO[109] pin. 01 SCKA (master). 10 SCKB (master). 11 SCKD (master).
22–23 Reserved	This field is reserved. Always preserve this field's reset value.
24–25 SINSELD	DSPI D data input select. Specifies the source of the DSPI D data input. 00 PCSA[3]_GPIO[99] pin. 01 SOUTA. 10 SOUTB. 11 SOUTC.
26–27 SSSELD	DSPI D slave select input select. Specifies the source of the DSPI D slave select input. 00 PCSB[1]_PCSD[0]_GPIO[106] pin. 01 PCSA0 (master). 10 PCSB0 (master). 11 PCSC0 (master).
28–29 SCKSELD	DSPI D clock input select. Specifies the source of the DSPI D clock input in slave mode. 00 PCSA[2]_SCKD_GPIO[98] pin. 01 Invalid value. 10 SCKB (master). 11 SCKC (master).
30–31 Reserved	This field is reserved. Always preserve this field's reset value.

8.2.18 eQADC Command FIFO Trigger Source Registers (SIU_ISEL4)

The eQADC Command FIFO[5:2] Trigger Source Register (SIU_ISEL4) is used to select a trigger source for a command FIFO. SIU_ISEL4 is used to select a trigger source for command FIFO[5:2] in eQADC_A. The cTSEL (combined Trigger Select) field is used to configure one of many possible trigger sources for each command FIFO.

To trigger the eQADC, the trigger source must change to the state that the input to the command FIFO has been programmed to recognize. A command FIFO trigger input can be programmed to recognize either rising or falling edges, and low or high gated trigger types.

8.2.20 eQADC Command FIFO Trigger Source Registers (SIU_ISEL6)

The eQADC Command FIFO[5:2] Trigger Source Register (SIU_ISEL6) is used to select a trigger source for a command FIFO. SIU_ISEL6 is used to select a trigger source for command FIFO[5:2] in eQADC_B. The cTSEL (combined Trigger Select) field is used to configure one of many possible trigger sources for each command FIFO.

To trigger the eQADC, the trigger source must change to the state that the input to the command FIFO has been programmed to recognize. A command FIFO trigger input can be programmed to recognize either rising or falling edges, and low or high gated trigger types.

9–15 CTSEL4_B	Trigger source selection for EQADC_B Command FIFO 4.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–23 CTSEL3_B	Trigger source selection for EQADC_B Command FIFO 3.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 CTSEL2_B	Trigger source selection for EQADC_B Command FIFO 2.

8.2.21 eQADC Command FIFO Trigger Source Registers (SIU_ISEL7)

The eQADC Command FIFO[1:0] Trigger Source Register (SIU_ISEL7) is used to select a trigger source for a command FIFO. SIU_ISEL7 is used to select a trigger source for command FIFO[1:0] in eQADC_B. The cTSEL (combined Trigger Select) field is used to configure one of many possible trigger sources for each command FIFO.

To trigger the eQADC, the trigger source must change to the state that the input to the command FIFO has been programmed to recognize. A command FIFO trigger input can be programmed to recognize either rising or falling edges, and low or high gated trigger types.

8.2.22 eTPU_A Input Select Register (SIU_ISEL8)

The SIU_ISEL8 register is used to multiplex the eTPU_A[24:29] inputs. These 6 eTPU_A channels can come from the output of the DSPI or the corresponding pad. When SIU_ISEL8 is in its default state, the eTPU pins listed in the figure below will not be enabled as inputs, irrespective of the SIU_PCR[PA] field (PCR138-143).

8.2.23 eQADC Advance Trigger Source Register (SIU_ISEL9)

The eQADC streaming mode requires a second trigger for command queue 0. Selectable source options for this trigger consist of eTPU, eMIOS or PIT channels. This mux register selects the source of the command queue 0 trigger.

8.2.24 Decimation Filter Register 1 (SIU_DECFIL1)

This register selects the source of the control signals for the integrators of decimation filters A to D. Each ZSELx field of this register may be programmed to route a single eTPU channel simultaneously to the Zero, Integrate and Read control inputs of one integrator. Each HSELx field may be programmed to route a single eTPU channel to the Halt control input of one integrator. See the Decimation Filter Chapter for details on the Zero, Integrate and Halt configuration and functionality.

8.2.25 Decimation Filter Register 2 (SIU_DECFIL2)

This register selects the source of the control signals for the integrators of decimation filters E to H. Each ZSELx field of this register may be programmed to route a single eTPU channel simultaneously to the Zero, Integrate and Read control inputs of one integrator. Each HSELx field may be programmed to route a single eTPU channel to the Halt control input of one integrator. See the Decimation Filter chapter for details on the Zero, Integrate, Read and Halt control configuration and functionality.

8.2.30 Sigma-Delta Gate Selection Register (SIU_SDGATE_SEL)

Each Sigma-Delta ADC supports an input that gates (disable) interrupt and DMA requests. The SIU_SDGATE_SEL register selects the source of the interrupt/DMA gating input. The sources selected by this register come from eTPU output channels. Gating DMA and interrupt requests is useful for applications like knock processing when—outside the knock window—the ADC results are not needed, but the Sigma-Delta ADC is still converting due to its architecture.

8.2.31 Sigma-Delta to eTPU_A Connection Configuration Register (SIU_SDETPUA)

This register configures the connection between Sigma-Delta ADCs and eTPU_A input channels. Two ADC signals can be connected to eTPU channel inputs. The first one is a signal that indicates valid data conversion completion. The second one is a watchdog signal that flags a conversion which is outside pre-programmed high/low threshold limits.

8.2.34 Trigger Burst Generator Control Registers for eQADC_A (SIU_TBG_CR_An)

These registers provide control bits for the Trigger Burst Generators (TBG) connected at the trigger inputs of the 6 CFIFOS of eQADC_A. There is one register for each eQADC_A CFIFO input. The numbering goes from 0 to 5, n=0 corresponding to address 0x950 and CFIFO0, n=5 corresponding to address 0x964 and CFIFO5. See Trigger Burst Generators for detailed information on the TBG feature.

Address: 0h base + 950h offset + (4d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SIU_TBG_CR_An field descriptions

Field	Description
0 GEN	Global enable bit. This bit enables the operation of the TBG module. If not enabled the TBG is in bypass mode, thus triggers selected by ISEL4-7 are routed directly to the CFIFO input. If enabled, then the TBG behavior depends upon the clock selection CLKSEL bits. 0 TBG is disabled, module operation is transparent regarding the triggers selected by ISEL4-7. 1 TBG is enabled, generating triggers according to ISEL4-7 selection and clock selection.
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–5 CLKSEL	Clock Selection bits. The clock selection bits select three clocks that are used to increment the TBG internal counter: system clock, ADC0 clock, ADC1 clock and no clock. If no clock is select the internal counter remains inactive and no triggers are generated to the corresponding eQADC CFIFO. 00 No clock selected. No triggers are generated independently of ISEL4-7 trigger selection. 01 System clock. TBG increments at system clock rate. 10 ADC0 clock. TBG increments at ADC0 clock rate. 11 ADC1 clock. TBG increments at ADC1 clock rate.
6–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 TRIGPER	Trigger Period. The Trigger period field defines the time interval from one trigger to the next in a trigger burst. The trigger period value is loaded into a TBG internal counter which performs a count down. When zero value is reached one trigger is generated for the corresponding eQADC CFIFO.

8.2.35 Trigger Burst Generator Control Registers for eQADC_B (SIU_TBG_CR_Bn)

These registers provide control bits for the Trigger Burst Generators (TBG) connected at the trigger inputs of the 6 CFIFOS of eQADC_B. There is one register for each eQADC_B CFIFO input. The numbering goes from 0 to 5, n=0 corresponding to address 0x968 and CFIFO0, n=5 corresponding to address 0x97C and CFIFO5. See Trigger Burst Generators for detailed information on the TBG feature.

Address: 0h base + 968h offset + (4d × i), where i=0d to 5d

SIU_TBG_CR_Bn field descriptions

Field	Description
0 GEN	Global enable bit. This bit enables the operation of the TBG module. If not enabled the TBG is in bypass mode, thus triggers selected by ISEL4-7 are routed directly to the CFIFO input. If enabled, then the TBG behavior depends upon the clock selection CLKSEL bits. It is necessary to clear this bit to change the CLKSEL and TRIGPER fields. 0 TBG is disabled, module operation is transparent regarding the triggers selected by ISEL4-7. 1 TBG is enabled, generating triggers according to ISEL4-7 selection and clock selection.
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–5 CLKSEL	Clock Selection bits. The clock selection bits select three clocks that are used to increment the TBG internal counter: peripheral clock (per_clk), ADC0 clock, ADC1 clock and no clock. If no clock is select the internal counter remains inactive and no triggers are generated to the corresponding eQADC CFIFO. NOTE: It is necessary to clear the global enable bit GEN when changing this field. 00 No clock selected. No triggers are generated independently of ISEL4-7 trigger selection. 01 Peripheral clock (per_clk). TBG increments at per_clk rate. 10 ADC0 clock. TBG increments at ADC0 clock rate. 11 ADC1 clock. TBG increments at ADC1 clock rate.
6–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 TRIGPER	Trigger Period. The Trigger period field defines the time interval from one trigger to the next in a trigger burst. The trigger period value is loaded into a TBG internal counter which performs a count down. When zero value is reached one trigger is generated for the corresponding eQADC CFIFO. NOTE: It is recommended to clear the global enable bit GEN when changing this field.

8.2.36 External Clock Control Register (SIU_ECCR)

The SIU_ECCR controls the timing relationship between the system clock and the external clocks ENGCLK and CLKOUT.

Address: 0h base + 984h offset = 984h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W

SIU_ECCR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 ENGDIV	Engineering Clock Division Factor. The ENGDIV field specifies the frequency ratio between the platform clock (plat_clk) and ENGCLK. The ENGCLK frequency is divided from the platform clock frequency according to the following equation: $EngineeringClockFrequency = \frac{PlatformClockFrequency}{(ENGDIV \times 2)}$ Setting ENGDIV to 0 makes the ENGCLK frequency equal to the platform clock frequency. NOTE: Maximum ENGCLK frequency is limited by the pad performance. Refer to the Electrical Specifications in the Data Sheet document for this device.
24 ECSS	Engineering clock source select. The ECSS bit selects the source clock to be divided to generate the ENGCLK clock. 0 The system clock is the source of the ENGCLK. 1 The crystal oscillator clock is the source of ENGCLK.
25–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 EBTS	External Bus Tap Select. Changes the phase relationship between the system clock and CLKOUT. Changing the phase relationship so that CLKOUT is advanced in relation to system clock increases the output hold time of the external bus signals to a non-zero value. It also increases the output delay times, increases the input hold times to non-zero values, and decreases the input setup times. Refer to the Data Sheet document for how the EBTS bit affects the electrical specifications.

Table continues on the next page...

SIU_ECCR field descriptions (continued)

Field	Description
	NOTE: The EBTS bit must not be modified while an external bus transaction is in progress. 0 External bus signals have zero output hold times. 1 External bus signals have non-zero output hold times.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 EBDF	External Bus Division Factor. Specifies the frequency ratio between the system clock and CLKOUT. The EBDF field must not be changed during an external bus access or while an access is pending. 00 Divide by 1. 01 Divide by 2. 10 Divide by 3. 11 Divide by 4.

8.2.37 System Clock Register (SIU_SYSDIV)

The SIU_SYSDIV register provides clock multiplexing control and clock frequency division factors to configure the system clocks. Please refer to the clocking section for a diagram showing how the fields of this register are used to control the various clock muxes and dividers.

NOTE

Do not change the contents of this register while the FEC is operating, otherwise transactions in the crossbar may be corrupted.

Address: 0h base + 9A0h offset = 9A0h

SIU_SYSDIV field descriptions

Field	Description
0 LCK	Write Lock Bit. When the LCK is written with a value of 1, writes to all other bits and fields in the SIU_SYSDIV register are disabled. The LCK bit can be set/cleared by software at any time. 0 SIU_SYSDIV register is unlocked and writes are permitted. 1 SIU_SYSDIV register is locked, and only writes to the LCK bit are permitted.
1–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 PLL0SEL	PLL0 Select. Selects the clock source for PLL0. 0 The crystal oscillator (XOSC) is the clock source for PLL0. 1 The internal RC oscillator (IRC) is the clock source for PLL0.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 PLL1SEL	PLL1 Select. Selects the clock source for PLL1. 0 The crystal oscillator (XOSC) is the clock source for PLL1. 1 The PHI1 output of PLL0 is the clock source for PLL1.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 PERCLKSEL	Peripheral Clock Select. Selects the clock source for eTPU and other communication peripherals that require non-FM clock for their protocol engines. 0 Clock is connected to the FM clock domain (output of the SYSCLKDIV divider), for legacy support. 1 Clock is connected to the non-FM clock domain (output of PLL0).
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–11 FMPERDIV	FM Clock Peripheral Divider. Selects the divider value for the clock that feeds the memory mapped portion of the peripheral interfaces, and also feeds peripheral engines that can tolerate FM modulation. CAUTION: For proper device operation, always use the FMPERDIV setting 00b for divide by 2. 00 Divide by 2. 01 Divide by 4. 10 Divide by 8. 11 Reserved.
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 PERDIV	Non-FM Clock Peripheral Divider. Selects the divider value for the clock that feeds protocol engines of peripherals that must be clocked by a stable non-FM clock. 00 Divide by 2. 01 Divide by 4. 10 Divide by 8. 11 Reserved.
16 MCANSEL	MCAN Select. Selects the clock source for both MCAN modules. 0 The crystal oscillator (XOSC) is the clock source for the MCAN modules. 1 The non-FM peripheral clock is the clock source for the MCAN modules.

Table continues on the next page...

SIU_SYSDIV field descriptions (continued)

Field	Description
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–19 SYSCLKSEL	System Clock Select. The SYSCLKSEL field directly selects the source of the system clock if the Progressive Clock Switch (PCS) is disabled. If the PCS is enabled, then the SYSCLKSEL field is a request to change the clock, and the actual changing is controlled by the PCS. In this case, information about the actual clock source driving the system clock is available in the SIU_PCSIFR[PCSMS] field. Note that if the PCS fails to switch (because, for example, it was programmed incorrectly), then the system clock will not switch to the clock requested by SYSCLKSEL, and SIU_PCSIFR[PCSMS] will still indicate the previous clock. 00 The system clock is driven by the 16 MHz Internal RC Oscillator (IRC). 01 The system clock is driven by the external oscillator (XOSC). 10 The system clock is driven by the FM PLL (PLL1). 11 The system clock is driven by the non-FM PLL (PLL0).
20–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 ETPUDIV	eTPU Clock Divider. Selects the divider value for the eTPU clock. 0 Divide by 2. 1 Divide by 1.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–29 SYSCLKDIV	System Clock Divider. Selects the divider value for the system clock coming out of PLL1. Note that the SYSCLKDIV divider is required in addition to the PLL output divider to allow other sources for the system clock (IRC, OSC) to be divided down to slowest frequencies to enable very low power modes. 000 Divide by 2. 001 Divide by 4. 010 Divide by 8. 011 Divide by 16. 100 Divide by 1. 101 Divide by 1. 110 Divide by 1. 111 Divide by 1.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 PCSEN	Progressive Clock Switch Enable. Enables or disables the progressive clock switching (PCS) feature on the system clock. 0 PCS disabled. 1 PCS enabled.

8.2.38 Halt Register 1 (SIU_HLT1)

This register is used to dispatch a request to various modules to halt their clock inputs. Each register bit drives a separate halt request signal. Modules respond differently to the halt request. The CPUs will allow their clock inputs to be halted only after the execution of the WAIT instruction. Most other modules will wait for internal activities to finish before allowing their clock inputs to be halted, but a few modules will allow the clocks to be halted immediately.

Some peripherals have an MDIS (module disable) bit in the module control register that can be set to disable the module clock, reducing power consumption. In most cases the peripheral registers are still readable and writeable. However, using the SIU_HALT1 register also disables the read/write functions of the disabled peripheral registers for additional power saving.

When the clocks of all CPUs have been halted and all cross-bar masters are idle, then the clocks of the following modules are also halted automatically: cross-bar, peripheral bridges, system RAM, DMA, STM and Semaphores. The interrupt controller and SWT_A/SWT_B clocks are never stopped.

Address: 0h base + 9A4h offset = 9A4h

SIU_HLT1 field descriptions

Field	Description
0 CORE0	Halt Core 0. Halts the clock inputs of Core 0 after the execution of the WAIT instruction. 0 No halt request. 1 Dispatch halt request.

Table continues on the next page...

SIU_HLT1 field descriptions (continued)

Field	Description
1 CORE1	Halt Core 1. Halt the clock inputs of Core 1 after the execution of the WAIT instruction. 0 No halt request. 1 Dispatch halt request.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 CSE	Halt CSE. Halt the clock inputs of the Cryptographic Services Engine. The clocks are halted immediately after this bit is set, therefore software must guarantee that the CSE module can be stopped prior to asserting the halt request. 0 No halt request. 1 Dispatch halt request.
4 ETPUC	Halt eTPU C. Dispatch a halt request to Enhanced Timing Processing Unit C and to the Reaction Module. These modules will hold the request until all internal activities are concluded, then they will allow their clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
5 ETPUA	Halt eTPU A/B. Dispatch a halt request to Enhanced Timing Processing Unit A/B. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
6 NPC	Halt NPC. Dispatch a halt request to the Nexus Port Controller. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. NOTE: When this bit is 1 and the NPC clock is halted, if any of the following Nexus clients gets out of the IDLE state, the NPC clock is re-enabled temporarily: • Core0 • Core1 • eDMA_A • eDMA_B • SIPI The NPC clock is re-enabled only during the period when any of these clients is out of the IDLE state. When all of these clients resume the IDLE state, the NPC clock is halted again automatically. 0 No halt request. 1 Dispatch halt request.
7 EBI	Halt EBI. Dispatch a halt request to the External Bus Interface module. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
8 EQADCB	Halt eQADC B. Dispatch a halt request to the Enhanced Queued Analog-to-Digital Converter B. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. This halt request prompts eQADC_B to enter the module's Stop mode. 0 No halt request. 1 Dispatch halt request.

Table continues on the next page...

SIU_HLT1 field descriptions (continued)

Field	Description
9 EQADCA	Halt eQADC A. Dispatch a halt request to the Enhanced Queued Analog-to-Digital Converter A. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. This halt request prompts eQADC_A to enter the module's Stop mode. 0 No halt request. 1 Dispatch halt request.
10 EMIOS0	Halt eMIOS 0. Halt the clock inputs of the Enhanced Modular I/O System 0. The clocks are halted immediately after this bit is set, therefore software must guarantee that the eMIOS_0 module can be stopped prior to asserting the halt request. 0 No halt request. 1 Dispatch halt request.
11 DECFIL	Halt DECFIL. Dispatch a halt request to all Decimation Filter modules. The modules will hold the request until all internal activities are concluded, then they will allow their clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
12 EMIOS1	Halt eMIOS 1. Halt the clock inputs of the Enhanced Modular I/O System 1. The clocks are halted immediately after this bit is set, therefore software must guarantee that the eMIOS_1 module can be stopped prior to asserting the halt request. 0 No halt request. 1 Dispatch halt request.
13 PIT	Halt PIT. Dispatch a halt request to the Periodic Interval Timer. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
14–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 FLEXCAND	Halt FlexCAN D. Dispatch a halt request to the Flexible Controller Area Network D. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
17 FLEXCANC	Halt FlexCAN C. Dispatch a halt request to the Flexible Controller Area Network C. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
18 FLEXCANB	Halt FlexCAN B. Dispatch a halt request to the Flexible Controller Area Network B. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
19 FLEXCANA	Halt FlexCAN A. Dispatch a halt request to the Flexible Controller Area Network A. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.

Table continues on the next page...

SIU_HLT1 field descriptions (continued)

Field	Description
20 DSPID	Halt DSPI D. Dispatch a halt request to the Deserial/Serial Peripheral Interface D. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
21 DSPIC	Halt DSPI C. Dispatch a halt request to the Deserial/Serial Peripheral Interface C. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
22 DSPIB	Halt DSPI B. Dispatch a halt request to the Deserial/Serial Peripheral Interface B. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
23 DSPIA	Halt DSPI A. Dispatch a halt request to the Deserial/Serial Peripheral Interface A. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
24 DSPIE	Halt DSPI E. Dispatch a halt request to the Deserial/Serial Peripheral Interface E. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 ESCIF	Halt eSCI F. Dispatch a halt request to the Enhanced Serial Communication Interface F. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
27 ESCIE	Halt eSCI E. Dispatch a halt request to the Enhanced Serial Communication Interface E. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
28 ESCID	Halt eSCI D. Dispatch a halt request to the Enhanced Serial Communication Interface D. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
29 ESCIC	Halt eSCI C. Dispatch a halt request to the Enhanced Serial Communication Interface C. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.
30 ESCIB	Halt eSCI B. Dispatch a halt request to the Enhanced Serial Communication Interface B. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted.

Table continues on the next page...

SIU_HLT1 field descriptions (continued)

Field	Description
	0 No halt request. 1 Dispatch halt request.
31 ESCIA	Halt eSCI A. Dispatch a halt request to the Enhanced Serial Communication Interface A. The module will hold the request until all internal activities are concluded, then it will allow its clock inputs to be halted. 0 No halt request. 1 Dispatch halt request.

8.2.39 Halt Acknowledge Register 1 (SIU_HLTACK1)

The SIU_HLTACK1 bits indicate that the request to halt the modules via the respective SIU_HLT1 bits have completed and the clock inputs to the modules have been disabled.

Address: 0h base + 9A8h offset = 9A8h

8.2.40 Core0 Reset Vector Register (SIU_RSTVEC0)

This register contains the reset vector, reset control and instruction execution type selection for Core0. The RST bit is qualified by the CORE0 halt bit in the SIU_HLT1 register, such that both must be 1 for a core reset to occur. The order in which the RST and core halt bits are asserted does not matter. After both halt and RST bits are asserted, internal logic places a request to halt the corresponding core clocks, but the core may continue to run until such time that it terminates any pending crossbar master bus cycles and interrupt controller interaction that might prevent their use by other bus masters. When all pending transactions finish, the core will be in reset state with clock stopped. Exit of reset state is done by negating either SIU_HLT1[CORE0] or the RST bit. Negating just one is enough to remove the core from reset state.

The reset value of the halt and RST bits for Core0 is 0 by default to allow Core0 to execute out of reset. The halt and RST bits for Core1 are 1 by default to prevent Core1 from executing out of reset.

Any attempt to reset both cores by setting both RST bits will result in an immediate system reset, with the cause of the reset recorded in the SIU_RSR[CPURS] bit.

NOTE

The halt acknowledge bit in the SIU_HLTACK1 register will not be asserted for a core in reset state. Even though setting the

halt bit is part of the procedure to put a core in reset state, the halt acknowledge bit is only asserted when the WAIT instruction is executed and the core is stopped, but not in reset state.

Address: 0h base + 9ACh offset = 9ACh

SIU_RSTVEC0 field descriptions

Field	Description
0–29 RSTVEC	Reset Vector. The RSTVEC value determines the initial program counter upon exiting reset. The MMU TLB entry 0 effective and real page number (EPN/RPN) is automatically loaded with RSTVEC[0:21] when reset is released and the TLB entry size is set to 4KB. In the e200z759 Core Reference Manual the reset vector is referred to as p_rstbase[0-21].
30 RST	Controls the assertion of RESET to the core. Writing 1 to this bit causes the core to enter reset, provided the respective SIU_HLT1 bit is also set. Reads of this bit indicate whether the core is being held in reset. 0 Core is not in reset. 1 Reset request.
31 VLE	VLE Select. The VLE bit selects whether the core executes VLE or Book E code at the reset vector address. 0 Book E. 1 VLE.

8.2.41 Core1 Reset Vector Register (SIU_RSTVEC1)

This register contains the reset vector, reset control and instruction execution type selection for Core1. The RST bit is qualified by the CORE1 halt bit in the SIU_HLT1 register, such that both must be 1 for a core reset to occur. The order in which the RST and core halt bits are asserted does not matter. After both halt and RST bits are asserted, internal logic places a request to halt the corresponding core clocks, but the core may continue to run until such time that it terminates any pending crossbar master bus cycles and interrupt controller interaction that might prevent their use by other bus masters. When all pending transactions finish, the core will be in reset state with clock stopped. Exit of reset state is done by negating either SIU_HLT1[CORE1] or the RST bit. Negating just one is enough to remove the core from reset state.

The reset value of the halt and RST bits for Core0 is 0 by default to allow Core0 to execute out of reset. The halt and RST bits for Core1 are 1 by default to prevent Core1 from executing out of reset.

Any attempt to reset both cores by setting both RST bits will result in an immediate system reset, with the cause of the reset recorded in the SIU_RSR[CPURS] bit.

NOTE

The halt acknowledge bit in the SIU_HLTACK1 register will not be asserted for a core in reset state. Even though setting the halt bit is part of the procedure to put a core in reset state, the halt acknowledge bit is only asserted when the WAIT instruction is executed and the core is stopped, but not in reset state.

8.2.42 Core0 PID mapping control register (SIU_C0PID)

This register allows an external tool to modify the logical to physical address mapping without interrupting normal application code execution in either core. An optional synchronization mechanism using the nex_wevto[2] watchpoint event output from each core allows the mapping that is selected by the tool to change deterministically, when a specified instruction address is reached or a specified load/store address is accessed. If the synchronization mechanism is not enabled, a write to the register is propagated immediately to the MMU.

8.2.44 Halt Register 2 (SIU_HLT2)

This register is used to dispatch a request to various modules to halt their clock inputs. Each register bit drives a separate halt request signal. Modules respond differently to the halt request. Most modules will wait for internal activities to finish before allowing their clock inputs to be halted, but a few modules will allow the clocks to be halted immediately.

Some peripherals have an MDIS (module disable) bit in the module control register that can be set to disable the module clock, reducing power consumption. In most cases the peripheral registers are still readable and writeable. However, using the SIU_HALT2 register also disables the read/write functions of the disabled peripheral registers for additional power saving.

When the clocks of all CPUs have been halted and all cross-bar masters are idle, then the clocks of the following modules are also halted automatically: cross-bar, peripheral bridges, system RAM, DMA, STM and Semaphores. The interrupt controller and SWT_A/SWT_B clocks are never stopped.

* Notes:

- RET field: RET is loaded with 1000b when the REE bit of the UTEST Reset Escalation Configuration DCF client is 1.

SIU_RCR field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 RET	Reset Escalation Threshold. This field defines the number of reset cycles not caused by POR that the device can execute before being held permanently in reset state, waiting for a POR. The defined number of non-POR reset cycles is the decimal value of RET plus 1, except when RET is 0. A value of 0 in this field disables the reset escalation feature. Any CPU write to the RET field re-initiates the escalation counting process.

8.2.50 Lock-Step Status Register (SIU_LOCKSTEP)

The SIU_LOCKSTEP register contains a status bit that indicates whether the checker core is enabled or not. The checker core is enabled by setting the LOCKSTEP_EN in the Miscellaneous DCF client. A reset cycle is required for a change in LOCKSTEP_EN to take effect.

Address: 0h base + 9D4h offset = 9D4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SIU_LOCKSTEP field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 LSE	Lock Step Enable. Indicates whether the checker core is enabled or not. 0 Lock step operation is disabled. 1 Lock step operation is enabled.

8.2.51 Progressive Clock Switch Interrupt Enable Register (SIU_PCSE)

The SIU_PCSE controls the generation of an interrupt request when the SIU_PCSIFR[PCSI] becomes set at the end of a progressive clock switch (PCS) operation.

Address: 0h base + 9D8h offset = 9D8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SIU_PCSIFR field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 PCSMS	PCS Status. Indicates the clock source which effectively drives the system clock. Note that the clock source indicated by PCSMS may be different than the one requested by SIU_SYSDIV[SYSCLKSEL] because the PCS may still be active, or because the PCS may have failed to switch to the new clock (for example, if it was programmed incorrectly). After the PCSI flag gets set, indicating that the PCS operation is finished, software can read the value of the PCSMS field to find out if the PCS switch was successful. 00 The system clock is driven by the 16 MHz Internal RC Oscillator (IRC). 01 The system clock is driven by the external oscillator (XOSC). 10 The system clock is driven by the FM PLL (PLL1). 11 The system clock is driven by the non-FM PLL (PLL0).
31 PCSI	PCS Interrupt Flag. Indicates the end of a progressive clock switch operation. Must be cleared by writing '1' to the bit. 0 No PCS operation finished since last time this flag was cleared. 1 PCS operation finished.

8.2.53 Fast Ethernet Controller Control Register (SIU_FECCR)

The SIU_FECCR is used to select between the Media Independent Interface Lite (MII-Lite) and the Reduced Media Independent Interface (RMII) modes of the Fast Ethernet Controller (FEC).

Address: 0h base + 9E0h offset = 9E0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SIU_FECCR field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 FM	FEC Mode. Selects between MII-Lite and RMII modes in the FEC module. Note that this bit does not affect the configuration of pads associated with the FEC operation. Pad configuration must be done in the PCR registers. 0 RMII mode is selected. 1 MII-Lite mode is selected.

8.2.54 ECC Error Injection Register (SIU_ECCEIR)

The SIU_ECCEIR is used to inject ECC errors into reading operations on the MCAN RAM array. This register is intended to support testing of the error reporting path from the MCAN ECC logic to the FCCU input. Before programming this register, it is recommended to disable MCAN operations and then access the MCAN memories directly with the CPU.

ECC errors will be introduced into the read data path, therefore the memory contents remain intact. As soon as the error injection is disabled, normal MCAN operation can be resumed without the need to fix any memory content.

Address: 0h base + 9E4h offset = 9E4h

SIU_ECCEIR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 INVC	Invert Control. Controls whether the ECC checkbits can be inverted during memory read operations on the MCAN memory array. 0 No checkbit substitution is performed on MCAN memory read accesses. 1 Checkbit substitution is performed on MCAN write operations onto the MCAN memory.
25–31 CHKINVM	Check Bit Invert Mask. This field specifies which bits of the ECC checkbits are inverted during read operations on the MCAN memory array. For each bit of this field: 0 The bit is not inverted. 1 The bit is inverted.

8.2.55 Parallel GPIO Pin Data Output Registers (SIU_PGPDO_n)

The PGPDO_x registers are written to by software to drive data out on external GPIO pins. These registers access the same GPIO pins accessed by the SIU_GPDO0 - SIU_GPDO511 registers, and they share the same hardware registers. For example, SIU_PGPDO0 bit 0 is the same as SIU_GPDO0 bit 7, SIU_PGPDO0 bit 1 is the same as SIU_GPDO1 bit 7, and so on.

The parallel GPIO read/write addresses map to the same physical addresses of the normal GPIO. This way both GPDO and corresponding PGPDO registers will be updated by a single write to either registers.

Address: 0h base + C00h offset + (4d × i), where i=0d to 15d

28 PGPDO28	Pin Data Out. This bit stores the data to be driven out on the external GPIO pin controlled by this register. 0 Logic low value is driven on the GPIO pin when the pin is configured as an output. 1 Logic high value is driven on the GPIO pin when the pin is configured as an output.
29 PGPDO29	Pin Data Out. This bit stores the data to be driven out on the external GPIO pin controlled by this register. 0 Logic low value is driven on the GPIO pin when the pin is configured as an output. 1 Logic high value is driven on the GPIO pin when the pin is configured as an output.
30 PGPDO30	Pin Data Out. This bit stores the data to be driven out on the external GPIO pin controlled by this register. 0 Logic low value is driven on the GPIO pin when the pin is configured as an output. 1 Logic high value is driven on the GPIO pin when the pin is configured as an output.
31 PGPDO31	Pin Data Out. This bit stores the data to be driven out on the external GPIO pin controlled by this register. 0 Logic low value is driven on the GPIO pin when the pin is configured as an output. 1 Logic high value is driven on the GPIO pin when the pin is configured as an output.

8.2.56 Parallel GPIO Pin Data Input Registers (SIU_PGPDIn)

The GPD_Ix registers are read-only registers that allow reading of external GPIO pins. These registers access the same GPIO pins accessed by the SIU_GPD_I0 - SIU_GPD_I15 registers, and they share the same hardware registers. For example, SIU_PGPD_I0 bit 0 is the same as SIU_GPD_I0 bit 7, SIU_PGPD_I0 bit 1 is the same as SIU_GPD_I1 bit 7, and so on.

The parallel GPIO read/write addresses map to the same physical addresses of the normal GPIO. This way both the GPD_I and corresponding PGPD_I registers are updated when a pin state changes, provided that the IBE bit is asserted in the corresponding PCR register.

Address: 0h base + C40h offset + (4d × i), where i=0d to 15d

SIU_PGPDIn field descriptions (continued)

Field	Description
30 PGPDI30	Pin Data In. This bit reflects the value of the external GPIO pin associated with the register, provided that the IBE bit is asserted in the corresponding PCR register. 0 The value of the GPIO pin is logic low. 1 The value of the GPIO pin is logic high.
31 PGPDI31	Pin Data In. This bit reflects the value of the external GPIO pin associated with the register, provided that the IBE bit is asserted in the corresponding PCR register. 0 The value of the GPIO pin is logic low. 1 The value of the GPIO pin is logic high.

8.2.57 Masked Parallel GPIO Pin Data Output Registers (SIU_MPGPDO_n)

The MPGPDOn are write-only registers that are used to drive data out on external GPIO pins. These registers access the same GPIO pins accessed by SIU_GPDO0 - SIU_GPDO511 bit registers. The 16 least significant bits in the SIU_MPGPDO share the same hardware registers used by SIU_GPDO. For example, SIU_MPGPDO_n bit 16 is the same as SIU_GPDO_n bit 7, SIU_MPGPDO0 bit 17 is the same as SIU_GPDO1 bit 7, and so on.

The mask bits qualify the write operation of the data bits. Writing to DATAn is only effective if the corresponding MASKn bit is written to logic one at the same time (same access to the register). The value that was written to SIU_MPGPDO cannot be read back by a read operation to the same register. It can, however, be accessed by reading the corresponding SIU_GPDO register.

Field	Description
21 DATA5	Pin Data Out. This bit stores the data to be driven out on the external GPIO pin controlled by this register. 0 Logic low is driven on the corresponding GPIO pin when the pin is configured as an output. 1 Logic high is driven on the corresponding GPIO pin when the pin is configured as an output.
22 DATA6	Pin Data Out. This bit stores the data to be driven out on the external GPIO pin controlled by this register. 0 Logic low is driven on the corresponding GPIO pin when the pin is configured as an output. 1 Logic high is driven on the corresponding GPIO pin when the pin is configured as an output.
23 DATA7	Pin Data Out. This bit stores the data to be driven out on the external GPIO pin controlled by this register. 0 Logic low is driven on the corresponding GPIO pin when the pin is configured as an output. 1 Logic high is driven on the corresponding GPIO pin when the pin is configured as an output.
24 DATA8	Pin Data Out. This bit stores the data to be driven out on the external GPIO pin controlled by this register. 0 Logic low is driven on the corresponding GPIO pin when the pin is configured as an output. 1 Logic high is driven on the corresponding GPIO pin when the pin is configured as an output.
25 DATA9	Pin Data Out. This bit stores the data to be driven out on the external GPIO pin controlled by this register. 0 Logic low is driven on the corresponding GPIO pin when the pin is configured as an output. 1 Logic high is driven on the corresponding GPIO pin when the pin is configured as an output.
26 DATA10	Pin Data Out. This bit stores the data to be driven out on the external GPIO pin controlled by this register. 0 Logic low is driven on the corresponding GPIO pin when the pin is configured as an output. 1 Logic high is driven on the corresponding GPIO pin when the pin is configured as an output.
27 DATA11	Pin Data Out. This bit stores the data to be driven out on the external GPIO pin controlled by this register. 0 Logic low is driven on the corresponding GPIO pin when the pin is configured as an output. 1 Logic high is driven on the corresponding GPIO pin when the pin is configured as an output.
28 DATA12	Pin Data Out. This bit stores the data to be driven out on the external GPIO pin controlled by this register. 0 Logic low is driven on the corresponding GPIO pin when the pin is configured as an output. 1 Logic high is driven on the corresponding GPIO pin when the pin is configured as an output.
29 DATA13	Pin Data Out. This bit stores the data to be driven out on the external GPIO pin controlled by this register. 0 Logic low is driven on the corresponding GPIO pin when the pin is configured as an output. 1 Logic high is driven on the corresponding GPIO pin when the pin is configured as an output.
30 DATA14	Pin Data Out. This bit stores the data to be driven out on the external GPIO pin controlled by this register. 0 Logic low is driven on the corresponding GPIO pin when the pin is configured as an output. 1 Logic high is driven on the corresponding GPIO pin when the pin is configured as an output.
31 DATA15	Pin Data Out. This bit stores the data to be driven out on the external GPIO pin controlled by this register. 0 Logic low is driven on the corresponding GPIO pin when the pin is configured as an output. 1 Logic high is driven on the corresponding GPIO pin when the pin is configured as an output.

8.2.58 Mask-Output High Register (SIU_DSPI_nH)

Each bit in the DSPI serialized output frame can contain a signal routed from the output of one of three on-chip sources. The sources on this device are the eTPU module, eMIOS module, or a software-updated GPO data register. The mapping between module or data register and the output frame for a single DSPI channel is performed by independent 32-bit registers, one for each module plus one for the data register.

These registers are one of the possible sources for the DSPI serialized output frame. The purpose of these registers is to allow any combination of bits in each half of the 32 bit serialized data frame to be updated with a single 32-bit write operation, while allowing other bits to maintain their previous state. This is accomplished by writing a 16 bit masked value coherently with an update value contained in a 16 bit output field, and only updating those bits in the output register for which the corresponding mask bit is set. The mask bits are write-only. A value written to a MASK bit only takes effect on the corresponding DATA bit on the same write cycle in which it is written. Reading a mask bit always returns zero.

8.2.60 Serialized Output Signal Selection Register for DSPI_A (SIU_ETPUBA)

Each bit in the DSPI serialized output frame can contain a signal routed from the output of one of three on-chip sources. The sources on this device are the eTPU module, eMIOS module, or a software-updated GPO data register. The mapping between module or data register and the output frame for a single DSPI channel is performed by independent 32-bit registers, one for each module plus one for the data register.

The following register is used by DSPI_A to select the sources of the serialized output when running in DSI or CSI configuration.

Each register bit enables a path from the eTPU_B channel, eMIOS channel and data register bit SIU_DSPIAH/SIU_DSPIAL to the equivalent bit position in the DSPI_A serialized output frame. The user must ensure that bit selections from each of these registers do not overlap. Multiple sources are logically ORed, which provides the potential for combining outputs from multiple timer channels and data registers to produce more complex bit behavior.

8.2.62 Serialized Output Signal Selection Register for DSPI_A (SIU_DSPIAHLA)

Each bit in the DSPI serialized output frame can contain a signal routed from the output of one of three on-chip sources. The sources on this device are the eTPU module, eMIOS module, or a software-updated GPO data register. The mapping between module or data register and the output frame for a single DSPI channel is performed by independent 32-bit registers, one for each module plus one for the data register.

The following register is used by DSPI_A to select the sources of the serialized output when running in DSI or CSI configuration.

Each register bit enables a path from the eTPU_B channel, eMIOS channel and data register bit SIU_DSPIAH/SIU_DSPIAL to the equivalent bit position in the DSPI_A serialized output frame. The user must ensure that bit selections from each of these

Memory Map and Register Definition

registers do not overlap. Multiple sources are logically ORed, which provides the potential for combining outputs from multiple timer channels and data registers to produce more complex bit behavior.

8.2.64 Serialized Output Signal Selection Register for DSPI_B (SIU_EMIOSB)

Each bit in the DSPI serialized output frame can contain a signal routed from the output of one of three on-chip sources. The sources on this device are the eTPU module, eMIOS module, or a software-updated GPO data register. The mapping between module or data register and the output frame for a single DSPI channel is performed by independent 32-bit registers, one for each module plus one for the data register.

The following register is used by DSPI_B to select the sources of the serialized output when running in DSI or CSI configuration.

Each register bit enables a path from the eTPU_A channel, eMIOS channel and data register bit SIU_DSPIBH/SIU_DSPIBL to the equivalent bit position in the DSPI_B serialized output frame. The user must ensure that bit selections from each of these registers do not overlap. Multiple sources are logically ORed, which provides the potential for combining outputs from multiple timer channels and data registers to produce more complex bit behavior.

8.2.66 Serialized Output Signal Selection Register for DSPI_C (SIU_ETPUAC)

Each bit in the DSPI serialized output frame can contain a signal routed from the output of one of three on-chip sources. The sources on this device are the eTPU module, eMIOS module, or a software-updated GPO data register. The mapping between module or data register and the output frame for a single DSPI channel is performed by independent 32-bit registers, one for each module plus one for the data register.

The following register is used by DSPI_C to select the sources of the serialized output when running in DSI or CSI configuration.

Each register bit enables a path from the eTPU_A/B channel, eMIOS channel and data register bit SIU_DSPICH/SIU_DSPICL to the equivalent bit position in the DSPI_C serialized output frame. The user must ensure that bit selections from each of these registers do not overlap. Multiple sources are logically ORed, which provides the potential for combining outputs from multiple timer channels and data registers to produce more complex bit behavior.

8.2.68 Serialized Output Signal Selection Register for DSPI_C (SIU_DSPICHL)

Each bit in the DSPI serialized output frame can contain a signal routed from the output of one of three on-chip sources. The sources on this device are the eTPU module, eMIOS module, or a software-updated GPO data register. The mapping between module or data register and the output frame for a single DSPI channel is performed by independent 32-bit registers, one for each module plus one for the data register.

The following register is used by DSPI_C to select the sources of the serialized output when running in DSI or CSI configuration.

Each register bit enables a path from the eTPU_A/B channel, eMIOS channel and data register bit SIU_DSPICH/SIU_DSPICL to the equivalent bit position in the DSPI_C serialized output frame. The user must ensure that bit selections from each of these registers do not overlap. Multiple sources are logically ORed, which provides the potential for combining outputs from multiple timer channels and data registers to produce more complex bit behavior.

SIU_DSPICHL field descriptions

Field	Description
0 DSPICH0	SIU_DSPICH Select. Select one bit of the DSPI_C GPO Mask Output High Register to source the serialized DSPI_C output. 0 This bit in the DSPI_C serialized output frame will not use the respective SIU_DSPICH bit. 1 This bit in the DSPI_C serialized output frame will use the respective SIU_DSPICH bit.
1 DSPICH1	SIU_DSPICH Select. Select one bit of the DSPI_C GPO Mask Output High Register to source the serialized DSPI_C output. 0 This bit in the DSPI_C serialized output frame will not use the respective SIU_DSPICH bit. 1 This bit in the DSPI_C serialized output frame will use the respective SIU_DSPICH bit.
2 DSPICH2	SIU_DSPICH Select. Select one bit of the DSPI_C GPO Mask Output High Register to source the serialized DSPI_C output. 0 This bit in the DSPI_C serialized output frame will not use the respective SIU_DSPICH bit. 1 This bit in the DSPI_C serialized output frame will use the respective SIU_DSPICH bit.
3 DSPICH3	SIU_DSPICH Select. Select one bit of the DSPI_C GPO Mask Output High Register to source the serialized DSPI_C output. 0 This bit in the DSPI_C serialized output frame will not use the respective SIU_DSPICH bit. 1 This bit in the DSPI_C serialized output frame will use the respective SIU_DSPICH bit.
4 DSPICH4	SIU_DSPICH Select. Select one bit of the DSPI_C GPO Mask Output High Register to source the serialized DSPI_C output. 0 This bit in the DSPI_C serialized output frame will not use the respective SIU_DSPICH bit. 1 This bit in the DSPI_C serialized output frame will use the respective SIU_DSPICH bit.
5 DSPICH5	SIU_DSPICH Select. Select one bit of the DSPI_C GPO Mask Output High Register to source the serialized DSPI_C output. 0 This bit in the DSPI_C serialized output frame will not use the respective SIU_DSPICH bit. 1 This bit in the DSPI_C serialized output frame will use the respective SIU_DSPICH bit.
6 DSPICH6	SIU_DSPICH Select. Select one bit of the DSPI_C GPO Mask Output High Register to source the serialized DSPI_C output. 0 This bit in the DSPI_C serialized output frame will not use the respective SIU_DSPICH bit. 1 This bit in the DSPI_C serialized output frame will use the respective SIU_DSPICH bit.
7 DSPICH7	SIU_DSPICH Select. Select one bit of the DSPI_C GPO Mask Output High Register to source the serialized DSPI_C output. 0 This bit in the DSPI_C serialized output frame will not use the respective SIU_DSPICH bit. 1 This bit in the DSPI_C serialized output frame will use the respective SIU_DSPICH bit.
8 DSPICH8	SIU_DSPICH Select. Select one bit of the DSPI_C GPO Mask Output High Register to source the serialized DSPI_C output.

8.2.69 Serialized Output Signal Selection Register for DSPI_C (SIU_ETPUBC)

Each bit in the DSPI serialized output frame can contain a signal routed from the output of one of three on-chip sources. The sources on this device are the eTPU module, eMIOS module, or a software-updated GPO data register. The mapping between module or data register and the output frame for a single DSPI channel is performed by independent 32-bit registers, one for each module plus one for the data register.

The following register is used by DSPI_C to select the sources of the serialized output when running in DSI or CSI configuration.

Each register bit enables a path from the eTPU_A/B channel, eMIOS channel and data register bit SIU_DSPICH/SIU_DSPICL to the equivalent bit position in the DSPI_C serialized output frame. The user must ensure that bit selections from each of these registers do not overlap. Multiple sources are logically ORed, which provides the potential for combining outputs from multiple timer channels and data registers to produce more complex bit behavior.

8.2.71 Serialized Output Signal Selection Register for DSPI_D (SIU_EMIOSD)

Each bit in the DSPI serialized output frame can contain a signal routed from the output of one of three on-chip sources. The sources on this device are the eTPU module, eMIOS module, or a software-updated GPO data register. The mapping between module or data register and the output frame for a single DSPI channel is performed by independent 32-bit registers, one for each module plus one for the data register.

The following register is used by DSPI_D to select the sources of the serialized output when running in DSI or CSI configuration.

The register bit enables a path from the eTPU_B channel or eMIOS channel to the equivalent bit position in the DSPI_D serialized output frame. The user must ensure that bit selections from each of these registers do not overlap. Multiple sources are logically ORed, which provides the potential for combining outputs from multiple timer channels and data registers to produce more complex bit behavior.

Address: 0h base + D74h offset = D74h

8.2.73 GPIO Pin Data Input Register (SIU_GPDIn)

Previous devices are limited to supporting a maximum of 256 general purpose input registers, and thus a maximum GPIO input assignment of GPIO[0:255]. The reason was that only 256 bytes of SIU address space were allocated for the GPIO Pin Data Input registers, and adjacent memory locations are unavailable. To accommodate the extended number of the GPIO pads, this device has a new memory map definition of 512 bytes for allocating up to 512 GPIO Pin Data Input registers. For compatibility, the first used 256 GPIO Pin Data Input registers are mapped to both the old and new locations.

Each SIU_GPDIn register specifies the input state for the GPDIn[n] pin. The *n* notation in the SIU_GPDIn register name relates to the *[n]* in GPIO[n] signal name. For example, SIU_GPDI246 contains the PDI246 bit for CNTXD_GPIO246. Gaps exist in the memory map where registers correspond to GPIO pins that are not implemented in the package.

Software reads the SIU_GPDIn registers to get the input state of the external GPIO pin. Each GPDIn register contains the input state of one external GPIO pin. If a GPDIn register is configured as output, and the input buffer enable bit is set to one in the PCR register, the SIU_GPDIn register reflects the state of the output pin.

Table 8-1191. Implemented GPIO Pin Data Input Registers

8.2.76 Input Multiplexing Register2 (SIU_IMUX2)

The SIU_IMUX registers specify the source of peripheral inputs that may come from multiple package pins. The registers allow selection from 4 sources for each input. Each SIU_IMUX register contains 16 inputs, each with 2 bits (4 sources).

Some registers are reserved for future use, and some fields within some of the registers are also reserved.

8.2.82 Input Multiplexing Register12 (SIU_IMUX12)

The SIU_IMUX registers specify the source of peripheral inputs that may come from multiple package pins. The registers allow selection from 4 sources for each input. Each SIU_IMUX register contains 16 inputs, each with 2 bits (4 sources).

Some registers are reserved for future use, and some fields within some of the registers are also reserved.

8.3 SIU_B

SIU_B contains a set of mirrored PCR configuration registers, GPO data registers, and GPI data registers for GPIO[240:243] balls.

By default after reset, the mirrored registers are disabled and provide no function. The disabled state is indicated by PA[2:0] = 111b in the mirrored PCR (PCR_{nM}) register.

When a mirrored PCR_{nM} is enabled by writing a different value to its PA[2:0]:

- The PCR_{nM} has priority over the equivalent non-mirrored PCR register.
- The PCR_{nM} controls the ball function and characteristics defined by its implemented bit fields.
- The mirrored GPO data (GPDO_{nM}) and GPI data (GPDIn_M) registers control and reflect the logic level.

When the mirrored registers are enabled, writes to the non-mirrored registers have no effect.

Offsets for SIU_B registers are relative to SIU_B's base address, which differs from SIU's base address.

8.3.1 Pad Configuration Register Mirrored (SIU_B_PCRnM)

By default after reset, each mirrored register is disabled and provides no function. The disabled state is indicated by the reset value of PA[2:0] = 111b.

When a mirrored PCR_{nM} is enabled by writing a different value to its PA[2:0]:

- The PCR_{nM} has priority over the equivalent non-mirrored PCR register.
- The PCR_{nM} controls the ball function and characteristics defined by its implemented bit fields.

When the mirrored registers are enabled, writes to the non-mirrored registers have no effect.

These 16-bit registers are read from or written to as:

- 16-bit values aligned on 16-bit boundaries, or
- 32-bit values aligned on 32-bit address boundaries.

The PCRs allow software to control the following range of electrical characteristics of the external pads:

- Weak pullup/down enable/disable
- Weak pullup/down selection
- Slew-rate selection for outputs
- Drive strength selection for outputs
- Input buffer enable (when direction is configured for output)
- Input hysteresis enable/disable
- Open drain/push-pull output selection
- Multiplexed function selection
- Data direction selection

NOTE

The actual characteristics available in any SIU_B_PCR n M depend on the type of pad it controls. See the SIU_B_PCR n M definition table.

All device pin names begin with the primary function, followed by the alternate function, and then GPIO. See [External signal descriptions, multiplexing, and attributes](#) for how to identify the source module for primary and alternate functions and the description of these signals. For an additional signal description, see the chapter for the module that uses the signal.

There are a number of input signals on the device that have multiple external pins as input sources. Only one input source can be active at any time for these pins. To achieve this, a set of multiplexers controlled by the SIU_IMUX registers select which input will drive the function. See [Input Multiplexing Register0 \(SIU_IMUX0\)](#) to [Input Multiplexing Register12 \(SIU_IMUX12\)](#) for more details.

[Table 8-2037](#) defines the symbols for PCR n M fields' reset values that appear in [Table 8-2038](#).

Table 8-2037. SIU_B_PCR n M field reset-value symbols

Symbol	Meaning
—	Not implemented in the PCR n M. Software should write a default value of 0.
0 or 1	Function is implemented. For the exact definition of the 0 or 1 reset value, see the applicable field's description.

Table 8-2038. SIU_B_PCR[240:243]M reset values

SIU_B_PCRnM field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–5 PA	Pin assignment. Selects the function of a multiplexed pad. A separate port enable output signal from the SIU is asserted for each value of this register. The size of the field can be from 1 to 3 bits, depending on the amount of multiplexing on the pad. 000 GPIO. 001 Primary function. See the description of the corresponding SIU_PCRn. 010 Alternate 1. See the description of the corresponding SIU_PCRn. 011 Alternate 2. See the description of the corresponding SIU_PCRn. 100 Alternate 3. See the description of the corresponding SIU_PCRn. 101 Invalid value. 110 Invalid value. 111 SIU_B's mirrored PCRnM, GPDO _n M, and GPDInM registers are disabled and provide no function.
6 OBE	Output buffer enable. Enables the pad as an output and drives the output buffer enable signal. 0 Disable output buffer for the pad. 1 Enable output buffer for the pad.
7 IBE	Input buffer enable. Enables the pad as an input and drives the input buffer enable signal. 0 Disable input buffer for the pad. 1 Enable input buffer for the pad.
8–9 DSC	Drive strength control. Controls the pad drive strength. 00 10 pF drive strength. 01 20 pF drive strength. 10 30 pF drive strength. 11 50 pF drive strength.
10 ODE	Open drain output enable. Controls output driver configuration for the pads. Either open drain or push/pull driver configurations can be selected. This feature applies to output pins only. 0 Disable open drain for the pad (push/pull driver enabled). 1 Enable open drain for the pad.
11 HYS	Input hysteresis. Controls whether hysteresis is enabled for the pad. 0 Disable hysteresis for the pad. 1 Enable hysteresis for the pad.
12–13 SRC	Slew rate control. Controls slew rate for the pad. Slew rate control pertains to pins with slow or medium I/O pad types, and the output signals are driven according to the value of this field. Actual slew rate depends on the pad type and load. Refer to the electrical specifications for this information. 00 Minimum slew rate. 01 Medium slew rate. 10 Invalid value. 11 Maximum slew rate.
14 WPE	Weak pull up/down enable. Controls whether the weak pullup/down devices are enabled/disabled for the pad. Pullup/down devices are enabled by default.

Table continues on the next page...

SIU_B_PCRnM field descriptions (continued)

Field	Description
	0 Disable weak pull device for the pad. 1 Enable weak pull device for the pad.
15 WPS	Weak pull up/down select. Controls whether weak pullup or weak pulldown devices are used for the pad when weak pullup/down devices are enabled. During reset, the weak pull up/down behavior is controlled by the WKPCFG bit of the Miscellaneous DCF client, or by the WKPCFG pin when operating in legacy mode ((LEG=1 in the Miscellaneous DCF client). The WPS bit determines whether weak pullup or pulldown devices are used after reset, or for pads in which the WKPCFG pin does not determine the reset weak pullup/down state. 0 Pulldown is enabled for the pad. 1 Pullup is enabled for the pad.

8.3.2 GPIO Pin Data Output Register Mirrored (SIU_B_GPDO_nM)

By default after reset, each mirrored register is disabled and provides no function. The disabled state is indicated by PA[2:0] = 111b in the mirrored PCR (PCR_nM) register.

When a mirrored PCR_nM is enabled by writing a different value to its PA[2:0], the mirrored GPO data (GPDO_nM) and GPI data (GPDInM) registers control and reflect the logic level.

When the mirrored registers are enabled, writes to the non-mirrored registers have no effect.

Each GPDO register specifies the output data for the function assigned to the GPIO[*n*] pin. The *n* notation in the SIU_B_GPDO_nM register name relate to the [*n*] in GPIO[*n*] signal name. For example, SIU_B_GPDO240M contains the PDO240 bit for CNTXD_GPIO240.

Software writes to the SIU_B_GPDO_nM registers to drive data out on the external pin. Each register drives one external pin, which allows independent control of the pin. Writes to the SIU_B_GPDO_nM register are not reflected to the pin when a primary or alternate function is assigned or when an input function is assigned to the pin.

If the direction of a GPIO signal changes from input to output, the SIU_B_GPDO_nM register value is automatically driven out to the external pin without the need for a software update.

Writes to a SIU_B_GPDO_nM register have no effect when a primary or alternate function is assigned.

SIU_B

Address: 0h base + 6F0h offset + (1d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7
Read	0						PDOn	
Write								
Reset	0	0	0	0	0	0	0	0

SIU_B_GPDO*n*M field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 PDOn	Pin Data Out. This bit stores the data to be driven out on the external GPIO. If the register is read, it returns the value written. 0 Logic low value is driven to the external GPIO pin when the pin is configured as an output. 1 Logic high value is driven to the external GPIO pin when the pin is configured as an output.

8.3.3 GPIO Pin Data Input Register Mirrored (SIU_B_GPDI*n*M)

By default after reset, each mirrored register is disabled and provides no function. The disabled state is indicated by PA[2:0] = 111b in the mirrored PCR (PCR*n*M) register.

When a mirrored PCR*n*M is enabled by writing a different value to its PA[2:0], the mirrored GPO data (GPDO*n*M) and GPI data (GPDI*n*M) registers control and reflect the logic level.

When the mirrored registers are enabled, writes to the non-mirrored registers have no effect.

Each SIU_B_GPDI*n*M register specifies the input state for the GPDI[*n*] pin. The *n* notation in the SIU_GPDI*n* register name relates to the [*n*] in GPIO[*n*] signal name. For example, SIU_B_GPDI240M contains the PDI240 bit for CNTXD_GPIO240.

Software reads the SIU_B_GPDI*n*M registers to get the input state of the external GPIO pin. Each GPDI register contains the input state of one external GPIO pin. If a GPDI register is configured as output, and the input buffer enable bit is set to 1 in the PCR*n*M register, the SIU_B_GPDI*n*M register reflects the state of the output pin.

Address: 0h base + 8F0h offset + (1d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7

SIU_B_GPDInM field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 PDIn	Pin Data In. This bit reflects the state on the external GPIO/GPI pin. If PCRnM[IBE] is 1, then: 0 Signal on pin is logic zero. 1 Signal on pin is logic one.

8.4 Functional Description

The following sections provide a functional overview of the SIU operation.

8.4.1 Pad configuration

The pad configuration registers (SIU_PCR) in the SIU allow software control over the following electrical characteristics of the external pads:

- Weak pullup/down enable/disable
- Weak pullup/down selection
- Slew-rate selection for outputs
- Drive strength selection for outputs
- Input buffer enable (when direction is configured for output)
- Input hysteresis enable/disable
- Open drain/push-pull output selection
- Multiplexed function selection
- Data direction selection

The pad configuration registers are provided to allow centralized control over external pins that are shared by more than one module. Each pad configuration register controls a single pin.

8.4.2 Interrupts

There are 16 external interrupt inputs $\overline{\text{IRQ}}[0]–\overline{\text{IRQ}}[15]$ to the SIU. The IRQ inputs can be configured for rising-edge events, falling-edge events, or both.

External interrupt requests are triggered by rising- and/or falling-edge events that are enabled by setting a bit in:

- IRQ rising-edge event enable register (SIU_IREER)
- IRQ falling-edge event enable register (SIU_IFEER)

If the bit is set in both registers, both rising- and falling-edge events trigger an interrupt request. Each IRQ has a counter that tracks the number of system clock cycles that occur between the rising- and falling-edge events. An IRQ counter exists for each IRQ rising- or falling-edge event enable bit.

The digital filter length field in the IRQ digital filter register (SIU_IDFR) specifies the minimum number of system clocks that the IRQ signal must hold a logic value to qualify the edge-triggered event as a valid state change. When the number of system clocks in the IRQ counter equals the value in the digital filter length field, the IRQ state latches and the IRQ counter is cleared.

If the previous filtered state of the IRQ does not match the current state, and the rising- or falling-edge event is enabled, the IRQ flag bit is set to 1. For example, the IRQ flag bit is set if a rising-edge event occurs under the following conditions:

- Previous filtered IRQ state was a logic 0
- Current latched IRQ state is a logic 1
- Rising-edge event is enabled for the IRQ

When the counter for an IRQ is not enabled, the state of the IRQ is held in the current and previous state latches. The IRQ counter operates independently of the IRQ or overrun flag bit. Clearing the IRQ flag or overrun flag bits does not clear or reload the counter.

8.4.2.1 External interrupts

The IRQ signals map to 16 independent interrupt requests output from the SIU. The IRQ flag bit is set when a rising-edge and/or falling-edge event occurs for the IRQ. An external IRQ signal is asserted when all of the following occur:

- Enable bit is set in the IRQ rising- and/or falling-edge event registers (SIU_IREER, SIU_IFEER)
- IRQ flag bit is set in the external interrupt status register (SIU_EISR)
- Enable bit is set in the DMA/Interrupt request enable register (SIU_DIRER)
- Select bit is cleared in the DMA/Interrupt select register (SIU_DIRSR)

The NMI pin function or platform SWT can generate either an NMI or a critical interrupt. FCCU may also generate NMI if any fault is configured to cause NMI and this fault is triggered.

When WKPCFG_NMI_GPIO213 is enabled as NMI, the pin will override the PCR configuration after reset. SIU_DIRER selects between critical and non maskable interrupt use, SIU_EISR reports status of NMI and SIU_IFEER selects edge sensitivity of NMI input. See in the figure below the NMI and critical interrupt connections.

Figure 8-1613. NMI, critical, and SWT interrupts

8.4.2.2 DMA transfers

DMA IRQ signals ($\overline{\text{IRQ}}[0]$ through $\overline{\text{IRQ}}[3]$) map to four independent DMA transfer or interrupt request outputs configured in the SIU. A DMA transfer or interrupt request asserts when all of the following occur:

- IRQ flag bit is set in the external interrupt status register (SIU_EISR)
- Enable bit is set in the DMA transfer or interrupt request enable register (SIU_DIRER)
- Select bit is set in the DMA transfer or interrupt request select register (SIU_DIRSR)

The SIU receives a “DMA transfer done” signal for each DMA or interrupt request transmitted. When the “DMA done” signal asserts, the IRQ flag bit is cleared.

8.4.2.3 Overruns

An overrun IRQ exists for each overrun flag bit in the overrun status register (SIU_OSR). An overrun IRQ asserts when all of the following occur:

- Enable bit is set in the IRQ rising- and/or falling-edge event registers (SIU_IREER, SIU_IFEER)
- IRQ flag bit is set in the external interrupt status register (SIU_EISR)
- Bit is set in the overrun request enable and overrun status registers (SIU_ORER, SIU_OSR)
- Rising- or falling-edge event triggers an interrupt request

The SIU outputs one overrun IRQ bit that is the logical OR of all of the IRQ overrun bits.

8.4.2.4 Edge-detect events

An IRQ asserts when:

- An edge-detect event is enabled
- An edge-detect event occurs

To assert an IRQ when an edge-detect event occurs:

1. Set the enable bit in the IRQ rising- and falling-edge event enable registers (SIU_IREER, SIU_IFEER)
2. Set the enable bits for the DMA/Interrupt request enable register (SIU_DIRER)

The IRQ bit is set in the external IRQ status register (SIU_EISR) when an edge-detect event occurs for that IRQ. The following figure illustrates the behavior of DMA/interrupt requests within the SIU.

Figure 8-1614. SIU DMA/interrupt request diagram

8.4.3 General Purpose I/O (GPIO)

All GPIO functions for the device are provided by the SIU. Each device pad that has a GPIO signal has a pin configuration register (PCR) in the SIU where the GPIO function is selected. In addition, each device GPIO signal has an input data register (SIU_GPDI n) and an output data register (SIU_GPDO n).

The SIU also implements several parallel GPIO registers (SIU_PGPDO n and SIU_PGPDIn) that can be used to access up to 32 GPIO bits in a single- and word-sized accesses. The values read/written to these parallel registers are coherent with the data read/written to the SIU_GPDO n and SIU_GPDI n registers.

8.4.4 Pin serialization for DSPI

The SIU has four 32-bit outputs to DSPI modules. Each data frame contains the result of the selection, bit by bit, of three sources of data. Each data frame could receive data from eTPU, eMIOS, or an internally implemented GPO register. These registers are defined to provide compliance with the AutoSAR requirements for a PORT driver and support for coherent bit manipulation of up to 16 serialized data bits in a multitasking or multi-processor system. Because the DSPI frame size has been extended to a maximum of 32 bits, the coherent bit manipulation mechanism is partitioned into two separate 16-bit halves of the frame. The purpose of these registers is to allow any combination of bits in each half of the 32-bit serialized data frame to be updated with a single 32-bit write

operation, while allowing other bits to maintain their previous state. This is accomplished by writing a 16-bit masked value coherently with an update value contained in a 16 bit output field, and only updating those bits in the output register for which the corresponding mask bit is set.

The selection of which bits are actually output on the DSPI data frame is determined by a separate signal selection register. Each register bit enables a path from a single eTPU channel, eMIOS channel, and masked GPO register bit to the equivalent bit position in the DSPI channel frame. Note that each DSPI bit position can be driven by multiple inputs. Software must ensure that the correct bit sources are enabled for correct insertion of the required bit in the bit frame. Multiple sources are logically ORed, which provides the potential for combining outputs from multiple timer channels and data registers to produce more complex bit behavior. An example of how these registers are used to create the DSPI serialized output is shown below.

Function & Channel Selection																																

Figure 8-1615. Example of pin multiplexing

8.4.5 Internal multiplexing

The internal multiplexing select registers (SIU_ISEL4–8, SIU_EIISR, and SIU_DISR) select the input sources for the following components:

- eTPUA[24:29] inputs
- eQADC command FIFO trigger sources
- SIU external interrupt request signals

8.4.5.1 eQADC external trigger input multiplexing

The eQADC external trigger inputs can connect to one of the following pins:

- External pin
- eTPU channel
- eMIOS channel
- Periodic interrupt timer

The input source for each eQADC external trigger is configured in the eQADC Command FIFO Trigger Source Select Registers (SIU_ISEL4–7). For example, you can select one of the following signals to source the ETRIG[0] input trigger for the eQADC:

- TXDC_ETRIG[0]_GPIO[244] pin
- eTPUA[30] channel output
- eMIOS_1 channel 2 output
- Extended trigger source selection

All ETRIG inputs are multiplexed in the same manner. If an eTPU or eMIOS channel is selected as an ETRIG input to the eQADC, you can activate the alternate function of that eTPU or eMIOS signal on the external pin.

8.4.6 Trigger Burst Generators (TBG)

The Trigger Burst Generator module generates triggers for the eQADC CFIFOs based on a trigger window provided by several sources connected to the IMUX. eTPU, eMIOS, PIT and external SoC inputs can be selected by the IMUX, thus allowed to provide a time window in which the triggers are generated by the Trigger Burst Generator (TBG) module. The TBG is in bypass out of reset, thus backwards compatible functionality is provided. In this backwards compatible setting, the triggers are generated by the signals connected to the IMUX, thus TBG is transparent to the trigger generation. The following figure shows the Trigger Burst Generator block diagram and the waveforms associated with the input trigger window, the output trigger burst (on the left) and the counter waveform (on the right).

Figure 8-1616. Trigger Burst Generator block diagram

The following figure is a block diagram of the Trigger Burst Generator module interconnection with other modules. The TBG is connected between the multiplexers controlled by ISEL4–7 and eQADC_A/b CIFIFO trigger inputs. There are six CFIFOs on each eQADC and two instances of the eQADC modules, thus 12 TBG instances are used in order to provide trigger burst for all CFIFOs.

Figure 8-1617. Trigger Burst Generator interconnection

The TBG instances generate a continuous sequence of triggers while the signals selected by ISEL4–7 are asserted. When the trigger sources deassert, then the trigger burst is stopped. The output is identified as the trigger window in the subsequent sections. The opening of a trigger window means that the ISEL4–7 mux outputs enable the TBGs to start generating triggers.

8.4.6.1 Clock selection for the trigger burst

There are three clocks that can be selected for the TBG module. The system clock, the ADC0 clock, and the ADC1 clock. If no clock is selected the output trigger remains negated. It is necessary to have GEN = 0 when changing the CLKSEL to avoid unwanted triggers.

Figure 8-1618 shows the timing diagram of the signals when the peripheral clock (per_clk) is selected to generate the trigger burst. In this case, the trigger counter is enabled to count in all per_clk pulses. Therefore, the time interval between two trigger pulses is calculated as (TRIGPER + 1) per_clk periods. The figure shows the counter values when TRIGPER is configured to 4.

The first trigger occurs after one clock cycle after the trigger window begins. And the last trigger pulse occurs before the trigger window ends. Therefore, there is no trigger pulse outside the trigger window.

NOTE

When the trigger period register is zero (TRIGPER = 0), the trigger output switches to ON one per_clk period after the trigger window is opened, and remains ON (no transition) until the trigger window is closed.

Figure 8-1618. Trigger Burst Generator timing diagram when per_clk is selected

Figure 8-1619 shows the timing diagram of the signals when the ADC0/1 clocks are selected to generate the trigger burst. In this case, the trigger counter is enabled to count only in the positive edge events of that ADC clock. Therefore, the time interval between two trigger pulses is calculated as (TRIGPER + 1) ADC clock periods.

NOTE

When the trigger period register is zero (TRIGPER = 0) the trigger output pulse occurs for each ADC clock pulse.

The first trigger occurs one system clock cycle after the first detected rising edge of the selected ADC clock after the opening of the trigger window. And the last trigger pulse occurs before the trigger window closes. Therefore, there is no trigger pulse outside the trigger window.

Figure 8-1619. Trigger Burst Generator timing diagram when ADC0/1 is selected

8.4.6.2 Trigger generator configuration procedure

The trigger burst generator (TBG) is disabled out of reset because the GEN bit at the SIU_TBG_CR_A/Bn register from reset state is clear. This means the trigger window and internal/external selector input signals are bypassed to the respective output ports.

It is recommended to disable the TBG by clearing the GEN bit when the trigger period has to be changed. However, the input trigger window signal at the input port is bypassed to the trigger burst output. If this unwanted trigger must be avoided, the GEN bit must be maintained set and the CLKSEL bit must be configured to all 0 (the trigger counter is cleared at this time). Then it is possible to safely change the trigger period.

Chapter 9

Crossbar Switch (XBAR)

9.1 Chip-specific XBAR information

This chip has one instance of the XBAR module.

9.1.1 XBAR master and slave assignments

The following table lists the XBAR physical port numbers and logical IDs for all master ports on this SoC.

- Each port number matches the default priority assigned to the corresponding physical master port. This default priority equals the reset value of the priority field for each master port in the PRS n registers.
- A priority value of 0 is the highest priority. There is no "disabled" value for the priority.
- A Nexus_3 module and core data bus share the same physical master port for each core.

The logical master ID corresponds to the logical address provided by the master module and is unique for each module. The logical master IDs are used by the bus masters connected to the XBAR. The Nexus master is identified by setting the MSB in the 4-bit field that supplies the master ID number.

Table 9-1. XBAR master ports and logical master IDs

Module	Physical master port	Logical master ID	Comment
Core0 instruction	0	0	
Core0 data	1	0	
Nexus_3_0		8	Nexus_3_0 arbitrates with Core0 data for XBAR port 1
Core1 instruction	2	1	
Core1 data	3	1	
Nexus_3_1		9	Nexus_3_1 arbitrates with Core1 data for XBAR port 3

Table continues on the next page...

Table 9-1. XBAR master ports and logical master IDs (continued)

Module	Physical master port	Logical master ID	Comment
eDMA_A	4	4	
eDMA_B	5	5	
CSE	6	3	CSE and SIPI are connected to master 6 port through a concentrator
SIPI		6	
FEC	7	2	FEC on dedicated master via 2:1 clock gasket

The following table lists the XBAR slave port assignments and the master ports that can access each slave port. Each of the two slave ports for the Flash Memory Controller (PFLASH) module is dedicated to a different core master port. The two slave ports for SRAM support concurrent data accesses to the SRAM.

Table 9-2. XBAR slave port assignments

Module	Slave port	Select Address	Accessible by master port numbers
PFLASH	0	Address[31:29] = 000b	0,1 ¹
EBI	1	Address[31:29] = 001b	0,1,2,3,4,5,6,7
PRAMC_0	2	Address[31:18] = 0100_0000_0000_00b	0,1,2,3,4,5,6,7
PFLASH	3	Address[31:29] = 000b	2,3,4,5,6,7
PRAMC_1	4	Address[31:18] = 0100_0000_0000_01b	0,1,2,3,4,5,6,7
—	5	—	—
AIPS_1 (Peripheral Bridge A)	6	Address[31:29] = 110b	0,1,2,3,4,5,6,7
AIPS_0 (Peripheral Bridge B)	7	Address[31:29] = 111b	0,1,2,3,4,5,6,7

1. Master ports 2,3,4,5,6,7 access the flash memory module through slave port 3.

9.1.2 Unimplemented PRS_n and CRS_n registers

On this chip, the PRS5 and CRS5 registers are not implemented. In [Memory Map / Register Definition](#), the locations of these registers are reserved and should not be accessed.

9.1.3 Reset value of PRS_n and CRS_n registers

The reset value of the XBAR_PRS_n registers is 7654_3210h.

The reset value of the XBAR_CRS_n registers is 00FF_0000h.

9.1.4 Master priority elevation

Each implemented XBAR slave has a corresponding [Control Register \(XBAR_CRSn\)](#) whose number is the same as the slave's physical port. Each of these registers has HPE_n fields corresponding to the physical port numbers of the implemented XBAR masters.

In general, set the HPE_n field for a particular master to 1 to allow the elevation of that master's priority of access to the applicable slave. For example, set XBAR_CRs1[HPE6] to 1 to allow the elevation of the SIPI module's priority of access to the EBI.

9.1.4.1 Master priority elevation not used by CSE or FEC

The CSE is connected to XBAR master physical port 6, and the FEC is connected to XBAR master physical port 7. The CSE and FEC cannot signal a request for priority elevation, regardless of the value of the HPE6 and HPE7 fields in every [Control Register \(XBAR_CRSn\)](#).

9.1.4.2 Additional programming for some masters' priority elevation

Enabling the elevation of priority requires additional programming for some masters. The following table summarizes this information. The table refers to fields in the HID1 register that [Hardware Implementation Dependent Register 1 \(HID1\)](#) defines further.

Table 9-3. Additional programming for priority elevation

Master	XBAR physical port	Additional programming	Result
Core0 instruction	0	In addition to setting HPE0 to 1 in XBAR_CRSn for the applicable slave, set to 1 either or both of these fields in the special-purpose HID1 register for core0: - Elevate External Exceptions (EEE), bit 22 - Elevate Critical Exceptions (ECE), bit 23	Core0's priority is elevated when an event occurs that corresponds to the HID1 field or fields whose value is 1: - External exception when HID1[EEE] is 1 - Critical or NMI exception when HID1[ECE] is 1
Core0 data	1	In addition to setting HPE1 to 1 in XBAR_CRSn for the applicable slave, set to 1 either or both of these fields in the special-purpose HID1 register for core0: - Elevate External Exceptions (EEE), bit 22 - Elevate Critical Exceptions (ECE), bit 23	Core0's priority is elevated when an event occurs that corresponds to the HID1 field or fields whose value is 1: - External exception when HID1[EEE] is 1 - Critical or NMI exception when HID1[ECE] is 1

Table continues on the next page...

Table 9-3. Additional programming for priority elevation (continued)

Master	XBAR physical port	Additional programming	Result
Core1 instruction	2	In addition to setting HPE2 to 1 in XBAR_CRSn for the applicable slave, set to 1 either or both of these fields in the special-purpose HID1 register for core1: - Elevate External Exceptions (EEE), bit 22 - Elevate Critical Exceptions (ECE), bit 23	Core1's priority is elevated when an event occurs that corresponds to the HID1 field or fields whose value is 1: - External exception when HID1[EEE] is 1 - Critical or NMI exception when HID1[ECE] is 1
Core1 data	3	In addition to setting HPE3 to 1 in XBAR_CRSn for the applicable slave, set to 1 either or both of these fields in the special-purpose HID1 register for core1: - Elevate External Exceptions (EEE), bit 22 - Elevate Critical Exceptions (ECE), bit 23	Core1's priority is elevated when an event occurs that corresponds to the HID1 field or fields whose value is 1: - External exception when HID1[EEE] is 1 - Critical or NMI exception when HID1[ECE] is 1
eDMA_A	4	In addition to setting HPE4 to 1 in XBAR_CRSn for the applicable slave, set eDMA_A's TCD[BWC] field to 01b.	Only eDMA_A can elevate its priority for the applicable slave.
eDMA_B	5	In addition to setting HPE5 to 1 in XBAR_CRSn for the applicable slave, set eDMA_B's TCD[BWC] field to 01b.	Only eDMA_B can elevate its priority for the applicable slave.

Hardware Implementation Dependent Register 1 (HID1)

The following HID1 details supplement and replace information in the *e200z759n3 Core Reference Manual* (document number e200z759n3CRM).

HID1 is the core register (SPR 1009) that controls XBAR priority elevation.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

9.2 Introduction

The information found here provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus masters and bus slaves using a crossbar switch structure. This structure allows all bus masters to access different bus slaves simultaneously, while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

9.2.1 Features

The crossbar switch includes these features:

- Symmetric crossbar bus switch implementation
 - Allows concurrent accesses from different masters to different slaves
 - Slave arbitration attributes configured on a slave-by-slave basis
- Up to single-clock 64-bit transfer
- Support for burst transfers of up to 16 beats of data
- Low-Power Park mode support
- Dynamic master priority elevation

9.3 Memory Map / Register Definition

Each slave port of the crossbar switch contains configuration registers. Read- and write-transfers require two bus clock cycles. The registers can be read from and written to only in supervisor mode. Additionally, these registers can be read from or written to only by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The CRS_n and PRS_n registers can be programmed to be read-only to prevent changes to their configuration. After being read-only protected, future writes to them will terminate with an error.

NOTE

This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular device, then unexpected results occur when writing to its registers. See the chip configuration details for the exact master/slave assignments for your device.

All references to the crossbar switch registers are based on the physical port connections.

XBAR memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
700	Priority Registers Slave (XBAR_PR57)	32	R/W	See section	9.3.1/447
710	Control Register (XBAR_CRS7)	32	R/W	See section	9.3.2/450

9.3.1 Priority Registers Slave (XBAR_PR5n)

The priority registers (PR5n) set the priority of each master port on a per slave port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses. After the CRSn[RO] bit is set, the PR5n register can only be read; attempts to write to it have no effect on PR5n and result in a bus-error response to the master initiating the write.

Two available masters must not be programmed with the same priority level. Attempts to program two or more masters with the same priority level result in a bus-error response and the PR5n is not updated.

NOTE

Valid values for the M_n priority fields depend on which masters are available on the chip. This information can be found in the chip-specific information for the crossbar.

- If the chip contains less than five masters, values 0 to 3 are valid. Writing other values will result in an error.
- If the chip contains five or more masters, valid values are 0 to n-1, where n is the number of masters attached to the Crossbar Switch. Other values will result in an error.

NOTE

See the chip-specific crossbar information for the reset value of this register.

XBAR_PRSn field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–3 M7	Master 7 Priority. Sets the arbitration priority for this port on the associated slave port. 000 This master has level 1, or highest, priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8, or lowest, priority when accessing the slave port.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–7 M6	Master 6 Priority. Sets the arbitration priority for this port on the associated slave port. 000 This master has level 1, or highest, priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8, or lowest, priority when accessing the slave port.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–11 M5	Master 5 Priority. Sets the arbitration priority for this port on the associated slave port. 000 This master has level 1, or highest, priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8, or lowest, priority when accessing the slave port.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 M4	Master 4 Priority. Sets the arbitration priority for this port on the associated slave port. 000 This master has level 1, or highest, priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8, or lowest, priority when accessing the slave port.

Table continues on the next page...

XBAR_PRSn field descriptions (continued)

Field	Description
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–19 M3	Master 3 Priority. Sets the arbitration priority for this port on the associated slave port. 000 This master has level 1, or highest, priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8, or lowest, priority when accessing the slave port.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–23 M2	Master 2 Priority. Sets the arbitration priority for this port on the associated slave port. 000 This master has level 1, or highest, priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8, or lowest, priority when accessing the slave port.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–27 M1	Master 1 Priority. Sets the arbitration priority for this port on the associated slave port. 000 This master has level 1, or highest, priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8, or lowest, priority when accessing the slave port.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 M0	Master 0 Priority. Sets the arbitration priority for this port on the associated slave port. 000 This master has level 1, or highest, priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8, or lowest, priority when accessing the slave port.

9.3.2 Control Register (XBAR_CRSn)

These registers control several features of each slave port and must be accessed using 32-bit accesses. After CRSn[RO] is set, the PRSn can only be read; attempts to write to it have no effect and result in an error response.

NOTE

See the chip-specific crossbar information for the reset value of this register.

Not all HPE_n fields may be active. See the chip-specific crossbar information for which masters support high priority elevation. Setting a field corresponding to a master that does not support high-priority elevation has no effect.

9.4 Functional Description

9.4.1 General operation

When a master accesses the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the

requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Because the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply waits.

After the master has control of the slave port it is targeting, the master remains in control of the slave port until it relinquishes the slave port by running an IDLE cycle or by targeting a different slave port for its next access.

The master can also lose control of the slave port if another higher-priority master makes a request to the slave port. However, if the master is running a fixed-length burst transfer it retains control of the slave port until that transfer completes.

The crossbar terminates all master IDLE transfers, as opposed to allowing the termination to come from one of the slave buses. Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it can park the slave port on the master port indicated by `CRSn[PARK]`. This is done to save the initial clock of arbitration delay that otherwise would be seen if the same master had to arbitrate to gain control of the slave port. The slave port can also be put into Low Power Park mode to save power, by using `CRSn[PCTL]`.

9.4.2 Register coherency

The operation of the crossbar is affected as soon as a register is written. The values of the registers do not track with slave-port-related master accesses, but instead track only with slave accesses.

9.4.3 Arbitration

The crossbar switch supports two arbitration algorithms:

- Fixed priority
- Round-robin

The arbitration scheme is independently programmable for each slave port.

9.4.3.1 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the priority registers (PRSn). If two masters request access to the same slave port, the master with the highest priority in the selected priority register gains control over the slave port.

NOTE

In this arbitration mode, a higher-priority master can monopolize a slave port, preventing accesses from any lower-priority master to the port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port, unless the slave port is in a parked state. The slave port performs an arbitration check at every clock edge to ensure that the proper master, if any, has control of the slave port.

The following table describes possible scenarios based on the requesting master port:

Table 9-24. How the Crossbar Switch grants control of a slave port to a master

When	Then the Crossbar Switch grants control to the requesting master
Both of the following are true: - The current master is not running a transfer. - The new requesting master's priority level is higher than that of the current master.	At the next clock edge
Both of the following are true: - The current master is running a fixed length burst transfer or a locked transfer. - The requesting master's priority level is higher than that of the current master.	At the end of the burst transfer or locked transfer
The requesting master's priority level is lower than the current master.	At the conclusion of one of the following cycles: - An IDLE cycle - A non-IDLE cycle to a location other than the current slave port

9.4.3.2 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the master port number (ID) of the last master to perform a transfer on the slave bus. The highest priority requesting

master becomes owner of the slave bus at the next transfer boundary, accounting for locked and fixed-length burst transfers. Priority is based on how far ahead the ID of the requesting master is to the ID of the last master.

After granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order: 4 then 5 then 0.

Parking may continue to be used in a round-robin mode, but does not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

9.4.3.3 Priority assignment

Each master port must be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within the priority registers (PRSn), the crossbar switch responds with a bus error and the registers are not updated.

9.5 Initialization/application information

No initialization is required for the crossbar switch.

Hardware reset ensures that all the register bits used by the crossbar switch are properly initialized to a valid state. However, settings and priorities may be programmed to achieve maximum system performance.

NOTE

- During configuration of the crossbar switch, all other masters must be idle.
- To prevent reconfiguration of the crossbar switch, write 1 to CRSn[RO].

Chapter 10

Crossbar Integrity Checker (XBIC)

10.1 Chip-specific XBIC information

This chip has one instance of the XBIC module.

10.1.1 XBIC master and slave assignments

The XBIC identifies each XBAR master and slave in terms of the master or slave's physical port number. See the "Physical master port" assignments in [Table 9-1](#) and the "Slave port" assignments in [Table 9-2](#).

10.1.2 Unimplemented MCR and ESR fields

On this chip, the MCR[SE5] and ESR[DPSE5] fields are not implemented. In [XBIC Module Control Register \(XBIC_MCR\)](#) and [XBIC Error Status Register \(XBIC_ESR\)](#), these fields are reserved.

10.2 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers.

10.3 Features

The XBIC has the following features:

- Verification of attribute information for all crossbar transfers

- EDC (72,64) code protects against single and double bit errors
- Verification of feedback information for each data phase during crossbar transfer
- Error injection for testing
 - Programmable master and slave port specifiers
 - Programmable 8-bit toggle vector to insert error in master EDC checkbit value
 - Address, EDC syndrome, master and slave port information captured on error
- Programmable integrity check enable on a per-slave-port basis
- Programmable integrity feedback check enable on a per-master-port basis

10.4 Block diagram

The crossbar transfer attribute information for all master and slave ports is routed to the XBIC, which calculates and checks the EDC parity over the attribute information as shown in the following diagram.

Figure 10-1. XBIC system block diagram

10.5 External signal description

The XBIC has no external interface signals.

10.6 Memory map and register definition

The XBIC programming model has four 32-bit registers. The programming model can only be accessed in supervisor mode using 32-bit (word) accesses. Attempted references with a different access size, to an undefined (reserved) address, with a non-supported access type (a write to a read-only register), or in user mode generate an error termination.

16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

10.6.2 XBIC Error Injection Register (XBIC_EIR)

The XBIC_EIR contains fields for controlling the XBIC error injection function. When an error is injected, the EDC syndrome associated with the programmed master and slave ports is modified, causing the XBIC to assert the error indication to the FCCU and capturing the transfer information in the XBIC_ESR and XBIC_EAR registers. Otherwise, transfers are not affected by XBIC error injection.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	EIE	0														
W

XBIC_EIR field descriptions

Field	Description
0 EIE	Error Injection Enable. 0 Error injection disabled 1 Error injection enabled
1–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–19 SLV	Target Slave Port. Error injection is enabled for the designated slave port. Other slave ports are unaffected.
20–23 MST	Target Master ID. Error injection is enabled for the designated master ID. Transfers with other master IDs are not affected.
24–31 SYN	Syndrome. This value is exclusive-ored with the calculated syndrome (which should be zero) to generate an error with the specified syndrome. A value of zero does not generate an error.

10.6.3 XBIC Error Status Register (XBIC_ESR)

The Error Status Register (XBIC_ESR) contains two types of error information about the last transfer. If an attribute integrity check error was detected, the slave port, the master port, and the syndrome are captured in the SLV, MST, and SYN fields. If there is a mismatch among internal signals (hready, hresp0, and hresp2) during the data phase, the slave and master port are catured in the DPSE0-7 and DPME0-7 fields.

This register is cleared only on reset.

NOTE

When the XBIC detects back-to-back faults on a system bus path through the crossbar switch, the fault information captured in the XBIC_ESR does not correspond to the initial fault event but rather the subsequent fault event. While the fault event is properly detected, diagnostic status information in the XBIC_ESR register describing the initial fault event is lost. This can only occur in the event of a series of bus transactions targeting the same crossbar slave target where the series of bus transactions are not separated by idle or stall cycles.

16 DPME7	Data phase master port error. 0 No error on master port 7 1 Data phase error on master port 7
17–19 SLV	Slave Port. The slave port targeted by the last transfer with an error.
20–23 MST	Master ID. The master ID value of the last transfer with an error.
24–31 SYN	Syndrom. The syndrome calculated for the last transfer with an error. For single bit errors the signal in error can be determined, see Table 10-6 .

10.6.4 XBIC Error Address Register (XBIC_EAR)

The Error Address Register (XBIC_EAR) contains the address of the first transfer in which an attribute integrity check error was detected on an enabled slave port. This register is only cleared on reset.

NOTE

When the XBIC detects back-to-back faults on a system bus path through the crossbar switch, the fault information captured in the XBIC_EAR does not correspond to the initial fault event but rather the subsequent fault event. While the fault event is properly detected, diagnostic status information in the XBIC_ESR register describing the initial fault event is lost. This can only occur in the event of a series of bus transactions targeting the same crossbar slave target where the series of bus transactions are not separated by idle or stall cycles.

10.7 Functional description

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar interface. The Module Control Register (XBIC_MCR) allows integrity checking to be enabled on a individual port basis. When an error is detected, it is captured in XBIC_ESR register and XBIC also sends out an error signal to the Fault Collection and Control Unit (FCCU). Detection of an error does not generate a bus error. The XBIC integrity checking is independent from the end-to-end ECC that covers the transfer address and data.

During the AHB address phase, the crossbar attribute information is checked using an 8-bit Error Detection Code (EDC), which detects any single- or double-bit errors. When an error is detected, due either to hardware fault or error injection, information related to the error is captured and reported in XBIC_ESR and XBIC_EAR. The cause of a single-bit error can be determined by the syndrome value reported in the XBIC_ESR as shown in [Table 10-6](#). Any other syndrome indicates a multi-bit error.

During the AHB data phase, the responding signals from the slave to master are checked when passing through the crossbar. When an error is detected, the information is captured in the XBIC_ESR DPSE0-7 and DPME0-7 fields.

The XBIC can also be programmed to intentionally inject EDC errors for testing. Error injection is targeted toward a single slave port and a single master ID at a time as determined by the settings in the Error Injection Register (XBIC_EIR). When an error is injected, the EDC syndrome is modified which causes the XBIC to assert the error indication to the FCCU. Otherwise transfers are unaffected by XBIC error injection. This approach allows the check logic to be verified without compromising the integrity of the data transfer. Once the error injection function is enabled by setting XBIC_EIR[EIE], errors are induced on all subsequent targeted transactions until XBIC_EIR[EIE] is cleared

Chapter 11

Peripheral Bridge (AIPS/PBRIDGE)

11.1 Chip-specific AIPS/PBRIDGE information

This chip has two instances of the AIPS (PBRIDGE) module:

- AIPS_0 (PBRIDGE_B)
- AIPS_1 (PBRIDGE_A)

11.1.1 Modules assigned to PACR_n and OPACR_n fields

Each module attached to the Peripheral Bridges is assigned to a memory map slot corresponding to an AIPS register field.

- Every on-platform module has an assigned PACR_n field within the PACRA to PACRD registers.
- Every off-platform module has an assigned OPACR_n field within the OPACRA to OPACRH registers.

The [Peripheral Access Control Register \(AIPS_PACR_n\)](#) description provides the location of each PACR_n field, and the [Off-Platform Peripheral Access Control Register \(AIPS_OPACR_n\)](#) description provides the location of each OPACR_n field.

The following tables provide the module slot assignments for this chip.

NOTE

Unused PACR_n and OPACR_n fields are reserved.

Table 11-1. AIPS_0 (PBRIDGE_B) PACR_n field assignments

Module	PACR field
AIPS_0	0

11.2 Introduction

The peripheral bridge converts the crossbar switch interface to an interface that can access most of the slave peripherals on this chip.

The peripheral bridge occupies 64 MB of the address space, which is divided into peripheral slots of 16 KB. (It might be possible that all the peripheral slots are not used. See the memory map chapter for details on slot assignments.) The bridge includes separate clock enable inputs for each of the slots to accommodate slower peripherals.

11.2.1 Features

Key features of the peripheral bridge are:

- Supports peripheral slots with 8-, 16-, and 32-bit datapath width
- Supports a pair of 32-bit transactions for selected 64-bit memory accesses
- Programming model provides memory protection functionality

11.2.2 General operation

The slave devices connected to the peripheral bridge are modules which contain a programming model of control and status registers. The system masters read and write these registers through the peripheral bridge.

The register maps of the peripherals are located on 16 KB boundaries. Each peripheral is allocated one or more 16-KB block(s) of the memory map.

11.3 Memory map/register definition

The 32-bit peripheral bridge registers can be accessed only in supervisor mode by trusted bus masters. Additionally, these registers must be read from or written to only by a 32-bit aligned access. The peripheral bridge registers are mapped into the Peripheral Access Control Register A PACRA[PACR0] address space.

AIPS memory map

11.3.1 Master Privilege Register A (AIPS_MPRA)

The MPRA specifies identical 4-bit fields defining the access-privilege level associated with a bus master to various peripherals on the chip. The register provides one field per bus master.

NOTE

At reset, the default value loaded into the MPRA fields is chip-specific. See the chip configuration details for the value of a particular device.

A register field that maps to an unimplemented master or peripheral behaves as read-only-zero.

Each master is assigned a logical ID from 0 to 15. See the master logical ID assignment table in the chip-specific AIPS information.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
	0 This master is not trusted for read accesses. 1 This master is trusted for read accesses.
26 MTW6	Master 6 Trusted for Writes Determines whether the master is trusted for write accesses. 0 This master is not trusted for write accesses. 1 This master is trusted for write accesses.
27 MPL6	Master 6 Privilege Level Specifies how the privilege level of the master is determined. 0 Accesses from this master are forced to user-mode. 1 Accesses from this master are not forced to user-mode.
28–31 Reserved	This field is reserved.

11.3.2 Master Privilege Register B (AIPS_MPRB)

The MPRB registers specifies identical 4-bit fields defining the access-privilege level associated with a bus master to the various peripherals on the chip. The register provides one field per bus master.

NOTE

At reset, the default value loaded into the MPRB fields is chip-specific. See the chip configuration information for the value on your particular device.

Accesses to registers or register fields which correspond to master or peripheral locations which are not implemented return zeros on reads, and are ignored on writes.

Each master is assigned a logical ID from 0 to 15. See the master logical ID assignment table in the AIPS chip-specific information.

11.3.3 Peripheral Access Control Register (AIPS_PACR_n)

Each PACR register consists of eight 4-bit PACR fields. Each PACR field defines the access levels for a particular on-platform peripheral. The peripheral assignment to each PACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

Every PACR field to which no peripheral is assigned is reserved. Reads to reserved locations return zeros, and writes are ignored.

The following table shows the location of each peripheral slot's PACR field in the PACR registers.

Offset	Register	[0:3]	[4:7]	[8:11]	[12:15]	[16:19]	[20:23]	[24:27]	[28:31]
0x20	PACRA	PACR0	PACR1	PACR2	PACR3	PACR4	PACR5	PACR6	PACR7

* Notes:

- The reset value is chip-dependent and can be found in the AIPS chip-specific information.

AIPS_PACR_n field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 SP0	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPRx[MPL _n] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
2 WP0	Write Protect Determines whether the peripheral allows write access. When this bit is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
3 TP0	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 SP1	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPRx[MPL _n] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
6 WP1	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
7 TP1	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this bit is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates.

Table continues on the next page...

AIPS_PACR_n field descriptions (continued)

Field	Description
	0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 SP2	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPRx[MPL _n] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
10 WP2	Write Protect Determines whether the peripheral allows write access. When this bit is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
11 TP2	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 SP3	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for access. When this bit is set, the master privilege level must indicate the supervisor access attribute, and the MPRx[MPL _n] control bit for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
14 WP3	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
15 TP3	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this bit is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates.

Table continues on the next page...

Field	Description
0	Accesses from an untrusted master are allowed.
1	Accesses from an untrusted master are not allowed.

11.3.4 Off-Platform Peripheral Access Control Register (AIPS_OPACR_n)

Each OPACR register consists of eight 4-bit OPACR fields. Each OPACR field defines the access levels for a particular off-platform peripheral. The peripheral assignment to each OPACR field is defined by the memory map slot of the peripheral. See the chip-specific AIPS information for the field assignment of a particular peripheral.

Every OPACR field to which no peripheral is assigned is reserved. Reads to reserved locations return zeros, and writes are ignored.

The following table shows the location of each peripheral slot's OPACR field in the OPACR registers.

Offset	Register	[0:3]	[4:7]	[8:11]	[12:15]	[16:19]	[20:23]	[24:27]	[28:31]

AIPS_OPACR_n field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 SP0	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPRx[MPL _n] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
2 WP0	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
3 TP0	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this bit is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 SP1	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for access. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPRx[MPL _n] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
6 WP1	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
7 TP1	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.

24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 SP6	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPRx[MPL _n] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
26 WP6	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
27 TP6	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 SP7	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPRx[MPL _n] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
30 WP7	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
31 TP7	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.

11.4 Functional description

The peripheral bridge functions as a bus protocol translator between the crossbar switch and the slave peripheral bus.

Support is provided for generating a pair of 32-bit slave accesses when performing certain 64-bit peripheral accesses.

The peripheral bridge manages all transactions destined for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

11.4.1 Access support

All combinations of access size and peripheral data port width are supported. An access that is larger than the target peripheral's data width will be decomposed to multiple, smaller accesses. Bus decomposition is terminated by a transfer error caused by an access to an empty register area.

Chapter 12

Platform Configuration Module (PCM)

12.1 PCM memory map and register descriptions

The Platform Configuration Module contains three miscellaneous configuration registers for the chip. Currently, the configuration registers are related to the operation of the FEC and intelligent bus bridging gasket. The module is mapped to AIPS_0 (PBRIDGE_B) on-platform slot 27 with a base address of FFF6_C000h.

NOTE

These registers can be accessed only in supervisor mode.

PCM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
0	FEC Burst Optimization Master Control Register (PCM_FBOMCR)	32	R/W	0000_0000h	12.1.1/490
4	Bus Bridge Configuration Register 1 (PCM_IAHB_BE1)	32	R/W	0303_0303h	12.1.2/491
8	Bus Bridge Configuration Register 2 (PCM_IAHB_BE2)	32	R/W	0303_0303h	12.1.3/494

12.1.1 FEC Burst Optimization Master Control Register (PCM_FBOMCR)

This register controls FEC burst optimization behavior on the system bus.

Address: 0h base + 0h offset = 0h

PCM_FBOMCR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 ACCERR	Accumulate Error This field determines whether an error response for the first half of the write burst is accumulated to the second half of the write burst or discarded. To complete the burst, the FEC interface to the system bus responds by indicating that the first half of the burst completed without error before it actually writes the data so that it can fetch the second half of the write data from the FIFO. When actually written onto the system bus, the first half of the write burst can have an error. Because this half initially responded without an error to the FIFO, the error is discarded or accumulated with the error response for the second half of the burst. 0 Any error to the first half of the write burst is discarded. 1 Any actual error response to the first half of the write burst is accumulated in the second half's response. In other words, an error response to the first half is seen in the response to the second half, even if the second half does not contain an error.
22 WBEN	Global write burst enable to XBAR slave port designated by FXSBE _n 0 Write bursting to all XBAR slave ports is disabled. 1 Write bursting is enabled to any XBAR slave port whose FXSBE _n bit is 1.
23 RBEN	Global read burst enable from XBAR slave port designated by FXSBE _n 0 Read bursting from all XBAR slave ports is disabled. 1 Read bursting is enabled from any XBAR slave port whose FXSBE _n bit is 1.

Table continues on the next page...

PCM_FBOMCR field descriptions (continued)

Field	Description
24–31 FXSBE[7:0]	FEC XBAR slave burst enable This field enables bursting by the FEC interface to the XBAR slave port controlled by each FXSBE_n bit. - When a particular FXSBE_n bit is 1, the XBAR slave port enabled by that bit can support the bursts allowed by RBEN and WBEN. RBEN enables read bursts from the XBAR slave port, and WBEN enables write bursts to the XBAR slave port. - When a particular FXSBE_n bit is 0, the FEC interface does not burst to the XBAR slave port controlled by that FXSBE_n bit. FXSBE_n assignments to XBAR slave ports are as follows: FXSBE0 = Flash memory FXSBE1 = EBI FXSBE2 = RAM FXSBE3 = reserved FXSBE4 = reserved FXSBE5 = reserved FXSBE6 = AIPS_1 (PBRIDGE_A) FXSBE7 = AIPS_0 (PBRIDGE_B)

Chapter 13

Semaphores (SEMA4)

13.1 Introduction

The module provides the hardware support needed in multi-core systems for implementing semaphores and provide a simple mechanism to achieve "lock/unlock" operations via a single write access. This approach eliminates architecture-specific implementations like atomic (indivisible) read-modify-write instructions or reservation mechanisms. The result is an architecture-neutral solution that provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

13.1.1 Multi-Core Programming 101: Software Gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism which is then used by system software to control access to shared data structures, shared hardware resources, etc. These "gating" mechanisms are used by the software to serialize (and synchronize) writes to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and processors.

Consider the following description of a typical use-case. Processor X enters a section of code where shared data values are to be updated. It must first acquire a semaphore; this can be considered "locking (or closing) a software gate." Once the gate has been locked, a properly-architected software system does not allow other processes (or processors) to execute the same code segment or modify the shared data structure protected by the gate, that is, other processes/processors are locked out. Many software implementations include a *spin-wait loop* within the lock function until the locking of the gate is accomplished. Once the lock has been obtained, Processor X continues execution and updates the data values protected by the particular lock. Once the updates are complete, Processor X unlocks (or opens) the software gate, allowing other processes/processors access to the updated data values.

There are three important rules that must be followed for a correctly-implemented system solution:

1. All writes to shared data values or shared hardware resources must be protected by a "gate" variable.
2. Once a processor locks a gate, accesses to the shared data or resources by other processes/processors must be blocked. This is enforced by software conventions.
3. The processor that locks a particular gate is the only processor that can open (unlock) that gate.

Information in the hardware gate identifying the locking processor can be extremely useful for system-level debugging.

The Hennessy/Patterson text on computer architecture offers the following description of software gating.

"One of the major requirements of a shared-memory architecture multiprocessor is being able to coordinate processes that are working on a common task. Typically, a programmer will use *lock variables* to synchronize the processes.

The difficulty for the architect of a multiprocessor is to provide a mechanism to decide which processor gets the lock and to provide the operation that locks a variable. Arbitration is easy for shared-bus multiprocessors, since the bus is the only path to memory. The processor that gets the bus locks out all the other processors from memory. If the CPU and bus provide an atomic swap operation, programmers can create locks with the proper semantics. The adjective *atomic* is key, for it means that a processor can both read a location **and** set it to the locked value in the same bus operation, preventing any other processor from reading or writing memory." [Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*, ppg. 471-472]

The classic text continues with a description of the steps required to lock/unlock a variable using an *atomic swap instruction*.

"Assume that 0 means unlocked and 1 means locked. A processor first reads the lock variable to test its state. A processor keeps reading and testing until the value indicates that the lock is unlocked. The processor then races against all other processes that were similarly "spin waiting" to see who can lock the variable first. All processes use a swap instruction that reads the old value and stores a 1 into the lock variable. The single winner will see the 0, and the losers will see a 1 that was placed there by the winner. (The losers will continue to set the variable to the locked value, but that doesn't matter.) The winning processor executes the code after the lock and then stores a 0 into the lock when it exits,

starting the race all over again. Testing the old value and then setting to a new value is why the atomic swap instruction is called *test and set* in some instruction sets."

[Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*, ppg. 472-473]

For multi-core SoCs developed in the Microcontroller Division, a hardware-enforced semaphore implementation as a platform IPS module is used for the following reasons:

- A smaller module size versus a platform reservation monitor for PowerPC-based designs and it does not introduce any timing-critical paths, for example, the AHB system bus address phase cycle like a reservation monitor
- Provides a more robust implementation with features not possible in a reservation-only approach
- Provides a more generic, architecture-neutral solution, applicable across *all* the processor families supported by the Microcontroller Division

The sole drawback to a hardware-based semaphore module is the limited number of semaphores versus the "infinite" number that can be supported with PowerPC reservation instructions.

13.1.2 Overview

The IPS_Semaphores module provides a platform IPS slave device which implements 16 hardware-enforced gates with the following features:

- Module definition supports 16 hardware-enforced gates in a dual-processor configuration, where cp0 is core processor 0 and cp1 is core processor 1
 - Hardware gates appear as a 16-entry byte-size array with read and write accesses
 - Processors lock gates by writing "processor_number+1" to the appropriate gate and must read back the gate value to verify the lock operation was successful
 - Once locked, the gate is unlocked by a write of zeroes from the locking processor
- Optional interrupt notification after a failed lock write provides a mechanism to indicate when the gate is unlocked

- Secure reset mechanisms are supported to clear the contents of individual semaphore gates or notification logic, as well as a clear_all capability
- Programming model allocates memory space to support up to 8 processors and up to 64 gates

A simplified block diagram of the Semaphores module is shown in [Figure 13-1](#). In the diagram, the register blocks named gate0, gate1,..., gate 15 include the finite state machines implementing the semaphore gates plus the interrupt notification logic.

Figure 13-1. IPS_Semaphores Block Diagram

13.1.3 Features

The Semaphores module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Support for 16 hardware-enforced gates in a dual-processor configuration
 - Each hardware gate appears as a 3-state, 2-bit state machine, with all 16 gates mapped as a byte-size array
 - 3-state implementation
 - if gate = 0b00, then state = unlocked
 - if gate = 0b01, then state = locked by processor 0
 - if gate = 0b10, then state = locked by processor 1
 - Uses the bus master number as a reference attribute plus the specified data patterns to validate all write operations
 - Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor
- Optional interrupt notification after a failed lock write provides a mechanism to indicate when the gate is unlocked
- Secure reset mechanisms are supported to clear the contents of individual gates or notification logic, as well as a clear_all capability
- Memory-mapped IPS slave peripheral platform module
 - Interface to the IPS bus for programming-model accesses
 - Two outputs (one per processor) for interrupt notification of failed lock writes

13.1.4 Modes of Operation

The Semaphores module does not support any special modes of operation. As a slave peripheral memory-mapped device located on the platform's IPS slave bus, it responds based strictly on the memory addresses of the connected bus. The IPS bus is used to access the Semaphores ' programming model.

13.2 External Signal Description

The Semaphores module does not include any external interfaces.

13.3 Memory map and register definition

The Semaphores module provides an IPS programming model mapped to an SPP-standard on-platform 16 KB space. The description here specifies a dual-core configuration with 16 semaphore gates. All the register names are prefixed with "Sema4" as an abbreviation for the full module name.

The programming model is referenced using 8-, 16- and 32-bit accesses. Reads can use any reference size, while writes are generally restricted to the size of the register. Exceptions to the write size restrictions are detailed in the individual register descriptions. Attempted references using inappropriate access sizes, to undefined (reserved) addresses, or with a non-supported access type (for example, a write to a read-only register) generate an IPS error termination.

Finally, the programming model allocates space for a definition with up to 64 gates and up to 8 processor cores, even though this definition is considerably larger than any currently-planned module implementations. The number of gates and supported processor cores are independent; there is no relationship between these two system variables.

The 16 KB Semaphores programming model map is shown in the following table.

SEMA4 memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Semaphores Gate 0 Register (SEMA4_Gate00)	8	R/W	00h	13.3.1/503

13.3.1 Semaphores Gate 0 Register (SEMA4_Gate00)

Each semaphore gate is implemented in a 2-bit finite state machine, right-justified in a byte data structure. The hardware uses the bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. 16- and 32-bit writes to multiple gates are allowed, but the write data operand must only update the state of a single gate. A byte write data value of 0x03 is defined as "no operation" and does not affect the state of the corresponding gate register. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes

Address: 0h base + 0h offset = 0h

Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. 16- and 32-bit writes to multiple gates are allowed, but the write data operand must only update the state of a single gate. A byte write data value of 0x03 is defined as "no operation" and does not affect the state of the corresponding gate register. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes

13.3.17 Semaphores Processor n IRQ Notification Enable (SEMA4_CPnINE)

The application of a hardware semaphore module provides an opportunity for implementation of helpful system-level features. An example is an optional mechanism to generate a processor interrupt after a failed lock attempt. Recall traditional software gate functions execute a spin-wait loop in an effort to obtain and lock the referenced gate. With this module, the processor that fails in the lock attempt could continue with other tasks and allow a properly-enabled notification interrupt to return its execution to the original lock function.

The optional notification interrupt function consists of two registers for each processor: an interrupt notification enable register (SEMA4_CPnINE) and the interrupt request register (SEMA4_CPnNTF). To support implementations with more than 16 gates, these registers can be referenced with aligned 16- or 32-bit accesses. For the SEMA4_CPnINE registers, unimplemented bits read as zeroes, and writes are ignored.

13.3.18 Semaphores Processor n IRQ Notification (SEMA4_CPnNTF)

The Semaphores module optionally allows the processor that fails in the lock attempt to continue with other tasks and allow a properly-enabled notification interrupt to return its execution to the original lock function rather than simply execute in a spin-wait loop.

The optional notification interrupt mechanism consists of two registers for each processor: an interrupt notification enable register (SEMA4_CPnINE) and the read-only notification interrupt request register (SEMA4_CPnNTF). To support implementations with more than 16 gates, these registers can be referenced with aligned 16- or 32-bit accesses. For the SEMA4_CPnNTF registers, unimplemented bits read as zeroes.

The notification interrupt is generated via a unique finite state machine, one per hardware gate. This machine operates in the following manner:

1. When an attempted lock fails, the FSM enters a first state where it waits until the gate is unlocked.
2. Once unlocked, the FSM enters a second state where it generates an interrupt request to the “failed lock” processor.
3. When the “failed lock” processor succeeds in locking the gate, the IRQ is automatically negated and the FSM returns to the idle state. However, if the other processor again locks the gate, the FSM returns to the first state, negates the interrupt request, and then waits for the gate to be unlocked (again).

The notification interrupt request is implemented in a 3-bit, 5-state machine, where two specific states are encoded and program-visible as SEMA4_CP0NTF[GNn] and SEMA4_CP1NTF[GNn].

13.3.19 Semaphores (Secure) Reset Gate n (SEMA4_RSTGT)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the Semaphores module implements a "secure" reset mechanism which allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the SEMA4_RSTGT memory location. The most significant byte (SEMA4_RSTGT[RSTGDP]) must be 0xE2; the least significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the SEMA4_RSTGT location. For this write, the upper byte (SEMA4_RSTGT[RSTGDP]) is the logical complement of the first data pattern (0x1D) and the lower byte (SEMA4_RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or that all gates are cleared.
3. Reads of the SEMA4_RSTGT location return information on the 2-bit state machine (SEMA4_RSTGT[RSTGSM]) which implements this function, the bus master performing the reset (SEMA4_RSTGT[RSTGMS]) and the gate number(s) last cleared (SEMA4_RSTGT[RSTGTN]). Reads of the SEMA4_RSTGT register do not affect the secure reset finite state machine in any manner.

		11	This state encoding is never used and therefore reserved.																				
	4 Reserved	Reserved. Always reads 0.																					
	5-7 RSTGMS	Reset Gate Bus Master. This 3-bit read-only field records the logical number of the bus master performing the gate reset function. The reset function requires that the two consecutive writes to this register be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs. The association between system bus master port numbers, the associated bus master device and the logical processor number is SoC-specific. See the chip configuration chapter for this information.																					
Write-Only	0-7 RSTGDP	Reset Gate Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the gate reset mechanism. For the first write, RSTGDP = 0xE2 while the second write requires RSTGDP = 0x1D.																					
8–15 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates. The corresponding secure IRQ notification state machine(s) are also reset.																						

13.3.20 Semaphores (Secure) Reset IRQ Notification (SEMA4_RSTNTF)

As with the case of the secure reset function and the hardware gates, it is recognized that system operation may require a reset function to re-initialize the state of the IRQ notification logic without requiring a system-level reset.

To support this special notification reset requirement, the Semaphores module implements a "secure" reset mechanism which allows an IRQ notification (or all the notifications) to be initialized by following a specific dual-write access pattern. When successful, the specified IRQ notification state machine(s) are reset. Using a technique similar to that required for the servicing of a software watchdog timer, the secure reset mechanism requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the IRQ notification(s). The required access pattern is:

- 1. A processor performs a 16-bit write to the SEMA4_RSTNTF memory location. The most significant byte (SEMA4_RSTNTF[RSTNDP]) must be 0x47; the least significant byte is a "don't_care" for this reference.
- 2. The same processor then performs a second 16-bit write to the SEMA4_RSTNTF location. For this write, the upper byte (SEMA4_RSTNTF[RSTNDP]) is the logical complement of the first data pattern (0xB8) and the lower byte (SEMA4_RSTNTF[RSTNTN]) specifies the notification(s) to be reset. This field can specify a single notification be cleared, or that all notifications are cleared.
- 3. Reads of the SEMA4_RSTNTF location return information on the 2-bit state machine (SEMA4_RSTNTF[RSTNSM]) which implements this function, the bus master performing the reset (SEMA4_RSTNTF[RSTNMS]) and the notification number(s) last cleared (SEMA4_RSTNTF[RSTNTN]). Reads of the SEMA4_RSTNTF register do not affect the secure reset finite state machine in any manner.

Address: 0h base + 104h offset = 104h

SEMA4_RSTNTF field descriptions (continued)

Field	Description		
	Access	Sub-Field	Description
	Read-Only	0-1 Reserved	Reserved. Always reads 0.
		2-3 RSTNSM	Reset Notification Finite State Machine. Reads of the SEMA4_RSTNTF register return the encoded state machine value. The reset state machine is maintained in a 2-bit, 3-state implementation, defined as:
			00 Idle, waiting for the first data pattern write.
			01 Waiting for the second data pattern write.
			10 The 2-write sequence has completed. Generate the specified notification reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. Note the RSTNSM = 10 state is valid for only a single machine cycle, so it is impossible for a read to return this value.
			11 This state encoding is never used and therefore reserved..
		4 Reserved	Reserved. Always reads 0.
		5-7 RSTNMS	Reset Notification Bus Master. This 3-bit read-only field records the logical number of the bus master performing the notification reset function. The reset function requires that the two consecutive writes to this register be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs. The association between system bus master port numbers, the associated bus master device and the logical processor number is SoC-specific. See the chip configuration chapter for this information.
	Write-Only	0-7 RSTNDP	Reset Notification Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the notification reset mechanism. For the first write, RSTNDP = 0x47 while the second write requires RSTNDP = 0xb8.
8-15 RSTNTN	Reset Notification Number. This 8-bit field specifies the specific IRQ notification state machine to be reset. This field is updated by the second write. If RSTNTN < 64, then reset the single IRQ notification machine defined by RSTNTN, else reset all the notifications.		

13.4 Functional Description

In this section, the functional operation of the Semaphores module, specifically the state machines of the SEMA4_GATn and SEMA4_CPnNTF registers are detailed.

13.4.1 SEMA4_GATEn Operation

Recall each of the SEMA4_GATEn registers implements a 2-bit, 3-state machine. The state transitions for each gate are shown in the following figure.

Figure 13-26. SEMA4_GATEn State Machine

The bus master number is used to identify core processor 0 (cp0) or core processor 1 (cp1). The Standard (or Reduced) Product Platform passes the AHB bus master number (`hmaster[2:0]`) through the AIPS (or AIPS-Lite) controller and drives an `aips_master[2:0]` output to the Semaphores module as an IPS sideband signal.

The state transitions for SEMA4_GATEn are defined in the following table.

Table 13-26. SEMA4_GATEn State Transitions

Current State	Next State	Transition	Description
—	idle	1	Any reset, whether a system reset or an individual gate reset, unconditionally forces the gate into the idle state.

Table continues on the next page...

**Table 13-26. SEMA4_GATEn State Transitions
(continued)**

Current State	Next State	Transition	Description
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor occurs, the gate remains in the idle state.
idle	cp0_lock	3	When a write of the "cp0_lock" data value is initiated by processor 0, the gate transitions into the cp0_lock state.
idle	cp1_lock	4	When a write of the "cp1_lock" value is initiated by processor 1, the gate transitions into the cp1_lock state.
cp0_lock	cp0_lock	5	Once in this state, the gate remains here if any attempted write is not from cp0 with the unlock data value.
cp0_lock	idle	6	The gate returns to the idle (unlocked) state once a write from cp0 with the unlock data value occurs.
cp1_lock	cp1_lock	7	Once in this state, the gate remains here if any attempted write is not from cp1 with the unlock data value.
cp1_lock	idle	8	The gate returns to the idle (unlocked) state once a write from cp1 with the unlock data value occurs.

13.4.2 SEMA4_CPnNTF Operation

The failed lock write notification interrupt request is implemented in a 3-bit, 5-state machine which records failed lock attempts and transitions based on gate locking and unlocking. Two specific states are encoded and program-visible as SEMA4_CP0NTF[GNn] and SEMA4_CP1NTF[GNn]. See the following figure.

Figure 13-27. IRQ Notification State Machine

The state transitions of the IRQ notification function are defined in the following. Specific states of this machine are program-visible as the SEMA4_CPnNTF registers. In particular, two states are program-visible:

```

if state = wait4_cp0_lock (0b110) // generate cp0_semaphore_int if properly enabled
    then SEMA4_CP0NTF[GNn] = 1; else SEMA4_CP0NTF[GNn] = 0
if state = wait4_cp1_lock (0b101) // generate cp1_semaphore_int if properly enabled
    then SEMA4_CP1NTF[GNn] = 1; else SEMA4_CP1NTF[GNn] = 0
  
```

Table 13-27. IRQ Notification State Transitions

Current State	Next State	Transition	Description
—	idle	1	Any reset, including a system reset or an individual notification or secure gate reset, unconditionally forces the machine into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor to an already-locked gate occurs, the machine remains in the idle state.
idle	wait4_cp1_unlock	3	When a write of the "cp0_lock" data value is initiated by processor 0 but the gate is already locked by cp1, the machine transitions into this state, where it waits for cp1 to unlock the gate.
idle	wait4_cp0_unlock	4	When a write of the "cp1_lock" data value is initiated by processor 1 but the gate is already locked by cp0, the machine transitions into this state, where it waits for cp0 to unlock the gate.
wait4_cp1_unlock	wait4_cp1_unlock	5	Once in this state, the machine remains here until the gate is unlocked.
wait4_cp1_unlock	wait4_cp0_lock	6	From this state, the machine transitions into the next state, waiting for cp0 to lock the gate, once it has been unlocked.
wait4_cp0_unlock	wait4_cp0_unlock	7	Once in this state, the machine remains here until the gate is unlocked.
wait4_cp0_unlock	wait4_cp1_lock	8	From this state, the machine transitions into the next state, waiting for cp1 to lock the gate, once it has been unlocked.
wait4_cp0_lock	wait4_cp0_lock	9	In this state, the machine generates the notification interrupt (if properly-enabled) and remains here until the gate is locked by processor 0 or the gate is again locked by processor 1.
wait4_cp0_lock	wait4_cp1_unlock	10	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is again locked by processor 1. With this transition, the notification interrupt request is negated.
wait4_cp0_lock	idle	11	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is finally locked by processor 0. With this transition, the notification interrupt request is negated.
wait4_cp1_lock	wait4_cp1_lock	12	In this state, the machine generates the notification interrupt (if properly-enabled) and remains here until the gate is locked by processor 1 or the gate is again locked by processor 0.
wait4_cp1_lock	wait4_cp0_unlock	13	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is again locked by processor 0. With this transition, the notification interrupt request is negated.
wait4_cp1_lock	idle	14	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is finally locked by processor 1. With this transition, the notification interrupt request is negated.

The Semaphores module generates two interrupt request output signals, one per processor, combining the SEMA4_CPnINE and SEMA4_CPnNTF registers, where the boolean equations are:

```

cp0_semaphore_int
=   sema4_cp0ine[ine0]    &   sema4_cp0ntf[gn0]
  |   sema4_cp0ine[ine1]    &   sema4_cp0ntf[gn1]
  |   sema4_cp0ine[ine2]    &   sema4_cp0ntf[gn2]
  |   ...
  |   sema4_cp0ine[ine15]   &   sema4_cp0ntf[gn15]
cp1_semaphore_int
=   sema4_cp1ine[ine0]    &   sema4_cp1ntf[gn0]
  |   sema4_cp1ine[ine1]    &   sema4_cp1ntf[gn1]
  |   sema4_cp1ine[ine2]    &   sema4_cp1ntf[gn2]
  |   ...
  |   sema4_cp1ine[ine15]   &   sema4_cp1ntf[gn15]

```

13.5 Initialization Information

The reset state of the IPS_Semaphores module allows it to begin operation without the need for any further initialization. All the internal state machines are cleared by any reset event, allowing the module to immediately begin operation.

13.6 Application Information

In an operational multi-core system, most interactions involving the Semaphores module involves reads and writes to the SEMA4_GATEn registers for implementation of the hardware-enforced software gate functions. Typical code segments for gate functions perform the following operations:

- To lock (close) a gate
 - The processor performs a byte write of "logical_processor_number + 1" to gate[i]
 - The processor reads back gate[i] and checks for a value of "logical_processor_number + 1"

If the compare indicates the expected value, then the gate is locked; proceed with the protected code segment. If the compare does not indicate the expected value, the lock operation failed; repeat the process beginning with byte write to gate[i] in spin-wait loop, or proceed with another execution path and wait for failed lock interrupt notification.

A simple C-language example of a `gateLock` function is shown in the following figure. This function follows the Hennessy/Patterson example described in [Multi-Core Programming 101: Software Gates](#).

```

#define UNLOCK      0
#define CP0_LOCK    1
#define CP2_LOCK    2

void gateLock (n)
int    n;
/* gate number to lock */
{
    int i;
    int current_value;
    int locked_value;

    i = processor_number(); /* obtain logical CPU number */

    if (i == 0)
        locked_value = CP0_LOCK;
    else
        locked_value = CP1_LOCK;

    /* read the current value of the gate and wait until the state == UNLOCK */
    do {
        current_value = gate[n];
    } while (current_value != UNLOCK);

    /* the current value of the gate == UNLOCK. attempt to lock the gate for this
       processor. spin-wait in this loop until gate ownership is obtained */
    do {
        gate[n] = locked_value; /* write gate with processor_number + 1 */
        current_value = gate[n]; /* read gate to verify ownership was obtained */
    } while (current_value != locked_value);
}

```

Figure 13-28. Sample gateLock Function

- To unlock (open) a gate
 - After completing the protected code segment, the locking processor performs a byte write of zeroes to gate[i], opening (unlocking) the gate

A few comments on the logical CPU number are appropriate. In this example, a reference to `processor_number()` is used to retrieve this hardware configuration value. Typically, the logical processor numbers are defined by a hardwired input vector to the individual cores. The exact method for accessing the logical processor number varies by architecture. For PowerPC cores, there is a processor ID register (PIR) which is SPR 286 and contains this value. A single instruction can be used to move the contents of the PIR into a general-purpose register: `mf spr rx, 286` where `rx` is the destination GPRn. Other architectures may support a specific instruction to move the contents of the logical processor number into a general-purpose register, e.g., `rdcpn rx` for a "read CPU number" instruction.

If the optional failed lock IRQ notification mechanisms are used, then accesses to the related registers (SEMA4_CPnINE, SEMA4_CPnNTF) are required. Note that there is no required negation of the failed lock write notification interrupt as the request is automatically negated by the Semaphores module once the gate has been successfully locked by the "failing" processor.

Finally, in the event a system state requires a software-controlled reset of a gate or IRQ notification register(s), accesses to the secure reset control registers (SEMA4_RSTGT, SEMA4_RSTNTF) are required. For these situations, it is recommended that the appropriate IRQ notification enable(s) (SEMA4_CPnINE) bits be disabled *before* initiating the secure reset 2-write sequence to avoid any race conditions involving spurious notification interrupt requests.

Chapter 14

Memory Protection Unit (MPU)

14.1 Chip-specific MPU information

This chip has two instances of the MPU module. Some feature details vary between the instances.

The following table summarizes the feature differences. The table does not list feature details that the instances share.

Table 14-1. MPU instance feature differences

Feature	MPU_0	MPU_1
Number of slave ports supported	Three numbered 0, 1, 2	Two numbered 1, 2

14.1.1 MPU master and slave assignments

The MPU identifies each XBAR master in terms of the master's logical ID. See the "Logical master ID" assignments in [Table 9-1](#).

Each MPU slave port mediates between an XBAR physical slave port and the module that is assigned to that physical slave port. For each MPU instance, the following tables show the alignment among the MPU slave ports, the XBAR physical slave ports, and the corresponding assigned modules.

Table 14-2. MPU_0 slave ports

MPU_0 slave port	XBAR physical slave port	Module assigned to XBAR physical slave port
0	1	EBI
1	2	PRAMC_0
2	6	AIPS_1 (Peripheral Bridge A)

Table 14-3. MPU_1 slave ports

MPU_1 slave port	XBAR physical slave port	Module assigned to XBAR physical slave port
1	4	PRAMC_1
2	7	AIPS_0 (Peripheral Bridge B)

14.1.2 MPU register reset values

The following table lists MPU register reset values that are specific to this chip. For the reset values of all other MPU registers, see [Memory map/register definition](#).

Table 14-4. Chip-specific MPU register reset values

Register	MPU_0 and MPU_1 reset value	Notes
CESR	0081_3200h	NSP field resets to 0011b ¹

1. CESR[NSP]'s reset value on MPU_1 is 3 even though MPU_1 has only two slave ports.

14.2 Introduction

The memory protection unit (MPU) provides hardware access control for all memory references generated in the device.

14.3 Overview

The MPU concurrently monitors all system bus transactions and evaluates their appropriateness using pre-programmed region descriptors that define memory spaces and their access rights. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with a protection error response.

14.3.1 Block diagram

A simplified block diagram of the MPU module is shown in the following figure.

Figure 14-1. MPU block diagram

The hardware's two-dimensional connection matrix is clearly visible with the basic access evaluation macro shown as the replicated submodule block. The crossbar switch slave ports are shown on the left, the region descriptor registers in the middle, and the peripheral bus interface on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and the access protection error. For details of the access evaluation macro, see [Access evaluation macro](#).

14.3.2 Features

The MPU implements a two-dimensional hardware array of memory region descriptors and the crossbar slave ports to continuously monitor the legality of every memory reference generated by each bus master in the system.

The feature set includes:

- 16 program-visible 128-bit region descriptors, accessible by four 32-bit words each
 - Each region descriptor defines a modulo-32 byte space, aligned anywhere in memory

- Region sizes can vary from 32 bytes to 4 Gbytes
- Two access control permissions defined in a single descriptor word
 - Masters 0–3: read, write, and execute attributes for supervisor and user accesses
 - Masters 4–7: read and write attributes
- Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues
- Alternate programming model view of the access control permissions word
- Priority given to granting permission over denying access for overlapping region descriptors
- Detects access protection errors if a memory reference does not hit in any memory region, or if the reference is illegal in all hit memory regions. If an access error occurs, the reference is terminated with an error response, and the MPU inhibits the bus cycle being sent to the targeted slave device.
- Error registers, per slave port, capture the last faulting address, attributes, and other information
- Global MPU enable/disable control bit

14.4 Memory map/register definition

The programming model is partitioned into three groups:

- Control/status registers
- The data structure containing the region descriptors
- The alternate view of the region descriptor access control values

The programming model can be referenced using only 32-bit accesses.

Attempted references of the following types generate an error termination:

- Non-32-bit references
- References to undefined—that is, reserved—addresses
- References with a non-supported access type, such as a write access to a read-only register or a read access of a write-only register

NOTE

See the chip configuration details for any chip-specific register information in this module.

MPU_CESR field descriptions

Field	Description
0–2 SPERR	Slave Port n Error Indicates a captured error in EARN and EDNRn. This bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing one to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction or equivalent can detect the presence of a captured error. The following shows the correspondence between the bit number and slave port number: • Bit 0 corresponds to slave port 0. • Bit 1 corresponds to slave port 1. • Bit 2 corresponds to slave port 2. 0 No error has occurred for slave port n. 1 An error has occurred for slave port n.
3–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
9–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 HRL	Hardware Revision Level Specifies the MPU's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
16–19 NSP	Number Of Slave Ports Specifies the number of slave ports connected to the MPU.
20–23 NRGD	Number Of Region Descriptors Indicates the number of region descriptors implemented in the MPU.

Field	Description
	0000 8 region descriptors 0001 12 region descriptors 0010 16 region descriptors
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 VLD	Valid Global enable/disable for the MPU. 0 MPU is disabled. All accesses from all bus masters are allowed. 1 MPU is enabled

14.4.2 Error Address Register, slave port n (MPU_EAR_n)

When the MPU detects an access error on slave port n, the 32-bit reference address is captured in this read-only register and the corresponding bit in CESR[SPERR_n] is set. Additional information about the faulting access is captured in the corresponding EDR_n at the same time. This register and the corresponding EDR_n contain the most recent access error; there are no hardware interlocks with CESR[SPERR_n], as the error registers are always loaded upon the occurrence of each protection violation.

Address: 0h base + 10h offset + (8d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MPU_EAR_n field descriptions

Field	Description
0–31 EADDR	Error Address Indicates the reference address from slave port n that generated the access error

14.4.3 Error Detail Register, slave port n (MPU_EDRn)

When the MPU detects an access error on slave port n, 32 bits of error detail are captured in this read-only register and the corresponding bit in CESR[SPERRn] is set. Information on the faulting address is captured in the corresponding EARN register at the same time. This register and the corresponding EARN register contain the most recent access error; there are no hardware interlocks with CESR[SPERRn] as the error registers are always loaded upon the occurrence of each protection violation.

Address: 0h base + 14h offset + (8d × i), where i=0d to 2d

MPU_EDRn field descriptions

Field	Description
0–15 EACD	Error Access Control Detail Indicates the region descriptor with the access error. • If EDRn contains a captured error and EACD is cleared, an access did not hit in any region descriptor. • If only a single EACD bit is set, the protection error was caused by a single non-overlapping region descriptor. • If two or more EACD bits are set, the protection error was caused by an overlapping set of region descriptors.
16–23 EPID	Error Process Identification Records the process identifier of the faulting reference. The process identifier is typically driven only by processor cores; for other bus masters, this field is cleared.
24–27 EMN	Error Master Number Indicates the bus master that generated the access error.
28–30 EATTR	Error Attributes Indicates attribute information about the faulting reference. NOTE: All other encodings are reserved. 000 User mode, instruction access 001 User mode, data access 010 Supervisor mode, instruction access 011 Supervisor mode, data access

MPU_RGD_n_WORD0 field descriptions

Field	Description
0–26 SRTADDR	Start Address Defines the most significant bits of the 0-modulo-32 byte start address of the memory region.
27–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

14.4.5 Region Descriptor n, Word 1 (MPU_RGDn_WORD1)

The second word of the region descriptor defines the 31-modulo-32 byte end address of the memory region. Writes to this register clear the region descriptor’s valid bit (RGDn_WORD3[VLD]).

Address: 0h base + 404h offset + (16d × i), where i=0d to 15d

- * Notes:
- Reset value of RGD0_WORD1 is FFFF_FFFFh
 - Reset value of RGD[1:15]_WORD1 is 0000_001Fh

MPU_RGDn_WORD1 field descriptions

Field	Description
0–26 ENDADDR	End Address Defines the most significant bits of the 31-modulo-32 byte end address of the memory region. NOTE: The MPU does not verify that ENDADDR ≥ SRTADDR.
27–31 Reserved	This field is reserved.

14.4.6 Region Descriptor n, Word 2 (MPU_RGDn_WORD2)

The third word of the region descriptor defines the access control rights of the memory region. The access control privileges depend on two broad classifications of bus masters:

- Bus masters 0–3 have a 5-bit field defining separate privilege rights for user and supervisor mode accesses. Each of these bus masters optionally includes a process identification field (if implemented for the master) within the definition.
- Bus masters 4–7 are limited to separate read and write permissions.

For the privilege rights of bus masters 0–3, there are three flags associated with this function:

- Read (r) refers to accessing the referenced memory address using an operand (data) fetch

- Write (w) refers to updating the referenced memory address using a store (data) instruction
- Execute (x) refers to reading the referenced memory address using an instruction fetch

Writes to RGDn_WORD2 clear the region descriptor's valid bit (RGDn_WORD3[VLD]). If only updating the access controls, write to RGDAACn instead because stores to these locations do not affect the descriptor's valid bit.

Address: 0h base + 408h offset + (16d × i), where i=0d to 15d

14.5 Functional description

In this section, the functional operation of the MPU is detailed, including the operation of the access evaluation macro and the handling of error-terminated bus cycles.

14.5.1 Access evaluation macro

The basic operation of the MPU is performed in the access evaluation macro, a hardware structure replicated in the two-dimensional connection matrix. As shown in the following figure, the access evaluation macro inputs the crossbar bus address phase signals and the contents of a region descriptor (RGD_n) and performs two major functions:

- Region hit determination
- Detection of an access protection violation

The following figure shows a functional block diagram.

Figure 14-96. MPU access evaluation macro

14.5.1.1 Hit determination

To determine whether the current reference hits in the given region, two magnitude comparators are used with the region's start and end addresses. The boolean equation for this portion of the hit determination is:

```
region_hit = ((addr[31:5] >= RGDn_Word0[SRTADDR]) & (addr[31:5] <= RGDn_Word1[ENDADDR])) &
RGDn_Word3[VLD]
```

where *addr* is the current reference address, *RGDn_Word0[SRTADDR]* and *RGDn_Word1[ENDADDR]* are the start and end addresses, and *RGDn_Word3[VLD]* is the valid bit.

NOTE

The MPU does not verify that $ENDADDR \geq SRTADDR$.

In addition to the comparison of the reference address versus the region descriptor's start and end addresses, the optional process identifier is examined against the region descriptor's PID and PIDMASK fields. A process identifier hit term is formed as follows:

```
pid_hit = ~RGDn_Word2[MxPE] |
((current_pid |
RGDn_Word3[PIDMASK]) == (RGDn_Word3[PID] | RGDn_Word3[PIDMASK]))
```

where the `current_pid` is the selected process identifier from the current bus master, and `RGD $n$ _Word3[PID]` and `RGD $n$ _Word3[PIDMASK]` are the process identifier fields from region descriptor n . For bus masters that do not output a process identifier, the MPU forces the `pid_hit` term to assert.

14.5.1.2 Privilege violation determination

While the access evaluation macro is determining region hit, the logic is also evaluating if the current access is allowed by the permissions defined in the region descriptor. Using the master and supervisor/user mode signals, a set of effective permissions is generated from the appropriate fields in the region descriptor. The protection violation logic then evaluates the access against the effective permissions using the specification shown below.

Table 14-100. Protection violation definition

Description	MxUM			Protection violation?
	r	w	x	
Instruction fetch read	—	—	0	Yes, no execute permission
	—	—	1	No, access is allowed
Data read	0	—	—	Yes, no read permission
	1	—	—	No, access is allowed
Data write	—	0	—	Yes, no write permission
	—	1	—	No, access is allowed

14.5.2 Putting it all together and error terminations

For each slave port monitored, the MPU performs a reduction-AND of all the individual terms from each access evaluation macro. This expression then terminates the bus cycle with an error and reports a protection error for three conditions:

- If the access does not hit in any region descriptor, a protection error is reported.
- If the access hits in a single region descriptor and that region signals a protection violation, a protection error is reported.
- If the access hits in multiple (overlapping) regions and all regions signal protection violations, a protection error is reported.

As shown in the third condition, granting permission is a higher priority than denying access for overlapping regions. This approach is more flexible to system software in region descriptor assignments. For an example of the use of overlapping region descriptors, see [Application information](#).

14.5.3 Power management

Disabling the MPU by clearing CESR[VLD] minimizes power dissipation. To minimize the power dissipation of an enabled MPU, invalidate unused region descriptors by clearing the associated RGDn_Word3[VLD] bits.

14.6 Initialization information

At system startup, load the appropriate number of region descriptors, including setting RGDn_Word3[VLD]. Setting CESR[VLD] enables the module.

If the system requires that all the loaded region descriptors be enabled simultaneously, first ensure that the entire MPU is disabled (CESR[VLD]=0).

Note

A region descriptor must be set to allow access to the MPU registers if further changes are needed.

14.7 Application information

In an operational system, interfacing with the MPU is generally classified into the following activities:

- Creating a new memory region—Load the appropriate region descriptor into an available RGDn, using four sequential 32-bit writes. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes. (Clearing RGDn_Word3[VLD] deletes/removes an existing memory region.)
- Altering only access privileges—To not affect the valid bit, write to the alternate version of the access control word (RGDAACn), so there are no coherency issues involved with the update. When the write completes, the memory region's access rights switch instantaneously to the new value.

- Changing a region's start and end addresses—Write a minimum of three words to the region descriptor (RGD_n_Word{0,1,3}). Word 0 and 1 redefine the start and end addresses, respectively. Word 3 re-enables the region descriptor valid bit. In most situations, all four words of the region descriptor are rewritten.
- Accessing the MPU—Allocate a region descriptor to restrict MPU access to supervisor mode from a specific master.
- Detecting an access error—The current bus cycle is terminated with an error response and EAR_n and EDR_n capture information on the faulting reference. The error-terminated bus cycle typically initiates an error response in the originating bus master. For example, a processor core may respond with a bus error exception, while a data movement bus master may respond with an error interrupt. The processor can retrieve the captured error address and detail information simply by reading E{A,D}R_n. CESR[SPERR] signals which error registers contain captured fault data.
- Overlapping region descriptors—Applying overlapping regions often reduces the number of descriptors required for a given set of access controls. In the overlapping memory space, the protection rights of the corresponding region descriptors are logically summed together (the boolean OR operator).

The following dual-core system example contains four bus masters:

- The two processors: CP0, CP1
- Two DMA engines: DMA1, a traditional data movement engine transferring data between RAM and peripherals and DMA2, a second engine transferring data to/from the RAM only

Consider the following region descriptor assignments:

Table 14-101. Overlapping region descriptor example

Region description	RGDn		CP0	CP1	DMA1	DMA2	
CP0 code	0		rwX	r--	—	—	Flash
CP1 code	1		r--	rwX	—	—	
CP0 data & stack	2		rw-	—	—	—	RAM
CP0 → CP1 shared data	2	3	r--	r--	—	—	
CP1 → CP0 shared data	4						
CP1 data & stack	4		—	rw-	—	—	
Shared DMA data	5		rw-	rw-	rw	rw	
MPU	6		rw-	rw-	—	—	Peripheral space
Peripherals	7		rw-	rw-	rw	—	

In this example, there are eight descriptors used to span nine regions in the three main spaces of the system memory map: flash, RAM, and peripheral space. Each region indicates the specific permissions for each of the four bus masters and this definition provides an appropriate set of shared, private and executable memory spaces.

Of particular interest are the two overlapping spaces: region descriptors 2 & 3 and 3 & 4.

The space defined by RGD2 with no overlap is a private data and stack area that provides read/write access to CP0 only. The overlapping space between RGD2 and RGD3 defines a shared data space for passing data from CP0 to CP1 and the access controls are defined by the logical OR of the two region descriptors. Thus, CP0 has $(rw- \mid r--) = (rw-)$ permissions, while CP1 has $(--- \mid r--) = (r--)$ permission in this space. Both DMA engines are excluded from this shared processor data region. The overlapping spaces between RGD3 and RGD4 defines another shared data space, this one for passing data from CP1 to CP0. For this overlapping space, CP0 has $(r-- \mid ---) = (r--)$ permission, while CP1 has $(rw- \mid r--) = (rw-)$ permission. The non-overlapped space of RGD4 defines a private data and stack area for CP1 only.

The space defined by RGD5 is a shared data region, accessible by all four bus masters. Finally, the slave peripheral space mapped onto the IPS bus is partitioned into two regions:

- One containing the MPU's programming model accessible only to the two processor cores
- The remaining peripheral region accessible to both processors and the traditional DMA1 master

This example shows one possible application of the capabilities of the MPU in a typical system.

Chapter 15

Interrupt Controller (INTC)

15.1 Chip-specific INTC information

The INTC on this chip supports two core processors. In the detailed INTC description, the cores are designated processor 0 and processor 1.

15.2 Introduction

The INTC:

- Provides priority-based preemptive scheduling of interrupt requests
- Schedules interrupt requests (IRQs) from software and internal peripherals to one or both processors (PRCs)
- Provides interrupt prioritization and preemption, interrupt masking, interrupt priority elevation, and protocol support

The INTC has two independent sets of priority arbitration/comparison, request selection, vector encoder and acknowledge logic—one set for each CPU. This arrangement allows each CPU to handle its software-assigned interrupt requests independently of the other CPU's operation, and it provides flexibility for the user to decide which core should handle which interrupt sources in the application. This flexibility comes from a set of configuration bits that allows any interrupt source to generate an interrupt request to Core 0, Core 1, or both cores.

For high-priority interrupt requests in these target applications, it is necessary to minimize the interval between the assertion of the interrupt request from the peripheral and the point at which the processor is performing useful work to service the interrupt request. The INTC supports this goal by providing a unique vector for each interrupt request source. It also provides 16 priorities so that lower priority ISRs do not delay the

execution of higher priority ISRs. Since each individual application will have different priorities for each source of interrupt request, the priority of each interrupt request is configurable.

When multiple tasks share a resource, coherent accesses to that resource need to be supported. The INTC supports the Priority Ceiling Protocol for coherent accesses. By providing a modifiable priority mask, the priority can be raised temporarily so that all tasks which share the resource are unable to preempt each other.

Multiple processors can assert interrupt requests to each other through software-settable interrupt requests. These same software-settable interrupt requests can also be used to separate the work involved in servicing an interrupt request into two parts, a high-priority portion and a low-priority portion. The high-priority portion is initiated by a peripheral interrupt request, but then the ISR can assert a software-settable interrupt request to finish the servicing in a lower priority ISR. Therefore these software-settable interrupt requests can be used instead of having the peripheral ISR schedule a task through the RTOS.

15.3 Block diagram

Interrupts implemented by the chip are defined in the *e200z759n3 Core Reference Manual*.

The block diagram for the INTC appears in the following figure.

Figure 15-1. INTC block diagram

15.4 Features

- Each peripheral interrupt source is software-steerable to interrupt request outputs of processor 0, processor 1, or both
- 8 software-settable interrupt request sources
- 9-bit vector
 - Unique vector for each interrupt request source
 - Hardware connection to processor or read from register
- Each interrupt source can be programmed to one of 16 priorities
- Each interrupt source can be triggered by software
- Preemption
 - Preemptive prioritized interrupt requests to processor
 - ISR with higher priority preempts ISRs or tasks with lower priorities
 - Automatic pushing or popping of preempted priority to or from a LIFO
 - Ability to modify the ISR or task priority; modifying the priority can be used to implement the Priority Ceiling Protocol for accessing shared resources
- Low latency
 - Three INTC clock cycles from receipt of interrupt request from peripheral to interrupt request to processor

15.5 Modes of operation

The interrupt controller has two handshaking modes with the processor: software vector mode and hardware vector mode. The state of the hardware vector enable bit, `INTC_MCR[HVEN_PRC $n$ ]`, determines which mode is used for each CPU.

In debug mode the interrupt controller operation is identical to its normal operation of software vector mode or hardware vector mode.

15.5.1 Software vector mode

In software vector mode, as shown in the following figure, the CPU branches to a common interrupt exception handler whose location is determined by an address derived from special purpose registers IVPR and IVOR4. The interrupt exception handler reads the INTC_IACKR_PCR n to determine the vector of the interrupt request source.

Figure 15-2. INTC software vector mode

The following figure shows the typical program flow for software vector mode.

N is the maximum number of usable interrupt vectors and includes eight software-settable IRQ vectors.

Figure 15-3. Program flow: software vector mode

The following figure shows how the common interrupt exception handler address is calculated by hardware. The upper half of the interrupt vector prefix register (IVPR) is added to the offset contained in the external input interrupt vector offset register (IVOR4). Because bits IVOR4[28:31] are not part of the offset value, the vector offset must be in a location in memory that is quad-word (16-byte) aligned.

Figure 15-4. Software vector mode: interrupt exception handler address calculation

As shown in the preceding figure, the common interrupt exception handler reads the `INTC_IACKR_PRCn` to determine the vector of the interrupt request source. The `INTC_IACKR_PRCn` register contains a 32-bit address for a vector table base address (VTBA) plus an offset to access the interrupt vector (INTVEC). The address is then used to branch to the corresponding routine for that peripheral or software interrupt source.

Reading the `INTC_IACKR_PRCn` acknowledges the INTC's interrupt request and negates the interrupt request to the processor. The interrupt request to the processor does not clear if a higher priority interrupt request arrives. Even in this case, INTVEC does not update to the higher priority request until the lower priority interrupt request is acknowledged by reading the `INTC_IACKR_PRCn`. The reading also pushes the PRI value in the INTC current priority register (`INTC_CPR_PRCn`) onto the LIFO and updates PRI in the `INTC_CPR_PRCn` with the priority of the interrupt request. The `INTC_CPR_PRCn` masks any peripheral or software settable interrupt request at the same or lower priority of the current value of the PRI field in `INTC_CPR_PRCn` from generating an interrupt request to the processor.

The interrupt exception handler must write to the end-of-interrupt register (`INTC_EOIR_PRCn`) to complete the operation. Writing to the `INTC_EOIR_PRCn` ends the servicing of the interrupt request. The INTC's LIFO is popped into the `INTC_CPR_PRCn`'s PRI field by writing to the `INTC_EOIR_PRCn`, and the size of a write does not affect the operation of the write. Those values and sizes written to this register neither update the `INTC_EOIR_PRCn` contents nor affect whether the LIFO pops. For possible future compatibility, write four bytes of all zeroes to the `INTC_EOIR_PRCn`. The timing relationship between popping the LIFO and disabling recognition of external input has no restriction. The writes can happen in either order.

However, disabling recognition of the external input before popping the LIFO eases the calculation of the maximum stack depth at the cost of postponing the servicing of the next interrupt request.

15.5.2 Hardware vector mode

The following figure shows the typical program flow for hardware vector mode.

Figure 15-5. Program flow: hardware vector mode

In hardware vector mode, the interrupt exception handler address is specific to the peripheral or software-settable interrupt source rather than being common to all of them. No IVOR is used. The interrupt exception handler address is calculated by hardware as shown in the following figure. The upper half of the interrupt vector prefix register (IVPR) is added to an offset, which corresponds to the peripheral or software interrupt source which caused the interrupt request. The offset matches the value in the Interrupt Vector field, INTC_IACKR_PRCn[INTVEC]. Each interrupt exception handler address is aligned on a quad word (16-byte) boundary. IVOR4 is not used in this mode, and software does not need to read INTC_IACKR_PRCn to get the interrupt vector number.

Figure 15-6. Hardware vector mode: interrupt exception handler address calculation

The processor negates INTC's interrupt request when automatically acknowledging the interrupt request. However, the interrupt request to the processor do not negate if a higher priority interrupt request arrives. Even in this case, the interrupt vector number does not update to the higher priority request until the lower priority request is acknowledged by the processor.

The assertion of the interrupt acknowledge signal pushes the PRI value in the INTC_CPR_PRC n onto the LIFO and updates PRI in the INTC_CPR_PRC n with the new priority.

15.6 External signal description

The INTC has no direct external MCU signals. However, there are external pins that can be configured in the SIU as external interrupt request input pins. When configured in this function, an interrupt on the pin sets an external interrupt flag. These flags can cause one of five peripheral interrupt requests to the interrupt controller.

15.7 Memory map and register definition

The actual availability and number of registers are chip-specific. For this information, see the chapter that describes how modules are configured and connected.

NOTE

For unimplemented locations in the memory map, read accesses return zeros and attempted write accesses are ignored.

The INTC register memory map is mirrored at 1 KB intervals. Referring to the following equation, the result of accessing any location when I is 1 to 15 is the same as the result of accessing a location when I is 0:

Offset + (400h x I), where I = 0 to 15

For example: PSR0 is accessed at 040h, 440h, 840h, and so on.

With the exception of the INTC_SSCIR n and INTC_PSR n registers, all of the registers are 32-bit. Any combination of accessing the four bytes of a register with a single access is supported, provided that the access does not cross a register boundary. These supported accesses include types and sizes of 8 bits, aligned 16 bits, misaligned 16 bits to the middle two bytes, and aligned 32 bits.

Although INTC_SSCIR n and INTC_PSR n are 8 bits wide, they can be accessed with a single 16-bit or 32-bit access, provided that the access does not cross a 32-bit boundary.

In software vector mode, the effects of a read of the INTC Interrupt Acknowledge register are the same regardless of the size of the read. In either software or hardware vector mode, the size of a write to the INTC End-of-Interrupt register does not affect the operation of the write.

15.7.2 INTC Current Priority Register for Processor *n* (INTC_CPR_PRC_{*n*})

The INTC_CPR_PRC_{*n*} masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR_PRC_{*n*}[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR_PRC_{*n*}) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC End-of-Interrupt register (INTC_EOIR_PRC_{*n*}) is written, the LIFO is popped into the INTC_CPR_PRC_{*n*}[PRI] field. An exception case in hardware vector mode to this behavior is described in [Hardware vector mode](#).

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See [Priority ceiling protocol](#).

NOTE

The PRI register address space must be configured as guarded and cache-inhibited prior to writing to the register.

NOTE

A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See [Ensuring coherency](#) for example code to ensure coherency.

Address: 0h base + 8h offset + (4d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

INTC_CPR_PRC_n field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 PRI	Priority of the currently executing ISR, according to the field values 15 (highest priority) down to 0 (lowest priority).

15.7.3 INTC Interrupt Acknowledge Register for Processor *n* (INTC_IACKR_PRC_n)

The Interrupt Acknowledge Register for Processor *n* provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

NOTE

Also, in software vector mode, the INTC_IACKR_PRC_n has side effects from reads. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read.

NOTE

Reading the INTC_IACKR_PRC_n has no side effects in hardware vector mode (when the corresponding INTC_MCR[HVEN_PRC_n] field is 1).

NOTE

In software vector mode, the INTC_IACKR_PRC_n must be read before setting MSR[EE]. No synchronization instruction is needed after reading the INTC_IACKR_PRC_n and before setting MSR[EE].

However, the time for the processor to recognize the assertion or negation of the external input to it is not defined by the book E architecture and can be greater than 0. Therefore, insert instructions between the reading of the INTC_IACKR_PRC_n and the setting of MSR[EE] that consumes at least two

processor clock cycles. This length of time allows the interrupt request negation to propagate through the processor before MSR[EE] is set.

Address: 0h base + 10h offset + (4d × i), where i=0d to 1d

INTC_IACKR_PRCn field descriptions

Field	Description
0–20 VTBA_PRCn	Vector Table Base Address Can be the base address of a vector table of addresses of ISRs. VTBA_PRCn uses only the left-most 20 bits when the corresponding VTES_PRCn bit in INTC_MCR is asserted.
21–29 INTVEC_PRCn	Interrupt Vector Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

15.7.4 INTC End Of Interrupt Register for Processor n (INTC_EOIR_PRCn)

Writing to the INTC_EOIR_PRCn signals the end of the servicing of the interrupt request. When the INTC_EOIR_PRCn is written, the priority last pushed on the LIFO is popped into INTC_CPR_PRCn. The values and size of data written to the INTC_EOIR_PRCn are ignored. Those values and sizes written to this register neither update the INTC_EOIR_PRCn contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

Address: 0h base + 18h offset + (4d × i), where i=0d to 1d

INTC_EOIR_PRCn field descriptions

Field	Description
0–31 EOI_PRCn	End of Interrupt Write four all-zero bytes to this field to signal the end of the servicing of an interrupt request.

15.7.5 INTC Software Set/Clear Interrupt Register (INTC_SSCIRn)

The INTC_SSCIR registers support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. With the exception of being set by software, this flag bit behaves the same as a flag bit set within a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a 1 to SETn will leave SETn unchanged at 0 but will set CLRn. Writing a 0 to SETn will have no effect. CLRn is the flag bit. Writing a 1 to CLRn will clear it. Writing a 0 to CLRn will have no effect. If a 1 is written to a pair of SETn and CLRn bits at the same time, CLRn is asserted, regardless of whether CLRn was asserted before the write.

Address: 0h base + 20h offset + (1d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7
Read	0						0	CLRn
Write							SETn	w1c
Reset	0	0	0	0	0	0	0	0

INTC_SSCIRn field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 SETn	Set flag bits. Writing a 1 will set the corresponding CLRn bit. Writing a 0 will have no effect. Each SETn is read as a 0.
7 CLRn	Clear flag bits. CLRn is the flag bit. Writing a 1 to CLRn will clear it provided that a 1 is not written simultaneously to its corresponding SETn bit. Writing a 0 to CLRn will have no effect. 0 Interrupt request not pending within INTC. 1 Interrupt request pending within INTC.

15.7.6 INTC Priority Select Register (INTC_PSRn)

The Priority Select Registers support the selection of an individual priority for each source of interrupt request, and the routing of the request to one or both processors. The unique vector of each peripheral or software-settable interrupt request determines which INTC_PSRn is assigned to that interrupt request. The software-settable interrupt requests 0–7 are assigned vectors 0–7, and their priorities are configured in INTC_PSR0 to INTC_PSR7, respectively. The peripheral interrupt requests are assigned to vectors in the range 8 to 511, and their priorities are configured in the range of registers INTC_PSR8 to INTC_PSR511, respectively.

NOTE

Interrupts are not detected while the PSRs are being written.
The PRC_SELn or PRIn field of an INTC_PSRn must not be modified while the corresponding peripheral or software settable interrupt request is asserted.

Address: 0h base + 40h offset + (1d × i), where i=0d to 511d

INTC_PSRn field descriptions

Field	Description
0–1 PRC_SELn	Processor select bits. If an interrupt source is enabled, PRC_SELn[3:0] selects whether the interrupt request is to be sent to processor 0, processor 1, or both. 00 Interrupt request sent to processor 0 01 Interrupt request sent to both processors 10 Reserved 11 Interrupt request sent to processor 1
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 PRIn	Priority select. Selects the priority for the interrupt requests. PRI has values 15 (highest priority) down to 0 (lowest priority).

15.8 Functional description

The functional description involves the areas of interrupt request sources, priority management, and handshaking with the processor. In addition, spaces in the memory map have been reserved for other possible implementations of the INTC.

15.8.1 Interrupt request sources

The INTC has two types of interrupt requests, peripheral and software-settable. These interrupt requests can assert on any clock cycle.

The INTC has no spurious vector support. Therefore, if an asserted peripheral or software-settable interrupt request, whose PRI_n value in $INTC\_PSR_n$ is higher than the PRI value in $INTC\_CPR_n$, negates before the interrupt request to the processor for that peripheral or software-settable interrupt request is acknowledged, then the interrupt request to the processor still can assert (or will remain asserted) for that peripheral or software-settable interrupt request. In this case, the interrupt vector will correspond to that peripheral or software-settable interrupt request. Also, the PRI value in the associated $INTC\_CPR_n$ is updated with the corresponding PRI_n value in $INTC\_PSR_n$.

Furthermore, clearing the peripheral interrupt request's enable bit in the peripheral, or (alternatively) setting its mask bit, has the same consequences as clearing its flag bit. Setting its enable bit or clearing its mask bit while its flag bit is asserted has the same effect on the INTC as an interrupt event setting the flag bit.

15.8.1.1 Peripheral interrupt requests

An interrupt event in a peripheral's hardware sets a flag bit which resides in that peripheral. The interrupt request from the peripheral is driven by that flag bit.

The time from when the peripheral starts to drive its peripheral interrupt request to the INTC, to the time that the INTC starts to drive the interrupt request to the processor, is three clocks.

Interrupt requests from devices external to this chip are classified as peripheral interrupt requests in this document. This type of external peripheral interrupts is handled by the SIU.

15.8.1.2 Software-settable interrupt requests

The software set/clear interrupt registers ($INTC\_SSCIR_n$) support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. An interrupt request is triggered by software by writing a 1 to a SET_n bit in $INTC\_SSCIR_n$. This write sets the corresponding CLR_n bit, which is a flag bit, resulting in the interrupt request. The interrupt request is cleared by writing a 1 to the CLR_n bit. Specific behavior includes the following:

- Writing a 1 to SET n leaves SET n unchanged at 0 but sets the flag bit (which is the CLR n bit).
- Writing a 0 to SET n has no effect.
- Writing a 1 to CLR n clears the flag (CLR n) bit.
- Writing a 0 to CLR n has no effect.
- If a 1 is written to a pair of SET n and CLR n bits at the same time, the flag (CLR n) is set, regardless of whether CLR n was asserted before the write.

The time from the write to the SET n bit, to the time that the INTC starts to drive the interrupt request to the processor, is four clocks.

15.8.1.3 Unique vector for each interrupt request source

Each peripheral and software-settable interrupt request is assigned a hardwired unique 9-bit vector. Software-settable interrupts 0–7 are assigned vectors 0–7, respectively. The peripheral interrupt requests are assigned vectors from 8 to a number as high as needed to cover all peripheral interrupt requests.

15.8.2 Priority management

The asserted interrupt requests are compared to each other based on their PRI n and PRC_SEL n values set in INTC_PSR n . The result of that comparison also is compared to PRI in the associated INTC_CPR n . The results of those comparisons are used to manage the priority of the ISR being executed by the associated processor. The associated LIFO also assists in managing that priority.

15.8.2.1 Current priority and preemption

The priority arbitrator, selector, encoder, and comparator logic shown in [Figure 15-1](#) are used to compare the priority of the asserted interrupt requests to the current priority. If the priority of any asserted peripheral or software-settable interrupt request is higher than the current priority for a given processor, then the interrupt request to the processor is asserted. Also, a unique vector for the preempting peripheral or software-settable interrupt request is generated for the associated INTC_IACKR n , and if in hardware vector mode, for the interrupt vector provided to the processor.

15.8.2.1.1 Priority arbitrator

The priority arbitrator for each processor compares all the priorities of all of the asserted interrupt requests assigned to that processor, both peripheral and software-settable. The output of the priority arbitrator is the highest of those priorities assigned to a given processor. Also, any interrupt requests which have this highest priority are output as asserted interrupt requests to the associated selector logic.

15.8.2.1.2 Selector

If only one interrupt request from the associated priority arbitrator is asserted, then it is passed as asserted to the associated encoder logic. If multiple interrupt requests from the associated priority arbitrator are asserted, then only the one with the lowest vector is passed as asserted to the associated encoder logic. The lower vector is chosen regardless of the time order of the assertions of the peripheral or software-settable interrupt requests.

15.8.2.1.3 Encoder

The encoder logic generates the unique 9-bit vector for the asserted interrupt request from the request selector submodule for the associated processor.

15.8.2.1.4 Comparator

The comparator logic compares the highest priority output from the associated priority arbitrator subblock with PRI in the associated INTC_CPR_n. If the comparator detects that this highest priority is higher than the current priority, then it asserts the interrupt request to the associated processor. This interrupt request to the processor asserts whether this highest priority is raised above the value of PRI in the associated INTC_CPR_n, or the PRI value in the associated INTC_CPR_n is lowered below this highest priority. This highest priority then becomes the new priority which is written to PRI in the associated INTC_CPR_n when the interrupt request to the processor is acknowledged. Interrupt requests whose PRI_n in INTC_PSR_n are zero will not cause a preemption because their PRI_n will not be higher than PRI in the associated INTC_CPR_n.

Another function of the comparator is to signal an update of the INTC_IACKR_n with the vector number of the first interrupt that arrives that has a priority higher than the current priority. Once the vector number and priority are captured, they cannot be superseded by a higher priority interrupt until an update of the INTC_CPR_n occurs.

15.8.2.2 Stack (LIFO)

The LIFO stores the preempted PRI values from the associated `INTC_CPRn`. Therefore, because these priorities are stacked within the INTC, if interrupts need to be enabled during the ISR, at the beginning of the interrupt exception handler the PRI value in the associated `INTC_CPRn` does not need to be loaded from the associated `INTC_CPRn` and stored onto the context stack. Likewise at the end of the interrupt exception handler, the priority does not need to be loaded from the context stack and stored into the associated `INTC_CPRn`.

The PRI value in the associated `INTC_CPRn` is pushed onto the LIFO when the associated `INTC_IACKRn` is read in software vector mode or the interrupt acknowledge signal from the associated processor is asserted in hardware vector mode. The priority is popped into PRI in the associated `INTC_CPRn` whenever the associated `INTC_EOIRn` is written. An exception case in hardware vector mode to this behavior is described in [Hardware vector mode](#).

Although the INTC supports 16 priorities, an ISR executing with PRI in the `INTC_CPRn` equal to 15 will not be preempted. Therefore, the LIFO supports the stacking of 15 priorities. However, the LIFO is only 14 entries deep. An entry for a priority of 0 is not needed because of the ways that pushing onto a full LIFO and popping an empty LIFO are treated. If the LIFO is pushed 15 or more times than it is popped, the priorities first pushed are overwritten. A priority of 0 would be an overwritten priority. However, the LIFO will pop zeroes if it is popped more times than it is pushed. Therefore, although a priority of 0 was overwritten, it is regenerated with the popping of an empty LIFO.

15.8.3 Handshaking with processor

This section describes handshaking with the processor.

15.8.3.1 Software vector mode handshaking

This section describes the software vector mode handshaking.

15.8.3.1.1 Acknowledging interrupt request to processor

A timing diagram of the interrupt request and acknowledge handshaking in software vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in [Figure 15-539](#). The INTC examines the peripheral and software-settable interrupt requests. When it finds an asserted peripheral or software-settable interrupt request with a higher priority than PRI in the associated `INTC_CPRn`, it asserts the

interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR n is updated with the preempting interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. The rest of the handshaking is described in [Software vector mode](#).

15.8.3.1.2 End of interrupt exception handler

Before the interrupt exception handling completes, INTC_EOIR_PRC n must be written. When it is written, the associated LIFO is popped so that the preempted priority is restored into PRI of the associated INTC_CPR_PRC n . Before it is written, the peripheral or software-settable flag bit must be cleared so that the peripheral or software-settable interrupt request is negated.

NOTE

To ensure proper operation across all Power Architecture MCUs, execute an **mbar** or **msync** instruction between the access to clear the flag bit and the write to the INTC_EOIR_PRC n .

When returning from the preemption, the INTC does not search for the peripheral or software-settable interrupt request whose ISR was preempted. Depending on how much the ISR has progressed, that interrupt request may no longer even be asserted. When PRI in the associated INTC_CPR_PRC n is lowered to the priority of the preempted ISR, the interrupt request for the preempted ISR or any other asserted peripheral or software-settable interrupt request at or below that priority will not cause a preemption. Instead, after the restoration of the preempted context, the processor will return to the instruction address that it had been going to execute next, before it was preempted. This next instruction is part of the preempted ISR or the interrupt exception handler's prolog or epilog.

Figure 15-539. Timing diagram of software vector mode handshaking

15.8.3.2 Hardware vector mode handshaking

A timing diagram of the interrupt request and acknowledge handshaking in hardware vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in [Figure 15-540](#). As in software vector mode, the INTC examines the peripheral and software-settable interrupt requests, and when it finds an asserted interrupt request with a higher priority than PRI in the associated INTC_CPR n , it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR n is updated with the preempting peripheral or software-settable interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the associated processor is asserted. In addition, the value of the interrupt vector to the associated processor matches the value of the INTVEC field in the associated INTC_IACKR n . The rest of the handshaking is described in [Hardware vector mode](#).

The handshaking near the end of the interrupt exception handler, that is the writing to the associated INTC_EOIR n , is the same as in software vector mode. See [End of interrupt exception handler](#).

Figure 15-540. Timing diagram for hardware vector mode handshaking

15.9 Initialization/application information

This section contains initialization/application information.

15.9.1 Initialization flow

After exiting reset, all of the $PRIn$ and PRC_SELn fields in $INTC\_PSRn$ are zero, and PRI in the $INTC\_CPRn$ registers is 15d. These reset values prevent the INTC from asserting the interrupt request to the processors. The enable or mask bits in the peripherals are reset such that the peripheral interrupt requests are negated. An initialization sequence for allowing the peripheral and software-settable interrupt requests to cause an interrupt request to the processor is:

- interrupt_request_initialization:
 - Configure $HVEN\_PRCn$ in $INTC\_MCR$.
 - Configure $VTBA\_PRCn$ in $INTC\_IACKR\_PRCn$.
 - Raise the $PRIn$ fields and set the PRC_SELn fields to the desired processor in $INTC\_PSRn$.
 - Set the enable bits or clear the mask bits for the peripheral interrupt requests.

- Lower PRI in INTC_CPR_PRCn to zero.
- Enable recognition of interrupts by the processor(s).

15.9.2 Interrupt exception handler

These example interrupt exception handlers excerpts use Power Architecture assembly code.

15.9.2.1 Software vector mode

code to clear flag bit which drives interrupt request to INTC

blr   # branch to epilog

```

15.9.3 ISR, RTOS, and task hierarchy

The RTOS and all of the tasks under its control typically execute with PRI in `INTC_CPRn` having a value of 0. The RTOS will execute the tasks according to whatever priority scheme it may have, but that priority scheme is independent and has a lower priority of execution than the priority scheme of the INTC. In other words, the ISRs execute above `INTC_CPRn` priority 0 and outside the control of the RTOS, the RTOS executes at `INTC_CPRn` priority 0, and while the tasks execute at different priorities under the control of the RTOS, they also execute at `INTC_CPRn` priority 0.

If a task shares a resource with an ISR and the Priority Ceiling Protocol (PCP) is being used to manage that shared resource, then the task's priority can be elevated in the `INTC_CPRn` while the shared resource is being accessed.

An ISR whose `PRIn` in `INTC_PSRn` has a value of 0 will not cause an interrupt request to the selected processor, even if its peripheral or software-settable interrupt request is asserted. For a peripheral interrupt request, not setting its enable bit or disabling the mask bit will cause it to remain negated, which consequently also will not cause an interrupt request to the processor. Since the ISRs are outside the control of the RTOS, this ISR will not run unless called by another ISR or the interrupt exception handler, perhaps after executing another ISR.

15.9.4 Order of execution

An ISR with a higher priority can preempt an ISR with a lower priority, regardless of the unique vectors associated with each of their peripheral or software-settable interrupt requests. However, if multiple peripheral or software-settable interrupt requests are asserted, more than one of these interrupt requests has the highest priority and that priority is high enough to cause preemption, the INTC selects the one with the lowest unique vector regardless of the order in time that they asserted. However, the ability to meet deadlines with this scheduling scheme is no less than if the ISRs execute in the time order that their peripheral or software-settable interrupt requests asserted.

The example in the following table shows the order of execution of both cases, ISRs with different priorities and ISRs with the same priority.

Table 15-534. Order of ISR execution example

Step #	Step Description	Code executing at end of step						PRI in INTC_CPR at end of step
		RTOS	ISR108 ₁	ISR208	ISR308	ISR408	interrupt exception handler	
1	RTOS at priority 0 is executing.	X						0
2	Peripheral interrupt request 100 at priority 1 asserts. Interrupt taken.		X					1
3	Peripheral interrupt request 400 at priority 4 asserts. Interrupt taken.					X		4
4	Peripheral interrupt request 300 at priority 3 asserts.					X		4
5	Peripheral interrupt request 200 at priority 3 asserts.					X		4
6	ISR408 completes. Interrupt exception handler writes to <code>INTC_EOIR_n</code> .						X	1

Table continues on the next page...

Table 15-534. Order of ISR execution example (continued)

Step #	Step Description	Code executing at end of step						PRI in INTC_CPR at end of step
		RTOS	ISR108 ¹	ISR208	ISR308	ISR408	interrupt exception handler	
7	Interrupt taken. ISR208 starts to execute, even though peripheral interrupt request 300 asserted first.			X				3
8	ISR208 completes. Interrupt exception handler writes to INTC_EOIR _n .						X	1
9	Interrupt taken. ISR308 starts to execute.				X			3
10	ISR308 completes. Interrupt exception handler writes to INTC_EOIR _n .						X	1
11	ISR108 completes. Interrupt exception handler writes to INTC_EOIR _n .						X	0
12	RTOS continues execution.	X						0

1. ISR108 executes for peripheral interrupt request 100 because the first eight ISRs are for software-settable interrupt requests.

15.9.5 Priority ceiling protocol

This section describes the priority ceiling protocol.

15.9.5.1 Elevating priority

The PRI field in INTC current priority register (INTC_CPR_n) is elevated in the OSEK PCP to the ceiling of all of the priorities of the ISRs that share a resource. This protocol therefore allows coherent accesses of the ISRs to that shared resource.

For example, ISR1 has a priority of 1, ISR2 has a priority of 2, and ISR3 has a priority of 3. They all share the same resource. Before ISR1 or ISR2 can access that resource, they must raise the PRI value in INTC_CPR_n to 3, the ceiling of all of the ISR priorities. After they release the resource, they must lower the PRI value in INTC_CPR_n to prevent further priority inversion. If they do not raise their priority, then ISR2 can preempt ISR1, and ISR3 can preempt ISR1 or ISR2, possibly corrupting the shared resource. Another possible failure mechanism is deadlock if the higher priority ISR needs the lower priority ISR to release the resource before it can continue, but the lower priority ISR cannot release the resource until the higher priority ISR completes and execution returns to the lower priority ISR.

Using the PCP instead of disabling processor recognition of all interrupts eliminates the time when accessing a shared resource that all higher priority interrupts are blocked. For example, while ISR3 cannot preempt ISR1 while it is accessing the shared resource, all of the ISRs with a priority higher than 3 can preempt ISR1.

15.9.5.2 Ensuring coherency

This section discusses how to ensure coherency.

15.9.5.2.1 Interrupt with blocked priority

A scenario can exist that can cause non-coherent accesses to the shared resource. As an example, ISR1 and ISR2 both share a resource. ISR1 has a lower priority than ISR2. ISR1 is executing, and it writes to the `INTC_CPRn`. The instruction following this store is a store to a value in a shared coherent data block. Either just before or at the same time as the first store, the INTC asserts the interrupt request to the processor because the peripheral interrupt request for ISR2 has asserted. As the processor is responding to the interrupt request from the INTC, and as it is aborting transactions and flushing its pipeline, it is possible (in some implementations) that both of these stores are executed. ISR2 thereby assumes that it can access the data block coherently, but the data block has been corrupted.

When the Current Priority Register's (INTC_CPR_PCR's) PRI field in the INTC is updated by software, external interrupts from the INTC to the core can be disabled so that an external interrupt will never be taken in the window of time when a system resource (PRI field) is being changed. Disabling interrupts and re-enabling them after the PRI elevation, as well as providing additional core clocks of delay after interrupts have been enabled, provides enough delay for the ISR that has elevated its PRI to be interrupted by a pending ISR before the ISR elevating PRI accesses a shared memory block.

To ensure coherent access to the shared data block, modifications to PRI in INTC_CPR_PRCx can be made by services managing shared resources with the following code sequence:

- disable processor recognition of interrupts
- PRI modification (guarded, cache inhibited)
- enable processor recognition of interrupts
- delay 5 core clocks
- coherent data access

The delay of 5 clocks minimum can be achieved by the following series of instructions:

```
or r1, r1, r1
```

```

or r1, r1, r1
or r1, r1, r1
or r1, r1, r1
or r1, r1, r1

```

The `or r1, r1, r1` is not dual issued because the destination of one “or” instruction is the source of the next, hence the instructions cannot be executed in parallel.

15.9.5.2.2 Raised priority preserved

The following figure shows the timing diagram for a scenario where a priority that is raised in one ISR is preserved after execution of a pre-empting ISR. The table following the figure explains the events. The example is for software vector mode. Except for the method of retrieving the vector and acknowledging the interrupt request to the processor, hardware vector mode is identical.

Figure 15-541. Timing diagram of raised priority preserved

Table 15-535. Raised priority preserved events

Event	Description
A	Peripheral interrupt request 200 asserts during execution of ISR108 running at priority 1.
B	Interrupt request to processor asserts. INTVEC in INTC_IACKRn updates with vector for that peripheral interrupt request.

Table continues on the next page...

Table 15-535. Raised priority preserved events (continued)

Event	Description
C	ISR108 writes to INTC_CPR _n to raise priority to 3 before accessing shared coherent data block.
D	PRI in INTC_CPR _n now at 3, reflecting the write. This write, just before accessing data block, is the last instruction the processor executes before being interrupted.
E	Interrupt exception handler prolog acknowledges interrupt by reading INTC_IACKR _n .
F	PRI of 3 pushed onto LIFO. PRI in INTC_CPR _n updates to 2, the priority of ISR208.
G	ISR208 clears its flag bit, deasserting its peripheral interrupt request.
H	Interrupt exception handler epilog writes to INTC_EOIR _n .
I	LIFO pops 3, restoring the raised priority onto PRI in INTC_CPR _n . Next value to pop from LIFO is the priority from before peripheral interrupt request 100 interrupted. ISR108 now can access data block coherently after interrupt exception handler executes rfi instruction.

15.9.6 Selecting priorities according to request rates and deadlines

The selection of the priorities for the ISRs can be made using Rate Monotonic Scheduling (RMS) or a superset of it, Deadline Monotonic Scheduling (DMS). In RMS, the ISRs which have higher request rates have higher priorities. In DMS, if the deadline is before the next time the ISR is requested, then the ISR is assigned a priority according to the time from the request for the ISR to the deadline, not from the time of the request for the ISR to the next request for it.

For example, ISR1 executes every 100 μ s, ISR2 executes every 200 μ s, and ISR3 executes every 300 μ s. ISR1 has a higher priority than ISR2 which has a higher priority than ISR3. However, if ISR3 has a deadline of 150 μ s, then it has a higher priority than ISR2.

The INTC supports 16 priorities, which may be many fewer than the number of ISRs. In this case, the ISRs should be grouped with other ISRs that have similar deadlines. For example, a priority could be allocated for every time the request rate doubles. ISRs with request rates around 1 ms would share a priority, ISRs with request rates around 500 μ s would share a priority, ISRs with request rates around 250 μ s would share a priority, and so on. With this approach, a range of ISR request rates of 2^{16} could be covered, regardless of the number of ISRs.

Reducing the number of priorities does cause some priority inversion, which reduces the processor's ability to meet its deadlines. However, reducing the number of priorities can reduce the size and latency through the interrupt controller. It also allows easier management of ISRs with similar deadlines that share a resource. They can be placed at the same priority without any further priority inversion, and they do not need to use the PCP to access the shared resource.

15.9.7 Software-settable interrupt requests

The software-settable interrupt requests can be used in two ways. They can be used to schedule a lower priority portion of an ISR and for processors to interrupt other processors in a multiple processor system.

15.9.7.1 Scheduling a lower priority portion of an ISR

A portion of an ISR needs to be executed at the PRI_n value in $INTC\_PSR_n$, which becomes the PRI value in $INTC\_CPR_n$ with the interrupt acknowledge. The ISR, however, can have a portion of it which does not need to be executed at this higher priority. Therefore, executing this later portion which does not need to be executed at this higher priority can prevent the execution of ISRs which do not have a higher priority than the earlier portion of the ISR but do have a higher priority than the later portion of the ISR needs. This preemptive scheduling inefficiency reduces the processor's ability to meet its deadlines.

One option is for the ISR to complete the earlier higher priority portion, but then schedule through the RTOS a task to execute the later lower priority portion. However, some RTOSs can require a large amount of time for an ISR to schedule a task. Therefore, a second option is for the ISR, after completing the higher priority portion, to set a SET_n bit in $INTC\_SSCIR_n$. Writing a '1' to SET_n causes a software-settable interrupt request. This software-settable interrupt request, which usually will have a lower PRI_n value in the $INTC\_PSR_n$, therefore will not cause preemptive scheduling inefficiencies.

After generating a software settable interrupt request, the higher priority ISR completes. The lower priority ISR is scheduled according to its priority. Execution of the higher priority ISR is not resumed after the completion of the lower priority ISR.

15.9.7.2 Scheduling an ISR on another processor

Since the SET_n bits in the $INTC\_SSCIR_n$ are memory mapped, processors in multiple processor systems can schedule ISRs on the other processors. One possible application is if one processor simply wants to command another processor to perform a piece of work, and the initiating processor does not need to use the results of that work. If the initiating processor needs to know if the processor executing the software-settable ISR has not completed the work before asking it to again execute that ISR, it can check if the corresponding CLR_n bit in $INTC\_SSCIR_n$ is asserted before again writing a 1 to the SET_n bit.

Another application is the sharing of a block of data. For example, a first processor has completed accessing a block of data and wants a second processor to then access it. Furthermore, after the second processor has completed accessing the block of data, the first processor again wants to access it. The accesses to the block of data must be done coherently. The procedure is that the first processor writes a 1 to a SET n bit on the second processor. The second processor, after accessing the block of data, clears the corresponding CLR n bit and then writes 1 to a SET n bit on the first processor, informing it that it now can access the block of data.

15.9.8 Lowering priority within an ISR

In implementations without the software-settable interrupt requests in INTC_SSCIR n , one way (besides scheduling a task through an RTOS) to prevent preemptive scheduling inefficiencies with an ISR whose work spans multiple priorities (as described in [Scheduling a lower priority portion of an ISR](#)) is to lower the current priority. However, the INTC has a LIFO whose depth is determined by the number of priorities.

Note

Lowering the PRI value in INTC_CPR n within an ISR to below the ISR's corresponding PRI value in INTC_PSR n allows more preemptions than the depth of the LIFO can support.

Therefore, through its use of the LIFO the INTC does not support lowering the current priority within an ISR as a way to avoid preemptive scheduling inefficiencies.

15.9.9 Negating an interrupt request outside of its ISR

This section discusses the negation of an interrupt service request outside of its ISR.

15.9.9.1 Negating an interrupt request as a side effect of an ISR

Some peripherals have flag bits which can be cleared as a side effect of servicing a peripheral interrupt request. For example, reading a specific register can clear the flag bits, and consequently their corresponding interrupt requests too. This clearing as a side effect of servicing a peripheral interrupt request can cause the negation of other peripheral interrupt requests besides the peripheral interrupt request whose ISR presently is executing. This negating of a peripheral interrupt request outside of its ISR can be a desired effect.

15.9.9.2 Negating multiple interrupt requests in one ISR

An ISR can clear other flag bits besides its own flag bit. One reason that an ISR clears multiple flag bits is because it serviced those other flag bits, and therefore the ISRs for these other flag bits do not need to be executed.

15.9.9.3 Proper setting of interrupt request priority

Whether an interrupt request negates outside of its own ISR due to the side effect of an ISR execution or the intentional clearing of a flag bit, the priorities of the peripheral or software-settable interrupt requests for these other flag bits must be selected properly. Their PRI_n values in $INTC\_PSR_n$ must be selected to be at or lower than the priority of the ISR that cleared their flag bits. Otherwise, those flag bits still can cause the interrupt request to the processor to assert. Furthermore, the clearing of these other flag bits also has the same timing relationship to the writing to $INTC\_SSCIR_n$ as the clearing of the flag bit that caused the present ISR to be executed. Refer to [End of interrupt exception handler](#) for more information.

A flag bit whose enable bit or mask bit is negating its peripheral interrupt request can be cleared at any time, regardless of the peripheral interrupt request's PRI_n value in $INTC\_PSR_n$.

15.9.10 Examining LIFO contents

Normally the user does not need to know the contents of the LIFO, or even how deep the LIFO is nested. Although the LIFO contents are not memory-mapped, the user can read the contents by popping the LIFO and reading the PRI field in the INTC current priority register ($INTC\_CPR_n$). Disabling processor recognition of interrupts while examining the LIFO contents provides a coherent view of the preempted priorities. The code sequence is:

```
pop_lifo:
    store to INTC_EOIR_PRCn
    load INTC_CPR_PRCn, examine PRI, and store onto stack
    if PRI is not zero or value when interrupts were enabled, branch to pop_lifo
```

When the examination is complete, the LIFO can be restored in software vector mode using this code sequence:

```
push_lifo:
    load stacked PRI value and store to INTC_CPR_PRCn
```

```
load INTC_IACKR_PRCn  
if stacked PRI values are not depleted, branch to push_lifo
```

Note

Reading the INTC_IACKR_PRC n acknowledges the interrupt request to the processor and updates the INTC_CPR_PRC n [PRI] with the priority of the preempting interrupt request. If the processor recognition of interrupts is disabled during the LIFO restoration, interrupt requests to the processor can go undetected. However, because the peripheral or software-settable interrupt requests are not cleared, the peripheral interrupt request to the processor re-asserts when INTC_CPR_PRC n [PRI] is lower than the priorities of those peripheral or software-settable interrupt requests.

15.10 Interrupt sources

See [Interrupt vector assignments](#) for the chip-specific list of interrupt sources.

Chapter 16

Direct Memory Access Controller (eDMA)

16.1 Chip-specific eDMA information

The chip has two instances of the eDMA module: eDMA_A and eDMA_B. Each instance supports 64 channels.

See [DMA request mapping](#) for the channel allocation of DMA requests for each module instance.

The eDMA has no direct external MCU signals. However, four external pins can be configured in the SIU to route external eDMA requests to four eDMA_A channels. See [DMA/Interrupt Request Select Register \(SIU_DIRSR\)](#) for details.

16.2 Introduction

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
 - Source address and destination address calculations
 - Data-movement operations
- Local memory containing transfer control descriptors for each of the 64 channels

16.2.1 eDMA system block diagram

[Figure 16-1](#) illustrates the components of the eDMA system, including the eDMA module ("engine").

Figure 16-1. eDMA system block diagram

16.2.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 16-1. eDMA engine submodules

Submodule	Function
Address path	This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI_n[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution. When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD_n{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD_n_CITER field, and a possible fetch of the next TCD_n from memory as part of a scatter/gather operation.
Data path	This block implements the bus master read/write datapath. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the 1st stage of the bus pipeline (address phase), while the data path module implements the 2nd stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

The transfer-control descriptor local memory is further partitioned into:

Table 16-2. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

16.2.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
 - Programmable source and destination addresses and transfer size
 - Support for enhanced addressing modes
- 64-channel implementation that performs complex data transfers with minimal intervention from a host processor
 - Internal data buffer, used as temporary storage to support 16- and 32-byte transfers
 - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
 - 32-byte TCD stored in local memory for each channel
 - An inner data transfer loop defined by a minor byte transfer count
 - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
 - Explicit software initiation
 - Initiation via a channel-to-channel linking mechanism for continuous transfers
 - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
 - One interrupt per channel, which can be asserted at completion of major iteration count
 - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing

- Support for complex data structures
- Error detection and error correction

In the discussion of this module, n is used to reference the channel number.

16.3 Modes of operation

The eDMA operates in the following modes:

Table 16-3. Modes of operation

Mode	Description
Normal	In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	DMA operation is configurable in Debug mode via the control register: • If CR[EDBG] is cleared, the DMA continues to operate. • If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.
Wait	Before entering Wait mode, the DMA attempts to complete its current transfer. After the transfer completes, the device enters Wait mode.

16.4 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions
- The second region corresponds to the local transfer control descriptor (TCD) memory

16.4.1 TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1, ... channel 63. Each TCD_n definition is presented as 11 registers of 16 or 32 bits.

Some registers are implemented as two 32-bit registers, and include an H and L suffix, signaling the high and low portions of the control function. This table provides a 32-bit view of the eDMA's memory map.

16.4.2 TCD initialization

The initialization of the TCD memory is performed by the eDMA controller after reset. The initialization runs for 256 eDMA clock cycles. All fields in the TCD memory are initialized to 0. All application read or write accesses to the TCD are delayed until the initialization is finished. Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

16.4.3 TCD structure

DMA Basics: TCD Structure

- One DMA engine has a number of channels to react to DMA requests
- Each channel has its own TCD

¹ The fields implemented in Word 2 depend on whether EDMA_CR[EMLM] bit is set to 0 or 1.

16.4.4 Reserved memory and bit fields

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

DMA memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
1668	TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (DMA_TCD51_NBYTES_MLOFFNO)	32	R/W	0000_0000h	16.4.31/ 714
1668	TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (DMA_TCD51_NBYTES_MLOFFYES)	32	R/W	0000_0000h	16.4.32/ 715
166C	TCD Last Source Address Adjustment (DMA_TCD51_SLAST)	32	R/W	0000_0000h	16.4.33/ 716
1670	TCD Destination Address (DMA_TCD51_DADDR)	32	R/W	0000_0000h	16.4.34/ 717
1674	TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD51_CITER_ELINKYES)	16	R/W	0000h	16.4.35/ 717
1674	DMA_TCD51_CITER_ELINKNO	16	R/W	0000h	16.4.36/ 718
1676	TCD Signed Destination Address Offset (DMA_TCD51_DOFF)	16	R/W	0000h	16.4.37/ 719
1678	TCD Last Destination Address Adjustment/Scatter Gather Address (DMA_TCD51_DLASTSGA)	32	R/W	0000_0000h	16.4.38/ 720
167C	TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD51_BITER_ELINKYES)	16	R/W	0000h	16.4.39/ 720
167C	TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCD51_BITER_ELINKNO)	16	R/W	0000h	16.4.40/ 721
167E	TCD Control and Status (DMA_TCD51_CSR)	16	R/W	0000h	16.4.41/ 722
1680	TCD Source Address (DMA_TCD52_SADDR)	32	R/W	0000_0000h	16.4.27/ 712
1684	TCD Transfer Attributes (DMA_TCD52_ATTR)	16	R/W	0000h	16.4.28/ 712
1686	TCD Signed Source Address Offset (DMA_TCD52_SOFF)	16	R/W	0000h	16.4.29/ 713
1688	TCD Minor Byte Count (Minor Loop Mapping Disabled) (DMA_TCD52_NBYTES_MLNO)	32	R/W	0000_0000h	16.4.30/ 713
1688	TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (DMA_TCD52_NBYTES_MLOFFNO)	32	R/W	0000_0000h	16.4.31/ 714
1688	TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (DMA_TCD52_NBYTES_MLOFFYES)	32	R/W	0000_0000h	16.4.32/ 715
168C	TCD Last Source Address Adjustment (DMA_TCD52_SLAST)	32	R/W	0000_0000h	16.4.33/ 716
1690	TCD Destination Address (DMA_TCD52_DADDR)	32	R/W	0000_0000h	16.4.34/ 717
1694	TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD52_CITER_ELINKYES)	16	R/W	0000h	16.4.35/ 717
1694	DMA_TCD52_CITER_ELINKNO	16	R/W	0000h	16.4.36/ 718

Table continues on the next page...

DMA memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
1696	TCD Signed Destination Address Offset (DMA_TCD52_DOFF)	16	R/W	0000h	16.4.37/ 719
1698	TCD Last Destination Address Adjustment/Scatter Gather Address (DMA_TCD52_DLASTSGA)	32	R/W	0000_0000h	16.4.38/ 720

16.4.5 Control Register (DMA_CR)

The CR defines the basic operating configuration of the DMA. The DMA arbitrates channel service requests in four groups of 16 channels each:

- Group 3 contains channels 63-48
- Group 2 contains channels 47-32
- Group 1 contains channels 31-16
- Group 0 contains channels 15-0

Arbitration within a group can be configured to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities; see the DCHPRI registers. For round-robin arbitration, the channel priorities are ignored and channels within each group are cycled through (from high to low channel number) without regard to priority.

NOTE

For correct operation, writes to the CR register must be performed only when the DMA channels are inactive; that is, when TCDn_CSR[ACTIVE] bits are cleared.

The group priorities operate in a similar fashion. In group fixed priority arbitration mode, channel service requests in the highest priority group are executed first, where priority level 3 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRPnPRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to any channel service requests occurring; otherwise, a configuration

error will be reported. For group round robin arbitration, the group priorities are ignored and the groups are cycled through (from high to low group number) without regard to priority.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. When minor loop offsets are enabled, the minor loop offset (MLOFF) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both prior to the addresses being written back into the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (EMLM is 1), TCDn word2 is redefined. A portion of TCDn word2 is used to specify multiple fields: a source enable bit (SMLOE) to specify the minor loop offset should be applied to the source address (TCDn_SADDR) upon minor loop completion, a destination enable bit (DMLOE) to specify the minor loop offset should be applied to the destination address (TCDn_DADDR) upon minor loop completion, and the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

When minor loop mapping is disabled (EMLM is 0), all 32 bits of TCDn word2 are assigned to the NBYTES field.

DMA_CR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 CX	Cancel Transfer 0 Normal operation 1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CX bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.
15 ECX	Error Cancel Transfer 0 Normal operation 1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating the Error Status register (DMAx_ES) and generating an optional error interrupt.
16–17 GRP3PRI	Channel Group 3 Priority Group 3 priority level when fixed priority group arbitration is enabled.
18–19 GRP2PRI	Channel Group 2 Priority Group 2 priority level when fixed priority group arbitration is enabled.
20–21 GRP1PRI	Channel Group 1 Priority Group 1 priority level when fixed priority group arbitration is enabled.
22–23 GRP0PRI	Channel Group 0 Priority Group 0 priority level when fixed priority group arbitration is enabled.
24 EMLM	Enable Minor Loop Mapping 0 Disabled. TCDn.word2 is defined as a 32-bit NBYTES field. 1 Enabled. TCDn.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.
25 CLM	Continuous Link Mode NOTE: Do not use continuous link mode with a channel linking to itself if there is only one minor loop iteration per service request, e.g., if the channel's NBYTES value is the same as either the source or destination size. The same data transfer profile can be achieved by simply increasing the NBYTES value, which provides more efficient, faster processing. 0 A minor loop channel link made to itself goes through channel arbitration before being activated again. 1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.
26 HALT	Halt DMA Operations

Table continues on the next page...

DMA_CR field descriptions (continued)

Field	Description
	0 Normal operation 1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.
27 HOE	Halt On Error 0 Normal operation 1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.
28 ERGA	Enable Round Robin Group Arbitration 0 Fixed priority arbitration is used for selection among the groups. 1 Round robin arbitration is used for selection among the groups.
29 ERCA	Enable Round Robin Channel Arbitration 0 Fixed priority arbitration is used for channel selection within each group. 1 Round robin arbitration is used for channel selection within each group.
30 EDBG	Enable Debug 0 When in debug mode, the DMA continues to operate. 1 When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system exits debug mode or the EDBG bit is cleared.
31 Reserved	This field is reserved. Reserved

16.4.6 Error Status Register (DMA_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
 - An illegal setting in the transfer-control descriptor, or
 - An illegal priority register setting in fixed-arbitration
- An error termination to a bus master read or write cycle
- The UCE bit shows an uncorrectable error occurred while the device has ECC protection on the TCD SRAM
- A cancel transfer with error bit that will be set when a transfer is canceled via the corresponding cancel transfer control bit

See [Fault reporting and handling](#) for more details.

DMA_ES field descriptions

Field	Description
0 VLD	Logical OR of all ERRH and ERRL status bits 0 No ERR bits are set. 1 At least one ERR bit is set indicating a valid error exists that has not been cleared.
1–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 UCE	Uncorrectable ECC error during channel execution. The UCE bit is set when an uncorrectable ECC error occurs on an access generated by the DMA only. If a CPU access to the TCD causes an uncorrectable ECC error, that access will receive a bus error response. NOTE: When the eDMA sees a RAM error on an IPS access (when the user is accessing a TCD), the error is reported as a bus abort. When the dma_engine (the execution engine is accessing a TCD) receives a RAM error, it is recorded in the Error Status register, DMA_ES[UCE], along with the channel number. 0 No uncorrectable ECC error 1 The last recorded error was an uncorrectable TCD RAM error
15 ECX	Transfer Canceled 0 No canceled transfers 1 The last recorded entry was a canceled transfer by the error cancel transfer input
16 GPE	Group Priority Error 0 No group priority error 1 The last recorded error was a configuration error among the group priorities. All group priorities are not unique.
17 CPE	Channel Priority Error 0 No channel priority error 1 The last recorded error was a configuration error in the channel priorities within a group. Channel priorities within a group are not unique.
18–23 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error, excluding GPE and CPE errors, or last recorded error canceled transfer.

Table continues on the next page...

DMA_ES field descriptions (continued)

Field	Description
24 SAE	Source Address Error 0 No source address configuration error. 1 The last recorded error was a configuration error detected in the TCDn_SADDR field. TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].
25 SOE	Source Offset Error 0 No source offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_SOFF field. TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE].
26 DAE	Destination Address Error 0 No destination address configuration error 1 The last recorded error was a configuration error detected in the TCDn_DADDR field. TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE].
27 DOE	Destination Offset Error 0 No destination offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_DOFF field. TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE].
28 NCE	NBYTES/CITER Configuration Error 0 No NBYTES/CITER configuration error 1 The last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields. • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE], or • TCDn_CITER[CITER] is equal to zero, or • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK]
29 SGE	Scatter/Gather Configuration Error 0 No scatter/gather configuration error 1 The last recorded error was a configuration error detected in the TCDn_DLASTSGA field. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. TCDn_DLASTSGA is not on a 32 byte boundary.
30 SBE	Source Bus Error 0 No source bus error 1 The last recorded error was a bus error on a source read
31 DBE	Destination Bus Error 0 No destination bus error 1 The last recorded error was a bus error on a destination write

16.4.7 Enable Request Register High (DMA_ERQH)

The ERQ{H,L} registers provide a bit map for the 64 channels to enable the request signal for each channel. ERQH supports channels 63-32, while ERQL covers channels 31-00. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ. The {S,C}ERQ registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQ{H,L}.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

16.4.8 Enable Request Register Low (DMA_ERQL)

The ERQ{H,L} registers provide a bit map for the 64 channels to enable the request signal for each channel. ERQH supports channels 63-32, while ERQL covers channels 31-00. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. These registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQ{H,L}.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

16.4.9 Enable Error Interrupt Register High (DMA_EEIH)

The EEI{H,L} registers provide a bit map for the 64 channels to enable the error interrupt signal for each channel. EEIH supports channels 63-32, while EEIL covers channels 31-00. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. The {S,C}EEI are provided so the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI{H,L} registers.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

16.4.11 Set Enable Request Register (DMA_SERQ)

The SERQ provides a simple memory-mapped mechanism to set a given bit in the ERQ {H,L} to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ {H,L} to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQ {H,L} to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	SAER	SERQ					
Reset	0	0	0	0	0	0	0	0

DMA_SERQ field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 SAER	Set All Enable Requests 0 Set only the ERQ {H,L} bit specified in the SERQ field 1 Set all bits in ERQ {H,L}
2-7 SERQ	Set Enable Request Sets the corresponding bit in ERQ{H,L}.

16.4.12 Clear Enable Request Register (DMA_CERQ)

The CERQ provides a simple memory-mapped mechanism to clear a given bit in the ERQ {H,L} to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ {H,L} to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ {H,L} to be cleared, disabling all DMA request inputs. If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 19h offset = 19h

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	CAER	CERQ					
Reset	0	0	0	0	0	0	0	0

DMA_CERQ field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAER	Clear All Enable Requests 0 Clear only the ERQ {H,L} bit specified in the CERQ field 1 Clear all bits in ERQ {H,L}
2–7 CERQ	Clear Enable Request Clears the corresponding bit in ERQ{H,L}.

16.4.13 Set Enable Error Interrupt Register (DMA_SEEI)

The SEEI provides a simple memory-mapped mechanism to set a given bit in the EEI {H,L} to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI {H,L} to be set. Setting the SAEE bit provides a global set function, forcing the entire EEI {H,L} contents to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Ah offset = 1Ah

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	SAEE	SEEI					
Reset	0	0	0	0	0	0	0	0

DMA_SEEI field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 SAEE	Sets All Enable Error Interrupts 0 Set only the EEI {H,L} bit specified in the SEEI field. 1 Sets all bits in EEI {H,L}
2-7 SEEI	Set Enable Error Interrupt Sets the corresponding bit in EEI {H,L}

16.4.14 Clear Enable Error Interrupt Register (DMA_CEEI)

The CEEI provides a simple memory-mapped mechanism to clear a given bit in the EEI {H,L} to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI {H,L} to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI {H,L} contents to be cleared, disabling all DMA request inputs. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Bh offset = 1Bh

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	CAEE	CEEI					
Reset	0	0	0	0	0	0	0	0

DMA_CEEI field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAEE	Clear All Enable Error Interrupts 0 Clear only the EEI {H,L} bit specified in the CEEI field 1 Clear all bits in EEI {H,L}
2–7 CEEI	Clear Enable Error Interrupt Clears the corresponding bit in EEI{H,L}

16.4.15 Clear Interrupt Request Register (DMA_CINT)

The CINT provides a simple, memory-mapped mechanism to clear a given bit in the INT {H,L} to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT {H,L} to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INT {H,L} to be cleared, disabling all DMA interrupt requests. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	CAIR	CINT					
Reset	0	0	0	0	0	0	0	0

DMA_CINT field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAIR	Clear All Interrupt Requests 0 Clear only the INT {H,L} bit specified in the CINT field 1 Clear all bits in INT {H,L}
2-7 CINT	Clear Interrupt Request Clears the corresponding bit in INT {H,L}

16.4.16 Clear Error Register (DMA_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR {H,L} to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR {H,L} to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR {H,L} contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Dh offset = 1Dh

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	CAEI	CERR					
Reset	0	0	0	0	0	0	0	0

DMA_CERR field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAEI	Clear All Error Indicators 0 Clear only the ERR {H,L} bit specified in the CERR field 1 Clear all bits in ERR {H,L}
2–7 CERR	Clear Error Indicator Clears the corresponding bit in ERR {H,L}

16.4.17 Set START Bit Register (DMA_SSRT)

The SSRT provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Eh offset = 1Eh

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	SAST	SSRT					
Reset	0	0	0	0	0	0	0	0

DMA_SSRT field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 SAST	Set All START Bits (activates all channels) 0 Set only the TCDn_CSR[START] bit specified in the SSRT field 1 Set all bits in TCDn_CSR[START]
2–7 SSRT	Set START Bit Sets the corresponding bit in TCDn_CSR[START]

16.4.18 Clear DONE Status Bit Register (DMA_CDNE)

The CDNE provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Fh offset = 1Fh

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	CADN	CDNE					
Reset	0	0	0	0	0	0	0	0

DMA_CDNE field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CADN	Clears All DONE Bits 0 Clears only the TCDn_CSR[DONE] bit specified in the CDNE field 1 Clears all bits in TCDn_CSR[DONE]
2–7 CDNE	Clear DONE Bit Clears the corresponding bit in TCDn_CSR[DONE]

16.4.19 Interrupt Request Register High (DMA_INTH)

The INT{H,L} provide a bit map for the 64 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptions, the eDMA engine generates an interrupt on a data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt-service routine associated with any given channel, the software must clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

Memory map/register definition

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT{H,L} register.

Address: 0h base + 20h offset = 20h

16.4.21 Error Register High (DMA_ERRH)

The ERR{H,L} provide a bit map for the 64 channels, signaling the presence of an error for each channel. ERRH supports channels 63-32, while ERRL covers channels 31-00. The eDMA engine signals the occurrence of a error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of EEI, then logically summed across groups of 16, 32 and 64 channels to form several group error interrupt requests. These are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, the software must clear the appropriate bit, negating the error-interrupt request. Typically, a write to CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected.

The contents of this register can also be polled, because a non-zero value indicates the presence of a channel error regardless of the state of EEI. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to CERR. On writes to ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no affect on the corresponding channel's current error status. CERR is provided so the error indicator for a single channel can easily be cleared.

16.4.23 Hardware Request Status Register High (DMA_HRSH)

The HRS{H,L} provide a bit map for the DMA channels, signaling the presence of a hardware request for each channel. HRSH supports channels 63-32, while HRSL covers channels 31-0. The hardware request status bits reflect the current state of the register and DMA request signals, qualified via the ERQ{H,L} fields, as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

NOTE

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ {H,L} bits.

The HRS bit for its respective channel remains asserted for the period when a Hardware Request is Present on the Channel. After the Request is completed and Channel is free, the HRS bit is automatically cleared by hardware.

Address: 0h base + 30h offset = 30h

16.4.25 Global PCU Output Register (DMA_GPOR_n)

The DMAGPORH and DMAGPORL registers provides coherency information to the Peripheral Coherency Unit (PCU). The DMAGPORH and DMAGPORL registers use a bit map for the implemented channels {16,32,64} to enable a global write signal to the PCU on a per channel basis. When the bit in the corresponding channel is set, the eDMA will signal the PCU whenever that channel is performing a write. The DMAGPORH and DMAGPORL registers perform no functions within the eDMA.

NOTE

See the PCU chapter for coherency information and global write usage.

Address: 0h base + 38h offset + (4d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DMA_GPOR_n field descriptions

Field	Description
0–31 GPOR	Global channel write control Setting a bit specifies the corresponding channel's writes are global.

16.4.26 Channel n Priority Register (DMA_DCHPRIn)

When fixed-priority channel arbitration is enabled ($CR[ERCA] = 0$), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15. When read, the GRPPRI bits of the DCHPRIn register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRIn registers. The group priority is assigned in the DMA control register.

Address: $0h \text{ base} + 100h \text{ offset} + (1d \times i)$, where $i=0d$ to $63d$

Bit	0	1	2	3	4	5	6	7
Read	ECP	DPA	GRPPRI		CHPRI			
Write								
Reset	0	0	*	*	*	*	*	*

* Notes:

- CHPRI field: See bit field description.
- GRPPRI field: See bit field description.

DMA_DCHPRIn field descriptions

Field	Description
0 ECP	Enable Channel Preemption. This field resets to 0. 0 Channel n cannot be suspended by a higher priority channel's service request. 1 Channel n can be temporarily suspended by the service request of a higher priority channel.
1 DPA	Disable Preempt Ability. This field resets to 0. 0 Channel n can suspend a lower priority channel. 1 Channel n cannot suspend any channel, regardless of channel priority.
2–3 GRPPRI	Channel n Current Group Priority Group priority assigned to this channel group when fixed-priority arbitration is enabled. This field is read-only; writes are ignored. NOTE: Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, $DCHPRI31[GRPPRI] = 0b01$ and $DCHPRI31[CHPRI]$ equals $0b1111$.
4–7 CHPRI	Channel n Arbitration Priority Channel priority when fixed-priority arbitration is enabled

Table continues on the next page...

DMA_DCHPRIn field descriptions (continued)

Field	Description
	NOTE: Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] = 0b01111.

DMA_TCDn_ATTR field descriptions

Field	Description
0–4 SMOD	Source Address Modulo 0 Source address modulo feature is disabled ≠0 This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.
5–7 SSIZE	Source data transfer size NOTE: Using a Reserved value causes a configuration error.

Table continues on the next page...

DMA_TCDn_SOFF field descriptions

Field	Description
0–15 SOFF	Source address signed offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

16.4.30 TCD Minor Byte Count (Minor Loop Mapping Disabled) (DMA_TCDn_NBYTES_MLNO)

This register, or one of the next two registers (TCD_NBYTES_MLOFFNO, TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is disabled (CR[EMLM] = 0)

If minor loop mapping is enabled, see the TCD_NBYTES_MLOFFNO and TCD_NBYTES_MLOFFYES register descriptions for the definition of TCD word 2.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 63d

DMA_TCDn_NBYTES_MLNO field descriptions

Field	Description
0–31 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. NOTE: An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.

16.4.31 TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (DMA_TCDn_NBYTES_MLOFFNO)

One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

If minor loop mapping is enabled and SMLOE or DMLOE is set, then refer to the TCD_NBYTES_MLOFFYES register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 63d

**DMA_TCDn_NBYTES_MLOFFNO field descriptions**

Field	Description
0 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR 1 The minor loop offset is applied to the SADDR
1 DMLOE	Destination Minor Loop Offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR 1 The minor loop offset is applied to the DADDR
2–31 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

16.4.32 TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (DMA_TCDn_NBYTES_MLOFFYES)

One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFNO), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

If minor loop mapping is enabled and SMLOE and DMLOE are cleared, then refer to the TCD_NBYTES_MLOFFNO register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

Memory map/register definition

Address: 0h base + 1008h offset + (32d × i), where i=0d to 63d

DMA_TCDn_SLAST field descriptions

Field	Description
0–31 SLAST	Last Source Address Adjustment Adjustment value added to the source address at the completion of the major iteration count. This value can be applied to restore the source address to the initial value, or adjust the address to reference the next data structure. This register uses two's complement notation; the overflow bit is discarded.

16.4.34 TCD Destination Address (DMA_TCDn_DADDR)

Address: 0h base + 1010h offset + (32d × i), where i=0d to 63d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DMA_TCDn_CITER_ELINKYES field descriptions

Field	Description
0 ELINK	Enable channel-to-channel linking on minor-loop complete

Table continues on the next page...

DMA_TCDn_CITER_ELINKYES field descriptions (continued)

Field	Description
	As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. NOTE: This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
1–6 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by this field by setting that channel's TCDn_CSR[START] bit.
7–15 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. NOTE: When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. NOTE: If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

16.4.36 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCDn_CITER_ELINKNO)

If TCDn_CITER[ELINK] is cleared, the TCDn_CITER register is defined as follows.

Address: 0h base + 1014h offset + (32d × i), where i=0d to 63d

DMA_TCDn_DLASTSGA field descriptions

Field	Description
0–31 DLASTSGA	Destination last address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: - Adjustment value added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. - This field uses two's complement notation for the final destination address adjustment. Otherwise: - This address points to the beginning of a 0-modulo-32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, otherwise a configuration error is reported.

16.4.39 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCDn_BITER_ELINKYES)

If the TCDn_BITER[ELINK] bit is set, the TCDn_BITER register is defined as follows.

Address: 0h base + 101Ch offset + (32d × i), where i=0d to 63d

DMA_TCDn_CSR field descriptions

Field	Description
0–1 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch.

Table continues on the next page...

DMA_TCDn_CSR field descriptions (continued)

Field	Description
	NOTE: If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00 No eDMA engine stalls. 01 Enable eDMA master high-priority elevation (HPE) mode. No eDMA engine stalls. 10 eDMA engine stalls for 4 cycles after each R/W. 11 eDMA engine stalls for 8 cycles after each R/W.
2–7 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: - No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: - After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit.
8 DONE	Channel Done This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero. The software clears it, or the hardware when the channel is activated. NOTE: This bit must be cleared to write the MAJORELINK or ESG bits.
9 ACTIVE	Channel Active This flag signals the channel is currently in execution. It is set when channel service begins, and is cleared by the eDMA as the minor loop completes or when any error condition is detected.
10 MAJORELINK	Enable channel-to-channel linking on major loop complete As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. NOTE: To support the dynamic linking coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.
11 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory. NOTE: To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0 The current channel's TCD is normal format. 1 The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.
12 DREQ	Disable Request If this flag is set, the eDMA hardware automatically clears the corresponding ERQ {H,L} bit when the current major iteration count reaches zero.

Table continues on the next page...

DMA_TCDn_CSR field descriptions (continued)

Field	Description
	0 The channel's ERQ {H,L} bit is not affected. 1 The channel's ERQ {H,L} bit is cleared when the major loop is complete.
13 INTHALF	Enable an interrupt when major counter is half complete. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT {H,L} register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes or other types of data movement where the processor needs an early indication of the transfer's progress. NOTE: If BITER = 1, do not use INTHALF. Use INTMAJOR instead. 0 The half-point interrupt is disabled. 1 The half-point interrupt is enabled.
14 INTMAJOR	Enable an interrupt when major iteration count completes. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero. 0 The end-of-major loop interrupt is disabled. 1 The end-of-major loop interrupt is enabled.
15 START	Channel Start If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution. 0 The channel is not explicitly started. 1 The channel is explicitly started via a software initiated service request.

16.5 Functional description

The operation of the eDMA is described in the following subsections.

16.5.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

Figure 16-1065. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel n . Channel activation via software and the $\text{TCD}_n\text{-CSR}[\text{START}]$ bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, the channel arbitration performs, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD_n . Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

The following diagram illustrates the second part of the basic data flow:

Figure 16-1066. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) sequence through the required source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

Figure 16-1067. eDMA operation, part 3

16.5.2 Fault reporting and handling

Channel errors are reported in the Error Status register (DMAx_ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed-Arbitration mode
- An uncorrectable ECC error, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.

- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal within a group, or any group priority levels being equal among the groups. All channel priority levels within a group must be unique and all group priority levels among the groups must be unique when fixed arbitration mode is enabled.

NOTE

When two channels have the same priority, a channel priority error exists and will be reported in the Error Status register. However, the channel number will not be reported in the Error Status register. When all of the channel priorities within a group are not unique, the channel number selected by arbitration is undetermined.

To aid in Channel Priority Error (CPE) debug, set the Halt On Error bit in the DMA's Control Register. If all of the channel priorities within a group are not unique, the DMA will be halted after the CPE error is recorded. The DMA will remain halted and will not process any channel service requests. Once all of the channel priorities are set to unique numbers, the DMA may be enabled again by clearing the Halt bit.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[E_LINK] bit does not equal the TCDn_BITER[E_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

If an uncorrectable ECC error occurs during a peripheral bus access, the access is terminated with a bus error. The occurrence of an uncorrectable ECC error during an eDMA engine read causes the eDMA engine to stop the active channel immediately. The ECC error and channel number are recorded in the eDMA's Error Status register.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (DMAx_ES) is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

NOTE

The cancel transfer request allows the user to stop a large data transfer in the event the full data transfer is no longer needed. The cancel transfer bit does not abort the channel. It simply stops the transferring of data and then retires the channel through its normal shutdown sequence. The application software must handle the context of the cancel. If an interrupt is desired (or not), then the interrupt should be enabled (or disabled) before the cancel request. The application software must clean up the transfer control descriptor since the full transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (DMAx_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

16.5.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRIn[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This allows for a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel.

16.5.4 Performance

This section addresses the performance of the eDMA module, focusing on two separate metrics:

- In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces.
- In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more relevant metric. In this environment, the speed of the source and destination address spaces remains important. However, the microarchitecture of the eDMA also factors significantly into the resulting metric.

16.5.4.1 Peak transfer rates

The peak transfer rates for several different source and destination transfers are shown in the following tables. These tables assume:

- Internal SRAM can be accessed with zero wait-states when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states, when viewed from the system bus data phase
- All internal peripheral bus accesses are 32-bits in size

NOTE

All architectures will not meet the assumptions listed above.
See the SRAM configuration section for more information.

This table compares peak transfer rates based on different possible system speeds. Specific chips/devices may not support all system speeds listed.

Table 16-1068. eDMA peak transfer rates (Mbytes/sec)

System Speed, Width	Internal SRAM-to-Internal SRAM	32 bit internal peripheral bus-to-Internal SRAM	Internal SRAM-to-32 bit internal peripheral bus
66.7 MHz, 64 bit	266.7	66.6	53.3
83.3 MHz, 64 bit	333.3	83.3	66.7
100.0 MHz, 64 bit	400.0	100.0	80.0
133.3 MHz, 64 bit	533.3	133.3	106.7
150.0 MHz, 64 bit	600.0	150.0	120.0

Internal-SRAM-to-internal-SRAM transfers occur at the core's datapath width. For all transfers involving the internal peripheral bus, 32-bit transfer sizes are used. In all cases, the transfer rate includes the time to read the source plus the time to write the destination.

16.5.4.2 Peak request rates

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, assume that the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel.

The eDMA design supports the following hardware service request sequence. Note that the exact timing from Cycle 7 is a function of the response times for the channel's read and write accesses. In the case of an internal peripheral bus read and internal SRAM write, the combined data phase time is 4 cycles. For an SRAM read and internal peripheral bus write, it is 5 cycles.

Table 16-1069. Hardware service request process

Cycle		Description
With internal peripheral bus read and internal SRAM write	With SRAM read and internal peripheral bus write	
1		eDMA peripheral request is asserted.
2		The eDMA peripheral request is registered locally in the eDMA module and qualified. TCD _n _CSR[START] bit initiated requests start at this point with the registering of the user write to TCD _n word 7.
3		Channel arbitration begins.
4		Channel arbitration completes. The transfer control descriptor local memory read is initiated.
5–6		The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles
7		The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here.
8–11	8–12	The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.
12	13	This cycle represents the data phase of the last destination write.
13	14	The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD _n fields into the local memory. The TCD _n word 7 is read and checked for channel linking or scatter/gather requests.

Table continues on the next page...

Table 16-1069. Hardware service request process (continued)

Cycle		Description
With internal peripheral bus read and internal SRAM write	With SRAM read and internal peripheral bus write	
14	15	The appropriate fields in the first part of the TCD _n are written back into the local memory.
15	16	The fields in the second part of the TCD _n are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.
16	17	The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.

Assuming zero wait states on the system bus, DMA requests can be processed every 9 cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (4 cycles) and SRAM-to-internal peripheral bus (5 cycles), DMA requests can be processed every 11.5 cycles ($4 + (4+5)/2 + 3$). This is the time from Cycle 4 to Cycle $x + 5$. The resulting peak request rate, as a function of the system frequency, is shown in the following table.

Table 16-1070. eDMA peak request rate (MReq/sec)

System frequency (MHz)	Request rate with zero wait states	Request rate with wait states
66.6	7.4	5.8
83.3	9.2	7.2
100.0	11.1	8.7
133.3	14.8	11.6
150.0	16.6	13.0

A general formula to compute the peak request rate with overlapping requests is:

$$\text{PEAKreq} = \text{freq} / [\text{entry} + (1 + \text{read\_ws}) + (1 + \text{write\_ws}) + \text{exit}]$$

where:

Table 16-1071. Peak request formula operands

Operand	Description
PEAKreq	Peak request rate
freq	System frequency
entry	Channel startup (4 cycles)
read_ws	Wait states seen during the system bus read data phase
write_ws	Wait states seen during the system bus write data phase

Table continues on the next page...

Table 16-1071. Peak request formula operands (continued)

Operand	Description
exit	Channel shutdown (3 cycles)

16.5.4.3 eDMA performance example

Consider a system with the following characteristics:

- Internal SRAM can be accessed with one wait-state when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states viewed from the system bus data phase
- System operates at 150 MHz

For an SRAM to internal peripheral bus transfer,

$$\text{PEAKreq} = 150 \text{ MHz} / [4 + (1 + 1) + (1 + 3) + 3] \text{ cycles} = 11.5 \text{ Mreq/sec}$$

For an internal peripheral bus to SRAM transfer,

$$\text{PEAKreq} = 150 \text{ MHz} / [4 + (1 + 2) + (1 + 1) + 3] \text{ cycles} = 12.5 \text{ Mreq/sec}$$

Assuming an even distribution of the two transfer types, the average peak request rate would be:

$$\text{PEAKreq} = (11.5 \text{ Mreq/sec} + 12.5 \text{ Mreq/sec}) / 2 = 12.0 \text{ Mreq/sec}$$

The minimum number of cycles to perform a single read/write, zero wait states on the system bus, from a cold start where no channel is executing and eDMA is idle are:

- 11 cycles for a software, that is, a TCD_n_CSR[START] bit, request
- 12 cycles for a hardware, that is, an eDMA peripheral request signal, request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering is absorbed in or overlaps the previous executing channel.

Note

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This

allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

16.6 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

16.6.1 eDMA initialization

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.
2. Write the channel priority levels to the DCHPRI n registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI registers if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQH and ERQL registers.
6. Request channel service via either:
 - Software: setting the TCD n _CSR[START]
 - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in the following table, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, as defined by TCD n _SADDR, to the destination, as defined by TCD n _DADDR, continue until the number of bytes specified by TCD n _NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCD n _SADDR, TCD n _DADDR, and TCD n _CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 16-1072. TCD Control and Status fields

TCDn_CSR field name	Description
START	Control bit to start channel explicitly when using a software initiated DMA service (Automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)
D_REQ	Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service
BWC	Control bits for throttling bandwidth control of a channel
E_SG	Control bit to enable scatter-gather feature
INT_HALF	Control bit to enable interrupt when major loop is half complete
INT_MAJ	Control bit to enable interrupt when major loop completes

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

**Figure 16-1068. Example of multiple loop iterations**

The following figure lists the memory array terms and how the TCD settings interrelate.

Figure 16-1069. Memory array terms

16.6.2 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per channel basis with the exception of two errors: Group Priority Error (ES[GPE]) and channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the Error Status register (DMAx_ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed group and fixed channel arbitration modes.
2. Group 1 is the highest priority and all channels are unique in that group.
3. Group 0 is the next highest priority and has two channels with the same priority level.
4. If Group 1 has any service requests, those requests will be executed.
5. After all of Group 1 requests have completed, Group 0 will be the next active group.

6. If Group 0 has a service request, then an undefined channel in Group 0 will be selected and a channel priority error will occur.
7. This repeats until the all of Group 0 requests have been removed or a higher priority Group 1 request comes in.

In this sequence, for item 2, the eDMA acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest channel/group priority with an active request is selected, but the lowest numbered channel/group with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

16.6.3 Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

16.6.3.1 Fixed group arbitration, Fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so that the channels within one group use "fixed" priorities, and that group is assigned the highest "fixed" priority of all groups, that group can take all the bandwidth of the eDMA controller. That is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

16.6.3.2 Round-robin group arbitration, fixed channel arbitration

At the occurrence of one or more DMA requests from one or more groups, the channel with the highest priority from a specific group will be serviced first. Groups are serviced starting with the highest group number with an service request and rotating through to the lowest group number containing a service request.

Once the channel request is serviced, the group round robin algorithm will select the highest pending request from the next group in the round robin sequence. Servicing continues round robin, always servicing the highest priority channel in the next group in the sequence, or just skipping a group if it has no pending requests.

If a channel requests service at a rate that equals or exceeds the round robin service rate, then that channel will always be serviced before lower priority channels in the same group, and thus the lower priority channels will never be serviced. The advantage of this scenario is that no one group will consume all the eDMA bandwidth. The highest priority channel selection latency is potentially greater than fixed/fixed arbitration. Excessive request rates on high priority channels could prevent the servicing of lower priority channels in the same group.

16.6.3.3 Round-robin group arbitration, round-robin channel arbitration

Groups will be serviced as described in [Round-robin group arbitration, fixed channel arbitration](#), but this time channels will be serviced in channel number order. Only one channel is serviced from each requesting group for each round robin pass through the groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to channel priority levels.

Because channels are serviced in round robin manner, any channel that generates DMA requests faster than a combination of the group round robin service rate and the channel service rate for its group will not prevent the servicing of other channels in its group. Any DMA requests that are not serviced are simply lost, but at least one channel will be serviced.

This scenario ensures that all channels will be guaranteed service at some point, regardless of the request rates. However, the potential latency could be quite high. All channels are treated equally. Priority levels are not used in round robin/round robin mode.

16.6.3.4 Fixed group arbitration, Round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in [Fixed group arbitration](#), [Fixed channel arbitration](#), but all the channels in the highest priority group will be serviced. Service latency will be short on the highest priority group, but could potentially be very much longer as the group priority decreases.

16.6.4 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

16.6.4.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one ($\text{TCDn\_CITER} = \text{TCDn\_BITER} = 1$). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the $\text{TCDn\_CSR}[\text{DONE}]$ bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA = -16
TCDn_CSR[INT_MAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the $\text{TCDn\_CSR}[\text{START}]$ bit requests channel service.

2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: $\text{TCDn\_CSR}[\text{DONE}] = 0$, $\text{TCDn\_CSR}[\text{START}] = 0$, $\text{TCDn\_CSR}[\text{ACTIVE}] = 1$.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
 - a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
 - b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
 - c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
 - d. Write 32-bits to location 0x2004 → second iteration of the minor loop.
 - e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
 - f. Write 32-bits to location 0x2008 → third iteration of the minor loop.
 - g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
 - h. Write 32-bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: $\text{TCDn\_SADDR} = 0x1000$, $\text{TCDn\_DADDR} = 0x2000$, $\text{TCDn\_CITER} = 1$ (TCDn_BITER).
7. The eDMA engine writes: $\text{TCDn\_CSR}[\text{ACTIVE}] = 0$, $\text{TCDn\_CSR}[\text{DONE}] = 1$, $\text{INT}[n] = 1$.
8. The channel retires and the eDMA goes idle or services the next channel.

16.6.4.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2  
TCDn_SLAST = -32  
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware, that is, eDMA peripheral, request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: $\text{TCDn\_CSR}[\text{DONE}] = 0$, $\text{TCDn\_CSR}[\text{START}] = 0$, $\text{TCDn\_CSR}[\text{ACTIVE}] = 1$.
4. eDMA engine reads: channel TCDn data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
 - a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
 - b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
 - c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
 - d. Write 32-bits to location 0x2004 → second iteration of the minor loop.
 - e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
 - f. Write 32-bits to location 0x2008 → third iteration of the minor loop.
 - g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
 - h. Write 32-bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes: $\text{TCDn\_SADDR} = 0x1010$, $\text{TCDn\_DADDR} = 0x2010$, $\text{TCDn\_CITER} = 1$.
7. eDMA engine writes: $\text{TCDn\_CSR}[\text{ACTIVE}] = 0$.
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware, that is, eDMA peripheral, requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: $\text{TCDn\_CSR}[\text{DONE}] = 0$, $\text{TCDn\_CSR}[\text{START}] = 0$, $\text{TCDn\_CSR}[\text{ACTIVE}] = 1$.

12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:
 - a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
 - b. Write 32-bits to location 0x2010 → first iteration of the minor loop.
 - c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
 - d. Write 32-bits to location 0x2014 → second iteration of the minor loop.
 - e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
 - f. Write 32-bits to location 0x2018 → third iteration of the minor loop.
 - g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
 - h. Write 32-bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: $TCDn\_SADDR = 0x1000$, $TCDn\_DADDR = 0x2000$, $TCDn\_CITER = 2$ ($TCDn\_BITER$).
15. eDMA engine writes: $TCDn\_CSR[ACTIVE] = 0$, $TCDn\_CSR[DONE] = 1$, $INT[n] = 1$.
16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

16.6.4.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567x) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes and the MOD field is set to 4, allowing for a 2⁴ byte (16-byte) size queue.

Table 16-1073. Modulo example

Transfer Number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

16.6.5 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

16.6.5.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD_n_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD_n_CSR[START] bit and the TCD_n_CSR[ACTIVE] bit. The minor-loop-complete condition is indicated by both bits reading zero after the TCD_n_CSR[START] was set. Polling the TCD_n_CSR[ACTIVE] bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

Stage	TCD _n _CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using hardware, that is, peripheral, initiated service requests is to read the `TCDn_CITER` field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

Stage	TCDn_CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the `TCDn_CSR[DONE]` bit.

The `TCDn_CSR[START]` bit is cleared automatically when the channel begins execution regardless of how the channel activates.

16.6.5.2 Reading the transfer descriptors of active channels

The eDMA reads back the true `TCDn_SADDR`, `TCDn_DADDR`, and `TCDn_NBYTES` values if read while a channel executes. The true values of the `SADDR`, `DADDR`, and `NBYTES` are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses, `SADDR` and `DADDR`, and `NBYTES`, which decrement to zero as the transfer progresses, can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

16.6.5.3 Checking channel preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal, that is, constantly rotating, when Round-Robin Arbitration mode is selected.

The TCD n _CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two TCD n _CSR[ACTIVE] bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

16.6.6 Channel Linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD n _CSR[START] bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD n _CITER[E_LINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] bit
2. Minor loop done → set TCD12_CSR[START] bit
3. Minor loop done → set TCD12_CSR[START] bit
4. Minor loop done, major loop done → set TCD7_CSR[START] bit

When minor loop linking is enabled (TCD n _CITER[E_LINK] = 1), the TCD n _CITER[CITER] field uses a nine bit vector to form the current iteration count. When minor loop linking is disabled (TCD n _CITER[E_LINK] = 0), the TCD n _CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD n _CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

Note

The TCD_n_CITER[E_LINK] bit and the TCD_n_BITER[E_LINK] bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, i.e, use another channel's TCD, at the end of a loop.

Table 16-1074. Channel Linking Parameters

Desired Link Behavior	TCD Control Field Name	Description
Link at end of Minor Loop	CITER[E_LINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of Major Loop	CSR[MAJOR_E_LINK]	Enable channel-to-channel linking on major loop completion
	CSR[MAJOR_LINKCH]	Link channel number when linking at end of major loop

16.6.7 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

16.6.7.1 Dynamically changing the channel priority

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode,
2. Disable all the channels within a group, change the channel priorities within that group only, then enable the appropriate channels.

The following two options are available for dynamically changing group priority levels:

1. Switch to Round-Robin Group Arbitration mode, change the group priorities, then switch back to Fixed Arbitration mode,
2. Disable all channels, change the group priorities, then enable the appropriate channels.

16.6.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e_link bit during channel execution (see the diagram in [TCD structure](#)). This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write 1 to the TCD.major.e_link bit.
2. Read back the TCD.major.e_link bit.
3. Test the TCD.major.e_link request status:
 - If TCD.major.e_link = 1, the dynamic link attempt was successful.
 - If TCD.major.e_link = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

NOTE

The user must clear the TCD.done bit before writing the TCD.major.e_link bit. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

16.6.7.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in eDMA programmer's model, thus replacing the current descriptor.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e_sg bit at the same time the eDMA engine is retiring the channel. The TCD.e_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e_link and TCD.e_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

NOTE

The user must clear the TCD.done bit before writing the TCD.major.e_link or TCD.e_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

16.6.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCD.major.e_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD identification (ID).

1. When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2. Write 1b to the TCD.d_req bit.

Should a dynamic scatter/gather attempt fail, setting the TCD.d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.

3. Write the TCD.dlast_sga field with the scatter/gather address.
4. Write 1b to the TCD.e_sg bit.
5. Read back the 16 bit TCD control/status field.

6. Test the TCD.e_sg request status and TCD.major.linkch value:

If e_sg = 1b, the dynamic link attempt was successful.

If e_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If e_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

16.6.7.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCD.dlast_sga field as a TCD identification (ID).

1. Write 1b to the TCD.d_req bit.

Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.

2. Write the TCD.dlast_sga field with the scatter/gather address.

3. Write 1b to the TCD.e_sg bit.

4. Read back the TCD.e_sg bit.

5. Test the TCD.e_sg request status:

If e_sg = 1b, the dynamic link attempt was successful.

If e_sg = 0b, read the 32 bit TCD dlast_sga field.

If e_sg = 0b and the dlast_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If e_sg = 0b and the dlast_sga changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

Chapter 17

Error Injection Module (EIM)

17.1 Chip-specific EIM information

This chip has one instance of the EIM.

17.1.1 EIM channels

The EIM on this chip supports 6 channels. The number of each channel corresponds to:

- A field in the EIM's EICHEN register
- An EICHD n _Word0 register
- An EICHD n _Word1 register
- An EICHD n _Word2 register

17.1.2 EIM channel assignments

Each EIM channel corresponds to a specific RAM array target. The EIM channel can inject errors on accesses to that specific RAM array. The following table shows the channel assignments.

Table 17-1. RAM array targets of EIM channels

EIM channel	RAM array target
0	PRAMC_0
1	PRAMC_1
2	FEC MIB
3	FEC RIF

17.2 Introduction

The Error Injection module is mainly used for diagnostic purposes. It provides a method for diagnostic coverage of the peripheral memories. See the chip-specific EIM information to determine which peripheral memories are supported by this method.

17.2.1 Overview

The Error Injection Module (EIM) provides support for inducing single-bit and multi-bit inversions on read data when accessing peripheral RAMs. Injecting faults on memory accesses can be used to exercise the SEC-DED ECC function of the related system.

NOTE

The following diagram shows an example EIM implementation with a 64-bit read data bus and an 8-bit checkbit bus.

Figure 17-1. EIM functional block diagram (64-bit read data bus and 8-bit checkbit bus)

17.2.2 Features

The EIM includes these features:

- Supports 6 error injection channels
- Protection against accidental enable and reconfiguration error injection function via two-stage enable mechanism

17.3 Memory map and register definition

The EIM provides an IPS programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an IPS error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation will result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and checkbit bus from target RAM are inverted on a read access.
- Consists of a 128-bit (16-byte) structure, composed of four 32-bit words, in the EIM programming model.

- Each descriptor consists of Error Injection Channel Descriptor Word0-1 (EICHD n _WORD0-1) and, depending on the implementation, Word2 (EICHD n _WORD2).
- When Word2 is unused, the corresponding word in the 16-byte structure is unused.
- The fourth word in the 16-byte structure is always unused.

The multiple channel descriptors are organized sequentially.

EIM_EICHD_n_WORD0 field descriptions

Field	Description
0–7 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. The width of the field for the channel is defined in the chip-specific EIM information. 0 The corresponding bit of the checkbit bus remains unmodified. 1 The corresponding bit of the checkbit bus is inverted.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

17.3.4 Error Injection Channel Descriptor, Word1
(EIM_EICHDn_WORD1)

The second word of the Error Injection Channel Descriptor defines the bits in the mask corresponding to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. Successful writes to this field clear the corresponding error injection channel valid field, EICHEN[EICHnEN].

Address: 0h base + 104h offset + (256d × i), where i=0d to 5d

EIM_EICHDn_WORD1 field descriptions

Field	Description
0–31 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. For details about which bits in this field are implemented for the applicable channel and how the bits map to bytes 0-3 of the read data bus, see the chip-specific EIM information. 0 The corresponding bit of bytes 0-3 on the read data bus remains unmodified 1 The corresponding bit of bytes 0-3 on the read data bus is inverted.

17.3.5 Error Injection Channel Descriptor, Word2
(EIM_EICHDn_WORD2)

The third word of the Error Injection Channel Descriptor, when present, defines the bits in the mask corresponding to bytes 4–7 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. Successful writes to this field clear the corresponding error injection channel valid field, EICHEN[EICHnEN].

Address: 0h base + 108h offset + (256d × i), where i=0d to 5d

EIM_EICHD n _WORD2 field descriptions

Field	Description
0–31 B4_7DATA_ MASK	Data Mask Bytes 4-7 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. For details about which bits in this field are implemented for the applicable channel and how the bits map to bytes 4-7 of the read data bus, see the chip-specific EIM information. 0 The corresponding bit of bytes 4-7 on the read data bus remains unmodified. 1 The corresponding bit of bytes 4-7 on the read data bus is inverted.

17.4 Functional description

The EIM provides protection against accidental enabling and reconfiguration of the error injection function by enforcing a two-stage enablement mechanism. To properly enable the error injection mechanism for a channel:

- Write 1 to the EICHEN[EICH n EN] field, where n denotes the channel number.
- Write 1 to EIMCR[GEIEN].

NOTE

When the use case for a channel requires writing any EICHD n _WORD register, write the EICHD n _WORD register before executing the two-stage enablement mechanism. A successful write to any EICHD n _WORD register clears the corresponding EICHEN[EICH n EN] field.

The EIM supports 6 error injection channels. Each channel:

- is assigned to a single memory array interface.
- intercepts the assigned memory read data bus and checkbit bus and injects errors by inverting the value transmitted for selected bits on each bus line.

On a memory read access, the applicable EICHD n _WORD registers define which bits of the read data and/or checkbit bus to invert.

Figure 17-1 depicts the interception and override of a 64-bit read data bus and an 8-bit checkbit data bus for an example memory array.

Chapter 18

Error Reporting Module (ERM)

18.1 Chip-specific ERM information

This chip has one instance of the ERM.

18.1.1 ERM memory channels

The ERM on this chip supports 20 memory channels. The number of each memory channel corresponds to:

- A field in the ERM's CR0, CR1, or CR2 register
- A field in the ERM's SR0, SR1, or SR2 register
- An ERM_EAR_n register
- An ERM_SYN_n register

18.1.2 Sources of memory error events

Each ERM channel corresponds to a source of potential memory error events. The following table shows the channel assignments.

Table 18-1. Memory error event sources for ERM channels

ERM channel	Memory event source
0	PRAMC_0
1	PRAMC_1
2	eDMA_A TCD ¹
3	eDMA_B TCD ¹
4	FEC MIB ¹

Table continues on the next page...

Table 18-1. Memory error event sources for ERM channels (continued)

ERM channel	Memory event source
5	FEC RIF ¹
6	PFLASH port 0
7	PFLASH port 1
8	AIPS_0
9	AIPS_1
10	FEC e2eECC
11	CSE
12	SIPI
13	Core0 instruction
14	Core0 data
15	Core1 instruction
16	Core1 data
17	eDMA_A e2eECC
18	eDMA_B e2eECC
19	EBI e2eECC

1. For these memory elements, the error address captured is the relative array address and not the system address.

18.1.3 Managing single-bit faults of TCD RAM for eDMA_A

When a single-bit ECC event occurs during a read of the TCD RAM for eDMA_A, the fault is correctly identified and forwarded to the ERM. However, the fault is not corrected before being used by eDMA_A.

To prevent eDMA_A's use of single-bit faults from the TCD RAM for eDMA_A: Ensure that ERM_CR0[ESCIE2] is set to 1 to enable the ERM to trigger an interrupt, and use the interrupt to manage properly any single-bit fault that occurs.

18.2 Introduction

18.2.1 Overview

The Error Reporting Module (ERM) provides information and optional interrupt notification on memory error events associated with ECC (Error Correction Code). The ERM collects ECC events on memory accesses for platform local memory arrays, such as

flash memory, system RAM, or peripheral RAMs. See the chip-specific ERM information for details about supported memory sources and specific memory channel assignments.

18.2.2 Features

The ERM includes these features:

- Capture address and syndrome information on single-bit correction and non-correctable ECC events
- Optional interrupt notification on captured ECC events
- Support for ECC event capturing for memory sources, with individual reporting fields and interrupt configuration per memory channel.

18.3 Memory map and register definition

The ERM provides an IPS programming model mapped to an on-platform peripheral slot. The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses or in user mode generates an IPS error termination. The ERM allows access to the programming model by all system bus masters.

The programming model can only be accessed in supervisor mode.

Attempted updates to the programming model while the ERM module is in the middle of an operation will result in non-deterministic behavior.

ERM_EAR n field descriptions

Field	Description
0–31 EAR	Memory n Error Address - This field contains the faulting system address of the last recorded ECC event on Memory n . NOTE: Refer to the chip-specific ERM information for details on Memory n mapping.

18.3.8 ERM Memory n Syndrome Register (ERM_SYN n)

The ERM_SYN n is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory n , where n denotes the memory channel. Any attempted write to ERM_SYN n is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Address: 0h base + 104h offset + (16d × i), where i=0d to 19d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ERM_SYN n field descriptions

Field	Description
0–7 SYNDROME	Memory n Syndrome - This field contains the ECC syndrome associated with the last recorded ECC event on Memory n . NOTE: Refer to the chip-specific ERM information for details on Memory n mapping.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

18.4 Functional description

18.4.1 Single-bit correction events

When a single-bit correction event on Memory n is detected, the ERM:

- Records the event by changing to 1 the value of the applicable Status Register bit: ERM_SR x [SBC n]
- Records the corresponding access address that initiated the event in the Memory n Error Address Register: ERM_EAR n
- Stores the corresponding ECC syndrome in the Memory n Error Syndrome Register: ERM_SYN n . This register identifies the bit position of the corrected data on single-bit data inversion.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to ERM_SRx[SBCn] to change its value to 0.

18.4.1.1 Optional interrupt notification for single-bit correction events

The ERM provides an option to generate an interrupt notification upon the report of a single-bit correction event. This sequence describes how to use the option:

1. To enable interrupt notifications for single-bit correction events on Memory *n*, set ERM_CRx[ESCIEn] to 1.
2. Subsequently, when a single-bit correction event on Memory *n* is detected, the ERM:
 - Records the event and address and stores the ECC syndrome as usual
 - Additionally sends an interrupt notification corresponding to the event
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to ERM_SRx[SBCn] to change its value to 0.

18.4.2 Non-correctable error events

When a non-correctable ECC error event on Memory *n* is detected, the ERM:

- Records the event by changing to 1 the value of the applicable Status Register bit: ERM_SRx[NCEn]
- Records the corresponding access address that initiated the event in the Memory *n* Error Address Register: ERM_EARn
- Stores the corresponding ECC syndrome in the Memory *n* Error Syndrome Register: ERM_SYNn
 - In the event of a non-correctable address bit inversion, ERM_SYNn identifies the pertinent address bit position.
 - In the event of a non-correctable, multi-bit data inversion, the syndrome value does not provide any additional diagnostic information.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to ERM_SRx[NCEn] to change its value to 0.

18.4.2.1 Optional interrupt notification for non-correctable error events

The ERM provides an option to generate an interrupt notification upon the report of a non-correctable ECC event. This sequence describes how to use the option:

1. To enable interrupt notifications for non-correctable error events on Memory n , set `ERM_CRx[ENCIE $n$ ]` to 1.
2. Subsequently, when a non-correctable error event on Memory n is detected, the ERM:
 - Records the event and address and stores the ECC syndrome as usual
 - Additionally sends an interrupt notification corresponding to the event
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to `ERM_SRx[NCE $n$ ]` to change its value to 0.

18.5 Initialization

For each ERM channel, prepare the corresponding memory array before enabling ERM interrupts about errors for that memory.

1. Initialize the memory to a known value so that the correct corresponding ECC codeword is stored.
2. During the memory's initialization, if the ERM captures information about any ECC error event, clear the corresponding `ERM_SRx[SBC $n$ ]` or `ERM_SRx[NCE $n$ ]` field that stores the record of the event.
3. Program the applicable `ERM_CRx[ESCI $n$ ]` and `ERM_CRx[ENCIE $n$ ]` fields to enable ERM interrupts as desired.

Chapter 19

Clocking

19.1 Introduction

This chapter describes the architecture for the system level clocks and includes the following information:

- System clock specifics
- Clock architecture
- Clock sources
- Clock monitoring
- Programmable clock dividers
- Clock control registers

The clock architecture of this device contains two clock domains coming from separate PLLs. The first one is the system clock for the cores, cross-bar switch, peripheral bridges, memories, debug logic and memory mapped portion of peripherals. The second one feeds the state machines and protocol engines of communication and timer peripheral modules. These two clock domains can be configured to be completely asynchronous between each other. The PLL generating the system clock (PLL1) can be configured to be frequency modulated to reduce electromagnetic emissions. The PLL generating the peripheral clock (PLL0) cannot be modulated. It is intended to provide an accurate reference clock for peripheral timer and communication functions that cannot tolerate frequency modulation.

The reference clock for PLL0 (non-FM) may come from the following possible sources:

- Crystal oscillator (XOSC)
- External clock (when XOSC is bypassed)
- Internal 16 MHz RC oscillator (IRC)

The reference clock for PLL1 (FM-modulated) may come from the following possible sources:

- Crystal oscillator (XOSC)
- External clock (when XOSC is bypassed)
- Output of PLL0

Out of reset, both clock domains (system and peripheral) are sourced directly from the IRC. After reset, software can select the PLLs or other clock sources (XOSC, external) to connect to system and peripheral clocks. A Progressive Clock Frequency Switch (PCFS) module is available after the system clock selector to allow gradual frequency changes that minimize transient currents. Clock Monitor Units (CMUs) are connected to outputs of clock dividers to verify that their clock frequencies stay within necessary operating limits. When an issue with a clock is found, the CMU sends a failure signal directly to the FCCU.

19.2 Clock generation

The top-level clock generation architecture can be seen in the figure below. All clock selectors and dividers are located and programmed in memory mapped registers of the SIU.

Notes: 1. The clock divider range in the PLL outputs (phi) is non-contiguous in by-2 steps: [2, 4, ..., 124, 126].

2. Divider values and mux selectors are located in SIU registers:
SIU_SYSDIV, SIU_SDCLKCFG, SIU_LFCLKCFG, SIU_PSCLKCFG

Figure 19-1. Clock generation diagram

19.3 SIU registers

The following table shows the relationship between the clocks of the clock generation diagram and the SIU registers.

Table 19-1. Relationship between clocks and SIU registers

Clock	Clock destination	Clock selector	Clock divider	CMU
PLL0	PLL0 input	SIU_SYSDIV.PLL0SEL	Internal to PLL0	
PLL1	PLL1 input	SIU_SYSDIV.PLL1SEL	Internal to PLL1	
core_clk	Core0, Core1, Checker Core	SIU_SYSDIV.SYSCLKSEL	SIU_SYSDIV.SYSCLKDIV	CMU_1 ¹
plat_clk	Platform modules: Cross-Bar, Peripheral Bridges, Memories, DMA, Flash Controller, Debug		Fixed at divided-by-2	CMU_2 ¹
fm_per_clk	Memory mapped registers of peripherals		SIUSYSDIV.FMPERDIV	CMU_3
per_clk	Protocol and communication engines of peripherals	SIU_SYSDIV.PERCLKSEL	SIU_SYSDIV.PERDIV	CMU_5
etpu_clk	eTPU A/B/C		SIU_SYSDIV.ETPUDIV	CMU_4
sd_clk	Sigma-Delta ADC		SIU_SDCLKCFG.SDDIV	CMU_6
psi5_rx_clk	PSI5 Rx clock input		SIU_PSCLKCFG.PSDIV	CMU_7
psi5_1us_clk	PSI5 1 MHz clock input		SIU_PSCLKCFG.PSDIV1M	CMU_8
LFAST PLL	LFAST PLL input	SIU_LFCLKCFG.LFCLKSEL	SIU_LFCLKCFG.LFDIV	
MCAN	MCAN Protocol Engine Clock	SIU_SYSDIV.MCANSEL	Internal to MCAN	
clkout	EBI CLKOUT pin		SIU_ECCR.EBDF	
eng_clk	Engineering clock pin	SIU_ECCR.ECSS	SIU_ECCR.ENGDIV	

1. CMU_1 and CMU_2 are physically connected to clock tree spots inside the checker core lake.

19.4 Operating frequencies

The device supports the maximum operating frequencies given in the following table.

Table 19-2. Maximum system and peripheral clock frequencies

Clock domain	Mode	Core (CORE_CLK)	eTPU (eTPU_CLK)	Platform (PLAT_CLK)	Peripherals memory mapped registers (FM_PER_CLK)	Peripherals protocol engines (PER_CLK)
Backwards compatible: one clock domain ¹	Double	264	132	132	132	132
	eTPU	200	200	100	100	100
Enhanced: dual clock domain ²	Normal	264	200	132	132	100

1. Clock selectors configured such that all clocks come from a single source, either PLL0 or PLL1.

2. Clock selectors configured such that both PLLs drive the clocks into two asynchronous domains.

NOTE

The essentially asynchronous clock domains of EVTO (eTPU_CLK) and NPC (CORE_CLK) require CORE_CLK to be set to a higher frequency than eTPU_CLK for guaranteed

EVTO capture by NPC. Because CORE_CLK can be set to FM (2% intentional jitter), the frequency of CORE_CLK minus 2% must be greater than the frequency of eTPU_CLK.

19.5 Default clock configuration

At power up, the IRC is the default clock for the entire system, with clock selectors configured such that all clocks come from a single clock domain. The default configuration after reset for all clock sources, selectors, and dividers is shown in the tables below.

Table 19-3. Reset configuration of clock sources

Source	Default after reset
IRC	Always enabled; it is the default clock source.
XOSC/External clock	Crystal oscillator and external bypass default state depends on DCF record or configuration pins (see SIU_RSR subsection of the SIU chapter).
PLL0	Disabled and powered down
PLL1	Disabled and powered down

Table 19-4. Reset configuration of clock selectors

Selector	Default after reset
SIU_SYSDIV.PLL0SEL	Selects XOSC
SIU_SYSDIV.PLL1SEL	Selects XOSC
SIU_SYSDIV.SYSCLKSEL	Selects the IRC
SIU_SYSDIV.PERCLKSEL	Selects core_clk
SIU_LFCLKCFG.LFCLKSEL	Selects the XOSC
SIU_SYSDIV.MCANSEL	Selects the XOSC
SIU_ECCR.ECSS	Selects plat_clk

Table 19-5. Reset configuration of clock dividers

Divider	Default after reset
SIU_SYSDIV.SYSCLKDIV	Divide-by-1
SIUSYSDIV.FMPERDIV	Divide-by-2
SIU_SYSDIV.PERDIV	Divide-by-2
SIU_SYSDIV.ETPUDIV	Divide-by-2
SIU_SDCLKCFG.SDDIV	Divide-by-1
SIU_PSCLKCFG.PSDIV	Divide-by-1

Table continues on the next page...

Table 19-5. Reset configuration of clock dividers (continued)

Divider	Default after reset
SIU_PSCLKCFG.PSDIV1M	Divide-by-1
SIU_LFCLKCFG.LFDIV	Divide-by-1
SIU_ECCR.EBDF	Divide-by-2
SIU_ECCR.ENGDIV	Divide-by-32

19.6 Clock sources

This chip has these clock sources:

- 16 MHz Internal RC oscillator (IRC)
- External oscillator (XOSC)
- PLL0 (non-FM PLL)
- PLL1 (FMPLL)

19.6.1 16 MHz RC oscillator (IRC)

This device has a 16 MHz internal RC oscillator that is always enabled and cannot be powered down. The IRC can be used as the source of system clock, peripheral clock and PLL clock references. The IRC is the default system and peripheral clock after reset.

The IRC has no dedicated software accessible register interface.

19.6.2 External oscillator (XOSC)

The external oscillator (XOSC) provides a clock source for the on-chip PLLs and some peripherals that require accurate clock reference (FlexCAN, MCAN, PIT, LFAST PLL, CMU_0). If required, it can also be used directly as a clock source to the main system and peripheral clocks. The XOSC does not have any software accessible register interface. Configuration is done using DCF records read from UTEST flash memory, which are read by the SSCM during reset and driven to the oscillator. Changing the XOSC configuration requires a reset cycle to take effect.

NOTE

The DCF configuration bits for the XOSC have triple-voting flip-flop (TVF) implementation to prevent undetectable errors in the system. See the Device Configuration Format chapter for more information on DCF programming.

19.6.2.1 XOSC configuration

The XOSC has the following configurable features:

- Crystal oscillator can be bypassed to source a clock directly from the EXTAL pin (bypass mode)
- Internal load capacitors can be selected for 20/40 MHz crystal oscillators
- Automatic Loop Control (ALC) can be applied to avoid the need of external series resistor
- Oscillator gain can be selected to match the crystal frequency range

Bypass configuration is controlled by bit 24 of the Miscellaneous DCF record. The selection of internal or external load capacitors on the XTAL/EXTAL pins is determined by bit 25 of the Miscellaneous DCF record. Load capacitor values are determined by the crystal manufacturer data sheet requirements, while accounting for stray PCB and on-chip capacitance. See the device data sheet for on-chip capacitance values.

When using internal load capacitors for the oscillator, the internal capacitance value is configured in the range of 1–16 pF, in approximate steps of 1 pF, by bits 26–30 of the Miscellaneous DCF record. The default value for the trimming bits (0b00000) selects the minimum internal capacitance value (about 1.8 pF).

The XOSC has the ability to be started with a crystal of 8 MHz, 20 MHz, or 40 MHz. Bits 18 and 21 of the Miscellaneous DCF record select which crystal source to use.

Automatic Loop Control (ALC) can be enabled by bit 17 of the Miscellaneous DCF record.

19.6.2.2 XOSC startup

During reset, the SSCM reads the XOSC_CNT field from the Miscellaneous DCF record and pre-loads this value to an internal counter clocked by XOSC. Upon reset exit, the counter counts 512 times XOSC_CNT. When counting finishes, it means that the XOSC clock is considered to be stable, and a flag called XOSC is set in the SIU_RSR register. This is a “set-once” bit, which software can check before attempting to use the external oscillator clock source soon after a reset cycle. This flag also enables CMU0 to start

monitoring the XOSC clock. From this moment on, if the XTAL clock fails, the SIU_RSR[XOSC] flag will not be negated to indicate the fail condition, but CMU0 will set a flag and also send an event signal to the FCCU.

19.6.3 PLL

This chip has a dual PLL subsystem that provides separate system and peripheral clocks.

The PLLs are disabled after reset. Enable them by software before selecting them as clock sources.

The following image is a block diagram of the dual PLL subsystem.

Figure 19-2. Dual PLL digital interface block diagram

19.6.3.1 PLL0 (non-FM)

PLL0 is the primary PLL. It provides a non-Frequency Modulated clock to the peripherals and the reference clock to PLL1.

19.6.3.1.1 PLL0 input clocks

The possible input clock sources for PLL0 are the XOSC and IRC. Select the clock reference using multiplexers controlled by the SIU_SYSDIV register.

19.6.3.1.2 PLL0 output clocks

The output clocks from PLL0 are PHI and PHI1.

- The PHI output clock drives various peripheral clocks and the system clock when PLL1 is not locked or active.
- The PHI1 output provides one of the input references for PLL1.

To generate the reference clock to PLL1, PLL0 has a dedicated output clock divider that is separate from the divider that generates the clock to peripherals.

19.6.3.2 PLL1 (FM)

PLL1 is a Frequency Modulated PLL (FMPLL) that is used to drive the system clock.

19.6.3.2.1 PLL1 input clocks

The possible input clock sources for PLL1 are PLL0 and the XOSC. Select the clock reference using multiplexers controlled by the SIU_SYSDIV register.

19.6.3.2.2 PLL1 output clocks

The output clock from PLL1 drives the system clock. The PHI output clock contains a fractional divider that can be applied to the loop divide of the PLL to achieve good granularity in the PLL1 PHI output clock frequency.

19.6.3.3 PLL register interface

This chip has a single digital interface for both PLLs. The digital interface provides register control of all available features of PLL0 and PLL1.

Before changing any of the dividers or FM configuration, you must force the PLLs into a disabled state by writing 00b to the CLKCFG field of the PLL0CR and PLL1CR registers. This method is the only way to power down the PLLs.

19.6.3.4 PLLDIG initialization information

Immediately after reset, PLL0 and PLL1 are disabled. The recommended procedure to program the PLLs and enter normal mode is:

1. Configure PLL0 and related modules.
 - a. With PLL0 disabled, program the desired PLL0 clock source in SIU_SYSDIV[PLL0SEL]. The default source is XOSC. Write 1 to SIU_SYSDIV[PLL0SEL] to select IRC as the source.
 - b. Program PLL0DV[PREDIV], PLL0DV[RFDPHI1], PLL0DV[MFD], and PLL0DV[RFDPHI].

- c. If necessary, modify the CMU frequency meter values (CMU_MDR and CMU_FDR) used to monitor the XOSC frequency. The XOSC frequency is compared to the IRCOSC source.
2. Ensure SIU_RSR[XOSC] is 1 to confirm that XOSC is stable.
3. Turn on PLL0.
 - a. Enable PLL0 by setting PLL0CR[CLKCFG] to 11b.
 - b. Poll PLL0SR[LOCK] until its value is 1.
4. Configure PLL1 and related modules.
 - a. With PLL1 disabled, program the PLL1 clock source in SIU_SYSDIV[PLL1SEL]. The default source is XOSC. Write 1 to SIU_SYSDIV[PLL1SEL] to select the PHI1 output of PLL0 as the source.
 - b. Program PLL1DV[MFD] and PLL1DV[RFDPHI].
 - c. If required:
 - Program the PLL1FM register with the desired frequency modulation parameters, and
 - Enable FM modulation by setting PLL1FM[MODEN] to 1.

The PLL1FM register must not be written after PLL1 is enabled and operating in normal mode.
5. Turn on PLL1.
 - a. Enable PLL1 by setting PLL1CR[CLKCFG] to 11b.
 - b. Poll PLL1SR[LOCK] until its value is 1.
6. Source the system clock and peripheral clock from the PLLs by programming SIU_SYSDIV[SYSCLKSEL] and SIU_SYSDIV[PERCLKSEL], respectively.

19.7 Clock gating

The SIU_HLT1 and SIU_HLT2 registers provide software-controlled clock gating. These registers dispatch request signals to various modules to halt their clock inputs. Modules respond differently to the halt request. The CPU allows its clock inputs to be halted only after the execution of the WAIT instruction. Most other modules wait for internal activities to finish before allowing their clock inputs to be halted by asserting a halt

acknowledge signal. A few modules do not implement the stop acknowledge protocol within them and allow their clocks to be halted immediately after the halt request is asserted.

Some peripherals have an internal memory mapped register that can be used to disable the module and to halt the clock input to the module. In most cases the peripheral registers of disabled modules are still readable and writable. However, the halt mechanism of the SIU_HALT registers disables the read/write functions of the peripheral registers for additional power saving.

When the clocks of all CPUs have been halted and all XBAR masters are idle, then the clocks of the following modules are also halted automatically: XBAR, Peripheral Bridges, system RAM, DMA, STM and Semaphores. The INTC and SWT_A/SWT_B clocks are never stopped.

19.8 Core and on-platform clocking

The clocks to the cores and on-platform modules come from the FM PLL. The core clock (CORE_CLK) is double the frequency of the platform clock (PLAT_CLK), but they are synchronous to each other (same clock domain). The frequency ratio between CORE_CLK and PLAT_CLK is fixed at 2:1.

The following modules belong to the core clock domain:

- Core0
- Core1
- Checker core
- Cache memories
- Nexus Port Controller (NPC)

The following modules belong to the platform clock domain:

- System RAM and RAM Controller
- Flash memory and Flash Memory Controller
- Crossbar Switch
- DMA

- SIPI
- EBI

The frequency modulated peripheral clock (FM_PER_CLK) mediates the communication between the Peripheral Bridges and memory-mapped registers within peripheral modules. This clock is part of the same FM clock domain as the core and platform clocks.

19.9 Peripheral clocks

Some modules have two clock domains implemented within them. One domain is for the state machines (protocol and/or timing engines) that require accurate non-FM clock sources, and the other domain is for the memory mapped registers that must be accessed by the Peripheral Bridges at the FM clock domain. These modules with separate clock domains can be connected directly to the two FM and non-FM clock sources.

Some other modules, like the eTPU, have a single clock domain with a single clock input. The following figure depicts all of these cases.

Figure 19-3. Clock distribution

19.9.1 eTPU clocking

The eTPUs have a separate clock domain specific to them (ETPU_CLK), coming from the non-FM PLL. The eTPU clock is synchronous to the other non-FM peripheral clock domain (PER_CLK), but is asynchronous to the FM-domain clocks (CORE_CLK, PLAT_CLK, FM_PER_CLK). The reason for a separate clock domain to the eTPUs is to allow them to run at higher speeds than other peripherals, thus optimizing performance and power.

The eTPU module itself has just one clock input that is used by all internal circuits, including timing engines and memory mapped registers. Because this single clock input is connected to the non-FM clock domain, a synchronization gasket mediates communications between the eTPUs and the peripheral bridges, which run at the FM-modulated clock domain. The operation of this gasket is transparent to software.

19.9.2 FlexCAN and MCAN clocking

The clock source for the CAN protocol engines can optionally come from the peripheral clock or from the XOSC. For the FlexCAN module, selection of the engine clock source is based on a register field internal to the FlexCAN module. Each FlexCAN instance can select a different source.

For the MCAN modules, selection of the engine clock source is based on the SIU_SYSDIV[MCANSEL] field. In this case, all MCAN instances receive the same clock.

19.9.3 LFAST clocking

This chip includes an LFAST module to support interprocessor communications in conjunction with the SIPI module. A PLL dedicated to the LFAST receives a 10 MHz to 20 MHz reference clock and generates the high-speed clock required to support LFAST serial communication. For low speed LFAST operation, the reference clock is used directly by the LFAST module.

The LFAST PLL reference clock source may come from the PLL peripheral clock domain, from the XOSC, or from an external LFAST device via the SIPI_REFCLK package pin. When this reference clock is generated internally, it can be output on the SIPI_REFCLK pin.

NOTE

For the SIPI_REFCLK pin, which SIU_PCR210 configures:

- If SIU_PCR210's IBE and OBE fields are both set to 1, OBE takes precedence and is output on the pin; the external input path of the pin to SIPI does not work.
- The external clock comes in only when IBE is set to 1 and OBE is cleared to 0.

19.9.4 PSI5 clocking

PSI5 requires two clocks, which have their own dividers coming from the peripheral clock domain.

19.9.5 Ethernet clocking

Only an external clock for RMII mode is supported. This chip does not generate an FEC clock internally. The external clock comes from a package pin and goes through the RMII gasket.

NOTE

While the FEC is operating, do not change clock configurations (muxes or dividers). Otherwise, FEC transactions in the crossbar might be corrupted.

19.9.6 SDADC clocking

The SDADC does not support the use of an external modulator. As a result, the only clock available is the internal clock (`sd_clk`), which is derived from the peripheral (non-FM) clock domain through a clock divider. The division factor for this divider is specified by the `SIU_SDCLKCFG[SDDIV]` field.

19.10 Serial boot clocking

Because the IRC is not accurate enough for the serial protocols, prior to entering serial boot mode the BAM switches the clock source to the external oscillator, using either the crystal or external reference—whichever one is effective at startup. No direct signal is available to an external host to indicate that serial boot has been initiated by the BAM.

19.11 MCKO

MCKO is an output clock from the Nexus Port Controller (NPC) to the development tools used for the timing of MSEO and MDO pin functions. MCKO is derived from the core clock (core_clk), and its frequency is determined by the value of the MCKO_DIV field in the port configuration register (PCR) located in the NPC.

19.12 CLKOUT / ENGCLK

CLKOUT is a device clock output derived from the platform clock and intended for, but not restricted to, use with the External Bus Interface (EBI). ENGCLK is a 50% duty cycle output clock derived from the platform clock or the crystal oscillator. Both clocks belong to the FM-PLL clock domain, but ENGCLK is not synchronous to CLKOUT (not edge aligned).

The external clock pins CLKOUT and ENGCLK are enabled during and immediately after reset. CLKOUT defaults to the platform clock frequency divided by two, and ENGCLK defaults to the platform clock frequency divided by 32.

19.13 Clock monitoring

For all safety-relevant clocks, this chip uses [Clock Monitor Unit \(CMU\)](#) modules to detect a missing clock or incorrect frequency. The IRC and XOSC are used as the clock monitor references.

The chip has nine instances of the CMU module. Each CMU module is programmed independently.

19.13.1 CMU-monitored clocks

The following table shows the clock or clocks monitored by each CMU module instance.

Table 19-6. CMU-monitored clocks

Monitor	Monitored clock(s)
CMU_0	PLL0, XOSC, IRC
CMU_1	Core0, Core1, Checker Core, RCCU
CMU_2	Platform modules: Crossbar, Peripheral Bridges, Memories, DMA, Flash Memory Controller, Debug

Table continues on the next page...

Table 19-6. CMU-monitored clocks (continued)

Monitor	Monitored clock(s)
CMU_3	Memory-mapped registers of peripherals
CMU_4	eTPU_A, eTPU_B, eTPU_C
CMU_5	Protocol and communication engines of peripherals
CMU_6	SDADC
CMU_7	PSI5 Rx clock input
CMU_8	PSI5 1 MHz clock input

19.13.2 CMU_0 configuration

CMU_0 automatically monitors the XOSC clock and is able to monitor PLL0.

The following figure is a block diagram for CMU_0 on this chip.

**Figure 19-4. CMU_0 block diagram**

19.13.2.1 CMU_0 monitoring of XOSC

CMU_0 is the only CMU instance that monitors the XOSC clock. CMU_0 uses the IRC clock to measure whether the XOSC clock's frequency is too slow.

CMU_0's clock monitoring of the XOSC is not controlled by software. Its monitoring of XOSC is always enabled automatically after the SIU_RSR[XOSC] field indicates that the XOSC clock is stable.

19.13.2.2 CMU_0 monitoring of PLL0

To enable CMU_0's monitoring of PLL0, the proper initialization sequence is:

1. Configure and enable PLL0.
2. Wait for PLL0 to lock.
3. Enable CMU_0 for monitoring by setting the CMU_0_CSR[CME] field.

19.13.3 CMU_1 to CMU_8 configuration

For CMU_1 to CMU_8:

- Each CMU operates independently from the module that it monitors, with no hardware interlock between them.
- The IRC is the reference clock.

The following figure is a block diagram for CMU_1 to CMU_5 on this chip.

Figure 19-5. CMU_1 to CMU_5 block diagram

The following figure is a block diagram for CMU_6 to CMU_8 on this chip.

Figure 19-6. CMU_6 to CMU_8 block diagram

To enable monitoring of each of CMU_1 to CMU_8, the proper initialization sequence is:

1. Enable the clock source corresponding to the particular CMU instance.
2. Ensure that the particular clock source is enabled, stable, and ready to be monitored.
 - If the XOSC is the clock source, then the SIU_RSR[XOSC] flag must be set.
 - If one of the PLLs is the clock source, then that PLL must be locked.
3. Enable the particular CMU instance for monitoring by setting the applicable CMU_x_CSR[CME] field.

19.13.4 CMU output signals to FCCU and INTC

The output signals of the CMUs are connected to the FCCU in the following way:

- The OLR output of CMU_0 is connected to the CMU_0_OSC channel of the FCCU.
- The FLC, FHH, and FLL outputs of CMU_0 are combined (ORed) together and then connected to the CMU_0_PLL channel of the FCCU.
- The FLC, FHH, and FLL outputs of CMU_1 to CMU_3 are all combined (ORed) together and then connected to the CMU_COMP channel of the FCCU.
- The FLC, FHH, and FLL outputs of CMU_4 and the FHH and FLL outputs of CMU_5 to CMU_8 are all combined (ORed) together and then connected to the CMU_OTHER channel of the FCCU.

The output signals of the CMUs are also connected to the INTC in the following way:

- All outputs from CMU_0 and CMU_1 are combined (ORed) together and then connected to interrupt vector 350.

- All outputs from CMU_2 and CMU_3 are combined (ORed) together and then connected to interrupt vector 351.
- All outputs from CMU_4 and CMU_5 are combined (ORed) together and then connected to interrupt vector 352.
- All outputs from CMU_6 and CMU_7 are combined (ORed) together and then connected to interrupt vector 353.
- All outputs from CMU_8 are combined (ORed) together and then connected to interrupt vector 354.

19.13.5 CMU register and field availability

[Table 19-7](#) specifies which registers and fields are available on a given CMU for this device.

Table 19-7. CMU register and field availability

Address offset	Register	CMU	Note
0x0000	CMU_CSR	All	The SFM, CKSEL1, and RCDIV fields are in CMU_0_CSR only.
0x0004	CMU_FDR	CMU_0	—
0x0008	CMU_HFREFR	All	—
0x000C	CMU_LFREFR	All	—
0x0010	CMU_ISR	All	The OLRI field is in CMU_0_ISR only. The FLCI field is available in ISR for CMU_0 to CMU_5 and not available in ISR CMU_6 to CMU_8. The FHFI and FLFI fields are available in ISR for all CMUs.
0x0014	Reserved	—	—
0x0018	CMU_MDR	CMU_0	—

19.13.6 CMU_0_CSR reset value

The chip-specific reset value of CMU_0_CSR is 0000_0000h.

The reset value of CSR for all other CMU instances, and the reset value of other registers for all CMU instances, appear in the CMU's [Register description and memory map](#).

19.13.7 CMU use restrictions

The following restrictions apply to CMU use:

- In CMU_0, $f_{\text{CLKMN0\_RMT}}$ must be greater than $f_{\text{CLKMT0\_RMN}} / 2^{\text{RCDIV}}$ by at least 0.5 MHz to guarantee correct CLKMN0_RMT monitoring. In CMU_1 to CMU_5, f_{CLKMN1} must be greater than $f_{\text{CLKMT0\_RMN}} / 4$ by at least 0.5 MHz to guarantee correct CLKMN1 monitoring. The accuracy of CLKMT0_RMN (IRC) is specified in the chip's Data Sheet.
- If the checker core and RCCU are disabled (via a DCF client), then the clock to the checker core lake is halted to save power. Because CMU_1 and CMU_2 are monitoring points in the clock tree inside the checker core lake, these CMUs cannot be used if the checker core is disabled.

19.13.8 Loss-of-clock behavior

Loss-of-clock detection is provided by the FLC output signals of the CMUs; see [Figure 19-4](#) and [Figure 19-5](#). The FLC output signals are combined with other CMU output signals and then routed to the FCCU, as explained in [CMU output signals to FCCU and INTC](#). The FCCU can be programmed to react to CMU failures with a system reset. Because the FCCU is clocked by the IRC, it can generate the reset request even in the absence of the system clock. The reset signal generated by the FCCU overwrites the system clock selection from SIU_SYSDIV[SYSCLKSEL], forcing the selection of the IRC as the clock source. This mechanism guarantees that the reset state machine continues to receive a (running) clock so that it can propagate the reset request generated by the FCCU.

NOTE

CMU_6 to CMU_8 monitor clocks whose frequency can be lower than the IRC frequency divided by 4, so they do not implement the FLC detection. The other signals (FLL, FHH) do not assert when the monitored clock stops. Therefore these CMUs cannot detect a loss-of-clock condition.

19.14 PLL loss of lock interrupt

Always write 1 to both PLL0CR[LOLIE] and PLL1CR[LOLIE] to keep the loss of lock interrupt function enabled.

The main interrupt functionality is determined by the FCCU via fault input NCF[23] for PLL0 and fault input NCF[24] for PLL1.

19.15 Debug mode

The clock generation modules (PLL0, PLL1, XOSC, and IRC) and clock monitoring units (CMUs) do not support entry into debug mode. Therefore, there is no possibility of freezing these modules in debug mode.

Chapter 20

Progressive Clock Switch (PCS)

20.1 Introduction

This chip contains a Progressive Clock Switch (PCS) module that can be used to prevent sudden voltage drops and overshoots when the system clock frequency is switched from one clock source to another.

20.2 Block diagram

The following figure is a block diagram of the PCS system.

Figure 20-1. PCS system

20.3 Features

The PCS module provides the following features:

- Progressive frequency switching to minimize power supply voltage drops and overshoots
- Clock switching done in two steps: ramp-down from source frequency to IRC frequency, then ramp-up to target frequency
- Fully programmable ramp-down and ramp-up characteristics
- Automatic monitoring of changes on clock switch selector to trigger progressive clock switching feature

20.4 Memory map and register definition

Before programming the PCS registers (PCS_SDUR, PCS_DIVC n , PCS_DIVE n , and PCS_DIVS n), select IRC as the system clock: ensure SIU_SYSDIV[SYSCLKSEL] is 00b. This selection preserves reliable progressive clock operation if, during the PCS register programming, a reset event occurs.

Any access to unused registers and write accesses to read-only registers:

- do not change register content
- cause a transfer error

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The byte order is big-endian. For example, the PCS_DIVC1 register's RATE field may be accessed as a word at address offset 704h, as a half-word at address offset 706h, or as a byte at address offset 707h.

PCS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
700	PCS Switch Duration Register (PCS_SDUR)	32	R/W	0000_0000h	20.4.1/815
704	PCS Divider Change Register for XOSC (PCS_DIVC1)	32	R/W	03E7_0000h	20.4.2/815
708	PCS Divider End Register for XOSC (PCS_DIVE1)	32	R/W	0000_03E7h	20.4.3/816
70C	PCS Divider Start Register for XOSC (PCS_DIVS1)	32	R/W	0000_03E7h	20.4.4/816
710	PCS Divider Change Register for PLL1 (PCS_DIVC2)	32	R/W	03E7_0000h	20.4.5/817
714	PCS Divider End Register for PLL1 (PCS_DIVE2)	32	R/W	0000_03E7h	20.4.6/818
718	PCS Divider Start Register for PLL1 (PCS_DIVS2)	32	R/W	0000_03E7h	20.4.7/818

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

PCS_SDUR field descriptions

Field	Description
0–7 SDUR	Switch Duration This value defines the duration of one PCS clock switch step in terms of IRC cycles.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

20.4.2 PCS Divider Change Register for XOSC (PCS_DIVC1)

This register defines the rate of frequency change and initial change value for the progressive system clock switching when switching the system clock source to or from the crystal oscillator XOSC on ramp-up and ramp-down, respectively.

NOTE

Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception, but the value will not be loaded with the new value.

Address: 0h base + 704h offset = 704h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PCS_DIVC2 field descriptions

Field	Description
0–15 INIT	Divider Change Initial Value This is initial change value of the clock divider for the clock ramp-up phase when switching to PLL1.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 RATE	Divider Change Rate This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching to/from PLL1.

20.4.6 PCS Divider End Register for PLL1 (PCS_DIVE2)

This register defines the final division value for the progressive system clock switching when switching the system clock source from PLL1 on ramp-down.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 714h offset = 714h

PCS_DIVE2 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVE	Divider End Value This is the clock divider end value for the clock ramp-down phase when switching from PLL1.

20.4.7 PCS Divider Start Register for PLL1 (PCS_DIVS2)

This register defines the initial division value for the progressive system clock switching when switching the system clock source to PLL1 on ramp-up.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, but the value will not be loaded with the new value.

Address: 0h base + 718h offset = 718h

PCS_DIVS2 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVS	Divider Start Value This is the start value of the clock divider for the clock ramp-up phase when switching to PLL1.

20.4.8 PCS Divider Change Register for PLL0 (PCS_DIVC3)

This register defines the rate of frequency change and initial change value for the progressive system clock switching when switching the system clock source to or from PLL0 on ramp-up and ramp-down, respectively.

NOTE

Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception, but the value will not be loaded with the new value.

Address: 0h base + 71Ch offset = 71Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PCS_DIVS3 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVS	Divider Start Value This is the start value of the clock divider for the clock ramp-up phase when switching to PLL0.

20.5 Functional description

The progressive clock switch feature is enabled by setting SIU_SYSDIV[PCSEN]. If PCSEN is set and a change to SIU_SYSDIV[SYSCLKSEL] is detected by the PCS interface logic (see the PCS block diagram), then a progressive clock switch operation is triggered in the PCS block. The following rules govern the operation:

- If the switching is from the IRC clock, then a ramp-up command is sent to the PCS.
- If switching is to the IRC clock, then a ramp-down command is sent to the PCS.
- If the switching is between two clock sources and neither one is the IRC, then ramp-down and ramp-up commands are simultaneously sent to the PCS.

When the PCS block receives ramp-up and a ramp-down commands simultaneously, it executes the processes in this sequence:

1. Ramp-down process
2. Ramp-up process

During ramp-down, the rate of the frequency change is based on the PCS_SDUR, PCS_DIVC n , and PCS_DIVE n registers, where n corresponds to the current system clock source selection. During ramp-up, the rate of the frequency change is based on the PCS_SDUR, PCS_DIVC n , and PCS_DIVS n registers, where n corresponds to the target system clock source selection.

NOTE

The progressive clock switching feature assumes that the IRC has the lowest clock frequency of the device. Do not attempt to use PCS when switching to or from a frequency that is less than than the IRC frequency.

When the PCS feature is enabled, the PCS module itself—not the SIU_SYSDIV[SYSCLKSEL] field—controls the selection of the clock source.

While a PCS switching process is in progress:

- The clock source selected by the PCS may differ from the one requested by SIU_SYSDIV[SYSCLKSEL].

- If software writes a new value to SIU_SYSDIV[SYSCLKSEL] that corresponds to a clock source different from the one at the start of the switching process, the new value is ignored until the PCS process finishes.
- If software writes a SIU_SYSDIV[SYSCLKSEL] value corresponding to the same clock source that was in effect at the start of the switching process, the PCS process aborts and returns to that original clock source.

At the end of the clock switching process:

- The SIU_PCSIFR[PCSI] flag is asserted in the SIU. An interrupt to the CPU is generated if enabled by SIU_PCSE[PCSE].
- The SIU_PCSIFR[PCSMS] field indicates the current clock source selected by the PCS. Software can read PCSMS to learn whether or not the PCS switching process succeeded.

If the PCS switching fails (for example, due to incorrect programming), the clock source will not switch to a different one requested by SIU_SYSDIV[SYSCLKSEL]. Instead, the clock source remains the one selected at the beginning of the attempted PCS switch.

20.5.1 Generic clock change requirements

For a maximum allowed change of the frequency (f_{chg}) and for a given source clock frequency f_{src} (current or target clock source), the following equation gives the maximum allowed frequency change rate a_{max} .

$$a_{\text{max}} = \frac{f_{\text{chg}}}{f_{\text{src}}}$$

20.5.2 Configuration of PCS_SDUR

The switch duration field PCS_SDUR[SDUR] defines the duration of one system clock switch step in terms of the IRC clock period. After the expiration of this time, the module changes the clock divider value, which changes the frequency of the system clock.

20.5.3 Configuration of PCS_DIVCn[RATE]

For a given maximum allowed frequency change rate a_{max} , the following table shows the value d based on the value programmed into the PCS_DIVCn[RATE] register.

Table 20-12. PCS_DIVCn[RATE] values

a_{max}	d	PCS_DIVCn[RATE]
0.05	0.012	12
0.10	0.048	48
0.15	0.112	112
0.20	0.184	184

20.5.4 Generic clock change properties

The following equation gives the number k of steps required to ramp down the source frequency (f_{src}) to reach the IRC frequency (f_{irc}).

$$k = \left\lceil 0.5 + \sqrt{0.25 - \frac{2 \left(1 - \frac{f_{\text{src}}}{f_{\text{irc}}} \right)}{d}} \right\rceil$$

The following equation gives the number k of steps required to ramp up the IRC frequency (f_{irc}) to reach the target frequency (f_{targ}).

$$k = \left\lceil 0.5 + \sqrt{0.25 - \frac{2 \left(1 - \frac{f_{\text{targ}}}{f_{\text{irc}}} \right)}{d}} \right\rceil$$

20.5.5 Clock ramp-down

The clock ramp-down:

- starts with the divider value 1 and with the given divider increment value PCS_DIVCn[RATE].
- ends with the given divider value PCS_DIVE_n[DIVE].

The following equation gives the divider end value for clock ramp-down.

$$\text{PCS\_DIVE}_n[\text{DIVE}] = \frac{f_{\text{curr}}}{f_{\text{irc}}} \times 1000 - 1$$

In the equation, f_{curr} is the frequency of the currently selected system clock source, and f_{irc} is the frequency of the IRC clock.

Figure 20-12. System clock ramp-down timing (k = 6 example)

20.5.6 Clock ramp-up

The clock ramp-up:

- starts with the given divider value $PCS\_DIVSn[DIVS]$ and with the given divider decrement value $PCS\_DIVCn[INIT]$.
- ends with the divider value 1.

The following equation gives the initial divider change start value $PCS\_DIVCn[INIT]$ for system clock ramp-up.

$$PCS\_DIVCn[INIT] = d \times k \times 1000$$

In the preceding equation, k is calculated from the second equation in [Generic clock change properties](#). The following equation gives the divider start value for clock ramp-up.

$$PCS\_DIVSn[DIVS] = \left(1 + d^{\frac{k(k+1)}{2}}\right) \times 1000 - 1$$

Figure 20-13. System clock ramp-up timing (k = 6 example)

Chapter 21

Dual PLL Digital Interface (PLLDIG)

21.1 Chip-specific PLLDIG information

The chip has one instance of the PLLDIG module. It includes two PLLs: PLL0 and PLL1.

For more chip-specific information, see the [Clocking](#) details, especially the [PLL](#) details.

21.2 Introduction

The chip provides a user interface and control over the dual PLL system composed of PLL0 and PLL1 analog blocks and the digital interface (PLLDIG). The two analog PLL blocks are cascaded, with the PHI1 output of PLL0 feeding the clock input of PLL1.

A key feature of the dual PLL architecture is the ability to drive peripherals from the PLL0 PHI output, which is non-modulated and independent of the core clock frequency. The core and platform clocks are driven by the PLL1 PHI frequency-modulated output.

21.3 Acronyms and Abbreviations

The following table contains sample acronyms and abbreviations used in this chapter.

Table 21-1. Acronyms and abbreviated terms

Term	Meaning
PLL	Phase Lock Loop
RFD	Reduced Frequency Divider
MFD	Multiplication Factor Divider
VCO	Voltage Controlled Oscillator
FMPLL	Frequency Modulated Phase Locked Loop

21.4 Block Diagram

Please refer to the “Clocking chapter” of this *Reference Manual* to see the block diagram.

21.5 Features

The Dual PLLDIG has the following features:

- Supports dual PLL in cascaded mode with PLL0 clock out as reference clock to PLL1.
- Reference clock pre-divider for finer frequency synthesis resolution.
- Reduced frequency divider for decreasing the PLL0/PLL1 output clock frequency without causing the PLLs to lose lock.
- Programmable frequency modulation on PLL1.
- Lock detect circuitry reports when the PLLs have achieved frequency lock, and continuously monitors lock status to report loss of lock conditions.
 - User-selectable ability to generate an interrupt request upon loss of lock.
 - The loss of lock indication is sent to the FCCU via the system glue logic.

21.6 Modes of operation

The operating mode of the PLLs is indicated by the value of PLL n CR[CLKCFG]. The various modes of operation for the PLL are:

- Normal mode with reference, with either PLL0 or both PLLs enabled
- PLL disabled

Normal mode is defined as the mode where the clocks are driven by the PLLs. When using a crystal for the clock reference, reset should remain asserted until the oscillator has stabilized.

21.6.1 Normal mode with reference, PLL0 or both PLLs enabled

In normal mode, PLL0 receives an input clock from the reference that can be prescaled by the pre-divider. PLL0 multiplies the frequency to create the PLL0 output clock. The user must supply a crystal that is within the appropriate frequency range, the crystal manufacturer's recommended external support circuitry and short signal route from the MCU to the crystal.

For information about the selection of a clock reference for each PLL, see [PLL](#) in the Clocking details.

PLL0 generates a non-modulated clock which drives PLL0 PHI1. PLL1 can generate a frequency modulated clock or a non-modulated clock (for example, locked on a single frequency). Write the PLL1FM register to program the modulation rate, modulation depth, and whether PLL modulating is enabled.

NOTE

PLL1 must be configured to work with a reference clock from PLL0 only after PLL0 has achieved lock.

For proper power sequencing of analog PLL blocks, write to PLL0CR[CLKCFG] before writing to PLL1CR[CLKCFG].

While powering down the PLLs: If PLL0:PHI1 is used as the source for PLL1, power down the PLLs in this sequence to ensure proper shutoff:

1. PLL1
2. PLL0

21.7 Memory map and register definition

This section provides the memory map and detailed descriptions of all registers for configuring the PLLs. The table below shows the memory map. Addresses are given as offsets from the module base address. All registers can be accessed using 8-bit, 16-bit or 32-bit addressing.

PLLDIG memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	PLLDIG PLL0 Control Register (PLLDIG_PLL0CR)	32	R/W	0000_0000h	21.7.1/830

Table continues on the next page...

PLLDIG memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4	PLLDIG PLL0 Status Register (PLLDIG_PLL0SR)	32	R/W	0000_0000h	21.7.2/831
8	PLLDIG PLL0 Divider Register (PLLDIG_PLL0DV)	32	R/W	2001_1008h	21.7.3/832
20	PLLDIG PLL1 Control Register (PLLDIG_PLL1CR)	32	R/W	0000_0000h	21.7.4/834
24	PLLDIG PLL1 Status Register (PLLDIG_PLL1SR)	32	R/W	0000_0000h	21.7.5/835
28	PLLDIG PLL1 Divider Register (PLLDIG_PLL1DV)	32	R/W	0001_0010h	21.7.6/836
2C	PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)	32	R/W	0000_0000h	21.7.7/837
30	PLLDIG PLL1 Fractional Divide Register (PLLDIG_PLL1FD)	32	R/W	0000_0000h	21.7.8/838

21.7.1 PLLDIG PLL0 Control Register (PLLDIG_PLL0CR)

Address: 0h base + 0h offset = 0h

PLLDIG_PLL0CR field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 CLKCFG	Clock Configuration This field can be used to change the operating mode. 00 PLL off 01 Reserved 10 Reserved 11 Normal mode with PLL running
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 LOLIE	Loss-of-lock interrupt enable

Table continues on the next page...

PLLDIG_PLL0CR field descriptions (continued)

Field	Description
	The LOLIE bit enables a loss-of-lock interrupt request when PLL0SR[LOLF] = 1. If PLL0SR[LOLF] = 0 or PLL0CR[LOLIE] = 0, the interrupt request is ignored. The interrupt request occurs only in normal mode, so the LOLIE bit has no effect if PLL is disabled. NOTE: See PLL loss of lock interrupt in the Clocking details for more information about configuring this field. 0 Ignore loss-of-lock. Interrupt not requested. 1 Enable interrupt request upon loss-of-lock.
29–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

21.7.2 PLLDIG PLL0 Status Register (PLLDIG_PLL0SR)

Address: 0h base + 4h offset = 4h

PLLDIG_PLL0SR field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 LOLF	Loss-of-lock flag

Table continues on the next page...

PLLDIG_PLL0SR field descriptions (continued)

Field	Description
	This bit provides the interrupt request flag for the loss-of-lock condition. Software must write 1 to LOLF to clear it to 0; writing 0 has no effect. The flag is set to 1 when the PLL loses lock or when the divider/modulation registers are changed on the fly. This flag bit is sticky in the sense that if lock is reacquired, the bit remains set to 1 until cleared by either writing 1 or asserting reset. The LOLF is not asserted when the PLL is disabled, but disabling the PLL will not automatically clear the LOLF if it was previously asserted while the PLL was in normal mode. 0 No loss of lock detected. Interrupt service not requested. 1 Loss of lock detected. Interrupt service requested.
29 LOCK	Lock status bit Indicates whether PLL has acquired lock. 0 PLL is unlocked. 1 PLL is locked.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

21.7.3 PLLDIG_PLL0 Divider Register (PLLDIG_PLL0DV)

The PLL0DV register provides the PHI/PHI1 output clock reduced frequency divider (RFDPHI and RFDPHI1), pre-divider (PREDIV), and loop divider (MFD). If this register's fields are modified without powering down the PLL, the PLL will lose lock and generate either an interrupt or a failure signal to the FCCU, based on which is enabled.

Address: 0h base + 8h offset = 8h

PLLDIG_PLL1CR field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 CLKCFG	Clock Configuration This field can be used to change the operating mode. 00 PLL off 01 Reserved 10 Reserved 11 Normal mode with PLL running
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 LOLIE	Loss-of-lock interrupt enable The LOLIE bit enables a loss-of-lock interrupt request when PLL1SR[LOLF] = 1. If PLL1SR[LOLF] = 0 or PLL1CR[LOLIE] = 0, the interrupt request is ignored. The interrupt request occurs only in normal mode, so the LOLIE bit has no effect if PLL is disabled. NOTE: See PLL loss of lock interrupt in the Clocking details for more information about configuring this field. 0 Ignore loss-of-lock. Interrupt not requested. 1 Enable interrupt request upon loss-of-lock.
29–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

21.7.5 PLLDIG PLL1 Status Register (PLLDIG_PLL1SR)

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W

PLLDIG_PLL1SR field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 LOLF	Loss-of-lock flag This bit provides the interrupt request flag for the loss-of-lock condition. Software must write 1 to LOLF to clear it to 0; writing 0 has no effect. The flag is set to 1 when the PLL loses lock or when the divider/modulation registers are changed on the fly. This flag bit is sticky in the sense that if lock is reacquired, the bit remains set to 1 until cleared by either writing 1 or asserting reset. The LOLF is not asserted when the PLL is disabled, but disabling the PLL will not automatically clear the LOLF if it was previously asserted while the PLL was in normal mode. 0 No loss of lock detected. Interrupt service not requested. 1 Loss of lock detected. Interrupt service requested.
29 LOCK	Lock status bit Indicates whether PLL has acquired lock. 0 PLL is unlocked. 1 PLL is locked.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

21.7.6 PLLDIG PLL1 Divider Register (PLLDIG_PLL1DV)

The PLL1DV register provides the PHI output clock reduced frequency divider (RFDPHI) and loop divider (MFD). If this register's fields are modified without powering down the PLL, the PLL will lose lock and generate either an interrupt or a failure signal to the FCCU, based on which is enabled.

Address: 0h base + 28h offset = 28h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

10–15 RFDPHI	PHI reduced frequency divider This 6-bit field determines the VCO clock post-divider for driving the PHI output clock. See the equations in Clock configuration .
16–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 MFD	Loop multiplication factor divider This 7-bit field controls the value of the divider in the feedback loop. The value specified by the MFD bits establishes the multiplication factor applied to the reference frequency. 00h to 09h Reserved 10h Divide by 16 11h Divide by 17 21h Divide by 33 22h Divide by 34 23h to 7Fh Reserved

21.7.7 PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)

The PLL1FM register enables frequency modulation on PLL1 and provides controls for the FM spread spectrum, modulation depth, and modulation rate. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). After the PLL is on and has locked, changing the values of PLL1FM[MODEN] and PLL1FM[MODSEL] can result in the PLL losing its lock. The PLL would then require power cycling to regain normal functionality.

Address: 0h base + 2Ch offset = 2Ch

PLLDIG_PLL1FM field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 MODEN	Modulation enable This bit enables the frequency modulation. 0 Frequency modulation disabled. 1 Frequency modulation enabled.
2 MODSEL	Modulation selection This bit selects whether modulation is centered around the nominal frequency or spread below the nominal frequency. 0 Center Spread modulation: Modulation centered around nominal frequency. 1 Down Spread modulation: Modulation spread below nominal frequency.
3–15 MODPRD	Modulation period

Table continues on the next page...

PLLDIG_PLL1FM field descriptions (continued)

Field	Description
	$\text{MODPRD} = \text{round}\left(\frac{f_{\text{ref}}}{4 \times f_{\text{mod}}}\right)$ MODPRD is the modulation period variable derived from the formula: where f_{ref} represents the frequency of the feedback divider and f_{mod} represents the modulation frequency.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–31 INCSTP	Increment step This field is the INCSTP variable derived from the formula: $\text{INCSTEP} = \text{round}\left(\frac{(2^{15} - 1) \times md \times \text{PLL1DV}[\text{MFD}]}{100 \times 5 \times \text{MODPRD}}\right)$ where md represents the peak modulation depth in percentage (+/- for centered modulation, $-2 \times md$ for modulation below nominal frequency) and MFD represents the nominal value of the feedback loop divider.

21.7.8 PLLDIG_PLL1 Fractional Divide Register (PLLDIG_PLL1FD)

The PLL1FD register provides the enable and fractional divide factor for the loop divider. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). After the PLL is running and has locked, changing the value of FDEN can result in the PLL losing its lock. The PLL would then require power cycling to regain normal functionality.

Address: 0h base + 30h offset = 30h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

PLLDIG_PLL1FD field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PLLDIG_PLL1FD field descriptions (continued)

Field	Description
1 FDEN	Fractional Divide Enable This bit enables the fractional divider in the loop divider for PLL1. 0 Fractional divide disabled. 1 Fractional divide enabled.
2–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 DTHDIS1	Rectangular Dither Disable Disables the Rectangular Phase/Frequency Detector dither. 0 Dither enabled 1 Dither disabled
15 DTHDIS0	Triangular Dither Disable Disables the Triangular Phase/Frequency Detector dither. 0 Dither enabled 1 Dither disabled
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 FRCDIV	Fractional divide input When the fractional divide is disabled, the VCO clock frequency is the product of the input clock and the loop divide factor (MFD). When fractional divide is enabled and dither is disabled (DTHDIS1 is 1), the VCO clock frequency is given by: $\text{VCO Frequency} = \text{InputClock} \times (\text{PLL1DV}[\text{MFD}] + (\text{FRCDIV} \div 2^{12}))$ When fractional divide is enabled and dither is enabled (DTHDIS1 is 0), the VCO clock frequency is given by: $\text{VCO Frequency} = \text{InputClock} \times (\text{PLL1DV}[\text{MFD}] + (\text{FRCDIV} \div 2^{12}) + (1 \div 2^{13}))$ In these equations, FRCDIV is the decimal equivalent of the FRCDIV field.

21.8 Functional description

This section explains the operation and configuration of the Dual PLLDIG module.

21.8.1 Input clock frequency

PLL0 and PLL1 are designed to operate over an input clock frequency range. The operating ranges for the PLLs are discussed in detail in the *Data Sheet*.

21.8.2 Clock configuration

The relationship between input and output frequency is determined by programming the PLL0DV and PLL1DV registers and calculated according to the following equations.

NOTE

In the following equations, use the programmed value for each register field. For example, when PLL0DV[RFDPHI] is programmed to the value 1, use the value 1 in the equation for that field.

$$f_{\text{pll0\_phi}} = f_{\text{pll0\_ref}} \times \frac{\text{PLL0DV[MFD]}}{\text{PLL0DV[PREDIV]} \times \text{PLL0DV[RFDPHI]}}$$

Figure 21-9. PLL0 PHI output frequency

$$f_{\text{pll0\_phi1}} = f_{\text{pll0\_ref}} \times \frac{\text{PLL0DV[MFD]}}{\text{PLL0DV[PREDIV]} \times \text{PLL0DV[RFDPHI1]}}$$

Figure 21-10. PLL0 PHI1 output frequency

$$f_{\text{pll1\_phi}} = f_{\text{pll1\_ref}} \times \frac{\text{PLL1DV[MFD]}}{2 \times \text{PLL1DV[RFDPHI]}}$$

Figure 21-11. PLL1 PHI output frequency (PLLDIG_PLL1FD[FDEN] = 0)

$$f_{\text{pll1\_phi}} = f_{\text{pll1\_ref}} \times \left(\frac{\text{PLL1DV[MFD]} + \frac{\text{PLL1FD[FRCDIV]}}{2^{12}} + \frac{1}{2^{13}}}{2 \times \text{PLL1DV[RFDPHI]}} \right)$$

Figure 21-12. PLL1 PHI output frequency (PLLDIG_PLL1FD[FDEN] = 1 and PLLDIG_PLL1FD[DTHDIS1] = 0)

NOTE

When PLLDIG_PLL1FD[FDEN] = 1 and PLLDIG_PLL1FD[DTHDIS1] = 1, in [Figure 21-12](#) remove from the numerator: + 1/(2¹³)

$$f_{\text{pll1\_phi}} = \frac{f_{\text{pll0\_ref}} \times \text{PLL0DV}[\text{MFD}] \times \text{PLL1DV}[\text{MFD}]}{\text{PLL0DV}[\text{PREDIV}] \times \text{PLL0DV}[\text{RFDPHI1}] \times \text{PLL1DV}[\text{RFDPHI}] \times 2}$$

Figure 21-13. PLL1 PHI output frequency when PLL0 PHI1 is PLL1 reference (PLLDIG_PLL1FD[FDEN] = 0)

$$f_{\text{pll1\_phi}} = \frac{f_{\text{pll0\_ref}} \times \text{PLL0DV}[\text{MFD}] \times (\text{PLL1DV}[\text{MFD}] + \frac{\text{PLL1FD}[\text{FRCDIV}]}{2^{12}} + \frac{1}{2^{13}})}{\text{PLL0DV}[\text{PREDIV}] \times \text{PLL0DV}[\text{RFDPHI1}] \times \text{PLL1DV}[\text{RFDPHI}] \times 2}$$

Figure 21-14. PLL1 PHI output frequency when PLL0 PHI1 is PLL1 reference (PLLDIG_PLL1FD[FDEN] = 1 and PLLDIG_PLL1FD[DTHDIS1] = 0)

NOTE

When PLLDIG_PLL1FD[FDEN] = 1 and PLLDIG_PLL1FD[DTHDIS1] = 1, in [Figure 21-14](#) remove from the numerator: + 1/(2¹³)

The relationship between the VCO frequency (f_{VCO}) and the output frequency of the PLLs is determined by the value of PLL1DV[RFDPHI], PLL0DV[RFDPHI], and PLL0DV[RFDPHI1], according to the following equations:

$$f_{\text{pll0\_VCO}} = f_{\text{pll0\_phi}} \times 2 \times \text{PLL0DV}[\text{RFDPHI}]$$

$$f_{\text{pll1\_VCO}} = f_{\text{pll1\_phi}} \times 2 \times \text{PLL1DV}[\text{RFDPHI}]$$

$$f_{\text{pll0\_VCO}} = f_{\text{pll0\_phi1}} \times 2 \times \text{PLL0DV}[\text{RFDPHI1}]$$

NOTE

$f_{\text{pll0\_phi1}}$ is the reference clock generated by PLL0 for PLL1.

When programming the PLLs, user software must not violate the maximum system clock frequency or max/min VCO frequency specification PLL0 and PLL1. Furthermore, the PLL0DV[PREDIV] value must not be set to any value that causes the input frequency to the phase detector of analog PLL blocks to go below the prescribed ranges.

The PLL n SR[LOCK] flag is immediately negated if the fields of PLL n DV are changed without powering down the analog PLLs.

NOTE

The PLL must be powered down and powered up by writing 00b to the PLL n CR[CLKCFG] fields before PLL0DV[PREDIV], PLL0DV[MFD], PLL1DV[MFD], or the reference input clock values are modified.

The recommended procedure to program the PLLs and engage normal mode appears in [Initialization information](#).

21.8.3 Loss of lock

In the event that the PLL loses lock, the PLL digital interface registers provide the flexibility to select whether to generate an interrupt. If an interrupt is asserted, a failure event is also sent to the FCCU.

A loss-of-lock interrupt and FCCU failure event are generated only when the PLL is operating in normal mode. The PLL n SR[LOLF] bits are not asserted when the PLLs are disabled (PLL n CR[CLKCFG]=00b). If an LOLF flag was asserted while the PLL was in normal mode and then the PLL is disabled, the PLL disabling does not automatically clear the flag.

The lock indication from the analog PLL is synchronized and stored in the status register. When the analog PLL loses lock or regains lock, the status register indicates it immediately (after synchronization time).

21.8.4 Frequency modulation

Frequency modulation uses a triangular profile as shown in [Figure 21-15](#). The modulation frequency and depth are controlled using PLL1FM[MODPRD] and PLL1FM[INCSTP].

Figure 21-15. Triangular frequency modulation

NOTE

The device maximum operating frequency includes the frequency modulation. If center modulation is used, the f_{sys} must be below f_{max} by MD percentage such that $f_{\text{max}} = f_{\text{sys}} \times (1 + (\text{MD}\% / 100))$.

The following equations define how to calculate PLL1FM[MODPRD] and PLL1FM[INCSTP] based on the frequency of the feedback divider (f_{ref}), the modulation frequency (f_{mod}) and the modulation depth percentage (MD).

$$\text{PLL1FM}[\text{MODPRD}] = \text{round} \left(\frac{f_{\text{pll1\_ref}}}{4 \times f_{\text{mod}}} \right)$$

Figure 21-16. PLL1FM[MODPRD] calculation

The equation to determine PLLFM[INCSTP] is shown in Figure 21-17.

$$\text{PLL1FM}[\text{INCSTP}] = \text{round} \left(\frac{(2^{15} - 1) \times \text{MD} \times \text{PLL1DV}[\text{MFD}]}{100 \times 5 \times \text{PLL1FM}[\text{MODPRD}]} \right)$$

Figure 21-17. PLL1FM[INCSTP] calculation

PLL1FM[MODPRD] and PLL1FM[INCSTP] are subject to the following restriction:

$$(\text{PLL1FM}[\text{MODPRD}] \times \text{PLL1FM}[\text{INCSTP}]) < 2^{15}$$

Figure 21-18. PLL1FM[MODPRD] and PLL1FM[INCSTP] restriction

Due to the preceding rounding operations, the effective modulation depth applied to the FMPLL is as shown in Figure 21-19.

$$\text{ModulationDepth} = \text{round} \left(\frac{\text{PLL1FM}[\text{MODPRD}] \times \text{PLL1FM}[\text{INCSTP}] \times 100 \times 5}{(2^{15} - 1) \times \text{PLL1DV}[\text{MFD}]} \right)$$

Figure 21-19. Modulation Depth

As an example, suppose the following configuration, in which PLL1DV[RFDPHI] represents the programmed value of that field:

- Input frequency: 40 MHz
- Loop divider (PLL1DV[MFD]): 20
- VCO frequency: 40 MHz × 20 = 800 MHz
- PLL output frequency: 800 MHz / (2 × PLL1DV[RFDPHI])
- Center spread (PLL1FM[MODSEL] = 0)
- Modulation frequency: 100 kHz
- Modulation depth: +/- 2.0% (4% peak-to-peak)
- PLL1FM[MODPRD] = round[(40 × 10⁶) / (4 × 100 × 10³)] = round[100.00] = 100
- PLL1FM[INCSTP] = round[((2¹⁵ - 1) × 2 × 20) / (100 × 5 × 100)] = round[26.2136] = 26
- PLL1FM[MODPRD] × PLL1FM[INCSTP] = 100 × 26 = 2600 (which is less than 2¹⁵)
- MD (quantized) = ((100 × 26 × 100 × 5) / ((2¹⁵ - 1) × 20)) = 1.983703%

In this example, the modulation error is 0.0163%.

The recommended sequence for programming the FM is:

1. Power down PLL1 by writing PLL1CR[CLKCFG] = 00b.
2. Program PLL1FM while PLL1 is powered down.
3. Power up PLL1 by writing PLL1CR[CLKCFG] = 11b.

21.9 Maximum lock time

Maximum lock time is for the condition when the operating mode of the PLL has changed from power-down to Normal mode, input control bits are stable, and supplies (analog and digital) have attained levels shown in the *Data Sheet*. It is also the time in which the PLLs regain lock after a loss of lock event, assuming all inputs are stable and supplies are within specifications.

21.10 Initialization information

Coming out of reset PLL0 and PLL1 are disabled. The Dual PLLDIG initialization procedure is described in [PLLDIG initialization information](#) in the Clocking details.

Chapter 22

Clock Monitor Unit (CMU)

22.1 Chip-specific CMU information

The chip has nine instances of the CMU module. Each CMU module is programmed independently.

For more chip-specific information, see [Clock monitoring](#).

22.2 Introduction

The Clock Monitor Unit (CMU), also referred to as Clock Quality Checker or Clock Fault Detector, serves three purposes:

- Measures the frequency of clock source CLKMT0_RMN with CLKMN0_RMT as the reference clock
- Monitors CLKMN0_RMT frequency with CLKMT0_RMN as reference clock
- Monitors CLKMN1 frequency with CLKMT0_RMN as reference clock and detects if the monitored clock frequency leaves an upper or lower frequency boundary

NOTE

See the "Clocking" chapter for chip-specific sources used by the CMU.

One of the tasks is to supervise the integrity of the various clock sources on the chip, for example CLKMN0_RMT or CLKMN1. If the monitored clock frequency is less than the reference clock, or it violates an upper or lower frequency boundary, the CMU detects and reports this event. These events signal the FCCU, which can take the necessary corrective actions as its configuration dictates.

The CMU can monitor CLKMN0_RMT, which must have a frequency higher than that of CLKMT0_RMN divided by the factor shown in CMU_CSR[RCDIV], and reports this event. The CMU can also monitor CLKMN1 and generate an event if CLKMN1 is greater than a high frequency boundary or less than a low frequency boundary. The upper and lower frequency boundaries are defined by the CMU High Frequency Reference Register (CMU_HFREFR) and CMU Low Frequency Reference Register (CMU_LFREFR).

The second task of the CMU is to provide a frequency meter, which allows measuring the frequency of a clock source against a reference clock. This is useful to correct/calculate the time deviation of a counter that is clocked by the metered clocks.

NOTE

See the "Clocking" chapter for the number of CMU instances on this chip.

22.2.1 Main features

- CLKMT0_RMN frequency measurement with CLKMN0_RMT as reference clock.
- CLKMN0_RMT monitoring with respect to $\text{CLKMT0\_RMN} \div 2^{\text{CSR[RCDIV]}}$ clock.
- Upper or lower frequency boundary monitoring of CLKMN1 with respect to $\text{CLKMT0\_RMN} \div 4$.
- Event generation for various failures detected inside monitoring unit.

22.3 Block diagram

The block diagram of the CMU module(s) is shown in the "Clocking" chapter of this Reference Manual.

22.4 Signals

The table below describes the signals on the boundary of the CMU (in alphabetical order).

Table 22-1. Signal description

Signal	I/O	Description
CLKMNO_RMT	I	Monitored Clock Signal 0/Metered Clock Signal Reference — Receives a clock signal that the CMU compares to a specified low-limit frequency to determine whether the frequency of the clock signal is greater than the specified limit. Also provides a reference clock signal for all metered clock signals.
CLKMN1	I	Monitored Clock Signal 1 — Receives a clock signal that the CMU compares to specified low-limit and high-limit frequencies to determine whether the frequency of the clock signal is between the specified limits.
CLKMT0_RMN	I	Metered Clock Signal 0/Monitored Clock Signal Reference — Receives a clock signal that the CMU measures against a reference clock frequency. Also provides a reference clock signal for all monitored clock signals.

NOTE

See the "Clocking" chapter for device specific clock sources of each CMU.

22.5 Register description and memory map

This section describes in address order all the CMU registers. Each description includes a standard register diagram with an associated figure number. The CMU memory map is listed in the following table.

NOTE

See "Clocking" chapter for register and field availability details.

CMU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	CMU Control Status Register (CMU_CSR)	32	R/W	See section	22.5.1/850
4	CMU Frequency Display Register (CMU_FDR)	32	R	0000_0000h	22.5.2/851
8	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)	32	R/W	0000_0FFFh	22.5.3/852
C	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)	32	R/W	0000_0000h	22.5.4/852
10	CMU Interrupt Status Register (CMU_ISR)	32	w1c	See section	22.5.5/853
18	CMU Measurement Duration Register (CMU_MDR)	32	R/W	0000_0000h	22.5.6/854

22.5.1 CMU Control Status Register (CMU_CSR)

CMU_CSR field descriptions (continued)

Field	Description
29–30 RCDIV	CLKMT0_RMN division factor. These bits specify the CLKMT0_RMN division factor. The output clock frequency is $f_{\text{CLKMT0\_RMN}} \div 2^{\text{CMU\_CSR}[\text{RCDIV}]}$. This output clock is used as reference clock to compare with CLKMN0_RMT for crystal clock monitor feature. 00 CLKMT0_RMN $\div$ 1 (No division) 01 CLKMT0_RMN $\div$ 2 10 CLKMT0_RMN $\div$ 4 11 CLKMT0_RMN $\div$ 8
31 CME	CLKMN1 monitor enable. 0 CLKMN1 monitor is disabled 1 CLKMN1 monitor is enabled

22.5.2 CMU Frequency Display Register (CMU_FDR)

The CMU_FDR is used to determine the measured frequency of:

- CLKMT0_RMN

with respect to the reference clock CLKMN0_RMT.

NOTE

The CMU_FDR should be read only when
CMU_CSR[SFM] = 0.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CMU_FDR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 FD	Measured frequency bits. This register displays the measured frequency (f_{sel}) with respect to the reference clock ($f_{\text{CLKMN0\_RMT}}$). The measured value is given by the following formula: $f_{\text{sel}} = (f_{\text{CLKMN0\_RMT}} \times \text{CMU\_MDR}[\text{MD}]) \div \text{CMU\_FDR}[\text{FD}]$

22.5.3 CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)

The HFREFR is configured for the high frequency reference that the CMU will use for comparing against the monitored clock. The figure and table below show the CMU_HFREFR register.

NOTE

For correct synchronization of CMU_HFREFR write data, the user must ensure that a time interval of 10 peripheral bus clock cycles + 40 CLKMT0_RMN clock cycles elapses before attempting subsequent writes to the same register.

Address: 0h base + 8h offset = 8h

CMU_HFREFR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 HFREF	High Frequency reference value. These bits determine the high reference value for the CLKMN1 frequency. The reference value is given by: $(\text{HFREF} \div 16) \times (f_{\text{CLKMT0\_RMN}} \div 4)$.

22.5.4 CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)

The LFREFR is configured for the low frequency reference that the CMU will use for comparing against the monitored clock. The figure and table below show the CMU_LFREFR register.

NOTE

For correct synchronization of CMU_LFREFR write data, the user must ensure that a time interval of 10 peripheral bus clock cycles + 40 CLKMT0_RMN clock cycles elapses before attempting subsequent writes to the same register.

Address: 0h base + Ch offset = Ch

CMU_LFREFR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 LFREF	Low Frequency reference value. These bits determine the low reference value for the CLKMN1 frequency. The reference value is given by: $(\text{LFREF} \div 16) \times (f_{\text{CLKMT0\_RMN}} \div 4)$.

22.5.5 CMU Interrupt Status Register (CMU_ISR)**NOTE**

All flags in the CMU_ISR are set asynchronously. This register must be read only after a CMU event is triggered. Otherwise, a read access on this register may fetch an incorrect value (see "Clocking" chapter for interrupt operation) .

NOTE

Before entering low-power stop modes, all clock frequency measurements in the CMU should be disabled. Failing to do so may result in ISR flags being spuriously set.

Address: 0h base + 10h offset = 10h

* Notes:

- OLRI field: Not all CMU blocks will utilize this feature. See the "Clocking" chapter for specific CMU implementation details.

CMU_ISR field descriptions

Field	Description
0–27 Reserved	This field is reserved.
28 FLCI	CLKMN1 frequency less than reference clock event status. This bit is set by hardware when CLKMN1 frequency becomes lower than reference clock frequency ($f_{\text{CLKMTO\_RMN}} \div 4$) value and CLKMN1 is 'ON'. It can be cleared by software by writing '1'. NOTE: This bit will show indeterministic behavior if the clock monitored by the CMU is not enabled . 0 No FLC event 1 FLC event occurred
29 FHHI	CLKMN1 frequency higher than high reference event status. This bit is set by hardware when CLKMN1 frequency becomes higher than the high frequency reference value determined by CMU_HFREFR[HFREF] and CLKMN1 is 'ON'. It can be cleared by software by writing '1'. 0 No FHH event 1 FHH event occurred
30 FLLI	CLKMN1 frequency less than low reference event status. This bit is set by hardware when CLKMN1 frequency becomes lower than the low frequency reference value determined by CMU_LFREFR[LFREF], and CLKMN1 is 'ON'. Software clears this field by writing a '1'. NOTE: This bit will show indeterministic behavior if the clock monitored by the CMU is not enabled . 0 No FLL event 1 FLL event occurred
31 OLRI	Oscillator frequency less than $f_{\text{CLKMTO\_RMN}} \div 2^{\text{CMU\_CSR[RCDIV]}}$ event status. This bit is set by hardware when the $f_{\text{CLKMN0\_RMT}}$ is less than $f_{\text{CLKMTO\_RMN}} \div 2^{\text{CMU\_CSR[RCDIV]}}$ frequency and CLKMN0_RMT is 'ON' . It can be cleared by software by writing '1'. NOTE: While entering STOP mode, OLRI may be triggered due to stoppage of XOSC. To avoid this, disable the XOSC before entering STOP mode. 0 No OLR event 1 OLR event occurred

22.5.6 CMU Measurement Duration Register (CMU_MDR)

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0												MD																			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

CMU_MDR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 MD	Measurement duration bits This field displays the measurement duration in terms of selected clock (CLKMT0_RMN) cycles. This value is loaded in the frequency meter down-counter. The down-counter starts counting when CMU_CSR[SFM] = 1. NOTE: Only values that do not cause a CMU_FDR[FD] overflow shall be written to CMU_MDR[MD]. There is no internal status of a CMU_FDR[FD] overflow.

22.6 Functional description

22.6.1 Frequency meter

The purpose of the frequency meter is to evaluate the deviation from the nominal metered source (such as CLKMT0_RMN) frequencies. Programming of the CMU_CSR[CKSEL1] field is used to select one of the metered clocks from a multiplexer that drives a simple Frequency Meter (see the CMU Block Diagram in the "Clocking" chapter). The reference clock for the Frequency Meter is the CLKMN0_RMT signal. The measurement starts when CMU_CSR[SFM] = 1. The measurement duration is given by the contents of CMU_MDR[MD] in terms of number of clock cycles of the selected metered clock. The CMU_CSR[SFM] bit is cleared by hardware once the frequency measurement is complete and the count is loaded in CMU_FDR[FD]. The frequency of the selected clock (f_{sel}) can be derived from the value loaded in the CMU_FDR[FD] as shown in the following equation:

$$f_{sel} = f_{CLKMN0\_RMT} \times \frac{CMU\_MDR[MD]}{CMU\_FDR[FD]}$$

22.6.2 CLKMN0_RMT supervisor

If frequency of CLKMN0_RMT is smaller than the frequency of CLKMT0_RMN $\div 2^{CMU\_CSR[RCDIV]}$ and CLKMN0_RMT is 'ON', then:

- The CMU writes 1 to CMU_ISR[OLRI].
- The CMU asserts the OLR signal.

Note

$f_{\text{CLKMN0\_RMT}}$ must be greater than $f_{\text{CLKMT0\_RMN}} \div 2^{\text{CMU\_CSR[RCDIV]}}$ by at least 0.5 MHz in order to guarantee correct $f_{\text{CLKMN0\_RMT}}$ monitoring.

22.6.3 CLKMN1 supervisor

The frequency of CLKMN1 (f_{CLKMN1}) can be monitored by programming CMU_CSR[CME] = 1. CLKMN1 monitoring starts as soon as CMU_CSR[CME] = 1. This monitor can be disabled at any time by programming CMU_CSR[CME] = 0.

If f_{CLKMN1} is greater than the reference value determined by fields CMU_HFREFR[HFREF] and CLKMN1 is 'ON', then:

- The CMU writes 1 to CMU_ISR[FHHI].
- The CMU asserts the FHH signal.

If f_{CLKMN1} is less than a reference clock frequency ($f_{\text{CLKMT0\_RMN}} \div 4$) and the CLKMN1 is 'ON', then:

- The CMU writes 1 to CMU_ISR[FLCI].
- The CMU asserts the FLC signal.

If f_{CLKMN1} is less than a reference value determined by the bits CMU_LFREFR[LFREF] and the CLKMN1 is 'ON', then:

- The CMU writes 1 to CMU_ISR[FLLI].
- The CMU asserts the FLL signal.

Note

f_{CLKMN1} must be greater than $f_{\text{CLKMT0\_RMN}} \div 4$ by at least 0.5 MHz in order to guarantee correct CLKMN1 monitoring.

An example of determining the $\text{HFREF}_{\text{Actual}}$ is as follows. Assume a $f_{\text{CLKMT0\_RMN}} = 16$ MHz with a accuracy of $\pm 5\%$ (see *Data Sheet* for actual value). In order to monitor a $f_{\text{CLKMN1}} = 200$ MHz, the ideal $\text{HFREF}_{\text{Ideal}} = 800$. The actual HFREF value will be 842 when the accuracy is taken into

consideration ($\text{HFREF}_{\text{Actual}} = (\text{HFREF}_{\text{Ideal}} \div 0.95)$). The actual
LFREF value will be 762 when accuracy is taken into
consideration ($\text{LFREF}_{\text{Actual}} = \text{LFREF}_{\text{Ideal}} \div 1.05$).

Chapter 23

Embedded Memories

23.1 Overview

This chip's features of embedded memory include:

- On-chip SRAM, including system SRAM and local instruction and data caches for each processor core
- On-chip system error correction code (ECC) flash memory
- End-to-end ECC (e2eECC) error detection and correction (not all modules support e2eECC)
- Embedded memories in select peripherals, including:
 - FlexCAN
 - M_CAN
 - eDMA
 - FEC
 - eTPU
 - CSE

For more information about embedded memory in a peripheral, see the peripheral's dedicated chapter.

23.2 End-to-end Error Correction Code (e2eECC)

To support market requirements related to improved functional and transient fault detection capabilities, this chip includes end-to-end ECC (e2eECC) support. This e2eECC is structurally different from traditional "ECC at memory" functionality because

it provides robust error detection capabilities from one endpoint of an information transfer to another endpoint, with temporary information storage in one or more intermediate components.

Memory protected by ECC/EDC traditionally generates and checks additional error parity information local to the memory unit to detect and/or correct errors that have occurred on data stored in the memory. In contrast, e2eECC generates error protection codes at the source of data generation. It sends the encoded data and error protection codes to intermediate storage when a memory write is initiated by a bus master, and it performs a data integrity check using the previously stored error protection codes at a data memory when a read of stored information is requested by a bus master. Depending on the particular memory unit, the intermediate storage may transform the generated error protection codes into another format for storage and then regenerate the codes for provision when a request is made to read the stored information, or it may simply store the original protection codes unaltered.

To protect additional information associated with an access, the error protection codes are generated on the basis of more than the data associated with a storage location. In particular, address information corresponding to the access location of the stored information is combined with the stored data at the data source to generate error protection codes that cover certain types of addressing errors in the system interconnection or in the memory unit. The error protection codes may be checked at the memory unit on a store operation to ensure that no address information or data has been corrupted while the request has transitioned through the device from the bus master source. The memory unit may simply store the received data and protection codes at the address it receives, or it may check the error protection codes to ensure that address decoding within the storage memory was performed properly (although not all address decoding errors can be detected this way).

On a read request from a bus master, the memory unit retrieves the data information and error protection codes corresponding to the received address from the storage location or locations and supplies the data along with the error protection codes to the requesting device. The requesting device uses a locally stored address value corresponding to the read request to check the returning data and error protection codes to ensure that no errors have occurred in either addressing the memory or in the retrieved data. This approach ensures that the address sent for the request was not corrupted, the addressed location was actually accessed (to the extent it is possible to ensure), and the stored data was error free, to the extent the ECC coding scheme is able to detect. As a result, the fault coverage provided by the end-to-end check is considerably more robust than the previous implementation of locally generated and checked/corrected error protection at each memory unit.

The following table compares the traditional and e2eECC approaches.

Table 23-1. ECC comparison of data write-then-read sequence

Traditional ECC	End-to-end ECC (e2eECC)
Bus master initiates data write	Bus master initiates data write and generates ECC checkbits based on 29-bit address and 64-bit data fields for the computational shell, or based on 30-bit address and 32-bit data field for the peripheral shell
Data write transfer routed from bus master to appropriate bus slave	Data write transfer (including checkbits) routed from bus master to appropriate bus slave
For a bus memory slave, generate the ECC checkbits based on the data value and store data + checkbits into the memory	For a bus memory slave, store data and checkbits into the memory
Bus master initiates data read of previously written memory location	Bus master initiates data read of previously written memory location
Data read transfer routed from bus master to appropriate bus slave	Data read transfer routed from bus master to appropriate bus slave
For a bus memory slave, the memory array is accessed, the controller performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction, and drives the read data onto the system bus interconnect	For a bus memory slave, the memory array is accessed, and the controller passes the read data and associated checkbits onto the system bus interconnection
The bus master captures the read data and continues	The bus master captures the read data and associated checkbits, performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction, and continues

The scope of differences in the operations "covered" by the ECC checks is readily apparent with the e2eECC concept, improving fault detection capabilities in two important aspects:

- The entire data transaction—from the initiating bus master, through the entire platform crossbar steering mechanism, to the destination slave target—is covered during write accesses. Likewise, a read is checked from the initiating bus master, through the crossbar steering mechanism, through the actual memory read and transmission of the data and checkbits back to the bus master, where the integrity and correctness of the entire transaction is checked.
- The selected ECC protects both the address field and the data field.

NOTE

Compared to MPC5676R: For every SRAM and DMA transfer initiation, e2eECC on MPC5777C requires 2 additional clock cycles. The performance impact of these additional clocks can be reduced through the use of bursting.

In general, e2eECC improves implementation. The traditional ECC approach places the checkbit decode and error syndrome generation with the error/no_error state, affecting whether the system bus transfer must be stalled (to correct a single bit error or report a

noncorrectable event) or is allowed to complete (for error-free transfers) in a critical timing arc that often sets the upper limit of the operating frequency of the microcontroller. With the e2eECC scheme, the checkbit decode and error syndrome logic is located in the requesting bus master with generally more degrees of implementation freedom; the error/no_error state determination is removed from the system bus cycle termination logic, producing an improved timing arc and generally higher operating speeds.

Errors that occur within the system interconnect are typically manifested as an incorrect address, incorrect write data, or incorrect read data to be presented to the slave or back to the master. Errors occurring within the storage typically manifest themselves eventually in corrupted read data or checkbits being returned to a requester.

The following diagram provides an overview of the e2eECC implementation on this chip.

Figure 23-1. e2eECC overview

NOTE

Due to the e2eECC implementation as it relates to the cores, treat ECC errors discovered during cache line fills as imprecise.

Chapter 24

RAM Controller (PRAMC)

24.1 Chip-specific PRAM information

This chip has two instances of the PRAM module.

24.1.1 PRAM optional read wait states

The following table shows programming values for the BO_DIS and FT_DIS fields of the PRAM's PRCR1 register and the resulting access timing for a WRAP4 burst. For additional information, see [Optional read wait-state](#).

Table 24-1. Read wait states for WRAP4 burst

BO_DIS	FT_DIS	WRAP4 timing
0	0	1-1-1-1
0	1	2-1-1-1
1	0	1-1-1-1
1	1	2-2-2-2

24.1.2 Reset effects on System RAM accesses

If any of the following types of reset event occurs during a read or write operation to System RAM, the completion of that access depends on the cycle at which the reset occurs. Data read from or written to System RAM before the reset event occurred is retained, but no other address locations are accessed or changed.

- External reset via RESET pin
- FCCU reset
- JTAG reset

- Software system reset
- Dual core reset

If the System RAM is cached, cache lines might retain indeterminate data that is not written to memory unless the region is set for writethrough mode.

NOTE

Standby memory might contain the previous data values if a reset occurs while the cache is running in copyback mode.

For descriptions of reset types, see [Reset sources](#).

24.1.2.1 Other reset types

The software external reset does not affect internal logic and therefore does not cause RAM corruption for any RAMs.

For all other reset types, no System RAM retention is guaranteed.

24.1.2.2 Other RAMs

For all other RAMs on the chip, no retention is guaranteed for any reset type.

24.2 Introduction

This section provides an overview of the Platform RAM Controller. The RAM controller acts as an interface between the system bus (AHB-Lite 2.v6) and the integrated system RAM. It converts the protocols between the system bus and the dedicated RAM array interface.

The RAM controller supports two 64-bit AHB interfaces and a 64-bit RAM array interface. The primary AHB port provides a connection to the platform crossbar for direct RAM access from the various crossbar masters. Shown below in [Figure 24-1](#) is a simplified block diagram depicting the position of the RAM controller within a typical platform architecture.

Figure 24-1. Simplified platform block diagram

The following list summarizes the key features of the RAM controller:

- System bus supports 64-bit data + 8-bit ECC AHB interfaces
- Array interface supports a 64-bit data + 8-bit ECC interface
- Late-write support via 64-bit data + 8-bit ECC storage buffer to support single-cycle write accesses
- Configurable read access timing (zero or one wait-state programmable) allowing use in large range of frequency targets
- Read-modify-write operation to support array write size less than a doubleword

The address path of the RAM controller contains a mux that chooses among the addresses presented on the system bus for a read request, either the address from the temporary holding register or the address from the late-write buffer. The temporary holding register contains the address which was presented during the AHB address phase of the write request. The request is stalled from being presented to the RAM by one cycle in order to present simultaneously the address and associated write data, which is not valid until the AHB dataphase. The late-write buffer holds write requests which are delayed to facilitate single-cycle response on the system bus.

The read datapath contains a mux that chooses the source of the read data to be presented on the system bus on a read request. In the event that a read request matches the contents of the late-write buffer, a RAM access is not required and the late-write buffer contents are selected onto the read databus. Otherwise, the read data is a result of a RAM access. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the RAM controller, including the late-write storage buffer, to support end-to-end ECC (e2eECC) coverage.

The write datapath contains the mux that chooses the source of the write data as well as the control logic for generating read-modify-write operations on writes that are less than 64 bits in size. A write operation can be performed to empty the contents of the late-write buffer. In the case of back-to-back writes, the write may be forced to bypass the late-write buffer and instead be stored directly, precisely in the RAM.

24.3 SRAM controller memory map and register definition

The RAM controller module provides an IPS programming model mapped to a standard on-platform peripheral slot. The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses generate an IPS error termination.

NOTE

Attempted updates to the PRAMC programming model while a PRAMC operation is in progress will result in non-deterministic behavior. Software must be architected to avoid this scenario by ensuring that PRAMC configuration changes are made only during system boot or when only one master is enabled. In multi-core devices, update the PRAMC configuration only when one core is active and no other masters, e.g., DMA or communications modules, are enabled. Move any instruction execution or memory references outside the system RAM while updating the PRAMC configuration, e.g., to the core local memory space.

PRAMC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
0	Platform RAM Configuration Register 1 (PRAMC_PRCR1)	32	R/W	0000_0100h	24.3.1/866

24.3.1 Platform RAM Configuration Register 1 (PRAMC_PRCR1)

The Platform RAM Configuration Register 1 (PRCR1) is used to specify operation of the RAM controller.

NOTE

This register is accessible only in supervisor mode. Accesses in user mode return a transfer error.

Address: 0h base + 0h offset = 0h

PRAMC_PRCR1 field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 Reserved	This field is reserved.
24 Reserved	This field is reserved.
25 P0_BO_DIS	Port p0 read burst optimization disable. NOTE: The number of cycles taken for a RAM access can vary ± 1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to the PRAMC controller clock frequency. 0 64-bit WRP4 read bursts are optimized such that the controller returns a 2-1-1-1 response when PRCR1[FT_DIS]=1 1 64-bit WRP4 read bursts are not optimized; the controller returns a 2-2-2-2 response when PRCR1[FT_DIS]=1
26–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 FT_DIS	Flow through disabled. This field defines the AHB response on reads. The state of this field has no impact on the response latency on writes. This bit is cleared by hardware reset. NOTE: Do not change the FT_DIS bit value while accessing system RAM. Relocate code programming the FT_DIS bit to another memory area, e.g., local core memory. 0 RAM read data is passed directly to the system bus, incurring no additional latency 1 RAM read data is registered prior to returning on the system bus, incurring 1 extra cycle of latency

24.4 Functional description

This section describes the functions of the RAM controller.

24.4.1 Read and Write operations

The RAM controller processes read and write requests to on-chip RAM and provides a register interface for access to performance tuning functions.

NOTE

The RAM controller register interface is accessible only in supervisor mode. Accesses in user mode return a transfer error.

24.4.1.1 Reads

Read transfers, of any size, can be configured to complete with a zero or one additional wait state response on the system bus.

24.4.1.2 Optional read wait-state

The RAM controller can be optionally programmed to register RAM read data prior to returning it on the system bus. Setting the `PRCRx[FT_DIS]` field inserts a register in the read data path for use when operating the controller at high frequencies. The state of `PRCRx[FT_DIS]` field has no effect on writes.

A random, initial access will take 2 clock cycles (2T) to complete if `PRCRx[FT_DIS]=0`, and a WRAP4 burst will have an access time of 2-2-2-2. A random, initial access will take 3 clock cycles (3T) to complete if `PRCRx[FT_DIS]=1`, and a WRAP4 burst will have an access time of 3-2-2-2.

NOTE

The number of cycles taken for a RAM access can vary ± 1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles

depending on RAM speed relative to the PRAMC controller clock frequency.

24.4.2 Writes

This section discusses various write operations of the RAM controller.

24.4.2.1 64-bit writes

Aligned 64-bit writes execute in a single AHB data phase cycle, allowing for zero wait states on back-to-back writes of these sizes. If, during the data phase of a write, a read is requested on the AHB, the write is registered in the late-write buffer, allowing the read to take place without a wait state. The valid buffered or late-write data is stored on the next available array address phase.

Back to back 64-bit writes execute slightly differently whereby the first write bypasses the late-write buffer. Rather, the write data is stored directly to the array in the same cycle in which it is valid on the AHB.

24.4.2.2 Less than 64-bit writes

Writes of size less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme's 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The write data is merged into the appropriate byte lanes along with the potentially corrected read data. A new codeword is generated based on the newly formed doubleword. The newly formed doubleword and its associated checkbits are subsequently written to the RAM. [Figure 24-3](#) provides details on the read-modify-write datapath. For details on the ECC coding scheme, refer to [Reliability considerations](#).

Figure 24-3. Read-modify-write datapath

On a read-modify-write operation, the array read data is registered after it is decoded and before it is merged with the AHB write data. Therefore, writes of size less than 64 bits require the insertion of one wait state before the data phase can be completed.

24.4.2.3 Unaligned writes

The RAM controller is compliant with the AMBA-AHB2.v6 Extensions specification with regard to byte strobes. The size of the transfer is sufficient to cover all bytes being written and covers more bytes in the case of an unaligned transfer. The address of the transfer is rounded down to the nearest boundary of the size of the transaction.

NOTE

Unaligned writes always generate read-modify-write operations in the RAM controller in order to preserve the validity of the ECC codeword.

24.5 Initialization/application information

It is essential that each memory address be written to a known value before it is read, to initialize the ECC. This includes reads generated from the read-modify-write operation which occurs when a write transfer of less than 64 bits or an unaligned write is requested. Without writing an address to a known value first, a read from this address will most likely generate an uncorrectable ECC event.

One possibility for initializing PRAMC memory space is to use a stored 64-bit word instruction such as Store Multiple Word (`e_stmw`) in Power Architecture VLE.

24.6 Reliability considerations

This section discusses reliability considerations of the RAM controller.

24.6.1 Hsiao ECC algorithm

The e2eECC scheme implements a single-error correction, double-error detection (SECDED) code using the so-called Hsiao odd-weight column criteria. These codes are named for M.Y. Hsiao, an IBM researcher who published extensively in the early 1970s on SECDED codes better suited for implementation in protecting (mainframe) computer memories than traditional Hamming codes.

The Hsiao codes are Hamming distance 4 implementations which provide the SECDED capabilities. The minimum odd-weight constraints defined by Hsiao are relatively simple in the resulting implementation of the parity check H matrix which defines the association between the data (and address) bits and the checkbits. They are:

1. There are no all-zeroes columns.
2. Every column is distinct.
3. Every column contains an odd number of ones, and hence is "odd weight".

In defining the H-matrix for this family of devices, these requirements from Hsiao were applied. Additionally, there are a variety of ECC codeword requirements associated with specific functional requirements associated with the system RAM that further dictated the specific column definitions. In any case, the resulting ECC is organized based on 64 data bits plus 29 address bits (the upper bits of the 32-bit address field minus the 3 bits which select the byte within the 64-bit (8-byte) data field).

The basic H-matrix for this (101, 93) code (93 is the total number of data bits, 101 is the total number of data bits (93) plus 8 checkbits) is shown in the following table. A '*' in the table indicates the corresponding data or address bit is XOR'ed to form the final checkbit value on the left. For 64-bit data writes, the table sections corresponding to D[63:32], D[31:0], and A[31:3] are logically summed (output of each table section is XOR'ed) together to the final value driven on the hwchkbit[7:0] outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit*.

Table 24-4. RAM controller basic H-matrix definition

Checkbits [7:0]								XOR sum								Data Bit ¹																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																												
																Byte 7								Byte 6								Byte 5								Byte 4																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																				
0	1	2	3	4	5	6	7																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																					

1. Bit numbering is AHB convention: bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.

2. Bit numbering is AHB convention: bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.

24.6.1.1 e2eECC considerations on less-than-64-bit write transactions

Recall writes of size less than 64-bit incur a read-modify-write action as a consequence of the ECC coding scheme 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The RAM controller uses the following checkbit manipulation technique to ensure any faults in the PRAMC control logic associated with performing the read-modify-write action will ultimately be detectable by e2eECC:

- On an 8-, 16-, or 32-bit write request, the write data is presented by the master on the AHB bus in the correct byte lanes, with the non-pertinent byte lanes zeroed out, and the associated checkbit is based on this "zero-padded" write data.

Consider the following example whereby the master presents a 16-bit write request at address 0x40000000:

- The RAM controller detects that the request is a less-than-64-bit write request and initiates a read to address 0x40000000. An ECC check and potential single-bit correction is performed on the data returned from the RAM.

If a non-correctable ECC event is detected, the AHB request is terminated with error on the system bus.

- The RAM controller isolates the pertinent byte lanes of the read data by zero-padding the non-pertinent byte lanes and calculating the checkbit contribution associated with the read data in the byte lanes to be updated as a result of the write request.

- Merge the non-pertinent read data bytes with the write data in the appropriate byte lanes. Take the checkbit value that was stored in the RAM and remove the checkbit contribution associated with the read data in the byte lanes to be updated. Then introduce the checkbits associated with the write data. The result is ultimately a checkbit value associated with the complete 64-bit data to be written to the array.

This technique calculates the ultimate checkbit value on a read-modify-write transaction through a series of data manipulations, taking care to avoid discarding the original checkbits provided by the requesting master, such that faults in the crossbar (XBAR) and RAM controller datapath and control logic are covered by e2eECC.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The RAM controller performs EDC after ECC check on all read-modify-write transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the FCCU module.

24.6.2 Transaction monitor

The integrity of the address and data on a system RAM transaction is covered by e2eECC check performed by the requesting master. Fault detection coverage of the address path and control within the RAM controller is handled by a transaction monitor which verifies the integrity of the transactions between the RAM controller and the RAM array. The transaction monitor verifies RAM transactions initiated to service the following types of transactions:

- Direct system bus read or write request
- Read followed by write to fulfill a read-modify write transaction
- Write transaction to empty the late-write buffer

The function of the transaction monitor relies on a feedback path between the RAM controller and RAM array, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated.

This feedback information is used by the RAM controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the RAM controller or the transmission path between the RAM controller and RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

Since writes to the RAM can be buffered, the transaction monitor also tracks the contents of the late-write buffer. When the late-write buffer is emptied, outputs from the RAM are evaluated against the expected contents of the late-write buffer as tracked by the transaction monitor.

As a countermeasure against false misses to the late-write buffer on reads, the transaction monitor also verifies the expected source of data returned on a read as supplied either from the RAM or from the late-write buffer.

Figure 24-4. RAM controller transaction monitor block diagram

Chapter 25

Flash Memory Controller (PFLASH)

25.1 Chip-specific PFLASH information

The PFLASH registers PFCR1, PFCR2, and PFAPR control the interaction of master modules with the flash memory array by enabling/disabling prefetch or by controlling access to the array on a per-master basis.

Fields in these registers refer to the masters' logical ID numbers. For example, the PFAPR[M2AP] field controls flash memory array access by logical master 2, and the PFAPR[M3AP] field controls flash memory array access by logical master 3.

- For the list of bus masters' logical IDs, see [XBAR master and slave assignments](#).
- For logical master ID numbers that are unused on this chip, the corresponding PFLASH register fields are reserved.

For more information about configuring the PFLASH, see the [Platform Flash Configuration Register 3 \(PFLASH_PFCR3\)](#) details.

25.2 Introduction

The flash memory controller has these functions:

- It acts as an interface between the system bus (AHB-Lite 2.v6) and the flash memory array.

The flash memory controller supports two 64-bit AHB buses and a 256-bit read data interface from each flash memory array. Each AHB port contains a 4-entry, 4-way set-associative mini-cache as well as an associated controller that prefetches sequential lines of data from the flash arrays into the mini-cache. This buffer mechanism serves to deliver flash read data with zero-wait state response on lines that reside in the cache. AHB requests that miss the cache generate the needed flash array access and are forwarded to

the AHB upon completion. Each mini-cache entry is 256 bits in size, matching the flash array page size and providing 512 bytes of total buffered storage. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the flash memory controller, including the mini-cache, to support end-to-end ECC (e2eECC) coverage.

25.3 Features

The following list summarizes the key features of the flash memory controller:

- Two 64-bit AHB interface ports (p0, p1) allowing simultaneous access to dedicated prefetch mini-cache per slave port.
- 256-bit read data bus + 64-bit write data bus
- Configurable read buffering and line prefetching support via 4-entry, 4-way set-associative mini-cache plus prefetch controller per AHB port to provide single-cycle "buffer hit" read response.
- Configurable access control based on read/write and AHB master ID attributes.
- Configurable access timing (wait-state programmable) allowing use in a wide range of frequency targets.
- Optional address pipelining capability to maximize throughput.
- Support for reporting of single- and multi-bit flash ECC events on a 64-bit doubleword boundary.

25.4 Block diagrams

[Figure 25-1](#) illustrates the connections of the flash memory controller and flash memory array within the chip.

Figure 25-1. Platform-centric simple block diagram with flash memory controller

25.5 Flash memory controller memory map

The flash memory controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model consists of flash memory access configuration.

The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses or in user mode generates an IPS error termination. The flash controller allows access to the programming model by all system bus masters.

The programming model can only be accessed in supervisor mode.

A write to any flash memory controller register, when executed concurrently with a flash memory access, will result in non-deterministic behavior and may include lockup of the flash memory controller. There is no idle indicator for the flash controller, so software must be architected to prevent any possible conflicts. The following recommendations will help.

- For multi-core devices, start only one core and execute initialization code to completion before starting the remaining cores.

- If flash must be reconfigured during application code execution, temporarily move all required code and data to system RAM before any writes to flash memory controller registers.
- If application software functionality includes invalidating a port read buffer, the recommended method for invalidating a port read buffer is:
 - a. Unlock the buffer's enable field by setting the PFLASH_PFCR3[BFEN_LK] field to '0'
 - b. Disable the buffer by setting it's associated enable field (PFLASH_PFCR1[Pn_BFEN]) to '0'
 - c. If needed, enable the buffer by setting it's associated enable field (PFLASH_PFCR1[Pn_BFEN]) to '1'

The above method requires updating flash memory controller registers, so software must ensure that no flash accesses are issued concurrently with any of the steps. In cases where that cannot be guaranteed, there is a workaround but its use is not generally recommended because it relies on a hardware side effect instead of the flash memory controller's built-in functions intended for invalidating port read buffers. The workaround is to issue an interlock write without an accompanying program or erase operation—an interlock write, without an accompanying program or erase, does not change any flash content.

NOTE

1. If this workaround is implemented in application code, note that an interlock write invalidates only the buffers associated with the system bus port on which the interlock write was issued.
2. See the flash memory chapter for the steps to issue an interlock write.
3. See the flash memory controller's chip-specific information for any restrictions on the interlock write data size.

PFLASH memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

16–18 APC	Address Pipeline Control. This field controls the number of cycles that a subsequent flash read from the opposite AHB port can be initiated prior to the previous read data being valid. This field applies to the configuration of Port0 and Port1. For valid RWSC and APC combinations please refer to the device data sheet. NOTE: 1. A value of '1' in the most significant bit causes the flash controller to function in retrograde/legacy mode, in which there is no pipelining between the sampling of flash read data and the presentation of the next address for flash lookup. 2. Flash operation is not guaranteed for RWSC/APC combinations other than those specified in the data sheet. 000 Pipelined access to the flash disabled. 001 A pipelined access can be initiated 1 cycle before the previous data is valid 010 A pipelined access can be initiated 2 cycles before the previous data is valid 011 A pipelined access can be initiated 3 cycles before the previous data is valid 1xx Pipelined access to the flash is disabled and one wait state is inserted before a subsequent access can be initiated
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 RWSC	Read Wait State Control. This field controls the number of wait-states to be added to the best-case flash array access time for reads. The best-case flash array access time for reads is one cycle. This field must be set to a value corresponding to the operating frequency of the flash memory controller and the actual read access time of the flash memory controller. For valid RWSC and APC combinations please refer to the device data sheet. NOTE: 1. Higher operating frequencies require non-zero settings for this field for proper flash operation. 2. Flash operation is not guaranteed for RWSC/APC combinations other than those specified in the device data sheet. This field applies to the configuration of Port0 and Port1. 0000 No additional wait-states are added 0001 One additional wait-state is added ... 1111 Fifteen additional wait-states are added
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 P0_DPFEN	Port0 Data Prefetch Enable. This field enables or disables prefetching initiated by a data read access. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Field	Description
27 P0_IPFEN	Port0 Instruction Prefetch Enable. This bit enables or disables prefetching initiated by an instruction read access. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 P0_PFLIM	Port0 PFlash Prefetch Limit. This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss. 10 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit. 11 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit.
31 P0_BFEN	Port0 PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BFEN_LK]=0. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

25.5.2 Platform Flash Configuration Register 2 (PFLASH_PFCR2)

The PFlash Configuration Register 2 (PFCR2) controls the operation of Port1 of the PFLASH_C55FM flash memory controller.

NOTE

See the chip-specific platform flash controller information for details about the masters.

PFLASH_PFCR3 field descriptions

Field	Description
0–1 P0_WCFG	Port0 Way Configuration. This field controls the configuration of the line buffers for a given set across all four ways in the controller cache. The indexed set can be organized as a "pool" of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 All four buffers in an indexed set are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved

25.6 Functional description

The flash memory controller interfaces between:

- The AHB system bus ports
- Flash memory array

For accesses targeting the flash array, the flash memory controller generates read and write enables, block selects, array address, write size and write data as inputs to the flash array. The flash memory controller captures read data from the flash array and drives it onto the AHB system bus. Up to four pages of data (256-bit page size) may be buffered in each of four ways of the flash memory controller mini-cache. Lines may be prefetched in advance of being requested, allowing single-cycle (zero AHB wait-states) read data responses on buffer hits.

Several prefetch control algorithms are available for controlling line read buffer fills. Prefetch triggering may be restricted to instruction accesses only, data accesses only, or may be unrestricted. Prefetch triggering may also be controlled on a per-master basis.

Buffers may also be selectively enabled or disabled for allocation by instruction and data prefetch.

Access protections may be applied on a per-master basis for both reads and writes to support security and privilege mechanisms.

25.6.1 Basic interface protocol

Read accesses are terminated under control of the appropriate wait state settings. Thus, the access time of the operation is determined by the setting of the PFCR1[RWSC] field. Access timing can be varied to account for the operating conditions of the SoC (frequency, voltage, temp) by appropriately setting the PFCR1[RWSC] field.

25.6.2 Access protections

On-chip Flash memory accesses are subject to restrictions based on chip security implementation and/or requirements based on functional restrictions of the flash memory, e.g., a read access to a flash block while it is currently being written is not allowed. When a prohibited access is attempted, a system bus error termination results.

The flash memory controller may invoke a system bus error termination in the following scenarios:

- Attempted access by an AHB master whose corresponding read access control or write access control settings do not allow the access, thus causing a protection violation. See [Platform Flash Access Protection Register \(PFLASH_PFAPR\)](#) for more detail. In this case the flash memory controller does not initiate the requested flash array access.
- The flash returns an error response on an attempted access to a partition that is unavailable. (see [Flash error response operation](#) or [Embedded Flash Memory](#)).
- Attempted access by an AHB master to a reserved region in the flash memory map.

The flash array may also signal an error response to terminate a requested access due to improper sequencing during program/erase operations, improper sequencing during array integrity testing. When an error response is received the flash memory controller does not update or validate a page read buffer. An error response may be signaled on a read or interlock write operation. For more information on the specifics related to signaling of flash errors, including flash ECC events, array integrity testing and read-while-write events, refer to the flash memory chapter.

25.6.2.1 PFAPR - Platform Flash Access Protection Register (PFAPR)

The flash memory controller provides programmable, configurable access protections for both read and write cycles on a per-master basis via the PFlash Access Protection Register (PFAPR). It allows restriction of read and write requests on a per-master basis. This functionality is described in [Platform Flash Access Protection Register \(PFLASH_PFAPR\)](#). Detection of a protection violation results in an error response from the flash memory controller on the AHB transfer.

25.6.3 Access pipelining

Accesses to the flash array may be pipelined by driving a subsequent access address and control signals while waiting for the current access to complete. Pipelined access requests are always run to completion and are not aborted by the flash memory controller. Flash access pipelining allows for improved performance by reducing the access latency seen by the AHB master. Access pipelining may be applied only to read cycles targeting the flash array. Address pipelining is enabled by setting the PFCR1[APC] field.

Access pipelining is only supported for normal flash access .

NOTE

Not all combinations of PFCR1[APC] (Address Pipeline Control) and PFCR1[RWSC] (Read Wait State Control)

settings are recommended or supported. Please refer to the device data sheet for guidance.

25.6.4 Line read buffers and prefetch operation

The AHB ports of the flash memory controller each contain a four-way set-associative mini cache, where each way contains four page buffers which are used to hold data read from the flash arrays. Each 256-bit buffer operates independently, and is filled using a single array access. The buffers are used for both prefetch and normal demand fetches.

Prefetch triggering is controllable on a per-master and access-type basis (see [Platform Flash Configuration Register 1 \(PFLASH_PFCR1\)](#)). Bus masters may be enabled or disabled from triggering prefetches, and triggering may be further restricted based on whether a read access is for instruction or data. A read access by the flash memory controller may trigger a prefetch to the next sequential line of array data on the cycle following the request. The access address is incremented by 32-bytes, and a subsequent flash access is initiated. A flash array prefetch is initiated if the data is not already resident in a line read buffer. Prefetched data is always loaded into the least-recently-used buffer.

Figure 25-6. Flash memory controller 4-entry, 4-way mini-cache organization

Once the candidate line buffer has been selected, the flash array is accessed and read data loaded into the buffer. If the buffer load was in response to a miss, the buffer which was loaded is immediately marked as most-recently-used. If the buffer load was in response to a speculative fetch to the next-sequential line address after a buffer hit, *the recently-used status is not changed*. Rather, it is marked as most-recently-used only after a subsequent buffer hit.

This policy maximizes performance based on reference patterns of flash accesses and allows for prefetched data to remain valid when non-prefetch enabled bus masters are granted flash access.

Several algorithms are available for prefetch control which trade off performance for power. They are described in [Platform Flash Configuration Register 1 \(PFLASH_PFCR1\)](#). More aggressive prefetching may increase power due to the number of potentially discarded prefetches, but may increase performance by lowering average read latency.

For prefetching to occur, all of the following must apply:

1. PFCR{1,2}[P{0,1}_BFEN] must be set to '1',
2. PFCR{1,2}[P{0,1}_PFLIM] must be non-zero, and
3. Either PFCR{1,2}[P{0,1}_IPFEN] or PFCR{1,2}[P{0,1}_DPFEN] must be asserted.

Refer to [Platform Flash Configuration Register 1 \(PFLASH_PFCR1\)](#) for a description of these controls.

25.6.5 Instruction/Data prefetch triggering

Port0 prefetch triggering may be enabled for instruction reads via the PFCR1[IPFEN] control field, while Port0 prefetching for data reads is enabled via the PFCR1[DPFEN] control field. Additionally, the PFCR1[PFLIM] must also be set to enable prefetching on Port0. Refer to [Platform Flash Configuration Register 1 \(PFLASH_PFCR1\)](#) for a description of these controls. Prefetches are never triggered by write cycles.

Port1 prefetch triggering may be enabled for instruction reads via the PFCR2[IPFEN] control field, while Port1 prefetching for data reads is enabled via the PFCR2[DPFEN] control field. Additionally, the PFCR2[PFLIM] must also be set to enable prefetching on Port1. Refer to [Platform Flash Configuration Register 2 \(PFLASH_PFCR2\)](#) for a description of these controls. Prefetches are never triggered by write cycles.

25.6.6 Per-Master prefetch triggering

Prefetch triggering may be controlled for individual bus masters. Refer to [Platform Flash Configuration Register 1 \(PFLASH_PFCR1\)](#) for a description of these controls.

25.6.7 Buffer allocation

Allocation of the line read buffers is controlled via the PFCR3 control register, specifically the line buffer configuration ({P0,P1}_WCFG) field. Refer to [Platform Flash Configuration Register 3 \(PFLASH_PFCR3\)](#). The buffers can be organized as a "pool" of available resources (with all four ways within a given set) or with a fixed partition between ways allocated to instruction or data accesses. For the fixed partitions, two

configurations are supported. In one configuration, ways 0 and 1 are allocated for instruction fetches and ways 2 and 3 for data accesses. In the second configuration, ways 0, 1 and 2 are allocated for instruction fetches and way 3 reserved for data accesses.

25.6.8 Reliability considerations

This section summarizes mechanism to enhance the reliability of flash by correcting and detecting faults.

25.6.8.1 e2eECC End-to-End ECC

25.6.8.1.1 e2eECC and flash accesses

There are multiple complications associated with the use of the standard e2eECC algorithm with flash memory. The basic issues involve: the default state of a flash block that is erased (all ones) and the fact that programming an erased flash involves changing the state of memory bit from a logical 1 to a logical 0. These factors require that the system level e2eECC must be modified on references to the flash memory in three ways.

First, the all-ones codeword, since it reflects the state of an erased flash location, is treated as a valid error free encoding; in particular, it is required that the checkbits associated with the all all-ones value and the all zeroes data value are required to be the same with a checkbit value of 0xFF. Second, since an erased flash block generates an all-ones data for all locations, the address field cannot be included in the ECC code used by the flash. The flash array implements special address re-encoding logic based on the decoded array address to protect against address faults. Third, there are additional ECC implications associated with the flash memory and its support for EEPROM emulation.

In summary, the basic operation of an NVM bit cell impacts the e2eECC algorithm used in the flash memory in multiple ways. The required ECC adjustments are handled by the platform flash controller before data is written to the flash array(s) or applied to read data accessed from the array(s). These adjustments are two-fold. Consider a flash write during a programming event:

1. Remove the address field from the ECC codeword by XOR'ing the address calculation of the H-matrix from the checkbits.
2. Invert the resulting 8-bit ECC checkbit vector. This step is required to support the all-ones erased state.

On a flash read operation, a similar but "reversed" set of steps are performed as the data is driven into the system bus interconnect:

1. Invert the 8-bit ECC checkbit vector read from the flash.
2. Factor the address field into the ECC checkbits by XOR'ing the address calculation of the H-matrix.

Consider the following flash ECC example. Let the flash block containing address 0x00345678 be erased. The following is the sequence of operations:

1. Read address 0x00345678. Flash array returns `fl_rdata = 0xFFFFFFFF_FFFFFFFF`, `fl_cdata = 0xFF`. The flash memory controller calculates the `addr_chkbit = 0xC4` using the H-matrix; it inverts the `fl_cdata` vector to 0x00 and factors in the `addr_chkbit = 0xC4` to produce the following valid e2eECC codeword:

`addr = 0x00345678`, `rdata = 0xFFFFFFFF_FFFFFFFF`, `rchkbit = 0xC4` ($0x00 \wedge 0xC4$)

2. Program address 0x00345678 with data = 0xBABEFACE_DEADBEEF. The initiating bus master calculates the e2eECC codeword as:

`addr = 0x00345678`, `wdata = 0xBABEFACE_DEADBEEF`, `wchkbit = 0xE3`

Before performing the interlock write to the flash array, the flash memory controller adjusts the `chkbit` value as `fl_wchkbit = 0xD8` ($0xE3 \wedge 0xFF \wedge 0xC4$) by toggling the original write checkbits and then factoring in the `addr_ecc`. Accordingly, the codeword stored in the flash array is:

`fl_data = 0xBABEFACE_DEADBEEF`, `fl_checkbit = 0xD8`

3. Read address 0x00345678. The flash array returns the stored codeword, `fl_rdata = 0xBABEFACE_DEADBEEF`, `fl_rchkbit = 0xD8`. The flash memory controller inverts the checkbit vector and factors in the address checkbits ($0xD8 \wedge 0xFF \wedge 0xC4$) to produce:

`addr = 0x00345678`, `rdata = 0xBABEFACE_DEADBEEF`, `rchkbit = 0xE3`

This read codeword matches the original e2eECC codeword generated by the write.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The flash memory controller performs EDC after ECC check on all flash transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the device fault collection module.

25.6.8.2 Flash address generation check

Fault detection coverage of the address and data are handled by ECC performed within the flash and e2eECC performed at the master. Fault detection coverage of the address path and control within the flash memory controller rely on a feedback path between the flash controller and flash. Recall on a requested access to flash, the flash memory controller must decode the system AHB bus signals to generate the corresponding flash interface signals to invoke a flash lookup. In addition to providing the requested read data, the flash also provides output sidebands reflecting the encoded address and block selects used to perform the actual row lookup.

This sideband information is used by the flash memory controller to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and flash array, the event is forwarded to the device fault collection module and the corresponding buffer is invalidated.

25.6.9 ECC on data flash accesses

For single-bit correction events, the corrected data and checkbits are returned to the requesting master.

In the event of a non-correctable error detection, a fixed, illegal opcode value (1555_1555h) is returned to the requesting master along with the associated ECC checkbits as determined by the requesting address.

When PFCR3[DERR_SUP] is enabled, ECC errors on data flash blocks are suppressed from being reported.

- In the event of a single-bit correction, the corrected data and checkbits are returned to the requesting master, and the single-bit correction event is suppressed from being reported.
- In the event of a non-correctable error detection, a fixed, illegal opcode value (1555_1555h) is returned to the requesting master along with the associated ECC checkbits as determined by the requesting address and the non-correctable error event is suppressed from being reported.

NOTE

EEPROM should be avoided for storage of executable code.

25.6.10 Array integrity considerations

During an array integrity sequence, the flash memory array ignores any incoming read requests. When a flash array integrity check is in progress, the flash memory controller terminates all flash access requests with an error. More specifically, it aborts the incoming flash access requests and terminates the system bus transfer with an error.

Chapter 26

Embedded Flash Memory (C55FMC)

26.1 Chip-specific C55FMC information

NOTE

In production devices of this chip, the one-time-programmable Test Mode Disable Seal is programmed—that is, UTest is sealed—at the factory. For more information about the seal, see [Test mode disable seal](#).

26.1.1 C55FMC register reset values

The following table lists C55FMC register reset values that are specific to this chip. For the reset values of all other C55FMC registers, see [Memory map and register definition](#).

Table 26-1. C55FMC register reset values

Register	Reset value
Extended Module Configuration Register (C55FMC_MCRE)	1001_2020h
Over-Program Protection 0 register (C55FMC_OPP0)	Dependent on customer settings ¹
Over-Program Protection 1 register (C55FMC_OPP1)	
Over-Program Protection 2 register (C55FMC_OPP2)	
Over-Program Protection 3 register (C55FMC_OPP3)	

1. The reset value of the C55FMC_OPPn registers, for each flash memory block mapped to a bit within each register, reflects whether the block has been marked as One Time Programmable (OTP). The C55FMC_OPPn registers have the same bit-to-block mapping as the C55FMC_LOCKn registers. A value of 1 indicates a block has been marked as OTP. The reset values of the C55FMC_OPPn are similar to the reset values of the TDM_OTPENn registers in the Tamper Detection Module (TDM).

26.1.2 Access to and configuration of blocks mapped to C55FMC_LOCK1 register

The CSE has exclusive access to the specific flash memory blocks that are mapped to the C55FMC_LOCK1 register. Other masters on the chip cannot access these particular blocks.

The only C55FMC register that configures the use of the CSE-exclusive blocks is the OPP1 register. The LOCK1 and SEL1 registers do not configure these blocks.

26.1.3 C55FMC_LOCK n register bit mapping

In the main program and erase interface, the C55FMC_LOCK n registers provide a means to protect flash memory blocks from being modified. Each implemented bit in a C55FMC_LOCK n register maps to a specific block.

26.1.3.1 C55FMC_LOCK0 register bit mapping

The flash memory blocks mapped to the [Lock 0 register \(C55FMC_LOCK0\)](#) bits are as follows.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Register Field	Reserved															A256KOPP[15:0]																
Flash Memory Block Name																																

26.2 Introduction

The primary function of the embedded flash memory is to serve as electrically programmable and erasable non-volatile memory (NVM) that may be used for instruction or data storage.

The following figure shows the top-level diagram and functional organization of the flash memory unit.

Figure 26-1. c55fmc block diagram

26.2.1 Overview

The embedded flash memory is addressable by word (32 bits) or double word (64 bits) for program operation, and page (256 bits) for read operation. Multiple word or double-word writes may be done to the flash memory to fill up the program page buffer (256 bits), enabling page programming (256 bits, requiring 4 double-word writes) and quad-page programming (1024 bits, requiring 16 double-word writes). Flash memory reads always return 256 bits, although read page buffering may be performed by the Bus Interface Unit (BIU).

For more details on the embedded flash memory architecture and features, see [Functional Description](#).

26.2.2 Features

The embedded flash memory includes these distinct features:

- Test information stored in a dedicated nonvolatile block (referred to as the UTest block)
- OTP space made available in the UTest block
- Read page size of 256 bits (8 words)
- ECC with single-bit correction, double-bit detection (all 1's valid)
- Quad Page programming (64-bit granularity)
- Software programmable block program/erase restriction control
- Erasing of selected block(s)
- Independent programming of the UTest NVM block
- Embedded hardware program and erase algorithms
- Support for reading while writing when the accesses are to different partitions
- Erase suspend, program suspend, and erase-suspended program
- UTest mode (user-accessible test modes) including Array Integrity and Margin Read
- Triple Voted Flops for flash functions requiring high reliability, e.g., internal trimming, redundancy, and mode control

26.2.3 Modes of operation

Following is a brief description of the embedded flash memory operating modes.

- *User mode* is the default operating mode of the embedded flash memory. In this mode, it is possible to read and write registers, read and interlock write the memory

array, program the memory array, and erase the memory array. In this mode program and erase operations are initiated by doing array and register writes, and are controlled by an internal state machine.

- *UTest mode* is a tiered test mode strategy in which a portion of the factory test modes are made available. This mode is protected but accessible.

26.3 UTest NVM block

The UTest NVM block may be enabled by the BIU. When the UTest NVM space is enabled, all operations are mapped to the UTest NVM block. User-mode programming of the UTest NVM block is enabled only when MCR[PEAS] is high. The UTest NVM block is an OTP block (assuming Test Mode Disable Seal is written) - thus erase is not allowed.

The UTest NVM block supports RWW, and is grouped with the blocks in partition 0.

The UTest NVM block may be locked against program by using the lock registers.

Programming of the UTest NVM space has restrictions that are similar to those of the main space in terms of how ECC is calculated. Only one program operation is allowed per 64-bit ECC segment.

The UTest NVM block contains specified data that is needed for embedded flash memory or SoC features.

26.4 Test mode disable seal

Also included in the UTest NVM block is a mechanism to disable factory entry into Test mode. Extreme care must be taken when using this feature, as blocks that are selected to be protected in this method will not be able to have possible failures analyzed by factory failure analysts. Once sealed, the UTest block becomes OTP (Erase Locked, and Over Program Protection enabled). The UTest Block also is not accessible in Test mode.

Protection of this sort prevents all high-voltage operations to the flash executed by the internal state-machine, as well as reads through this state machine, and reads through the Array Integrity state machine when using Test mode interfaces.

UTest operations Margin Read and Array Integrity are also protected by preventing MISR updates on blocks selected for protection, although reads will still be done and single bit corrections and double bit detections will be logged. Protection through other interfaces is protected by normal User mode protection mechanisms, and are device-specific.

The method to disable factory entry into Test mode is to first program the Test Mode Disable Seal location to be 0x2D3C_4B5A. Once the next reset is asserted, Test mode will be disabled.

It is possible to create a password to enable factory entry into test mode. This can be programmed into the Test Mode Disable Override Passcode. The passcode may not be 0x0000_0000, 0xFFFF_FFFF, or 0x5555_5555. These are all invalid passcodes and will not be accepted to override. If it is desired by the customer that override never be possible, one of the three invalid passcodes should be put into this location. Passcode may be entered to authenticate entry (if enabled) by doing a 32-bit register write to register address 0x90. The UTest NVM block is always protected even if the Test Mode Disable Seal password is written. UTest operations Margin Read and Array Integrity are always protected even if the Test Mode Disable Seal password is written.

Only blocks selected in the Test Mode Disable Block Select field(s) are controlled by the Test Mode Disable feature. Thus it is possible for customers to selectively pick blocks that have this type of protection, and will not be eligible for factory failure analysis. Bits programmed to 0 in the Test Mode Disable Block Select field(s) will designate blocks that are controlled by the Test Mode Disable feature. If either Test Mode Disable Block Select - 0 or Test Mode Disable Block Select - 1 have a 0 programmed, that block will be protected. In order to provide two opportunities to select blocks for the Test Mode Disable, two regions are available, Test Mode Disable Block Select - 0 and Test Mode Disable Block Select - 1. The bit of these two regions are logically ANDed, to define which blocks are effectively selected for the Test Mode Disable feature. The Block Select field is organized as follows, and aligns with how blocks are defined in the LOCK registers.

Table 26-2. Test mode disable block select

Block	Bits used to select blocks
Low Block Disable	Data[13:0]
Unused	Data[15:14]
Mid Block Disable	Data[31:16]
High Block Disable	Data[47:32]
256K Block Disable	Data[95:48]

26.5 Memory map and register definition

The embedded flash memory map consists of a flash memory array (which includes main array space and UTest NVM space) and a region of registers associated with the programming model that enable flash memory array operation and modification.

The address space consists of 16 KB, 32 KB, 64 KB, and 256 KB blocks.

C55FMC_MCR field descriptions

Field	Description
0 RVE	Read Voltage Error RVE provides information on previous reads monitoring the read pump voltage. If the read voltage is detected to be out of range, this bit is set to indicate that previous reads requested may have been

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without voltage issues 1 A previous read may have been corrupted due to read voltage being out of range
1 RRE	Read Reference Error RRE provides information on previous reads monitoring the read reference. If the read reference is detected to be out of range, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without reference issues 1 A previous read may have been corrupted due to read reference being out of range
2 AEE	Address Encode Error AEE provides information on previous reads monitoring the address encode feature. On every read request to the flash, the incoming address is compared to an encoded address (row, column, and block) coming back from the memory array using the read data sense amplifier timing. If these two values do not match (zero selected, multiple selected, wrong selected), or the timing is incorrect, an address encode error will be recorded. If an address encode mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without address encode mismatches 1 A previous read may be corrupted based on address encode mismatch
3 EEE	ECC after ECC Error EEE provides information on previous reads monitoring the ECC after ECC feature. On every read request to the flash, ECC is recalculated serially, and if there is a mismatch between the ECC calculations (taking into account corrections or detections) a late error will be reported. If an ECC after ECC mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without ECC after ECC mismatches 1 A previous read may be corrupted based on ECC calculation errors
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 EER	ECC Event Error This bit provides information on previous reads. If a double bit detection occurred, the EER bit is set to a '1'. This bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be set by software. In the event of a single bit detection and correction, this bit is not set. If EER is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of EER) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring normally. 1 An ECC Error occurred during a previous read.
17 RWE	Read-While-Write Event Error This bit provides information on previous read-while-write (RWW) reads. If an RWW error occurs, this bit is set to 1. The bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be written to a 1. If RWE is not set, or remains 0, this indicates that all previous RWW reads (from the last

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	reset, or clearing of RWE) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring normally. 1 A read-while-write error occurred during a previous read.
18 SBC	Single Bit Correction SBC provides information on previous reads, if the SBCE is set. If a single bit correction occurred, the SBC bit is set to a 1. This bit must then be cleared, or a reset must occur before this bit returns to a 0 state. If SBC is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of SBC) did not require a correction. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without corrections. 1 A Single Bit Correction occurred during a previous read.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 PEAS	Program Access Space PEAS indicates which space is valid for program or erase operations — either main array space or UTest NVM space. It should be noted that if the flash is sealed, and the Test Mode Disable Seal is programmed, erase is not allowed on the UTest NVM space. PEAS = 0 indicates the main address space is active for all program or erase operations. PEAS = 1 indicates the UTest NVM address space is active for program or erase (if applicable) operations. The value in PEAS is captured and held when the UTest NVM block is enabled with the first interlock write done for program operations (and erase operations if the flash is unsealed). The value of PEAS is retained between sampling events (in other words, subsequent first interlock writes). The value in PEAS may be changed during erase-suspended program, and reverts back to its original state once the erase-suspended program is completed. PEAS is read only. 0 UTest NVM address space is disabled for program/erase and main address space enabled. 1 UTest NVM address space is enabled for program/erase and main address space disabled.
21 DONE	State Machine Status DONE indicates whether the embedded flash memory is performing a high voltage operation. DONE is set to a 1 on termination of the embedded flash memory reset. DONE is read only. DONE is set to a 1 at the end of program and erase high voltage sequences. NOTE: This bit transitions from a 0 to 1 during reset and remains at 1 after reset. 0 Flash memory is executing a high voltage operation. 1 Flash memory is not executing a high voltage operation.
22 PEG	Program/Erase Good The PEG bit indicates the completion status of the last flash memory program or erase sequence for which high voltage operations were initiated. The value of PEG is updated automatically during the program and erase high voltage operations. Aborting a program/erase high voltage operation causes PEG to be cleared, indicating the sequence failed. PEG is set to a 1 when the embedded flash memory is reset. PEG is read only. The value of PEG is valid only when PGM = 1 or ERS = 1 and after DONE transitions from 0 to 1 due to an abort or the completion of a program/erase operation. PEG is valid until PGM/ERS makes a 1 to 0 transition or EHV makes a 0 to 1 transition. The value in PEG is not valid after a 0 to 1 transition of DONE caused by PSUS or ESUS being set to logic 1. If PGM and ERS are both 1 when DONE makes a qualifying 0 to 1 transition the value of PEG indicates the completion status of the PGM sequence. This happens in an erase-suspended program operation.

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	PEG will be 0 if an Erase-Suspended Program is attempted to a block that has been selected for Erase. PEG will also be 0 in the event of an error in the interlock write for program only. An error in the interlock write occurs when the ECC value provided to the flash memory does not match the ECC calculated within the flash memory. In the event of this, high voltage will not be applied to the array, and PEG will indicate a failed program. NOTE: 1. If program or erase operations are attempted on blocks that are locked, the response from embedded flash memory is PEG = 1, indicating that the operation was successful, and the contents of the block are properly protected from the program or erase operation. PEG = 1 is also true if an abort occurs during an HV request to a locked block. 2. If a program operation is attempted to a location marked as OTP, the response from the embedded flash memory is PEG = 0, indicating that the operation was not allowed, and the value interlocked was not programmed, since the desired doubleword was already programmed with a previous program operation. 0 Program or erase operation failed. 1 Program or erase operation successful.
23 PECIE	Program/Erase Complete Interrupt Enable PECIE provides a mechanism to trigger an interrupt request upon the assertion of the DONE flag due to a high voltage event (program or erase) finishing (normal, abort, suspend). If PECIE is written while not in a high voltage event, the interrupt will not immediately trigger, but will trigger after the next high voltage event is completed. 0 An interrupt request will not be generated when the DONE flag is set. 1 An interrupt request will be generated when the DONE flag is set.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 PGM	Program PGM is used to set up embedded flash memory for a program operation. A 0 to 1 transition of PGM initiates a program sequence. A 1 to 0 transition of PGM ends the program sequence. PGM can be set only under one of the following conditions: • User mode read (ERS is low and UTE is low) • Erase suspend (ERS and ESUS are 1) with EHV low PGM can be cleared only when PSUS and EHV are low and DONE is high. PGM is cleared on reset. 0 Flash memory is not executing a program sequence. 1 Flash memory is executing a program sequence.
28 PSUS	Program Suspend PSUS is used to indicate the embedded flash memory is in program suspend or in the process of entering a suspend state. The embedded flash memory is in program suspend when PSUS = 1 and DONE = 1. PSUS can be set high only when PGM and EHV are high. A 0 to 1 transition of PSUS starts the sequence which sets DONE and places the embedded flash memory in program suspend. The embedded flash memory enters suspend within Tpsus of this transition. PSUS can be cleared only when DONE and EHV are high. A 1 to 0 transition of PSUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to program. The embedded flash memory cannot exit program suspend and clear DONE while EHV is low. PSUS is cleared on reset. 0 Program sequence is not suspended. 1 Program sequence is suspended.

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
29 ERS	Erase ERS is used to set up embedded flash memory for an erase operation. A 0 to 1 transition of ERS initiates an erase sequence. A 1 to 0 transition of ERS ends the erase sequence. ERS can only be set in user mode read (PGM is low and UTE is low). ERS can be cleared only when ESUS and EHV are low and DONE is high. ERS is cleared on reset. 0 Flash memory is not executing an erase sequence. 1 Flash memory is executing an erase sequence.
30 ESUS	Erase Suspend ESUS is used to indicate that the embedded flash memory is in erase suspend or in the process of entering a suspend state. The embedded flash memory is in erase suspend when ESUS = 1 and DONE = 1. ESUS can be set high only when ERS and EHV are high and PGM is low. A 0 to 1 transition of ESUS starts the sequence which sets DONE and places the flash memory in erase suspend. The embedded flash memory enters suspend within T_{es} of this transition. ESUS can be cleared only when DONE and EHV are high and PGM is low. A 1 to 0 transition of ESUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to erase. The embedded flash memory cannot exit erase suspend and clear DONE while EHV is low. ESUS is cleared on reset. 0 Erase sequence is not suspended. 1 Erase sequence is suspended.
31 EHV	Enable High Voltage The EHV bit enables the embedded flash memory for a high voltage program/erase operation. EHV is cleared on reset. EHV must be set after an interlock write to start a program/erase sequence. EHV may be set, initiating a program/erase, after an interlock under one of the following conditions: • Erase (ERS = 1, ESUS = 0) • Program (ERS = 0, ESUS = 0, PGM = 1, PSUS = 0) • Erase-suspended program (ERS = 1, ESUS = 1, PGM = 1, PSUS = 0) If a program operation is to be initiated while an erase is suspended, EHV must be cleared while in erase suspend before setting PGM. In normal operation, a 1 to 0 transition of EHV with DONE high, PSUS low, and ESUS low terminates the current program/erase high-voltage operation. In an erase-suspended program operation, a 1 to 0 transition of EHV with DONE high, ESUS high, PGM high, ERS high, and PSUS low terminates the program that is the current high voltage operation. When an operation is aborted, there is a 1 to 0 transition of EHV with DONE low and the suspend bit for the current program/erase sequence low. An abort causes the value of PEG to be cleared, indicating a failed program/erase; address locations being operated on by the aborted operation contain indeterminate data after an abort. EHV may not be written to a 1 after an abort is requested (EHV being cleared) and before DONE transitions high. A suspended operation cannot be aborted. EHV may be written during suspend. EHV must be high for the embedded flash memory to exit suspend. EHV may not be written after a suspend bit is set high and before DONE transitions high. EHV may not be set low after the current suspend bit is set low and before DONE transitions low. NOTE: Aborting a high voltage operation leaves FC addresses in an indeterminate data state. This may be recovered by executing an erase on the affected blocks. 0 Flash memory is not enabled to perform a high voltage operation. 1 Flash memory is enabled to perform a high voltage operation.

26.5.2 Extended Module Configuration Register (C55FMC_MCRE)

NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

C55FMC_MCRE field descriptions

Field	Description
0 HT	High Temperature Enabled. HT provides configuration information of the module. If the flash is tuned for high temperature operation (165 °C) at reduced performance (slower read at 165 °C and less and slower program and erase at 150 °C or less), and limited features at this temperature (no margin reads), the HT status bit will be a 1. Default is 150 °C as maximum operating temperature, and the HT status bit will be a 0. HT is read only. 0 150 °C maximum operating temperature. NOTE: 165 °C operating temperature maximum is not supported on this device. 1 Reserved
1–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 n256K	Number of 256 KB blocks. The value of this field is dependent upon the size of the embedded flash memory. This field is read only. 00000 Zero 256 KB blocks. 00001 Two 256 KB blocks (512 KB total). 00010 Four 256 KB blocks (1 MB total). 00011 Six 256 KB blocks (1.5 MB total). 00100 Eight 256 KB blocks (2 MB total).

C55FMC_LOCK0 field descriptions

Field	Description
0 TSLOCK	UTest NVM Lock. This bit is used to lock the UTest NVM block from programs (erase protection not needed since UTest NVM is OTP and not erasable). A value of 1 in the TSLOCK register signifies that the UTest NVM block is locked for program. A value of 0 in the TSLOCK register signifies that the UTest NVM block is available to receive program pulses. The TSLOCK register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, TSLOCK register is not writable if a high voltage operation is suspended.

Table continues on the next page...

C55FMC_LOCK0 field descriptions (continued)

Field	Description
	0 UTest NVM block is available to be programmed. 1 UTest NVM block is locked and cannot be programmed.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 LOWLOCK	Low Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Low Blocks starts at LOWLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. Low Blocks exist in partitions 0 and 1. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations
16–31 MIDLOCK	Mid Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Mid Blocks starts at MIDLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. Mid Blocks exist in partitions 2 and 3. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations

26.5.4 Lock 1 register (C55FMC_LOCK1)

The Lock 1 (LOCK1) register provides a means to protect blocks from being modified.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
16–31 MIDSEL	Mid Block Select. A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the Mid Blocks starts at MIDLSEL[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Mid Blocks exist in partitions 2 and 3. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. MIDSEL is also not writable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 0 The block is not selected 1 The block is selected for erase

26.5.8 Select 1 register (C55FMC_SEL1)

The Select 1 (SEL1) register provides a means to select blocks to be operated on during erase.

Address: 0h base + 3Ch offset = 3Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

C55FMC_SEL3 field descriptions

Field	Description
0–15 Reserved	This field is reserved. Reserved, reset to 0.
16–31 A256KSEL	256 KB Block Select. A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the 256 KB blocks starts with 256KSEL[0] and continues until all blocks are accounted. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. 256KSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 1 The block is selected for erase. 0 The block is not selected.

26.5.11 Address register (C55FMC_ADR)

The Address register (ADR) provides the first failing address in the event of a failure (ECC or PGM/Erase state machine), as well as single bit correction information.

Address: 0h base + 50h offset = 50h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SAD	aH	aM	aL	a256k	a64k	a32k	a16k	ADDR							
W

R	ADDR														0	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C55FMC_ADR field descriptions

Field	Description
0 SAD	UTest NVM Address. The SAD bit qualifies the address captured during an ECC Event Error, Single Bit Correction, or State Machine operation. SAD has the same characteristics as ADDR related to capturing of addresses. The SAD field is not writable. 0 Address captured is from main array Space. 1 Address captured is from UTest NVM array space.
1 aH	Address High region. The aH bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aH is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from high address region. 1 Address captured or to be accessed is from high address region.
2 aM	Address Mid region. The aM bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aM is set, then the ADDR field maps to that region. See ADDR description for more information.

Table continues on the next page...

C55FMC_ADR field descriptions (continued)

Field	Description
	0 Address captured or to be accessed is not from mid address region. 1 Address captured or to be accessed is from mid address region.
3 aL	Address Low region. The aL bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aL is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from low address region. 1 Address captured or to be accessed is from low address region.
4 a256k	Address 256 KB region. The a256k bit qualifies the address field (ADDR) to the region. If a256k is set, then the ADDR field maps to that region. See ADDR description for more information. The a256k register is writable. 0 Address captured or to be accessed is not from 256 KB region. 1 Address captured or to be accessed is from 256 KB region.
5 a64k	Address 64 KB region. The a64k bit qualifies the address field (ADDR) to the region. If a64k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 64 KB region. 1 Address captured or to be accessed is from 64 KB region.
6 a32k	Address 32 KB region. The a32k bit qualifies the address field (ADDR) to the region. If a32k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 32 KB region. 1 Address captured or to be accessed is from 32 KB region.
7 a16k	Address 16 KB region. The a16k bit qualifies the address field (ADDR) to the region. If a16k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 16 KB region. 1 Address captured or to be accessed is from 16 KB region.
8–28 ADDR	Address. The ADR provides the first failing address in the event of ECC event error (EER set), Single Bit Correction (SBC set), as well as providing the address of a failure that may have occurred in a state machine operation (PEG cleared). ECC event errors take priority over Single Bit Corrections, which take priority over state machine errors. This is especially valuable in the event of an RWW operation, where the read senses an ECC error or Single Bit correction, and the state machine fails simultaneously. The failing address for ECC event error is held until EER is cleared. The failing address for Single Bit Correction is held until an ECC event error, or until SBC is cleared. State machine address is held until an ECC event error or Single Bit Correction event occurs, or until the next state machine event (PEG cleared) occurs. This address is always a doubleword address that selects 64 bits. ADDR[23:3] is an offset from a base address of 0x0 for each block size region. The aH, aM, aL, a16k, a32k, a64k, and a256k qualify the block size region the ADDR field.
29–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

26.5.12 UTest 0 register (C55FMC_UT0)

The User Test 0 (UT0) register provides a means to control UTest. UTest mode gives the ability to perform test features on the flash memory. This register is only writable when the flash memory is put into UTest mode by writing a passcode.

Address: 0h base + 54h offset = 54h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R			0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

C55FMC_UT0 field descriptions

Field	Description
0 UTE	U-Test Enable. This status bit gives indication when U-Test is enabled. All bits in UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 are locked when this bit is 0. This bit is not writeable to a 1, but may be cleared. The reset value is 0. The method to set this bit is to provide a password, and if the password matches, the UTE bit is set to reflect the status of enabled, and is enabled until it is cleared by a register write. The UTE password will only be accepted if PGM = 0 and ERS = 0 (program and erase are not being requested). UTE can only be cleared if AID = 1, MRE and AIE = 0. While clearing UTE, writes to set AIE or MRE will be ignored. For UTE, the password 0xF9F9_9999 must be written to the UT0 register. 0 All bits in the UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 registers are locked 1 Bits in the UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 registers are unlocked
1 SBCE	Single Bit Correction Enable. SBCE enables Single Bit Correction results to be observed in SBC. ECC corrections that occur when SBCE is cleared will not be logged.

Table continues on the next page...

C55FMC_UT0 field descriptions (continued)

Field	Description
	0 Single Bit Corrections observation is disabled. 1 Single Bit Correction observation is enabled.
2–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 CPR	Customer Programmable Read Voltage and Reference Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Read Voltage and Reference Error detection will be noted. This bit may not be set while CPE and CPA are set. If CPE or CPA are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable Read Voltage and Reference Detection Error is not enabled 1 Customer Programmable Read Voltage and Reference Detection Error is enabled
14 CPA	Customer Programmable Address Encode Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Address Encode Error detection will be noted. This bit may not be set while CPE and CPR are set. If CPE or CPR are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable Address Encode Detection Error is not enabled 1 Customer Programmable Address Encode Detection Error is enabled
15 CPE	Customer Programmable EDC after ECC Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a EDC after ECC Error detection will be noted. This bit may not be set while CPR and CPA are set. If CPR or CPA are high, this bit will be locked. If attempts are made o write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable EDC after ECC Detection Error is not enabled 1 Customer Programmable EDC after ECC Detection Error is enabled
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 NAIBP	Next Array Integrity Break Point. If AIBPE is set, NAIBP will be set once a single bit correction (if enabled) or double bit detection is noted during the Array Integrity test. NAIBP is not writable to 1, but may be cleared to 0. Clearing NAIBP to 0, will enable the Array Integrity operation to be re-started after a breakpoint is encountered. If the Array Integrity operation completes without encountering another correction or detection, AID will be set with NAIBP remaining 0. 1 Array Integrity state machine is at a break point. 0 Array Integrity state machine is not currently at a break point.
23 AIBPE	Array Integrity Break Point Enable. If you want to enable breakpoints during an array integrity test, AIBPE may be set. See NAIBP description for more information about array integrity breakpoints. 1 Array Integrity breakpoints are enabled during Array Integrity Checks. 0 Array Integrity breakpoints are not enabled.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 AISUS	Array Integrity Suspend. AISUS enables a suspend of an Array Integrity Operation. Array Integrity may be suspend by Setting AISUS, and resumed by clearing AISUS. AISUS is writeable only when AID is low. AISUS is clearable only when AID is high. Attempting to write AISUS and AIE on the same clock cycle will result in only AIE getting written.

Table continues on the next page...

C55FMC_UT0 field descriptions (continued)

Field	Description
	1 Array integrity sequence is suspended. 0 Array integrity sequence not suspended.
26 MRE	Margin Read Enable. MRE combined with MRV enables user margin reads to be done. Normal user reads are not affected by MRE, although user reads while the margin read operation is ongoing are not supported. MRE is not writable if AID is low, or if AISUS is high, or if NAIBP is high. 1 Margin reads are enabled. 0 Margin reads are not enabled.
27 MRV	Margin Read Value. MRV selects the margin level that is being checked. Margin can be checked to an erased level (MRV=1) or to a programmed level (MRV=0). In order for this value to be valid, MRE must also be set. MRV is not writable if AID is low, or if AISUS is high, or if NAIBP is high. 1 One's margin reads are requested. 0 Zero's margin reads are requested.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 AIS	Array Integrity Sequence. AIS determines the address sequence to be used during array integrity checks. The default sequence (AIS = 0) is meant to replicate sequences that normal user code follows, and thoroughly checks the read propagation paths. This sequence is proprietary. The alternative sequence (AIS = 1) is logically sequential. It should be noted that the time to run a sequential sequence is shorter than the time to run the proprietary sequence. AIS is not writeable if AIE is high. 1 Array integrity sequence is sequential. 0 Array integrity sequence is proprietary sequence.
30 AIE	Array Integrity Enable. AIE set to one starts the array integrity check done on all selected blocks. The address sequence is determined by AIS, and the MISR (UM0 through UM9) can be checked after the operation is complete, to determine if a correct signature has been obtained. Once an array integrity operation is requested (AIE=1), it may be terminated by clearing AIE if the operation has finished (AID = 1) or aborted by clearing AIE if the operation is ongoing (AID = 0). AIE is not simultaneously writable to a 1 as UTE is being cleared to a 0. 0 Array integrity checks are not enabled. 1 Array integrity checks are enabled.
31 AID	Array Integrity Done. AID is cleared upon an array integrity check being enabled (to signify the operation is ongoing). Once completed, AID is set to indicate that the array integrity check is complete. At this time the MISR (UMR registers) can be checked. AID may also assert if breakpoints are enabled (AIBPE is set), an abort is requested or a suspend is requested. AID cannot be written, and is status only. 0 Array integrity check is ongoing. 1 Array integrity check is done.

26.5.13 UMISR register (C55FMC_UMn)

The Multiple Input Signature registers provide a means to evaluate array integrity.

Address: 0h base + 58h offset + (4d × i), where i=0d to 8d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	MISR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C55FMC_UMn field descriptions

Field	Description
0–31 MISR	MISR[31:0]. The MISR registers accumulate a signature from an array integrity event. The MISR captures all data fields, as well as ECC fields, and the ECC error signal. Data (read and ECC) captured in the MISR is after the ECC logic, and represents corrected data (if required). The MISR can be seeded to any value by writing the MISR registers. NOTE: Writing the MISR register during an array integrity operation (including suspend or breakpoint) although possible, is not recommended. A write of the MISR registers at this point may alter the final signature in an unpredictable way. The MISR register provides a means to calculate a MISR during array integrity operations. The MISR can be represented by the following polynomial: $x^{289} + x^7 + x^6 + x^5 + x^4 + x^2 + 1$ The MISR is calculated by taking the previous MISR value and then "exclusive ORing" the new data. In addition the most significant bit (in this case it is MISR[288]), is then "exclusive ORed" into input of MISR[7], MISR[6], MISR[5], MISR[4], MISR[2] and MISR[0]. The result of the "exclusive OR" is shifted left on each read. The MISR register is used in array integrity operations. If during address sequencing, reads extend into an invalid address location (in other words, greater than the maximum address for a given array size) then reads are still executed to the array, but the results from the array read are not deterministic. In this instance, the MISR registers is not recalculated, and the previous value is retained.

26.5.14 UMISR register (C55FMC_UM9)

The Multiple Input Signature registers provide a means to evaluate array integrity.

Address: 0h base + 7Ch offset = 7Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

* Notes:

- MIDOPP field: The reset value of the MIDOPP field is set at the factory and varies among devices. See the chip-specific C55FMC information for details.
- LOWOPP field: The reset value of the LOWOPP field is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

C55FMC_OPP0 field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 LOWOPP	Low Block Over-Program Protection[13:0]. A value of 1 in a bit of the over-program protection register signifies that the corresponding block is protected from over-programming. A value of 0 in the OPP register signifies that the corresponding block is available to be over-programmed. The block numbering for the Low Blocks starts at LOWOPP[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOWOPP register is not writable, and is status only. The default value of the LOWOPP bits is not OPP. In the event that blocks are not present (due to configuration or total memory size), the OPP bits default not OPP, and will remain 0. 1 The corresponding block is protected from over-programming. 0 The corresponding block is available to be over-programmed.
16–31 MIDOPP	Mid Block Over-Program Protection[15:0]. A value of 1 in a bit of the over-program protection register signifies that the corresponding block is protected from over-programming. A value of 0 in the OPP register signifies that the corresponding block is available to be over-programmed. The block numbering for the Mid Blocks starts at MIDOPP[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for.

Table continues on the next page...

C55FMC_OPP0 field descriptions (continued)

Field	Description
	The MIDOPP register is not writable, and is status only. The default value of the MIDOPP bits is not OPP. In the event that blocks are not present (due to configuration or total memory size), the OPP bits default not OPP, and will remain 0. 1 The corresponding block is protected from over-programming. 0 The corresponding block is available to be over-programmed.

26.5.16 Over-Program Protection 1 register (C55FMC_OPP1)

The Over-Program Protection 1 (OPP1) register provides a means to protect blocks from being over programmed. This register shows the over-program protection status.

NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

Address: 0h base + 84h offset = 84h

C55FMC_OPP1 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 HIGHOPP	High Block Over-Program Protection[15:0]. A value of 1 in a bit of the over-program protection register signifies that the corresponding block is protected from over-programming. A value of 0 in the OPP register signifies that the corresponding block is available to be over-programmed. The block numbering for the High Blocks starts at HIGHOPP[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. The HIGHOPP register is not writable, and is status only. The default value of the HIGHOPP bits is not OPP. In the event that blocks are not present (due to configuration or total memory size), the OPP bits default not OPP, and will remain 0. 1 The corresponding block is protected from over-programming. 0 The corresponding block is available to be over-programmed.

26.5.17 Over-Program Protection 2 register (C55FMC_OPP2)

The Over-Program Protection 2 (OPP2) register provides a means to protect blocks from being over programmed. This register shows the over-program protection status.

NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

26.6 Functional Description

The embedded flash memory consists of address spaces in four groupings:

- Low address space
- Mid address space
- High address space
- 256 KB address space

The main address space is divided into partitions. Each address space mentioned above consists of a partition pair. Partitions are used to determine locations for valid read-while-write (RWW) operations. While the embedded flash memory is performing a write (program or erase) to a given partition, it can simultaneously perform a read from any other partition. For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written). For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.

The main address space is also divided into blocks to implement independent erase and program protection. The UTest NVM block also exists as a block, and has independent program protection. The UTest NVM block is included to support systems that require nonvolatile memory (NVM) for security or to store system initialization information.

A number of MCR bits are protected against write when another bit, or set of bits, is in a specific state. These write locks are covered on a bit-by-bit basis in [Module Configuration Register \(C55FMC_MCR\)](#). The write locks do not consider the effects of trying to write two or more bits simultaneously. The embedded flash memory does not allow bits to be written simultaneously which put the device into an illegal state. This is implemented through a priority mechanism among the bits. The bit changing priorities are detailed in the following table.

Table 26-32. MCR bit set/clear priority levels

Priority level	MCR Bit(s)
1	ERS
2	PGM
3	EHV
4	ESUS, PSUS

If two or more MCR bits are written simultaneously only the bit with the lowest priority number is accepted for modification. Setting two bits with the same priority number is prevented by existing write locks or do not put the flash memory in an illegal state.

For example, setting ERS and PGM simultaneously results in only ERS being set. Attempting to clear EHV while setting PSUS results in EHV being cleared, while PSUS is unaffected.

Each read of the embedded flash memory retrieves a page, or eight consecutive words (256 bits), of information. The address for each word retrieved within a page differs from the other addresses in the page only by address bits [4:2]. The flash memory page read architecture easily supports both cache and burst mode at the BIU level for high-speed read applications.

The embedded flash memory supports fault tolerance through error correction code (ECC) and error detection. ECC implemented within the embedded flash memory corrects single-bit failures and detects double-bit failures.

A software mechanism is provided to independently lock and unlock each block.

Program and erase of the embedded flash memory requires multiple system clock cycles to complete. The program and erase sequence may be suspended or aborted.

The embedded flash memory may reside in various modes. The modes that are available include:

- User mode
- UTest mode

Each of these modes is discussed in detail in the following sections.

26.6.1 User Mode

In user mode the embedded flash memory may be read and written (register writes and interlock writes), programmed or erased. The following sub-sections define all actions that may be performed in user mode.

26.6.1.1 Read and write

The default state of the embedded flash memory is read. The main and UTest NVM address space can be read only in the read state. The MCR is always available for read. The embedded flash memory enters the read state on reset. The embedded flash memory is in the read state under four sets of conditions:

- The read state is active when the embedded flash memory is enabled (User Mode Read).
- The read state is active when MCR[PGM] or MCR[ERS] are high and high-voltage operation is ongoing (read-while-write).

NOTE

Reads done to the partition(s) being operated on (either erased or programmed) result in an error and the MCR[RWE] bit is set.

- The read state is active when MCR[PGM] and MCR[PSUS] are high (program suspend).
- The read state is active when MCR[ERS] and MCR[ESUS] are high and MCR[PGM] is low (erase suspend).

In embedded flash memory, flash core reads return 256 bits (1 page). Register reads return 32 bits of data.

NOTE

Flash core reads are done through the BIU. In many cases the BIU does read page buffering to allow sequential reads to be done with higher performance. This could provide a data coherency issue that must be handled with software. Data coherency may be an issue after a program or erase operation, as well as UTest NVM block operations.

In user mode, registers may be written. Array may be written to do interlock writes.

Register reads to unmapped register address space return all zeroes.

Register writes to unmapped register address space have no effect.

Interlock writes that are attempted during a high-voltage operation (MCR[EHV] = 1 or MCR[DONE] = 0) will result in the interlock write being ignored, and address and data will not be updated.

NOTE

Care must be taken when doing 32-bit interlock writes. Performing two 32-bit interlock writes to the same word location is not supported. In addition, mixing 32-bit interlock writes with 64-bit interlock writes to the same double-word location is not supported. If these combinations are done, and a program operation is executed, the result will be MCR[PEG] = 0. See the Module Configuration Register (MCR) section for more information.

26.6.1.2 Program

A flash memory program sequence operates on any page within the flash core. Within a page, up to eight words may be altered in a single program operation. Also, up to four pages can be altered in a single program operation. Whenever the array is programmed, the ECC bits also get programmed. ECC is handled on a 64-bit boundary. Thus, if only one word in any given 64-bit ECC segment is programmed, the adjoining word (in that segment) should not be programmed, since ECC calculation has already completed for that 64-bit segment. Attempts to program the adjoining word will probably result in an operation failure. It is recommended that all programming operations be from 64 bits to 1024 bits, and be 64-bit aligned. The programming operation should completely fill selected ECC segments within the page. Only one program is allowed per 64-bit ECC segment between erases.

Warning

In rare cases over-programming of a 64-bit ECC segment may be done (EEPROM emulation).

Programming changes the value stored in an array bit from logic 1 to logic 0 only. Programming cannot change a stored logic 0 to a logic 1.

NOTE

If a logic 0 is attempted to be over-programmed by a logic 1, the resulting operation will fail ($MCR[PEG] = 0$), and the 0's that are interlocked will be merged (ORed) with 0's that are already present in the 64-bit ECC segment, unless the block is designated as an Over-Program Protected block.

Addresses in locked/disabled blocks cannot be programmed. Values may be programmed in any or all of eight words, within a page, with a single program sequence. Page-bound words have addresses which differ only in address bits [4:2]. Up to four pages can be programmed at once on a quad-page boundary, which differ only in address bits [6:5]. The program operation consists of the following sequence of events:

1. Change the value in the $MCR[PGM]$ bit from a 0 to a 1.

NOTE

Ensure the block that contains the address to be programmed is unlocked.

2. Write the first address to be programmed with the program data. The embedded flash memory latches address bits [22:7] and SoC-specific UTest NVM enable at this time. The embedded flash memory latches data written as well. This write is referred to as

a program data interlock write. An interlock write may be done as a 64-bit transaction or a 32-bit transaction. Refer to the Flash Memory Controller chapter for information on the size of writes that are allowed.

3. If more than one word or doubleword is to be programmed, write each additional address in the page with data to be programmed. This is referred to as a program data write. The embedded flash memory ignores address bits [22:7] and SoC-specific UTest NVM enable for program data writes. All unwritten data words default to 0xFFFF_FFFF.
4. Write a logic 1 to the MCR[EHV] bit to start the internal program sequence or skip to step 9 to terminate.
5. Wait until the MCR[DONE] bit goes high.

NOTE

Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more addresses are to be programmed, return to step 2.
9. Write a logic 0 to the MCR[PGM] bit to terminate the program sequence.

The first write after a program is initiated determines the quad-page address to be programmed. Program may be initiated with the 0 to 1 transition of the MCR[PGM] bit or by clearing the MCR[EHV] bit at the end of a previous program. This first write is referred to as an interlock write. The interlock write determines if the UTest NVM or normal array space is to be programmed by sampling SoC-specific UTest NVM enable and causing MCR[PEAS] to be set/cleared.

In the case of an erase-suspended program, the values in MCR[PEAS] may be modified via the program interlock write, enabling erase-suspended programs to and from UTest NVM space.

An interlock write must be performed before setting MCR[EHV]. A program sequence may be terminated by clearing MCR[PGM] prior to setting MCR[EHV].

After the interlock write, additional writes affect the data to be programmed at the word location determined by address bits [4:2], as well as the page location within a 1024-bit segment (determined by address bits [6:5]). Unwritten locations default to a data value of 0xFFFF_FFFF. If multiple writes are done to the same location, the data for the last write is used in programming.

While DONE is low, EHV is high, and PSUS is low, then EHV may be cleared, resulting in a program abort. A program abort forces the embedded flash memory to step 8 of the program sequence. An aborted program results in PEG being set low, indicating a failed operation. The data space being operated on before the abort contains indeterminate data. A program sequence may not be aborted while in program suspend.

Warning

Aborting a program operation leaves the flash core addresses being programmed in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

26.6.1.2.1 Program software locking

A software mechanism is provided to independently lock/unlock blocks against program and erase.

Software locking is done through the LOCK0, LOCK1, LOCK2, and LOCK3 registers. These may be written through register writes, and may be read through register reads.

26.6.1.2.2 Program hardware locking

Hardware locking which only affects the program operation is also available for UTest, 16 KB, 32 KB, 64 KB, and 256 KB blocks.

26.6.1.2.3 Program suspend/resume

The program sequence may be suspended to allow read access to the flash core. It is not possible to erase during a program suspend, or to program during a program suspend. These operations are prevented by register locking described in the Module Configuration Register (MCR) section. Read-while-write operation may also be used to read the array during a program sequence, providing the read is to a different partition.

A program suspend can be initiated by changing the value of the MCR[PSUS] bit from a 0 to a 1. MCR[PSUS] can be set high at any time when MCR[PGM] and MCR[EHV] are high. A 0 to 1 transition of MCR[PSUS] causes the embedded flash memory to start the sequence to enter program suspend, which is a read state. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended. At this time flash core reads may be attempted. Once suspended, the flash core may only be read. During suspend, all reads to flash core locations targeted for program, and blocks targeted for erase, return indeterminate data.

The program sequence is resumed by writing a logic 0 to MCR[PSUS]. MCR[EHV] must be set to a 1 before clearing MCR[PSUS] to resume operation. When the operation resumes, the embedded flash memory continues the program sequence from one of a set of predefined points. This may extend the time required for the program operation.

NOTE

Repeated suspends at a high frequency may result in the operation not completing normally. Although suspend frequency is not limited, enabling at least 20 μ s between suspend resume and future suspend requests improve the opportunity for the flash to complete the operation successfully.

26.6.1.2.4 Over-program protection enable

One-time programming can be enabled on a block basis. In an over-program protection enabled block, any doubleword which has already been programmed cannot be programmed again. The over-program protection enable does not affect erase operation. Attempts to over-program will result in MCR[PEG] being cleared. If any doubleword within the quad-page has an over-program protection violation, MCR[PEG] will be cleared, and no doublewords will be programmed.

One-time programming can be enabled for 16 KB, 32 KB, 64 KB, or 256 KB blocks.

Over-program protection is enabled by sideband signals, and if enabled, the program operation will be modified to check for programmed bits prior to doing a high-voltage program event.

26.6.1.2.5 Successful program address

To enable the SoC to create logic to authenticate operations with a program (such as in a diary operation), the flash module provides the last successful address programmed as a sideband signal. This value will be held until the next successful program. A successful program is defined as a program operation of data that is not all 1's to an unlocked block, and the operation results in MCR[PEG] returning a 1. If any doubleword within the pages being programmed is interlocked with all 1's, the sideband signal will not be updated. An address of all 1's, and each of the block size selects selected, is the default (and invalid) address after reset.

26.6.1.3 Erase

Erase changes the value stored in all bits of the selected block(s) to logic 1. An erase sequence operates on any combination of blocks in the main address space. The erase sequence is fully automated within the flash memory. Blocks to be erased must be selected prior to initiating the erase sequence. Locked/disabled blocks cannot be erased. If multiple blocks are selected for erase during an erase sequence, the blocks are erased sequentially starting with the lowest numbered block and terminating with the highest (low first, mid second, high last, 16 KB first, 32 KB second, 64 KB third, last blocks are 256 KB). The erase sequence consists of the following events:

1. Change the value in the MCR[ERS] bit from 0 to 1.
2. Select the block or blocks to be erased by writing ones to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers.

NOTE

Lock and Select are independent. If a block is selected and locked, no erase occurs.

3. Write to any address in flash memory. This is referred to as an erase interlock write. An erase interlock write to UTest NVM space is not allowed if sealed (since erase is not allowed in the UTest NVM space when sealed).
4. Write a logic 1 to the MCR[EHV] bit to start an internal erase sequence or skip to step 9 to terminate.
5. Wait until the MCR[DONE] bit goes high.

NOTE

Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more blocks are to be erased, return to step 2.
9. Write a logic 0 to the MCR[ERS] bit to terminate the erase.

After setting ERS, one write, referred to as an interlock write, must be performed before EHV can be set to a 1. Data words written during erase sequence interlock writes are ignored. The erase sequence may be terminated by clearing ERS before setting EHV.

An erase operation may be aborted by clearing EHV, assuming DONE is low, EHV is high, and ESUS is low. An erase abort forces the embedded flash memory to step eight of the erase sequence. An aborted erase results in PEG being set low, indicating a failed operation. The block(s) being operated on before the abort contain indeterminate data. An erase sequence may not be aborted while in erase suspend.

26.6.1.3.1 Erase software locking

Software Locking affect erase operation. For details on this see [Program software locking](#).

26.6.1.3.2 Erase hardware locking

Hardware locking which only affects the erase operation is also available for UTest, 16 KB, 32 KB, 64 KB, and 256 KB blocks.

26.6.1.3.3 Erase suspend/resume

The erase sequence may be suspended to allow read access to the flash core. The erase sequence may also be suspended to program (Erase-Suspended Program) the flash core. A program started during erase suspend can in turn be suspended. Only one erase suspend and one program suspend are allowed at a time during an operation. It is not possible to erase during an erase suspend, or program during a program suspend. During suspend, all reads to flash core locations targeted for program and blocks targeted for erase return indeterminate data.

Read-while-write operation may also be used to read the array during an erase sequence, provided the read is to a partition not selected for erase.

An erase suspend can be initiated by changing the value of the MCR[ESUS] bit from a 0 to a 1. MCR[ESUS] can be set to a 1 at any time when MCR[ERS] and MCR[EHV] are high and MCR[PGM] is low. A 0 to 1 transition of MCR[ESUS] causes the embedded flash memory to start the sequence which places it in erase suspend. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended and further actions are attempted. Once suspended, the array may be read or a program sequence may be initiated (erase-suspended program). Before initiating a program sequence, MCR[EHV] must first be cleared. If a program sequence is initiated, the values of SoC-specific UTest NVM enable is recaptured. Once the erase-suspended program is completed, the value of PEAS is returned to its erase value. Flash core reads that occur while MCR[ESUS] = 1 from the block(s) being erased will return indeterminate data.

The erase sequence is resumed by writing a logic 0 to MCR[ESUS]. MCR[EHV] must be set to a 1 and MCR[PGM] must be cleared (in the event of an erase-suspended program) before MCR[ESUS] can be cleared to resume the operation. The embedded flash memory continues the erase sequence from one of a set of predefined points. This may extend the time required for the erase operation.

NOTE

1. In an erase-suspended program, programming flash core locations in blocks which were being operated on will respond by completing the operation with a fail code (MCR[PEG] = 0). Programming voltages will not be applied to the memory array in this case.
2. Repeated suspends at a high frequency may result in the operation not completing normally. Although suspend frequency is not limited, enabling at least 5ms between suspend resume and future suspend requests improve the opportunity for the flash to complete the operation successfully.

26.6.2 UTest mode

UTest mode is a mode into which customers can put the embedded flash memory so as to do specific tests that check the integrity of the embedded flash memory.

26.6.2.1 Array integrity self check

The Array Integrity (AI) operation is a flash-specific self-test feature in which a MISR signature value is generated from data read from selected flash blocks. After the operation is complete, customer code compares the resulting MISR signature to the expected value to determine if an incorrect read or ECC detection occurred.

Array integrity operations are fully contained within the flash module. Results of Array integrity operations are not reported beyond the boundary of the flash module.

During array integrity test, user mode array reads are ignored to ensure the array integrity operation is not corrupted. User mode array reads may be executed if suspended or at a breakpoint.

AI read operations are executed using a predefined address sequence selected via the UT0[AIS] register field value. The data to be read is customer-specific, e.g., user program code that has been programmed into the flash memory. Any random or nonrandom code is valid. The expected MISR signature is calculated based on the specific data to be read.

Note that array integrity MISR signature calculations are performed after ECC detection and correction so correctable ECC events do not cause the MISR signature to deviate from the expected value.

The Array integrity check consists of the following sequence:

1. Enable UTest mode by setting the UT0[UTE] bit to 1.
2. Select one or more blocks for an array integrity check by writing 1's to the appropriate bits in the SEL0 – SEL3 registers. Blocks selected for AI test do not need to be unlocked.

Flash blocks that have not been selected are still read as part of the array integrity sequence to enable full transition coverage. Reads on unselected blocks are not captured in the MISR. Selecting fewer blocks may not result in a faster array integrity execution time, depending on the combinations of blocks selected and the sequence.

Blocks protected with the Test Mode Disable Seal are still read as part of the array integrity sequence. The resulting read on sealed blocks is not captured in the MISR, but the Single Bit Correction, Double Bit Detection and breakpoints are still honored.

NOTE

It is not possible to do array integrity operations on the UTest NVM block.

3. If desired, set the UT0[AIS] bit to 1 for sequential addressing only.

For normal integrity checks of the flash memory, sequential addressing is recommended. If it is required to more fully check the read path (in a diagnostic mode), it is recommended that UT0[AIS] be left at 0, to use the address sequence that checks the read path more fully, and examine read transitions. This sequence takes more time.

4. Seed the MISR registers (UM0 — UM9) with desired values.
5. If breakpoints are desired, set UT0[AIBPE] to 1, and ensure that MCR[EER] and MCR[SBC] are cleared. If it is desired to break on single-bit correction, the UT0[SBCE] must be set.
6. Initiate AI by setting the UT0[AIE] bit to 1.

The array integrity operation may be aborted prior to UT0[AID] going high. This may be done by clearing the UT0[AIE] bit and continuing to the next step. It should be noted that in the event of an aborted array integrity check the MISR registers contain a signature for the portion of the operation that was completed prior to the abort, and are not deterministic. Prior to doing another array integrity operation, the UM0 – UM9 registers may need to be initialized to the desired seed value by doing register writes.

The array integrity operation may be suspended prior to UT0[AID] going high. UT0[AISUS] may be set to request an array integrity suspend. After the UT0[AISUS] bit is set, the user should wait for UT0[AID] bit to go high, which

indicates the flash has entered the suspend state, and normal reads to the flash may be done. After the UT0[AID] bit goes high, the UT0[AISUS] bit may be cleared to resume the array integrity sequence.

7. Wait until the UT0[AID] bit goes high, indicating that array integrity test is complete.
8. If breakpoints are enabled, check the UT0[NAIBP] bit. If set to 1, the MCR[EER], MCR[SBC], and ADDR registers may be checked to determine the cause of the break and the address of the break. Prior to resuming the operation, clear the MCR[SBC] or MCR[EER] bits, then resume the operation by clearing the UT0[NAIBP] bit. Continue to wait until the UT0[AID] bit goes high. If breakpoints are not enabled, or if the UT0[NAIBP] bit is low when the UT0[AID] bit goes high, the operation is complete. Continue to the next step.
9. Read values in the MISR registers (UM0 — UM9) to ensure correct signature.

NOTE

Array integrity reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

10. Write a logic 0 to the UT0[AIE] bit to complete array integrity test.

26.6.2.2 User margin read

User Margin Read is a flash-specific self-test feature that enables reads to be done at a Program margin or Erase margin level.

Margin reads are performed with an internal read reference voltage that has been adjusted, i.e., "margined" toward the threshold voltage being checked. The read reference voltage is either margined toward a 0 (programmed bit) or margined towards a 1 (erased bit), depending on the margin read operation selected.

User margin read is done using the array integrity interface, and has all the associated features of the array integrity interface (MISR and Breakpoints). User margin read is a self-timed event, and is independent of system clocks or wait states selected.

Margin read operations are fully contained within the flash module. Results of margin read operations are not reported beyond the boundary of the flash module.

During margin read operations, user mode array reads are ignored to ensure the operation is not corrupted. User mode array reads may be executed if suspended or at a breakpoint.

ECC corrections and detections are noted during the user margin read test. Note that margin read MISR signature calculations are performed *after* ECC detection and correction so correctable ECC events do not cause the MISR signature to deviate from the expected value.

The data to be read is customer-specific, e.g., user program code that has been programmed into the flash memory. Any random or non-random code is valid. The expected MISR signature is calculated based on the specific data to be read. After the operation is completed the margin read results can be checked by reading the MCR[EER] and MCR[SBC] bits to determine if zero, one, or two bits are being detected by the margin read, and comparing the generated MISR signature to the expected value.

The use model for margin read is in the event of a user-detected single bit correction (through user reads). A margin read may be done to check for a possible second bit falling within the selected margin levels.

The procedure for doing margin reads is:

1. Enable UTest mode by setting the UT0[UTE] bit to 1.
2. Select one or more blocks for margin read check by writing 1's to the appropriate bits in SEL0 – SEL3 registers. Blocks selected for margin read do not need to be unlocked.

Flash blocks that have not been selected are still read as part of the margin read sequence to enable full transition coverage. Reads on unselected blocks are not captured in the MISR. Selecting fewer blocks does not result in a faster margin read execution time.

Blocks protected with the Test Mode Disable Seal are still read as part of the margin read sequence. The resulting read on sealed blocks is not captured in the MISR, but the Single Bit Correction, Double Bit Detection and breakpoints are still honored.

NOTE

It is not possible to do margin read operations on the UTest NVM block.

3. Set the UT0[AIS] bit to 1 for sequential addressing only.
4. Seed the MISR registers (UM0 — UM9) with desired values.
5. If breakpoints are desired, set UT0[AIBPE] to 1, and ensure that MCR[EER] and MCR[SBC] are cleared. If it is desired to break on single-bit correction, the UT0[SBCE] bit must be set to 1.
6. Initiate margin read by setting the UT0[MRE] bit to 1.
7. Select either one's margin or zero's margin by setting the UT0[MRV] bit to the appropriate value.
8. Set the UT0[AIE] bit.

During margin read operations, with UT0[AID] low, it is not recommended to attempt write operations to the MCR[SBC] and MCR[EER] bits. It is recommended that these bits only be written during suspend, breakpoints, or at completion of the Margin Read operation.

9. Wait until the UT0[AID] bit goes high, indicating that margin read test is complete.

If breakpoints were enabled or a suspend was requested during margin read, the operation may be at a breakpoint or a suspend state. See Step 8 in section [Array integrity self check](#) for more information.

10. Read values in the MISR registers (UM0 — UM9) to ensure correct signature.

NOTE

Margin reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

11. Write a logic 0 to the UT0[AIE] bit.

26.7 Initialization information

A reset is the highest priority operation for the embedded flash memory and terminates all other operations.

The embedded flash memory uses reset to initialize register and status bits to their default reset values. If the embedded flash memory is executing a program or erase operation (PGM or ERS = 1) and a reset is issued, the operation is aborted and the embedded flash memory disables the high-voltage logic without damage to the high-voltage circuits. Reset aborts all operations and forces the embedded flash memory into user mode ready to receive accesses.

After reset is requested, MCR[DONE] goes low, and remains low during reset and reset recovery. At the end of reset recovery, MCR[DONE] transitions from a 0 to a 1.

After reset is completed, register reads may be done, although it should be noted that registers that require updating from UTest NVM information, or other inputs, may not read updated values until MCR[DONE] transitions high.

During reset recovery, register writes are not allowed until the MCR[DONE] bit transitions high to indicate reset recovery is completed.

Warning

Resetting during a program or erase operation leaves the flash core blocks being programmed or erased in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

Chapter 27

External Bus Interface (EBI)

27.1 Chip-specific EBI information

The EBI is not available on the BGA416 package.

27.1.1 EBI use cases

The following table summarizes the primary use cases of the EBI on this chip.

Table 27-1. EBI use cases

Use case	EBI configuration
EBI used for external boot	Selected when the SIU_RSR[BOOTCFG] value of 10b or 11b determines the boot configuration. In this case, the Boot Assist Module (BAM) configures the SIU's applicable PCRs and the EBI registers according to the 10b or 11b value of SIU_RSR[BOOTCFG] and the value of RCHW[PS0]. For details, see the Functional Description of the BAM. User code can modify the SIU's applicable PCRs and EBI registers at any time.
EBI not used for external boot	User code must configure SIU's applicable PCRs and the EBI registers to select the appropriate mode.

27.1.2 EBI signal names

The following table aligns the chip-level pin/ball names for EBI signals with the module-level signal names.

For detailed EBI signal descriptions that use the module-level signal names, see [External Signal Description](#).

Table 27-2. EBI signals: chip-to-module alignment

Chip-level pin/ball name	Chip-level I/O	Module-level signal name	Note
D_ADD[9:30]	Output	ADDR[3:31]	ADDR[31] maps to $\overline{D\_CS}[2]$. $\overline{D\_CS}[2]$ is the primary function. The secondary function is EBI data only in non-muxed mode and address/data in muxed mode.
$\overline{D\_BDIP}$	Output	$\overline{BDIP}$	—
D_CLKOUT	Output	CLKOUT	—
$\overline{D\_CS}[0:3]$	Output	$\overline{CAL\_CS}[0:3]$	$\overline{D\_CS}[2]$ maps to ADDR[31]. $\overline{D\_CS}[2]$ is the primary function. The secondary function is EBI data only in non-muxed mode and address/data in muxed mode.
D_ADD_DAT[0:31]	Input/output	DATA[0:31]	In non-multiplexed mode, D_ADD_DAT[0:15] provide data only.
$\overline{D\_OE}$	Output	$\overline{OE}$	—
D_RD_WR	Output	RD_WR	—
$\overline{D\_TA}$	Input/output	$\overline{TA}$	—
$\overline{D\_TEA}$	Input/output	$\overline{TEA}$	—
$\overline{D\_TS}$	Output	$\overline{TS}$	—
$\overline{D\_WE}[0:3]$	Output	$\overline{WE}[0:3]/\overline{BE}[0:3]$	—
D_ALE	Output	—	When asserted, the Address Latch Enable (D_ALE) signal indicates that a valid address is present during a multiplexed bus access using a D_ADD_DAT signal. D_ALE can be used in conjunction with an external latch to hold the state of the address access when connecting the MCU to a non-multiplexed bus compatible memory.

27.1.3 EBI supported configurations

The following table shows the function of the external pins in each of the possible muxed/non-muxed usage configurations allowed for this device.

In any muxed mode, an external latch is needed to latch address [16:30] in 16-bit mode or address [16:29] in 32-bit mode. The latch must be connected to D_ADD_DAT pins.

Table 27-3. Function of EBI pins for supported configurations

Mode	$\overline{D\_WE}[0:3]$	D_ADD[9:15]	D_ADD[16:30] ¹ D_ADD_DAT[16:30] ²	D_ADD_DAT [0:15]	D_CS2 ³
Non-muxed 16-bit mode	write/byte enable [0:1]	Address [9:15]	Address [16:30]	Data [0:15]	Address [31]
Muxed 32-bit mode	write/byte enable [0:3]	Address [9:15]	Address [16:30] / Data [16:30]	Address [0:15] / Data [0:15]	Address [31] / Data [31]
Muxed 16-bit mode: EBI_MCR[D16_31] is 1	write/byte enable [0:1]	Address [9:15]	Address [16:30] / Data [0:14]	Not used	Address [31] / Data [15]
Muxed 16-bit mode: EBI_MCR[D16_31] is 0	write/byte enable [0:1]	Address [9:15]	Not used	Address [16:31] / Data [0:15]	Not used

1. D_ADD[16:30] SIU PCR functionality must be selected in non-multiplexed mode: AD_MUX is 0.

2. D_ADD_DAT[16:30] SIU PCR functionality must be selected in multiplexed mode: AD_MUX is 1.
3. D_CS2 is the primary function. The secondary function is EBI data only in non-muxed mode and address/data in muxed mode.

27.1.4 EBI CLKOUT division for slower-speed modes

[Slower-Speed Modes](#) explains that the external CLKOUT frequency can be divided by writing a clock control register in a block outside the EBI. On this chip, the register field SIU_ECCR[EBDF] enables CLKOUT division by a programmable value from 1 to 4.

27.1.5 EBI register reset values

The following table identifies chip-specific reset values of EBI registers.

Table 27-4. EBI register chip-specific reset values

Register	Reset value	Notes
MCR	0000_0800h	The DBM and D16_31 fields both reset to 0.
CAL_BR n	2000_0002h	The bits BA[0:2] have the fixed value 001b.
CAL_OR n	E000_0000h	The bits AM[0:2] have the fixed value 111b.

27.1.6 EBI_TESR in Module Disable mode

When EBI_MCR[MDIS] is 1 so that the EBI is in Module Disable mode, EBI_TESR cannot be written.

27.2 Introduction

27.2.1 Overview

The External Bus Interface (EBI) handles the transfer of information between the internal buses and the memories or peripherals in the external address space. The EBI includes a memory controller that generates interface signals to support a variety of external memories. This includes Single Data Rate (SDR) burst mode flash, SRAM, and asynchronous memories. It supports up to four regions (via chip selects), each with its own programmed attributes (plus up to four calibration chip-select regions).

27.2.2 Features

Note

This list is a superset list of all possible features the EBI supports. See the chip-specific EBI information for details on specifics for a particular device due to package limitations.

- 32-Bit Address bus with transfer size indication
- 32-Bit Data bus (16-bit Data Bus Mode also supported)
- Multiplexed Address on Data pins (single master)
- Memory controller with support for various memory types:
 - synchronous burst SDR flash and SRAM
 - asynchronous/legacy flash and SRAM
- Burst support (wrapped only)
- Bus monitor
- Port size configuration per chip select (16 or 32 bits)
- Configurable wait states
- Configurable internal or external transfer acknowledge ($\overline{TA}$) per chip select
- Support for Dynamic Calibration with up to four chip selects
- Four Write/Byte Enable ($\overline{WE}[0:3]/\overline{BE}[0:3]$) signals
- Slower-speed clock modes
- Stop and Module Disable Modes for power savings
- Optional automatic CLKOUT gating to save power and reduce EMI
- Misaligned access support (for chip-select accesses only)
- Compatible with MPC5xx external bus (with some limitations)

27.2.3 Modes of Operation

The mode of the EBI is determined by the MDIS, DBM, and AD_MUX bits in the EBI_MCR. See [EBI Module Configuration Register \(EBI_MCR\)](#) for details. Slower-speed modes, Debug Mode, Stop Mode, and Factory Test Mode are modes that the MCU may enter, in parallel to the EBI being configured in one of its block-specific modes.

27.2.3.1 Single Master Mode

In Single Master Mode, the EBI responds to internal requests matching one of its regions, but ignores all externally-initiated bus requests. The MCU is the only master allowed to initiate transactions on the external bus in this mode; therefore, it acts as a parked master and does not have to arbitrate for the bus before starting each cycle. Single Master Mode is entered when MDIS=0 in the EBI_MCR.

27.2.3.2 Module Disable Mode

The Module Disable Mode is used for MCU power management. The clock to the non-memory mapped logic in the EBI can be stopped while in Module Disable Mode. Logic on the MCU external to the EBI is needed to fully implement the Module Disable Mode (to shut off the clock). Internal master requests made to the external bus in Module Disable Mode are terminated with transfer error (internally, no external $\overline{\text{TEA}}$ assertion). Module Disable Mode is entered when MDIS=1 in the EBI_MCR.

27.2.3.3 Stop Mode

The EBI supports the IPI Green-Line Interface Stop Mode mechanism used for MCU power management. When a request is made to enter Stop Mode (controlled in device logic outside EBI), the EBI block completes any pending bus transactions and acknowledges the stop request. After the acknowledgement, the system clock input may be shut off by the clock driver on the MCU. While the clocks are shut off, the EBI is not accessible. While in stop mode, accesses to the EBI from the internal master will terminate with transfer error (internally, no external $\overline{\text{TEA}}$ assertion).

27.2.3.4 Slower-Speed Modes

In slower-speed modes, the external CLKOUT frequency is divided (by 2, 3, etc.) compared with that of the internal system bus. The EBI behavior remains dictated by the mode of the EBI, except that it drives and samples signals at the CLKOUT frequency

rather than the internal system frequency. This mode is selected by writing a clock control register in a block outside of the EBI. Refer to the device-specific documentation to see which slower-speed modes are available for a particular MCU (1/2, 1/3, etc.).

27.2.3.5 16-Bit Data Bus Mode

For MCUs that have only 16 data bus signals pinned out, or for systems where the use of a different multiplexed function (e.g. GPIO) is desired on 16 of the 32 data pins, the EBI supports a 16-bit Data Bus Mode. In this mode, only 16 data signals are used by the EBI. The user can select which 16 data signals are used (DATA[0:15] or DATA[16:31]) by writing the D16_31 bit in the EBI_MCR.

For EBI-mastered accesses, the operation in 16-bit Data Bus Mode (DBM=1, PS=x) is similar to a chip-select access to a 16-bit port in 32-bit Data Bus Mode (DBM=0, PS=1), except for the case of a non-chip-select access of exactly 32-bit size.

EBI-mastered non-chip-select accesses of exactly 32-bit size are supported via a two (16-bit) beat burst for both reads and writes. See [Non-Chip-Select Burst in 16-bit Data Bus Mode](#). Non-chip-select transfers of non-32-bit size are supported in standard non-burst fashion.

16-bit Data Bus Mode is entered when DBM=1 in the EBI_MCR. Some MCUs may have DBM=1 by default out of reset. See the device-specific documentation for the DBM and D16_31 reset values.

27.2.3.6 Multiplexed Address on Data Bus Mode

This mode covers several cases aimed at reducing pin count on MCU and external components. In this mode, the DATA pins will drive (for internal master cycles) the address value on the first clock of the cycle (while $\overline{TS}$ is asserted).

The memory controller supports per-chip-select selection of multiplexing address/data through the BRx[AD_MUX] bit.

Address on Data bus multiplexing also supports the 16-bit data bus mode (MCR[DBM]=1) and 16-bit memories (ORx[PS]=1). The user can select which 16 data signals are used (DATA[0:15] or DATA[16:31]) by writing the D16_31 bit in the EBI_MCR. For either setting of D16_31, the 16 LSBs of external address (ADDR[16:31]) are driven onto the selected 16 DATA pins. If additional address lines are required to interface to the memory, then non-muxed address pins are sometimes (see note below) required to complete the address space (e.g. ADDR[8:15] are commonly present as non-muxed address pins).

Note

The EBI also drives the unused 16 DATA signals with the MSBs of the external address, zero-padded in front (e.g. when D16_31 bit is set for a device with 24 ADDR pins, the EBI drives (0b00000000,ADDR[8:15]) on DATA[0:15]. This allows the device to optionally use DATA[8:15] for the upper 8 external address lines instead of requiring separate non-muxed ADDR[8:15] pins. This is relevant primarily for devices that support both 32-bit and 16-bit A/D muxed operation, so therefore have DATA[0:31] pins present on the device, and in that case are not required to have separate ADDR pins.

For more details (e.g. timing diagrams), see [Address Data Multiplexing](#).

27.2.3.7 Debug Mode

When the MCU is in Debug Mode, the EBI behavior is unaffected and remains dictated by the mode of the EBI.

27.3 External Signal Description

27.3.1 Overview

The following table lists the external pins used by the EBI. Not all signals listed here are available external to the chip.

Table 27-5. Signal Properties

Name	I/O Type	Function	Pull ¹
ADDR[3:31]	I/O	Address bus	-
BDIP	Output	Burst Data in Progress	Up
CLKOUT ²	Output	Clockout	-
CAL_CS[0:3]	Output	Calibration Chip Selects	Up
DATA[0:31]	I/O	Data bus ³	-
OE	Output	Output Enable	Up
RD_WR	I/O	Read_Write	Up
TA	I/O	Transfer Acknowledge	Up
TEA	I/O	Transfer Error Acknowledge	Up

Table continues on the next page...

Table 27-5. Signal Properties (continued)

Name	I/O Type	Function	Pull ¹
TS	I/O	Transfer Start	Up
WE[0:3]/BE[0:3]	Output	Write/Byte Enables	Up

1. This column shows which signals require a weak pullup or pulldown. The EBI block does not contain these pullup/pulldown devices within the block. They are assumed to be in another module of the MCU (e.g. pads module).
2. The CLKOUT signal is driven by the System Clock Block outside the EBI.
3. In Address/Data multiplexing modes, Data will also show the address during the address phase.

27.3.2 Detailed Signal Descriptions

Note

This section lists the superset of signals for the EBI. Refer to the chip-specific EBI information for package limitations and possible signal renaming.

27.3.2.1 ADDR [3:31] — Address Lines 3-31

The ADDR[3:31] signals specify the physical address of the bus transaction.

The ADDR[3:31] address lines correspond to bits 3-31 of the EBI's 32-bit internal address bus.

27.3.2.2 $\overline{\text{BDIP}}$ — Burst Data in Progress

$\overline{\text{BDIP}}$ is asserted to indicate that the master is requesting another data beat following the current one.

This signal is driven by the EBI on all EBI-mastered external burst cycles, but is only sampled by burst mode memories that have a corresponding pin. See [Burst Transfer](#).

27.3.2.3 CLKOUT — Clockout

CLKOUT is a general-purpose clock output signal to connect to the clock input of SDR external memories and in some cases to the input clock of another MCU in multi-master configurations.

27.3.2.4 $\overline{\text{CAL\_CS}}$ [0:3] — Calibration Chip Selects 0-3

$\overline{\text{CAL\_CS}}_x$ is asserted by the master to indicate that this transaction is targeted for a particular memory bank on the Calibration external bus.

The calibration chip selects are driven only by the EBI. External master accesses on the Calibration bus are not supported. In all other aspects, the calibration chip-selects behave exactly as the primary chip-selects. See [Memory Controller with Support for Various Memory Types](#) for details on chip-select operation.

27.3.2.5 DATA [0:31] — Data Lines 0-31

The DATA[0:31] signals contain the data to be transferred for the current transaction.

DATA[0:31] is driven by the EBI when it owns the external bus and it initiates a write transaction to an external device.

DATA[0:31] is driven by an external device during a read transaction from the EBI.

For 8-bit and 16-bit transactions, the byte lanes not selected for the transfer do not supply valid data.

DATA[0:31] is driven by the EBI in the address phase with the ADDR value if the Address on Data multiplexing mode is enabled. See [Multiplexed Address on Data Bus Mode](#) for details.

In 16-bit Data Bus Mode, (or for chip-select accesses to a 16-bit port), only DATA[0:15] or DATA[16:31] are used by the EBI, depending on the setting of the D16_31 bit in the EBI_MCR. See [16-Bit Data Bus Mode](#).

27.3.2.6 $\overline{\text{OE}}$ — Output Enable

$\overline{\text{OE}}$ is used to indicate when an external memory is permitted to drive back read data. External memories must have their data output buffers off when $\overline{\text{OE}}$ is negated. $\overline{\text{OE}}$ is only asserted for chip-select accesses.

For read cycles, $\overline{\text{OE}}$ is asserted one clock after $\overline{\text{TS}}$ assertion (by default with EBI_BR[EOE]=0b00) and held until the termination of the transfer. For write cycles, $\overline{\text{OE}}$ is negated throughout the cycle.

27.3.2.7 RD_ $\overline{\text{WR}}$ — Read / Write

RD_ $\overline{\text{WR}}$ indicates whether the current transaction is a read access or a write access.

$\overline{\text{RD\_WR}}$ is driven in the same clock as the assertion of $\overline{\text{TS}}$ and valid address, and is kept valid until the cycle is terminated.

27.3.2.8 $\overline{\text{TA}}$ — Transfer Acknowledge

$\overline{\text{TA}}$ is asserted to indicate that the slave has received the data (and completed the access) for a write cycle, or returned data for a read cycle. If the transaction is a burst read, $\overline{\text{TA}}$ is asserted for each one of the transaction beats. For write transactions, $\overline{\text{TA}}$ is only asserted once at access completion, even if more than one write data beat is transferred.

$\overline{\text{TA}}$ is driven by the EBI when the access is controlled by the chip selects (and $\text{SETA}=0$). Otherwise, $\overline{\text{TA}}$ is driven by the slave device to which the current transaction was addressed.

See [Termination Signals Protocol](#) for more details.

27.3.2.9 $\overline{\text{TEA}}$ — Transfer Error Acknowledge

$\overline{\text{TEA}}$ is asserted by either the EBI or an external device to indicate that an error condition has occurred during the bus cycle.

$\overline{\text{TEA}}$ is asserted by the EBI when the internal bus monitor detected a timeout error.

See [Termination Signals Protocol](#) for more details.

27.3.2.10 $\overline{\text{TS}}$ — Transfer Start

$\overline{\text{TS}}$ is asserted by the current bus owner to indicate the start of a transaction on the external bus.

$\overline{\text{TS}}$ is only asserted for the first clock cycle of the transaction, and is negated in the successive clock cycles until the end of the transaction.

27.3.2.11 $\overline{\text{WE}}[0:3] / \overline{\text{BE}}[0:3]$ — Write/Byte Enables 0-3

Write enables are used to enable program operations to a particular memory. These signals can also be used as byte enables for read and write operation by setting the WEBS bit in the appropriate Base Register. $\overline{\text{WE}}[0:3]/\overline{\text{BE}}[0:3]$ are only asserted for chip-select accesses.

For chip-select accesses to a 16-bit port, only $\overline{WE}[0:1]/\overline{BE}[0:1]$ are used by the EBI, regardless of which half of the DATA bus is selected via the D16_31 bit in the EBI_MCR.

See [Four Write/Byte Enable \(\$\overline{WE}/\overline{BE}\$ \) Signals](#) for more details on $\overline{WE}[0:3]/\overline{BE}[0:3]$ functionality.

27.3.3 Signal Output Buffer Enable Logic by Mode

The following table describes how the EBI drives its output buffer enable (OBE) signals. These are internal signals from the EBI to device logic outside the EBI, that determine when the EBI strongly drives values on pins. When the OBE for an EBI signal is asserted (1), the EBI strongly drives the value on that pin. When the OBE is negated (0), the EBI does not drive the signal, and the value is determined by internal or external pullups/pulldowns, and/or device logic outside EBI block. The logic in the following table can be overwritten by device logic, so see the device-specific documentation for any exceptions to the logic below.

NOTE

In the table below, Module Disable Mode assumes that the clock to the EBI is shut off when MDIS=1. This is an optional device feature. If the clocks are left running to EBI even when MDIS=1, then the EBI OBE behavior is as if in Single Master Mode (though EBI accesses are not supported in this scenario).

Signal	Module Disable Mode (MDIS=1)	Single Master Mode (MDIS=0)
ADDR[3:31]	0	1
BDIP	0	1
CAL_CS[0:3]	0	1
DATA[0:31]	0	Only 1 during write access or on Address phase when Addr/Data muxing is enabled.
$\overline{OE}$	0	1
RD_W $\overline{R}$	0	1
TA	0	Only 1 during chip-select (or cal-chip-select) SETA=0 access
TEA	0	Only 1 for 2 cycles when timeout occurs
TS	0	1
WE[0:3]/BE[0:3]	0	1

27.4 Memory map and register definition

This section provides a detailed description of all registers accessible in this module.

The following table gives an overview of the module registers implemented.

NOTE

Other than the exceptions noted below, EBI registers must not be written while a transaction to the EBI is in progress (or within 2 CLKOUT cycles after a transaction has just completed, to allow internal state machines to go IDLE). In those cases, the behavior is undefined.

Exceptions that can be written while an EBI transaction is in progress:

- All bits in EBI_TESR

See [Bootling from External Memory](#) for related application information.

EBI memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	EBI Module Configuration Register (EBI_MCR)	32	R/W	See section	27.4.1/973

27.4.1 EBI Module Configuration Register (EBI_MCR)

The EBI Module Configuration Register contains bits that configure various attributes associated with EBI operation.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0					0			0								
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	ACGE	0				0				MDIS	0				D16_31	AD_MUX	DBM
W																	
Reset	0	0	0	0	1	0	0	0	0	0	0	0	0	*	0	*	

* Notes:

- DBM field: Reset value is device-specific. Refer to the device-specific documentation for the reset value for a particular MCU.
- D16_31 field: Reset value is device-specific. Refer to the device-specific documentation for the reset value for a particular MCU.

EBI_MCR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 ACGE	Automatic CLKOUT Gating Enable The ACGE bit enables the EBI feature of turning off CLKOUT (holding it high) during idle periods in-between external bus accesses. 0 Automatic CLKOUT Gating is disabled 1 Automatic CLKOUT Gating is enabled
17–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

EBI_MCR field descriptions (continued)

Field	Description
25 MDIS	Module Disable Mode The MDIS bit controls an internal EBI "enable clk" signal which can be used (if MCU logic supports) to control the clocks to the EBI. The MDIS bit allows the clock to be stopped to the non-memory mapped logic in the EBI, effectively putting the EBI in a software controlled power-saving state. See Module Disable Mode for more information. No external bus accesses can be performed when the EBI is in Module Disable Mode (MDIS=1). 0 Module Disable Mode is inactive (assert "enable clk" signal) 1 Module Disable Mode is active (negate "enable clk" signal)
26–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 D16_31	Data Bus 16_31 Select The D16_31 bit controls whether the EBI uses the DATA[0:15] or DATA[16:31] signals, when in 16-bit Data Bus Mode (DBM=1) or for chip-select accesses to a 16-bit port (PS=1). NOTE: There is one usage case where D16_31=0 cannot be used. For systems that are using both a 32-bit non-chip-select device AND a 16-bit device (chip-select or non-chip-select), the user must set D16_31=1. Otherwise (if D16_31=0 is used), when an access to the 16-bit device is performed, the 32-bit non-chip-select device may decode the wrong upper address bits and may respond to that access, causing contention on the shared address/data lines going to both devices. This is due to the 32-bit device expecting address 8:15 on DATA[8:15] pins, whereas D16_31=0 has address 24:31 on those pins. This contention case is avoided when D16_31=1, because the shared address/data pins have the same functions for both the 16-bit and 32-bit memory accesses (address 16:31 on DATA[16:31] pins). This contention case is also avoided when only chip-select devices are used, since the devices ignore accesses when their corresponding chip-select is not asserted. 0 DATA[0:15] signals are used for 16-bit port accesses 1 DATA[16:31] signals are used for 16-bit port accesses
30 AD_MUX	Address on Data Bus Multiplexing Mode The AD_MUX bit controls whether non-chip-select accesses have the address driven on the data bus in the address phase of a cycle. 0 Only Data on data pins for non-CS accesses. 1 Address on Data Multiplexing Mode is used for non-CS accesses.
31 DBM	Data Bus Mode The DBM bit controls whether the EBI is in 32-bit or 16-bit Data Bus Mode. 0 32-bit Data Bus Mode is used 1 16-bit Data Bus Mode is used

27.4.2 EBI Transfer Error Status Register (EBI_TESR)

The EBI Transfer Error Status Register contains a bit for each type of transfer error on the external bus. A bit set to logic 1 indicates what type of transfer error occurred since the last time the bits were cleared. Each bit can be cleared by reset or by writing a 1 to it. Writing a 0 has no effect. For some MCUs with this EBI, this register may not be writable in Module Disable Mode due to the use of power saving clock modes. Refer to the device-specific documentation for details.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	1	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	

EBI_BMCR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 BMT	Bus Monitor Timing This field defines the timeout period, in 8 external bus clock resolution, for the Bus Monitor. See Bus Monitor for more details on bus monitor operation. Timeout Period = (2 + (8 * BMT)) / external bus clock frequency.
24 BME	Bus Monitor Enable This bit controls whether the bus monitor is enabled for internal to external bus cycles. The BME bit is ignored (treated as 0) for chip-select accesses with internal TA (SETA=0). 0 Disable bus monitor 1 Enable bus monitor (for external TA accesses only)
25–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

27.4.4 EBI Calibration Base Register (EBI_CAL_BRn)

The EBI Base Registers are used to define the base address and other attributes for the corresponding chip select.

NOTE

An MCU may have some of the upper bits of the BA field tied to a fixed value internally in order to restrict the address range of the EBI for that MCU. Refer to the device-specific documentation to see which bits are tied off, if any, for a particular MCU. Tied-off bits can be read but not written. These bits are ignored by the EBI during the chip-select address comparison. However, the internal bridge of the MCU most likely requires that the chip-select banks be located in memory regions corresponding to the fixed values chosen.

Table 27-11. EOE Values

Value	Timing of OE Assertion
0b00 ¹	Assert OE 1 CLKOUT cycle after TS assertion (see Figure 27-17)
0b01	Assert OE the same CLKOUT cycle as TS assertion (see Figure 27-20)
0b10	Assert OE one internal clock cycle after TS assertion (see Figure 27-20) ²
0b11	Reserved

1. The 0b00 timing case also applies when EBI_BR[ADMUX]=1, regardless of EOE value in Base Register.
2. In divided bus speed modes (where the EBI runs at a slower frequency than the internal system bus), the EBI uses the internal higher-frequency clock (ipg_clk) to assert OE partway through the CLKOUT cycle where TS is asserted. In 1:1 bus speed mode (where CLKOUT and internal system bus run at same frequency), the behavior for EOE Value 0b10 is identical to that of Value 0b00.

Table 27-12. SBL, BL Values

Value		Burst Length ¹	PS	# Beats in Burst ²
SBL	BL			
0	0 ³	8-word ⁴	0 (32-bit)	8
			1 (16-bit)	16
0	1	4-word	0 (32-bit)	4
			1 (16-bit)	8
1	X	2 word ⁴	0 (32-bit)	2
			1 (16-bit)	4

1. Total amount of data fetched in a burst transfer, measured in 32-bit words.
2. Number of external data beats used in external burst transfer. The size of each beat is determined by PS value.
3. An 8-word burst length is only supported for devices using 64-bit AMBA data bus width to EBI.

Memory map and register definition

4. A word always refers to 32-bits of data, regardless of PS.

Address: $0h \text{ base} + 40h \text{ offset} + (8d \times i)$, where $i=0d$ to $3d$

* Notes:

- BA field: Some upper bits of the BA field may be tied to a fixed value, in which case the reset value is this fixed value and not zero. See the chip-specific EBI information to see which bits this applies to, if any.

EBI_CAL_BRn field descriptions

Field	Description
0–16 BA	Base Address These bits are compared to the corresponding unmasked address signals among ADDR[0:16] of the internal address bus to determine if a memory bank controlled by the memory controller is being accessed by an internal bus master. Some upper bits of the BA field may be tied to a fixed value, in which case the reset value is this fixed value and not zero. See the chip-specific EBI information to see which bits this applies to, if any.
17–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 LWRN	Late RD_W$\overline{R}$ Negation The LWRN bit determines the timing of RD_W$\overline{R}$ signal negation for a write transfer (except for SETA=1 transfers, where RD_W$\overline{R}$ negates with $\overline{CS}$ by default, so LWRN has no effect). 0 Negate (set up to high level) RD_W$\overline{R}$ one CLKOUT cycle earlier than $\overline{CS}$ negation. See Figure 27-22. 1 Negate (set up to high level) RD_W$\overline{R}$ the same CLKOUT cycle as $\overline{CS}$ negation. See Figure 27-26.
20 PS	Port Size The PS bit determines the data bus width of transactions to this chip-select bank. NOTE: In the case where the DBM bit in EBI_MCR is set for 16-bit Data Bus Mode, the PS bit value is ignored and is always treated as a '1' (16-bit port). 0 32-bit port 1 16-bit port
21–22 EOE	Early OE The EOE field determines the timing of OE signal assertion for a read transfer. When EBI_BR[ADMUX]=1, the EOE value is ignored and treated as 0b00 (in order to avoid contention on shared address/data bus for muxed transfers).

Table continues on the next page...

EBI_CAL_BRn field descriptions (continued)

Field	Description
23 SBL	Short Burst Length The SBL bit provides support for a 2-word external burst (see Figure 27-46 in Small Access Example #5: 32-byte Read to 32-bit Port with SBL=1). When SBL=1, the number of beats in a burst is automatically determined by the EBI to be 2 or 4 according to the Port Size (PS bit), regardless of BL bit value. When SBL=0, the number of beats in a burst is determined by the BL bit. See Table 27-12 under BL bit description for SBL and BL encodings.
24 AD_MUX	Address on Data Bus Multiplexing The AD_MUX bit controls whether accesses for this chip select have the address driven on the data bus in the address phase of a cycle 0 Address on Data Multiplexing Mode is disabled for this chip select. 1 Address on Data Multiplexing Mode is enabled for this chip select.
25 BL	Burst Length The BL bit (along with SBL bit) determines the amount of data transferred in a burst for this chip select, measured in 32-bit words. When SBL=0, the number of beats in a burst is automatically determined by the EBI to be 4, 8, or 16 according to the Port Size (PS bit) so that the burst fetches the number of words chosen by BL. For internal AMBA data bus width of 32-bits, the BL bit is ignored (treated as 1). When SBL=1, the BL bit value is a don't care. See Table 27-12 for SBL and BL encodings.
26 WEBS	Write Enable / Byte Select This bit controls the functionality of the WE[0:3]/BE[0:3] signals. 0 The WE[0:3]/BE[0:3] signals function as WE[0:3] 1 The WE[0:3]/BE[0:3] signals function as BE[0:3]
27 TBDIP	Toggle Burst Data in Progress This bit determines how long the $\overline{\text{BDIP}}$ signal is asserted for each data beat in a burst cycle. See TBDIP Effect on Burst Transfer for details. 0 Assert $\overline{\text{BDIP}}$ throughout the burst cycle, regardless of wait state configuration 1 Only assert $\overline{\text{BDIP}}$ (BSCY+1) external cycles before expecting subsequent burst data beats
28 GCSN	Gaurantee CS Negation The GCSN bit allows support for gauranteeing that the EBI will negate CS between all back-to-back transfer cases (even those that are part of a set of Small Accesses). See Figure 27-31. 0 Default operation (CS may or may not negate between transfers, depending on the particular back-to-back case). 1 Negate CS between all external transfers. This adds an extra dead cycle for some back-to-back cases.
29 SETA	Select External Transfer Acknowledge The SETA bit controls whether accesses for this chip select will terminate (end transfer without error) based on externally asserted TA or internally asserted TA. SETA should only be set when the BI bit is 1 as well, since burst accesses with SETA=1 are not supported. Setting SETA=1 causes the BI bit to be ignored (treated as 1, burst inhibited). 0 Transfer Acknowledge (TA) is an output from the EBI, data phase will be terminated by the EBI 1 Transfer Acknowledge (TA) is an input to the EBI, data phase will be terminated by an external device
30 BI	Burst Inhibit This bit determines whether or not burst read accesses are allowed for this chip-select bank. The BI bit is ignored (treated as 1) for chip-select accesses with external TA (SETA=1).

Table continues on the next page...

EBI_CAL_BRn field descriptions (continued)

Field	Description
	0 Enable burst accesses for this bank 1 Disable burst accesses for this bank . This is the default value out of reset (or when SETA=1).
31 V	Valid bit The user writes this bit to indicate that the contents of this Base Register and Option Register pair are valid. The appropriate CS signal does not assert unless the corresponding V-bit is set. 0 This bank is not valid 1 This bank is valid

2. The 0b00 timing case also applies when EBI_BR[ADMUX]=1, regardless of EOE value in Base Register.
3. In divided bus speed modes (where the EBI runs at a slower frequency than the internal system bus), the EBI uses the internal higher-frequency clock (ipg_clk) to assert OE partway through the CLKOUT cycle where TS is asserted. In 1:1 bus speed mode (where CLKOUT and internal system bus run at same frequency), the behavior for EOE Value 0b10 is identical to that of Value 0b00.
4. Total amount of data fetched in a burst transfer, measured in 32-bit words.
5. Number of external data beats used in external burst transfer. The size of each beat is determined by PS value.
6. An 8-word burst length is only supported for devices using 64-bit AMBA data bus width to EBI.
7. A word always refers to 32-bits of data, regardless of PS.

27.4.5 EBI Calibration Option Register (EBI_CAL_ORn)

The EBI Option Registers are used to define the address mask and other attributes for the corresponding chip select.

NOTE

An MCU may have some of the upper bits of the AM field tied to a fixed value internally in order to restrict the address range of the EBI for that MCU. See the corresponding Note for the Base Register BA field for more details. Refer to the device-specific documentation to see which bits are tied off, if any, for a particular MCU. Tied-off bits can be read but not written.

Table 27-17. BSCY Values

Value	Meaning
00	0-clock cycle wait states (1 clock per data beat)
01	1-clock cycle wait states (2 clocks per data beat)
10	2-clock cycle wait states (3 clocks per data beat)
11	3-clock cycle wait states (4 clocks per data beat)

Address: $0h \text{ base} + 44h \text{ offset} + (8d \times i)$, where $i=0d$ to $3d$

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	AM															
W																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	AM	0	APS	0	AWE	0	SCY						0	BSCY		0
W	AM	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Reset	0*	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

* Notes:

- AM field: Some upper bits of the AM field may be tied to a fixed value, in which case the reset value is this fixed value and not zero. See the chip-specific EBI information to see which bits this applies to, if any.

EBI_CAL_ORn field descriptions

Field	Description
0–16 AM	Address Mask This field allows masking of any corresponding bits in the associated Base Register . Masking the address independently allows external devices of different size address ranges to be used . Any clear bit masks the corresponding address bit . Any set bit causes the corresponding address bit to be used in comparison with the address pins. Address mask bits can be set or cleared in any order in the field, allowing a resource to reside in more than one area of the address map. This field can be read or written at any time. Some upper bits of the AM field may be tied to a fixed value, in which case the reset value is this fixed value and not zero. See the chip-specific EBI information to see which bits this applies to, if any.
17–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 APS	Address by Port Size The user writes this bit to cause the EBI to shift the address it drives out for accesses to this chip-select, such that the lowest address bit addresses an element of data that matches the port size specified in the corresponding EBI_BR[PS] field. APS=0, PS=X: Default Byte Addressing APS=1, PS=0: Word Addressing: EBI drives internal address 6:29 to ADDR[8:31] APS=1, PS=1: Half-Word Addressing: EBI drives internal address 7:30 to ADDR[8:31] See Address by Port Size for additional details.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 AWE	Address / Write Enable Select The user writes this bit to cause the EBI to drive its internal WE[0:3] onto the upper 4 address bus signals (such as in systems where upper 4 address bus signals are not needed and separate WE[0:3] pins are not available). AWE has no effect on the other address bits besides the upper 4. For example, for an SoC using a 24-bit address bus, the upper 4 bits are ADDR[8:11]. See Address / Write Enable Multiplexing for additional details. 0 Default address function driven on 4 upper address bus signals 1 WE[0:3] driven into 4 upper address bus signals
22–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

EBI_CAL_ORn field descriptions (continued)

Field	Description
24–27 SCY	Cycle length in clocks This field represents the number of wait states (external cycles) inserted after the address phase in the single transfer case, or in the first beat of a burst, when the memory controller handles the external memory access. Values range from 0 to 15. This is the main parameter for determining the length of the cycle. These bits are ignored when SETA=1. The total cycle length for the first beat (including the TS cycle) = (2+SCY) external clock cycles. See Example Wait State Calculation for related application information.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 BSCY	Burst beats length in clocks This field determines the number of wait states (external cycles) inserted in all burst beats except the first, when the memory controller starts handling the external memory access and thus is using SCY[0:3] to determine the length of the first beat. These bits are ignored when SETA=1. The total memory access length for each beat is (1 + BSCY) external clock cycles. The total cycle length (including the TS cycle) = (2+SCY) + (#beats² - 1) * (BSCY+1).
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

2. #beats is the number of beats (4,8,16) determined by BL and PS bits in Base Register.

27.5 Functional Description

27.5.1 External Bus Interface Features

27.5.1.1 29-Bit Address Bus with Transfer Size Indication

The transfer size for an external transaction is indicated by the TSIZ[0:1] signals during the clock where address is valid. Valid transaction sizes are 8, 16 and 32 bits. SoCs may choose to pin-out less than 29 address pins externally (device-specific option), but a full 32-bit decode is done internally to determine the target of the transaction and whether a chip select should be asserted.

27.5.1.2 32-Bit Data Bus (16-bit Data Bus Mode also supported)

The entire 32-bit data bus is available for external memory accesses. There is also a 16-bit Data Bus Mode available via the DBM bit in EBI_MCR. See [16-Bit Data Bus Mode](#).

27.5.1.3 Multiplexed Address on Data Pins (singlemaster)

When this mode is enabled, the address shows up on the data pins during the address phase of the cycle. This mode can be enabled separately for non-chip-select accesses and per chip-select access. See [Multiplexed Address on Data Bus Mode](#).

27.5.1.4 Memory Controller with Support for Various Memory Types

The EBI contains a memory controller that supports a variety of memory types, including synchronous burst mode flash and SRAM, and asynchronous/legacy flash and SRAM with a compatible interface.

Each chip-select bank is configured via its own pair of Base and Option Registers. Each time an internal to external bus cycle access is requested, the internal address is compared with the base address of each valid Base Register (with 17 bits having mask). See the following figure. If a match is found, the attributes defined for this bank in its BR and OR are used to control the memory access. If a match is found in more than one bank, the lowest bank matched handles the memory access (e.g., bank 0 is selected over bank 1).

A match on a valid calibration chip-select register overrides a match on any non-calibration chip-select register, with CAL_CS0 having the highest priority. Thus the full priority of the chip-selects is: CAL_CS0,...,CAL_CS3,CS0,...,CS3

Figure 27-14. Bank Base Address & Match Structure

When a match is found on one of the chip-select banks, all its attributes (from the appropriate Base and Option Registers) are selected for the functional operation of the external memory access, such as:

- Number of wait states for a single memory access, and for any beat in a burst access
- Burst enable
- Port size for the external accessed device

See [/EBI Calibration Base Register \(EBI_CAL_BR \$n\$ \)](#) and [/EBI Calibration Option Register \(EBI_CAL_OR \$n\$ \)](#) for a full description of all chip-select attributes.

When no match is found on any of the chip-select banks, the default transfer attributes shown in the following table are used.

Table 27-35. Default Attributes for Non-Chip-Select Transfers

CS Attribute	Default Value	Comment
PS	0	32-bit port size
BL, SBL	0	burst length is don't care since burst is disabled
WEBS	0	$\overline{WE}$ not used for non-CS accesses
TBDIP	0	don't care since burst is disabled
BI	1	burst inhibited
SCY	0	don't care since external $\overline{TA}$ is used
BSCY	0	don't care since external $\overline{TA}$ is used
AD_MUX	0 ¹	Address on Data multiplexing
SETA	1	Select external $\overline{TA}$ to terminate access
EOE	0	$\overline{OE}$ not used for non-CS accesses
GCSN	0	$\overline{CS}/\overline{CAL\_CS}$ not used for non-CS accesses

1. For non-CS transfers, the AD_MUX attribute is determined by EBI_MCR[AD_MUX]

27.5.1.5 Burst Support (wrapped only)

The EBI supports burst read accesses of external burstable memory. To enable bursts to a particular memory region, clear the BI (Burst Inhibit) bit in the appropriate Base Register. External burst lengths of 2, 4 and 8 words are supported. Burst length is configured for each chip select by using the BL and SBL bits in the appropriate Base Register. See [Burst Transfer](#) for more details on burst operation.

In 16-bit data bus mode (DBM=1 in EBI_MCR), a special 2-beat burst case is supported for reads and writes for 32-bit non-chip-select accesses only. This is to allow 32-bit coherent accesses to another MCU. See [Non-Chip-Select Burst in 16-bit Data Bus Mode](#).

Bursting of accesses that are not controlled by the chip selects is not supported for any other case besides the special case of 32-bit accesses in 16-bit data bus mode.

Burst writes are not supported for any other case besides the special case of 32-bit non-chip-select writes in 16-bit data bus mode. Internal requests to write >32 bits (such as a cache line) externally are broken up into separate 32-bit or 16-bit external transactions according to the port size. See [Small Accesses \(Small Port Size and Short Burst Length\)](#) for more detail on these cases.

27.5.1.6 Bus Monitor

When enabled (via the BME bit in the EBI_BMCR), the bus monitor detects when no $\overline{TA}$ assertion is received within a maximum timeout period for external $\overline{TA}$ accesses. The timeout for the bus monitor is specified by the BMT field in the EBI_BMCR. Each time a timeout error occurs, the BMTF bit is set in the EBI_TESR. The timeout period is measured in external bus (CLKOUT) cycles. Thus the effective real-time period is multiplied (by 2, 3, etc.) when a slower-speed mode is used, even though the BMT field itself is unchanged.

27.5.1.7 Port Size Configuration per Chip Select (16 or 32 bits)

The EBI supports memories with data widths of 16 or 32 bits. The port size for a particular chip select is configured by writing the PS bit in the corresponding Base Register.

27.5.1.8 Configurable Wait States

From 0 to 15 wait states can be programmed for any cycle that the memory controller generates, via the SCY bits in the appropriate Option Register. From 0 to 3 wait states between burst beats can be programmed using the BSCY bits in the appropriate Option Register.

27.5.1.9 Configurable internal or external $\overline{TA}$ per chip select

Each chip select can be configured (via the SETA bit) to have $\overline{TA}$ driven internally (by the EBI), or externally (by an external device). See [/EBI Calibration Base Register \(EBI_CAL_BR_n\)](#) for more details on SETA bit usage.

27.5.1.10 Support for Dynamic Calibration with up to four chip selects

The EBI contains four calibration chip select signals, controlling four independent memory banks on an optional second external bus for calibration. See [Calibration Bus Operation](#) for more details on using the calibration bus.

27.5.1.11 Four Write/Byte Enable ($\overline{\text{WE}}$ / $\overline{\text{BE}}$) Signals

The functionality of the $\overline{\text{WE}}[0:3]/\overline{\text{BE}}[0:3]$ signals depends on the value of the WEBS bit in the corresponding Base Register. Setting WEBS to 1 configures these pins as $\overline{\text{BE}}[0:3]$, while resetting it to 0 configures them as $\overline{\text{WE}}[0:3]$. $\overline{\text{WE}}[0:3]$ are asserted only during write accesses, while $\overline{\text{BE}}[0:3]$ is asserted for both read and write accesses. The timing of the $\overline{\text{WE}}[0:3]/\overline{\text{BE}}[0:3]$ signals remains the same in either case.

The upper Write/Byte Enable ($\overline{\text{WE}}0/\overline{\text{BE}}0$) indicates that the upper eight bits of the data bus (DATA[0:7]) contain valid data during a write/read cycle. The upper middle Write/Byte Enable ($\overline{\text{WE}}1/\overline{\text{BE}}1$) indicates that the upper middle eight bits of the data bus (DATA[8:15]) contain valid data during a write/read cycle. The lower middle Write/Byte Enable ($\overline{\text{WE}}2/\overline{\text{BE}}2$) indicates that the lower middle eight bits of the data bus (DATA[16:23]) contain valid data during a write/read cycle. The lower Write/Byte Enable ($\overline{\text{WE}}3/\overline{\text{BE}}3$) indicates that the lower eight bits of the data bus (DATA[24:31]) contain valid data during a write/read cycle.

Note

The exception to the preceding $\overline{\text{WE}}/\overline{\text{BE}}$ description is that for 16-bit port transfers (DBM=1 or PS=1), only the $\overline{\text{WE}}[0:1]/\overline{\text{BE}}[0:1]$ signals are used, regardless of whether DATA[0:15] or DATA[16:31] are selected (via the D16_31 bit in the EBI_MCR). This means for the case where DATA[16:31] are selected, that $\overline{\text{WE}}0$ indicates that DATA[16:23] contains valid data, and $\overline{\text{WE}}1$ indicates that DATA[24:31] contains valid data.

The Write/Byte Enable lines affected in a transaction for a 32-bit port (PS = 0) and a 16-bit port (PS=1) are shown in the following table. Only Big Endian byte ordering is supported by the EBI.

Table 27-36. Write/Byte Enable Signals Function 1

Transfer Size	TSIZ[0:1]	Address		32-Bit Port Size				Also applies when DBM=1 for 16-bit data bus mode. 16-Bit Port Size ²			
		A30	A31	WE0/ BE0	WE1/ BE1	WE2/ BE2	WE3/ BE3	WE0/ BE0	WE1/ BE1	WE2/ BE2	WE3/ BE3
Byte	01	0	0	X				X			
	01	0	1		X				X		
	01	1	0			X		X			
	01	1	1				X		X		
16-bit	10	0	0	X	X			X	X		
	10	1	0			X	X	X	X		
32-bit	00	0	0	X	X	X	X	X ^{3, 3}	X ³		
Burst	00	0	0	X	X	X	X	X	X		

1. This table applies to aligned internal master transfers only. In the case of a misaligned internal master transfer that is split into multiple aligned external transfers, not all of the write enables X'd in the table will necessarily assert. See [Misaligned Access Support](#).
2. Also applies when DBM=1 for 16-bit data bus mode.
3. This case consists of two 16-bit external transactions, but for both transactions the $\overline{WE}[0:1]/\overline{BE}[0:1]$ signals are the only $\overline{WE}/\overline{BE}$ signals affected.

27.5.1.12 Slower-Speed Clock Modes

For memories that cannot run with a full-speed external bus, the EBI supports slower-speed clock modes. See [Slower-Speed Modes](#) for more details on this feature. The timing diagrams for slower-speed modes are identical to those for full-speed mode, except that the frequency of CLKOUT is reduced.

27.5.1.13 Stop and Module Disable Modes for Power Savings

See [Modes of Operation](#) for a description of the power saving modes.

27.5.1.14 Optional Automatic CLKOUT Gating

The EBI has the ability to hold the external CLKOUT pin high when the EBI's internal master state machine is idle and no requests are pending. The EBI outputs a signal to the pads logic in the MCU to disable CLKOUT. This feature is disabled out of reset, and can be enabled or disabled by the ACGE bit in the EBI_MCR.

Note

This feature must be disabled for multi-master systems. In those cases, one master is getting its clock source from the other master and needs it to stay valid continuously.

27.5.1.15 Misaligned Access Support

The EBI has limited misaligned access support. Misaligned non-burst chip-select transfers from internal masters are supported. The EBI aligns the accesses when it sends them out to the external bus (splitting them into multiple aligned accesses if necessary), so that external devices are not required to support misaligned accesses. Burst accesses (internal master) must match the internal bus size (64-bit aligned). See [Misaligned Access Support](#) for more details.

27.5.1.16 Compatible with MPC5xx External Bus (with some limitations)

The EBI is compatible with the external bus of the MPC5xx parts, meaning that it supports most devices supported by the MPC5xx family of parts. However, there are some differences between this EBI and that of the MPC5xx parts that the user needs to be aware of before assuming that an MPC5xx-compatible device works with this EBI. See [Summary of Differences from MPC5xx](#) for details.

Note

Due to testing and complexity concerns, multi-master (or master/slave) operation between an eSys MCU and MPC5xx is not guaranteed.

27.5.2 External Bus Operations

The following sections provide a functional description of the external bus, the bus cycles provided for data transfer operations, and error conditions.

27.5.2.1 External Clocking

The CLKOUT signal sets the frequency of operation for the bus interface directly. Internally, the MCU uses a phase-locked loop (PLL) circuit to generate a master clock for all of the MCU circuitry (including the EBI) which is phase-locked to the CLKOUT

signal. In general, all signals for the EBI are specified with respect to the rising-edge of the CLKOUT signal, and they are guaranteed to be sampled as inputs or changed as outputs with respect to that edge.

27.5.2.2 Reset

Upon detection of internal reset assertion, the EBI immediately ends all transactions (abruptly, not through normal termination protocol), and ignores any transaction requests that take place while reset is asserted.

27.5.2.3 Basic Transfer Protocol

The basic transfer protocol defines the sequence of actions that must occur on the external bus to perform a complete bus transaction. A simplified scheme of the basic transfer protocol is shown in the following figure.

Figure 27-15. Basic Transfer Protocol

The arbitration phase is where bus ownership is requested and granted. This phase is not needed in Single Master Mode because the EBI is the permanent bus owner in this mode.

The address transfer phase specifies the address for the transaction and the transfer attributes that describe the transaction. The signals related to the address transfer phase are $\overline{TS}$, ADDR (or DATA if Address/Data multiplexing is used), $\overline{CAL\_CS}[0:3]$, $\overline{RD\_WR}$, $TSIZ[0:1]$, and $\overline{BDIP}$. The address and its related signals (with the exception of $\overline{TS}$, $\overline{BDIP}$) are driven on the bus with the assertion of the $\overline{TS}$ signal, and kept valid until the bus master receives $\overline{TA}$ asserted (the EBI holds them one cycle beyond $\overline{TA}$ for writes and external $\overline{TA}$ accesses). Note that for writes with internal $\overline{TA}$, $\overline{RD\_WR}$ is not held one cycle past $\overline{TA}$.

The data transfer phase performs the transfer of data, from master to slave (in write cycles) or from slave to master (on read cycles), if any is to be transferred. The data phase may transfer a single beat of data (1-4 bytes) for non-burst operations or a 2-beat, 4-beat, 8-beat, or 16-beat burst of data (2 or 4 bytes per beat depending on Port Size) when burst is enabled. On a write cycle, the master must not drive write data until after the address transfer phase is complete. This is to avoid electrical contentions when switching between drivers. The master must start driving write data one cycle after the address transfer cycle. The master can stop driving the data bus as soon as it samples the $\overline{TA}$ line asserted on the rising edge of CLKOUT. To facilitate asynchronous write

support, the EBI keeps driving valid write data on the data bus until 1 clock after the rising edge where $\overline{\text{RD\_WR}}$ and $\overline{\text{WE}}$ are negated (for chip-select accesses only). See [Figure 27-22](#) for an example of write timing. On a read cycle, the master accepts the data bus contents as valid on the rising edge of the CLKOUT in which the $\overline{\text{TA}}$ signal is sampled asserted. See [Figure 27-17](#) for an example of read timing.

The termination phase is where the cycle is terminated by the assertion of either $\overline{\text{TA}}$ (normal termination) or $\overline{\text{TEA}}$ (termination with error). Termination is discussed in detail in [Termination Signals Protocol](#).

Note

In the timing diagrams in this document, asynchronous relationships between signals that switch in the same CLKOUT cycle are not guaranteed. For example, in [Figure 27-22](#), $\overline{\text{WE}}$ and write DATA change during the same CLKOUT cycle. There is no guarantee that DATA will be stable before $\overline{\text{WE}}$ assertion. External devices should not be latching write DATA on $\overline{\text{WE}}$ assertion, but instead must use a signal edge that takes place in a later CLKOUT cycle, such as $\overline{\text{WE}}$ negation.

Note

The timing diagrams in the following sections may show signals not implemented on some chips. Refer to [Table 27-5](#) for a list of your chip's signals.

27.5.2.4 Single Beat Transfer

The flow and timing diagrams in this section assume that the EBI is configured in Single Master Mode. Therefore, arbitration is not needed and is not shown in these diagrams.

27.5.2.4.1 Single Beat Read Flow

The handshakes for a single beat read cycle are illustrated in the following flow and timing diagrams.

Figure 27-16. Basic Flow Diagram of a Single Beat Read Cycle

Figure 27-17. Single Beat 32-bit Read Cycle, $\overline{\text{CS}}$ Access, Zero Wait States

Figure 27-18. Single Beat 32-bit Read Cycle, $\overline{\text{CS}}$ Access, One Wait State

*The EBI drives address and control signals an extra cycle because it uses a latched version of the external TA (1 cycle delayed) to terminate the cycle.

Figure 27-19. Single Beat 32-bit Read Cycle, $\overline{CS}$ Access, SETA=1, Zero Wait States

Figure 27-20. Single Beat 32-bit Read Cycle, $\overline{CS}$ Access, Zero Wait States (EOE=0b01, 0b10)

27.5.2.4.2 Single Beat Write Flow

The handshakes for a single beat write cycle are illustrated in the following flow and timing diagrams.

Figure 27-21. Basic Flow Diagram of a Single Beat Write Cycle

Figure 27-22. Single Beat 32-bit Write Cycle, $\overline{CS}$ Access, Zero Wait States

Figure 27-23. Single Beat 32-bit Write Cycle, $\overline{CS}$ Access, One Wait State

* The EBI drives address and control signals an extra cycle because it uses a latched version of the external $\overline{TA}$ (1 cycle delayed) to terminate the cycle.

Figure 27-24. Single Beat 32-bit Write Cycle, $\overline{CS}$ Access, SETA=1, Zero Wait States

* The EBI drives address and control signals an extra cycle because it uses a latched version of the external $\overline{TA}$ (1 cycle delayed) to terminate the cycle.

Figure 27-25. Single Beat 32-bit Write Cycle, Non- $\overline{CS}$ Access, Zero Wait States

* Negation of $\overline{RD\_WR}$ signal is in the same CLKOUT cycle as $\overline{CS}$ negation when $EBI\_BR[LWRN]=1$ (one cycle later than the default $LWRN=0$ timing).

Figure 27-26. Single Beat 32-bit Write Cycle, $\overline{CS}$ Access, Zero Wait States, $LWRN=1$

27.5.2.4.3 Back-to-Back Accesses

Due to internal bus protocol, one dead cycle is necessary between back-to-back external bus accesses that are not part of a set of small accesses (see [Small Accesses \(Small Port Size and Short Burst Length\)](#) for small access timing). A dead cycle refers to a cycle between the $\overline{TA}$ of a previous transfer and the $\overline{TS}$ of the next transfer.

Note

In some cases, $\overline{CS}$ remains asserted during this dead cycle, such as the cases of back-to-back writes or read-after-write to the same chip-select (with $EBI\_BR[GCSN]=0$). See [Figure 27-30](#) and [Figure 27-32](#). However, if $EBI\_BR[GCSN]=1$ for the first access (see [Figure 27-31](#) and [Figure 27-33](#)), then the EBI inserts an extra dead cycle between the accesses for these cases in order to guarantee $\overline{CS}$ negation between accesses.

Besides this dead cycle, in most cases, back-to-back accesses on the external bus do not cause any change in the timing from that shown in the previous diagrams, and the two transactions are independent of each other. The only exceptions to this are listed below:

- Back-to-back accesses where the first access ends with an externally-driven $\overline{\text{TA}}$ or $\overline{\text{TEA}}$. In these cases, an extra cycle is required between the end of the first access and the $\overline{\text{TS}}$ assertion of the second access. See [Termination Signals Protocol](#) for more details.
- 4-word burst transfers (using 64-bit AMBA bus) whose starting address is not 0x20 aligned. In these cases, an extra cycle is required between the end of the 2nd 4-word burst access and the $\overline{\text{TS}}$ assertion of a subsequent access. See [Figure 27-44](#).

The following diagrams show a few examples of back-to-back accesses on the external bus.

Figure 27-27. Back-to-Back 32-bit Reads to the Same $\overline{\text{CS}}$ Bank

Figure 27-36. Read After Write to Different $\overline{CS}$ Banks

27.5.2.5 Burst Transfer

The EBI supports wrapping 32-byte or 16-byte critical-doubleword-first burst transfers. Bursting is supported only for internally-requested (e.g. core, dma, etc.) 32-byte or 16-byte read accesses to external devices that use the chip selects⁶.

Accesses to devices operating without a chip select are always single beat. If an internal request to the EBI indicates a size of less than 32 bytes, the request is fulfilled by running one or more single-beat external transfers, not by an external burst transfer.

An 8-word wrapping burst reads eight 32-bit words by supplying a starting address that points to one of the words (doubleword aligned) and requiring the memory device to sequentially drive each word on the data bus. The selected slave device must internally increment ADDR[27:29] (also ADDR30 in the case of a 16-bit port size device) of the supplied address for each transfer, until the address reaches an 8-word boundary, and then wrap the address to the beginning of the 8-word boundary. The address and transfer attributes supplied by the EBI remain stable during the transfers. Termination of each beat transfer occurs by the EBI asserting $\overline{TA}$ (SETA=1 is not supported for burst transfers). The EBI requires that addresses be aligned to a doubleword boundary on all burst cycles.

The following table shows the burst order of beats returned for an 8-word burst to a 32-bit port.

6. Except for the special case of a 32-bit non-chip-select access in 16-bit data bus mode. See [Non-Chip-Select Burst in 16-bit Data Bus Mode](#).

Table 27-37. Wrap Bursts Order

Burst Starting Address ADDR[27:28]	Burst Order(Assuming 32-bit Port Size)
00	word0 -> word1 -> word2 -> word3 -> word4 -> word5 -> word6 -> word7
01	word2 -> word3 -> word4 -> word5 -> word6 -> word7 -> word0 -> word1
10	word4 -> word5 -> word6 -> word7 -> word0 -> word1 -> word2 -> word3
11	word6 -> word7 -> word0 -> word1 -> word2 -> word3 -> word4 -> word5

The general case of burst transfers assumes that the external memory has 32-bit port size and 8-word burst length (SBL=0, BL=0). The EBI can also burst from 16-bit port size memories, taking twice as many external beats to fetch the data as compared to a 32-bit port with the same burst length. The EBI can also burst from 16-bit or 32-bit memories that have a 4-word burst length (SBL=0, BL=1 in the appropriate Base Register). In this case, two external 4-word burst transfers (wrapping on 4-word boundary) are performed to fulfill the internal 8-word request⁷. This operation is considered atomic by the EBI, so the EBI does not allow other unrelated master accesses or bus arbitration to intervene between the transfers. For more details and a timing diagram, see [Small Access Example #3: 32-byte Read to 32-bit Port with BL=1](#).

The EBI can also burst from 16-bit or 32-bit memories that have a 2-word burst length (SBL=1, BL=X in the appropriate Base Register). In this case, four⁸ external 2-word burst transfers (wrapping on 2-word boundary) are performed to fulfill the internal 8-word request. This operation is considered atomic by the EBI, so the EBI does not allow other unrelated master accesses or bus arbitration to intervene between the transfers. For more details and a timing diagram, see [Small Access Example #5: 32-byte Read to 32-bit Port with SBL=1](#).

During burst cycles, the $\overline{\text{BDIP}}$ (Burst Data In Progress) signal is used to indicate the duration of the burst data. During the data phase of a burst read cycle, the EBI receives data from the addressed slave. If the EBI needs more than one data, it asserts the $\overline{\text{BDIP}}$ signal. Upon receiving the data prior to the last data, the EBI negates $\overline{\text{BDIP}}$. Thus, the slave stops driving new data after it receives the negation of $\overline{\text{BDIP}}$ on the rising edge of the clock. Some slave devices have their burst length and timing configurable internally and thus may not support connecting to a $\overline{\text{BDIP}}$ pin. In this case, $\overline{\text{BDIP}}$ is driven by the EBI normally, but the output is ignored by the memory and the burst data behavior is determined by the internal configuration of the EBI and slave device. When the TBDIP bit is set in the appropriate Base Register, the timing for $\overline{\text{BDIP}}$ is altered. See [TBDIP Effect on Burst Transfer](#) for this timing.

7. This case (of 2 external 4-word burst transfers being required) applies only to AMBA data bus width of 64 bits.

8. Applies to 64-bit AMBA data bus width. For 32-bit AMBA data bus width, only two transfers are performed.

Since burst writes are not supported by the EBI⁹, the EBI negates $\overline{\text{BDIP}}$ during write cycles.

9. Except for the special case of a 32-bit non-chip-select access in 16-bit data bus mode. See [Non-Chip-Select Burst in 16-bit Data Bus Mode](#).

Figure 27-37. Basic Flow Diagram of a Burst Read Cycle

Figure 27-38. Burst 32-bit Read Cycle, Zero Wait States

Figure 27-39. Burst 32-bit Read Cycle, One Initial Wait State

27.5.2.5.1 TBDIP Effect on Burst Transfer

Some memories require different timing on the $\overline{\text{BDIP}}$ signal than the default to run burst cycles. Using the default value of $\text{TBDIP}=0$ in the appropriate EBI Base Register results in $\overline{\text{BDIP}}$ being asserted ($\text{SCY}+1$) cycles after the address transfer phase, and being held asserted throughout the cycle regardless of the wait states between beats (BSCY). The following figure shows an example of the $\text{TBDIP}=0$ timing for a 4-beat burst with $\text{BSCY}=1$.

Functional Description

Figure 27-40. Burst 32-bit Read Cycle, One Wait State between Beats, TBDIP=0

When using TBDIP=1, the $\overline{\text{BDIP}}$ behavior changes to toggle between every beat when BSCY is a non-zero value. Figure 27-41 shows an example of the TBDIP=1 timing for the same 4-beat burst shown in Figure 27-40.

Figure 27-41. Burst 32-bit Read Cycle, One Wait State between Beats, TBDIP=1

27.5.2.6 Small Accesses (Small Port Size and Short Burst Length)

In this context, a small access refers to an access whose burst length and port size (SBL, BL, PS bits in Base Register for chip-select access or default burst disabled, 32-bit port for non-chip-select access) are such that the number of bytes requested by the internal master cannot all be fetched (or written) in one external transaction. If this is the case, the EBI initiates multiple transactions until all the requested data is transferred. It should be noted that all the transactions initiated to complete the data transfer are considered as an atomic transaction, so the EBI does not allow other unrelated master accesses to intervene between the transfers.

The following table shows all the combinations of burst length, port size, and requested byte count that cause the EBI to run multiple external transactions to fulfill the request.

Table 27-38. Small Access Cases

Byte Count Requested by internal master	Burst Length	Port Size	# External Accesses to Fulfill Request
Non-Burstable Chip-Select Banks (BI=1) or Non-Chip-Select Access			
4	1 beat	16-bit	2/1 ¹
8	1 beat	32-bit	2
8	1 beat	16-bit	4
16 ^{2, 2}	1 beat	32-bit	4
16 ²	1 beat	16-bit	8
32 ^{3, 3}	1 beat	32-bit	8
32 ³	1 beat	16-bit	16
Burstable Chip-Select Banks (BI=0)			
32 ³	4 words	16-bit (8 beats), 32-bit (4 beats)	2
32 ⁴	2 words	16-bit (4 beats), 32-bit (2 beats)	4

1. In 32-bit data bus mode (DBM=0 in EBI_MCR), two accesses are performed. In 16-bit data bus mode (DBM=1), one 2-beat burst access is performed and this is not considered a "small access" case. See [Non-Chip-Select Burst in 16-bit Data Bus Mode](#) for this special DBM=1 case.
2. Only supported for case of 32-bit internal AMBA data bus.
3. Only supported for case of 64-bit internal AMBA data bus.
4. SBL=1 (2-word burst case).

In most cases, the timing for small accesses is the same as for normal single-beat and burst accesses, except that multiple back-to-back external transfers are executed for each internal request. These transfers have no additional dead cycles in-between that are not present for back-to-back stand-alone transfers except for the case of writes with an internal request size of >64 bits, discussed in [Small Access Example #2: 32-byte Write with External TA](#).

The following sections show a few examples of small accesses. The timing for the remaining cases in the preceding table can be extrapolated from these and the other timing diagrams in this document.

27.5.2.6.1 Small Access Example #1: 32-bit Write to 16-bit Port

The following figure shows an example of a 32-bit write to a 16-bit port, requiring two 16-bit external transactions.

Figure 27-42. Single Beat 32-bit Write Cycle, 16-bit Port Size, Basic Timing

27.5.2.6.2 Small Access Example #2: 32-byte Write with External $\overline{TA}$

The following figure shows an example of a 32-byte write to a non-chip-select device using external $\overline{TA}$, requiring eight 32-bit external transactions. Note that due to the use of external $\overline{TA}$, $\overline{RD\_WR}$ does not toggle between the accesses unless that access is the end of a 64-bit boundary. In this case, an extra cycle is required between $\overline{TA}$ and the next $\overline{TS}$ in order to get the next 64-bits of write data internally and $\overline{RD\_WR}$ negates during this extra cycle.

* This extra cycle is required after accesses 2, 4, and 6 to get the next 64-bits of internal write data.

**Four more external accesses (not shown) are required to complete the internal 32-byte request. The timing of these is the same as accesses 1-4 shown in this diagram.

Figure 27-43. 32-Byte Write Cycle with External $\overline{TA}$, Basic Timing

27.5.2.6.3 Small Access Example #3: 32-byte Read to 32-bit Port with BL=1

Figure 27-44 shows an example of a 32-byte read to a 32-bit burst enabled port with burst length of 4 words, requiring two 4-word (16-byte) external transactions. For this case, the address for the 2nd 4-word burst access is calculated by adding 0x10 to the lower 5 bits of the 1st address (no carry), and then masking out the lower 4 bits to fix them at zero.

Table 27-39. Examples of 4-word Burst Addresses

1st Address	Lower 5 bits of 1st Address + 0x10 (no carry)	Final 2nd Address (After Masking Lower 4 Bits)
0x000	0x10	0x10
0x008	0x18	0x10
0x010	0x00	0x00
0x018	0x08	0x00
0x020	0x30	0x30
0x028	0x38	0x30
0x030	0x20	0x20
0x038	0x28	0x20

Figure 27-44. 32-Byte Read with B-T-B 4-Word Bursts to 32-bit Port, Zero Wait States

27.5.2.6.4 Small Access Example #4: 64-bit Read to 16-bit Port

The following figure shows an example of a 64-bit read to a 16-bit port, requiring four 16-bit external transactions.

* Or DATA[16:31], based on D16_31 bit in EBI_MCR.

Figure 27-45. Single Beat 64-bit Read Cycle, 16-bit Port Size, Basic Timing

27.5.2.6.5 Small Access Example #5: 32-byte Read to 32-bit Port with SBL=1

Figure 27-44 shows an example of a 32-byte read to a 32-bit burst enabled port with burst length of 2 words, requiring four 8-byte external transactions. For this case, the address for the 2nd-4th 2-word burst accesses is calculated by adding 0x08 to the lower 5 bits of the 1st address (no carry), and then masking out the lower 3 bits to fix them at zero.

Table 27-40. Examples of 2-word Burst Addresses

1st Address	Lower 5 bits of 1st Address + 0x08 (no carry)	Final 2nd-4th Addresses (After Masking Lower 3 Bits)
0x000	0x08	0x08, 0x10, 0x18
0x008	0x10	0x10, 0x18, 0x00
0x010	0x18	0x18, 0x00, 0x08
0x018	0x00	0x00, 0x8, 0x10
0x020	0x28	0x28, 0x30, 0x38
0x028	0x30	0x30, 0x38, 0x20
0x030	0x38	0x38, 0x20, 0x28
0x038	0x20	0x20, 0x28, 0x30

Figure 27-46. 32-Byte Read with 4 B-T-B 2-Word Bursts to 32-bit Port, Zero Wait States (SBL=1)

27.5.2.7 Size, Alignment and Packaging on Transfers

Table 27-41 shows the allowed sizes that an internal master can request from the EBI. The behavior of the EBI for request sizes not shown below is undefined. No error signal is asserted for these erroneous cases.

Table 27-41. Transaction Sizes Supported by EBI

# Bytes (internal master)	# Bytes (external master)
1	1
2	2

Table continues on the next page...

Table 27-41. Transaction Sizes Supported by EBI (continued)

# Bytes (internal master)	# Bytes (external master)
4	4
3 ¹	
8	
32 ²	

1. Some misaligned access cases may result in 3-byte writes. These cases are treated as power-of-2 sized requests by the EBI, using WE_BE[0:3] to make sure only the appropriate 3 bytes get written.
2. Only supported for case of 64-bit internal AMBA data bus.

Even though misaligned non-burst transfers from internal masters are supported, the EBI naturally aligns the accesses when it sends them out to the external bus, splitting them into multiple aligned accesses if necessary. See [Misaligned Access Support](#) for these cases.

Natural alignment for the EBI means:

- Byte access can have any address
- 16-bit access, address bit 31 must be 0
- 32-bit access, address bits 30-31 must be 0
- For burst accesses of any size, address bits 29-31 must be 0

The EBI never generates a misaligned external access, so a multi-master system with two e200-based MCUs can never have a misaligned external access from one to the other. In the erroneous case that an externally-initiated misaligned access does occur, the EBI errors the access (by asserting $\overline{TEA}$ externally) and does not initiate the access on the internal bus.

The EBI requires that the portion of the data bus used for a transfer to/from a particular port size be fixed. A 32-bit port must reside on data bus bits 0-31, and a 16-bit port must reside on bits 0-15.

In the following figures and tables the following convention is adopted:

- The most significant byte of a 32-bit operand is OP0, and OP3 is the least significant byte.
- The two bytes of a 16-bit operand are OP0 (most significant) and OP1, or OP2 (most significant) and OP3, depending on the address of the access.
- The single byte of a byte-length operand is OP0, OP1, OP2, or OP3, depending on the address of the access.

This can be seen in [Figure 27-47](#).

Figure 27-47. Internal Operand Representation

[Figure 27-48](#) shows the device connections on the DATA[0:31] bus.

Figure 27-48. Interface to Different Port Size Devices

[Table 27-42](#) lists the bytes required on the data bus for read cycles. The bytes indicated as ‘-’ are not required during that read cycle.

[Table 27-43](#) lists the patterns of the data transfer for write cycles when accesses are initiated by the MCU. The bytes indicated as ‘-’ are not driven during that write cycle.

Table 27-42. Data Bus Requirements for Read Cycles

Transfer Size	TSIZ[0:1]	Address		32-Bit Port Size				16-Bit Port Size ¹	
		A30	A31	D0:D7	D8:D15	D16:D23	D24:D31	D0:D7 ²	D8:D15 ³
Byte	01	0	0	OP0	-	-	-	OP0	-
	01	0	1	-	OP1	-	-	-	OP1
	01	1	0	-	-	OP2	-	OP2	-
	01	1	1	-	-	-	OP3	-	OP3
16-bit	10	0	0	OP0	OP1	-	-	OP0	OP1
	10	1	0	-	-	OP2	OP3	OP2	OP3
32-bit	00	0	0	OP0	OP1	OP2	OP3	OP0/OP2 ⁴	OP1/OP3

1. Also applies when DBM=1 for 16-bit data bus mode.
2. For address/data muxed transfers, DATA[16:23] are used externally, not DATA[0:7].
3. For address/data muxed transfers, DATA[24:31] are used externally, not DATA[8:15].
4. This case consists of two 16-bit external transactions, the first fetching OP0 and OP1, the second fetching OP2 and OP3.

Table 27-43. Data Bus Contents for Write Cycles

Transfer Size	TSIZ[0:1]	Address		32-Bit Port Size				16-Bit Port Size ¹	
		A30	A31	D0:D7	D8:D15	D16:D23	D24:D31	D0:D7 ²	D8:D15 ³
Byte	01	0	0	OP0	-	-	-	OP0	-
	01	0	1	-	OP1	-	-	-	OP1
	01	1	0	-	-	OP2	-	OP2	-
	01	1	1	-	-	-	OP3	-	OP3
16-bit	10	0	0	OP0	OP1	-	-	OP0	OP1
	10	1	0	-	-	OP2	OP3	OP2	OP3
32-bit	00	0	0	OP0	OP1	OP2	OP3	OP0/OP2 ⁴	OP1/OP3

1. Also applies when DBM=1 for 16-bit data bus mode.
2. For address/data muxed transfers, DATA[16:23] are used externally, not DATA[0:7].
3. For address/data muxed transfers, DATA[24:31] are used externally, not DATA[8:15].
4. This case consists of two 16-bit external transactions, the first writing OP0 and OP1, the second writing OP2 and OP3.

27.5.2.8 Termination Signals Protocol

The termination signals protocol was defined in order to avoid electrical contention on lines that can be driven by various sources. In order to do that, a slave must not drive signals associated with the data transfer until the address phase is completed and it recognizes the address as its own. The slave must disconnect from signals immediately after it acknowledges the cycle and not later than the termination of the next address phase cycle.

For EBI-mastered non-chip-select accesses, the EBI requires assertion of $\overline{TA}$ from an external device to signal that the bus cycle is complete. The EBI uses a latched version of $\overline{TA}$ (1 cycle delayed) for these accesses to help make timing at high frequencies. This

results in the EBI driving the address and control signals 1 cycle longer than required, as seen in Figure 27-49. However, the DATA does not need to be held 1 cycle longer by the slave, because the EBI latches DATA every cycle during non-chip-select accesses. During these accesses, the EBI does not drive the $\overline{TA}$ signal, leaving it up to an external device (or weak internal pullup) to drive $\overline{TA}$.

For EBI-mastered chip-select accesses, when the SETA bit is 0, the EBI drives $\overline{TA}$ the entire cycle, asserting according to internal wait state counters to terminate the cycle. When the SETA bit is 1, the EBI samples the $\overline{TA}$ for the entire cycle. During idle periods on the external bus, the EBI drives $\overline{TA}$ negated as long as it is granted the bus; when it no longer owns the bus, it lets go of $\overline{TA}$.

If no device responds by asserting $\overline{TA}$ within the programmed timeout period (BMT in EBI_BMCR) after the EBI initiates the bus cycle, the internal Bus Monitor (if enabled) asserts $\overline{TEA}$ to terminate the cycle. An external device may also drive $\overline{TEA}$ when it detects an error on an external transaction. $\overline{TEA}$ assertion causes the cycle to terminate and the processor to enter exception processing for the error condition. To properly control termination of a bus cycle for a bus error with external circuitry, $\overline{TEA}$ must be asserted at the same time or before (external) $\overline{TA}$ is asserted. $\overline{TEA}$ must be negated before the second rising edge after it was sampled asserted in order to avoid the detection of an error for the following bus cycle initiated. $\overline{TEA}$ is only driven by the EBI during the cycle where the EBI is asserting $\overline{TEA}$ and the cycle immediately following this assertion (for fast negation). During all other cycles, the EBI relies on a weak internal pullup to hold $\overline{TEA}$ negated. This allows an external device to assert $\overline{TEA}$ when it needs to indicate an error. External devices must follow the same protocol as the EBI, only driving $\overline{TEA}$ during the assertion cycle and 1 cycle afterwards for negation.

When $\overline{TEA}$ is asserted from an external source, the EBI uses a latched version of $\overline{TEA}$ (1 cycle delayed) to help make timing at high frequencies. This means that for any accesses where the EBI drives $\overline{TA}$ (chip-select accesses with SETA=0), a $\overline{TEA}$ assertion that occurs 1 cycle before or during the last $\overline{TA}$ of the access could be ignored by the EBI, since it will have completed the access internally before it detects the latched $\overline{TEA}$ assertion. This means that non-burst chip-select accesses with no wait states (SCY=0) cannot be reliably terminated by external $\overline{TEA}$. If external error termination is required for such a device, the EBI must be configured for SCY>=1.

Note

For the cases discussed above where $\overline{TEA}$ "could be ignored", this is not guaranteed. For some small access cases (which always use chip-select and internally-driven $\overline{TA}$), a $\overline{TEA}$ that occurs 1 cycle before or during the $\overline{TA}$ cycle or for SCY=0 may in fact lead to terminating the cycle with error. However, proper error termination is not guaranteed for these cases, so $\overline{TEA}$

must always be asserted at least 2 cycles before an internally-driven $\overline{TA}$ cycle for proper error termination.

External $\overline{TEA}$ assertion that occurs during the same cycle that $\overline{TS}$ is asserted by the EBI is always treated as an error (terminating the access) regardless of SCY.

The following table summarizes how the EBI recognizes the termination signals provided from an external device.

Table 27-44. Termination Signals Protocol

$\overline{TEA}^{1,1}$	$\overline{TA}^1$	Action
Negated	Negated	No Termination
Asserted	X	Transfer Error Termination
Negated	Asserted	Normal Transfer Termination

1. Latched version (1 cycle delayed) used for externally driven $\overline{TEA}$ and $\overline{TA}$.

The following figure shows an example of the termination signals protocol for back-to-back reads to two different slave devices who properly "take turns" driving the termination signals. This assumes a system using slave devices that drive termination signals.

* The EBI drives address and control signals an extra cycle because it uses a latched version of $\overline{TA}$ (1 cycle delayed) to terminate the cycle. An external master is not required to do this.

**This is the earliest that the EBI can start another transfer, in the case of continuing a set of small accesses. For all other cases, an extra cycle is needed before the EBI can start another $\overline{TS}$.

Figure 27-49. Termination Signals Protocol Timing Diagram

27.5.2.9 Non-Chip-Select Burst in 16-bit Data Bus Mode

The timing diagrams in this section apply only to the special case of a non-chip-select 32-bit access in 16-bit data bus mode (DBM=1 in EBI_MCR).

For this case, a special 2-beat burst protocol is used for reads and writes, so that a slave device (using the same EBI) can internally generate one 32-bit read or write access (thus 32-bit coherent), as opposed to two separate 16-bit accesses.

Note

If the device does not support multi-master systems, the original intent of this protocol does not apply. However, this 2-beat burst protocol can also occur in a single-master system, if a non-chip-select 32-bit access to a 16-bit port is performed.

Figure 27-50 shows a 32-bit (and non-chip-select in a single-master system) read from an external master in 16-bit data bus mode.

Figure 27-51 shows a 32-bit (and non-chip-select in a single-master system) write from an external master in 16-bit data bus mode.

Figure 27-50. 32-bit Read from MCU with DBM=1

Figure 27-51. 32-bit Write to MCU with DBM=1

27.5.2.10 Calibration Bus Operation

Some devices with this EBI have a second external bus, intended for calibration use. This bus consists of a second set of the same signals present on the Primary external bus, except that arbitration, (and optionally other signals also) are excluded. Both busses can be supported with one EBI block, by using the calibration chip-selects to steer accesses to the calibration bus instead of the primary external bus.

Since the calibration bus has no arbitration signals, the arbitration on the primary bus controls accesses on the calibration bus as well, and no external master accesses can be performed on the calibration bus. Accesses cannot be performed in parallel on both external busses. However, back-to-back accesses can switch from one bus to the other, as determined by the type of chip-select each address matches.

The timing diagrams and protocol for the calibration bus is identical to the primary bus, except that some signals are missing on the calibration bus. See the device-specific documentation for the calibration bus signal list for a particular MCU.

There is an inherent dead cycle between a calibration chip-select access and a non-calibration access (chip-select or non-chip-select), just like the one between accesses to two different non-calibration chip-selects (described in [Back-to-Back Accesses](#)).

Figure 27-52 shows an example of a non-calibration chip-select read access followed by a calibration chip-select read access. Note that this figure is identical to Figure 27-28, except the CSy is replaced by CAL_CSy. Timing for other cases on calibration bus can similarly be derived from other figures in this document (by replacing $\overline{\text{CS}}$ with $\overline{\text{CAL\_CS}}$).

Figure 27-52. Back-to-Back 32-bit Reads to $\overline{\text{CS}}$, $\overline{\text{CAL\_CS}}$ Banks

27.5.2.11 Misaligned Access Support

This section describes all the misaligned cases supported by the EBI. These cases are a subset of the full set of cases allowed by the AMBA AHB V6 specification. The EBI works under the assumption that all internal masters on the device do not produce any misaligned access cases (to the EBI) other than the ones below.

27.5.2.11.1 Misaligned Access Support (64 bit AMBA)

Table 27-45 shows all the misaligned access cases supported by the EBI (using a 64-bit AMBA implementation), as seen on the internal master AMBA bus. All other misaligned cases are not supported. If an unsupported misaligned access to the EBI is attempted (such as non-chip-select or burst misaligned access), the EBI errors the access on the internal bus and does not start the access (nor assert $\overline{TEA}$) externally.

Table 27-45. Misalignment Cases Supported by a 64 bit AMBA EBI (internal bus)

27	(2 AHB transfers)	000	1111_1110	11	1

1. Misaligned case number. Only transfers where HUNALIGN=1 are numbered as misaligned cases.
2. Address on internal master AHB bus, not necessarily address on external ADDR pins.
3. Internal byte strobe signals on AHB bus. Shown with Big-Endian byte ordering in this table, even though internal master AHB bus uses Little-Endian byte-ordering (EBI flips order internally).
4. Internal signal on AHB bus; 00=8-bits, 01=16 bits, 10=32 bits, 11=64-bits. HSIZE is driven according to the smallest aligned container that contains all the requested bytes. This results in extra EBI external transfers in some cases.
5. Internal signal on AHB bus that indicates that this transfer is misaligned (when 1).
6. For this case, the EBI internally treats HSIZE as 10 (4-byte access), if PS=1 (16-bit port).
7. For this case, the EBI internally treats HSIZE as 00(1-byte access).
8. For this case, the EBI internally treats HSIZE as 01 (2-byte access).
9. For this case, the EBI internally treats HSIZE as 10 (4-byte access).

[Table 27-46](#) shows which external transfers are generated by the EBI for the misaligned access cases in [Table 27-45](#), for each port size.

The number of external transfers for each internal AHB master request is determined by the HSIZE value for that request (adjusted internally in some cases, see table footnotes) relative to the port size. For example, a Word write to @011 with 16-bit port size (case #10 in [Table 27-45](#)) results in 4 external 16-bit transfers because the HSIZE is 64-bits. For cases where two or more external transfers are required for one internal transfer request, these external accesses are considered part of a "small access" set, as described in [Small Accesses \(Small Port Size and Short Burst Length\)](#).

Since all transfers are aligned on the external bus, normal timing diagrams and protocol apply. Note that the TSIZ[0:1] signals are not intended to be used for misaligned accesses, so they are not specified in [Table 27-46](#).

2. Port size; 0=32 bits, 1=16 bits.
3. External ADDR pins, not necessarily the address on internal master AHB bus.
4. External WE_BE pins. Note that these pins have negative polarity, opposite of the internal byte strobes in [Table 27-45](#).

27.5.2.12 Address Data Multiplexing

Address/Data multiplexing enables the design of a system with reduced pin count. In such a system, multiplexed address/data functions (on DATA pins) are used, instead of having separate address and data pins. Compared to the normal EBI specification (e.g. 24 address pins+32 data pins), only 32 data pins are required. Compared to a 16-bit bus implementation, only 24 pins are required (e.g. ADDR[8:15] + ADDR[16:31]/DATA[16:31]).

When performing a small access read, as described in [Small Accesses \(Small Port Size and Short Burst Length\)](#), with A/D multiplexing enabled for this access, the EBI inserts an idle clock cycle with $\overline{OE}$ negated and $\overline{CS}$ asserted (for GCSN=0), to allow for the memory to three-state the bus prior to the EBI driving the address on the next clock. This clock gap already exists (for other reasons) for non-small-access transfers, so no additional clock gap is inserted for those cases. See [Figure 27-53](#) for an example of a small access read with A/D multiplexing enabled.

In general, timing diagrams in A/D multiplexing mode are very similar to other diagrams in this document (including support for Burst accesses), except for the behavior of the ADDR and DATA busses, which can be seen in the following figure.

* While the EBI drives all of ADDR[3:31] to valid address, typically only ADDR[3:15] (or less) are used in the system, as DATA[16:31] (or DATA[0:15]) would be used for address and data on an external muxed device.

** Or DATA[0:15], based on D16_31 bit in EBI_MCR.

Figure 27-53. Small access (32-bit read to 16-bit port) on Address/Data multiplexed bus

27.5.2.13 Address / Write Enable Multiplexing

Address/Write Enable multiplexing enables the design of a system with reduced pin count (saves 4 pins). The typical usage is the case where the SoC is connected to an external chip-select device that requires write-enable functionality, but does not require the full address bus width. In such a system, the user can set EBI_OR[AWE]=1 to cause the EBI to drive its internal WE[0:3] signals onto the upper 4 ADDR pins, instead of relying on separate WE[0:3] pins (which may not be present on some SoCs).

In general, timing diagrams using ADDR/WE multiplexing (EBI_OR[AWE]=1) are very similar to other diagrams in this document, except for the behavior of the upper 4 ADDR signals, which can be seen in the following figure.

Figure 27-54. Single Beat 32-bit Write Cycle, $\overline{CS}$ Access, Zero Wait States, AWE=1

27.5.2.14 Address by Port Size

Address by Port Size (EBI_OR[APS]=1) provides a way to increase the memory size supported by the EBI for external chip-select devices with 16 or 32-bit port size.

For example, consider an SoC that has ADDR[8:31] pinned out and connects to an external 32-bit chip-select memory:

- If APS=0, then ADDR[31] is not connected to the memory and thus only 22 address lines (ADDR[8:29]) are left to connect to the memory.
- If APS=1, then the EBI drives internal address 6:29 to external ADDR[8:31], thus giving the user a 24-bit address range to access the 16-bit memory.

In general, timing diagrams using APS=1 are very similar to other diagrams in this document, except for the shifting of the ADDR signals, which can be seen in [Figure 27-55](#) and [Figure 27-56](#).

Figure 27-55. Single Beat 32-bit Read Cycle, $\overline{\text{CS}}$ Access, Zero Wait States, APS=1, PS=0

Figure 27-56. Single Beat 16-bit Read Cycle, $\overline{\text{CS}}$ Access, Zero Wait States, APS=1, PS=1

27.5.2.15 32-bit AMBA Burst on 64-bit AMBA Case

This section only applies for those SoC's that use the EBI with an AMBA bus width of 64 bits. This section is N/A for those SoC's that use the EBI in a 32-bit AMBA configuration (determined by SoC parameter).

On some SoCs that use this EBI, the internal AMBA master is capable of requesting a WRAP4 32-bit burst even with a 64-bit AMBA bus width. This case is supported by the AMBA standard, but is rarely used on SoCs, since normally the full AMBA width is used when bursting (for optimum performance). A scenario where this case occurs is when there is a 32-bit AMBA master connecting through a 32->64 bit gasket that drives requests to the EBI's 64-bit AMBA bus.

In the 32-bit burst on 64-bit AMBA case, the EBI returns data on the appropriate half of the 64-bit AMBA bus, based on the address of the transfer (address bit 2 using N:0 numbering), and then alternates halves on each AMBA burst beat. Examples below are based on AMBA data bus numbering 63:0.

- For a burst starting at address 0x0 (or 0x8, 0x10, etc.), the 4 beats of data are returned on hrddata [63:32], [31:0], [63:32], [31:0].
- For a burst starting at address 0x4 (or 0xC, 0x14, etc.), the 4 beats of data are returned on hrddata [31:0], [63:32], [31:0], [63:32]

Note

For the case of a 32-bit burst on 64-bit AMBA where EBI_BR[BL]=0 and EBI_BR[SBL]=0, the external burst size (8 words) is mismatched to the internal burst size (4 words). In this case, to avoid erroneous data due to different wrapping boundaries, the EBI disables external burst for that access and splits the internal burst request to multiple single external accesses.

27.5.2.16 Internal AMBA Master Burst Read Abort Case

On some SoCs that use this EBI, the internal AMBA master has the capability to abort the AMBA burst read early, without performing the 4 requests that are normally part of an AMBA WRAP4 burst sequence. For example, instead of the usual htrans=NSEQ, SEQ, SEQ, SEQ, the master might do 1 of these cases:

- htrans=NSEQ (with hburst=WRAP4), SEQ (0-2 times), NSEQ (2nd NSEQ aborts prior burst)
- htrans=NSEQ (with hburst=WRAP4), SEQ (0-2 times), IDLE (IDLE aborts prior burst)

In these cases, the EBI has already started the burst externally, but will abort it early (without asserting $\overline{\text{TEA}}$ or internal hresp), and only returns the beats of data on the internal AMBA bus corresponding to the AMBA NSEQ/SEQ requests received. In a

subset of these master burst abort cases, there may be extra $\overline{\text{TS}}/\overline{\text{TA}}$ transfers on the external bus after the internal AMBA master has aborted (e.g. finishing a “small access” set of transfers). These extra read accesses are extraneous and can just be ignored.

This feature is not part of the AMBA standard, but is implemented in some AMBA masters for performance reasons. The master burst abort feature applies to reads only. The behavior of the EBI for an aborted AMBA burst write is undefined (not supported).

27.6 Initialization/Application Information

27.6.1 Booting from External Memory

The EBI block does not support booting directly to external memory (i.e. fetching the first instruction after reset externally). One common method for an MCU to resemble an external boot with this EBI is to use an internal Boot Assist Module on the MCU, which fetches the first instruction internally and configures EBI registers before branching to an external address to “boot” externally. Refer to the device-specific documentation to see how/if external boot is supported for a particular MCU.

If code in external memory needs to write EBI registers, this must be done in a way that avoids modifying EBI registers while external accesses are being performed, such as the following method:

- Copy the code that is doing the register writes (plus a return branch) to internal SRAM
- Branch to internal SRAM to run this code, ending with a branch back to external flash

27.6.2 Running with SDR (Single Data Rate) Burst Memories

This includes FLASH and SRAM memories with a compatible burst interface. $\overline{\text{BDIP}}$ is required only for some SDR memories. The following figure shows a block diagram of an MCU connected to a 32-bit SDR burst memory.

* May or may not be connected, depending on the memory used.

** Flash memories typically use one $\overline{WE}$ signal as shown, RAMs use 2 or 4 (16-bit or 32-bit)

Figure 27-57. MCU Connected to SDR Burst Memory

Refer to [Figure 27-38](#) for an example of the timing of a typical Burst Read operation to an SDR burst memory. Refer to [Figure 27-22](#) for an example of the timing of a typical Single Write operation to SDR memory.

27.6.3 Running with Asynchronous Memories

The EBI also supports asynchronous memories. In this case, the CLKOUT, $\overline{TS}$, and $\overline{BDIP}$ pins are not used by the memory and bursting is not supported. However, the EBI still drives these outputs, and always drives and latches all signals at posedge CLKOUT (i.e., there is no "asynchronous mode" for the EBI). The data timing is controlled by setting the SCY bits in the appropriate Option Register to the proper number of wait states to work with the access time of the asynchronous memory, just as done for a synchronous memory.

27.6.3.1 Example Wait State Calculation

This example applies to any chip-select memory, synchronous or asynchronous.

As an example, say we have a memory with 50ns access time, and we are running the external bus @ 66 MHz (CLKOUT period: 15.2ns). Assume the input data spec for the MCU is 4ns.

number of wait states = (access time) / (CLKOUT period) + (0 or 1) (depending on setup time)

$50/15.2 = 3$ with 4.4ns remaining (so we need at least 3 wait states, now check setup time)

$15.2 - 4.4 = 10.8\text{ns}$ (this is the achieved input data setup time)

Since actual input setup (10.8ns) is greater than the input setup spec (4.0ns), 3 wait states is sufficient. If the actual input setup was less than 4.0ns, we would have to use 4 wait states instead.

27.6.3.2 Timing and Connections for Asynchronous Memories

The connections to an asynchronous memory are the same as for a synchronous memory, except that the CLKOUT, $\overline{\text{TS}}$, and $\overline{\text{BDIP}}$ signals are not used. Figure 27-58 shows a block diagram of an MCU connected to an asynchronous memory.

* Flash memories typically use one $\overline{\text{WE}}$ signal as shown, RAMs use 2 or 4 (16-bit or 32-bit)

Figure 27-58. MCU Connected to Asynchronous Memory

Figure 27-59 shows a timing diagram of a read operation to a 16-bit asynchronous memory using 3 wait states.

Figure 27-60 shows a timing diagram of a write operation to a 16-bit asynchronous memory using 3 wait states.

Figure 27-59. Read Operation to Asynchronous Memory, Three Initial Wait States

Figure 27-60. Write Operation to Asynchronous Memory, Three Initial Wait States

27.6.4 Connecting an MCU to Multiple Memories

The MCU can be connected to more than one memory at a time.

The following figure shows an example of how two memories could be connected to one MCU.

* May or may not be connected, depending on the memory used.

** Flash memories typically use one $\overline{WE}$ signal as shown, RAMs use 2 or 4 (16-bit or 32-bit)

Figure 27-61. MCU Connected to Multiple Memories

27.6.5 EBI Operation with Reduced Pinout MCUs

Some MCUs with this EBI may not have all the pins described in this document pinned out for a particular package. Some of the most common pins to be removed are DATA[16:31], arbitration pins ($\overline{BB}$, $\overline{BG}$, $\overline{BR}$), and TSIZ[0:1]. This section describes how

to configure dual-MCU systems for each of those scenarios, as well as describing limitations to EBI operation when other pins are missing ($\overline{\text{TA}}$, $\overline{\text{TEA}}$, $\overline{\text{BDIP}}$). More than one section may apply if the applicable pins are not present on one or both MCUs.

27.6.5.1 No Transfer Acknowledge ($\overline{\text{TA}}$) Pin

If an MCU has no $\overline{\text{TA}}$ pin available, this restricts the MCU to chip-select accesses only (no MCU->MCU transfers are possible). Non-chip-select accesses have no way for the EBI to know which cycle to latch the data. The EBI has no built-in protection to prevent non-chip-select accesses in this scenario; it is up to the user to make certain they set up chip-selects and external memories correctly to ensure all external accesses fall in a valid chip-select region.

27.6.5.2 No Transfer Error ($\overline{\text{TEA}}$) Pin

If an MCU has no $\overline{\text{TEA}}$ pin available, this eliminates the feature of terminating an access with $\overline{\text{TEA}}$. This means if an access times out in the EBI bus monitor, the EBI (master) will still terminate the access early, but there will be no external visibility of this termination, so the slave device might end up driving data much later, when a subsequent access is already underway. Therefore, the EBI bus monitor should be disabled when no $\overline{\text{TEA}}$ pin exists.

27.6.5.3 No Burst Data in Progress ($\overline{\text{BDIP}}$) Pin

If an MCU has no $\overline{\text{BDIP}}$ pin available, this eliminates burst support only if the burstable memory being used requires $\overline{\text{BDIP}}$ to burst. Many external memories use a self-timed configurable burst mechanism that does not require a dynamic burst indicator. Check the applicable external memory specification to see if $\overline{\text{BDIP}}$ is required in your system.

27.6.6 Summary of Differences from MPC5xx

Below is a summary list of the significant differences between this EBI and that of the MPC5xx parts.

- No memory controller support for external masters
 - must configure each master in multi-master system to drive its own chip selects
 - rationale: save complexity, no requirement for this feature

- Burst mechanism updated to be compatible with e200z core with 32-byte cache line
 - rationale: required for performance and compatibility with e200z core
- Removed these variable timing attributes from Option Register:
 - CSNT, ACS, TRLX, EHTR
 - rationale: reduces tester edgesets and complexity, no clear requirements for these features
- Removed reservation support on external bus
 - rationale: reservation not supported on internal bus, useless to support on external
- Removed Address Type (AT), Write-Protect (WP), and dual-mapping features
 - rationale: these functions can be replicated by Memory Management Unit (MMU) in e200z core
- Removed support for 8-bit ports
 - rationale: reduces complexity and not required
- Removed boot chip-select operation
 - rationale: on-chip Boot Assist Module (BAM) handles boot (and configuration of EBI registers)
- Open drain mode and pullup resistors no longer required for multi-master systems, extra cycle needed to switch between masters
 - rationale: saves customer hassle for multi-master system setup, at negligible performance cost
- Address decoding for external master accesses uses 4-bit code to determine internal slave instead of straight address decode
 - rationale: needed for compatibility with internal bridge address decoding and memory map
- Removed support for 3-master systems
 - rationale: very difficult to manage with internal bridge address decoding method and keep memory maps unique; not an essential feature to justify complexity of supporting
- Removed LBDIP Base Register bit, now late $\overline{\text{BDIP}}$ assertion is default behavior

- rationale: unaware of any memories that require $\overline{\text{BDIP}}$ to assert earlier than LBDIP timing, so reduce number of CS control bits and complexity
- Modified arbitration protocol to require extra cycles when switching between masters
 - rationale: could not use exact Oak protocol and make timing for full-speed operation; adding dead cycles to protocol allows bus to run full-speed in external master mode and makes this feature not limit overall EBI frequency
- Modified TSIZ[0:1] functionality to only indicate size of current transfer, not give information on ensuing transfers that may be part of the same atomic sequence
 - rationale: simpler and more intuitive functionality, no clear requirement for anything else
- Added support for 32-bit coherent read & write non-chip-select accesses in 16-bit data bus mode
 - rationale: some internal registers must be accessed all 32 bits at once to function as expected
- Added misaligned access support
 - rationale: some eSys cores require use of misaligned accesses for optimum performance
- Added calibration access support
 - rationale: support related device logic added to multiple eSys devices's, requested customer feature
- Added support for larger external address bus (up to 29 bits)
 - rationale: support larger external memory sizes
- Added support for address/data multiplexing
 - rationale: new feature to reduce minimum pin count
- Added support for using either half of data bus for 16-bit port transfers
 - rationale: helps A/D muxed usability, while maintaining backwards compatibility

Chapter 28

Analog Modules Overview

28.1 Introduction

This chip has the following modules for the primary purpose of analog measurement:

- Two EQADC modules, each containing two internal ADCs
- Four Sigma-Delta (SD) ADC modules
- Two Temperature Sensors
- Twelve Decimation Filters

28.2 EQADC subsystem

The integration of the two EQADC modules on this chip, EQADC_A and EQADC_B, is orthogonal except for the connection of the ADCs to specific external pins and internal channels.

Each EQADC module:

- has a hardware interface to twelve on-chip Decimation Filter modules to allow transfers of conversion and filtered values between the EQADC and Decimation Filters without CPU or DMA interaction. EQADC_A also has this hardware interface to the REACM2 module.
- has internal channel connections with the Power Management Controller module.

The following diagram shows the connections of the two EQADCs to other on-chip components and external pins.

Figure 28-1. EQADC subsystem

28.3 SDADC connections to other modules

The integration of the four SDADC modules on this chip is orthogonal except for the connection of the ADCs to specific external pins and internal channels.

Each SDADC module:

- has an independent digital interface with register interfaces, control hardware, DMA and interrupt requests, and so on
- connects to a subset of external pins that also connect to an eQADC module
- connects to eTPU channels to support:
 - conversion result interrupt and DMA requests and flag to eTPU (with hardware gating)
 - high/low conversion limit checking with interrupt request and flag to eTPU

The following diagram shows the connections of an SDADC module to other on-chip components and external pins.

NOTE: SDADC_4 has a 4:1 differential or 8:1 single-ended mux.

Figure 28-2. SDADC connections to other modules

Chapter 29

Sigma Delta Analog-to-Digital Converter (SDADC) Digital Interface

29.1 Chip-specific SDADC information

This chip has four instances of the SDADC module: SDADC_1, SDADC_2, and SDADC_3, and SDADC_4.

The following table summarizes varying features among the instances.

Table 29-1. SDADC instance channels and muxes

Instance	# channels	Channels	Single-ended input mux	Differential input mux
SDADC1, SDADC_2, and SDADC_3	4	AN[0] to AN[3]	4:1	2:1
SDADC_4	8	AN[0] to AN[7]	8:1	4:1

29.1.1 SDADC triggers and synchronous start

Each SDADC instance can be triggered to start a conversion either by a software write to [Software Trigger Key Register \(SDADC_STKR\)](#) or by a hardware trigger input selected in [Module Configuration Register \(SDADC_MCR\)](#) by writing the [TRIGSEL](#) field. See [Hardware triggering](#) for more information about triggering SDADC instances.

To support the synchronous start of all SDADC instances, the trigger output of each instance connects as a trigger input to every other instance.

Figure 29-1. SDADC simultaneous start connectivity

Additional hardware trigger inputs connect to eTPU channels. The following table shows all of the hardware trigger inputs for each SDADC instance.

Table 29-2. SDADC trigger inputs

MCR[TRIGSEL] value	SDADC_1 trigger input	SDADC_2 trigger input	SDADC_3 trigger input	SDADC_4 trigger input
0000	Reserved	SDADC_1 trigger output	SDADC_1 trigger output	SDADC_1 trigger output
0001	SDADC_2 trigger output	Reserved	SDADC_2 trigger output	SDADC_2 trigger output
0010	SDADC_3 trigger output	SDADC_3 trigger output	Reserved	SDADC_3 trigger output
0011	SDADC_4 trigger output	SDADC_4 trigger output	SDADC_4 trigger output	Reserved
0100 - 0111	Reserved	Reserved	Reserved	Reserved
1000	eTPU_A channel 20	eTPU_A channel 22	eTPU_A channel 24	eTPU_A channel 26
1001	eTPU_A channel 21	eTPU_A channel 23	eTPU_A channel 25	eTPU_A channel 27
1010	eTPU_B channel 20	eTPU_B channel 22	eTPU_B channel 24	eTPU_B channel 26
1011	eTPU_B channel 21	eTPU_B channel 23	eTPU_B channel 25	eTPU_B channel 27

Table continues on the next page...

Table 29-2. SDADC trigger inputs (continued)

MCR[TRIGSEL] value	SDADC_1 trigger input	SDADC_2 trigger input	SDADC_3 trigger input	SDADC_4 trigger input
1100	eTPU_C channel 15	eTPU_C channel 17	eTPU_C channel 19	eTPU_C channel 21
1101	eTPU_C channel 16	eTPU_C channel 18	eTPU_C channel 20	eTPU_C channel 22
1110 - 1111	Reserved	Reserved	Reserved	Reserved

29.1.2 Connections among SDADCs and eTPUs

For information about SDADC and eTPU connections, see:

- [SDADC triggers and synchronous start](#)
- [SDADC connections to other modules](#)
- SIU details about the mapping of DMA/interrupt gating and mux advance inputs as well as the mapping of end-of-conversion and watchdog flag outputs

29.2 Introduction

The Sigma-Delta Analog-to-Digital Converter (SDADC) digital interface block controls the on-chip SDADC and holds control and status registers accessible for application. It provides accurate conversion data for a wide range of applications.

29.3 Overview

The SDADC digital interface block provides all control information for operating mode selection (single-ended or differential), analog input gain, decimation rate, high-pass filter enable, etc. It also generates the bias controls for common mode voltage selection, to bias the positive and negative terminals to different voltage levels (for example, half scale bias, reference ground, reference supply) for diagnostics. It generates the analog multiplexer control signals for the selected channels. To assist synchronous operation across multiple ADC blocks, hardware trigger support is implemented to start data conversion.

The following figure depicts the block diagram of an SDADC and its digital control block.

Figure 29-2. SDADC block diagram

29.4 Features

The features of the SDADC are as follows:

- 16-bit data resolution output
- Single-ended input or differential input mode of operation
- Programmable wraparound mechanism for both modes of operation

- Configurable trigger sources: hardware or software
- Configurable initial entry and wraparound values for the loop
- Configurable biasing for negative input terminal in single-ended mode
- Gain and offset calibration support using fixed bias for input terminals
- Programmable decimation rate
- Programmable gain for analog inputs
- Optional high-pass filter for pure AC application
- Hardware trigger support for synchronous operation of multiple SDADC blocks
- Trigger event output generation by software
- Programmable FIFO structure for storing up to 16 datawords of 16-bit converted data
- Interrupt/DMA request generation based on various conditions:
 - Data buffer above threshold
 - Data buffer overrun
 - Watchdog (WDG) crossover event
- Programmable threshold range watchdog support
- Low consumption mode
- Optional conversion process halt mechanism on SoC debug request

29.5 Modes of operation

This section describes the different operation modes of the SDADC. When exiting reset, the mode of operation is determined by the Module Configuration Register (MCR).

29.5.1 Differential input mode

This mode is entered by negating the MCR[MODE] bit. In this mode, a pair of analog inputs are connected to positive and negative terminals of ADC modulator. In order to support gain and offset calibration for diagnostics, it is possible in this mode to select fixed bias voltages to both input terminals.

29.5.2 Single-ended input mode

This mode is entered by asserting the MCR[MODE] bit. In this mode, the negative input terminal is biased with a fixed voltage based on selection information in MCR, and the other analog input is connected to the selected external analog channel.

29.6 External signal description

The following table shows the list of signals driven by external pins. See the chip-specific details about SDADC signals and package pinouts for information about signal muxing and availability external to the chip.

Table 29-3. Signal properties

Name	Function	I/O	Reset	Pull-up
AN[0:7]	Single-ended analog inputs or Differential pairs of analog inputs	I	—	—
VREFP	Voltage reference for SDADC	I	—	—
VREFN	Ground reference for SDADC	I	—	—
AVDD	Analog voltage supply for SDADC	I	—	—
AVSS	Analog ground supply for SDADC	I	—	—
DVDD	Digital voltage supply for SDADC	I	—	—
DVSS	Digital ground supply for SDADC	I	—	—

29.7 Memory map and register definition

This section provides the memory map for the SDADC block.

SDADC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (SDADC_MCR)	32	R/W	0000_0000h	29.7.1/1057
4	Channel Selection Register (SDADC_CSR)	32	R/W	0000_0000h	29.7.2/1060
8	Reset Key Register (SDADC_RKR)	32	R/W	0000_A50Fh	29.7.3/1062

14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 HPFEN	High Pass Filter Enable 0 High-pass (DC removal) filter is disabled 1 High-pass (DC removal) filter is enabled
16 WDGEN	Watchdog Enable This bit enables the WDG monitor. 0 WDG is disabled 1 WDG is enabled
17–18 TRIGEDSEL	Trigger Edge Selection 00 Falling edge of trigger input is selected 01 Rising edge of trigger input is selected 10 Both edges of trigger input are selected 11 Both edges of trigger input are selected

Table continues on the next page...

SDADC_MCR field descriptions (continued)

Field	Description
19 TRIGEN	Trigger Enable This field enables the hardware trigger input to initiate a fresh conversion. Upon receiving a trigger event, SDADC reset input is asserted and deasserted synchronously with respect to the peripheral clock. The reset pulse width is fixed to four peripheral clock cycles. The trigger event is ignored if the SDADC internal modulator is not enabled ($MCR[EN] = 0$). 0 Trigger input is disabled 1 Trigger input is enabled
20–23 TRIGSEL	Trigger Input Selection This field selects which input will be used for hardware triggered conversions. 0000 Input trigger 0 is selected. See chip-specific information for trigger source. 0001 Input trigger 1 is selected. See chip-specific information for trigger source. 0010 Input trigger 2 is selected. See chip-specific information for trigger source. 0011 Input trigger 3 is selected. See chip-specific information for trigger source. 0100 Input trigger 4 is selected. See chip-specific information for trigger source. 0101 Input trigger 5 is selected. See chip-specific information for trigger source. 0110 Input trigger 6 is selected. See chip-specific information for trigger source. 0111 Input trigger 7 is selected. See chip-specific information for trigger source. 1000 Input trigger 8 is selected. See chip-specific information for trigger source. 1001 Input trigger 9 is selected. See chip-specific information for trigger source. 1010 Input trigger 10 is selected. See chip-specific information for trigger source. 1111 Input trigger 15 is selected. See chip-specific information for trigger source.
24 FRZ	Freeze This field enables stopping the SDADC conversions at the end of the current channel conversion when the chip enters debug mode. When the chip enters debug mode, further conversions by the SDADC analog block will be stopped, and converted data output from the SDADC analog block are ignored. The ongoing channel conversion will be completed and the converted data is stored. When the chip exits debug mode, SDADC resumes the job that was left before halting the conversions. 0 Conversions are not stopped 1 Conversions are stopped
25–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 VCOMSEL	Common Voltage Bias Selection This field selects the common voltage bias for the negative input terminal of the SDADC during single-ended mode ($MODE = 1$). 0 Negative input terminal is biased with VREFN 1 Negative input terminal is biased with VREFP/2 (half-scale bias)
28 WRMODE	Wrap-Around Mode This bit selects the wraparound mechanism for conversion of programmed sequence of channels.

Table continues on the next page...

SDADC_MCR field descriptions (continued)

Field	Description
	0 Wraparound mechanism disabled (in this case the default software control mechanism will be enabled) 1 Wraparound mechanism enabled
29 GECEN	Accurate Gain Error Mode Enable This bit selects the accurate gain error mode, and must be set during gain error calibration as well as during conversions requiring accurate gain error mode. It can be kept '0' if gain error calibration mode is not needed. 0 Gain error calibration mode disabled 1 Gain error calibration mode enabled
30 MODE	Mode selection 0 Differential input mode selected 1 Single-ended input mode selected
31 EN	Enable for SDADC block 0 SDADC internal modulator placed in low consumption mode 1 SDADC internal modulator enabled

29.7.2 Channel Selection Register (SDADC_CSR)

The Channel Selection Register (CSR) selects analog inputs AN[0:7] to be connected to positive and negative terminals of the SDADC and controls the biasing of analog inputs to half-scale bias through 100 kOhm resistance.

Address: 0h base + 4h offset = 4h

SDADC_CSR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 BIASEN	Bias enable

Table continues on the next page...

SDADC_CSR field descriptions (continued)

Field	Description																																																								
	If BIASEN[i] = 1, analog input AN[i] (could be single-ended input or differential analog input) is connected to half-scale bias through a 100 kOhm resistor.																																																								
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.																																																								
21–23 ANCHSEL_WRAP	Analog Channel Selection Wraparound Value (ANCHSEL_WRAP) When in wraparound mode, this field indicates the maximum value of the wraparound counter, after which it will wrap around back to initial value 000. This value should be programmed before enabling wraparound mechanism (MCR[WRMODE] = 1).																																																								
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.																																																								
29–31 ANCHSEL	Analog Channel Selection(ANCHSEL) Based on single-ended or differential mode of operation (MCR[MODE]), common mode voltage selection (MCR[VCOMSEL]), this field defines the connectivity of analog inputs to either positive or negative polarity terminals of the SDADC according to the following table. Wraparound Mode: • This field also indicates the initial entry value for the first loop of the wraparound sequence from where the wraparound counter will start incrementing when wraparound mode is entered (when wraparound mechanism enabled (MCR[WRMODE] = 1)). • If this field is written any time during wraparound mode (when MCR[WRMODE] = 1), the present value of the wraparound counter will be updated with the value of ANCHSEL - the next trigger will act on the updated channel, and the next increment will be on the updated channel. Here, the value of ANCHSEL chosen should be < ANCHSEL_WRAP; otherwise it will be ignored by hardware. • Wraparound will always be from initial counter value 000. <table><tr><th>MODE</th><th>VCOMSEL</th><th>ANCHSEL</th><th>INP (positive terminal)</th><th>INM (negative terminal)</th></tr><tr><td rowspan="16">1</td><td rowspan="8">0</td><td>000</td><td>AN[0]</td><td>VREFN</td></tr><tr><td>001</td><td>AN[1]</td><td>VREFN</td></tr><tr><td>010</td><td>AN[2]</td><td>VREFN</td></tr><tr><td>011</td><td>AN[3]</td><td>VREFN</td></tr><tr><td>100</td><td>AN[4]</td><td>VREFN</td></tr><tr><td>101</td><td>AN[5]</td><td>VREFN</td></tr><tr><td>110</td><td>AN[6]</td><td>VREFN</td></tr><tr><td>111</td><td>AN[7]</td><td>VREFN</td></tr><tr><td rowspan="8">1</td><td>000</td><td>AN[0]</td><td>VREFP/2</td></tr><tr><td>001</td><td>AN[1]</td><td>VREFP/2</td></tr><tr><td>010</td><td>AN[2]</td><td>VREFP/2</td></tr><tr><td>011</td><td>AN[3]</td><td>VREFP/2</td></tr><tr><td>100</td><td>AN[4]</td><td>VREFP/2</td></tr><tr><td>101</td><td>AN[5]</td><td>VREFP/2</td></tr><tr><td>110</td><td>AN[6]</td><td>VREFP/2</td></tr><tr><td>111</td><td>AN[7]</td><td>VREFP/2</td></tr></table>	MODE	VCOMSEL	ANCHSEL	INP (positive terminal)	INM (negative terminal)	1	0	000	AN[0]	VREFN	001	AN[1]	VREFN	010	AN[2]	VREFN	011	AN[3]	VREFN	100	AN[4]	VREFN	101	AN[5]	VREFN	110	AN[6]	VREFN	111	AN[7]	VREFN	1	000	AN[0]	VREFP/2	001	AN[1]	VREFP/2	010	AN[2]	VREFP/2	011	AN[3]	VREFP/2	100	AN[4]	VREFP/2	101	AN[5]	VREFP/2	110	AN[6]	VREFP/2	111	AN[7]	VREFP/2

SDADC_RKR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 RESET_KEY	Reset Key This field, when written with 5AF0h, is used to generate the reset for the SDADC block and to reload the internal counter with the start value programmed in OSDR. Any write access to this register which is different from the predefined key is ignored. Read access will always return the inverted key.

29.7.4 Status Flag Register (SDADC_SFR)

The Status Flag Register (SFR) contains status and flag bits. These bits are set by hardware and reflect the status of the SDADC and indicate the occurrence of events that may generate an interrupt or a DMA request. Software can clear some flags by writing '1' to those bits. Writing a '0' to a flag has no effect.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SDADC_SFR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 ANCHSEL_CNT	Analog Channel Selection Counter(ANCHSEL_CNT) This field reflects the current value of the internal Analog Channel Selection Counter. It indicates the present number of the channel selected through the analog multiplexer.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 DFEF	Data FIFO Empty Flag This field is asserted when there is no dataword in the FIFO.

Table continues on the next page...

SDADC_SFR field descriptions (continued)

Field	Description
	0 Data FIFO is not empty 1 Data FIFO is empty
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 WTHH	Watchdog Upper Threshold Cross Over Event This field is set when Converted Data crosses Upper Threshold of WDG. It can be cleared by software writing '1' to clear. NOTE: This bit is also cleared by an acknowledgement from the DMA module when all of the following conditions are met: - SDADC_RSER[WTHDIRE]=1 (When this field is set by the occurrence of a watchdog upper threshold cross over event, a request is generated) - SDADC_SFR[WTHDIRS]=1 (The request generated when this field is set is a DMA request) - SDADC_RSER[GDIGE]=0 OR, if SDADC_RSER[GDIGE]=1, the external gating signal is asserted 0 Watchdog Upper Threshold Cross Over Event did not occur 1 Watchdog Upper Threshold Cross Over Event occurred
28 WTHL	Watchdog Lower Threshold Cross Over Event This field is set when Converted Data crosses Lower Threshold of WDG. It can be cleared by software writing '1' to clear. NOTE: This bit is also cleared by an acknowledgement from the DMA module when all of the following conditions are met: - SDADC_RSER[WTHDIRE]=1 (When this field is set by the occurrence of a watchdog lower threshold cross over event, a request is generated) - SDADC_SFR[WTHDIRS]=1 (The request generated when this field is set is a DMA request) - SDADC_RSER[GDIGE]=0 OR, if SDADC_RSER[GDIGE]=1, the external gating signal is asserted 0 Watchdog Lower Threshold Cross Over Event did not occur 1 Watchdog Lower Threshold Cross Over Event occurred
29 CDVF	Converted Data Valid Flag This field gives the actual status of data coming from the SDADC block. The converted data is not valid or is corrupted whenever there is a change in configuration settings determined by MCR, channel selection programmed in CSR. Any write access to the registers MCR and CSR will reset this flag. This flag is set automatically after an internal timer counts a number of output clock fd clock cycles specified by the value of SDADC_OSDR[OSD]. 0 Data output from SDADC is not valid 1 Data output from SDADC is valid
30 DFORF	Data FIFO Overrun Flag This field indicates that software or DMA failed to prevent FIFO from overflowing with converted datawords. Software can clear this bit by writing '1' to it after reading the FIFO contents through CDR. This flag remains set if software or DMA failed to clear the condition that caused this flag setting. If DFORF is set, further datawords will not be received into FIFO even if sufficient room exists. 0 No overrun has occurred since the last time the flag was cleared 1 Overrun has occurred or the DFORF has not been cleared since the last overrun occurred

Table continues on the next page...

SDADC_SFR field descriptions (continued)

Field	Description
31 DFFF	Data FIFO Full Flag This bit is set when the number of converted datawords in the FIFO is equal to or more than the number indicated by FCR[FTHLd]. Software can clear this bit by writing '1' to it. This bit is also cleared by an acknowledgement from the DMA controller when DMA request generation is selected. This bit remains set if software or DMA failed to clear the condition that caused this flag setting. Even if DFFF is set, datawords will continue to be received until an overrun condition occurs. Datawords will not be received if the converted data is not valid (CDVF = 0). NOTE: Whenever MCR[EN] is cleared in order to stop the SDADC or change the channel configuration, it is necessary to also clear the RSER[DFFDIRE] bit alongwith. Similarly if DMA or software is too slow in not reading the FIFO datawords resulting in DFFF condition it is advisable to stop the SDADC by clearing the MCR[EN] followed by clearing of RSER[DFFDIRE] bit. Both these action will ensure safe operation. 0 The number of datawords in FIFO is less than the number indicated by FCR[FTHLd] 1 The number of datawords in FIFO is equal to or greater than the number indicated by FCR[FTHLd] at some point in time since this flag was last cleared

29.7.5 Request Select and Enable Register (SDADC_RSER)

The Request Select and Enable Register (RSER) serves two purposes:

- Enables the flag bits in SFR to generate DMA requests or interrupt requests.
- Selects the type of request to generate.

Refer to the field descriptions for the type of requests that are supported.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0													WTHDIRS	DFFDIRS	
W

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDADC_RSER field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 WTHDIRS	WDG Threshold Cross Over Event DMA/Interrupt Request Select When SFR[WTHH/WTHL] and RSER[WTHDIRE] fields are set, this field selects between generating a DMA request or an interrupt request. 0 Interrupt request is selected 1 DMA request is selected
15 DFFDIRS	Data FIFO Full DMA/Interrupt Request Select When the SFR[DFFF] and SFR[DFFDIRE] fields are set, this field selects between generating a DMA request or an interrupt request. 0 Interrupt request is selected 1 DMA request is selected
16 GDIGE	Global DMA/Interrupt Gating Enable This field determines whether all module interrupts and DMA requests need to be gated by an external gating signal or not. 0 No impact of external gating signal on module DMA/interrupt requests 1 All module DMA/interrupt requests are qualified only when external gating signal is asserted
17–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 WTHDIRE	WDG Threshold Cross Over Event DMA/Interrupt Request Enable This field enables the SFR[WTHH/WTHL] field to generate a request. The WTHDIRS field determines which is selected, a DMA request or an interrupt request. The final DMA/interrupt request also depends on the gating signal if enabled by the GDIGE field. 0 Interrupt/DMA request is disabled on WDG Threshold Cross Over Event 1 Interrupt/DMA request is enabled on WDG Threshold Cross Over Event
29 CDVEE	Conversion Data Valid Event Enable The status of SFR[CDVF] gated with RSER[CDVEE] is passed on as an event on “conversion_flag” output port, which can be used at SoC level for indication of valid data conversion window. Once enabled, the event output will remain asserted as long as valid data conversions are ongoing. 0 Event output disabled 1 Event output assertion/deassertion based on the SFR[CDVF] field
30 DFORIE	Data FIFO Overrun Interrupt Enable This bit enables the SFR[DFORF] field to generate an interrupt request. The final interrupt request also depends on the gating signal if enabled by the GDIGE field. 0 Interrupt request is disabled when data FIFO overrun condition occurs 1 Interrupt request is enabled when data FIFO overrun condition occurs
31 DFFDIRE	Data FIFO Full DMA/Interrupt Request Enable This field enables the SFR[DFFF] field to generate a request. The DFFDIRS field determines which is selected, a DMA request or an interrupt request. The final DMA/interrupt request also depends on the gating signal if enabled by the GDIGE field.

Table continues on the next page...

SDADC_RSER field descriptions (continued)

Field	Description
0	Interrupt/DMA request is disabled when data FIFO full condition occurs
1	Interrupt/DMA request is enabled when data FIFO full condition occurs

29.7.6 Output Settling Delay Register (SDADC_OSDR)

The Output Settling Delay Register (OSDR) provides a delay value to qualify the converted output data coming from the SDADC.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																							OSD								
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

SDADC_OSDR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 OSD	Output Settling Delay This field defines the delay to qualify the conversion data stored in CDR. Whenever the SDADC block is reset in order to start the conversion from a fresh state, an internal timer is loaded with this start value. The counter counts down with output clock f_d until it reaches zero, and then it generates a flag which qualifies the converted data. The output clock f_d is equal to $f_s / (2 \times \text{OSR})$, where f_s is the input sampling clock frequency. See the electrical specifications for the settling delays. NOTE: Refer to the t_{settling} and t_{LATENCY} parameters in the device datasheet for the minimum allowed output settling delay values.

29.7.7 FIFO Control Register (SDADC_FCR)

The FIFO Control Register (FCR) provides the ability to enable or disable the FIFO functionality, and to control the amount of available FIFO depth to be used.

NOTE

- 1. It is important to note that the FIFO depth is set at the factory and cannot be changed but the amount of available FIFO space actually used can be set by specifying the value in the FTHLD field. The FSIZE field indicates the amount of FIFO space available. By setting the value of FTHLD to be less than the FIFO depth indicated by FSIZE, the FIFO is considered to be full when the number of data words in the FIFO is equal or greater than FTHLD.
- 2. This register may be read at any time, but should only be written when SDADC is disabled (MCR[EN] = 0).

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															0
W																FRST
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0														FSIZE	
W					FTHLD								FOWEN			FE
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

SDADC_FCR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 FRST	FIFO Flush Reset This is functional soft reset to flush the current FIFO content and initialize the internal FIFO pointers. This is W1S(write one shot) bit which can be written as '1' but always read as '0'. Use this option only after disabling the ADC i.e. MCR[EN]='0'. 0 No effect. 1 Generate a single cycle reset event to flush the FIFO.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 FTHLD	FIFO Threshold When the number of datawords in the data FIFO is greater than the value in FTHLD field, the FIFO full event is flagged. An interrupt or a DMA request will be generated as determined by DFFDIRE and DFFDIRS fields of RSER. For proper operation, the value in the FTHLD field must be set to be less than or equal to the FIFO size as indicated by FSIZE.
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 FOWEN	FIFO Over Write Enable When set the built-in FIFO structure allows the overwriting of new converted data over older converted data after the FIFO has number of entries equal to the FSIZE. In this case overrun will not be seen. 0 Data FIFO OW option disabled. 1 Data FIFO OW option enabled.
29–30 FSIZE	FIFO Size The maximum number of converted datawords that can be stored in the data FIFO before an overrun occurs. This field is read-only. The reset value of this field depends on the implementation parameter to define the FIFO size. 00 FIFO depth = 1 dataword 01 FIFO depth = 4 datawords 10 FIFO depth = 8 datawords 11 FIFO depth = 16 datawords
31 FE	FIFO Enable When this field is set the built-in FIFO structure is enabled. The size of the FIFO structure is indicated by the FSIZE field. If this field is not set then the FIFO depth is set to one dataword regardless of the value in the FSIZE field. 0 Data FIFO is not enabled for multiple datawords; FIFO depth is one dataword 1 Data FIFO is enabled; FIFO depth is indicated by FSIZE

29.7.8 Software Trigger Key Register (SDADC_STKR)

The Software Trigger Key Register (STKR) allows generating the trigger event output by a software write operation.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																ST_KEY															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

SDADC_STKR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 ST_KEY	Software Trigger Key This bitfield, when written with FFFFh, is used to generate a trigger event output which can be used to trigger conversions of multiple SDADC blocks synchronously depending on the chip's implementation. Any write access to this register which is different from the predefined key is ignored. Read access will always return 0000h.

29.7.9 Converted Data Register (SDADC_CDR)

The Converted Data Register (CDR) stores the converted data in the data FIFO.

The conversion result in the CDATA word is a 16-bit, signed value.

NOTE

When SDADC_MCR[PGAN]=111b (programmable gain is 16), the least significant bit of the conversion data in SDADC_CDR[CDATA] is always 0.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SDADC_CDR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 CDATA	Converted Data Register (CDATA[13:0]) The converted datawords can be read from FIFO by reading this register. The data width is 16 bits which has actual 16-bit data (bits 15 down to 0) coming from ADC.

29.7.10 WDG Threshold Register (SDADC_WTHHLR)

This is the Converted Data Range WDG Threshold register.

NOTE

A single WDG monitor will check for lower and upper threshold crossover events.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	THR _H																THR _L															
W

SDADC_WTHHLR field descriptions

Field	Description
0–15 THRH	WDG Upper Threshold Value This indicates the upper threshold for the converted data on any channel, above which threshold a crossover event would be flagged through SFR[WTHH].
16–31 THRL	WDG Lower Threshold Value This indicates the lower threshold for the converted data on any channel, below which threshold cross over event would be flagged through SFR[WTHL].

29.8 Functional description

The SDADC has the following distinct available modes determined by fields in MCR:

- Differential input mode
- Single-ended input mode
- Low consumption mode

29.8.1 Differential input mode

Differential input mode is entered when the SDADC_MCR[MODE] field is set to '0' and the SDADC_MCR[EN] field is set to '1'. In differential input mode, a pair of analog inputs among AN[0:7] is connected to the input terminals of the SDADC modulator block. The module supports four differential pairs: AN[0,1], AN[2,3], AN[4,5], and AN[6,7].

The modulator block has two input terminals, positive (INP) and negative (INM). The selection of input pair depends on the SDADC_CSR[ANCHSEL] field. The connectivity of each analog input in a given differential pair, whether it is connected to positive or negative terminal, is determined according to the Analog input AN[0:7] selection table in the Channel Selection Register description.

The differential input mode can also be used to perform gain and offset calibration, where the input terminals are biased with fixed voltages coming from the bias block.

29.8.2 Single-ended input mode

Single-ended input mode is entered by setting the SDADC_MCR[MODE] and SDADC_MCR[EN] fields to '1'. In this mode, one of the analog inputs among AN[0:7] is selected via the SDADC_CSR[ANCHSEL] field and is connected to the positive terminal. The negative input terminal is biased with a fixed internal voltage. There are two internal bias voltages available: reference ground (VREFN) and half-scale bias (VREFP/2). The selection of this common mode voltage is controlled via the SDADC_MCR[VCOMSEL] field.

29.8.3 Low consumption mode

This is the default mode after exiting from reset. This mode is exited by asserting the MCR[EN] field to enable the SDADC block. When data conversion is not required, the SDADC internal modulator can be put in low consumption mode to reduce power consumption.

29.8.4 Analog input multiplexing and bias support

The complete selection and connectivity of analog inputs AN[0:7] is based on the ANCHSEL field of CSR and the MODE and VCOMSEL bits of MCR, according to the Analog input AN[0:7] selection table in the Channel Selection Register description. Each analog input can be biased to half scale ($AVDD/2$) via on-chip 100 k Ω resistance. This allows simple AC coupling to the external analog inputs through a capacitor. This biasing is applicable irrespective of whether analog channel is selected through multiplexer or not.

29.8.5 Programmable gain and decimation rate

All analog inputs can be configured to have a selectable input gain as defined in the PGAN field description in MCR. This means the input signal is sampled and the result is amplified by the factor determined by PGAN before providing the same to modulator.

The SDADC module is provided with a fixed input sampling clock f_s . The input signal is grossly oversampled by the modulator in order to reduce quantization noise. To support different passbands with a fixed sampling clock, a programmable decimation rate is implemented. The process of decimation, to eliminate redundant data at the output while retaining the necessary information, is controlled by the field PDR in MCR.

29.8.6 High-pass filter support

For pure AC applications, it is useful to remove any DC component in the input signal. An optional high-pass filter is implemented which can be enabled by asserting the MCR[HPFEN] field. The -3 dB frequency of the filter is fixed (not programmable) and is specified in the device data sheet. This high-pass filter is implemented in the decimation filter logic of the SDADC.

29.8.7 Data conversion

The SDADC operates in a continuous conversion mode as soon as it is enabled. There is an inherent settling time required after SDADC startup before conversion data is considered valid.

NOTE

During that period, the Converted Data Valid Flag bit (SDADC_SFR[CDVF]) reads '0'.
