Settling time duration depends on the latency and output settling time specifications. To account for the settling time, an internal timer is implemented that counts down from a start value determined by the value of the SDADC_OSDR[OSD] field.

The internal countdown timer is triggered by an SDADC reset, i.e., by writing the value 5AF0h to the SDADC_RKR[RESET_KEY] field.

NOTE

An SDADC reset is required any time there is a change to the SDADC configuration (via changes to the SDADC_MCR register settings), or a change to analog channel selection (via SDADC_CSR register settings).

When the timer reaches '0', the SDADC_SFR[CDVF] field is asserted and converted data is loaded into data FIFO on every rising edge of the output clock (f_d).

Any write access to the SDADC_MCR or SDADC_CSR register causes the SDADC_SFR[CDVF] flag to be cleared, indicating that data coming from SDADC is not valid. If the SDADC_SFR[CDVF] flag is '0', the following flags are blocked from becoming asserted:

- Data FIFO Full Flag (SDADC_SFR[DFFF])
- Data FIFO Overrun Flag (SDADC_SFR[DFORF])

If the SDADC_SFR[DFFF] bit is already set, the data FIFO is already full before SDADC_SFR[CDVF] deassertion.

Wraparound Control Mechanism: Here a wraparound logic includes all analog channels of the input multiplexer from Ain("000") to Ain(CSR[ANCHSEL_WRAP]) in both Single ended and Differential ended mode in wraparound sequence triggered by hardware or software source:

- MCR[WRMODE] bit would enable or disable the wraparound mechanism. Clearing the WRMODE bit automatically switches FSM back to Software control mode.
- Every valid trigger advances the wraparound counter to next channel to be converted.
- Wraparound Counter: An internal wraparound counter which points to analog channel to be converted takes the initial entry value for the first loop of execution from CSR[ANCHSEL] while entering wraparound mode. From next loop onwards the counter wraparounds to default initial value "000". Maximum value of the counter (wraparound value) should be programmed in CSR[ANCHSEL_WRAP] before entering wraparound mode. The definition of ANCHSEL and ANCHSEL_WRAP is provided in the Analog input AN[0:7] selection table in the Channel Selection Register description.
- Upon entering or during wraparound mode user should take care to program ANCHSEL value less than ANCHSEL_WRAP value; otherwise hardware would reject the new ANCHSEL value.

- Possible trigger sources:
 - SOURCE1 (Software Bit): writing to STKR.ST_KEY at any time during the wraparound mode (irrespective of MCR[TRIGEN or TRIGSEL] setting) generates a trigger pulse. Each such trigger initiates a fresh conversion and advances the wraparound counter by one.

NOTE

Care should be taken while programming the TRIGEN/TRIGSEL of each SDADC instance that no unintended simultaneous SW triggering of multiple instances happen.

- SOURCE2 (Hardware Trigger): Here external trigger output enabled by MCR[TRIGEN or TRIGEDSEL or TRIGSEL] before entering wraparound mode for selective or all SDADC instances provides trigger. Each such valid trigger initiates a fresh conversion and advances the wraparound counter by one. One of the hw_trig_in ports can be used to connect the external trigger output.
- Next channel number to be converted can be updated by software even in the middle of wraparound sequence execution. This can be done by rewriting CSR[ANCHSEL]. After CSR[ANCHSEL] is rewritten, the next trigger takes updated value and the wraparound counter would increment from the updated value.
- Current wraparound counter value can be read from the SFR[ANCHSEL_CNT] bitfield.

29.8.8 Hardware triggering

Software Control Mechanism: SDADC conversion can be triggered by various hardware events coming from either external pins or internal timers. The field TRIGSEL of MCR selects which hardware event is to be used for triggering conversions. This trigger event, which is synchronous to the peripheral clock, is enabled by asserting MCR[TRIGEN]. As soon as a trigger event is detected, reset input of SDADC block is asserted synchronously for four cycles. This will ensure that SDADC starts from a fresh state when reacting to the input trigger event. The SDADC internal modulator must be enabled before enabling the trigger event — otherwise the trigger event will be ignored.

If the same trigger event is provided to multiple SDADC digital interface modules and the respective enable controls (TRIGEN bit MCR) are asserted, synchronous operation of multiple SDADC blocks can be achieved with output results being updated at the same time. Once the reset input is deasserted, the first valid conversion output is stored in data FIFO after a configurable delay determined by OSD[OSD].

It is also possible to generate a software trigger event output by a write access of STKR with a predefined key. This event output can be used as a trigger to achieve synchronous software start of multiple SDADC blocks.

In case of a hardware trigger, the skew/jitter will be less than 100 ns. It will be more than one ADC clock cycle due to synchronization. In case of a software trigger, all SDADCs start synchronous sampling.

Wraparound Control Mechanism: In wraparound control mode, hardware and software triggers are equally valid. The hardware trigger source should be selected before enabling the wraparound mode.

29.8.9 Interrupt/DMA request support

The SDADC has one condition that generates interrupts only and another that generates interrupts or DMA request.

The DFFF field is asserted when the data FIFO full condition is detected, indicating that the number of converted datawords stored in data FIFO is equal to or greater than the value indicated by threshold determined by FCR[FTHLD]. The interrupt or DMA request is generated only when RSER[DFFDIRE] is asserted. RSER[DFFDIRS] selects whether a DMA request or an interrupt request is generated.

The data FIFO overrun flag (DFORF) indicates the FIFO overflow condition. Further converted datawords cannot be received and data is lost. The interrupt request is generated only when RSER[DFORIE] is asserted.

Apart from above, a WDG threshold crossover event can also generate an interrupt or DMA request.

If RSER[GDIGE] is set, all module interrupt/DMA requests are qualified only when an external global gating signal is asserted.

29.8.10 Gain calibration support

To perform gain calibration, the following sequence needs to be applied.

1. Select differential mode of operation by writing MCR[MODE] to '0'.
2. Enable gain error calibration mode by writing MCR[GECEN] to '1'.
3. Configure the mux selection ANCHSEL field of CSR to '110'. This configuration will apply VREFP on positive terminal and VREFN on negative terminal.
4. Disable the bias on all input analog channels by writing ENBIAS field of CSR to 00h.

5. Disable the high-pass filter by deasserting MCR[HPFEN].
6. Generate a reset event by writing 5AF0h to RESET_KEY of RKR.
7. Read the digital output (CDR[CDATA]) stored in FIFO after the output settling time. Expected output if there is no gain error is 0111_1001_1001_1001b, corresponding to full positive scale after attenuation inserted by the internal filter (1×0.95). The measurement should be repeated to reduce contribution of noise during the calibration process. D_p is the average value of attenuated positive full scale given by $D_p = \text{AVERAGE}(\text{CDR}[\text{CDATA}])$.
8. Change the mux selection ANCHSEL field of CSR to '111'. This configuration will apply VREFN on positive terminal and VREFP on negative terminal.
9. Generate a reset event by writing 5AF0h to RESET_KEY of RKR.
10. Read the digital output (CDR[CDATA]) stored in FIFO after the output settling time. Expected output if there is no gain error is 1000_0110_0110_0110b, corresponding to full negative scale after attenuation inserted by the internal filter (-1×0.95). The measurement should be repeated to reduce contribution of noise during calibration process. D_n is the average value of attenuated negative full scale given by $D_n = \text{AVERAGE}(\text{CDR}[\text{CDATA}])$.
11. The SDADC calibrated gain can be calculated as:

$$\text{Gain} = (D_p - D_n) / 2^{16}$$
12. The measured gain value can be used to nullify the gain errors in the digital output. For calibrated conversion, the data CDR[CDATA] provided by the SDADC should be normalized using the calculated gain: $\text{CDATA}_{\text{norm}}$ is given by $\text{CDATA}_{\text{norm}} = \text{CDR}[\text{CDATA}] / \text{Gain}$.

Note

- a. The gain error calibration should only be done with gain equal to '1' (in other words, PGAN = 000). Nevertheless, the calculated gain can be applied to normalized data also for conversion with $\text{GAIN} > 1$.
- b. MCR[GECEN] = 1 ensures the accurate gain error mode is enabled. This bit should be set both during calibration process and after calibration, for application data conversion. Application data conversion must then be normalized using the measured gain.
- c. The higher the number of full-scale conversion (D_p , D_n) done, the higher the rejection of noise during the calibration. The number of conversion is dependent on application noise. It is recommended to run at least 16 conversions when calculating an average value.

29.8.11 Offset calibration support

To perform offset calibration, the following sequence must be applied.

1. Select differential mode of operation by writing SDADC_MCR[MODE] to '0'.
2. Configure the SDADC_CSR[ANCHSEL] mux selection field to '100' or '101' as required.
 - a. SDADC_CSR[ANCHSEL] = '100' in case of data conversion after calibration in "single ended mode with negative input= $V_{SS\_HV\_ADR\_D}$ "
 - b. SDADC_CSR[ANCHSEL] = '101' in case of data conversion after calibration in "differential mode" and "single ended mode with negative input = $(V_{DD\_HV\_ADR\_D} - V_{SS\_HV\_ADR\_D}) / 2$ "
3. Disable the bias on all input analog channels by writing ENBIAS field of CSR to 00h.
4. Disable the high pass filter by deasserting SDADC_MCR[HPFEN].
5. Generate a reset event by writing 5AF0h to RESET_KEY of RKR.
6. Read the digital output stored in FIFO after the output settling time.
7. The measured offset can be used to nullify the offset error in the digital output.
Expected output is 00_0000_0000_0000b. The SDADC offset can be calculated as:
Offset = Expected Output – Actual Output

Note

The offset must be calculated for each SDADC_MCR[PGAN] field setting since it is expected to vary with gain configuration of SDADC.

29.9 Initialization information

To initialize the SDADC registers for data conversion, the following sequence is required.

1. Enable the SDADC by asserting MCR[EN].
2. Configure MCR to select the required mode, polarity, common mode voltage, input gain, and decimation rate.
3. Enable high-pass filter if required.
4. Select the required analog channel for data conversion. It is possible to select the bias for each channel for AC coupling applications.
5. Configure OSD delay according to SDADC startup time or latency from reset exit.
6. Generate a reset event by writing 5AF0h to RESET_KEY of RKR. Otherwise, if data conversion need to be triggered by a hardware event, assert MCR[TRIGEN].

7. DFFF interrupt or DMA request will be generated after the data FIFO has reached threshold to indicate that data can be transferred.

29.9.1 Data conversion step

To acquire a data from SDADC, the following sequence is required:

1. Enable the SDADC by asserting MCR[EN].
2. Configure MCR to select the required mode, polarity, common mode voltage, input gain, and decimation rate.
3. Enable high-pass filter is required.
4. Select the required analog channel for data conversion. It is possible to select the bias for each channel for AC coupling applications.
5. Configure OSD delay according to SDADC required startup time or latency from reset exit.
6. Generate a reset event writing 5AF0h in RESET_KEY field of RKR register.
7. Wait till FIFO empty flag DFEF of SFR register is clear.
8. Read data by CDATA of CDR register.

Repeat steps from 6 to 8 for new acquisitions.

NOTE

The time elapsed between reset event and Read data by CDATA field of CDR register are:

- Reset event <- -> Data Valid flag(CDVS) = Output settling Time delay (OSDR has to be set at least to 16) (Refer to the t_{settling} and t_{LATENCY} parameters in the device datasheet for the minimum allowed output settling delay values.).
- Data Valid flag <- -> Data FIFO is not empty = $0.5 * \text{CLK\_Out} + 3 * \text{CLK\_In}$
- Data FIFO is not empty <- -> read Data (safety point) = $2 * \text{CLK\_In}$, where $\text{CLK\_Out} = \text{CLK\_In} / (2 * \text{OSR})$

Chapter 30

Enhanced Queued Analog-to-Digital Converter (EQADC)

30.1 Chip-specific EQADC information

This chip has two instances of the EQADC module: EQADC_A and EQADC_B.

Each EQADC module:

- controls two independent Redundant Signed Digit (RSD) analog-to-digital (ADC) converter cores: ADC0 and ADC1.
- has an independent digital interface with register interfaces, control hardware, DMA and interrupt requests, and so on.

Chip-specific features of the EQADCs include:

- 24 dedicated external analog input pins to each EQADC module
- 16 pins shared between the two modules
- 6 additional pins share the dedicated EQADC_B channel inputs for greater pinout flexibility
- No support for external converters or an external device; the SSI interface is not present
- Addition of a Burst Trigger Generator, which is described in the SIU chapter
- Addition of bias/diagnostic pull up/down in the pad cell to support sharing ADC pins with SDADC inputs
- Targets up to 1.5M Sample/s (ADC_CLK=24 MHz) for differential conversions

The value of the external bypass between capacitor REFBYPC and VRL should be 100 nf.

NOTE

Due to legacy reasons, both ADC0 and ADC1 must be enabled for accurate conversion results.

NOTE

An 8 ms wait time from VDDA power up to enabling ADC is required to pre-charge the external 100 nf capacitor on REFBYPC pin. This time must be guaranteed by crystal startup time plus reset duration or user. The ADC internal bias generator circuit will start up after 10 μ s upon VRH/VRL and VDDA/VSSA power up and produces a stable/required bias current to the pre-charge circuit, but the current to other analog circuits are disabled until ADCs are enabled. As soon as the ADCs are enabled, the bias currents to all of analog circuits will be enabled.

30.1.1 EQADC connections to other modules

Each EQADC module:

- has a hardware interface to twelve on-chip Decimation Filter modules to allow transfers of conversion and filtered values between the EQADC and Decimation Filters without CPU or DMA interaction. EQADC_A also has this hardware interface to the REACM2 module.
- has internal channel connections with the Power Management Controller module.

30.1.1.1 On-chip Decimation Filters as DSP module

The EQADC transfers commands from multiple Command FIFOs (CFIFOs) to the on-chip ADCs. The multiple Result FIFOs (RFIFOs) can receive data from the on-chip ADCs or from the on-chip DSP module (Decimation Filters). Data from the on-chip ADCs can be routed to the side interface, processed by the Decimation Filters, and then routed back through the side interface to the RFIFOs.

30.1.1.2 Sources of software and external hardware triggers

The EQADC supports software and external hardware triggers (via package pins) from the PIT-RTI, eTPU, and eMIOS modules to initiate transfers of commands from the CFIFOs to the on-chip ADCs.

30.1.1.3 Routing conversion results to REACM2 and DECFILTER modules

To route the results of an EQADC conversion to the REACM2 module or a DECFILTER module, use one or more of the [Alternate Configuration 1-14 Control Registers \(ADC_ACR1-14\)](#).

1. Define an alternate configuration, including a destination for conversion results, by programming an ADC_ACRn register.
2. For the desired conversion, select that ADC_ACRn register.

The value of ADC_ACRn[DEST] determines one or more destinations for the conversion result.

- A DEST value that is greater than 0 selects one or more destinations on the EQADC's parallel side interface (PSI).
- The REACM2 and DECFILTER modules are destinations on the PSI.

The DAM field of the [EQADC Module Configuration Register \(EQADC_MCR\)](#) also affects the destination selection.

See [Table 30-121](#) for general information about destinations selected by EQADC_MCR[DAM] and ADC_ACRn[DEST], including when DEST is 0. For DEST values greater than 0, that table shows the PSI destinations as numbered simply 1 to 15. The following table correlates those numbered destinations with the REACM2 and DECFILTER modules.

Table 30-1. Conversion destination selection details for PSI

EQADC instance	EQADC_MCR[DAM]	ADC_ACRn[DEST]	First destination	Second destination
EQADC_A and EQADC_B	0	0001	1: DECFILTER_A	—

30.1.1.4 STAC server IDs

STAC server IDs are defined in [STAC server IDs](#) in the chip-specific eTPU information.

30.1.2 EQADC Stop mode entry

On this chip, SIUL_HLT1[EQADCx] is the chip-level control for issuing a request to an EQADC instance to enter its Stop mode.

30.1.3 EQADC pre-gain control

On this chip, the analog ADC option to select x1, x2, or x4 pre-gain is available only for differential conversions. Single-ended conversions can use only x1 pre-gain.

The PRE_GAIN field of the [Alternate Configuration 1-14 Control Registers \(ADC_ACR1-14\)](#) controls the selection.

30.1.4 CFIFO and RFIFO depth

Every CFIFO and RFIFO, including CFIFO0, has four entries.

30.1.5 EQADC pin pullup/pulldown control

This following table shows the analog and digital EQADC pins with pullup/pulldown control and the registers that provide the control.

Table 30-2. EQADC pins with pullup/pulldown and control registers

Pin function	EQADC_A	EQADC_B	Pullup/pulldown control registers
Analog	ANA0 to ANA7 ANA16 to ANA23	ANB0 to ANB7	ADC Pull Up/Down Control Register x (ADC_PUDCRx, x=0-39)
Digital	—	ANB8 to ANB23 ANB40 to ANB45	Pad Configuration Register (SIU_PCRn)

30.1.6 EQADC pin-to-channel mapping

For both EQADC_A and EQADC_B, the following table shows the pin-to-channel mapping to show which signals go to which ADC.

Table 30-3. EQADC_A and EQADC_B pin-to-channel mapping

1. AN8x-ANx11 and ANx16-ANx19 have alternate functions when used with an external multiplexer.
2. After calibration, the 50% reference point reads approximately 20 mV below 50% (VRH-VRL). The 50% reference point should not be used to calibrate the EQADC. Use the 25% and 75% reference points to calibrate the EQADC.
3. This function is present when using an external multiplexer.
4. Select the desired PMC voltage using the channel select field [ADC_CS](#) of the [ADC Channel Select Register \(PMC_ADC_CS\)](#)

30.2 Introduction

30.2.1 Module overview

The Enhanced Queued Analog-to-Digital Converter (EQADC) block provides accurate and fast conversions for a wide range of applications. The EQADC provides a parallel interface to two on-chip analog-to-digital converters (ADCs), and a parallel side interface to one or more on-chip digital signal processing (DSP) modules (for example, a decimation filter). The two on-chip ADCs are architected to allow access to all the analog channels.

The EQADC transfers commands from multiple Command FIFOs (CFIFOs) to the on-chip ADCs. The multiple Result FIFOs (RFIFOs) can receive data from the on-chip ADCs or from an on-chip DSP module. Data from the on-chip ADCs can be routed to the side interface, processed by the on-chip DSP and then routed back through the side interface to the RFIFOs. The EQADC supports software and external hardware triggers from other blocks to initiate transfers of commands from the CFIFOs to the on-chip

ADCs. It also monitors the fullness of CFIFOs and RFIFOs, and accordingly generates DMA or interrupt requests to control data movement between the FIFOs and the system memory, which is external to the EQADC.

30.2.2 Block diagram

Figure 30-1 is the block diagram for the EQADC.

Figure 30-1. EQADC Block Diagram

Figure 30-1 shows the primary components inside the EQADC. The EQADC consists of the *FIFO Control Unit* which controls the CFIFOs and the RFIFOs, the *ADC Control Logic* which controls the two on-chip ADCs, and the *EQADC Parallel Side Interface*

(EQADC PSI) which allows communication with on-chip eQADC companion¹ modules. There are 6 CFIFOs and 6 RFIFOs, each with 4 entries, except CFIFO0 that can have 8 entries.

The *FIFO Control Unit* performs the following functions:

- It prioritizes the CFIFOs to determine what CFIFOs will have their commands transferred.
- Supports software and hardware triggers to start command transfers from a particular CFIFO.
- Decodes command data from the CFIFOs, and accordingly, sends these commands to one of the two on-chip ADCs.
- Decodes result data from on-chip ADCs and transfers data to the appropriate RFIFO or to the parallel side interface.

The *ADC Control Logic* manages the execution of commands bound for on-chip ADCs. It interfaces with the CFIFOs via two 2-entry command buffers (CBuffers) with abort control and with the RFIFOs and side interface via the *Result Format and Calibration Sub-Block*. The *ADC Control Logic* performs the following functions:

- Buffers command data for execution.
- Decodes command data and accordingly generates control signals for the two on-chip ADCs.
- Detects abort request, stores aborted commands and buffers immediate conversion commands.
- Formats and calibrates conversion result data coming from the on-chip ADCs.
- Generates the internal multiplexer control signals and the select signals used by the external multiplexers.

The EQADC PSI allows for a full duplex, synchronous, parallel communication between the EQADC and several on-chip companion modules.

Figure 30-1 also depicts data flow through the EQADC. Commands are contained in system memory in a user defined data structure. The most likely data structure to be used is a queue as depicted in the Figure 30-1². Command data is moved from the command

1. Depending on the device, companion modules may be DSP modules, decimation filters, or any other processing block.
 2. Command and result data can be stored in system memory in any user defined data structure. However, in this document it will be assumed that the data structure of choice is a queue, since it is the most likely data structure to be used and because queues are the only type of data structure supported by the DMAC.

queue (CQueue) to the CFIFOs by either the host CPU or by the DMAC. Once a CFIFO is triggered and becomes the highest priority CFIFO using a certain CBuffer, command data is transferred from the CFIFO to the on-chip ADCs. The ADC executes the command, and the result is moved through the *Result Format and Calibration Sub-Block* to either the side interface or to the RFIFO. Data from the on-chip companion module bypasses the *Result Format and Calibration Sub-Block* and is moved directly to its specified RFIFO. When data is stored in an RFIFO, data is moved from the RFIFO by the host CPU or by the DMAC to a data structure in system memory depicted in the [Figure 30-1](#) as a result queue (RQueue).

For users familiar with the QADC, the EQADC system upgrades the functionality provided by that block. See [EQADC versus QADC](#) for a comparison between the EQADC and QADC.

30.2.3 Features

The EQADC block includes these distinctive features:

- Two independent on-chip RSD Cyclic ADCs
 - 8, 10, and 12 bits Resolution
 - Differential conversions
 - Differential channels include variable gain amplifier for improved dynamic range (x1; x2; x4)
 - Differential channels include programmable pull-up and pull-down resistors for biasing and sensor diagnostics (200k ohms; 100k ohms; 5k ohms)
 - Sample times of 2 (default), 8, 64 or 128 ADC clock cycles
 - Provides time stamp information when requested
 - Parallel interface to EQADC CFIFOs and RFIFOs
 - Supports both right-justified unsigned and signed formats for conversion results
 - The REFBYPC pin stabilizes one of internal generated reference
 - Temperature sensor
 - Ability to measure directly Vdd
- Automatic application of ADC calibration constants

- Provision of reference voltages (25% VREF and 75% VREF) for ADC calibration purposes
- 40 input channels available to the two on-chip ADCs
- 4 pairs of differential analog input channels
- Parallel Side Interface to communicate with several on-chip companion modules
- STAC bus to import an alternative timebase to the internal time stamp
- Priority Based CFIFOs
 - Supports six CFIFOs with fixed priority. The lower the CFIFO number, the higher its priority. When commands of distinct CFIFOs are bound for the same CBuffer, the higher priority CFIFO is always served first.
 - Immediate conversion command feature with conversion abort control
 - Streaming mode operation of CFIFO0 to execute some commands several times
 - Supports software and several hardware trigger modes to arm a particular CFIFO
 - Generates interrupt when command coherency is not achieved
- External Hardware Triggers
 - Supports rising edge, falling edge, high level and low level triggers
 - Supports configurable digital filter
 - Supports controls to bypass the trigger digital filters
- Two Triggers operation mode for queue0
 - Additional internal trigger (not filtered) called Advance trigger that is used to enable the external trigger of queue0 and to control the loop behavior of CFIFO0
- Supports 4 to 8 external 8-to-1 muxes which can expand the input channel number from 40 to 96

30.3 Modes of operation

This section describes the operation modes of the EQADC.

30.3.1 Normal Mode

This is the default operational mode when the EQADC is not in background debug or stop mode.

30.3.2 Debug Mode

Upon a debug mode entry request, EQADC behavior will vary according to the status of the DBG field in [EQADC Module Configuration Register \(EQADC_MCR\)](#). If DBG is programmed to 0b00, the debug mode entry request is ignored. If DBG is programmed to 0b10 or to 0b11, the EQADC will enter debug mode.

During debug mode, the EQADC will not transfer commands from any CFIFOs, no null messages will be transmitted to the device, no data will be returned to any RFIFO, no hardware trigger event will be captured, and all EQADC registers can be accessed as in Normal mode. The latter implies that CFIFOs can still be triggered using software triggers, since no scheme is implemented to write-protect registers during debug mode. DMA and interrupt requests continue to be generated as in Normal Mode.

If at the time the debug mode entry request is detected, there are commands in the on-chip CBuffers that were already under execution, these commands will be completed but the generated results, if any, will not be sent to the RFIFOs until debug mode is exited. Commands whose execution has not started will not be executed until debug mode is exited.

The clock associated with an on-chip ADC stops, during its low phase, after the ADC ceases executing commands. The time base counter will only stop after all on-chip ADCs cease executing commands.

When exiting debug mode, the EQADC relies on the CFIFO operation modes and on the CFIFO status to determine the next command entry to transfer.

The EQADC internal behavior after the debug mode entry request is detected differs depending on the status of command transfers.

- No command transfer is in progress.

The EQADC immediately halts future command transfers from any CFIFO.

If a null message is being transmitted, EQADC will complete the serial transmission before halting future command transfers. If valid data (conversion result or data read from an ADC register) is received at the end of transmission, it will not be sent to an RFIFO until debug mode is exited.

If the null message transmission is aborted, the EQADC will complete the abort procedure before halting future command transfers from any CFIFO. The message of the CFIFO that caused the abort of the previous serial transmission will only be transmitted after debug mode is exited.

- Command transfer is in progress.

EQADC will complete the transfer and update CFIFO status before halting future command transfers from any CFIFO. Command transfers to the internal CBuffers are considered completed when a command is written to the buffers.

- Command/Null message transfer through serial interface was aborted but next serial transmission did not start.

If the debug mode entry request is detected between the time a previous serial transmission was aborted and the start of the next transmission, the EQADC will complete the abort procedure before halting future command transfers from any CFIFO. The message of the CFIFO that caused the abort of the previous serial transmission will only be transmitted after debug mode is exited.

30.3.3 Stop Mode

Upon a stop mode entry request detection, the EQADC progressively halts its operations until it reaches a static, stable state from which it can recover when returning to Normal mode. EQADC then asserts an acknowledge signal, indicating that it is static and that the clock input can be stopped. . The latter implies that, as long as the system clock is running, CFIFOs can still be triggered using software triggers, since no scheme is implemented to write-protect registers during stop mode.

If at the time the stop mode entry request is detected, there are commands in the on-chip CBuffers that were already under execution, these commands will be completed but the generated results, if any, will not be sent to the RFIFOs until stop mode is exited. Commands whose execution has not started will not be executed until stop mode is exited.

After these remaining commands are executed, the clock input to the ADCs and the bias generator circuit is stopped. The ADC clock stops during its low phase. The time base counter will only stop after all on-chip ADCs cease executing commands. Only then, the stop acknowledge signal is asserted. When exiting stop mode, the EQADC relies on the CFIFO operation modes and on the CFIFO status to determine the next command entry to transfer.

The EQADC internal behavior after the stop mode entry request is detected differs depending on the status of the command transfer.

- No command transfer is in progress

The EQADC immediately halts future command transfers from any CFIFO.

If a null message is being transmitted, EQADC will complete the transmission before halting future command transfers. If valid data (conversion result or data read from an ADC register) is received at the end of the transmission, it will not be sent to an RFIFO until stop mode is exited.

If the null message transmission is aborted, the EQADC will complete the abort procedure before halting future command transfers from any CFIFO. The message of the CFIFO that caused the abort of the previous serial transmission will only be transmitted after stop mode is exited.

- Command transfer is in progress

EQADC will complete the transfer and update CFIFO status before halting future command transfers from any CFIFO. Command transfers to the internal CBuffers are considered completed when a command is written to the buffers.

30.4 External signal description

30.4.1 Overview

The following is a list of external pins.

Note

At chip integration level, some of the digital and analog signals listed here might share pins or not be available to the chip. Refer to the Signals chapter for details.

Table 30-4. External signals

Name	Port	Function	Reset state	Type
AN0/DAN0+	Input	Single-ended analog input / Differential analog input positive terminal	—	Analog
AN1/DAN0-	Input	Single-ended analog input / Differential analog input negative terminal	—	Analog

Table continues on the next page...

Table 30-4. External signals (continued)

Name	Port	Function	Reset state	Type
AN2/DAN1+	Input	Single-ended analog input / Differential analog input positive terminal	—	Analog
AN3/DAN1-	Input	Single-ended analog input / Differential analog input negative terminal	—	Analog
AN4/DAN2+	Input	Single-ended analog input / Differential analog input positive terminal	—	Analog
AN5/DAN2-	Input	Single-ended analog input / Differential analog input negative terminal	—	Analog
AN6/DAN3+	Input	Single-ended analog input / Differential analog input positive terminal	—	Analog
AN7/DAN3-	Input	Single-ended analog input / Differential analog input negative terminal	—	Analog
AN8/ANW	Input	Single-ended analog input / Single-ended analog input from external multiplexers	—	Analog
AN9/ANX	Input	Single-ended analog input / Single-ended analog input from external multiplexers	—	Analog
AN10/ANY	Input	Single-ended analog input / Single-ended analog input from external multiplexers	—	Analog

ETRIG3	Input	External trigger for CFIFO3	—	Digital
ETRIG4	Input	External trigger for CFIFO4	—	Digital
ETRIG5	Input	External trigger for CFIFO5	—	Digital

1. Can be disabled or not using configuration parameters.

30.4.2 Detailed signal descriptions

30.4.2.1 AN0/DAN0+ — Single-ended analog input/Differential analog input positive terminal

AN0 is a single-ended analog input to the two on-chip ADCs. DAN0+ is the positive terminal of the differential analog input DAN0 (DAN0+ - DAN0-).

30.4.2.2 AN1/DAN0- — Single-ended analog input/Differential analog input negative terminal

AN1 is a single-ended analog input to the two on-chip ADCs. DAN0- is the negative terminal of the differential analog input DAN0 (DAN0+ - DAN0-).

30.4.2.3 AN2/DAN1+ — Single-ended analog input/Differential analog input positive terminal

AN2 is a single-ended analog input to the two on-chip ADCs. DAN1+ is the positive terminal of the differential analog input DAN1 (DAN1+ - DAN1-).

30.4.2.4 AN3/DAN1- — Single-ended analog input/Differential analog input negative terminal

AN3 is a single-ended analog input to the two on-chip ADCs. DAN1- is the negative terminal of the differential analog input DAN1 (DAN1+ - DAN1-).

30.4.2.5 AN4/DAN2+ — Single-ended analog input/Differential analog input positive terminal

AN4 is a single-ended analog input to the two on-chip ADCs. DAN2+ is the positive terminal of the differential analog input DAN2 (DAN2+ - DAN2-).

30.4.2.6 AN5/DAN2- — Single-ended analog input/Differential analog input negative terminal

AN5 is a single-ended analog input to the two on-chip ADCs. DAN2- is the negative terminal of the differential analog input DAN2 (DAN2+ - DAN2-).

30.4.2.7 AN6/DAN3+ — Single-ended analog input/Differential analog input positive terminal

AN6 is a single-ended analog input to the two on-chip ADCs. DAN3+ is the positive terminal of the differential analog input DAN3 (DAN3+ - DAN3-).

30.4.2.8 AN7/DAN3- — Single-ended analog input/Differential analog input negative terminal

AN7 is a single-ended analog input to the two on-chip ADCs. DAN3- is the negative terminal of the differential analog input DAN3 (DAN3+ - DAN3-).

30.4.2.9 AN8/ANW — Single-ended analog input/ Single-ended analog input from external multiplexers

AN8 is a single-ended analog input to the two on-chip ADCs. ANW is a single-ended analog input to one of the on-chip ADCs in external multiplexed mode.

30.4.2.10 AN9/ANX/TBIAS — Single-ended analog input/ Single-ended analog input from external multiplexers/Test Bias

AN9 is a single-ended analog input to the two on-chip ADCs. ANX is a single-ended analog input to one of the on-chip ADCs in external multiplexed mode. TBIAS is used during factory test to verify the bias generator circuit.

30.4.2.11 AN10/ANY — Single-ended analog input/ Single-ended analog input from external multiplexers

AN10 is a single-ended analog input to the two on-chip ADCs. ANY is a single-ended analog input to one of the on-chip ADCs in external multiplexed mode.

30.4.2.12 AN11/ANZ — Single-ended analog input/ Single-ended analog input from external multiplexers

AN11 is a single-ended analog input to the two on-chip ADCs. ANZ is a single-ended analog input to one of the on-chip ADCs in external multiplexed mode.

30.4.2.13 AN12/T50PVREF — Single-ended analog input/ Test 50% VREF analog output

AN12 is a single-ended analog input to the two on-chip ADCs. T50PVREF is used during ADC factory test.

30.4.2.14 AN13/T25PVREF — Single-ended analog input/ Test 25% VREF analog output

AN13 is a single-ended analog input to the two on-chip ADCs. T25PVREF is used during ADC factory test.

30.4.2.15 AN14/T75PVREF — Single-ended analog input/ Test 75% VREF analog output

AN14 is a single-ended analog input to the two on-chip ADCs. T75PVREF is used during ADC factory test.

30.4.2.16 AN15 — Single-ended analog input

AN15 is a single-ended analog inputs to the two on-chip ADCs.

30.4.2.17 AN16/ANR — Single-ended analog input/ Single-ended analog input from external multiplexers

AN16 is a single-ended analog input to the two on-chip ADCs. ANR is a single-ended analog input to one of the on-chip ADCs in external multiplexed mode. The external multiplexing capability is a device option.

30.4.2.18 AN17/ANS — Single-ended analog input/ Single-ended analog input from external multiplexers

AN17 is a single-ended analog input to the two on-chip ADCs. ANS is a single-ended analog input to one of the on-chip ADCs in external multiplexed mode. The external multiplexing capability is a device option.

30.4.2.19 AN18/ANT — Single-ended analog input/ Single-ended analog input from external multiplexers

AN18 is a single-ended analog input to the two on-chip ADCs. ANT is a single-ended analog input to one of the on-chip ADCs in external multiplexed mode. The external multiplexing capability is a device option.

30.4.2.20 AN19/ANU — Single-ended analog input/ Single-ended analog input from external multiplexers

AN19 is a single-ended analog input to the two on-chip ADCs. ANU is a single-ended analog input to one of the on-chip ADCs in external multiplexed mode. The external multiplexing capability is a device option.

30.4.2.21 AN20-AN39 — Single-ended analog input

AN20 through AN39 are single-ended analog inputs to the two on-chip ADCs.

30.4.2.22 INA_ADC0_0 - INA_ADC0_9 — Single-ended analog input

INA_ADC0_0 through INA_ADC0_9 are single-ended analog inputs to the on-chip ADC0.

30.4.2.23 INA_ADC1_0 - INA_ADC1_9 — Single-ended analog input

INA_ADC1_0 through INA_ADC1_9 are single-ended analog inputs to the on-chip ADC1.

30.4.2.24 MA0-MA2 — External multiplexer control signals

MA0, MA1, and MA2 combined form a select signal associated with external multiplexers.

30.4.2.25 VRH, VRL — Voltage reference high and voltage reference low

VRH and VRL are voltage references for the ADCs. VRH is the highest voltage reference, while VRL is the lowest voltage reference.

30.4.2.26 VDDA, VSSA — 5V VDD and VSS for the 5V analog components

VDDA is the positive power supply pin for the ADCs and VSSA is the negative power supply pin for the ADCs. Refer to electrical specifications.

30.4.2.27 REFBYPC — Reference Bypass Capacitor

The REFBYPC pin is used to connect an external bypass capacitor between REFBYPC and VRL. See section "Chip-specific EQADC information" for the capacitor value. This bypass capacitor is used to provide a stable reference voltage for the ADC.

NOTE

Prior EQADC versions have had two of these pins. To achieve accurate calibration, more time may be required with only one pin.

30.4.2.28 ETRIG0-ETRIG5 — External triggers

The external trigger signals are for hardware triggering. The EQADC can detect rising edge, falling edge, high level and low level on each of the external trigger signals. ETRIGx triggers CFIFOx. The EQADC also supports configurable digital filters for these external trigger signals. These digital filters can be bypassed by individual input control signals called eqadc_intern_trig_selx.

30.5 Memory map and register definition

This section provides memory maps and detailed descriptions of all registers. Data written to or read from reserved areas of the memory map is undefined.

This section provides memory maps and detailed descriptions of all registers. Data written to or read from reserved areas of the memory map is undefined.

EQADC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
0	EQADC Module Configuration Register (EQADC_MCR)	32	R/W	0000_0000h	30.5.1/1106

EQADC_MCR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 ICEA0	Immediate Conversion Command Enable ADC0 ICEA0 enables the EQADC to abort on-chip ADC0 current conversion and to start the immediate conversion command from CFIFO0 in the requested ADC0. 0 Disable immediate conversion command request. 1 Enable immediate conversion command request.
25 ICEA1	Immediate Conversion Command Enable ADC1 ICEA1 enables the EQADC to abort on-chip ADC1 current conversion and to start the immediate conversion command from CFIFO0 in the requested ADC1. 0 Disable immediate conversion command request. 1 Enable immediate conversion command request.
26 DAM	Alternate Configuration Destination Addressing Mode DAM selects between two modes of sending the same conversion result to two different destinations. This is applied mainly when using Alternate Conversion Commands.

Table continues on the next page...

EQADC_MCR field descriptions (continued)

Field	Description
0	Legacy mode. Uses a defined set of pairs of companion module destinations in the PSI as defined by Table 30-121 in Alternate Configuration 1-14 Control Registers (ADC_ACR1-14) . The Extended Alternate Configuration registers (ADC_EACR1-14) are not considered.
1	Selects the Extended Alternate Configuration Registers to send result to two destinations. These destinations can be RFIFOs and companion modules connected to the PSI. See Extended Alternate Configuration 1-14 Control Registers (ADC_EACR1-14) for details.
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 DBG	Debug enable The DBG field defines the EQADC response to a debug mode entry request. . 0b00 Do not enter debug mode. 0b01 Reserved. 0b10 Enter debug mode. 0b11 Enter debug mode.

30.5.2 EQADC Test Register (EQADC_TST)

The EQADC Test Register (EQADC_TST) is used for test purposes only. This register can only be read/written in a test access, accessing the EQADC_TST register in any other way will result in a transfer error. In a non-test access to the EQADC_TST register, read data is undefined and written data is ignored.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

EQADC_TST field descriptions

Field	Description
0–31 Reserved	This field is reserved.

30.5.3 EQADC External Trigger Digital Filter Register (EQADC_ETDFR)

The EQADC External Trigger Digital Filter Register (EQADC_ETDFR) is used to set the minimum time a signal must be held in a logic state on the CFIFO triggers inputs to be recognized as an edge or level gated trigger. The Digital Filter Length field specifies the minimum number of system clocks that must be counted by the digital filter counter to recognize a logic state change. However, there is a control signal that can be used to bypass the digital filter when this is not needed.

The count specifies the sample period of the digital filter which is calculated according to the following equation:

$FilterPeriod = (SystemClockPeriod \times 2^{DFL}) + 1 (SystemClockPeriod)$

Minimum clock counts for which an ETRIG signal needs to be stable to be passed through the filter are shown in Table 30-9 . See External trigger event detection for more information on the digital filter.

NOTE

The DFL field must only be written when the MODEx of all CFIFOs are configured to disabled.

NOTE

When the digital filter is bypassed by using the input control, the DFL is not considered and the trigger input signal is not filtered.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

30.5.4 EQADC CFIFO Push Register (EQADC_CFPRn)

The EQADC CFIFO Push Registers (EQADC_CFPR) provide a mechanism to fill the CFIFOs with command messages from the CQueues. Refer to [EQADC command FIFOs](#) for more information on the CFIFOs and to [Message format in EQADC](#) for a description on command message formats.

NOTE

Only whole words must be written to EQADC_CFPR. Writing half-words or bytes to EQADC_CFPR will still push the whole 32-bit CF_PUSH field into the corresponding CFIFO, but undefined data will fill the areas of CF_PUSH that were not specifically designated as target locations for the write.

Memory map and register definition

Address: 0h base + 10h offset + (4d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EQADC_CFPR_n field descriptions

Field	Description
0–31 CF_PUSHX	CFIFO Push Data x When CFIFO_x is not full, writing to the whole word or any bytes of EQADC_CFPR_x will push the 32-bit CF_PUSH_x value into CFIFO_x. Writing to the CF_PUSH_x field also increments the corresponding CFCTR_x value by one in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n) . When the CFIFO_x is full, the EQADC ignores any write to the CF_PUSH_x. Reading the EQADC_CFPR_x always returns zero.

30.5.5 EQADC Result FIFO Pop Register (EQADC_RFPR_n)

The EQADC Result FIFO Pop Registers (EQADC_RFPR) provide a mechanism to retrieve data from RFIFOs.

Address: 0h base + 30h offset + (4d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EQADC_RFPR_n field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 RF_POPX	Result FIFO Pop Data x When RFIFO_x is not empty, the RF_POP_x contains the next unread entry value of RFIFO_x. Reading a word, a half-word, or any bytes from EQADC_RFPR_x will pop one entry from RFIFO_x and cause the RFCTR_x field to be decremented by one in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n) . When the RFIFO_x is empty, any read on EQADC_RFPR_x returns undefined data value and does not decrement the RFCTR_x value. Writing to EQADC_RFPR_x has no effect.

30.5.6 EQADC CFIFO Control Register 0 (EQADC_CFCR0)

The EQADC CFIFO Control Registers (EQADC_CFCR) contain bits that affect CFIFOs. These bits specify the CFIFO operation mode and can invalidate all of the CFIFO contents.

Address: 0h base + 50h offset = 50h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

EQADC_CFCR0 field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 CFEEE0	CFIFO0 Entry Number Extension Enable The CFEEE0 bit is used to enable the extension of the CFIFO0 entries. When in extended mode, the CFIFO0 total entries is the sum of normal entries plus the defined value for extension. For more details, see CFIFO0 streaming mode description . 0 CFIFO0 has a normal value of entries. 1 Enable the extension of CFIFO0 entries.
4 STRME0	CFIFO0 Streaming Mode Operation Enable The STRME0 bit is used to enable the streaming mode of operation of CFIFO0. In this case, it is possible to repeat some sequence of commands of this FIFO. For more details, refer to CFIFO0 streaming mode description . 0 Streaming mode of CFIFO0 is disabled. 1 Enable the streaming mode of CFIFO0.
5 SSE0	CFIFO Single-Scan Enable Bit 0

Table continues on the next page...

EQADC_CFCR0 field descriptions (continued)

Field	Description
	The SSEx bit is used to set the SSSx bit in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) . Writing a "1" to SSEx will set the SSSx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn), if the CFIFO is in single-scan mode. When SSSx is already asserted, writing a "1" to SSEx also has no effect. If the CFIFO is in continuous-scan mode or is disabled, writing a "1" to SSEx will not set SSSx. Writing a "0" to SSEx has no effect. SSEx always is read as "0". 0 No effect. 1 Set the SSSx bit.
6 CFINV0	CFIFO Invalidate Bit 0 The CFINVx bit causes the EQADC to invalidate all entries of CFIFOx. Writing a "1" to CFINVx will reset the value of CFCTRx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) . Writing a "1" to CFINVx also resets the Push Next Data Pointer, Transfer Next Data Pointer to the first entry of CFIFOx in Figure 30-123. CFINVx always is read as "0". Writing a "0" has no effect. NOTE: Writing CFINVx only invalidates commands stored in CFIFOx; previously transferred commands that are waiting for execution, that is commands stored in the CBuffers, will still be executed, and results generated by them will be stored in the appropriate RFIFO. NOTE: CFINVx must not be written unless the MODEx is configured to disabled, and CFIFO status is IDLE. 0 No effect. 1 Invalidate all of the entries in the corresponding CFIFO.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–11 MODE0	CFIFO Operation Mode 0 The MODEx field selects the CFIFO operation mode for CFIFOx. See CFIFO scan trigger modes for more information on CFIFO trigger mode. NOTE: If MODEx is not disabled, it must not be changed to any other mode besides disabled. If MODEx is disabled and the CFIFO status is IDLE, MODEx can be changed to any other mode. 0000 Disabled 0001 Software Trigger, Single Scan 0010 Low Level Gated External Trigger, Single Scan 0011 High Level Gated External Trigger, Single Scan 0100 Falling Edge External Trigger, Single Scan 0101 Rising Edge External Trigger, Single Scan 0110 Falling or Rising Edge External Trigger, Single Scan 0111 Reserved 1000 Reserved 1001 Software Trigger, Continuous Scan 1010 Low Level Gated External Trigger, Continuous Scan 1011 High Level Gated External Trigger, Continuous Scan 1100 Falling Edge External Trigger, Continuous Scan 1101 Rising Edge External Trigger, Continuous Scan 1110 Falling or Rising Edge External Trigger, Continuous Scan 1111 Reserved
12–15 AMODE0	CFIFO0 Advance Trigger Operation Mode 0

Table continues on the next page...

EQADC_CFCR0 field descriptions (continued)

Field	Description
	The AMODE0 field selects the trigger mode for the ATRIG0 trigger signal in streaming mode. The use of reserved values drives to unknown behavior of the block. NOTE: If AMODE0 is not disabled, it must not be changed to any other mode besides disabled. If AMODE0 is disabled and the CFIFO0 status is IDLE, AMODE0 can be changed to any other mode. NOTE: For the streaming mode of operation when the ATRIG0 is used to enable the ETRIG0 or to advance the command queue, the normal mode of operation is external trigger single scan. Other settings are not fully tested. 0000 Disabled 0001 Software Trigger, Single Scan 0010 Low Level Gated External Trigger, Single Scan 0011 High Level Gated External Trigger, Single Scan 0100 Falling Edge External Trigger, Single Scan 0101 Rising Edge External Trigger, Single Scan 0110 Falling or Rising Edge External Trigger, Single Scan 0111 Reserved 1000 Reserved 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 SSE1	CFIFO Single-Scan Enable Bit 1 The SSEx bit is used to set the SSSx bit in EQADC FIFO and Interrupt Status Register (EQADC_FISRn). Writing a "1" to SSEx will set the SSSx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn), if the CFIFO is in single-scan mode. When SSSx is already asserted, writing a "1" to SSEx also has no effect. If the CFIFO is in continuous-scan mode or is disabled, writing a "1" to SSEx will not set SSSx. Writing a "0" to SSEx has no effect. SSEx always is read as "0". 0 No effect. 1 Set the SSSx bit.
22 CFINV1	CFIFO Invalidate Bit 1 The CFINVx bit causes the EQADC to invalidate all entries of CFIFOx. Writing a "1" to CFINVx will reset the value of CFCTRx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn). Writing a "1" to CFINVx also resets the Push Next Data Pointer, Transfer Next Data Pointer to the first entry of CFIFOx in Figure 30-123. CFINVx always is read as "0". Writing a "0" has no effect. NOTE: Writing CFINVx only invalidates commands stored in CFIFOx; previously transferred commands that are waiting for execution, that is commands stored in the CBuffers, will still be executed, and results generated by them will be stored in the appropriate RFIFO. NOTE: CFINVx must not be written unless the MODEx is configured to disabled, and CFIFO status is IDLE.

12–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 SSE3	CFIFO Single-Scan Enable Bit 3 The SSEx bit is used to set the SSSx bit in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) . Writing a "1" to SSEx will set the SSSx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) , if the CFIFO is in single-scan mode. When SSSx is already asserted, writing a "1" to SSEx also has no effect. If the CFIFO is in continuous-scan mode or is disabled, writing a "1" to SSEx will not set SSSx. Writing a "0" to SSEx has no effect. SSEx always is read as "0". 0 No effect. 1 Set the SSSx bit.
22 CFINV3	CFIFO Invalidate Bit 3 The CFINVx bit causes the EQADC to invalidate all entries of CFIFOx. Writing a "1" to CFINVx will reset the value of CFCTRx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) . Writing a "1" to CFINVx also resets the Push Next Data Pointer, Transfer Next Data Pointer to the first entry of CFIFOx in Figure 30-123 . CFINVx always is read as "0". Writing a "0" has no effect. NOTE: Writing CFINVx only invalidates commands stored in CFIFOx; previously transferred commands that are waiting for execution, that is commands stored in the CBuffers, will still be executed, and results generated by them will be stored in the appropriate RFIFO. NOTE: CFINVx must not be written unless the MODEx is configured to disabled, and CFIFO status is IDLE.

EQADC_CFCR2 field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 SSE4	CFIFO Single-Scan Enable Bit 4 The SSE_x bit is used to set the SSS_x bit in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n). Writing a "1" to SSE_x will set the SSS_x in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n), if the CFIFO is in single-scan mode. When SSS_x is already asserted, writing a "1" to SSE_x also has no effect. If the CFIFO is in continuous-scan mode or is disabled, writing a "1" to SSE_x will not set SSS_x. Writing a "0" to SSE_x has no effect. SSE_x always is read as "0". 0 No effect. 1 Set the SSS_x bit.
6 CFINV4	CFIFO Invalidate Bit 4 The CFINV_x bit causes the EQADC to invalidate all entries of CFIFO_x. Writing a "1" to CFINV_x will reset the value of CFCTR_x in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n). Writing a "1" to CFINV_x also resets the Push Next Data Pointer, Transfer Next Data Pointer to the first entry of CFIFO_x in Figure 30-123. CFINV_x always is read as "0". Writing a "0" has no effect. NOTE: Writing CFINV_x only invalidates commands stored in CFIFO_x; previously transferred commands that are waiting for execution, that is commands stored in the CBuffers, will still be executed, and results generated by them will be stored in the appropriate RFIFO. NOTE: CFINV_x must not be written unless the MODE_x is configured to disabled, and CFIFO status is IDLE.

EQADC_IDCR0 field descriptions

Field	Description
0 NCIE0	Non-Coherency Interrupt Enable 0 NCIE_x enables the EQADC to generate an interrupt request when the corresponding NCF_x in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n) is asserted. 0 Disable non-coherency interrupt request. 1 Enable non-coherency interrupt request.
1 TORIE0	Trigger Overrun Interrupt Enable 0 TORIE_x enables the EQADC to generate an interrupt request when the corresponding TORF_x in EQADC DMA/interrupt request is asserted. Apart from generating an independent interrupt request for a CFIFO_x Trigger Overrun event, the EQADC also provides a combined interrupt at which the Result FIFO Overflow Interrupt, the Command FIFO Underflow Interrupt, and the Command FIFO Trigger Overrun Interrupt requests of ALL CFIFOs are ORed. When RFOIE_x, CFUIE_x, and TORIE_x are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOF_x, CFUF_x, and TORF_x (assuming that all interrupts are enabled). See EQADC DMA/interrupt request for details. 0 Disable trigger overrun interrupt request. 1 Enable trigger overrun interrupt request.
2 PIE0	Pause Interrupt Enable 0 PIE_x enables the EQADC to generate an interrupt request when the corresponding PF_x in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n) is asserted.

Table continues on the next page...

EQADC_IDCR0 field descriptions (continued)

Field	Description
	0 Disable pause interrupt request. 1 Enable pause interrupt request.
3 EOQIE0	End of Queue Interrupt Enable 0 EOQIEx enables the EQADC to generate an interrupt request when the corresponding EOQFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. 0 Disable End of Queue interrupt request. 1 Enable End of Queue interrupt request.
4 CFUIE0	CFIFO Underflow Interrupt Enable 0 CFUIEx enables the EQADC to generate an interrupt request when the corresponding CFUFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. Apart from generating an independent interrupt request for a CFIFOx underflow event, the EQADC also provides a combined interrupt at which the Result FIFO Overflow Interrupt, the Command FIFO Underflow Interrupt, and the Command FIFO Trigger Overrun Interrupt requests of ALL CFIFOs are ORed. When RFOIEx, CFUIEx, and TORIEx are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOFx, CFUFx, and TORFx (assuming that all interrupts are enabled). See EQADC DMA/interrupt request for details. 0 Disable Underflow Interrupt request. 1 Enable Underflow Interrupt request.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 CFFE0	CFIFO Fill Enable 0 CFFEx enables the EQADC to generate an interrupt request (CFFSx is negated) or DMA request (CFFSx is asserted) when CFFFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. NOTE: CFFEx must not be negated while a DMA transaction is in progress. 0 Disable CFIFO Fill DMA or Interrupt request. 1 Enable CFIFO Fill DMA or Interrupt request.
7 CFFS0	CFIFO Fill Select 0 CFFSx selects if a DMA or interrupt request is generated when CFFFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. If CFFEx is asserted, the EQADC generates an interrupt request when CFFSx is negated, or it generates a DMA request if CFFSx is asserted. NOTE: CFFSx must not be negated while a DMA transaction is in progress. 0 Generate interrupt request to move data from the system memory to CFIFOx. 1 Generate DMA request to move data from the system memory to CFIFOx.
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 RFOIE0	RFIFO Overflow Interrupt Enable 0 RFOIEx enables the EQADC to generate an interrupt request when the corresponding RFOFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. Apart from generating an independent interrupt request for an RFIFOx overflow event, the EQADC also provides a combined interrupt at which the Result FIFO Overflow Interrupt, the Command FIFO Underflow Interrupt, and the Command FIFO Trigger Overrun Interrupt requests of ALL CFIFOs are ORed. When

Field	Description
17 TORIE3	Trigger Overrun Interrupt Enable 3 TORIE_x enables the EQADC to generate an interrupt request when the corresponding TORF_x in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n) is asserted. Apart from generating an independent interrupt request for a CFIFO_x Trigger Overrun event, the EQADC also provides a combined interrupt at which the Result FIFO Overflow Interrupt, the Command FIFO Underflow Interrupt, and the Command FIFO Trigger Overrun Interrupt requests of ALL CFIFOs are ORed. When RFOIE_x, CFUIE_x, and TORIE_x are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOF_x, CFUF_x, and TORF_x (assuming that all interrupts are enabled). See EQADC DMA/interrupt request for details. 0 Disable trigger overrun interrupt request. 1 Enable trigger overrun interrupt request.
18 PIE3	Pause Interrupt Enable 3 PIE_x enables the EQADC to generate an interrupt request when the corresponding PF_x in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n) is asserted. 0 Disable pause interrupt request. 1 Enable pause interrupt request.
19 EOQIE3	End of Queue Interrupt Enable 3 EOQIE_x enables the EQADC to generate an interrupt request when the corresponding EOQF_x in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n) is asserted. 0 Disable End of Queue interrupt request. 1 Enable End of Queue interrupt request.
20 CFUIE3	CFIFO Underflow Interrupt Enable 3 CFUIE_x enables the EQADC to generate an interrupt request when the corresponding CFUF_x in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n) is asserted. Apart from generating an independent interrupt request for a CFIFO_x underflow event, the EQADC also provides a combined interrupt at which the Result FIFO Overflow Interrupt, the Command FIFO Underflow Interrupt, and the Command FIFO Trigger Overrun Interrupt requests of ALL CFIFOs are ORed. When RFOIE_x, CFUIE_x, and TORIE_x are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOF_x, CFUF_x, and TORF_x (assuming that all interrupts are enabled). See EQADC DMA/interrupt request for details. 0 Disable Underflow Interrupt request. 1 Enable Underflow Interrupt request.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 CFFE3	CFIFO Fill Enable 3 CFFE_x enables the EQADC to generate an interrupt request (CFFS_x is negated) or DMA request (CFFS_x is asserted) when CFFF_x in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n) is asserted. NOTE: CFFE_x must not be negated while a DMA transaction is in progress. 0 Disable CFIFO Fill DMA or Interrupt request. 1 Enable CFIFO Fill DMA or Interrupt request.
23 CFFS3	CFIFO Fill Select 3

Table continues on the next page...

EQADC_IDCR1 field descriptions (continued)

Field	Description
	CFFSx selects if a DMA or interrupt request is generated when CFFFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. If CFFEx is asserted, the EQADC generates an interrupt request when CFFSx is negated, or it generates a DMA request if CFFSx is asserted. NOTE: CFFSx must not be negated while a DMA transaction is in progress. 0 Generate interrupt request to move data from the system memory to CFIFOx. 1 Generate DMA request to move data from the system memory to CFIFOx.
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 RFOIE3	RFIFO Overflow Interrupt Enable 3 RFOIEx enables the EQADC to generate an interrupt request when the corresponding RFOFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. Apart from generating an independent interrupt request for an RFIFOx overflow event, the EQADC also provides a combined interrupt at which the Result FIFO Overflow Interrupt, the Command FIFO Underflow Interrupt, and the Command FIFO Trigger Overrun Interrupt requests of ALL CFIFOs are ORed. When RFOIEx, CFUIEx, and TORIEx are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOFx, CFUFx, and TORFx (assuming that all interrupts are enabled). See EQADC DMA/interrupt request for details. 0 Disable Overflow Interrupt request. 1 Enable Overflow Interrupt request.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 RFDE3	RFIFO Drain Enable 3 RFDEx enables the EQADC to generate an interrupt request (RFDSx is negated) or DMA request (RFDSx is asserted) when RFDFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. NOTE: RFDEx must not be negated while a DMA transaction is in progress. 0 Disable RFIFO Drain DMA or Interrupt request. 1 Enable RFIFO Drain DMA or Interrupt request.
31 RFDS3	RFIFO Drain Select 3 RFDSx selects if a DMA or interrupt request is generated when RFDFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. If RFDEx is asserted, the EQADC generates an interrupt request when RFDSx is negated, or it generates a DMA request when RFDSx is asserted. NOTE: RFDSx must not be negated while a DMA transaction is in progress. 0 Generate interrupt request to move data from RFIFOx to the system memory. 1 Generate DMA request to move data from RFIFOx to the system memory.

30.5.11 EQADC Interrupt and DMA Control Register 2 (EQADC_IDCR2)

The EQADC Interrupt Control Registers (EQADC_IDCR) contain bits to enable the generation of interrupt or DMA requests when the corresponding flag bits are set in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#).

Address: 0h base + 68h offset = 68h

13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 RFDE4	RFIFO Drain Enable 4 RFDE_x enables the EQADC to generate an interrupt request (RFDS_x is negated) or DMA request (RFDS_x is asserted) when RFDF_x in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n) is asserted. NOTE: RFDE_x must not be negated while a DMA transaction is in progress. 0 Disable RFIFO Drain DMA or Interrupt request. 1 Enable RFIFO Drain DMA or Interrupt request.
15 RFDS4	RFIFO Drain Select 4 RFDS_x selects if a DMA or interrupt request is generated when RFDF_x in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n) is asserted. If RFDE_x is asserted, the EQADC generates an interrupt request when RFDS_x is negated, or it generates a DMA request when RFDS_x is asserted. NOTE: RFDS_x must not be negated while a DMA transaction is in progress. 0 Generate interrupt request to move data from RFIFOx to the system memory. 1 Generate DMA request to move data from RFIFOx to the system memory.
16 NCIE5	Non-Coherency Interrupt Enable 5 NCIE_x enables the EQADC to generate an interrupt request when the corresponding NCF_x in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n) is asserted. 0 Disable non-coherency interrupt request. 1 Enable non-coherency interrupt request.
17 TORIE5	Trigger Overrun Interrupt Enable 5 TORIE_x enables the EQADC to generate an interrupt request when the corresponding TORF_x in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n) is asserted. Apart from generating an independent interrupt request for a CFIFOx Trigger Overrun event, the EQADC also provides a combined interrupt at which the Result FIFO Overflow Interrupt, the Command FIFO Underflow Interrupt, and the Command FIFO Trigger Overrun Interrupt requests of ALL CFIFOs are ORed. When RFOIE_x, CFUIE_x, and TORIE_x are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOF_x, CFUF_x, and TORF_x (assuming that all interrupts are enabled). See EQADC DMA/interrupt request for details. 0 Disable trigger overrun interrupt request. 1 Enable trigger overrun interrupt request.
18 PIE5	Pause Interrupt Enable 5 PIE_x enables the EQADC to generate an interrupt request when the corresponding PF_x in EQADC FIFO and Interrupt Status Register (EQADC_FISR_n) is asserted. 0 Disable pause interrupt request.

Table continues on the next page...

EQADC_IDCR2 field descriptions (continued)

Field	Description
	1 Enable pause interrupt request.
19 EOQIE5	End of Queue Interrupt Enable 5 EOQIE5 enables the EQADC to generate an interrupt request when the corresponding EOQFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. 0 Disable End of Queue interrupt request. 1 Enable End of Queue interrupt request.
20 CFUIE5	CFIFO Underflow Interrupt Enable 5 CFUIE5 enables the EQADC to generate an interrupt request when the corresponding CFUFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. Apart from generating an independent interrupt request for a CFIFOx underflow event, the EQADC also provides a combined interrupt at which the Result FIFO Overflow Interrupt, the Command FIFO Underflow Interrupt, and the Command FIFO Trigger Overrun Interrupt requests of ALL CFIFOs are ORed. When RFOIE5, CFUIE5, and TORIE5 are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOFx, CFUFx, and TORFx (assuming that all interrupts are enabled). See EQADC DMA/interrupt request for details. 0 Disable Underflow Interrupt request. 1 Enable Underflow Interrupt request.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 CFFE5	CFIFO Fill Enable 5 CFFEx enables the EQADC to generate an interrupt request (CFFSx is negated) or DMA request (CFFSx is asserted) when CFFFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. NOTE: CFFEx must not be negated while a DMA transaction is in progress. 0 Disable CFIFO Fill DMA or Interrupt request. 1 Enable CFIFO Fill DMA or Interrupt request.
23 CFFS5	CFIFO Fill Select 5 CFFSx selects if a DMA or interrupt request is generated when CFFFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. If CFFEx is asserted, the EQADC generates an interrupt request when CFFSx is negated, or it generates a DMA request if CFFSx is asserted. NOTE: CFFSx must not be negated while a DMA transaction is in progress. 0 Generate interrupt request to move data from the system memory to CFIFOx. 1 Generate DMA request to move data from the system memory to CFIFOx.
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 RFOIE5	RFIFO Overflow Interrupt Enable 5 RFOIE5 enables the EQADC to generate an interrupt request when the corresponding RFOFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. Apart from generating an independent interrupt request for an RFIFOx overflow event, the EQADC also provides a combined interrupt at which the Result FIFO Overflow Interrupt, the Command FIFO Underflow Interrupt, and the Command FIFO Trigger Overrun Interrupt requests of ALL CFIFOs are ORed. When RFOIE5, CFUIE5, and TORIE5 are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOFx, CFUFx, and TORFx (assuming that all interrupts are enabled). See EQADC DMA/interrupt request for details.

Table continues on the next page...

EQADC_IDCR2 field descriptions (continued)

Field	Description
	0 Disable Overflow Interrupt request. 1 Enable Overflow Interrupt request.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 RFDE5	RFIFO Drain Enable 5 RFDEx enables the EQADC to generate an interrupt request (RFDSx is negated) or DMA request (RFDSx is asserted) when RFDFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. NOTE: RFDEx must not be negated while a DMA transaction is in progress. 0 Disable RFIFO Drain DMA or Interrupt request. 1 Enable RFIFO Drain DMA or Interrupt request.
31 RFDS5	RFIFO Drain Select 5 RFDSx selects if a DMA or interrupt request is generated when RFDFx in EQADC FIFO and Interrupt Status Register (EQADC_FISRn) is asserted. If RFDEx is asserted, the EQADC generates an interrupt request when RFDSx is negated, or it generates a DMA request when RFDSx is asserted. NOTE: RFDSx must not be negated while a DMA transaction is in progress. 0 Generate interrupt request to move data from RFIFOx to the system memory. 1 Generate DMA request to move data from RFIFOx to the system memory.

30.5.12 EQADC FIFO and Interrupt Status Register (EQADC_FISR_n)

The EQADC FIFO and Interrupt Status Registers (EQADC_FISR) contain flag and status bits for each CFIFO and RFIFO pair. Write "1" to a flag bit to clear it. Writing "0" has no effect. Status bits are read only. These bits indicate the status of the FIFO itself.

Address: 0h base + 70h offset + (4d × i), where i=0d to 5d

EQADC_FISR_n field descriptions

Field	Description
0 NCFX	Non-Coherency Flag NCFx is set whenever a command sequence being transferred through CFIFOx becomes non coherent. If NCIE_x in EQADC Interrupt and DMA Control Register 0 (EQADC_IDCR0) and NCFx are asserted, an interrupt request will be generated. Write "1" to clear NCFx. Writing a "0" has no effect. For more information refer to Command sequence non-coherency detection. 0 Command sequence being transferred by CFIFOx is coherent. 1 Command sequence being transferred by CFIFOx became non-coherent.

Table continues on the next page...

EQADC_FISR_n field descriptions (continued)

Field	Description
1 TORFX	Trigger Overrun Flag for CFIFO_x TORF_x is set when trigger overrun occurs for the specified CFIFO in edge or level trigger mode. Trigger overrun occurs when an already triggered CFIFO receives an additional trigger. When TORI_{Ex} in EQADC Interrupt and DMA Control Register 0 (EQADC_IDCR0) and TORF_x are asserted, an interrupt request will be generated. Apart from generating an independent interrupt request for a CFIFO_x Trigger Overrun event, the EQADC also provides a combined interrupt at which the Result FIFO Overflow Interrupt, the Command FIFO Underflow Interrupt, and the Command FIFO Trigger Overrun Interrupt requests of ALL CFIFOs are ORed. When RFOI_{Ex}, CFUI_{Ex}, and TORI_{Ex} are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOF_x, CFUF_x, and TORF_x (assuming that all interrupts are enabled). See EQADC DMA/interrupt request for details. Write "1" to clear the TORF_x bit. Writing a "0" has no effect. NOTE: The trigger overrun flag will not set for CFIFOs configured for software trigger mode. 0 No trigger overrun occurred. 1 Trigger overrun occurred.
2 PFX	Pause Flag x PF behavior changes according to the CFIFO trigger mode. In edge trigger mode, PF_x is set when the EQADC completes the transfer of an entry with an asserted Pause bit from CFIFO_x. In level trigger mode, when CFIFO_x is in TRIGGERED status, PF_x is set when CFIFO status changes from TRIGGERED due to the detection of a closed gate. An interrupt routine, generated due to the asserted PF, can be used to verify if a complete scan of the CQueue was performed. If a closed gate is detected while no command transfers are taking place, it will have immediate effect on the CFIFO status. If a closed gate is detected while a command transfer to an on-chip CBuffer is taking place, it will only affect the CFIFO status when the transfer completes. The transfer of entries bound for the on-chip ADCs is considered completed when they are stored in the appropriate CBuffer. In software trigger mode, PF_x will never become asserted. If PI_{Ex} in EQADC Interrupt and DMA Control Register 0 (EQADC_IDCR0) and PF_x are asserted, an interrupt will be generated. Write "1" to clear the PF_x. Writing a "0" has no effect. See Pause status for more information on the Pause Flag. NOTE: In edge trigger mode, an asserted PF_x only implies that the EQADC has finished transferring a command with an asserted PAUSE bit from CFIFO_x. It does not imply that result data for the current command and for all previously transferred commands has been returned to the appropriate RFIFO. NOTE: In software or level trigger mode, when the EQADC completes the transfer of an entry from CFIFO_x with an asserted PAUSE bit, PF_x will not be set and transfer of commands will continue without pausing. 0 Entry with asserted PAUSE bit was not transferred from CFIFO_x (CFIFO in edge trigger mode), or CFIFO status did not change from TRIGGERED due to detection of a closed gate (CFIFO in level trigger mode). 1 Entry with asserted PAUSE bit was transferred from CFIFO_x (CFIFO in edge trigger mode), or CFIFO status changes from TRIGGERED due to detection of a closed gate (CFIFO in level trigger mode).
3 EOQFX	End of Queue Flag x EOQF_x indicates that an entry with an asserted EOQ bit was transferred from CFIFO_x to the on-chip ADCs - see Message format in EQADC for details about command message formats. When the EQADC completes the transfer of an entry with an asserted EOQ bit from CFIFO_x, EOQF_x will be set. The transfer of entries bound for the on-chip ADCs is considered completed when they are stored in the appropriate

Table continues on the next page...

EQADC_FISR_n field descriptions (continued)

Field	Description
	CBuffer. If the EOQIE_x bit in EQADC Interrupt and DMA Control Register 0 (EQADC_IDCR0) and EOQF_x are asserted, an interrupt will be generated. Write "1" to clear the EOQF_x bit. Writing a "0" has no effect. Refer to CQueue completion status for more information on the End of Queue Flag. NOTE: An asserted EOQF_x only implies that the EQADC has finished transferring a command with an asserted EOQ bit from CFIFO_x. It does not imply that result data for the current command and for all previously transferred commands has been returned to the appropriate RFIFO. 0 Entry with asserted EOQ bit was not transferred from CFIFO_x. 1 Entry with asserted EOQ bit was transferred from CFIFO_x.
4 CFUF _x	CFIFO Underflow Flag x CFUF_x indicates an underflow event on CFIFO_x. CFUF_x is set when CFIFO_x is in TRIGGERED state and it becomes empty. No commands will be transferred from an underflowing CFIFO, nor will command transfers from lower priority CFIFOs be blocked. When CFUIE_x in EQADC Interrupt and DMA Control Register 0 (EQADC_IDCR0) and CFUF_x are both asserted, the EQADC generates an interrupt request. Apart from generating an independent interrupt request for a CFIFO_x underflow event, the EQADC also provides a combined interrupt at which the Result FIFO Overflow Interrupt, the Command FIFO Underflow Interrupt, and the Command FIFO Trigger Overrun Interrupt requests of ALL CFIFOs are ORed. When RFOIE_x, CFUIE_x, and TORIE_x are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOF_x, CFUF_x, and TORF_x (assuming that all interrupts are enabled). See EQADC DMA/interrupt request for details. Write "1" to clear CFUF_x. Writing a "0" has no effect. 0 No CFIFO underflow event occurred. 1 A CFIFO underflow event occurred.
5 SSS _x	CFIFO Single-Scan Status Bit x An asserted SSS_x bit enables the detection of trigger events for CFIFOs programmed into single-scan level- or edge-trigger mode, and works as trigger for CFIFOs programmed into single-scan software-trigger mode. See Single-scan mode for further details. The SSS_x bit is set by writing a "1" to the SSE_x bit in EQADC CFIFO Control Register 0 (EQADC_CFCR0). The EQADC clears the SSS_x bit when a command with an asserted EOQ bit is transferred from a CFIFO in single-scan mode, when a CFIFO is in single-scan level-trigger mode and its status changes from TRIGGERED due to the detection of a closed gate, or when the value of the CFIFO operation mode (MODE_x) in EQADC CFIFO Control Register 0 (EQADC_CFCR0) is changed to disabled. Writing to SSS_x has no effect. SSS_x has no effect in continuous-scan or in disabled mode. 0 CFIFO in single-scan level- or edge-trigger mode will ignore trigger events, or CFIFO in single-scan software-trigger mode is not triggered. 1 CFIFO in single-scan level- or edge-trigger mode will detect a trigger event, or CFIFO in single-scan software-trigger mode is triggered.
6 CFFF _x	CFIFO Fill Flag x CFFF_x is set when the CFIFO_x is not full. When CFFEx in EQADC Interrupt and DMA Control Register 0 (EQADC_IDCR0) and CFFF_x are both asserted, an interrupt or a DMA request will be generated depending on the status of the CFFS_x bit. When CFFS_x is negated (interrupt requests selected), software clears CFFF_x by writing a "1" to it. Writing a "0" has no effect. When CFFS_x is asserted (DMA requests selected), CFFF_x is automatically cleared by the EQADC when the CFIFO becomes full. NOTE: Writing "1" to CFFF_x when CFFS_x is asserted (DMA requests selected) is not allowed. NOTE: When generation of interrupt requests is selected (CFFS_x=0), CFFF_x must only be cleared in the ISR after the CFIFO_x push register is accessed.

Table continues on the next page...

EQADC_FISR_n field descriptions (continued)

Field	Description
	0 CFIFO _x is full. 1 CFIFO _x is not full.
7–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 RFOFX	RFIFO Overflow Flag x RFOF_x indicates an overflow event on RFIFO_x. RFOF_x is set when RFIFO_x is already full, and a new data is received from the on-chip ADCs. The RFIFO_x will not overwrite older data in the RFIFO, and the new data will be ignored. When RFOI_x in EQADC Interrupt and DMA Control Register 0 (EQADC_IDCR0) and RFOF_x are both asserted, the EQADC generates an interrupt request. Apart from generating an independent interrupt request for an RFIFO_x overflow event, the EQADC also provides a combined interrupt at which the Result FIFO Overflow Interrupt, the Command FIFO Underflow Interrupt, and the Command FIFO Trigger Overrun Interrupt requests of ALL CFIFOs are ORed. When RFOI_x, CFUI_x, and TORI_x are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOF_x, CFUF_x, and TORF_x (assuming that all interrupts are enabled). See EQADC DMA/interrupt request for details. Write "1" to clear RFOF_x. Writing a "0" has no effect. 0 No RFIFO overflow event occurred. 1 An RFIFO overflow event occurred.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 RFDFX	RFIFO Drain Flag x RFDF_x indicates if RFIFO_x has valid entries or not. RFDF_x is set when the RFIFO_x has at least one valid entry in it. When RFDE_x in EQADC Interrupt and DMA Control Register 0 (EQADC_IDCR0) and RFDF_x are both asserted, an interrupt or a DMA request will be generated depending on the status of the RFDS_x bit. When RFDS_x is negated (interrupt requests selected), software clears RFDF_x by writing a "1" to it. Writing a "0" has no effect. When RFDS_x is asserted (DMA requests selected), RFDF_x is automatically cleared by the EQADC when the RFIFO becomes empty. NOTE: Writing "1" to RFDF_x when RFDS_x is asserted (DMA requests selected) is not allowed. NOTE: When the generation of interrupt requests is selected (RFDS_x=0), RFDF_x must only be cleared in the ISR after the RFIFO_x pop register is accessed. 0 RFIFO _x is empty. 1 RFIFO _x has at least one valid entry.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–19 CFCTRX	CFIFO Entry Counter CFCTR_x indicates the number of commands stored in the CFIFO_x. When the EQADC completes transferring a piece of new data from the CFIFO_x, it decrements CFCTR_x by one. Writing a word or any bytes to the corresponding EQADC CFIFO Push Register (EQADC_CFPR_n) increments CFCTR_x by one. Writing any value to CFCTR_x has no effect.
20–23 TNXTPTRX	CFIFO Transfer Next Pointer TNXTPTR_x indicates the index of the next entry to be removed from CFIFO_x when it completes a transfer. When TNXTPTR_x is zero, it points to the entry with the smallest memory-mapped address inside CFIFO_x. TNXTPTR_x is only updated when a command transfer is completed. If the maximum index number (CFIFO depth minus one) is reached, TNXTPTR_x is wrapped to zero, else, it is incremented by one. For details, see CFIFO basic functionality. Writing any value to TNXTPTR_x has no effect.

Table continues on the next page...

EQADC_FISR_n field descriptions (continued)

Field	Description
24–27 RFCTR _x	RFIFO_x Entry Counter RFCTR_x indicates the number of data items stored in the RFIFO_x. When the EQADC stores a piece of new data into RFIFO_x, it increments RFCTR_x by one. Reading the whole word, half-word or any bytes of the corresponding EQADC Result FIFO Pop Register (EQADC_RFPR_n) decrements RFCTR_x by one. Writing any value to RFCTR_x itself has no effect. NOTE: When the DMA request is selected ((RFDS_x=1), the decrement of RFCTR_x should be done only readings controlled by the DMA external block. Flushing of the RFIFO_x decrements the RFCTR_x to zero and can lead the DMA system to a locked state (DMA request ON).
28–31 POPNXTPTR _x	RFIFO_x Pop Next Pointer POPNXTPTR_x indicates the index of the entry that will be returned when EQADC_RFPR_x is read. When POPNXTPTR_x is zero, it points to the entry with the smallest memory-mapped address inside RFIFO_x. POPNXTPTR_x is updated when EQADC_RFPR_x is read. If the maximum index number (RFIFO depth minus one) is reached, POPNXTPTR_x is wrapped to zero, else, it is incremented by one. For details refer to RFIFO basic functionality. Writing any value to POPNXTPTR_x has no effect.

30.5.13 EQADC CFIFO Transfer Counter Register 0 (EQADC_CFTCR0)

The EQADC CFIFO Transfer Counter Registers (EQADC_CFTCR) record the number of commands transferred from a CFIFO. The EQADC_CFTCR supports the monitoring of command transfers from a CFIFO.

Address: 0h base + 90h offset = 90h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

EQADC_CFTCR0 field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 TC_CF0	Transfer Counter for CFIFO0 TC_CF_x counts the number of commands which have been completely transferred from CFIFO_x. The transfer of entries bound for the on-chip ADCs is considered completed when they are stored in the appropriate CBuffer. The EQADC increments the TC_CF_x value by one after a command is transferred. TC_CF_x resets to zero after EQADC completes transferring a command with an asserted EOQ bit. Writing any value to TC_CF_x sets the counter to that written value. NOTE: If CFIFO_x is in TRIGGERED state when its MODE_x field is programmed to disabled, the exact number of entries transferred from the CFIFO until that point - TC_CF_x - is only known after the CFIFO status changes to IDLE, as indicated by CFS_x. For details refer to Disabled Mode.

Table continues on the next page...

Table continues on the next page...

EQADC_CFTCR2 field descriptions (continued)

Field	Description
	TC_CFx counts the number of commands which have been completely transferred from CFIFOfx. The transfer of entries bound for the on-chip ADCs is considered completed when they are stored in the appropriate CBuffer. The EQADC increments the TC_CFx value by one after a command is transferred. TC_CFx resets to zero after EQADC completes transferring a command with an asserted EOQ bit. Writing any value to TC_CFx sets the counter to that written value. NOTE: If CFIFOfx is in TRIGGERED state when its MODEx field is programmed to disabled, the exact number of entries transferred from the CFIFO until that point - TC_CFx - is only known after the CFIFO status changes to IDLE, as indicated by CFSx. For details refer to Disabled Mode.

30.5.16 EQADC CFIFO Status Snapshot Register 0 (EQADC_CFSSR0)

The EQADC CFIFO Status Snapshot Registers (EQADC_CFSSR) contain status fields to track the operation status of each CFIFO and the transfer counter of the last CFIFO to initiate a command transfer to the internal CBuffers. EQADC_CFSSR0-1 are related to the on-chip CBuffers (CBuffer0-1). All fields of a particular EQADC_CFSSR register are captured at the beginning of a command transfer to the CBuffer associated with that register. Note that captured status register values are associated with previous command transfer. This means that the CFSSR registers capture the status registers before the status registers change because of the transfer of the current command that is about to be popped from the CFIFO. The EQADC_CFSSR registers are read only. Writing to the EQADC_CFSSR registers has no effect.

30.5.18 EQADC CFIFO Status Register (EQADC_CFSR)

The EQADC CFIFO Status Register (EQADC_CFSR) contains the current CFIFO status. The EQADC_CFSR registers is read only. Writing to the EQADC_CFSR register has no effect.

Table 30-43. Current CFIFO Status

CFIFO Status	Field Value	Explanation
IDLE	0b00	CFIFO is disabled. CFIFO is in single-scan edge or level trigger mode and does not have SSS asserted. EQADC completed the transfer of the last entry of the CQueue in single-scan mode.
Reserved	0b01	Not applicable.
WAITING FOR TRIGGER	0b10	CFIFO Mode is modified to continuous-scan edge or level trigger mode. CFIFO Mode is modified to single-scan edge or level trigger mode and SSS is asserted. CFIFO Mode is modified to single-scan software trigger mode and SSS is negated. CFIFO is paused. EQADC transferred the last entry of the queue in continuous-scan edge trigger mode.
TRIGGERED	0b11	CFIFO is triggered

EQADC_STACCCR field descriptions (continued)

Field	Description
16–19 STACBS2	STAC Bus Timebase Bits Selection 2 The STACBSm field selects 16 bits from the total of 24 bits that are received from the STAC Bus interface as described in Table 30-45 . Consider TBASEm[0:23] the selected time base from slot SRVm.
20–23 SRV2	STAC Bus Server Data Slot Selector 2 The field SRVm indicates the slot number that contains the desired time base value sent by the STAC Bus server. It is possible to have up to 16 different sources to be selected.
24–27 STACBS1	STAC Bus Timebase Bits Selection 1 The STACBSm field selects 16 bits from the total of 24 bits that are received from the STAC Bus interface as described in Table 30-45 . Consider TBASEm[0:23] the selected time base from slot SRVm.
28–31 SRV1	STAC Bus Server Data Slot Selector 1 The field SRVm indicates the slot number that contains the desired time base value sent by the STAC Bus server. It is possible to have up to 16 different sources to be selected.

30.5.20 EQADC CFIFO0 Register (EQADC_CF0Rn)

The EQADC CFIFO Registers (EQADC_CFxRw) (x=0, ..., 5; w=0, ..., 3) provide visibility of the contents of a CFIFO for debugging purposes. Each CFIFO has four registers which are uniquely mapped to its four 32-bit entries. See [EQADC command FIFOs](#) for more information on CFIFOs. These registers are read only. Data written to these registers is ignored.

Address: 0h base + 100h offset + (4d × i), where i=0d to 3d

EQADC_CF1Rn field descriptions

Field	Description
0–31 CFIFO1_DATAw	CFIFO1 Data w (w = 0, ..., 3) Reading CFIFOx_DATAw returns the value stored on the wth entry of CFIFOx. Each CFIFO is composed of four 32-bit entries, with register 0 being mapped to the one with the smallest memory mapped address.

30.5.23 EQADC CFIFO2 Register (EQADC_CF2Rn)

The EQADC CFIFO Registers (EQADC_CF_xR_w) (x=0, ..., 5; w=0, ..., 3) provide visibility of the contents of a CFIFO for debugging purposes. Each CFIFO has four registers which are uniquely mapped to its four 32-bit entries. See [EQADC command FIFOs](#) for more information on CFIFOs. These registers are read only. Data written to these registers is ignored.

Address: 0h base + 180h offset + (4d × i), where i=0d to 3d

[illegible]

EQADC_CF2Rn field descriptions

Field	Description
0–31 CFIFO2_DATAw	CFIFO2 Data w (w = 0, ..., 3) Reading CFIFOx_DATAw returns the value stored on the wth entry of CFIFOx. Each CFIFO is composed of four 32-bit entries, with register 0 being mapped to the one with the smallest memory mapped address.

30.5.24 EQADC CFIFO3 Register (EQADC_CF3Rn)

The EQADC CFIFO Registers (EQADC_CFxRw) ($x=0, \dots, 5$; $w=0, \dots, 3$) provide visibility of the contents of a CFIFO for debugging purposes. Each CFIFO has four registers which are uniquely mapped to its four 32-bit entries. See [EQADC command FIFOs](#) for more information on CFIFOs. These registers are read only. Data written to these registers is ignored.

30.5.33 On-chip ADC registers

This section describes a list of registers that control on-chip ADC operation. The ADC registers are not part of the CPU accessible memory map. These registers can only be accessed indirectly through configuration commands. There are non memory mapped registers that are individual per ADC, plus other registers that are shared by both ADCs. The address, usage, and access privilege of each register is shown in [Table 30-111](#). Data written to or read from reserved areas of the memory map is undefined.

Their assigned addresses are the values used to set the ADC_REG_ADDRESS field of the read/write configurations commands bound for the on-chip ADCs. These are half-word addresses. Further, the following restrictions apply when accessing these registers:

- Registers ADC0_CR, ADC0_GCCR, ADC0_OCCR, ADC0_AGR1/2 and ADC0_AOR1/2 can only be accessed by configuration commands sent to CBuffer0.
- Registers ADC1_CR, ADC1_GCCR, ADC1_OCCR, ADC1_AGR1/2 and ADC1_AOR1/2 can only be accessed by configuration commands sent to CBuffer1.
- Registers ADC_TSCR, ADC_TBCR, ADC_ACR1-14, ADC_EACR1-14 and ADC_PUDCR0-7 can be accessed by configuration commands sent to CBuffer0 or to CBuffer1. A data write to any of these registers through a configuration command sent to CBuffer0 will write the same memory location as when writing to it through a configuration command sent to CBuffer1.

Note

Simultaneous write accesses from CBuffer0 and CBuffer1 to any of the shared registers are not allowed.

Table 30-111. On-Chip ADC Memory Map

ADC address	Use	Access

0xFF	Reserved for dummy write command ³	Write

1. Throughout the table, ADC0/ADC1 indicates that if the command is stored in CBuffer0 it will be applied to ADC0 and if in CBuffer1 it applies to ADC1. If this indication is omitted the register applies for both ADC0 and ADC1, independent of the CBuffer used.
2. See the chip-specific EQADC information for details about which analog inputs have pull up/pull down control
3. Defined as an address for dummy write operation. Read is not allowed.

30.5.33.1 ADC0/1 Control Registers (ADC0_CR and ADC1_CR)

The ADC0/1 Control Registers (ADC0/1_CR) is used to define the standard configuration of the ADC. In the standard configuration, the parameters contained in the Alternate Configuration Control Registers (ADC_ACR1-14) are fixed at their reset value. A conversion uses the standard configuration when the conversion command (with the standard format) is written to address 0x00 of the on-chip ADC memory map. Refer to [Conversion command format for the standard configuration](#).

ADC0 Register address: 0x01

Figure 30-104. ADC0/1 Control Registers (ADC0/1_CR)

Table 30-112. ADC0/1_CR field descriptions

Field	Description
ADC0/1_EN	Enable bit for ADC0/1 ADC0/1_EN enables ADC0/1 to perform A/D conversions. See Enabling and disabling the on-chip ADCs for details. Note: The bias generator circuit inside the ADC hard macro ceases functioning when both ADC0_EN and ADC1_EN bits are negated. Note: Conversion commands sent to the CBuffer of a disabled ADC are ignored by the ADC control hardware. Note: When the ADC0/1_EN status is changed from asserted to negated, the ADC Clock will not stop until it reaches its low phase.
	0 ADC is disabled. Clock supply to ADC0/1 is stopped.
	1 ADC is enabled and ready to perform A/D conversions.
ADC0/1_EMUX	External Multiplexer enable for ADC0/1 When ADC0/1_EMUX is asserted, the MA pins will output digital values according to the number of the external channel being converted for selecting external multiplexer inputs. See Internal/external multiplexing for a detailed description about how ADC0/1_EMUX affects channel number decoding. Note: Both ADC0/1_EMUX bits must not be asserted at the same time. Note: The ADC0/1_EMUX bit must only be written when the ADC0/1_EN bit is negated. ADC0/1_EMUX can be set during the same write cycle used to set ADC0/1_EN.
	0 External multiplexer disabled; no external multiplexer channels can be selected.
	1 External multiplexer enabled; external multiplexer channels can be selected.

Table continues on the next page...

Table 30-112. ADC0/1_CR field descriptions (continued)

Field	Description
ADC0/1_TBSEL[0:1]	Timebase Selection for ADC0/1 The ADC0/1_TBSEL[0:1] field selects the time information to be used as timestamp according to Table 30-113. Note: This selection is overridden by the corresponding field ATBSEL in the ADC_ACR1-14 registers when the alternate conversion command is used.
ADC0/1_ODD_PS	Clock Prescaler Odd Rates Selector for ADC0/1 The ADC0/1_CLK_DTY field controls the duty rate of the ADC0/1 clock when the ADC0/1_CLK_PS field is asserted. The generated clock has an odd number of system clock cycles, therefore this field is used to select a clock duty higher or lower than 50%.
	0 Even divide factor is selected. The final divide factor is dependent of ADC0/1_CLK_PS field.
	1 Odd divide factor is selected. The final divide factor is dependent of ADC0/1_CLK_PS field.
ADC0/1_CLK_DTY	Clock Duty Rate Selector for ADC0/1 (for odd divide factors) The ADC0/1_ODD_PS field is used together with the ADC0/1_CLK_PS field to define even/odd divide factors in the generation of the ADC0/1 clocks. See Table 30-114 for available divide factors.
	0 clock low interval is longer 1 clock cycle than high pulse.
	1 clock high pulse is longer 1 clock cycle than low portion.
ADC0/1_CLK_SEL	Clock Selector for ADC0/1 The ADC0/1_CLK_SEL is used to select between the system clock signal or the prescaler output signal. The prescaler provides the system clock signal divided by a even factor from 2 to 64. This is required to permit the ADC to run as fast as possible when the device is in Low Power Active mode and system clock is around 1 MHz. Note: The ADC0/1_CLK_SEL bits must only be written when the ADC0/1_EN bit is negated. ADC0/1_CLK_SEL can be set during the same write cycle used to set ADC0/1_EN.
	0 Prescaler output clock is selected.
	1 System clock is selected - maximum frequency.
ADC0/1_CLK_PS[0:4]	Clock Prescaler Field for ADC0/1 The ADC0/1_CLK_PS field controls the system clock divide factor for the ADC0/1 clock as in Table 30-114. See ADC clock and conversion speed for details about how to set ADC0/1_CLK_PS. Note: The ADC0/1_CLK_PS field must only be written when the ADC0/1_EN bit is negated. This field can be configured during the same write cycle used to set ADC0/1_EN.

Table 30-113. Timebase selection

ADC0/1_TBSEL[0:1]	Definition
00	Selects internally generated time base as time stamp.
01	Selects imported time base 1 indicated by SRV1 bit field of EQADC_STACCCR register.
10	Selects imported time base 2 indicated by SRV2 bit field of EQADC_STACCCR register.

30.5.33.2 ADC Time Stamp Control Register (ADC_TSCR)

The ADC Time Stamp Control Register (ADC_TSCR) contains a system clock divide factor used in the making of the time base counter clock. It determines at what frequency the time base counter will run. ADC_TSCR can be accessed by configuration commands sent to CBuffer0 or to CBuffer1. A data write to ADC_TSCR through a configuration command sent to CBuffer0 will write the same memory location as when writing to it through a configuration command sent to CBuffer1.

Note

Simultaneous write accesses from CBuffer0 and CBuffer1 to ADC_TSCR are not allowed.

Table 30-115. ADC_TSCR field descriptions

Field	Description
TBC_CLK_PS[0:3]	Time Base Counter Clock Prescaler The TBC_CLK_PS field contains the system clock divide factor for the time base counter. It controls the accuracy of the time stamp. The prescaler is disabled when TBC_CLK_PS is set to 0b0000. See Table 30-116. Note: If TBC_CLK_PS is not set to disabled, it must not be changed to any other value besides disabled. If TBC_CLK_PS is set to disabled it can be changed to any other value.

30.5.33.3 ADC Time Base Counter Registers (ADC_TBCR)

The ADC Time Base Counter Register (ADC_TBCR) contains the current value of the time base counter. ADC_TBCR can be accessed by configuration commands sent to CBuffer0 or to CBuffer1. A data write to ADC_TBCR through a configuration command sent to CBuffer0 will write the same memory location as when writing to it through a configuration command sent to CBuffer1.

Note

Simultaneous write accesses from CBuffer0 and CBuffer1 to ADC_TBCR are not allowed.

ADC0/1 Register address: 0x03

**Figure 30-106. ADC Time Base Counter Register (ADC_TBCR)**

Table 30-117. ADC_TBCR field descriptions

Field	Description
TBC_VALUE[0:15]	Time Base Counter VALUE Field The TBC_VALUE field contains the current value of the time base counter. Reading TBC_VALUE returns the current value of time base counter. Writes to TBC_VALUE register load the written data to the counter. The time base counter counts from 0x0000 to 0xFFFF and wraps when reaching 0xFFFF.

30.5.33.4 ADC0/1 Gain Calibration Constant Registers (ADC0_GCCR and ADC1_GCCR)

The ADC0/1 Gain Calibration Constant Register (ADC0/1_GCCR) contains the gain calibration constant used to fine-tune the ADC0/1 conversion results. See [ADC calibration feature](#) for details about the calibration scheme used in the EQADC.

ADC0 Register address: 0x04

ADC1 Register address: 0x04

Figure 30-107. ADC0/1 Gain Calibration Constant Registers (ADC0/1_GCCR)

Table 30-118. ADC0/1_GCCR field descriptions

Field	Description
GCC0/1[0:14]	Gain calibration constant for ADC0/1 GCC0/1 contains the gain calibration constant used to fine-tune ADC0/1 conversion results. It is a unsigned 15-bit fixed pointed value. The gain calibration constant is an unsigned fixed point number expressed in the GCC_INT.GCC_FRAC binary format. The integer part of the gain constant (GCC_INT) contains a single binary digit while its fractional part (GCC_FRAC) contains fourteen digits. For details about the GCC data format, see MAC unit and operand data format .

30.5.33.5 ADC0/1 Offset Calibration Constant Registers (ADC0_OCCR and ADC1_OCCR)

The ADC0/1 Offset Calibration Constant Register (ADC0/1_OCCR) contains the offset calibration constant used to fine-tune of ADC0/1 conversion results. The offset constant is a signed 14-bit integer value. See [ADC calibration feature](#) for details about the calibration scheme used in the EQADC.

ADC0 Register address: 0x05

ADC1 Register address: 0x05

Figure 30-108. ADC0/1 Offset Calibration Constant Registers (ADC0/1_OCCR)

Table 30-119. ADC0/1_OCCR field descriptions

Field	Description
OCC0/1[0:13]	Offset Calibration Constant of ADC0/1 OCC0/1 contains the offset calibration constant used to fine-tune ADC0/1 conversion results. Negative values should be expressed using the two's complement representation.

30.5.33.6 Alternate Configuration 1-14 Control Registers (ADC_ACR1-14)

The Alternate Configuration Control Registers (ADC_ACR1-14) are used to configure the alternate configurations of the ADC. There are 14 possible alternate configurations, each one associated with one of the ADC_ACR1-14 registers. All alternate configurations share the same standard configuration parameters from the ADC0/1_CR

registers, plus additional configuration parameters contained in the ADC_ACR1-14. A conversion uses one of the alternate configurations when the conversion command (with the alternate configuration format) is written to an address in the range 0x08-0x15 of the on-chip ADC memory map. It also can use the Extended Alternated Configurations as described in [Extended Alternate Configuration 1-14 Control Registers \(ADC_EACR1-14\)](#) if bit DAM=1. See [Conversion command format for alternate configurations](#).

ADC0/1 Register address: 0x30

ADC0/1 Register address: 0x60
ADC0/1 Register address: 0x64

¹ Reserved for expansion of DEST.

Figure 30-109. Alternate Configuration 1-14 Control Registers (ADC_ACR1-14)

Table 30-120. ADC_ACR1-14 field descriptions

Field	Description				
RET_INH	Result Transfer Inhibit / Decimation Filter Pre-Fill This bit is used to inhibit the transfer of the result data from the peripheral module to the result queue. When the module is a Decimation Filter, this bit sets the filter in a special mode (PRE-FILL) in which it does not generate decimated samples out from the conversion results received from the EQADC block, but the conversion samples are used by the filter algorithm. This feature allows a proper initialization of the Decimation Filter without generating any decimated result. Or this bit is useful for sending the result of the ADC to the STAC bus master but not putting the result in the result queue. Note: Refer to the block guide of each peripheral module to obtain the correct behavior of the companion module to the PRE-FILL mode. <table><tr><td>0</td><td>Result transfer to result queue / Decimation Filter in filtering mode</td></tr><tr><td>1</td><td>No result transfer to result queue / Decimation Filter PRE-FILL mode</td></tr></table>	0	Result transfer to result queue / Decimation Filter in filtering mode	1	No result transfer to result queue / Decimation Filter PRE-FILL mode
0	Result transfer to result queue / Decimation Filter in filtering mode				
1	No result transfer to result queue / Decimation Filter PRE-FILL mode				

Table continues on the next page...

Table 30-120. ADC_ACR1-14 field descriptions (continued)

Field	Description
DEST[0:3]	Conversion Result Destination Selection The DEST[0:3] field selects the primary destination of the conversion result generated by the Alternate Conversion Command as shown in Table 30-121. This field also affects the behavior of the FMTA bit and the FFMT bit of the conversion command for alternate configurations (see Conversion command format for alternate configurations). And this field is affected by DAM bit of the EQADC Module Configuration Register (see EQADC Module Configuration Register (EQADC_MCR)). There is also configurations to send the conversion result to a second destination using the Extended Alternate Configuration registers (Extended Alternate Configuration 1-14 Control Registers (ADC_EACR1-14)).
FMTA	Conversion Data Format for Alternate Configuration If the DEST field is not 0b000, the FMTA bit specifies how the 12-bit conversion data returned by the ADCs is formatted into the 16-bit data which is sent to the parallel side interface.
	0 Right justified unsigned
	1 Right justified signed
RPSI	Return Parallel Side Interface The RPSI bit is used in the companion modules that have two PSI interfaces (PSI0 and PSI1), which are connected to two eQADCs. It specifies in the companion module if the data received from one PSI should be transmitted to the same PSI or to the other one. Note: The companion module may take samples from two eQADCs, allowing double sample rate. If the RPSI bits are different, the results are sent to just one of the eQADCs. Note: It is not allowed to use RPSI=1 when the SoC has only one eQADC. It can occur errors in the companion module due to routing error.
	0 Companion module results from this eQADC are sent back to the same eQADC using the same PSI.
	1 Companion module results from this eQADC are sent to the other PSI
RESSEL[0:1]	ADC Resolution Selection The RESSEL[0:1] field selects the resolution of the ADC.
	00 ADC set to 12-bits resolution
	01 ADC set to 10-bits resolution
	10 ADC set to 8-bits resolution
	11 Reserved
ATBSEL[0:1]	Alternate Command Timebase Selector The ATBSEL[0:1] field selects the time information to be used as timestamp Note: This selection overrides the corresponding fields ADC0/1_TBSEL in the ADC0/1_CR registers when the alternate conversion command is used.
	00 Selects internally generated time base as time stamp
	01 Selects imported time base 1 indicated by SRV1 bit field of EQADC_STACCCR register.
	10 Selects imported time base 2 indicated by SRV2 bit field of EQADC_STACCCR register.
	11 Reserved

Table continues on the next page...

Table 30-120. ADC_ACR1-14 field descriptions (continued)

Field	Description
PRE_GAIN[0:1]	ADC Pre-gain control The PRE_GAIN[0:1] controls the gain of the ADC input stage by changing the internal ADC iterations in the gain stage.
	00 X1 gain
	01 X2 gain
	10 X4 gain
	11 Reserved

Table 30-121. Conversion destination selection

DAM	DEST[0:3]	First Destination	Second Destination	Description
0	0000	RFIFOn	-	The conversion result is sent to the RFIFOn (where n = MESSAGE_TAG). The data format is specified by the FFMT bit in the Conversion Command Message.
	0001 - 0111	1-7	-	The conversion result is sent to the Parallel Side Interface. Up to seven devices can be connected to the parallel interface, using the DEST field to select which one receives the conversion result. The data format is specified by the FMTA bit in the Alternate Configuration Control Register.
	1000	1	5	The conversion result is sent to the Parallel Side Interface to two destinations. The transferred data is the same for both destinations. - The data format is specified by the FMTA bit in the Alternate Configuration Control Register. - The FLUSH command is sent to both destinations.
	1001	2		
	1010	3		
	1011	4		
	1100	1	7	
	1101	2		
	1110	3		
	1111	4		
1	0000	RFIFOn	Depends on DEST2 (Table 30-125)	For DEST = 0, the conversion result is sent to the RFIFOs.The data format is specified by the FFMT bit in the Conversion Command Message. Note: It is not possible to have FLUSH control for DEST2 >0 because FFMT is used for format of DEST, not for FLUSH.
	0001 - 1111	1-15		The conversion result is sent to the Parallel Side Interface. Up to fifteen devices can be connected to the parallel interface, using the DEST field to select which one receives the conversion result. The data format is specified by the FMTA bit in the Alternate Configuration Control Register.

30.5.33.7 ADC0/1 Alternate Gain Registers (ADC0_AGR1-2 and ADC1_AGR1-2)

The Alternate Gain Registers (ADC0_AGRx and ADC1_AGRx, x=1-2) contain the gain calibration constants used to fine-tune the ADCs conversion results for alternate configurations 1 or 2. A conversion from an ADC uses the corresponding ADC0_AGRx or ADC1_AGRx register when the conversion command (with the alternate configuration format) is written to an address in the range 0x08-0x09 of the on-chip ADC memory map. See [ADC calibration feature](#) for details about the calibration scheme used in the EQADC.

Field	Description
ALTGCC0/1x[0:14]	Alternate Gain Calibration Constant ALTGCC0/1x[0:14] contain the gain calibration constants used to fine-tune ADC0/1 conversion results for alternate configurations 1 and 2. The gain calibration constants are 15-bit unsigned fixed point numbers expressed in the <i>GCC_INT.GCC_FRAC</i> binary format. The integer part of the gain constants (<i>GCC_INT</i>) contain a single binary digit while their fractional part (<i>GCC_FRAC</i>) contain fourteen digits. For details about the GCC data format, see MAC unit and operand data format.

30.5.33.8 ADC0/1 Alternate Offset Register (ADC0_AOR1-2 and ADC1_AOR1-2)

The Alternate Offset Registers (ADC0_AORx and ADC1_AORx, x=1-2) contain the offset calibration constants used to fine-tune ADCs conversion results for alternate configurations 1 and 2. The offset constants are signed 14-bit integer values. See [ADC calibration feature](#) for details about the calibration scheme used in the EQADC.

ADC0 Register address: 0x32
ADC0 Register address: 0x36

Field	Description
ALTOCC0/1x[0:13]	Alternate Offset Calibration Constant ALTOCC0/1x[0:13] contain the offset calibration constants used to fine-tune ADCs conversion results for alternate configurations 1 or 2. Negative values should be expressed using the two's complement representation.

30.5.33.9 Extended Alternate Configuration 1-14 Control Registers (ADC_EACR1-14)

The Extended Alternate Configuration Control Registers (ADC_EACR1-14) are used together with the Alternate Configuration Control Registers (ADC_ACR1-14) of the same number to complement the alternate configurations of the ADC. A conversion uses one pair of the alternate configuration regs (normal and extended) when the conversion

command (with the alternate conversion format) is written to an address in the range 0x08-0x15 of the on-chip ADC memory map. See [Conversion command format for alternate configurations](#).

Figure 30-112. Extended Alternate Configuration 1-14 Control Registers (ADC_EACR1-14)

Table 30-124. ADC_EACR1-14 field descriptions

Field	Description
RET_INH2	Result Transfer Inhibit 2 / Decimation Filter Pre-Fill 2 Same definition of DEST field but to the peripheral module indicated by DEST2.
	0 Result transfer to result queue / Decimation Filter in filtering mode
	1 No result transfer to result queue / Decimation Filter PRE-FILL mode
DEST2[0:3]	Conversion Result Destination 2 Selection The DEST2[0:3] field selects the second destination of the conversion result generated by the Alternate Conversion Command. However this selection only can occur when DAM = 1 (see EQADC Module Configuration Register (EQADC_MCR)), as shown in previous Table 30-121 for DEST field. In addition, the eQADC operation due to this field is also affected by the ADC_ACRx DEST field, by the ADC_EACRx TEN2 field, by MESSAGE_TAG field, by the ADC_EACRx MESSAGE_TAG2 field as defined in Table 30-125 .
FMTA2	Conversion Data Format for Alternate Configuration DEST2 The FMTA2 bit specifies how the 12-bit conversion data returned by the ADCs is formatted into the 16-bit data which is sent to the RFIFOs or the parallel side interface defined by DEST2. See Table 30-125 for more details.
	0 Right justified unsigned

Table continues on the next page...

Table 30-124. ADC_EACR1-14 field descriptions (continued)

Field	Description
	1 Right justified signed
RPSI2	Return Parallel Side Interface for DEST2 The RPSI2 bit is used in the companion module that has two PSI interfaces (PSI0 and PSI1) that are connected to two eQADCs. It specifies in the companion module if the data received from one PSI should be transmitted to the same PSI or to the other one. Note: The companion module may take samples from two eQADCs, allowing double sample rate. If the RPSI bits are different, the results are sent to just one of the eQADCs. Note: It is not allowed to use RPSI2=1 when the SoC has only one eQADC. It can occur errors in the companion module due to routing error.
	0 Companion module results from this eQADC are sent back to the same eQADC using the same PSI.
	1 Companion module results from this eQADC are sent to the other PSI
FLEN2	Flush Enable to DEST2 The FLEN2 bit enables the transfer of the flush command given by the FFMT field from the alternate conversion command when DEST>0.
	0 No flush command is transmitted to DEST2.
	1 Flush command is sent to DEST2 if specified by FFMT when DEST>0.
TEN2	Enable MESSAGE_TAG2 to DEST2 This bit specifies if the MESSAGE_TAG2 value should be used to the result transfer of DEST2. See Table 30-125 for more details.
	0 MESSAGE_TAG2 is disabled.
	1 MESSAGE_TAG2 is enabled.
MESSAGE_TAG2[0:3]	MESSAGE TAG 2 Field Same as the MESSAGE_TAG field in the Conversion Command as described in Conversion command format for the standard configuration. Table 30-129 describes the meaning of the MESSAGE_TAG2.

Table 30-125. Conversion Destinations Selection (DAM = 1)

DEST [0:3]	DEST2 [0:3]	TEN 2	MESSAGE _TAG2 = MESSAGE _TAG	(FMTA2=FFMT) or (FMTA2=FMTA) & (RET2=RET) & (RPSI2=RPSI) & (Flush2=Flush)	First Dest.	Second Dest.	Description
0000	0000	0	X	X	RFIFOn	-	The conversion result is sent to the RFIFOn (where n = MESSAGE_TAG), and the data format is specified by the FFMT bit in the alternate conversion command.
		1	1	1			
				0		RFIFOn	- Same as above but the conversion result is sent again to RFIFOn if FMTA2 is different from FFMT. - OBS: Two values are sent to the same RFIFO for one ADC conversion.
			0	X		RFIFOy	- The conversion result is sent to the RFIFOn (where n = MESSAGE_TAG), and the data format is specified by the FFMT bit in the alternate conversion command. - The conversion result is also sent to RFIFOy (where y = MESSAGE_TAG2) and the data format is specified by the FMTA2.

Table continues on the next page...

Table 30-125. Conversion Destinations Selection (DAM = 1) (continued)

DEST [0:3]	DEST2 [0:3]	TEN 2	MESSAGE _TAG2 = MESSAGE _TAG	(FMTA2=FFMT) or (FMTA2=FMTA) & (RET2=RET) & (RPSI2=RPSI) & (Flush2=Flush)	First Dest.	Second Dest.	Description
0000	0001 - 1111	0	X	X	RFIFOn	1 - 15	- The conversion result is sent to the RFIFOn (where n = MESSAGE_TAG), and the data format is specified by the FFMT bit. - The conversion result is also sent to PSI using the DEST2 field and the MESSAGE_TAG value. The data format is specified by the FMTA2 bit. There is not flush command. RET2 and RPSI2 are also used. - OBS: If the companion block addressed by DEST2 sends data back to the same eQADC, this result is sent to RFIFOn (two values to the same RFIFO for one ADC conversion). Note: It is not possible to have FLUSH control for DEST2>0 because FFMT is used for format of DEST, not for FLUSH.
		1	1	X			
			0	X			Same as above, but if the companion block addressed by DEST2 sends data back to the eQADC, this data is sent to RFIFOy given by MESSAGE_TAG2.

Table continues on the next page...

Table 30-125. Conversion Destinations Selection (DAM = 1) (continued)

DEST [0:3]	DEST2 [0:3]	TEN 2	MESSAGE _TAG2 = MESSAGE _TAG	(FMTA2=FFMT) or (FMTA2=FMTA) & (RET2=RET) & (RPSI2=RPSI) & (Flush2=Flush)	First Dest.	Second Dest.	Description
0001 - 1111	0000	0	X	X	1 - 15	-	The conversion result is sent to PSI using the DEST field and the MESSAGE_TAG value. The data format is specified by the FMTA bit. The flush command depends on FFMT command field.
		1	1	X		RFIFOn	- The conversion result is sent to PSI using the DEST field and the MESSAGE_TAG value. The data format is specified by the FMTA bit. The flush command depends on FFMT command field. - The conversion result is also sent to the RFIFOn (where n = MESSAGE_TAG2), and the data format is specified by the FMTA2 bit field. - OBS: If the companion block addressed by DEST sends data back to the same eQADC, this result is sent to RFIFOn (two values to the same RFIFO for one ADC conversion).
			0	X		RFIFOy	Same as above, but if the companion block addressed by DEST sends data back to the eQADC, this data is sent to RFIFOn=MESSAGE_TAG.

Table continues on the next page...

Table 30-125. Conversion Destinations Selection (DAM = 1) (continued)

DEST [0:3]	DEST2 [0:3]	TEN 2	MESSAGE _TAG2 = MESSAGE _TAG	(FMTA2=FFMT) or (FMTA2=FMTA) & (RET2=RET) & (RPSI2=RPSI) & (Flush2=Flush)	First Dest.	Second Dest.	Description
0001 - 1111	0001 - 1111 (Equal to DEST)	0	X	1	1 - 15	-	The conversion result is sent to PSI using the DEST field and the MESSAGE_TAG value. The data format is specified by the FMTA bit. The flush command depends on FFMT command field.
				0			
		1	1	0		1 - 15 (Equal to 1st Dest)	- Same as above. - The conversion result is sent again to PSI to the same DEST=DEST2. However, the PSI data bus value is different. - OBS: The data related to DEST is sent first. And the data related to DEST2 is sent later.
				1		-	The conversion result is sent to PSI using the DEST field and the MESSAGE_TAG value. The data format is specified by the FMTA bit. The flush command depends on FFMT command field.
				0		1 - 15 (Equal to 1st Dest)	- Same as above. - The conversion result is also sent to PSI using the DEST2=DEST field and with the MESSAGE_TAG2 value. The data format is specified by the FMTA2 bit. The flush command depends on FLEN2 bit field. RET2 and RPSI2 are also used.
				X			

Table continues on the next page...

Table 30-125. Conversion Destinations Selection (DAM = 1) (continued)

DEST [0:3]	DEST2 [0:3]	TEN 2	MESSAGE _TAG2 = MESSAGE _TAG	(FMTA2=FFMT) or (FMTA2=FMTA) & (RET2=RET) & (RPSI2=RPSI) & (Flush2=Flush)	First Dest.	Second Dest.	Description
0001 - 1111	0001 - 1111 (Not equal to DEST)	0	X	0	1-15	1 - 15 (Not equal to 1st Dest)	- The conversion result is sent to PSI using the DEST field and the MESSAGE_TAG value. The data format is specified by the FMTA bit. The flush command depends on FFMT command field. - The conversion result is also sent to PSI using the DEST2 (not equal DEST) field and with the MESSAGE_TAG2 value. The data format is specified by the FMTA2 bit. The flush command depends on FLEN2 bit field. RET2 and RPSI2 are also used. - OBS1: If the companion blocks addressed by DEST and DEST2 send data back to the same eQADC, these results are sent to the same RFIFO (two values to the same RFIFO for one ADC conversion). - OBS2: The data related to DEST is sent first. And the data related to DEST2 is sent later. Note: When sending timestamp in this case, the values sent to RFIFO can be out of order due to the prioritization of reading in the receiving part of the PSI sub-block.
				1			Same as above, except OBS2. In this case, the data is sent to DEST and DEST2 at the same time.
		1	1	1			Same as first case above.
				0			
			0	X			Same as first case, except OBS1 and Note2.

30.5.33.10 **ADC Pull Up/Down Control Register x (ADC_PUDCRx, x=0-39)**

The ADC Pull Up/Down Control Register *x* (ADC_PUDCR_{*x*}) contains configuration bits for pull up and pull down resistors present at ADC input channels *x*, *x*=0 to 39.

ADC0/1 Register address: 0x70-0x97

30.6 Functional description

30.6.1 Overview

The EQADC provides a parallel interface to two on-chip ADCs and a parallel side interface to on-chip companion modules, like a decimation filter. The two on-chip ADCs are architected to allow access to all the analog channels.

Initially, command data is contained in system memory in a user defined data structure which is likely to be a queue as depicted in [Figure 30-1³](#). Command data is moved between the CQueues and CFIFOs by the host CPU or by the DMAC which respond to interrupt and DMA requests generated by the EQADC. The EQADC supports software and hardware triggers from other blocks or external pins to initiate transfers of commands from the multiple CFIFOs to the on-chip ADCs.

CFIFOs can be configured in single-scan or continuous-scan mode. When a CFIFO is configured in single-scan mode, the EQADC scans the CQueue one time. The EQADC stops transferring commands from the triggered CFIFO after detecting the EOQ bit set in the last transfer. After an EOQ bit is detected, software involvement is required to rearm the CFIFO so that it can detect new trigger events.

3. Command and result data can be stored in system memory in any user defined data structure. However, in this document it will be assumed that the data structure of choice is a queue, since it is the most likely data structure to be used and because queues are the only type of data structure supported by the DMAC.

When a CFIFO is configured for continuous-scan mode, the whole CQueue is scanned multiple times. After the detection of an asserted EOQ bit in the last command transfer, command transfers can continue or not depending on the mode of operation of the CFIFO.

CFIFO0 has a special configuration option to allow a repetitive sequence of conversion commands (streaming mode) with high priority characteristics (abort operation) or not. This feature is useful with the immediate conversion command feature that allows the immediate execution of a conversion command or a sequence of commands with critical timing even with the possibility of abortion of some current ADC conversion in progress. The aborted command is stored and executed again as soon as the critical timing commands have been finished.

The multiple Result FIFOs (RFIFOs) can receive data from the on-chip ADCs or from on-chip companion modules. Data from the on-chip ADCs can be routed to the side interface, processed by the on-chip companion modules and then routed back through the side interface to the RFIFOs.

30.6.2 Data flow in EQADC

30.6.2.1 Overview and basic terminology

Figure 30-115 shows how command data flows inside the EQADC system. A Command Message is the predefined format at which command data is stored on the CQueues. A Command message has 32 bits and is composed of two parts: a CFIFO header and an ADC Command. Command messages are moved from the CQueues to the CFIFOs by the host CPU or by the DMAC as they respond to interrupt and DMA requests generated by the EQADC. The EQADC generates these requests whenever a CFIFO is not full. *The FIFO Control Unit* will only transfer to a CBuffer the ADC command part of the Command Message. Information in the CFIFO header together with the upper bit of the ADC command is used by the *FIFO Control Unit* to arbitrate which triggered CFIFO will be transferring the next command.

Figure 30-115. Command Flow during EQADC operation

ADC commands sent to the on-chip CBuffers are executed in a first-in-first-out basis with exception when the immediate conversion command function is enabled. Three types of results can be expected: data read from an ADC register, a conversion result, or a time stamp.

Note

While the EQADC pops commands out from a CFIFO, it also is checking the number of entries in the CFIFO and generating requests to fill it. The process of pushing and popping commands to and from a CFIFO can occur simultaneously. However, this is not true for CFIFO0 when configured to operate in streaming mode for popping.

The *FIFO Control Unit* expects all incoming results to be shaped in a predefined Result Message format. [Figure 30-116](#) shows how result data flows inside the EQADC system. Results generated on the on-chip ADCs are adjusted considering the selected resolution of the ADC and are formatted into result messages inside the *Result Format and Calibration Sub-Block*. This result message can be routed directly to one of the RFIFOs or to an on-chip companion module via the parallel side interface. After the data is processed by the companion module, it can be routed back to one of the RFIFOs via the side interface with the correct format. A result message is composed of an RFIFO header

and an ADC Result. The *FIFO Control Unit* decodes the information contained in the RFIFO header to determine the RFIFO to which the ADC result should be sent. Once in an RFIFO, the ADC result is moved to the corresponding RQueue by the host CPU or by the DMAC as they respond to interrupt and DMA requests generated by the EQADC. The EQADC generates these requests whenever an RFIFO has at least one entry.

Note

While conversion results are returned, the EQADC is checking the number of entries in the RFIFO and generating requests to empty it. The process of pushing and popping ADC results to and from an RFIFO can occur simultaneously.

Figure 30-116. Result Flow during EQADC operation

30.6.2.2 Message format in EQADC

This section explains the command and result message formats used for on-chip ADC operation

A Command Message is the predefined format at which command data is stored on the CQueues. A Command message has 32 bits and is composed of two parts: a CFIFO header and an ADC Command. The size of the CFIFO header is fixed to 6 bits, and it works as inputs to the *FIFO Control Unit*. It controls when a CQueue ends, when it pauses. Information contained in the CFIFO header, together with the upper bit of the ADC Command is used by the *FIFO Control Unit* to arbitrate which triggered CFIFO will transfer the next command. ADC commands are encoded inside the least significant 26 bits of the command message.

A Result message is composed of an RFIFO header and an ADC Result. The *FIFO Control Unit* decodes the information contained in the RFIFO header to determine the RFIFO to which the ADC result should be sent. An ADC result is always 16 bits long.

30.6.2.2.1 Message Formats for On-Chip ADC Operation

This section describes the Command/Result message formats used for on-chip ADC operation.

30.6.2.2.1.1 Conversion command format for the standard configuration

Figure 30-117 describes the format for conversion commands when interfacing with the on-chip ADCs in the standard configuration. The standard configuration is selected when the lowest byte (bits 24-31) of the conversion command is set to zero. In the standard configuration, the conversion result is always routed to one of the RFIFOs. A time stamp information can be optionally requested.

Figure 30-117. Conversion command format for the standard configuration

**Table 30-128. Conversion command format for the standard configuration
— field descriptions**

Field	Description
EOQ	End Of Queue Bit NOTE: The EOQ bit is asserted in the last command of a CQueue to indicate to the EQADC that a scan of the CQueue is completed. EOQ instructs the EQADC to reset its current CFIFO transfer counter value (TC_CF) to zero. Depending on the CFIFO mode of operation, the CFIFO status will also change upon the detection of an asserted EOQ bit on the last transferred command - see CFIFO scan trigger modes for details. If both the PAUSE and EOQ bits are asserted in the same command message the respective flags are set, but the CFIFO status changes as if only the EOQ bit were asserted.
	0 Not the last entry of the CQueue.
	1 Last entry of the CQueue.
PAUSE	Pause Bit The Pause bit allows software to create sub-queues within a CQueue. When the EQADC completes the transfer of a command with an asserted Pause bit, the CFIFO enters the WAITING FOR TRIGGER state. See CFIFO operation status for a description of the state transitions. The Pause bit is only valid when CFIFO operation mode is configured to single or continuous-scan edge trigger mode. Note: If both the PAUSE and EOQ bits are asserted in the same command message the respective flags are set, but the CFIFO status changes as if only the EOQ bit were asserted.
	0 Do not enter WAITING FOR TRIGGER state after transfer of the current Command Message.
	1 Enter WAITING FOR TRIGGER state after transfer of the current Command Message.
REP	Repeat/loop Start Point Indication Bit The REP bit is asserted in the command to indicate where is the start point of the sub-queue to be repeated when the streaming mode is enabled. The PAUSE bit indicates the end point of the sub-queue. Therefore, both can occur in the same command or in separated ones. If two or more REP bits are read before a PAUSE bit, this is an error case and the intermediary REP bits are ignored.
	0 It is not the start point of a loop.
	1 Indicates the start point of the sub-queue to be repeated.
Reserved	Reserved
BN	Buffer Number Bit BN indicates which buffer the message will be stored in.
	0 Message stored in buffer 0.
	1 Message stored in buffer 1.
CAL	CALibration Bit CAL indicates if the returning conversion result must be calibrated.
	0 Do not calibrate conversion result.
	1 Calibrate conversion result.

Table continues on the next page...

Table 30-128. Conversion command format for the standard configuration — field descriptions (continued)

Field	Description								
MESSAGE_TAG[0:3]	MESSAGE_TAG Field The MESSAGE_TAG allows the EQADC to separate returning results into different RFIFOs. Table 30-129 describes the meaning of the MESSAGE_TAG. When the EQADC transfers a command, the MESSAGE_TAG is included as part of the command. Eventually on-chip ADC returns the result with the same MESSAGE_TAG. The EQADC separates incoming messages into different RFIFOs by decoding the MESSAGE_TAG of the incoming data. Note: The MESSAGE_TAG value can be particularly used in a companion module (that uses the PSI) as the address to the annexed conversion result. The data can be routed to different sub-blocks based on the MESSAGE_TAG, similar to what is done with the RFIFOs in the eQADC. Additionally, in the companion module it is not required to follow Table 30-129.								
LST[0:1]	Long Sampling Time These two bits determine the duration of the sampling time in ADC clock cycles. <table> <tr> <td>00</td><td>2 sampling cycles (ADC clock cycles)</td></tr> <tr> <td>01</td><td>8 sampling cycles (ADC clock cycles)</td></tr> <tr> <td>10</td><td>64 sampling cycles (ADC clock cycles)</td></tr> <tr> <td>11</td><td>128 sampling cycles (ADC clock cycles)</td></tr> </table>	00	2 sampling cycles (ADC clock cycles)	01	8 sampling cycles (ADC clock cycles)	10	64 sampling cycles (ADC clock cycles)	11	128 sampling cycles (ADC clock cycles)
00	2 sampling cycles (ADC clock cycles)								
01	8 sampling cycles (ADC clock cycles)								
10	64 sampling cycles (ADC clock cycles)								
11	128 sampling cycles (ADC clock cycles)								
TSR	Time Stamp Request TSR indicates the request for a time stamp. When TSR is asserted, the on-chip <i>ADC Control Logic</i> returns a time stamp for the current conversion command after the conversion result is sent to the RFIFOs. See Time stamp feature for details. <table> <tr> <td>0</td><td>Return conversion result only.</td></tr> <tr> <td>1</td><td>Return conversion time stamp after the conversion result.</td></tr> </table>	0	Return conversion result only.	1	Return conversion time stamp after the conversion result.				
0	Return conversion result only.								
1	Return conversion time stamp after the conversion result.								
FMT	Conversion Data Format FMT specifies to the EQADC how to format the 12-bit conversion data returned by the ADCs into the 16-bit format which is sent to the RFIFOs. See ADC result format for on-chip ADC operation for details. <table> <tr> <td>0</td><td>Right justified unsigned.</td></tr> <tr> <td>1</td><td>Right justified signed.</td></tr> </table>	0	Right justified unsigned.	1	Right justified signed.				
0	Right justified unsigned.								
1	Right justified signed.								
CHANNEL_NUMBER[0:7]	Channel Number Field The CHANNEL_NUMBER field selects the analog input channel. The software programs this field with the channel number corresponding to the analog input pin to be sampled and converted. See Channel assignment for details.								

Table 30-129. MESSAGE_TAG description

MESSAGE_TAG[0:3]	MESSAGE_TAG Meaning
0b0000	Result is sent to RFIFO 0
0b0001	Result is sent to RFIFO 1
0b0010	Result is sent to RFIFO 2
0b0011	Result is sent to RFIFO 3
0b0100	Result is sent to RFIFO 4

Table continues on the next page...

**Table 30-129. MESSAGE_TAG description
(continued)**

MESSAGE_TAG[0:3]	MESSAGE_TAG Meaning
0b0101	Result is sent to RFIFO 5
0b0110 - 0b0111	Reserved
0b1000	Null Message Received
0b1001	Reserved for customer use ¹
0b1010	Reserved for customer use ²
0b1011 - 0b1111	Reserved

1. These messages are treated as null messages. Therefore, they must obey the format for incoming null messages and return valid BUSY0/1 fields. "

30.6.2.2.1.2 Conversion command format for alternate configurations

Figure 30-118 describes the format for conversion commands when interfacing with the on-chip ADCs in one of the 14 alternate configurations. An alternate configuration is selected when the lowest byte (bits 24-31) of the conversion command is set to a value in the range 0x08-0x15. Each value in this range selects one of the 14 alternate configuration (0x08 selects Alternate Configuration 1, 0x15 selects Alternate Configuration 14). In the alternate configurations, the conversion result can be routed to one of the RFIFOs and/or to the parallel side interface to communicate with an on-chip companion module, or to one or two on-chip companion modules. Bit fields in the corresponding Alternate Configuration Control Register and Extended Alternate Configuration Control Register select the Internal RFIFO or Parallel Side Interface as the destination for the conversion result. A time stamp information can be optionally requested.

All fields, except FFMT and ALT_CONFIG_SEL, are identical to the ones in the standard configuration format. Only the fields which are different from the standard format will be described here.

Figure 30-118. Conversion command format for alternate configurations

Table 30-130. Conversion command format for alternate configurations — field descriptions

Field	Description
EOQ	See Table 30-128
PAUSE	See Table 30-128
REP	See Table 30-128
EB	See Table 30-128
BN	See Table 30-128
CAL	See Table 30-128
MESSAGE_TAG	See Table 30-128
LST	See Table 30-128
TSR	See Table 30-128
FFMT	Flush or Format The function of this bit depends on the DEST field of the Alternate Configuration Control Register. If DEST is equal to 0b000, then FFMT defines the format in which the 12-bit conversion result are stored in the RFIFOs. If DEST is not equal to 0b000, then the FFMT bit is used to send a flush (soft-reset) signal through the parallel side interface to the companion module addressed by the DEST field. In case DEST is not equal to 0b000, the FMTA bit in the Alternate Configuration Control register is used to define the conversion result format. Note: The flush signal can be asserted along with a valid conversion result. In this case the companion module should execute the software-reset first and then consider the conversion result as a valid data for the filtering algorithm.
	0 Conversion Result Format set to right justified unsigned if DEST is equal to 0b000. No flush signal is sent through the side interface if DEST is not equal to 0b000.
	1 Conversion Result Format set to right justified signed if DEST is equal to 0b000. A flush signal is sent through the side interface if DEST is not equal to 0b000.
CHANNEL_NUMBER[0:7]	See Table 30-128

Table continues on the next page...

	0x15 Alternate configuration 14

30.6.2.2.1.3 Write configuration command format for on-chip ADC operation

Figure 30-119 describes the command message format for a write configuration command when interfacing with the on-chip ADCs. A write configuration command is used to set the control registers of the on-chip ADCs. No conversion data will be returned for a write configuration command. Write configuration commands are differentiated from read configuration commands by a negated R/W bit.

Figure 30-119. Write configuration command format for on-chip ADC operation

Table 30-131. Write configuration command format for on-chip ADC operation — field descriptions

Field	Description
EOQ	End Of Queue Bit
PAUSE	Pause Bit
REP	Repeat/loop Start Point Indication Bit
BN	Buffer Number Bit See Conversion command format for the standard configuration .
R/W	Read/Write bit A negated R/W indicates a write configuration command. 0 Write
ADC_REGISTER_HIGH_BYTE[0:7]	ADC Register High Byte Field REGISTER_HIGH_BYTE is the value to be written into the most significant 8 bits of control/configuration register when the R/W bit is negated.s
ADC_REGISTER_LOW_BYTE[0:7]	ADC Register Low Byte Field REGISTER_LOW_BYTE is the value to be written into the least significant 8 bits of a control/configuration register when the R/W bit is negated.
ADC_REG_ADDRESS[0:7]	ADC Register Address The ADC_REG_ADDRESS field selects a register on the ADC register set to be written or read. Only half-word addresses can be used.

30.6.2.2.1.4 Read configuration command format for on-chip ADC operation

Figure 30-120 describes the command message format for a read configuration command when interfacing with the on-chip ADCs. A read configuration command is used to read the contents of the on-chip ADC registers which are only accessible via command messages. Read configuration commands are differentiated from write configuration commands by an asserted R/W bit.

Figure 30-120. Read configuration command format for on-chip ADC operation

Table 30-132. Read configuration command format for on-chip ADC operation — field descriptions

Field	Description
EOQ	End Of Queue Bit
PAUSE	Pause Bit
REP	Repeat/loop Start Point Indication Bit
BN	Buffer Number Bit See Conversion command format for the standard configuration .
R/W	Read/Write bit An asserted R/W bit indicates a read configuration command. 1 Read
MESSAGE_TAG[0:3]	MESSAGE_TAG Field See Conversion command format for the standard configuration..
ADC_REG_ADDRESS[0:7]	ADC Register Address The ADC_REG_ADDRESS field selects a register on the ADC register set to be written or read. Only half-word addresses can be used.

30.6.2.2.1.5 ADC result format for on-chip ADC operation

When the *FIFO Control Unit* receives a return data message, it decodes the MESSAGE_TAG field and stores the 16-bit data into the appropriate RFIFO. This section describes the *ADC result* portion of the *result message* returned by the on-chip ADCs. The 16-bit data stored in the RFIFOs can be:

- Data read from an ADC register with a read configuration command. In this case, the stored 16-bit data corresponds to the contents of the ADC register that was read.
- A time stamp. In this case, the stored 16-bit data is the value of the time base counter latched when the EQADC detects the end of the analog input voltage sampling. For details see [Time stamp feature](#).
- A conversion result, coming directly from the ADCs. In this case, the stored 16-bit data contains a right justified 14-bit result data. The conversion result can be calibrated or not depending on the status of CAL bit in the command that requested the conversion⁴. When the CAL bit is negated, this 14-bit data is obtained by executing a 2-bit left-shift on the 12-bit data resultant from the resolution adjustment on the 8 or 10 or 12-bit data received from the ADC. The resolution adjustment consists of changing the conversion result input from 8, 10 or 12 bits right aligned to a 12-bit word left aligned - see [ADC resolution selection feature](#) for details. When the CAL bit is asserted, this 14-bit data is the result of the calculations performed in

4. In case the conversion result is routed through an on-chip DSP via side interface, the calibration is applied before the data is sent to the DSP.

the EQADC MAC unit using the 12-bit data result of the resolution adjustment and the calibration constants GCC and OCC, or ALTGCC and ALTOCC - see [ADC calibration feature](#) for details. Then, this 14-bit data is further formatted into a 16-bit format according to the status of the FMT bit in conversion command of the standard configuration or FFMT bit in the conversion command of the alternate configurations⁵. When FMT/FFMT is asserted, the 14-bit result data is reformatted to look as if it was measured against an imaginary ground at VREF/2 (the MSB bit of the 14-bit result is inverted), and is sign-extended to a 16-bit format as in [Figure 30-121](#). When FMT/FFMT is negated, the EQADC zero-extends the 14-bit result data to a 16-bit format as in [Figure 30-122](#). Correspondence between the analog voltage in a channel and the calculated digital values is shown in [Table 30-134](#).

Figure 30-121. ADC Result Format when FMT=1 (Right Justified Signed)

Figure 30-122. ADC result format when FMT=0 (right justified unsigned)

Table 30-133. ADC result formats — field descriptions

Field	Description
SIGN_EXT[0:1]	Sign Extension field SIGN_EXT only has meaning when FMT is asserted. SIGN_EXT is 0b00 when CONVERSION_RESULT is positive, and 0b11 when CONVERSION_RESULT is negative.
CONVERSION_RESULT[0:13]	Conversion Result field CONVERSION_RESULT is a digital value corresponding to the analog input voltage in a channel when the conversion command was initiated. The two's complement representation is used to express negative values.

In [Table 30-134](#) :

- VREF=VRH-VRL=5.12V. Resulting in one 12-bit count (LSB) =1.25mV.
- The two's complement representation is used to express negative values.

5. For simplicity, the following text will refer to FMT only, but when using alternate configurations, see [Conversion command format for alternate configurations](#).

Table 30-134. Correspondence between analog voltages and digital values

30.6.3 Command/result queues

The Command and Result queues (CQueues and RQueues) are actually part of the EQADC system although they are not hardware implemented inside the EQADC. Each CQueue entry is a 32-bit Command Message. The last entry of a CQueue has the EOQ bit asserted to indicate that it is the last entry of the CQueue. RQueue entry is a 16-bit data.

See [Overview and basic terminology](#) for a description of the message formats and their flow in EQADC.

See [CQueue and RQueues usage](#) for examples of how CQueues and RQueues can be used.

30.6.4 EQADC command FIFOs

30.6.4.1 CFIFO basic functionality

There are six prioritized CFIFOs located in the EQADC. Each CFIFO is four entries deep, except CFIFO0 that can be configured to eight entries deep in extended mode, and each CFIFO entry is 32 bits long. A CFIFO serves as a temporary storage location for the command messages stored on the CQueues in the system memory. When a CFIFO is not full, the EQADC sets the corresponding CFFF bit in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#). If CFFE is asserted in [EQADC Interrupt and DMA Control Register 0 \(EQADC_IDCR0\)](#), the EQADC generates requests for more commands from a CQueue. An interrupt request, served by the host CPU, is generated when CFFS is negated, and a DMA request, served by the DMAC, is generated when CFFS is asserted. The host CPU or the DMAC respond to these requests by writing to the [EQADC CFIFO Push Register \(EQADC_CFPR_n\)](#) to fill the CFIFO.

Note

The DMAC should be configured to write a single command (32-bit data) to the CFIFO push registers for every asserted DMA request it acknowledges. See [EQADC/DMAC interface](#) for DMAC configuration guidelines.

Note

CFIFO0 can be configured to work in an alternative way called Streaming Mode. This mode is very different from the mode described here because it maintains some stored commands to execute them several times in sequence and in loop.

Note

Only whole words must be written to EQADC_CFPR. Writing half-words or bytes to EQADC_CFPR will still push the whole 32-bit CF_PUSH field into the corresponding CFIFO, but undefined data will fill the areas of CF_PUSH that were not specifically designated as target locations for writing.

Figure 30-123 describes the important components in the CFIFO. Each CFIFO is implemented as a circular set of registers to avoid the need to move all entries at each push/pop operation. The Push Next Data Pointer points to the next available CFIFO location for storing data written into the EQADC Command FIFO Push Register. The Transfer Next Data Pointer points to the next entry to be removed from CFIFO_x when it completes a transfer. The *CFIFO Transfer Counter Control Logic* counts the number of entries in the CFIFO and generates DMA or interrupt requests to fill the CFIFO. TNXTPTR in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#) indicates the index of the entry that is currently being addressed by the Transfer Next Data Pointer, and CFCTR, in the same register, provides the number of entries stored in the CFIFO. Using TNXTPTR and CFCTR, the absolute addresses for the entries indicated by the Transfer Next Data Pointer and by the Push Next Data Pointer can be calculated using the following formulas:

Transfer Next Data Pointer Address = CFIFO_x_BASE_ADDRESS + TNXTPTR_x*4

Push Next Data Pointer Address = CFIFO_x_BASE_ADDRESS + [(TNXTPTR_x + CFCTR_x) mod CFIFO_DEPTH] * 4

where

- $a \bmod b$ returns the remainder of the division of a by b .
- CFIFO_x_BASE_ADDRESS is the smallest memory mapped address allocated to a CFIFO_x entry.
- CFIFO_DEPTH is the number of entries contained in a CFIFO - four in this implementation.

When CFS_x in [EQADC CFIFO Status Register \(EQADC_CFSR\)](#) is TRIGGERED, the EQADC generates the proper control signals for the transfer of the entry pointed by Transfer Next Data Pointer. CFUF_x in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#) is set when a CFIFO_x underflow event occurs. A CFIFO underflow occurs when the CFIFO is in TRIGGERED state and it becomes empty. No commands will be transferred from an underflowing CFIFO, nor will command transfers from lower priority CFIFOs be blocked. CFIFO_x is empty when the Transfer Next Data Pointer *x* equals the Push Next Data Pointer *x* and CFCTR_x is zero. CFIFO_x is full when the Transfer Next Data Pointer *x* equals the Push Next Data Pointer *x* and CFCTR_x is not zero.

When the EQADC completes the transfer of an entry from CFIFO_x: the transferred entry is popped from CFIFO_x, the CFIFO counter CFCTR in the [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#) is decremented by one, and Transfer Next Data Pointer *x* is incremented by one (or wrapped around) to point to the next entry in the CFIFO. The transfer of entries bound for the on-chip ADCs is considered completed when they are stored in the appropriate CBuffer.

When the EQADC_CFPR_x is written and CFIFO_x is not full, the CFIFO counter CFCTR_x is incremented by one, and the Push Next Data Pointer *x* then is incremented by one (or wrapped around) to point to the next entry in the CFIFO.

When the EQADC_CFPR_x is written but CFIFO_x is full, the EQADC will not increment the counter value and will not overwrite any entry in CFIFO_x.

Figure 30-123. CFIFO Diagram

The detailed behavior of the Push Next Data Pointer and Transfer Next Data Pointer is described in the example shown in [Figure 30-124](#) where a CFIFO with 16 entries is shown for clarity of explanation, the actual hardware implementation has only four entries. In this example, CFIFOx with 16 entries is shown in sequence after pushing and transferring entries.

NOTE: x=0, 1, 2, 3, 4, 5

Figure 30-124. CFIFO Entry Pointer Example

30.6.4.2 CFIFO0 streaming mode description

CFIFO0 can be configured to operate in streaming mode to allow repetition of a group of commands several times without the need of refilling the registers as in the normal mode of operation of CFIFOs. This mode makes use of the additional bit in the Conversion Command Word (CCW) called 'Repeat' (REP bit). The purpose of this bit is to mark in the command queue, where to start a repeating sequence. This location is stored in an additional pointer 'Repeat Pointer'.

Streaming mode requires 2 trigger inputs. The standard queue 0 trigger, in this mode referred to as Repeat Trigger and a new internal trigger input to the eQADC called Advance Trigger (no filter available).

CFIFO0 is configured to operate in streaming mode by setting the bit STRME0 as described in [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#). CFIFO0 is eight entries deep in extended mode by setting the bit CFEEE0 in the same EQADC_CFCR register, and each entry is 32 bits long. This CFIFO0 serves as a local storage of a few commands that need to be executed sequentially as in a FIFO but can contain sub-queues that need to be executed several times. The CFFF0 bit in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#) is used to assure the CFIFO0 is not full and command messages are stored from address 0x0 to 0x7.

30.6.4.2.1 CFIFO0 operation in streaming mode

In Streaming mode, the CFIFO0 is filled with CCWs using the DMA exactly the same as existing modes. The CFIFO executes commands as per the existing modes until it executes a Conversion Command Word with the Repeat bit set. When this CCW is executed, the Repeat Pointer is set to point to this FIFO location and from this CCW onwards, CFIFO0 entries is not invalidated, that is, the Repeat Pointer prevents this and subsequent entries from being overwritten.

The queue continues to execute until a CCW with an asserted Pause bit is completed; then the queue stops and enters the Pause state, waiting for a trigger. This is the same as normal behavior.

The Pause state is exited in one of two ways: Repeat Trigger or Repeat Trigger with Advance Trigger. The Repeat trigger with no Advance trigger causes the Transfer Next Data Pointer to be loaded with the Repeat Pointer location and CCWs are then executed from the Repeat Pointer back to the Pause bit. This means that a section of the CFIFO0 is repeatedly executed every time a Repeat Trigger occurs.

The Repeat trigger with the Advance trigger pending causes all CCWs from the Repeat pointer to the Pause bit to be invalidated and the CCW after the pause bit to be executed. This is achieved by invalidating the Repeat Pointer. The effect is that the queue advances beyond the repeating section of the CFIFO0 to execute new CCWs.

Note that the Advance trigger can occur at any time between Repeat triggers, but is only granted when the next Repeat trigger occurs. Prior to that it is pending.

In a typical application, the queue is made of some configuration commands to the ADC (to flush the decimator or turn on pad pull-up/down) followed by a repeating section of ADC conversions on one or more ADC channels from one or more sensors; followed by a few more configuration commands; then more repeating ADC conversions, until the

entire engine cycle is complete; when the queue is restarted. The mechanism described permits any number of repeating sub-queues to be loaded and executed, interspersed by configuration commands.

30.6.4.2.2 Triggering description in streaming mode

The additional trigger signal ATRIG0 is detected by a separate circuit that is configured by the bit field AMODE0 as described in [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#). This trigger signal is used as an advance control of pop pointer of CFIFO0. In addition, it is used as the enable trigger for the Repeat trigger. This means it is necessary to have an Advance trigger first to enable the detection of the Repeat trigger. When the Repeat trigger is enabled, the Advance trigger is used to advance the pop pointer beyond some loop sub-queue. And it is used to disable the Repeat trigger by executing a Pause without a previous REP bit. [Figure 30-125](#) and [Figure 30-126](#) illustrate these two triggers dependency.

Figure 30-125. Advance trigger and repeat trigger relationship Block Diagram

In Streaming mode, the CFIFO0 is filled with CCWs using the DMA as usual. The two triggers are configured to positive edge and single scan mode.

The SSS bit is asserted and the trigger detector of the Repeat trigger is disabled in the start of the queue. It is necessary to receive the first Advance trigger to enable the detector of the other trigger. This enable is useful when the Repeat trigger is received all the time and the trigger signal can be disabled when it is not desired.

The Advance trigger is received and detected and the Repeat trigger detector is enabled. No commands are executed until now.

The Repeat trigger is detected and the commands start to be executed in sequence. If a REP bit is decoded with the PAUSE bit, the loop is configured and the CFIFO0 commands stop to be executed. The next Repeat trigger is waited to start the execution of the loop again, or the Advance trigger can be detected to break the loop and advance the queue in CFIFO0. The Repeat trigger detector remains enabled.

If the Advance trigger is received and the next command in the CFIFO0 does not present the REP bit set, this means the CFIFO0 is not starting a new loop. In this case (outside a loop) if a PAUSE bit is decoded, this means to disable the Repeat trigger detector. This can be useful if the Repeat trigger is not required for some interval of time. The Repeat trigger detector is enabled again when the next Advance trigger event is detected.

Figure 30-126. Timing diagram of typical use of Advance trigger and Repeat trigger

30.6.4.2.3 CFIFO0 diagram description in streaming mode

Figure 30-127 represents the main components of CFIFO0 in streaming mode. However, some signals behave in a different way from the common operation. The Push Next Data Pointer points to the next available CFIFO0 location for storing data written into the EQADC Command FIFO Push Register. The Transfer Next Data Pointer points to the next entry to be transferred to Cbuffer. The Repeat Pointer points to the first entry of the repeating sub-queue. TNXTPTR in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#) indicates the index of the entry that is currently being addressed by the Transfer Next Data Pointer, and CFCTR, in the same register, provides the number of entries stored in the CFIFO.

When CFS0 in [EQADC CFIFO Status Register \(EQADC_CFSR\)](#) is TRIGGERED, the EQADC generates the proper control signals for the transfer of the entry pointed by Transfer Next Data Pointer. CFUF0 in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#) is set when CFIFO0 underflow event occurs. A CFIFO underflow occurs when the CFIFO is in TRIGGERED state and it is empty. No commands will be transferred from an underflowing CFIFO, nor will command transfers from lower priority CFIFOs be blocked. CFIFO0 is empty when CFCTR0 is zero. CFIFO0 is full when $(CFCTR0 \bmod CFIFO\_DEPTH)$ is zero but CFCTR0 is not zero.

When the EQADC completes the transfer of an entry from CFIFO0 in loop condition: the transferred entry is not popped from CFIFO0, the CFIFO counter CFCTR in the [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#) is not decremented by one, and Transfer Next Data Pointer 0 is incremented by one (or wrapped around) to point to the next entry in the CFIFO0.

Figure 30-127. CFIFO0 in streaming mode diagram

The detailed behavior of the Push Next Data Pointer and Transfer Next Data Pointer is described in the example shown in [Figure 30-128](#) where a CFIFO with 16 entries is shown for clarity of explanation, the actual hardware implementation has only four/eight entries. In this example, CFIFO0 with 16 entries is shown in sequence after pushing and transferring entries.

Figure 30-128. CFIFO0 in streaming mode entry pointer example

Figure 30-129. CFIFO0 in streaming mode entry pointer example (continued)

30.6.4.2.4 Streaming mode error conditions

In the repeat state, the existing error conditions still apply, but now there are new ways to trigger them. Now, the CCWs are not being invalidated so the DMA is not able to load more CCWs into those locations. So a queue overflow becomes more likely, and occurs if the repeat loop is longer than 8 entries. If all CCWs in the CFIFO0 are executed and no Pause bit or EOQ bit is detected, the eQADC will signal an underflow error. In practice this may limit a repeating queue to 7 entries since otherwise an underflow will occur at the point a Repeat with Advance trigger occurs, and there is no command in the CFIFO0 to execute. The exception is a final command with both a Pause and an EOQ bit set. The End of Queue bit EOQ continues to operate as in normal mode, unless the Repeat mode is enabled. In this case the Pause bit takes precedence and a Repeat trigger causes the jump back described. A Repeat trigger with Advance trigger causes the queue to end.

Another error condition occur when the repeat trigger is in the TRIGGERED state and a new repeat trigger is received. In this case, a trigger overflow occurs but the CFIFO0 is defined to not restart the loop. The trigger in this case is not used in the CFIFO0, but the overflow is indicated.

30.6.4.3 CFIFO common prioritization and command transfer

The CFIFO priority is fixed according to the CFIFO number. A CFIFO with a smaller number has a higher priority. When commands of distinct CFIFOs are bound for the same destination (CBuffer), the higher priority CFIFO is always served first. A TRIGGERED, not-underflowing CFIFO will start the transfer of its commands when:

- its commands are bound for an internal CBuffer that is not full, and it is the highest priority triggered CFIFO sending commands to that CBuffer.

A triggered CFIFO with commands bound for a certain CBuffer consecutively transfers its commands to it until:

- an asserted End Of Queue bit is reached, or;
- an asserted Pause bit is encountered and the CFIFO is configured for edge trigger mode, or;
- CFIFO is configured for level trigger mode and a closed gate is detected, or;
- in case its commands are bound for an internal CBuffer, a higher priority CFIFO that uses the same internal CBuffer is triggered

The prioritization logic of the EQADC, depicted in [Figure 30-130](#), is composed of three independent sub-blocks: one prioritizing CFIFOs with commands bound for CBuffer0, another prioritizing CFIFOs with commands for CBuffer1. As these two sub-blocks are independent, simultaneous writes to CBuffer0, to CBuffer1 are allowed. The hardware identifies the destination of a command by decoding the BN bit in the command message - see [Message format in EQADC](#) for details.

Note

Triggered but empty CFIFOs, underflowing CFIFOs, are not considered for prioritization. No data from these CFIFOs will be sent to the CBuffers and nor will they stop lower priority CFIFOs from transferring commands.

Whenever CBuffer0 is able to receive new entries, the prioritization sub-block selects the highest-priority triggered CFIFO with a command bound for CBuffer0, and writes its command into the buffer. In case CBuffer0 is able to receive new entries but there are no triggered CFIFOs with commands bound for it, nothing is written to the buffer. The sub-block prioritizing CBuffer1 usage behaves in the same way.

Figure 30-130. CFIFO prioritization logic

30.6.4.4 CFIFO prioritization in abort mode

The CFIFO priority does not change when the EQADC is configured to allow abortion of conversion execution in on-chip ADC analog blocks. However, CFIFO0 is the only one that can be enabled to abort conversions.

This feature is necessary when the timing of some conversion is very important. In normal priority scheme, when CFIFO0 is triggered, its conversion command can be put behind 2 pending conversion commands in the Cbuffer due to the queue structure. Considering that these 2 pending commands are from lower priority CFIFOs and that the delay between the trigger and the sampling of the command from CFIFO0 can be unacceptable, EQADC can be configured to permit immediate conversion commands from CFIFO0 with abort function.

When CFIFO0 is triggered and abort is enabled, up to 2 commands in Cbuffer0 or Cbuffer1 are stored in a side register. The abort request signal is generated to ADC0 or ADC1 and the confirmation of ADC reset/ready is waited to send the command from CFIFO0 to the decoded Cbuffer.

After the transfer of all commands from CFIFO0, the recovery phase restores the up to 2 commands that were in Cbuffer when the abort occurred. After this recovery phase, it is established the normal process of prioritization of commands from CFIFOs.

30.6.4.5 External trigger event detection

The digital filters for trigger signals can be individually bypassed by asserting the input control signals `eqadc_intern_trig_sel5-0`. When the filter is bypassed, the ETRIG input signal is not filtered and the logic after the filter receives a copy of this input trigger signal.

The Digital Filter Length field in [EQADC External Trigger Digital Filter Register \(EQADC_ETDFR\)](#) specifies the minimum number of system clocks that the ETRIG0-5 signals must be held at a logic level to be recognized as valid. All ETRIG signals are filtered. A counter for each queue trigger is implemented to detect a transition between logic levels. The counter counts at the system clock rate. The corresponding counter is cleared and restarted each time the signal transitions between logic levels. When the corresponding counter matches the value specified by the Digital Filter Length field in [EQADC External Trigger Digital Filter Register \(EQADC_ETDFR\)](#), the EQADC considers the ETRIG logic level to be valid and passes that new logic level to the rest of the EQADC.

The filter is only for filtering the ETRIG signal. Logic after the filter checks for transitions between filtered values, such as for detecting the transition from a filtered logic level zero to a filter logic level one in rising edge external trigger mode. The EQADC can detect rising edge, falling edge, or level gated external triggers. The digital filter will always be active independently of the status of the MODEx field in [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#), but the edge, level detection logic is only active when MODEx is set to a value different from disabled, and in case MODEx is set to single scan mode, when the SSS bit is asserted. Note that the time necessary for an external trigger event to result into a CFIFO status change is not solely determined by the DFL field in the [EQADC External Trigger Digital Filter Register \(EQADC_ETDFR\)](#). After being synchronized to the system clock and filtered, a trigger event is checked against the CFIFO trigger mode. Only then, after a valid trigger event is detected, the EQADC accordingly changes the CFIFO status. See [Figure 30-131](#) for an example.

Obs.

- 1: This delay is about 2 clocks when the filter bypass control is asserted.

Figure 30-131. ETRIG event propagation example

30.6.4.6 CFIFO scan trigger modes

The EQADC supports two different scan modes, single-scan and continuous-scan. Refer to [Table 30-135](#) for a summary of these two scan modes. When a CFIFO is triggered, the EQADC scan mode determines whether the EQADC will stop command transfers from a CFIFO, and wait for software intervention to rearm the CFIFO to detect new trigger events, upon detection of an asserted EOQ bit in the last transfer. See [Message format in EQADC](#) for details about command formats.

CFIFOs can be configured in single-scan or continuous-scan mode. When a CFIFO is configured in single-scan mode, the EQADC scans the CQueue one time. The EQADC stops future command transfers from the triggered CFIFO after detecting the EOQ bit set in the last transfer. After a EOQ bit is detected, software involvement is required to rearm the CFIFO so that it can detect new trigger events.

When a CFIFO is configured for continuous-scan mode, no software involvement is necessary to rearm the CFIFO to detect new trigger events after an asserted EOQ is detected. In continuous-scan mode the whole CQueue is scanned multiple times.

The EQADC also supports different triggering mechanisms for each scan mode. The EQADC will not transfer commands from a CFIFO until the CFIFO is triggered. The combination of scan modes and triggering mechanisms allows the support of different requirements for scanning input channels. The scan mode and trigger mechanism are configured by programming the MODEx field in [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#).

Enabled CFIFOs can be triggered by software or external trigger events. The elapsed time from detecting a trigger to transferring a command is a function of clock frequency, trigger synchronization, trigger filtering or not, programmable trigger events, command

transfer, CFIFO prioritization, CBuffer availability, etc. Fast and predictable transfers can be achieved by ensuring that the CFIFO is not underflowing and that the target CBuffer is not full when the CFIFO is triggered.

30.6.4.6.1 Disabled Mode

The MODEx field in [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#) for all of the CFIFOs can be changed from any other mode to disabled at any time. No trigger event can initiate command transfers from an CFIFO which has its MODE field programmed to disabled.

Note

If MODEx is not disabled, it must not be changed to any other mode besides disabled. If MODEx is disabled and the CFIFO status is IDLE, MODEx can be changed to any other mode.

If MODEx is changed to disabled:

- The CFIFO execution status will change to IDLE. The timing of this change depends on whether a command is being transferred or not:
 - When no command transfer is in progress, the EQADC switches the CFIFO to IDLE status immediately.
 - When a command transfer to an on-chip CBuffer is in progress, the EQADC will complete the transfer, update TC_CF, and switch CFIFO status to IDLE. Command transfers to the internal CBuffers are considered completed when a command is written to the buffers.
- The CFIFOs are not invalidated automatically. The CFIFO still can be invalidated by writing a "1" to the CFINVx bit in [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#). Certify that CFS has changed to IDLE before setting CFINVx.
- The TC_CFx value also is not reset automatically, but it can be reset by writing "0" to it.
- The SSS bit in [EQADC FIFO and Interrupt Status Register \(EQADC_FISRn\)](#) is negated. The SSS bit can be set even if a "1" is written to the SSE bit in [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#) in the same write that the MODEx field is changed to a value other than disabled.
- The trigger detection hardware is reset. If MODEx is changed from disabled to an edge trigger mode, a new edge, matching that edge trigger mode, is needed to trigger the command transfers from the CFIFO.

Note

CFIFO fill requests, which generated when CFFF is asserted, are not automatically halted when MODEx is changed to disabled. CFIFO fill requests will still be generated until CFFE is cleared in [EQADC Interrupt and DMA Control Register 0 \(EQADC_IDCR0\)](#).

30.6.4.6.2 Single-scan mode

In single-scan mode, a single pass through a sequence of command messages in a CQueue is performed.

In single-scan software trigger mode, the CFIFO is triggered by an asserted Single-Scan Status bit (SSS) in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#). The SSS bit is set by writing "1" to the Single-Scan Enable bit (SSE) in [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#).

In single-scan edge- or level-trigger mode, the respective triggers are only detected when the SSS bit is asserted. When the SSS bit is negated, all trigger events for that CFIFO are ignored. Writing a "1" to the SSE bit can be done during the same write cycle that the CFIFO operation mode is configured.

Only the EQADC can clear the SSS bit. Once SSS is asserted, it remains asserted until the EQADC completes the CQueue scan, or the CFIFO operation mode (MODEx) in [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#) is changed to disabled. The SSSx bit will be negated while MODEx is disabled.

30.6.4.6.2.1 Single-Scan Software Trigger

When single-scan software trigger mode is selected, the CFIFO is triggered by an asserted SSS bit. The SSS bit is asserted by writing "1" to the SSE bit. Writing to SSE while SSS is already asserted will not have any effect on the state of the SSS bit, nor will it cause a trigger overrun event.

The CFIFO commands start to be transferred when the CFIFO becomes the highest priority CFIFO using a not-full on-chip CBuffer. When an asserted EOQ bit is encountered, the EQADC will clear the SSS bit. Setting the SSS bit is required for the EQADC to start the next scan of the queue.

The Pause bit has no effect in single-scan software trigger mode.

30.6.4.6.2.2 Single-scan edge trigger

When SSS is asserted and an edge triggered mode is selected for a CFIFO, an appropriate edge on the associated trigger signal causes the CFIFO to become TRIGGERED. For example, if rising-edge trigger mode is selected, the CFIFO becomes TRIGGERED when a rising edge is sensed on the trigger signal. The CFIFO commands start to be transferred when the CFIFO becomes the highest priority CFIFO using a not-full on-chip CBuffer.

When an asserted EOQ bit is encountered, the EQADC clears SSS and stops command transfers from the CFIFO. An asserted SSS bit and a subsequent edge trigger event are required to start the next scan for the CFIFO. When an asserted Pause bit is encountered, the EQADC stops command transfers from the CFIFO, but SSS remains set. Another edge trigger event is required for command transfers to continue. A trigger overrun happens when the CFIFO is in TRIGGERED state and an edge trigger event is detected.

30.6.4.6.2.3 Single-scan level trigger

When SSS is asserted and a level gated trigger mode is selected, the input level on the associated trigger signal puts the CFIFO in TRIGGERED state. When the CFIFO is asserted to high-level gated trigger, a high level signal opens the gate, and a low level closes the gate. When the CFIFO is set to low-level gated trigger mode, a low level signal opens the gate, and a high level closes the gate. If the corresponding level is already present, setting the SSS bit triggers the CFIFO. The CFIFO commands start to be transferred when the CFIFO becomes the highest priority CFIFO using a not-full on-chip CBuffer.

The EQADC clears the SSS bit and stops transferring commands from a TRIGGERED CFIFO when an asserted EOQ bit is encountered or when CFIFO status changes from TRIGGERED due to the detection of a closed gate. If a closed gate is detected while no command transfers are taking place and the CFIFO status is TRIGGERED, the CFIFO status is immediately changed to IDLE, the SSS bit is negated, and the PF flag is asserted. Once the transmission is completed, the TC_CF counter is updated, the SSS bit is negated, the PF flag is asserted, and the CFIFO status is changed to IDLE. An asserted SSS bit and a level trigger are required to restart the CFIFO. Command transfers will restart from the point they have stopped.

The Pause bit has no effect in single-scan level-trigger mode.

30.6.4.6.3 Continuous-scan mode

In continuous-scan mode, multiple passes looping through a sequence of command messages in a CQueue are executed. When a CFIFO is programmed for a continuous-scan mode, the SSE bit in the [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#) does not have any effect.

30.6.4.6.3.1 Continuous-scan software trigger

When a CFIFO is programmed to continuous-scan software trigger mode, the CFIFO is triggered immediately. The CFIFO commands start to be transferred when the CFIFO becomes the highest priority CFIFO using a not-full on-chip CBuffer. When a CFIFO is programmed to run in continuous-scan software trigger mode, the EQADC will not halt transfers from the CFIFO until the CFIFO operation mode is modified to disabled or a higher priority CFIFO preempts it. Although command transfers will not stop upon detection of an asserted EOQ bit, the EOQF is set and, if enabled, an EOQ interrupt request is generated.

The Pause bit has no effect in continuous-scan software trigger mode.

30.6.4.6.3.2 Continuous-scan edge trigger

When rising, falling, or either edge trigger mode is selected for a CFIFO, a corresponding edge on the associated ETRIG signal places the CFIFO in TRIGGERED state. The CFIFO commands start to be transferred when the CFIFO becomes the highest priority CFIFO using a not-full on-chip CBuffer.

When an EOQ or a Pause is encountered, the EQADC halts command transfers from the CFIFO and, if enabled, the appropriate interrupt requests are generated. Another edge trigger event is required to resume command transfers but no software involvement is required to rearm the CFIFO in order to detect such event.

A trigger overrun happens when the CFIFO is already in TRIGGERED state and a new edge trigger event is detected.

30.6.4.6.3.3 Continuous-scan level trigger

When high or low level gated trigger mode is selected, the input level on the associated trigger signal places the CFIFO in TRIGGERED state. When high-level gated trigger is selected, a high-level signal opens the gate, and a low level closes the gate. The CFIFO commands start to be transferred when the CFIFO becomes the highest priority CFIFO.

using a not-full on-chip CBuffer. Although command transfers will not stop upon detection of an asserted EOQ bit at the end of a command transfer, the EOQF is asserted and, if enabled, an EOQ interrupt request is generated.

The EQADC stops transferring commands from a TRIGGERED CFIFO when CFIFO status changes from TRIGGERED due to the detection of a closed gate. If a closed gate is detected while no command transfers are taking place and the CFIFO status is TRIGGERED, the CFIFO status is immediately changed to WAITING FOR TRIGGER and the PF flag is asserted. Once the transmission is completed, the TC_CF counter is updated, the PF flag is asserted, and the CFIFO status is changed to WAITING FOR TRIGGER. Command transfers will restart as the gate opens.

The Pause bit has no effect in continuous-scan level-trigger mode.

30.6.4.6.4 CFIFO scan trigger mode start/stop summary

Table 30-135 summarizes the start and stop conditions of command transfers from CFIFOs for all of the single-scan and continuous-scan trigger modes.

Table 30-135. CFIFO scan trigger mode - command transfer start/stop summary

Trigger mode	Requires asserted SSS to recognize trigger events?	Command transfer start/restart condition	Stop on asserted EOQ bit ¹ ?	Stop on asserted Pause bit ² ?	Other command transfer stop condition ^{3,4}
Single Scan Software	Don't Care	Asserted SSS bit.	Yes	No	None.
Single Scan Edge	Yes	A corresponding edge occurs when the SSS bit is asserted.	Yes	Yes	None.
Single Scan Level	Yes	Gate is opened when the SSS bit is asserted.	Yes	No	EQADC also stops transfers from the CFIFO when CFIFO status changes from TRIGGERED due to the detection of a closed gate. ⁵
Continuous Scan Software	No	CFIFO starts automatically after being configured into this mode.	No	No	None.
Continuous Scan Edge	No	A corresponding edge occurs.	Yes	Yes	None.
Continuous Scan Level	No	Gate is opened.	No	No	EQADC also stops transfers from the CFIFO when CFIFO status changes from TRIGGERED due to the detection of a closed gate. ⁵

1. See [CQueue completion status](#) for more information on EOQ.

2. See [Pause status](#) for more information on Pause.
3. EQADC always stops command transfers from a CFIFO when the CFIFO operation mode is disabled.
4. EQADC always stops command transfers from a CFIFO when a higher priority CFIFO is triggered. See [CFIFO common prioritization and command transfer](#) for information on CFIFO priority.
5. If a closed gate is detected while no command transfers are taking place, it will have immediate effect on the CFIFO status.

30.6.4.7 CFIFO and trigger status

30.6.4.7.1 CFIFO operation status

Each CFIFOs has its own CFIFO status field. CFIFO status (CFS) can be read from [EQADC CFIFO Status Register \(EQADC_CFSR\)](#). [Figure 30-132](#) and [Table 30-136](#) indicate the CFIFO status switching condition. See [Table 30-43](#) for the meaning of each CFIFO operation status. The last CFIFO to transfer a command to an on-chip CBuffer can be read from the LCFTCB n ($n=0,1$) fields in [EQADC CFIFO Status Snapshot Register 0 \(EQADC_CFSSR0\)](#).

Figure 30-132. State machine of CFIFO status

Table 30-136. Command FIFO status switching condition

No.	From current CFIFO status (CFS)	To new CFIFO status (CFS)	Status switching condition
1	IDLE (00)	IDLE (0b00)	- CFIFO Mode is programmed to disabled, OR - CFIFO Mode is programmed to single-scan edge or level trigger mode and SSS is negated.
2		WAITING FOR TRIGGER (0b10)	- CFIFO Mode is programmed to continuous-scan edge or level trigger mode, OR - CFIFO Mode is programmed to single-scan edge or level trigger mode and SSS is asserted, OR - CFIFO Mode is programmed to single-scan software trigger mode.
3		TRIGGERED (0b11)	CFIFO Mode is programmed to continuous-scan software trigger mode
4	WAITING FOR TRIGGER (10)	IDLE (0b00)	CFIFO Mode is modified to disabled mode.
5		WAITING FOR TRIGGER (0b10)	No trigger occurred.
6		TRIGGERED (0b11)	- Appropriate edge or level trigger occurred, OR - CFIFO Mode is programmed to single-scan software trigger mode and SSS bit is asserted.

Table continues on the next page...

**Table 30-136. Command FIFO status switching condition
(continued)**

No.	From current CFIFO status (CFS)	To new CFIFO status (CFS)	Status switching condition
7	TRIGGERED (11)	IDLE (0b00)	- CFIFO in single-scan mode, EQADC detects the EOQ bit asserted at end of command transfer, and CFIFO Mode is not modified to disabled. OR - CFIFO, in single-scan level trigger mode, and the gate closes while no commands are being transferred from the CFIFO, and CFIFO Mode is not modified to disabled. OR - CFIFO, in single-scan level trigger mode, and EQADC detects a closed gated at end of command transfer, and CFIFO Mode is not modified to disabled. OR - CFIFO Mode is modified to disabled mode and CFIFO was not transferring commands. - CFIFO Mode is modified to disabled mode while CFIFO was transferring commands, and CFIFO completes or aborts the transfer.
8		WAITING FOR TRIGGER (0b10)	- CFIFO in single or continuous-scan edge trigger mode, EQADC detects the Pause bit asserted at the end of command transfer, the EOQ bit in the same command is negated, and CFIFO Mode is not modified to disabled, OR - CFIFO in continuous-scan edge trigger mode, EQADC detects the EOQ bit asserted at the end of command transfer, and CFIFO Mode is not modified to disabled, OR - CFIFO, in continuous-scan level trigger mode, and the gate closes while no commands are being transferred from the CFIFO, and CFIFO Mode is not modified to disabled, OR - CFIFO, in continuous-scan level trigger mode, and EQADC detects a closed gated at end of command transfer, and CFIFO Mode is not modified to disabled.
9		TRIGGERED (0b11)	No event to switch to IDLE or WAITING FOR TRIGGER status has happened.

30.6.4.7.2 CQueue completion status

The End of Queue Flag (EOQF) in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#) is asserted when the EQADC completes the transfer of a CFIFO entry with an asserted EOQ bit. Software sets the EOQ bit in the last Command Message of a CQueue to indicate that this entry is the end of the CQueue - see [Message format in EQADC](#) for information on command message formats. The transfer of entries bound for the on-chip ADCs is considered completed when they are stored in the appropriate CBuffer.

The command with a EOQ bit asserted is valid and will be transferred. When EOQIE in [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#) and EOQF are asserted, the EQADC will generate an End of Queue interrupt request.

In single-scan modes, command transfers from the corresponding CFIFO will cease when EQADC completes the transfer of a entry with an asserted EOQ. Software involvement is required to rearm the CFIFO so that it can detect new trigger events.

Note

An asserted EOQFx only implies that EQADC has finished transferring a command with an asserted EOQ bit from CFIFOx. It does not imply that result data for the current command and for all previously transferred commands has been returned to the appropriate RFIFO.

30.6.4.7.3 Pause status

In edge trigger mode, when the EQADC completes the transfer of a CFIFO entry with an asserted Pause bit, the EQADC will stop future command transfers from the CFIFO and set the corresponding Pause Flag (PF) in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#). See [Message format in EQADC](#) for information on command message formats. The EQADC ignores the Pause bit in command messages in any software and external level trigger mode. The EQADC sets the PF flag upon detection of an asserted Pause bit only in single or continuous-scan edge trigger mode. When the PF flag is set for a CFIFO in single-scan edge trigger mode, the SSS bit will not be cleared in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#).

In level trigger mode, the definition of the PF flag has been redefined. In level trigger mode, when CFIFOx is in TRIGGERED status, PFx is set when CFIFO status changes from TRIGGERED due to detection of a closed gate. The pause flag interrupt routine can be used to verify if the a complete scan of the CQueue was performed. If a closed gate is detected while no command transfers are taking place, it will have immediate effect on the CFIFO status.

When PIE in [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#) and PF are asserted, the EQADC will generate a Pause interrupt request.

Note

In edge trigger mode, an asserted PFx only implies that the EQADC finished transferring a command with an asserted PAUSE bit from CFIFOx. It does not imply that result data for the current command and for all previously transferred commands has been returned to the appropriate RFIFO.

Note

In software or level trigger mode, when the EQADC completes the transfer of an entry from CFIFO_x with an asserted Pause bit, PF_x will not be set and command transfers will continue without pausing.

30.6.4.7.4 Trigger overrun status

When a CFIFO is configured for edge- or level-trigger mode and is in TRIGGERED state, an additional trigger occurring for the same CFIFO results in a trigger overrun. The trigger overrun bit for the corresponding CFIFO will be set (TORF_x = 1) in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#). When TORIE in [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#) and TORF are asserted, the EQADC generates a trigger overrun interrupt request.

Note

The trigger overrun flag will not set for CFIFOs configured for software trigger mode.

30.6.4.7.5 Command sequence non-coherency detection

The EQADC provides a mechanism to indicate if a command sequence has been completely executed without interruptions. A command sequence is defined as a group of consecutive commands bound for the same CBuffer and it is expected to be executed without interruptions. A command sequence is coherent if its commands are executed in order without interruptions. Since commands are stored in the CBuffers before being executed in the EQADC, a command sequence is coherent if, while it is transferring commands to a CBuffer, the buffer is only fed with commands from that sequence without ever becoming empty.

A command sequence starts when:

- a CFIFO in TRIGGERED state transfers its first command to CBuffer.
- the CFIFO is constantly transferring commands and the previous command sequence ended.
- the CFIFO resumes command transfers after being interrupted.

And a command sequence ends when:

- an asserted EOQ bit is detected on the last transferred command.

- CFIFO is in edge-trigger mode and asserted PAUSE bit is detected on the last transferred command.
- the CBuffer to which the next command is bound is different from the one to which the last command was transferred.

Figure 30-133 shows examples of how the EQADC would detect command sequences when transferring commands from a CFIFO to a CBuffer. The smallest possible command sequence can have a single command as shown in example 3 of Figure 30-133.

CQueue with a two command sequences

CF5_CB1_CM0
CF5_CB1_CM1
CF5_CB1_CM2
CF5_CB1_CM3 (Pause = 1)
CF5_CB1_CM4
CF5_CB1_CM5
CF5_CB1_CM6 (EOQ = 1)

Example 1

Assuming that these commands are transferred by a CFIFO configured for edge trigger mode and the command transfers are never interrupted, the EQADC would check for non-coherency of two command sequences: one formed by commands 0, 1, 2, 3, and the other by commands 4, 5, 6.

CQueue with a three command sequences

CF5_CB1_CM0
CF5_CB1_CM1
CF5_CB1_CM2
CF5_CP5_CB0_CM3
CF5_CB0_CM4
CF5_CB1_CM5
CF5_CB1_CM6 (EOQ = 1)

Example 2

Assuming that command transfers from the CFIFO are never interrupted, the EQADC would check for non-coherency of three command sequences. The first being formed by commands 0, 1, 2, the second by commands 3, 4 and the third by commands 5, 6. Note that even when the commands of this CQueue are transferred through a CFIFO in continuous-scan mode, the first three commands and the last two commands of this CQueue would still constitute two distinct command sequences, although they are all bound for the same CBuffer, since an asserted EOQ ends a command sequence.

CQueue with a seven command sequences

CF5_CB1_CM0
CF5_CB2_CM1
CF5_CB3_CM2
CF5_CF5_CB1_CM3
CF5_CB0_CM4
CF5_CB2_CM5
CF5_CB1_CM6 (EOQ = 1)

Example 3

The EQADC would check for non-coherency of seven command sequences, all containing a single command, but NCF would never get set.

CF_xCB_aCM_n - Command *n* in CFIFO_x bound for CBuffer_a

Figure 30-133. Command sequence examples

The NCF flag is used to indicate command sequence non-coherency. When the NCFx flag is asserted, it indicates that the command sequence being transferred through CFIFOx became non-coherent. The NCF flag only becomes asserted for CFIFOs in TRIGGERED state.

A command sequence is non-coherent when, after transferring the first command of a sequence from a CFIFO to a CBuffer, it cannot successively send all the other commands of the sequence before any of the following conditions are true:

- The CFIFO through which commands are being transferred is preempted by a higher priority CFIFO which sends commands to the same CBuffer. The NCF flag becomes asserted immediately after the first command transfer from the preempting CFIFO, that is the higher priority CFIFO, to the CBuffer in use is completed. See [Figure 30-134](#).

-

Once a command sequence starts to be transferred, the EQADC will check for the command sequence coherency until the command sequence ends or until one of the conditions below becomes true.

- The command sequence became non-coherent.
- The CFIFO status changed from TRIGGERED.
- The CFIFO underflew.

Once command transfers restart/continue, the non-coherency hardware will behave as if the command sequence started from that point. [Figure 30-135](#) depicts how the non-coherency hardware will behave when a non-coherency event is detected.

Note

If MODEx is changed to disabled while a CFIFO is transferring commands, the NCF flag for that CFIFO will not become asserted.

(a) CFIFO0 and CFIFO5 both have commands to be sent to CBuffer1, and both are not triggered

(b) CFIFO5 becomes triggered and transfers two commands to CBuffer1

(c) CFIFO0 becomes triggered and transfers a command to CBuffer1. The sequence sent through CFIFO5 becomes non-coherent.

* TNXTPTR - Transfer Next Data Pointer
CFx_CBa_CMn - Command *n* in CFIFOx bound for CBuffera

Figure 30-134. Non-coherency event when different CFIFOs use the same CBuffer

Figure 30-135. Non-coherency detection when transfers from a command sequence are interrupted

30.6.5 EQADC result FIFOs

30.6.5.1 RFIFO basic functionality

There are six RFIFOs located in the EQADC. Each RFIFO is four entries deep, and each RFIFO entry is 16 bits long. Each RFIFO serves as a temporary storage location for the one of the RQueues allocated in system memory. Result data is saved in the RFIFOs before being moved into the system RQueues. When an RFIFO is not empty, the EQADC sets the corresponding RFDF bit in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#). If RFDE is asserted in [EQADC Interrupt and DMA Control Register 0 \(EQADC_IDCR0\)](#), the EQADC generates a request so that an RFIFO entry is moved to the RQueue. An interrupt request, served by the host CPU, is generated when RFDS is negated, and a DMA request, served by the DMAC, is generated when RFDS is asserted. The host CPU or the DMAC responds to these requests by reading [EQADC Result FIFO Pop Register \(EQADC_RFPR_n\)](#) to retrieve data from the RFIFO.

Note

The DMAC should be configured to read a single result (16-bit data) from the RFIFO pop registers for every asserted DMA request it acknowledges. See [EQADC/DMAC interface](#) for DMAC configuration guidelines.

Note

Reading a word, a half-word, or any bytes from EQADC_RFPRx will pop an entry from RFIFOx, and the RFCTRx field will be decremented by one.

Note

When the DMA is selected ((RFDSx=1), readings should be done only controlled by the DMA protocol. Other ways to flush the RFIFOx to empty the memory can cause a locked DMA request (permanent ON).

Figure 30-136 describes the important components in the RFIFO. Each RFIFO is implemented as a circular set of registers to avoid the need to move all entries at each push/pop operation. The Pop Next Data Pointer always points to the next RFIFO message to be retrieved from the RFIFO when reading EQADC_RFPR. The Receive Next Data Pointer points to the next available RFIFO location for storing the next incoming message from the on-chip ADCs. The *RFIFO Counter Logic* counts the number of entries in RFIFO and generates interrupt or DMA requests to drain the RFIFO.

POPNXTPTR in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#) indicates which entry is currently being addressed by the Pop Next Data Pointer, and RFCTR, in the same register, provides the number of entries stored in the RFIFO. Using POPNXTPTR and RFCTR, the absolute addresses for Pop Next Data Pointer and Receive Next Data Pointer can be calculated using the following formulas:

Pop Next Data Pointer Address = RFIFOx_BASE_ADDRESS + POPNXTPTRx*4

Receive Next Data Pointer Address = RFIFOx_BASE_ADDRESS + [(POPNXTPTRx + RFCTRx) mod RFIFO_DEPTH] * 4

where

- $a \bmod b$ returns the remainder of the division of a by b .
- RFIFOx_BASE_ADDRESS is the smallest memory mapped address allocated to an RFIFOx entry.
- RFIFO_DEPTH is the number of entries contained in a RFIFO - four in this implementation.

When a new message arrives and RFIFOx is not full, the EQADC copies its contents into the entry pointed by the Receive Next Data Pointer. The RFIFO counter RFCTRx in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#) is incremented by one, and the Receive Next Data Pointer x is also incremented by one (or wrapped around) to

point to the next empty entry in RFIFOx. However, if the RFIFOx is full, the EQADC sets the RFOF in [EQADC FIFO and Interrupt Status Register \(EQADC_FISRn\)](#). The RFIFOx will not overwrite the older data in the RFIFO, the new data will be ignored, and the Receive Next Data Pointer x is not incremented or wrapped around. RFIFOx is full when the Receive Next Data Pointer x equals the Pop Next Data Pointer x and RFCTR_x is not zero. RFIFOx is empty when the Receive Next Data Pointer x equals the Pop Next Data Pointer x and RFCTR_x is zero.

When the EQADC RFIFO Pop Register x is read and the RFIFOx is not empty, the RFIFO counter RFCTR_x is decremented by one, and the POP Next Data Pointer is incremented by one (or wrapped around) to point to the next RFIFO entry.

When the EQADC RFIFO Pop Register x is read and RFIFOx is empty, EQADC will not decrement the counter value and the POP Next Data Pointer x will not be updated. The read value will be undefined.

Figure 30-136. RFIFO diagram

The detailed behavior of the Pop Next Data Pointer and Receive Next Data Pointer is described in the example shown in [Figure 30-137](#) where an RFIFO with 16 entries is shown for clarity of explanation, the actual hardware implementation has only four entries. In this example, RFIFOx with 16 entries is shown in sequence after popping or receiving entries.

Figure 30-137. RFIFO entry pointer example

30.6.5.2 Distributing result data into RFIFOs

Data to be moved into the RFIFOs can come from different sources: from ADC0, from ADC1, or from the on-chip companion module through the PSI. All result data comes with the MESSAGE_TAG / MESSAGE_TAG2 field and the DEST / DEST2 field defining what should be done with the received data. The EQADC hardware decodes the MESSAGE_TAG / MESSAGE_TAG2 and DEST/DEST2 fields and:

- stores the 16-bit data into the appropriate RFIFO if the MESSAGE_TAG / MESSAGE_TAG2 indicates a valid RFIFO number, or;
- sends the 16-bit data, the MESSAGE_TAG / MESSAGE_TAG2 and the DEST / DEST2 data through the PSI to an on-chip companion module (as a decimation filter), or;
- ignores the data in case of a null or "reserved for customer use" MESSAGE_TAG / MESSAGE_TAG2.

In general received data is moved into RFIFOs as they become available, while an exception happens when multiple results from different sources become available at the same time. In that case, result data from ADC0 is processed first, result data from ADC1 is only process after all ADC0 data is processed, and finally returned data from companion module is only processed after all data from ADC0/1 is processed.

When time-stamped results return from the on-chip ADCs, the conversion result and the time stamp are always moved to the RFIFOs in consecutive clock cycles in order to guarantee they are always stored in consecutive RFIFO entries.

30.6.6 On-chip ADC configuration and control

30.6.6.1 Enabling and disabling the on-chip ADCs

The on-chip ADCs have an enable bit (ADC0/1_EN) in [ADC0/1 Control Registers \(ADC0_CR and ADC1_CR\)](#) that allows the enabling of the ADCs only when necessary. When the enable bit for an ADC is negated, the clock input to that ADC is stopped. The ADCs are disabled out of reset - ADC0/1_EN bits are negated - to allow for their safe configuration. The ADC must only be configured when its enable bit is negated. Once the enable bit of an ADC is asserted, clock input to is started.

Note

Conversion commands sent to the CBuffer of a disabled ADC are ignored by the ADC control hardware.

Note

Due to legacy reasons, the EQADC will always wait 120 ADC clocks before issuing the first conversion command following the enabling of one of on-chip ADCs, or the exiting of stop mode. There are two independent counters checking for this delay: one clocked by ADC0_CLK and another by

ADC1_CLK. Conversion commands can start to be executed whenever one of these counters completes counting 120 ADC clocks.

30.6.6.2 ADC clock and conversion speed

The clock input to the ADCs is defined by setting the ADC0/1_ODD_PS, the ADC0/1_CLK_SEL and the ADC0/1_CLK_PS fields in [ADC0/1 Control Registers \(ADC0_CR and ADC1_CR\)](#). When the ADC0/1_CLK_SEL is set, the ADC clock frequency is the same as the system clock, but it has the inverted phase. When it is clear, the ADC0/1_ODD_PS and the ADC0/1_CLK_PS fields select the clock divide factor by which the system clock will be divided as shown in [Table 30-114](#). The ADC clock frequency is calculated as below and must not exceed ADC_MAX_CLOCK. This is also the maximum frequency of system clock when the ADC0/1_CLK_SEL is asserted.

$$\text{ADCClockFrequency} = \frac{\text{SystemClockFrequency(MHz)}}{\text{SystemClockDivideFactor}}$$

[Figure 30-138](#) depicts how the ADC clocks for ADC0 and ADC1 are generated.

Figure 30-138. ADC0/1 clock generation

The ADC conversion speed (in K samples per second: Ksps) is calculated by the following formula. The *number of sampling cycles* is determined by the LST bits in the command message—see [Conversion command format for the standard configuration](#)—

and can take one of the following values: 2, 8, 64, or 128 ADC clock cycles. The *number of AD conversion cycles* is 13 for differential conversions and 14 for single-ended 12-bit resolution and unitary input gain conversions. The maximum conversion speed is achieved when the ADC Clock frequency is set to its maximum and the number of sampling cycles set to its minimum (2 cycles). The maximum conversion speed is ADC_MAX_CONV_RATE.

$$\text{ADCConversionSpeed} = \frac{\text{ADCClockFrequency(MHz)}}{(\text{NumberOfSamplingCycles} + \text{NumberOfADCConversionCycles})}$$

Table 30-137 shows an example of how the ADC0/1_CLK_PS can be set when using a 120 MHz system clock and the corresponding conversion speeds for all possible ADC clock frequencies. The table also shows that according to the system clock frequency, certain clock divide factors are invalid (2, 4, 6, 8 clock divide factors in the example) because their use would result in a ADC clock frequency higher than the maximum one supported by the ADC. The ADC clock frequency must not exceed ADC_MAX_CLOCK.

Table 30-137. ADC Clock configuration example (system clock frequency=120 MHz)

ADC0/1_CLK_PS [0:4]	ADC0/1_ODD_PS	System clock divide factor	ADC clock (system clock = 120 MHz)	Differential conversion speed with default sampling time (2 cycles)	Single-ended conversion speed with default sampling time (2 cycles)

	1	65	1.85 MHz	123 Ksps	115 Ksps

30.6.6.3 Time stamp feature

The on-chip ADCs can provide a time stamp for the conversions they execute. A time stamp is the value of the time base counter latched when the EQADC detects the end of the analog input voltage sampling. A time stamp for a conversion command is requested by setting the TSR bit in the corresponding command. When TSR is negated, that is a time stamp is not requested, the ADC returns a single result message containing the conversion result. When TSR is asserted, that is a time stamp is requested, the ADC returns two result messages; one containing the conversion result, and afterwards another containing the time stamp for that conversion. The result messages are sent in this order to the RFIFOs and both messages are sent to the same RFIFO was specified in the MESSAGE_TAG field of the executed conversion command.

The time stamp can be provided by an external source using the STAC bus (more details in [STAC bus client sub-module \(STACC\)](#)) or by the internal time base counter. The selection between the two sources is done by field ADC0/1_TBSEL in the ADC0/1_CR register or by field ATBSEL in registers ADC_ACR1-14. See [Table 30-113](#) and the ATBSEL field description in [Alternate Configuration 1-14 Control Registers \(ADC_ACR1-14\)](#) for selection details.

The time base counter is a 16-bit up counter that wraps after reaching 0xFFFF. It is disabled after reset and it is enabled according to the setting of TBC_CLK_PS field in [ADC Time Stamp Control Register \(ADC_TSCR\)](#). TBC_CLK_PS defines if the counter is enabled or disabled, and, if enabled, at what frequency it is incremented. The time stamps are returned regardless of whether the time base counter is enabled or disabled. The time base counter can be reset by writing 0x0000 to [ADC Time Base Counter Registers \(ADC_TBCR\)](#) with a write configuration command.

30.6.6.3.1 STAC bus client sub-module (STACC)

The STAC sub-block STACC extracts the external time base from the STAC bus to the EQADC. Figure 30-139 provides a block diagram for the STACC sub-module that contains actually two slot selectors.

Figure 30-139. STAC bus client block diagram

The STAC bus data stream is composed by several identified time slots. Each time slot contains a time value from a specified source. The bits SRV1/2[0:3] in register EQADC_STACCR are used to select the desired time slots of the STAC bus to be used internally by the EQADC. Figure 30-140 shows a timing diagram for the STACC.

- NOTES: 1. Maximum of 16 Time Slots (TS[n])
2. In this case, SRV bits were set to capture TS[01]

Figure 30-140. Timing diagram for the STAC bus and STACC output

Every time the selected time slot change, the STACC outputs are updated. As this time base is an external data to the EQADC, this output is not affected by the stop or by the debug internal state.

After the slot selection is done and the timebase data is extracted, the STACBS1/2 bits select 16 bits from the original 24-bit timebase data. These selected bits are the timebase to be used internal to the EQADC.

30.6.6.4 ADC pre-gain feature

Each ADC can be configured to have a selectable input gain as defined in [Alternate Configuration 1-14 Control Registers \(ADC_ACR1-14\)](#). This means the input signal is sampled and the result is amplified by factor 2, or 4 before the conversion phase. In present implementation of this feature, the conversion is 1 or 2 ADC clock cycles longer for gain 2 or gain 4, respectively.

30.6.6.5 ADC resolution selection feature

The ADCs conversion resolutions can be 8 bits, 10 bits or 12 bits as described in [Alternate Configuration 1-14 Control Registers \(ADC_ACR1-14\)](#). For conversions at a resolution less than 12, the ADC is executing less operations and the conversion time is smaller. In this ADC, it is verified that there is 1 ADC clock cycle for each bit of resolution. Therefore, for the same ADC clock frequency, the ADC sample frequency is higher for lower resolutions.

When a conversion is undertaken at a resolution less than 12, the result is presented by the ADC in right justified format in the 12-bit input bus e.g.: 0000xxxxxxx for 8 bits and 00xxxxxxxxxx for 10 bits. The EQADC inverts the result to left justified format i.e.: xxxxxxxx0000 for 8 bits and xxxxxxxxxx00 for 10 bits. This is because the same calibration coefficients in the MAC can then be used. The left shift operation is done just after the conversion result enters the EQADC, in the Resolution Adjustment block prior to the MAC, as illustrated in [Figure 30-143](#).

30.6.6.6 ADC calibration feature

30.6.6.6.1 Overview

There are three sets of calibration coefficients for each ADC. Each set is composed by a gain factor and an offset factor: GCCn/OCCn, ALTGCCn1/ALTGCCn1, and ALTGCCn2/ALTGCCn2, where n is the ADC number 0 or 1. The pair GCCn/OCCn is selected when it is used the normal configuration or the alternate configurations 3 to 8. The pair ALTGCCn1/ALTGCCn1 is used only when the alternate configuration 1 is selected. And the pair ALTGCCn2/ALTGCCn2 is for the alternate configuration 2. The description below is for a generic pair of gain/offset GCC/OCC.

The EQADC provides a calibration scheme to remove the effects of gain and offset errors from the results generated by the on-chip ADCs. Only results generated by the on-chip ADCs are calibrated. The main component of calibration hardware is a Multiply-and-Accumulate (MAC) unit, one per on-chip ADC, that is used to calculate the following transfer function which relates a calibrated result to a raw, uncalibrated one.

$$\text{CAL\_RES} = \text{GCC} * \text{RAW\_RES} + \text{OCC} + 2;$$

where:

- CAL_RES is the calibrated result corresponding the input voltage V_i .
- GCC is the gain calibration constant.
- RAW_RES is the raw, uncalibrated result with resolution adjustment corresponding to an specific input voltage V_i .
- OCC is the offset calibration constant.
- The addition of two reduces the maximum quantization error of the ADC. See [Quantization error reduction during calibration](#).

Calibration constants GCC and OCC are determined by taking two samples of known reference voltages and using these samples to calculate the values for the constants. For details and an example about how to calculate the calibration constants and use them in result calibration see [ADC Result Calibration](#). Once calculated, GCC is stored in [ADC0/1 Gain Calibration Constant Registers \(ADC0_GCCR and ADC1_GCCR\)](#) and OCC in [ADC0/1 Offset Calibration Constant Registers \(ADC0_OCCR and ADC1_OCCR\)](#), from where their values are fed to the MAC unit. The alternate gain values are stored in [ADC0/1 Alternate Gain Registers \(ADC0_AGR1-2 and ADC1_AGR1-2\)](#) and the alternate offset values in [ADC0/1 Alternate Offset Register \(ADC0_AOR1-2 and ADC1_AOR1-2\)](#). Since the analog characteristics of each on-chip ADCs differs, each ADC has an independent pair of calibration constants.

A conversion result is calibrated according to the status of CAL bit in the command that initiated the conversion. If the CAL bit is asserted, the EQADC will automatically calculate the calibrated result before sending the result to the appropriate RFIFO or companion module. If the CAL bit is negated, the result is not calibrated, it bypasses the calibration hardware, and is directly sent to the appropriate RFIFO or companion module.

30.6.6.6.2 MAC unit and operand data format

The MAC unit diagram is shown in [Figure 30-141](#). Each on-chip ADC has a separate MAC unit to fine-tune its conversion results. The description below considers the general calibration constant registers but it is the same for the alternate calibration constants.

The OCC0/1 operand is a 14-bit signed value stored in [ADC0/1 Offset Calibration Constant Registers \(ADC0_OCCR and ADC1_OCCR\)](#)." The RAW_RES operand is the raw uncalibrated result, and it is the direct output from the on-chip ADCs but passing through the resolution adjustment block. The GCC0/1 operand is a 15-bit fixed point unsigned value stored in [ADC0/1 Gain Calibration Constant Registers \(ADC0_GCCR and ADC1_GCCR\)](#)." The GCC is expressed in the *GCC_INT.GCC_FRAC* binary format. The integer part of the GCC (GCC_INT=GCC[1]) contains a single binary digit while its fractional part (GCC_FRAC=GCC[2:15]) contains 14 bits - see [Figure 30-142](#). The gain constant equivalent decimal value ranges from 0 to 1.999938..., as shown in [Table 30-139](#). Two is always added to the MAC output - see [Quantization error reduction during calibration](#). CAL_RES output is the calibrated result, and it is a 14-bit unsigned value. CAL_RES is truncated to 0x3FFF, in case of a overflow, and to 0x0000, in case of an underflow.

30.6.6.7 ADC control logic overview and command execution

[Figure 30-143](#) shows the basic logic blocks involved in the ADC Control and how they interact. CFIFOs/RFIFOs interact with CBuffers/*Abort Cont/Result Message Return Logic* through the *FIFO Control Unit*. The EB and BN bits in the Command Message uniquely identify the CBuffer to which a command should be sent. The *FIFO Control Unit* decodes these bits and sends the ADC command to the proper CBuffer. Other blocks of logic are the *Resolution Adjustment*, *Result Format and Calibration Sub-Block*, the *Time Stamp Logic*, and the *MUX Control Logic*.

The *Resolution Adjustment Sub-Block* receives the 12-bit data bus directly from the ADC and changes the received conversion results from right aligned format of ADC to the left aligned format depending on the selected resolution of the conversion. This operation helps the calibration processing to use the calibration coefficients always with the same format.

The *Result Format and Calibration Sub-Block* formats the returning data into Result Messages and sends them to the RFIFOs ⁶. The returning data can be data read from an ADC register, a conversion result, or a time stamp. The formatting and calibration of conversion results also take place inside this sub-block.

The *Time Stamp Logic* latches the value of the time base counter or the STAC bus time base when detecting the end of the analog input voltage sampling, and sends it to the *Result Format and Calibration Sub-Block* as time stamp information.

The *MUX Control Logic* generates the proper MUX control signals and, when the ADC0/1_EMUX bits are asserted, the MA signals based on the channel numbers extracted from the ADC Command.

When the on-chip ADC abort feature is not enabled, ADC Commands are stored in the CBuffers as they come and they are executed in the first-in-first-out basis. After the execution of a command in ENTRY1 finishes all commands are shifted one entry. After the shift, ENTRY0 is always empty and ready to receive a new command. Execution of configuration commands only start when they reach ENTRY1. Consecutive conversion commands are pipelined and their execution can start while in ENTRY0. This is explained below.

AD conversion accuracy can be affected by the settling time of the input channel multiplexers. Some time is required for the channel multiplexers internal capacitances to settle after the channel number is changed. If the time prior to sampling is not long enough to absorb this settling, then the settling time will take from ADC sampling time which may result in inaccurate sampling and ultimately compromise conversion result accuracy - see [Figure 30-144](#) (a). This could be avoided by switching the multiplexers in preparation for the next command's sampling during the AD conversion phase of the current command as showed in [Figure 30-144](#) (b). In EQADC, this is done in the following way; when a conversion command is in buffer ENTRY1 and another conversion command is identified in ENTRY0, then the channel number of ENTRY0 is sent to the *MUX Control Logic* some cycles before the sampling phase of the command in ENTRY0 starts. In this way, sampling for the next command can promptly start after the current conversion finishes because the internal capacitance of the multiplexers will be settled by that time, allowing for more accurate sampling. This is specially important for applications that require high conversion speeds, that is with the ADC running at maximum clock frequency and with the analog input voltage sampling time set to a minimum (2 ADC clock cycles), when the short sampling time does not allow the multiplexers to completely settle. The second advantage of pipelining conversion

6. The result messages may also be routed to an on-chip companion module via the side interface, and then fed back to the RFIFOs.

commands is to provide precise conversion intervals, which means the time intervals between two consecutive conversions are the same. This is important for any digital signal process application.

When the on-chip ADC abort feature is enabled, ADC Commands from CFIFO0 should be considered immediately, even stopping the execution of some command that is already in ENTRY1. When the abort request is sent to the ADC, the already stored commands in the CBuffers are copied in a temporary set of registers. The first ADC command from CFIFO0 is sent after the abort acknowledge indication from ADC. The process is the same as usual until the transfer of the last command from CFIFO0. Then the temporarily stored commands that were postponed by the abortion are recovered and they are pipelined for execution. After the last command from this temporary memory is transferred, the next commands are pipelined from the CFIFOs.

Figure 30-144. Overlapping consecutive conversion commands

30.6.7 Internal/external multiplexing

30.6.7.1 Channel assignment

The internal analog multiplexers select one of the 40 analog input pins for conversion, based on the `CHANNEL_NUMBER` field of a Command Message. The analog input pin channel number assignments and the pin definitions vary depending on how the `ADC0/1_EMUX` are configured. Allowed combinations of `ADC0/1_EMUX` bits are shown in [Table 30-140](#) together with references to tables indicating how `CHANNEL_NUMBER` field of each conversion command must be set to avoid channel selection conflicts.

During differential conversions the analog multiplexer passes differential signals to both the positive and negative terminals of the ADC. The differential conversions can only be initiated on four channels: DAN0, DAN1, DAN2, and DAN3. See chip-specific section for the channel numbers used to select differential conversions.

Table 30-140. ADC0/1_EMUX bits combinations

ADC0_EMUX	ADC1_EMUX	CHANNEL_NUMBER should be set as in	
		ADC0	ADC1
0	0	See chip-specific section for details	See chip-specific section for details
0	1	See chip-specific section for details	See chip-specific section for details
1	0	See chip-specific section for details	See chip-specific section for details
1	1	Reserved ¹	

1. ADC0_EMUX and ADC1_EMUX must not be asserted at the same time

See the chip-specific EQADC information for channel number assignments for the non-multiplexed mode. The two on-chip ADCs can access the same analog input pins but simultaneous conversions are not allowed. Also, when one ADC is performing a differential conversion on a pair of pins, the other ADC must not access either of these two pins as single-ended channels. The 43 single-ended channels and 4 differential pairs are shared between the two ADCs.

See the chip-specific EQADC information for the channel number assignments for multiplexed mode. The two on-chip ADCs can access the same analog input pins but simultaneous conversions are not allowed. Also, when one ADC is performing a differential conversion on a pair of pins, the other ADC must not access either of these two pins as single-ended channels. The ADC with the ADC0/1_EMUX bit asserted can access 4 differential pairs, 39 single-ended, and, at most, 64 externally multiplexed channels. See [External multiplexing](#) for a detailed explanation about how external multiplexing can be achieved.

30.6.7.2 External multiplexing

The EQADC can use from one to eight external multiplexer chips to expand the number of analog signals that may be converted. Up to 64 analog channels can be converted through external multiplexer selection. The externally multiplexed channels are automatically selected by the CHANNEL_NUMBER field of a Command Message, in the same way done with internally multiplexed channels. The software selects the external multiplexed mode by setting the ADC0/1_EMUX bit in either ADC0_CR or ADC1_CR depending on which ADC will perform the conversion. See the chip-specific EQADC information for the channel number assignments for the multiplexed mode.

There are 4 differential pairs, 39 single-ended, and, at most, 64 externally multiplexed channels which can be selected. Only one ADC can have its ADC0/1_EMUX bit asserted at a time.

Figure 30-145 shows the maximum configuration of eight external multiplexer chips connected to the EQADC. The external multiplexer chip selects one of eight analog inputs and connects it to a single analog output, which is fed to a specific input of the EQADC. The EQADC provides three multiplexed address signals, MA0, MA1, and MA2, to select one of eight inputs. These three multiplexed address signals are connected to all eight external multiplexer chips. The analog output of the eight multiplex chips are each connected to eight separate EQADC inputs, ANR, ANS, ANT, ANU, ANW, ANX, ANY, and ANZ. The MA pins correspond to the three least significant bits of the channel number that selects ANR, ANS, ANT, ANU, ANW, ANX, ANY, and ANZ with MA0 being the most significant bit - See Table 30-141. In that table, '0' means pin is driven LOW and '1' that pin is driven HIGH.

Table 30-141. Encoding of MA pins

Channel number selecting ANR, ANS, ANT, ANU, ANW, ANX, ANY, ANZ (decimal)								MA0	MA1	MA2
ANR	ANS	ANT	ANU	ANW	ANX	ANY	ANZ			
224	232	240	248	64	72	80	88	0	0	0
225	233	241	249	65	73	81	89	0	0	1
226	234	242	250	66	74	82	90	0	1	0
227	235	243	251	67	75	83	91	0	1	1
228	236	244	252	68	76	84	92	1	0	0
229	237	245	253	69	77	85	93	1	0	1
230	238	246	254	70	78	86	94	1	1	0
231	239	247	255	71	79	87	95	1	1	1

When the external multiplexed mode is selected for either ADC, the EQADC automatically creates the MA output signals from CHANNEL_NUMBER field of a Command Message. The EQADC also converts the proper input channel (ANR, ANS, ANT, ANU, ANW, ANX, ANY, and ANZ) by interpreting the CHANNEL_NUMBER field. As a result, up to 64 externally multiplexed channels appear to the conversion queues as directly connected signals.

Figure 30-145. Example of external multiplexing

30.6.8 EQADC DMA/interrupt request

Table 30-142 lists methods to generate interrupt requests in the EQADC queuing control and triggering control. The DMA/interrupt request select bits and the DMA/interrupt enable bits are described in [EQADC Interrupt and DMA Control Register 0 \(EQADC_IDCR0\)](#) and the interrupt flag bits are described in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#). Figure 30-146 depicts all interrupts and DMA requests generated by the EQADC. For details, see [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#) and [EQADC Interrupt and DMA Control Register 0 \(EQADC_IDCR0\)](#).

Table 30-142. EQADC FIFO interrupt summary

Interrupt	Condition	Clearing mechanism
Non Coherency Interrupt	NClEx = 1 NCFx = 1	Clear NCFx bit by writing a "1" to the bit.
Result FIFO Overflow Interrupt ¹	RFOlEx = 1 RFOF _x = 1	Clear RFOF _x bit by writing a "1" to the bit.
Command FIFO Underflow Interrupt ¹	CFUIEx = 1 CFUF _x = 1	Clear CFUF _x bit by writing a "1" to the bit.
Result FIFO Drain Interrupt	RFDE _x = 1 RFDS _x = 0 RFDF _x = 1	Clear RFDF _x bit by writing a "1" to the bit.
Command FIFO Fill Interrupt	CFFEx = 1 CFFS _x = 0 CFFF _x = 1	Clear CFFF _x bit by writing a "1" to the bit.
End of Queue Interrupt	EOQlEx = 1 EOQF _x = 1	Clear EOQF _x bit by writing a "1" to the bit.
Pause Interrupt	PIEx = 1 PF _x = 1	Clear PF _x bit by writing a "1" to the bit.
Trigger Overrun Interrupt ¹	TORlEx = 1 TORF _x = 1	Clear TORF _x bit by writing a "1" to the bit.

1. Apart from generating an independent interrupt request for when a RFIFO Overflow Interrupt, a CFIFO Underflow Interrupt, and a CFIFO Trigger Overrun Interrupt occurs, the EQADC also provides a combined interrupt request at which these requests from ALL CFIFOs are ORed. Refer to [Figure 30-146](#) for details.

Table 30-143 describes a list of methods to generate DMA requests in the EQADC. For details, see [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#) and [EQADC Interrupt and DMA Control Register 0 \(EQADC_IDCR0\)](#).

Table 30-143. EQADC FIFO DMA Summary

DMA Request	Condition	Clearing Mechanism
Result FIFO Drain DMA ¹ Request	RFDEx = 1 RFDSx = 1 RFDFx = 1	The EQADC automatically clears the RFDFx when RFIFOx becomes empty. Writing "1" to the RFDFx bit is not allowed.
Command FIFO Fill DMA Request	CFFEx = 1 CFFSx = 1 CFFFx = 1	The EQADC automatically clears the CFFFx when CFIFOx becomes full. Writing "1" to the CFFFx bit is not allowed.

1. Additional readings from RFIFOx (not from DMA control) can clear the RFDFx bit and can lock the DMAx circuit to a locked state. The DMAx request remains ON, despite RFDFx is cleared.

On-chip ADC configuration and control

Figure 30-146. EQADC DMA and interrupt requests

30.6.9 EQADC Parallel Side Interface (PSI) sub-block

Figure 30-147. EQADC Parallel Side Interface block diagram

The EQADC PSI sub-block allows communication between the EQADC and the companion modules through a local slave bus that has the EQADC block as the master and the companion modules as the slaves. However, due to implementation constraints, a limited number of addresses is defined and a maximum of 15 different slave blocks to be enabled.

The conversion result goes through the Result Formatting and Calibration sub-block and the corresponding MESSAGE_TAG / MESSAGE_TAG2 and DEST/DEST2 fields are decoded to decide the destination of the conversion result data. When the DEST field is not zero as described in [Alternate Configuration 1-14 Control Registers \(ADC_ACR1-14\)](#), the MESSAGE_TAG bits, control bits, and the conversion result data are sent to the transmission section of the PSI sub-block. This set of data is processed and sent to the corresponding on-chip companion module.

The configuration bit DAM is described in [EQADC Module Configuration Register \(EQADC_MCR\)](#). The DEST2/MESSAGE_TAG2 fields are only used as defined in [Extended Alternate Configuration 1-14 Control Registers \(ADC_EACR1-14\)](#) when

DAM=1. DAM bit selects between two different "tap modes", each defining a different way to select the second destination. When DAM=0 the DEST field can set the transmission section to send the same result data / MESSAGE_TAG to two destinations. See [Table 30-121](#) in [Alternate Configuration 1-14 Control Registers \(ADC_ACR1-14\)](#). When DAM=1, the two destinations are selected as described in [Table 30-125](#).

The companion module can also send back to EQADC the result of some processing in the received data. In this case, the receiver section of the PSI sub-block treats this request and receives the result data with the corresponding MESSAGE_TAG or TAG field. This TAG is used by the decoder to select which RFIFO will be written with the received companion module data.

A companion module with two PSIs can be connected to two EQADCs. For this case, there is the bit field RPSI described in [Alternate Configuration 1-14 Control Registers \(ADC_ACR1-14\)](#) and the bit field RPSI2 described in [Alternate Configuration 1-14 Control Registers \(ADC_ACR1-14\)](#) that control the routing of the companion module output result to any PSI.

30.6.9.1 Input / output signals description

The information content of the input and the output data buses from/to the companion modules are described in [Figure 30-148](#). The input data format is used in the Read cycle and corresponds to the data supplied by some companion module. The output data format is used in the Write cycle of this interface block and contains information / controls to some companion module.

Figure 30-148. PSI input and output data buses content

Table 30-144. PSI input and output data buses content — field descriptions

Field	Description
FLUSH	Master block Flush request/control bit The FLUSH signal is used to request a Flush flow in the slave block. More details is presented in Conversion command format for alternate configurations .
	0 No flush request.
	1 Flush request
RPSI	Return Parallel Side Interface The RPSI bit is used in the companion module that has two PSI interfaces (PSI0 and PSI1) which can be connected to two eQADCs. It specifies in the companion module if the data received from one PSI should be transmitted to the same PSI connected to this eQADC or to the other one. This bit is defined by the bit field RPSI described in Alternate Configuration 1-14 Control Registers (ADC_ACR1-14) or by the bit field RPSI2 described in Alternate Configuration 1-14 Control Registers (ADC_ACR1-14) .
	0 Results from this sample must be transmitted back using the same PSI (eQADC).
	1 Results from this sample must be transmitted to the other PSI (eQADC)
CTRL	Control bits This field is used for the control of the companion module.
	00 INH_RET or PREFILL - This mode indicates that the companion module should not send back some RESULT_DATA corresponding to the accompanying ADC_CONV_RESULT data. When the slave module is the Decimation Filter, this control enables the PREFILL filter mode.

Table continues on the next page...

Table 30-144. PSI input and output data buses content — field descriptions (continued)

Field	Description
	01 CONVERSION RESULT - It indicates that the ADC_CONV_RESULT field should be treated as a valid sample data. This control mode is useful to Decimation Filter to put the filter em normal mode instead of prefill mode.
	10 TIME STAMP o REGISTER READ - A time stamp indicates that the ADC_CONV_RESULT field should follow a bypass flow in the companion module, returning back to the EQADC without any modification.
	11 Reserved
MESSAGE_TAG[0:3]	Message tag bits field This field indicates the RFIFO destination associated with the ADC_CONV_RESULT sample. This value is stored by the companion module and is used to address the destination RFIFO register when a RESULT_DATA is generated due to that ADC_CONV_RESULT sample. Note: In case the companion module only receives data from eQADC and does not return any result to eQADC RFIFOs, the MESSAGE_TAG field can be used as a destination router in the companion module. The eQADC module can send conversion results to sub-blocks in the companion module that are addressed by the MESSAGE_TAG value.
TAG[0:3]	Companion module tag bits This bit field is used to address the appropriate destination RFIFO in the EQADC for the accompanying RESULT_DATA bits. However, it can be used too in the companion module to select the destination of the conversion result data. In eQADC application, this is used to address the appropriate RFIFO in the eQADC block. In this case, the possible values are only from 0000 to 0101.
ADC_CONV_RESULT[0:15]	ADC Conversion Result Data This bit field is the ADC conversion result data after passing through the calibration and formatting block.
RESULT_DATA[0:15]	Companion Module Result Data This bit field corresponds to the companion module data processing result to EQADC.

30.6.9.2 PSI Transmitter / Write Section

The transmission sub-block formats the data bus from RFIFO control sub-block to send to the PSI slave wdata bus. The transmission data is registered and its content is described in [Input / output signals description](#). The transmission has higher priority than reception. This is done to avoid the use of memory to store transmission data and it is not used waiting time for transmission.

The destination companion module for the transmission data is obtained by decoding the DEST[0:3] and DEST2 bits. The not null decimal value of DEST[0:3] or DEST2 is used to set one or two corresponding module enable signals as already described. For example, DEST[0:3] value equal to 0x1 that corresponds to the decimal value 1 is going to set only the module enable 1. All other module enable from 2 to 15 are not set due to DEST.

However, using the DEST2 value there are cases that two module enables are set, as described in [Table 30-121](#) in [Alternate Configuration 1-14 Control Registers \(ADC_ACR1-14\)](#).

30.6.9.3 PSI Receiver / Read Section

The receiver sub-block receives data from some companion module using the PSI slave bus interface. The companion module sends a read request to EQADC using the DMA read request line. The PSI logic sends a read command if there is no transmission request. The received data has the structure described in [Input / output signals description](#).

The receiver section can receive read request from several companion modules at the same time. A prioritization scheme is used to decide which request should be served first. The request with lower index has higher priority.

Note

In case of receiving data (D1, D2) and timestamp (T1, T2) from two companion modules with the same TAG at almost the same time, the RFIFOx can receive the pair data/timestamp out of order due to the present prioritization logic in the PSI receiver. An expected sequence (D1 T1 D2 T2) can be changed to (D1 D2 T2 T1) if D2/T2 has higher priority than T2. [Table 30-125](#) presents some cases that presents this inversion.

30.6.10 Analog sub-block

30.6.10.1 Analog to digital converter (ADC)

30.6.10.1.1 ADC architecture

Figure 30-149. RSD ADC block diagram

The RSD Cyclic ADC consists of two main portions, the analog RSD Stage, and the digital control and calculation block, as shown in [Figure 30-149](#). To begin an analog to digital conversion, a differential input is passed into the analog RSD stage. The signal is passed through the RSD stage, and then from the RSD stage output, back to its input to be passed again. To complete a 12-bit conversion, the signal must pass through the RSD stage 12 times. For 10-bit and 8-bit resolution, the signal must pass 10 or 8 times through the RSD. Each time an input signal is read into the RSD stage, a digital sample is taken by the digital control/calculation block. The digital control/calculation block uses this sample to tell the analog block how to condition the signal. The digital block also saves each successive sample and adds them according to the RSD algorithm at the end of the entire conversion cycle.

30.6.10.1.2 RSD Overview

Figure 30-150. RSD stage block diagram

On each pass through the RSD stage, the input signal will be multiplied by exactly two, and summed with either $-V_{REF}$, 0, or V_{REF} , depending on the Logic Control. The Logic Control will determine $-V_{REF}$, 0, or V_{REF} depending on the two comparator inputs. As the Logic Control sets the summing operation, it also sends a digital value to the RSD adder. Each time an analog signal passes through the RSD single-stage, a digital value is collected by the RSD adder. At the end of an entire AD conversion cycle, the RSD adder uses these collected values to calculate the 12-bit/10-bit/8-bit digital output.

[Figure 30-151](#) shows the transfer function for the RSD stage. Note how the digital value (a, b) is dependent on the two comparator inputs.

Figure 30-151. RSD Stage Transfer Function

In each pass through the RSD stage, the residue will be sent back to be the new input, and the digital signals, *a* and *b*, will be stored. For the 12-bit ADC, input signal is sampled during the input phase, and after each of the 12 passes through the RSD stage. Thus, 13 total *a* and *b* values are collected. Upon collecting all these values, they will be added according to the RSD algorithm to create the 12-bit digital representation of the original analog input. The bits are added in the following manner:

30.6.10.1.3 RSD adder

The array, *s1* to *s12*, will be the digital output of the RSD ADC with *s1* being the MSB and *s12* being the LSB.

Figure 30-152. RSD adder

30.6.10.1.4 Variable Gain Amplification (VGA) for pre-gain

The VGA starts after sampling completes. It is enabled by a 2-bit signal PRE_GAIN described in [Alternate Configuration 1-14 Control Registers \(ADC_ACR1-14\)](#).

The ADC takes 2, 8, 64 or 128 clock cycles to do sampling which is selected by the LST[0:1] field in the conversion command message. After the sampling, if 2x VGA is enabled, there is a 2x gain stage without comparison before the regular conversion cycles. When 4x VGA is enabled, there are the 2x gain stage without comparison by 2 times before the normal conversion processing.

30.7 Initialization/application information

30.7.1 Multiple queues control setup example

This section provides an example of how to configure multiple CQueues. [Table 30-145](#) describes how each CQueue can be used for a different application. Also documented in this section are general guidelines on how to initialize the on-chip ADCs and how to configure the CQueues and the EQADC.

Table 30-145. Application of each CQueue

CQueue number	CQueue type	Running speed	Number of contiguous conversions	Example
0	Very fast burst time-based CQueue	every 2 μ s for 200 μ s; pause for 300 μ s and then repeat	2	Injector current profiling
1	Fast hardware-triggered CQueue	every 900 μ s	3	Current sensing of PWM controlled actuators

Table continues on the next page...

Table 30-145. Application of each CQueue (continued)

CQueue number	CQueue type	Running speed	Number of contiguous conversions	Example
2	Fast repetitive time-based CQueue	every 2 ms	8	Throttle position
3	Software-triggered CQueue	every 3.9 ms	3	Command triggered by software strategy
4	Repetitive angle-based CQueue	every 625 μ s	7	Airflow read every 30 degrees at 8000 RPM
5	Slow repetitive time-based CQueue	every 100 ms	10	Temperature sensors

30.7.1.1 EQADC initialization

The following steps provide an example about how to configure the EQADC controls and how to initialize the on-chip ADCs. In this example, all conversion commands will be transferred through CFIFO0.

1. Load all required configuration commands in the RAM in such way that they form a queue; this data structure will be referred below as CQueue0. [Figure 30-153](#) shows an example of a CQueue able to configure the on-chip ADCs. Although, this example uses the DMAC to store commands in CFIFO0, configuration commands could have also been directly written to the CFIFO0 push register.
2. Select source driving EQADC hardware trigger ports (ETRIG). Before proceeding to next step, allow some time (minimum of two system clocks - filter period is set to minimum after reset) so that the logic level at the source is filtered and reaches the EQADC control logic.

Note

ETRIG ports could be driven by an external pin or by the output port of other blocks in the device, such as timers. In order to avoid unexpected triggering of CFIFOs in hardware trigger modes, the source driving the ETRIG port must be selected and set to a known logic level before putting the CFIFOs into the WAITING FOR TRIGGER state.

The trigger filter bypass control inputs must be set considering the characteristics of the trigger signal. A particular case to assert the bypass control is when a device's internal signal with one clock width pulse is used.

3. Configure [EQADC External Trigger Digital Filter Register \(EQADC_ETDFR\)](#).
4. Configure the DMAC to transfer data from CQueue0 to CFIFO0 in the EQADC.
5. Configure [EQADC Interrupt and DMA Control Register 0 \(EQADC_IDCR0\)](#).
 - Set CFFS0 to configure the EQADC to generate a DMA request to load commands from CQueue 0 to the CFIFO0.
 - Set CFFE0 to enable the EQADC to generate a DMA request to transfer commands from CQueue0 to CFIFO0; Command transfers from the RAM to the CFIFO0 will start immediately.
 - Set EOQIE0 to enable the EQADC to generate an interrupt after transferring all of the commands of CQueue0 through CFIFO0.
6. Configure [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#).
 - Write 0b0001 to the MODE0 field in EQADC_CFCR0 to program CFIFO0 for software single-scan mode.
 - Write "1" to SSE0 to assert SSS0 and trigger CFIFO0.
7. Since CFIFO0 is in single-scan software mode and it is also the highest priority CFIFO, the EQADC starts to transfer configuration commands to the on-chip ADCs.
8. When all of the configuration commands have been transferred, CF0 in [EQADC FIFO and Interrupt Status Register \(EQADC_FISR_n\)](#) will be set. The EQADC generates a End of Queue interrupt. The initialization procedure is complete.

		CQueue in system memory
Command Address	0x0	Configuration Command to CBuffer0 - Ex: Write ADC0_CR
	0x1	Configuration Command to CBuffer0 - Ex: Write ADC_TSCR
	0x2	Configuration Command to CBuffer1 - Ex: Write ADC1_CR

Figure 30-153. Example of a CQueue configuring the on-chip ADCs

The initialization procedure described above does not generate ADC clocks that are in phase because the timing at which the ADC0/1_EN bits, in [ADC0/1 Control Registers \(ADC0_CR and ADC1_CR\)](#), are set is different. Below follows an example on how to simultaneously set these bits so that in-phase ADC clocks are generated. In this example, ADC0/1_CLK are configured to the same frequency.

1. Push an ADC0_CR write configuration command in CFIFO0 that enables ADC0 (ADC0_EN=1) and that sets the ADC0_CLK_PS to an appropriate value. For example, 0x80800801.
2. Push an ADC1_CR write configuration command in CFIFO1 that enables ADC1 (ADC1_EN=1) and that sets the ADC1_CLK_PS to an appropriate value. For example, 0x82800801.
3. Configure CFIFO0 and CFIFO1 to single scan software trigger mode and simultaneously trigger them by writing 0x04100410 to the EQADC_CFCR0 register - see [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#).

30.7.1.2 Configuring EQADC for applications

This section provides an example based on the applications in [Table 30-145](#). The example describes how to configure multiple CQueues to be used for those applications and provides a step-by-step procedure to configure the EQADC and the associated CQueue structures. In the example, the "Fast hardware-triggered CQueue", described on the second row of [Table 30-145](#), will have its commands transferred to CBuffer1; the conversion commands will be executed by ADC1. The generated results will be returned to RFIFO3 before being transferred to the RQueues in the RAM by the DMAC.

Note

There is no fixed relationship between CFIFOs and RFIFOs with the same number. The results of commands being transferred through CFIFO1 can be returned to any RFIFO, regardless of its number. The destination of a result is determined by the MESSAGE_TAG field of the command that requested the result. See [Message format in EQADC](#) for details.

Step One: Setup the CQueues and RQueues.

1. Load the RAM with configuration and conversion commands. [Figure 30-154](#) is an example of how CQueue1 commands should be set.

- Each trigger event will cause four commands to be executed. When the EQADC detects the Pause bit asserted, it will wait for another trigger to restart transferring commands from the CFIFO.
- At the end of the CQueue, the "EOQ" bit is asserted as shown in [Figure 30-154](#).
- Results will be returned to RFIFO3 as specified in the MESSAGE_TAG field of commands.

2. Reserve memory space for storing results.

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

CFIFO Header

ADC Command

Fields LST, TSR, FMT, and CHANNEL_NUMBER are not showed for clarity {Statement}.

¹ MESSAGE_TAG field is only defined for read configuration commands {Statement}.

Figure 30-154. Example of CQueue commands

Step Two: Configure the DMAC to handle data transfers between the CQueues/RQueues in RAM and the CFIFOs/RFIFOs in the EQADC.

1. For transferring, set the source address of the DMAC to point to the start address of CQueue1. Set the destination address of the DMAC to point to EQADC_CFPR1. See [EQADC CFIFO Push Register \(EQADC_CFPRn\)](#).
2. For receiving, set the source address of the DMAC to point to EQADC_RFPR3. See [EQADC Result FIFO Pop Register \(EQADC_RFPRn\)](#). Set the destination address of the DMAC to point to the starting address of RQueue1.

Step Three: Configure the EQADC Control Registers.

3. Configure [EQADC Interrupt and DMA Control Register 0 \(EQADC_IDCR0\)](#).
 - Set EOQIE1 to enable the End of Queue Interrupt request.
 - Set CFFS1 and RFDS3 to configure the EQADC to generate DMA requests to push commands into CFIFO1 and to pop result data from RFIFO3.
 - Set CFINV1 to invalidate the contents of CFIFO1.
 - Set RFDE3 and CFFE1 to enable the EQADC to generate DMA requests. Command transfers from the RAM to the CFIFO1 will start immediately.
 - Set RFOIE3 to indicate if RFIFO3 overflows.
 - Set CFUIE1 to indicate if CFIFO1 underflows.
4. Configure MODE1 to continuous-scan rising edge external trigger mode in [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#).

Step Four: Command transfer to ADCs and Result data reception.

When an external rising edge event occurs for CFIFO1, the EQADC automatically will begin transferring commands from CFIFO1 when it becomes the highest priority CFIFO trying to send commands to CBuffer1. The received results will be placed in RFIFO3 and then moved to RQueue1 by the DMAC.

30.7.2 EQADC/DMAC interface

This section provides an overview about the EQADC/DMAC interface and general guidelines about how the DMAC should be configured in order for it to correctly transfer data between the queues in system memory and the EQADC FIFOs.

Note

Advanced DMACs provide more functionality than the ones discussed in this section.

30.7.2.1 CQueue/CFIFO transfers

In transfers involving CQueues and CFIFOs, the DMAC moves data from a queued source to a single destination as showed in Figure 30-155. The location of the data to be moved is indicated by the source address, and the final destination for that data, by the destination address. The DMAC contains a data structure containing these addresses and other parameters used in the control of data transfers. For every DMA request issued by the EQADC, the DMAC has to be configured to transfer a single command (32-bit data) from the CQueue, pointed to by the source address, to the CFIFO push register, pointed to by the destination address. After the service of a DMA request is completed, the source address has to be updated to point to the next valid command. The destination address remains unchanged. When the last command of a queue is transferred one of the following actions is recommended. Refer to the DMAC block guide for details about how this functionality is supported.

- The corresponding DMA channel should be disabled. This might be desirable for CFIFOs in single scan mode.
- The source address should be updated to pointed to a valid command which can be the first command in the queue that has just been transferred (cyclic queue), or the first command of any other CQueue. This is desirable for CFIFOs in continuous scan mode, and at some cases, for CFIFOs in single scan mode.

Figure 30-155. CQueue/CFIFO interface

30.7.2.2 RQueue/RFIFO transfers

In transfers involving RQueues and RFIFOs, the DMAC moves data from a single source to a queue destination as showed in [Figure 30-156](#). The location of the data to be moved is indicated by the source address, and the final destination for that data, by the destination address. For every DMA request issued by the EQADC, the DMAC has to be configured to transfer a single result (16-bit data), pointed to by the source address, from the RFIFO pop register to the RQueue, pointed to by the destination address. After the service of a DMA request is completed, the destination address has to be updated to point to the location where the next 16-bit result will be stored. The source address remains unchanged. When the last expected result is written to the RQueue, one of the following actions is recommended. Refer to the DMAC block guide for details about how this functionality is supported.

- The corresponding DMA channel should be disabled.
- The destination address should be updated pointed to the next location where new coming results are stored, which can be the first entry of the current RQueue (cyclic queue), or the beginning of a new RQueue.

Figure 30-156. RQueue/RFIFO Interface

30.7.3 Sending immediate command setup example

In the EQADC, there is no immediate command register for sending a command immediately after writing to that register. However, a CFIFO can be configured to perform the same function as an immediate command register. The following steps illustrate how to configure CFIFO5 as an immediate command CFIFO. The results will be returned to RFIFO5.

1. Configure [EQADC Interrupt and DMA Control Register 0 \(EQADC_IDCR0\)](#).
 - Clear CFIFO Fill Enable5 (CFFE5 = 0) in EQADC_IDCR2.
 - Clear CFIFO Underflow Interrupt Enable5 (CFUIE5 = 0) in EQADC_IDCR2.
 - Clear RFDS5 to configure the EQADC to generate interrupt requests to pop result data from RFIFO5.
 - Set RFIFO Drain Enable5 (RFDE5 = 1) in EQADC_IDCR2.
2. Configure [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#).
 - Write "1" to CFINV5 in EQADC_FCR2. This will invalidate the contents of CFIFO5.
 - Set MODE5 to Continuous-Scan Software Trigger mode in EQADC_CFCR2.
3. To transfer a command, write it to EQADC CFIFO Push Register 5 (EQADC_CFPR5) with Message Tag = 0b0101. See [EQADC CFIFO Push Register \(EQADC_CFPRn\)](#).
4. Up to four commands can be queued in CFIFO5. Check the CFCTR5 status in EQADC_FISR5 before pushing another command to avoid overflowing the CFIFO. See [EQADC FIFO and Interrupt Status Register \(EQADC_FISRn\)](#).
5. When the EQADC receives a conversion result for RFIFO5, it generates an interrupt request. RFIFO Pop Register 5 (EQADC_RFPR5) can be popped to read the result. See [EQADC Result FIFO Pop Register \(EQADC_RFPRn\)](#).

30.7.4 Modifying queues

More CQueues may be needed than the six supported by the EQADC. These additional CQueues can be supported by interrupting command transfers from a configured CFIFO, even if it is TRIGGERED and transferring, modifying the corresponding CQueue in the RAM or associating another CQueue to it, and restarting the CFIFO. More details on disabling a CFIFO are described in [Disabled Mode](#).

1. Determine the resumption conditions when later resuming the scan of the CQueue at the point before it was modified.
 - Change MODEx in [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#) to Disabled. See [Disabled Mode](#) for a description of what happens when MODEx is changed to Disabled.

- Poll CFSx until it becomes IDLE in [EQADC CFIFO Status Register \(EQADC_CFSR\)](#).
 - Read and save TC_CFx in [EQADC CFIFO Transfer Counter Register 0 \(EQADC_CFTCR0\)](#) for later resuming the scan of the queue. The TC_CFx provides the point of resumption.
 - Since all result data may not have been stored in the appropriate RFIFO at the time MODEx is changed to disable, wait for all expected results to be stored in the RFIFO/RQueue before reconfiguring the DMAC to work with the modified RQueue. The number of results that must return can be estimated from the TC_CFx value obtained above.
2. Disable the DMAC from responding to the DMA request generated by CFFFx and RFDFx in [EQADC FIFO and Interrupt Status Register \(EQADC_FISRn\)](#).
 3. Write "0x0000" to the TC_CFx field.
 4. Load the new configuration and conversion commands into RAM. Configure the DMAC to support the new CQueue/RQueue, but do not configure it yet to respond to DMA requests from CFIFOx/RFIFOx.
 5. If necessary, modify [EQADC Interrupt and DMA Control Register 0 \(EQADC_IDCR0\)](#) to suit the modified CQueue.
 6. Write "1" to CFINVx in [EQADC CFIFO Control Register 0 \(EQADC_CFCR0\)](#) to invalidate the entries of CFIFOx. Perform any other modifications to EQADC_CFCR except changing MODEx from Disabled.
 7. Configure the DMAC to respond to DMA requests generated by CFFFx and RFDFx.
 8. Change MODEx to the modified CFIFO operation mode. Write "1" to SSEx to trigger CFIFOx if MODEx is software trigger.

30.7.5 CQueue and RQueues usage

[Figure 30-157](#) is an example of CQueue and RQueue usage. It shows the CQueue0 commands requesting results that will be stored in RQueue0 and RQueue1, and CQueue1 commands requesting results that will be stored only in RQueue1. Some Command Messages request data to be returned from the on-chip ADC, but some only configure them and do not request returning data. When a CQueue contains both write and read commands like CQueue0, the CQueue and RQueue entries will not be aligned; as shown in [Figure 30-157](#), the result for the second command of CQueue0 is the first entry of RQueue0. The figure also shows that CQueue and RQueue entries can also become

unaligned even if all commands in a CQueue request data as CQueue1. CQueue1 entries became unaligned to RQueue1 entries because a result requested by the forth CQueue0 command was sent to RQueue1. This happens because the system can be configured so that several CQueues can have its results sent to a single RQueue.

Figure 30-157. EQADC Command and Result Queues

30.7.6 ADC Result Calibration

The ADC result calibration process consists of two steps: determining the gain and offset calibration constants, and calibrating the raw results generated by the on-chip ADCs by solving the following equation discussed in [ADC calibration feature](#).

$$\text{CAL\_RES} = \text{GCC} * \text{RAW\_RES} + \text{OCC} + 2$$

Figure 30-158. Equation for CAL_RES

The calibration constants GCC and OCC can be calculated from equation [Figure 30-159](#), [Figure 30-160](#), and [Figure 30-161](#) provided that two pairs of expected (CAL_RES) and measured (RAW_RES) result values are available for two different input voltages. Most likely calibration points to be used are 25% VREF⁷ and 75% VREF since they are far apart but not too close to the end points of the full input voltage range. This allows for calculations of more representative calibration constants. The EQADC provides these voltages via channel numbers 43 and 44. The raw, uncalibrated results for these input voltages are obtained by converting these channels with conversion commands that have the CAL bit negated.

The transfer equations for when sampling these reference voltages are:

$$\text{CAL\_RES}_{75\% \text{VREF}} = \text{GCC} * \text{RAW\_RES}_{75\% \text{VREF}} + \text{OCC} + 2;$$

$$\text{CAL\_RES}_{25\% \text{VREF}} = \text{GCC} * \text{RAW\_RES}_{25\% \text{VREF}} + \text{OCC} + 2;$$

Thus;

$$\text{GCC} = (\text{CAL\_RES}_{75\% \text{VREF}} - \text{CAL\_RES}_{25\% \text{VREF}}) / (\text{RAW\_RES}_{75\% \text{VREF}} - \text{RAW\_RES}_{25\% \text{VREF}})$$

Figure 30-159. Equation for GCC

$$\text{OCC} = \text{CAL\_RES}_{75\% \text{VREF}} - \text{GCC} * \text{RAW\_RES}_{75\% \text{VREF}} - 2$$

Figure 30-160. Equation for OCC, form 1

or

$$\text{OCC} = \text{CAL\_RES}_{25\% \text{VREF}} - \text{GCC} * \text{RAW\_RES}_{25\% \text{VREF}} - 2$$

Figure 30-161. Equation for OCC, form 2

After being calculated, the GCC and OCC values must be written to ADC registers: [ADC0/1 Gain Calibration Constant Registers \(ADC0_GCCR and ADC1_GCCR\)](#) and [ADC0/1 Offset Calibration Constant Registers \(ADC0_OCCR and ADC1_OCCR\)](#) using write configuration commands.

7. VREF=VRH-VRL

The EQADC will automatically calibrate the results, according to equation [Figure 30-158](#), of every conversion command that has its CAL bit asserted using the GCC and OCC values stored in the ADC calibration registers.

30.7.6.1 MAC configuration procedure

The following steps illustrate how to configure the calibration hardware, namely, determining the values of the gain and offset calibration constants, and the writing of these constants to the calibration registers. The procedure below should be performed for ADC0 and for ADC1.

1. Convert channel 44 with a command that has its CAL bit negated and obtain the raw, uncalibrated result for 25%VREF (RAW_RES_{25%VREF}).
2. Convert channel 43 with a command that has its CAL bit negated and obtain the raw, uncalibrated result for 75%VREF (RAW_RES_{75%VREF}).
3. Since the expected values for the conversion of these voltages are known (CAL_RES_{25%VREF} and CAL_RES_{75%VREF}), GCC and OCC values can be calculated from [Figure 30-159](#) and [Figure 30-160](#) using these values, and the ones determined in steps 1 and 2.
4. Reformat GCC and OCC to the proper data formats as specified in [MAC unit and operand data format](#). GCC is an unsigned 15-bit fixed point value and OCC is a signed 14-bit value.
5. Write GCC value to [ADC0/1 Gain Calibration Constant Registers \(ADC0_GCCR and ADC1_GCCR\)](#), and OCC value to [ADC0/1 Offset Calibration Constant Registers \(ADC0_OCCR and ADC1_OCCR\)](#) using write configuration commands.

30.7.6.2 Example

The raw results obtained when sampling reference voltages 25%VREF and 75%VREF were, respectively, 3798 and 11592. The results that should have been obtained from the conversion of these reference voltages are, respectively, 4096 and 12288. Therefore, using equations [Figure 30-159](#) and [Figure 30-160](#), the gain and offset calibration constants are:

$$GCC = (12288 - 4096) / (11592 - 3798) = 1.05106492 \rightarrow 1.05102539 = 0x4344$$

$$OCC = 12288 - 1.05106492 * 11592 - 2 = 102.06 \rightarrow 102 = 0x0066$$

[Table 30-146](#) shows, for this particular case, examples of how the result values change according to GCC and OCC when result calibration is executed (CAL=1) and when it is not (CAL=0).

Table 30-146. Calibration example

Input voltage	Raw result (CAL=0)		Calibrated result (CAL=1)	
	Hexadecimal	Decimal	Hexadecimal	Decimal
25% VREF	0x0ED6	3798	0x1000	4095.794
75% VREF	0x2D48	11592	0x3000	12287.486

30.7.6.3 Quantization error reduction during calibration

[Figure 30-162](#) shows how the ADC transfer curve changes due to the addition of two to the MAC output during the calibration - see MAC output equation at [Overview](#) . The maximum absolute quantization error is reduced by half leading to an increase in accuracy.

Figure 30-162. Quantization error reduction during calibration

30.7.7 EQADC versus QADC

This section describes how the EQADC upgrades the QADC functionality. The section also provides a comparison between the EQADC and QADC in terms of their functionality. This section targets the users familiar with terminology in QADC. [Figure 30-163](#) is an overview of a QADC. [Figure 30-164](#) is an overview of the EQADC system.

Figure 30-163. QADC overview

Figure 30-164. EQADC system overview

The EQADC system consists of queues in RAM, an external device, the EQADC, and on-chip ADCs. As compared with the QADC, the EQADC system requires extra hardware.

- A DMA or an MCU is required to move data between the EQADC's FIFOs and Queues in the system memory.

Since there are only FIFOs inside the EQADC, much of the terminology or use of the register names, register contents, and signals of the EQADC involve "FIFO" instead of "Queue". These register names, register contents, and signals are functionally equivalent to the "Queue" counterparts in the QADC. [Table 30-147](#) lists how the EQADC register, register contents, and signals are related to QADC.

Table 30-147. Terminology comparison between QADC and EQADC

QADC terminology	EQADC terminology	Function
CCW	Command Message	In the QADC, the hardware only executes conversion command words. In the EQADC, not all commands are conversion commands; some are configuration commands.
Queue Trigger	CFIFO Trigger	In the QADC, a trigger event is required to start the execution of a queue. In the EQADC, a trigger event is required to start command transfers from a CFIFO. When a CFIFO is TRIGGERED and transferring, commands are continuously moved from CQueues to CFIFOs. Thus, the trigger event initiates the "execution of a queue" indirectly.
Current Word Pointer Queue x (CWPQx)	Counter Value of Commands Transferred from Command FIFOx (TC_CFx)	In the QADC, CWPQx allows the last executed command on queue x to be determined. In the EQADC, the TC_CFx value allows the last transferred command on CQueue x to be determined.
Queue Pause Bit (P)	CFIFO Pause Bit	In the QADC, detecting a pause bit in the CCW will pause the queue execution. In the EQADC, detecting a pause bit in the Command will pause command transfers from a CFIFO.
Queue Operation Mode (MQx)	CFIFO Operation Mode (MODEx)	The EQADC supports all queue operation modes in the QADC except operation modes related to a periodic timer. A timer elsewhere in the system can provide the same functionality if it is connected to ETRIGx.
Queue Status (QS)	CFIFO Status (CFSx)	In the QADC, the Queue Status is read to check whether a queue is idle, active, paused, suspended, or trigger pending. In the EQADC, the CFIFO Status is read to check whether a queue is IDLE, WAITING FOR TRIGGER (idle or paused in QADC), or TRIGGERED (suspended or trigger pending in QADC). What CFIFO is currently "active" can be determined by reading the LCFTCBn field on the EQADC_CFSSR registers.

The EQADC and QADC also have similar procedures for the configuration or execution of applications. [Table 30-148](#) shows the steps required for the QADC versus the steps required for the EQADC system.

Table 30-148. Usage comparison between QADC and EQADC system

Procedure	QADC	EQADC System
Analog Control Configuration	Configure analog device by writing to the QADC registers.	Program configuration commands into command queues.
Prepare Scan Sequence	Program scan commands into command queues.	Program scan commands into command queues.
Queue Control Configuration	Write to the QADC Control Registers.	Write to the EQADC Control Registers.

Table continues on the next page...

Table 30-148. Usage comparison between QADC and EQADC system (continued)

Procedure	QADC	EQADC System
Data Transferred between Queues and Buffers	Not Required.	Program the DMAC or the CPU to handle the data transfer.
Queue Execution	Require Software or External Trigger events to start queue execution.	Require Software or External Trigger events to start command transfers from a CFIFO.

Chapter 31

Decimation Filter (DECFILTER)

31.1 Chip-specific DECFILTER information

This chip has 12 instances of the DECFILTER module.

31.1.1 DECFILTER instance interconnections

The instances of the DECFILTER module on this chip are interconnected.

31.1.1.1 DECFILTER connections for Cascade mode

The DECFILTER module instances on this chip can be configured to work in the Cascade mode of operation to obtain a more complex filtering function. The output result of a filter block is connected to the input of the next filter by means of a dedicated interface. The following table shows the instance connections.

Table 31-1. DECFILTER instance interconnections for Cascade mode

Cascade output from	Cascade input to
DECFILTER_A	DECFILTER_B
DECFILTER_B	DECFILTER_C
DECFILTER_C	DECFILTER_D
DECFILTER_D	DECFILTER_E
DECFILTER_E	DECFILTER_F
DECFILTER_F	DECFILTER_G
DECFILTER_G	DECFILTER_H
DECFILTER_H	DECFILTER_I
DECFILTER_I	DECFILTER_J
DECFILTER_J	DECFILTER_K
DECFILTER_K	DECFILTER_L
DECFILTER_L	DECFILTER_A

31.1.1.2 Stopping clock to DECFILTER instances

On this chip, the clock input can be stopped to all DECFILTER module instances collectively or to individual DECFILTER module instances. The following table summarizes the options.

Table 31-2. DECFILTER options to stop clock

Option	Program to 1	Note
Stop clock to all DECFILTER instances at once	SIU_HLT1[DECFIL]	The clock is stopped after all DECFILTER instances acknowledge the halt request.
Stop clock to individual DECFILTER instance	DECFILTER_MCR[MDIS]	—

31.1.2 DECFILTER connections to other modules

The DECFILTER module instances on this chip interact with the EQADC and eTPU modules.

31.1.2.1 DECFILTER connections with EQADCs

For information about DECFILTER connections with the EQADC modules, see:

- [Analog Modules Overview](#)
- [EQADC connections to other modules](#)
- [Routing conversion results to REACM2 and DECFILTER modules](#)

On this chip, the parallel side interfaces (PSIs) of the DECFILTER modules are connected to the EQADC modules:

- PSI0 inputs of all DECFILTER instances are connected to EQADC_A.
- PSI1 inputs of all DECFILTER instances are connected to EQADC_B.

31.1.2.2 DECFILTER connections with eTPUs

On this chip, select channels from eTPU module instances function as the Zero, Integrate, and Read inputs to the integrators of DECFILTER module instances. For a given DECFILTER integrator, one eTPU channel is routed to all three of the Zero, Integrate, and Read inputs.

In the SIU_DECFILn registers:

- Each ZSELx field selects the eTPU channel to route to the DECFILTER integrator's Zero, Integrate, and Read inputs.
- Each HSELx field selects the eTPU channel to route to the DECFILTER integrator's Halt input.

The following diagram shows the connections to DECFILTER_A as an example.

- The combined Zero, Integrate, and Read (ZIR) inputs to DECFILTER_A appear as the ZIRA signal.
- HALTA is the Halt input to DECFILTER_A.

Figure 31-1. Example: Zero, Integrate, and Read (ZIR) and Halt connections between eTPU_A and DECFILTER_A

31.2 Introduction

This chapter describes the Decimation Filter block.

31.2.1 Overview

The decimation filter is a dedicated hardware block, designed to decimate fixed point sample conversion results, generated by a master block such as an Analog to Digital Converter (eQADC). Two dedicated parallel side interfaces (PSI0 and PSI1) provide bi-directional communication between two master blocks and the filter. A third interface is provided for use by the CPU, allowing setup of the filter parameters and read/write of the configuration registers and filter samples.

The Decimation Filter receives data samples from the master blocks (eQADCs) in the PSI RX sub-block. Each sample arrives at the decimation filter with an identifier tag and associated commands. The input information is decoded by the PSI RX and control logic sub-blocks. When receiving a filtering command, the data is transferred to the filter tap register's sub-block and is processed by the filter using the MAC (Multiply and Accumulate) unit, the coefficient register, and the control logic sub-blocks. The result is then returned to the master block by the PSI TX sub-block, accompanied by the corresponding tag information that provides an address for the data.

To summarize normal mode, the decimation filter works as a slave block on the third slave-bus line, and there are up to two PSI master blocks such as the ADC to send and read data. This is illustrated in the application example in [Application Information](#).

Note

The normal use is to receive the data stream from one specific PSI and transmit the results using one specific PSI. Input and output timing care is necessary if data is received from both PSI and output results are sent to both PSI alternately.

The decimation filter can also function in a standalone mode. In this mode, the input data is supplied and the output results are read by the chip core processor (CPU) using status and interrupt signals or DMA requests.

Mixed modes are also provided, allowing input data fed from the PSI interfaces, and output results read by the CPU or DMA, or input fed from CPU or DMA and output directed to a selected PSI interface.

An integrator unit independently accumulates the values of filter outputs. The integration can be restricted to time windows defined by hardware signals or software.

Two or more decimation filter blocks can also be configured to work in the cascade mode of operation to obtain a more complex filtering function. The output result of a filter block is connected to the input of the next filter by means of a dedicated interface.

All signals in the interface are generated in the system clock domain.

[Figure 31-2](#) shows the block diagram for the decimation filter.

31.2.2 Features

The Decimation Filter block includes these distinctive features:

- Selectable 4th order IIR filter, or an 8th order FIR filter
 - Input/output with 16-bit (fixed point) two's complement signed values
 - Internal taps with 16-bit (feed-forward portion of first IIR) and 24-bit (feedback portion) resolutions (fixed point) for two's complement signed value
 - 24-bit programmable filter coefficients (fixed point) for two's complement signed value
 - MAC unit with 51-bit fixed point accumulator
 - Convergent rounding methodology
 - Two's complement overflow or saturation selection
 - 58 clock cycles to process the input
- Implements two local slave-bus interface to two master blocks (e.g. the eQADC blocks)
- Input and output buffers with DMA capability
- Slave-bus interface to device
- Filter taps access for debug
- Filter initialization (flush) and stabilization (prefill) commands
- Timestamp support
- Decimation controlled by an internal counter or from an on-chip independent trigger signal (triggered output result).
- Integrator unit accumulates filter output values, signaled or absolute, with 32-bit resolution. The integrator can be controlled by software or hardware signals.
- Cascade of two or more individual blocks to compose a more complex filter.

31.2.3 Modes of operation

This section describes the operation modes of the Decimation Filter. The modes are selected using the following DECFILTER_MCR register fields: MDIS, FREN, FRZ, ISEL, MIXM, and CASCD (see [Module Configuration Register \(DECFILTER_MCR\)](#)).

The mode selection is summarized in the following table.

Table 31-3. Operation Mode Selection

Mode	MDIS	FREN, FRZ	ISEL	MIXM	CASCD
Normal	0	(0, 0)	0	0	00
Standalone		or	1	0	
PSI ¹ Input Mixed		(0, 1)	0	1	
PSI Output Mixed		or	1	1	
Cascade		(1, 0)	0 or 1	0	01 or 10 or 11
Freeze ²		1, 1	X	X	X
Low Power	1	X	X	X	X
Reserved	All other combinations				

1. The physical input / output can be PSI0 or PSI1.

2. Freeze mode can also be activated from outside the Decimation Filter, depending on the MCU, if FREN=1.

31.2.3.1 Normal mode

This is the default operational mode of the decimation filter block. It corresponds to the prefill/filter operation with input data supplied through any of the two PSI slave-bus interfaces (i.e. its input data is the ADC conversion result), with output going to the same or to the other PSI interface.

31.2.3.2 Standalone mode

Standalone mode differs from normal mode because the input data is not supplied by the master blocks through the PSI interfaces. Data is provided by the central processor using the device slave-bus interface or DMA interface signals. Once the data is filtered the decimated result is available in the Output Buffer register. The filter output is also consumed by a CPU or DMA mastering the same device slave-bus interface. This operation mode can be used to debug the filter stability or to decimate data in System RAM.

31.2.3.3 PSI Input Mixed mode

In this mode the input is selected from any of the two PSI slave-bus interfaces, but the output is directed to the device slave-bus interface, where it can be read by the CPU or DMA.

31.2.3.4 PSI Output Mixed mode

This mode works inverted from the PSI Input Mixed Mode: the input is selected from the deviceslave-bus interface, fed either by the CPU or DMA, and the output is directed to one of the two PSI slave-bus interfaces. If an eQADC is connected to one PSI interface, the output is directed to an RFIFO selected by the tag field in the DECFILTER_IB register (see [Interface Input Buffer \(DECFILTER_IB\)](#)).

31.2.3.5 Cascade mode

Cascade mode is a filter structure mode with two or more individual filter blocks connected in a chain to form a more complex filter function. The output result of the first block (head block) is connected to the input of the next block (middle or tail block) to be filtered again. More details in [Cascade mode description](#).

31.2.3.6 Low Power mode

Low power mode corresponds to the module disable mode or stop mode. In the module disable mode the two PSI slave-bus lines are disabled and it is not possible to enter Freeze mode. The system clock is stopped. In stop mode, the system clock is also stopped.

31.2.3.7 Freeze mode

Freeze mode is also known as debug mode. All filter action is frozen, either through software or by the hardware SoC debug request signal. If a freeze request comes when the filter is processing an input, it enters freeze mode only after the processing finishes.

31.3 External signal description

Note

The Decimation Filter does not provide metastability protection or filtering for these signals.

31.3.1 Decimation trigger signal

The decimation trigger signal is used to control the output of the decimation filter, allowing decimation to be driven externally. For more details, see [Triggered Output Result Description](#).

31.3.2 Integrator enable signal

The integrator enable signal is used to enable the hardware integrator. For more details, see [Integrator Enabling and Halting](#).

31.3.3 Integrator halt signal

The integrator halt signal is used to halt the hardware integrator. For more details, see [Integrator Enabling and Halting](#).

31.3.4 Integrator reset signal

The integrator reset signal is used to reset the hardware integrator. For more details, see [Integrator Reset](#).

31.3.5 Integrator output request signal

The integrator output request signal is used to update the integrator output result. For more details, see [Integrator Outputs](#).

31.4 Memory map and register definition

This section provides the memory maps and detailed descriptions of all registers. Accesses to reserved areas of the memory map can return a bus error.

This module communicates with three distinct slave-bus lines. One is related to the device integration and the two others are related to the PSI master blocks for data transfers. Below both memory maps are described.

The addresses of the Decimation Filter registers are specified as offsets from the module's base address, described in the following table. The registers allocated in this memory map are sufficient for a 4th order IIR filter implementation.

All registers are 32-bit wide.

NOTE

Reserved fields in the registers should not be written.

DECFILTER memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (DECFILTER_MCR)	32	R/W	See section	31.4.1/1284

31.4.1 Module Configuration Register (DECFILTER_MCR)

The Decimation Filter module configuration register provides configuration control bits for the Decimation Filter internal logic.

NOTE

One must not modify this register contents when the status bit BSY is set, except for fields FREN, FRZ, and IDIS. To guarantee that BSY does not set during the read-modify-write operation, set IDIS=1 and wait for BSY=0 beforehand.

The following table describes the device interface behavior determined by the combination of ISEL and MIXM bits of this register.

Table 31-6. ISEL/MIXM Definition — Read/Write from/to Input/Output Buffers

I S E L	MIX M	Mode	Operation	Devicelave-bus Interface		PSI slave-bus interfaces	
				Input Buffer	Output Buffer	Input Buffer	Output Buffer

Table continues on the next page...

Table 31-6. ISEL/MIXM Definition — Read/Write from/to Input/Output Buffers (continued)

I S E L	MIX M	Mode	Operation	Device slave-bus Interface		PSI slave-bus interfaces	
0	0	Normal	Read	Always, by DMA or interrupt ¹ request if EDME=1	Always, no DMA or interrupt	forbidden, write only	By decfil request ²
	1	PSI Input Mixed			Always, issues DMA or interrupt ¹		Disabled
	0	Normal	Write	Forbidden	no effect, read only	Enabled	(read only)
	1	PSI Input Mixed					
1	0	Standalone	Read	Always, no DMA or interrupt	Always, issues DMA or interrupt ¹	forbidden, write only	Disabled
	1	PSI Output Mixed			Always, no DMA or interrupt		By decfil request ²
	0	Standalone	Write	Enabled, by DMA or interrupt request ¹	no effect, read only	Forbidden	read only
	1	PSI Output Mixed					

1. bit DSEL selects between interrupt or DMA request
2. Decimation filter issues a read request to the master block

NOTE

ISEL completely selects the output when the filter is configured as cascade tail, and is ignored when it is configured as cascade middle.

ISEL must not be modified during the filter operation (when the status bit BSY is set). In addition, the interface not selected by ISEL must not be used to write into the input buffer.

DECFILTER_MCR field descriptions

Field	Description
0 MDIS	Module Disable The MDIS bit puts the Decimation Filter in low power mode. Communication through the two PSI slave-bus Interfaces are ignored in this mode. Writes to the configuration register are allowed with the exception of writes to the FREN and SRES bits, which are ignored. Writes to the Coefficient registers are also allowed. The Decimation Filter cannot enter Freeze mode once in disable mode. Once the module is disabled it no longer receives the system clock. 0 Normal Mode 1 Low Power Mode
1 FREN	Freeze Enable The FREN bit enables the Decimation Filter to enter freeze mode if the SoC debug request signal or the FRZ bit is asserted. See Freeze Mode Description for more details. 0 Decimation Filter Freeze mode disabled 1 Decimation Filter Freeze mode enabled
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 FRZ	Freeze Mode The FRZ bit controls the freeze mode of the Decimation Filter. For this bit to take effect the FREN freeze enable bit also needs to be asserted. While in freeze mode the MAC operations are halted. See Freeze Mode Description for more details. 0 Decimation Filter in Normal Mode 1 Decimation Filter in Freeze Mode
4 SRES	Software-reset bit The SRES is a self-negated bit which provides the CPU with the capability to initialize the Decimation Filter through the slave-bus interface. This bit always reads as zero. See Soft-Reset Command Description for more details. 0 No action 1 Software-Reset
5–6 CASCD	Cascade Mode Configuration The CASCD[1:0] bit field configures the block to work in cascade mode of operation. For more details about the cascade mode, see Cascade mode description.

Table continues on the next page...

DECFILTER_MCR field descriptions (continued)

Field	Description
	NOTE: Any change to this field must follow the procedure described in Cascade Freeze, Stop, and Configuration Change Procedures. 00 No cascade mode (single block) 01 Cascade Mode, Head block config. 10 Cascade Mode, Tail block config. 11 Cascade Mode, Middle block config.
7 IDEN	Input Data Interrupt Enable The IDEN bit enables the Decimation Filter to generate interrupt requests on all new input data written to the Interface Input Buffer register or Input/Output Buffers register. 0 Input Data Interrupt Disabled 1 Input Data Interrupt Enabled
8 ODEN	Output Data Interrupt Enable The ODEN bit enables the Decimation Filter to generate interrupt requests on all new data written to the filter Output buffer. It is independent of how ISEL and MIXM are set. 0 Output Data Interrupt Disabled 1 Output Data Interrupt Enabled
9 ERREN	Error Interrupt Enable The ERREN bit enables the Decimation Filter to generate interrupt requests based on the assertion of the DECFILTER_MSR register error flags OVF, DIVR, SVR, OVR, or IVR. 0 Error Interrupts Disabled 1 Error Interrupts Enabled
10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–12 FTYPE	Filter Type Selection bits The FTYPE[1:0] bits select the filter type. NOTE: Bypass must not be configured in cascade mode (see field CASCD). 00 Filter Bypass In Bypass configuration the filter is disabled. 01 IIR Filter - 1 x 4th order 10 FIR Filter - 1 x 8th order 11 reserved
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 SCAL	Filter Scaling Factor The SCAL[1:0] bit field selects the scaling factor used by the filter algorithm. 00 Scaling Factor = 1 01 Scaling Factor = 4 10 Scaling Factor = 8 11 Scaling Factor = 16

Table continues on the next page...

DECFILTER_MCR field descriptions (continued)

Field	Description
16 IDIS	Input Disable The IDIS bit disables the block input, so that writes to the input buffer have no effect (either from the device slave-bus or from the two PSI interfaces), and input DMA or interrupt requests are not issued. Input disabling is needed to change the block configuration to or from cascade mode. See Saturation for more details. NOTE: IDIS resets in 1 (hardware reset only), and the module configuration procedures for previous versions (without IDIS bit) are upward compatible provided that the DECFILTER_MCR register is written with 0 into the IDIS position (previously reserved). 0 Input enabled 1 Input disabled
17 SAT	Saturation Enable The SAT bit enables the saturation of the filter output. See Saturation for more details. 0 Disables Saturation 1 Enable Saturation
18 ISEL	Input Selection The ISEL bit selects the source of input data to the Filter. Possible data sources are the master block (eQADC) of any PSI slave-bus interface, or the CPU/DMA on the device slave-bus interface. Each device slave-bus write to the Interface Input Buffer register or DMA transfer to the input buffer is interpreted as a new sample to be processed by the filter. The output interface used is the same as the one selected by ISEL if the output selection bit MIXM=0. When MIXM=1, the output selection (slave-bus or device slave-bus) is contrary to the input selection (see ISEL/MIXM Definition table and the MIXM bit definition), configuring a mixed mode operation. The slave-bus interface can always read the input/output buffers, however the PSI slave-bus interfaces can only read the output buffer by request of the decimation filter, in normal or input mixed modes. This behaviour is outlined in detail in Table 31-6 NOTE: There is no configuration register to select between the two PSI interfaces as the active one. Both are active when ISEL=0. 0 Filter input from any of the two PSI slave-bus interfaces 1 Filter input from the device slave-bus interface
19 MIXM	Mixed Mode The MIXM field selects the interface used for filter output, either device slave-bus or the PSI slave-bus, in relation to the interface selected by ISEL (see ISEL bit definition and ISEL/MIXM Definition table for more details). NOTE: MIXM must be set to 0 (zero) when the filter is configured as cascade mode. 0 Interface selected by ISEL is used for output, configuring normal or standalone mode 1 Interface NOT selected by ISEL is used for output, configuring mixed mode.
20–23 DEC_RATE	Decimation Rate Selection The DEC_RATE[3:0] field selects the decimation rate used by the Decimation Filter. The decimation rate defines the number of data samples from the master block that is required to generate one decimated result in the Decimation Filter output. 0000 No Decimation: one filter output for each sample input 0001 - 1111 One filter output for each (DEC_RATE+1) sample inputs

Table continues on the next page...

DECFILTER_MCR field descriptions (continued)

Field	Description
24 SDIE	Integrator Data Interrupt Enable The SDIE field enables output buffer interrupts due to integrator data result being ready (at registers DECFILTER_FINTVAL and DECFILTER_FINTCNT): 0 Integration ready does not cause an output interrupt. 1 Integration ready causes an output interrupt
25 DSEL	DMA Selection The DSEL bit determines whether the data transfers — to the input buffer (write to) and from the output buffer (read from) — are performed by DMA requests or by interrupt requests. This bit can also be active when PSI inputs are selected with Enhanced Debug (ISEL=0, EDME=1), in which case the input buffer generates read requests only (see Enhanced Debug Monitor Description). 0 Interrupt requests are generated 1 DMA requests are generated
26 IBIE	Input Buffer Interrupt Request Enable The IBIE bit enables the Decimation Filter to generate interrupt requests when: • device slave-bus input is selected (ISEL=1) and DSEL=0 when the input buffer is available to receive new data; • PSI inputs are selected with Enhanced debug (ISEL=0, EDME=1) and DSEL=0 when the input buffer has data to be read by the device CPU. 0 Input Buffer Interrupt Request Disabled 1 Input Buffer Interrupt Request Enabled
27 OBIE	Output Buffer Interrupt Request Enable The OBIE bit enables the Decimation Filter interrupt requests when outputs are directed to the device slave-bus (ISEL != MIXM) and DMA is not selected (DSEL=0). 0 Output Buffer Interrupt Request Disabled 1 Output Buffer Interrupt Request Enabled
28 EDME	Enhanced Debug Monitor Enable The EDME bit defines the enhanced debug monitor when input selection is from any PSI (ISEL=0). In this case, the raw data fed from the PSI Master blocks is also, in parallel, made available in the register DECFILTER_EDID (see Enhanced Debug Monitor Description), generating an input interrupt or DMA request. 0 Enhanced debug monitor enabled (read requests of input data from master block enabled) 1 Enhanced debug monitor disabled
29 TORE	Triggered Output Result Enable The TORE bit enables an input trigger signal to force the decimation filter to send the next result of the filter back to the master block. For more details, see Triggered Output Result Description. NOTE: TORE must only be asserted when PSI is selected as output (normal or PSI output mixed modes). TORE must not be asserted with the filter bypassed (FTYPE=00). 0 Output buffer update using an external signal is disabled 1 Output buffer update using an external signal is enabled

Table continues on the next page...

DECFILTER_MCR field descriptions (continued)

Field	Description
30–31 TMODE	Trigger Mode The TMODE field selects the way the trigger signal controls the output result sampling function enabled by the TORE bit. NOTE: The TMODE definition replaces, and is upward compatible with, the TRFE bit definition found in previous versions of the Decimation Filter. 00 output is posted at the rising edge of the trigger signal 01 output is posted whenever the trigger signal is a logical 0 10 output is posted at the falling edge of the trigger signal 11 output is posted whenever the trigger signal is a logical 1

1. bit DSEL selects between interrupt or DMA request
2. Decimation filter issues a read request to the master block

31.4.2 Module Status Register (DECFILTER_MSR)

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	BSY	0	DEC_COUNTER				0	0	0	0	0	0	0	0	0	0
W							IDFC	ODFC		IBIC	OBIC		DIVRC	OVFC	OVRC	IVRC
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0						IDF	ODF	0	IBIF	OBIF	0	DIVR	OVF	OVR	IVR

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DECFILTER_MSR field descriptions

Field	Description
0 BSY	Decimation Filter Busy indication

Table continues on the next page...

DECFILTER_MSR field descriptions (continued)

Field	Description
	The BSY bit indicates that the Decimation Filter is processing new input data from the master block in normal mode or from the device core in standalone mode. BSY is not asserted when the filter is disabled (FTYPE = 00). However, the BSY bit is asserted when the soft reset is executed. 0 Decimation Filter Idle 1 Decimation Filter Busy
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–5 DEC_COUNTER	Decimation Counter The DEC_COUNTER[3:0] field indicates the current value of the DEC_COUNTER Decimation Counter (see Figure 31-2), which counts the number of input data samples received by the Decimation Filter. When the value of this counter matches the DEC_RATE[3:0] Configuration Register field, one decimated result is generated and the DEC_COUNTER counter is re-initialized at zero. This register is cleared by a soft reset or a flush command.
6 IDFC	Input Data Flag Clear bit The IDFC bit clears the IDF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears IDF
7 ODFC	Output Data Flag Clear bit The ODFC bit clears the ODF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears ODF
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 IBIC	Input Buffer Interrupt Request Clear bit The IBIC bit clears the IBIF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears IBIF
10 OBIC	Output Buffer Interrupt Request Clear bit The OBIC bit clears the OBIF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears OBIF
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 DIVRC	DIVR Clear bit The DIVRC bit clears the DIVR Debug Filter Input Data Read Overrun indication bit in the Status Register. This bit is self negated, therefore it is always read as zero.

Table continues on the next page...

DECFILTER_MSR field descriptions (continued)

Field	Description
	0 No action 1 Clears DIVR
13 OVFC	OVF Clear bit The OVFC bit clears the OVF Output Overflow bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears OVF
14 OVRC	OVR Clear bit The OVRC bit clears the OVR Output Overrun bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears OVR
15 IVRC	IVR Clear bit The IVRC bit clears the IVR Filter Input Overrun indication bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears IVR
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 IDF	Input Data Flag The IDF bit flag indicates when new data is available at the DECFILTER_IB register or at the PSI bus data, input and output. This flag generates an Interrupt Request if enabled by the IDEN bit in the Configuration Register. This Flag is cleared by the IDFC Status bit or by a soft reset of the decimation filter. NOTE: OBS: This flag is not used for read / write requests. It is used only to announce the input data event. For read / write request flag, refer to IBIF. 0 Sample not received 1 New Sample received
23 ODF	Output Data Flag The ODF bit flag indicates when a new decimated sample is available at the DECFILTER_OB register or at the PSI bus data, input and output. This flag generates an Interrupt Request if enabled by the ODEN bit in the Configuration Register. This Flag is cleared by the ODFC Status bit or by a soft reset of the decimation filter. NOTE: OBS: This flag is not used for read requests. It is used only to announce the output data event. For read request flag, refer to OBIF. 0 No new Decimated Output Sample available 1 New Decimated Output Sample available
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DECFILTER_MSR field descriptions (continued)

Field	Description
25 IBIF	Input Buffer Interrupt Request Flag The IBIF bit flag indicates that the input buffer DECFILTER_IB is available to be filled with new data when Enhanced Debug Monitor is off. In Enhanced Debug Monitor, it indicates the input buffer DECFILTER_IB was filled with a new sample and is ready to be read. IBIF assertion also asserts the interrupt signal when enabled by the IBIE bit in the Configuration Register when DMA is not selected (DSEL=0) and the input buffer requires access from the device slave-bus (ISEL != EDME). This Flag is cleared by the IBIC Status bit or by a soft reset of the decimation filter. 0 No action 1 New Sample is requested (ISEL = 1, EDME=0) or new sample is available in Enhanced Debug Monitor (ISEL=0, EDME=1).
26 OBIF	Output Buffer Interrupt Request Flag The OBIF bit flag indicates that a new decimated sample is available at the DECFILTER_OB register. This flag generates an Interrupt Request if enabled by the OBIE bit in the Configuration Register and with ISEL != MIXM and DSEL=0. This Flag is cleared by the OBIC Status bit or by a soft reset of the decimation filter. 0 No new Decimated Output available 1 New Decimated Output available
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 DIVR	Enhanced Debug Monitor Input Data Read Overrun The DIVR bit indicates that a received sample in the Filter Interface Input Register was overwritten by a new sample and was not read by the Core. This flag generates an Interrupt Request if enabled by the ERREN bit in the Configuration Register. This Flag is cleared by the DIVRC Status bit or by a soft reset of the decimation filter. 0 Input Data Read Overrun did not occur in Enhanced Debug monitor 1 Enhanced Debug Monitor Input Data Read Overrun occurred
29 OVF	Filter Overflow Flag The OVF bit indicates that an overflow occurred in the filtered sample result. This flag generates an Interrupt Request if enabled by the ERREN bit in the Configuration Register. This Flag is cleared by the OVFC Status bit or by a soft reset of the decimation filter. 0 No overflow 1 Overflow occurred
30 OVR	Output Interface Buffer Overrun The OVR bit indicates that a decimated sample was overwritten by a new sample in the Interface Output Buffer Register. This flag generates an Interrupt Request if enabled by the ERREN bit in the Configuration Register. This Flag is cleared by the OVRC Status bit or by a soft reset of the decimation filter. 0 No Output Overrun 1 Filter Output Overrun occurred
31 IVR	Input Interface Buffer Overrun The IVR bit indicates that a received sample in the Filter Interface Input Register was overwritten by a new sample. This was probably caused by a violation of the Decimation Filter maximum throughput. This flag generates an Interrupt Request if enabled by the ERREN bit in the Configuration Register. This Flag is cleared by the IVRC Status bit or by a soft reset of the decimation filter.

Table continues on the next page...

DECFILTER_MSR field descriptions (continued)

Field	Description
	NOTE: IVR does not set due to input register writes when input is disabled (DECFILTER_MCR bit IDIS=1).
0	Input Buffer Overrun did not occur
1	Input Buffer Overrun occurred

31.4.3 Module Extended Config Register (DECFILTER_MXCR)

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R					0										0	0
W	SDMAE	SSIG	SSAT	SCSAT											SRQ	SZRO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R		0			0				0					0		
W	SISEL		SZROSEL			SHLTSEL				SRQSEL					SENSEL	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DECFILTER_MXCR field descriptions

Field	Description
0 SDMAE	Integrator DMA Enable The SDMAE bit enables the DMA request when an integrator output is requested (see Integrator Outputs). NOTE: The DMA channel used is the same one used for filter outputs, and any configuration that generates DMA requests from both of those sources is not allowed. 0 integrator DMA request disabled 1 integrator DMA request enabled
1 SSIG	Integrator Signal operation selection

Table continues on the next page...

DECFILTER_MXCR field descriptions (continued)

Field	Description
	The SSIG bit defines how the filtered data signal is treated for integration: 0 integrator input takes the absolute value of filter output 1 integrator input takes signaled filter output
2 SSAT	Integrator Saturated operation selection The SSAT bit defines how the integrator accumulator behaves in case of an overflow. NOTE: In saturated operation the overflown integration sum holds the value 0xFFFFFFFF for absolute integration (SSIG=0), or values 0x7FFFFFFF (positive saturation) and 0x80000000 (negative saturation) for signaled integration (SSIG=1). NOTE: Non-saturated mode is not supported with signaled integration, therefore one must not configure SSIG=1 and SSAT=0. 0 integrator accumulator holds a modulo 2^{17} value (considering the 15-bit fractional part) on an overflow. 1 integrator accumulator saturates on an overflow
3 SCSAT	Integrator Counter Saturated operation selection The SCSAT bit defines how the integrator sample counter behaves in case of an overflow. 0 integrator sample counter holds a modulo 2^{32} value on an overflow. 1 integrator sample counter saturates on an overflow, holding a value of 0xFFFFFFFF.
4–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 SRQ	Integrator Output Request The SRQ bit is used to command the update of the integrator output, reflected in the registers DECIFILTER_FINTVAL and DECIFILTER_FINTCNT. It may also cause a DMAor interrupt request, depending on the DECIFILTER_MCR bit SDIE and DECIFILTER_MXCR bit SDMAE. This is a write-only bit, so reads always return 0. For more details see Integrator Reset. 0 no integrator output update request 1 requests integrator output update
15 SZRO	Integrator Zero The SZRO bit is used to zero the integrator sum. This is a write-only bit, reads always return 0. For more details see Integrator Reset. NOTE: If bits SRQ and SZRO are both written 1 at the same time, the integrator is reset only after the registers DECIFILTER_FINTVAL and DECIFILTER_FINTCNT are updated. 0 does not zero integrator sum 1 zeroes integrator sum
16 SISEL	Integrator Input Selection The SISEL bit selects the input of the integrator. For more details see Integrator Inputs. 0 decimated filter outputs feed the integrator 1 filter outputs before the decimation feed the integrator
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DECFILTER_MXCR field descriptions (continued)

Field	Description
18–19 SZROSEL	Integrator Zero Control Mode Selection The SZROSEL field defines the use of the integrator zero hardware input signal. For more details see Integrator Reset. 00 hardware integrator zero request disabled 01 integrator zero on toggle of hardware signal 10 integrator zero on rising edge of hardware signal 11 integrator zero on falling edge of hardware signal
20–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 SHLTSEL	Integrator Halt Control Selection The SHLTSEL field defines the integrator halting mechanism. When the integrator is halted, the integration accumulator remains unaltered on filter outputs independently of the enabling selected by SENSEL. For more details see Integrator Enabling and Halting. 00 hardware halt control signal disabled 01 integrator halted, independently of the hardware signal 10 integrator halted when signal is at logical 0 11 integrator halted when signal is at logical 1
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–27 SRQSEL	Integrator Output Read Request Mode Selection The SRQSEL field defines the use of the integrator output request hardware input signal. An integrator output request updates the registers DECFILTER_FINTVAL and DECFILTER_FINTCNT, also causing a DMA or interrupt request. Note that DMA or interrupt requests due to integrator output updates depend on the DECFILTER_MXCR bit SDMAE and DECFILTER_MCR bit SDIE. When continuous output is on, an integrator output request is issued whenever a new filter output is accumulated. For more details see Integrator Outputs. 000 hardware output request disabled 001 integrator output request on toggle of hardware signal 010 integrator output request on rising edge of hardware signal 011 integrator output request on falling edge of hardware signal 100 reserved 101 continuous output request on, independently of hardware signal 110 continuous output request on when signal is at logical 0 111 continuous output request on when signal is at logical 1
28–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 SENSEL	Integrator Enable Control Selection The SENSEL field defines the integrator enabling mechanism. When the integrator is enabled, filter outputs selected by the SISEL bit are added to the integration accumulator. When the integrator is disabled, the integration accumulator remains unaltered on filter outputs. For more details see Integrator Enabling and Halting. 00 integrator disabled, independently of the hardware enable control signal 01 integrator enabled, independently of the hardware signal

Table continues on the next page...

DECFILTER_MXCR field descriptions (continued)

Field	Description
10	integrator enabled when signal is at logical 0
11	integrator enabled when signal is at logical 1

31.4.4 Module Extended Status Register (DECFILTER_MXSR)

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R				0				0		0	0	0	0	0	0	0
W								SDFC			SSEC	SCEC		SSOVFC	SCOVFC	SVRC
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DECFILTER_MXSR field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SDFC	Integrator Output Data Flag Clear bit The SDFC bit clears the SDF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SDF

Table continues on the next page...

DECFILTER_MXSR field descriptions (continued)

Field	Description
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 SSEC	Integrator Sum Exception Clear bit The SSEC bit clears the SSE flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SSE
11 SCEC	Integrator Count Exception Clear bit The SCEC bit clears the SCE flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SCE
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 SSOVFC	Integrator Sum Overflow Clear bit The SSOVFC bit clears the SSOVF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SSOVF
14 SCOVFC	Integrator Count Overflow Clear bit The SCOVFC bit clears the SCOVF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SCOVF
15 SVRC	SVR Clear bit The SVRC bit clears the SVR Integrator Data Overrun indication bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SVR
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 SDF	Integrator Data Flag The SDF bit flag indicates when a new integrator result is available at the DECFILTER_FINTVAL register. This flag generates an Interrupt Request if enabled by the SDIE bit in the Configuration Register. This flag is cleared by the SDFC Status bit or by a soft reset of the decimation filter. 0 no new integrator result available 1 new integrator result available
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DECFILTER_MXSR field descriptions (continued)

Field	Description
26 SSE	Integrator Sum Exception flag The SSE bit indicates an exceptional condition of the integrator accumulator. This flag generates an Interrupt Request if enabled by the DECFILTER_MCR bit ERREN, and it is cleared by the SSEC bit or by a soft reset. Integrator exceptions are defined in section "Integrator Exceptions". 0 No exception in the integrator accumulator. 1 Integrator accumulator exception.
27 SCE	Integrator Count Exception flag The SCE bit indicates an exceptional condition of the integrator counter. This flag generates an Interrupt Request if enabled by the DECFILTER_MCR bit ERREN, and it is cleared by the SSEC bit or by a soft reset. Integrator exceptions are defined in section "Integrator Exceptions". 0 No exception in the integrator counter. 1 Integrator counter exception.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 SSOVF	Integrator Sum Overflow Flag The SSOVF bit indicates an overflow of the integrator accumulator. This flag is cleared by the SSOVFC bit or by a soft reset. NOTE: The SSOVF bit samples the integrator accumulator overflow condition when and only when either registers DECFILTER_FINTVAL or DECFILTER_CINTCNT are updated. Therefore, only one of the register pairs (DECFILTER_FINTVAL/DECFILTER_FINTCNT and DECFILTER_CINTVAL/DECFILTER_CINTCNT) must be used by the application, in order to avoid races. 0 No overflow in the integrator accumulator. 1 Integrator accumulator overflow.
30 SCOVF	Integrator Count Overflow Flag The SCOVF bit flag indicates an overflow of the internal integrated sample counter. This flag is cleared by the SCOVFC bit or by a soft reset. NOTE: The SCOVF bit samples the integrator accumulator overflow condition when and only when either registers DECFILTER_FINTVAL or DECFILTER_CINTCNT are updated. Therefore, only one of the register pairs (DECFILTER_FINTVAL/DECFILTER_FINTCNT and DECFILTER_CINTVAL/DECFILTER_CINTCNT) must be used by the application, in order to avoid races. 0 No overflow in the integrator sample counter. 1 Integrator sample counter overflow.
31 SVR	Integrator Data Overrun The SVR bit indicates that an integration value and count in the registers DECFILTER_FINTVAL and DECFILTER_FINTCNT was overwritten by a new integrator output request and was not read by the CPU or DMA. This flag generates an Interrupt Request if enabled by the ERREN bit in the Configuration Register. This Flag is cleared by the SVRC bit or by a soft reset. 0 Integrator Data Overrun did not occur. 1 Integrator Data Overrun occurred.

31.4.5 Interface Input Buffer (DECFILTER_IB)

The Input Buffer Register provides access to the Input buffer of the decimation filter when the filter is in the standalone or PSI output mixed modes of operation. Writes to this register are interpreted as requests to the Decimation Filter to process new sample data. Writes to this register when ISEL=0 are not allowed.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0			PSIOSEL	INTAG				0						PREFILL	FLUSH
W

DECFILTER_IB field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 PSIOSEL	PSI Output Selection The PSIOSEL bit selects the output PSI to send result filter in PSI output mixed mode. In standalone mode this bit has no effect. For more details, see Return PSI (RPSI) and PSI Output Selector (PSIOSEL) . NOTE: The value of PSIOSEL should be constant for some data stream when in output mixed mode. Therefore, the output data is sent to a specific PSI and avoids undesired output overrun events. 0 PSI0 is selected to send result data (in PSI output mixed mode) 1 PSI1 is selected to send result data (in PSI output mixed mode)
4–7 INTAG	Decimation filter input tag bits The INTAG[3:0] bit field is defined as a selector signal and it is used to identify different destinations for the INPBUF[15:0] data. When the PSI master block is an eQADC, it is used in PSI output mixed mode to address the appropriate RFIFO in the eQADC block.
8–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DECFILTER_IB field descriptions (continued)

Field	Description
14 PREFILL	Decimation Filter Prefill/Filter control bit The PREFILL bit selects the Decimation Filter operation mode. For more details, see Filter Prefill Control Description 0 Decimation Filter normal sample 1 Decimation Filter prefill sample
15 FLUSH	Decimation Filter Flush control bit Assertion of the FLUSH bit initializes the Decimation Filter to a initial state, as defined in Flush Command Description. This bit is self negated and it is cleared only when the data is read and the flush is executed. 0 no flush request 1 flush request
16–31 INPBUF	Input Buffer Data The INPBUF[15:0] bit field carries the sample data to be filtered. This data buffer can be written from the two PSI slave-bus interfaces or by the device slave-bus interface. See Input Buffer Description for more details.

31.4.6 Interface Output Buffer (DECFILTER_OB)

Address: 0h base + 14h offset = 14h

DECFILTER_OB field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 PSIOSEL	Selected PSI Output The PSIOSEL bit indicates the selected PSI output that sends the filter result back to the master block. This field has no meaning when in standalone mode or PSI input mixed mode. For more details, see Return PSI (RPSI) and PSI Output Selector (PSIOSEL) . 0 PSI0 is selected to send result data 1 PSI1 is selected to send result data
12–15 OUTTAG	Decimation filter output tag bits The OUTTAG[3:0] bit field is defined as a selector signal and it is used to identify different destinations for the OUTBUF[15:0] data. When an eQADC is the PSI block master, it holds the same number used to address the destination RFIFO.

Table continues on the next page...

DECFILTER_OB field descriptions (continued)

Field	Description
16–31 OUTBUF	Output Buffer Data The OUTPBUF[15:0] bit field is the result data in the decimation filter Output Buffer. It represents a fixed point signed number in two's complement format and is updated only when a decimated result is ready to be transmitted, meaning it contains the last decimated result from the filter.

31.4.7 Filter Coefficient (DECFILTER_COEFn)

Address: 0h base + 20h offset + (4d × i), where i=0d to 8d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	COEFnSIGNR								COEFn																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

DECFILTER_COEFn field descriptions

Field	Description
0–7 COEFnSIGNR	COEFn sign repeated Bit COEFn[23] is repeated 8 times.
8–31 COEFn	Coefficient n field The COEFn[23:0] bit fields are the digital filter coefficients registers. The coefficients are fractional signed values in two's complement format, in the range (Coef is greater than or equal to -1 and less than 1). NOTE: Reads to this register are sign-extended, meaning the coefficient's sign bit is copied to all 8 most significant register bits. NOTE: Writing to these fields when BSY=1 is not allowed.

31.4.8 Filter TAP (DECFILTER_TAPn)

The TAP register stores, on each filter node, the input sample data and, for the IIR type, the filter intermediary results.

Address: 0h base + 78h offset + (4d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	TAPnSIGNR								TAPn																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

DECFILTER_TAPn field descriptions

Field	Description
0–7 TAPnSIGNR	TAPn sign repeated Bit TAPn[23] is repeated 8 times.
8–31 TAPn	TAPn Register The read-only TAPn[23:0] bit fields shows the contents of the digital filter tap registers, as fractional signed values in two's complement format, in the range (Coef is greater than or equal to -1 and less than 1). NOTE: Reads to this register are sign-extended, meaning the coefficient's sign bit is copied to all 8 most significant register bits. The content of these registers is meaningless when BSY=1.

31.4.9 Enhanced Debug Input Data (DECFILTER_EDID)

The Enhanced Debug Input Data Register provides read-only access to the sample data received by the decimation filter when the input is selected from the device slave-bus (ISEL=0), allowing the monitoring of filter operation. See [Enhanced Debug Monitor Description](#) for more details. Writes to this register are not allowed.

Address: 0h base + D0h offset = D0h

DECFILTER_FINTVAL field descriptions

Field	Description
0–31 SUM_VALUE	Integration Sum Value The SUM_VALUE[31:0] field holds the sum of filtered output values. The 17 most significant bits hold the integer part, and the 15 least significant ones the fractional part of the integration value. The control of the integration sum and update of this register is determined by the register DECFILTER_MXCR. The register is updated only upon an integration output request. SUM_VALUE should be taken as an unsigned number when the integrator is configured for absolute operation (DECFILTER_MXCR bit SSIG=0), and a two's complement signed number otherwise. NOTE: If the DECFILTER_MXCR bit SSAT=1, the integration sum is saturated, so that if the accumulation overflows DECFILTER_FINTVAL holds the value 0xFFFFFFFF for absolute integration (SSIG=0), or values 0x7FFFFFFF (positive saturation) and 0x80000000 (negative saturation) for signaled integration (SSIG=1). If SSAT=0, DECFILTER_FINTVAL holds the integration sum modulo 2^{17} (considering the 15-bit fractional part).

31.4.11 Final Integer Count Register (DECFILTER_FINTCNT)

Address: 0h base + E4h offset = E4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DECFILTER_FINTCNT field descriptions

Field	Description
0–31 COUNT	Integration Count Value The COUNT field holds the count of filtered outputs integrated. The control of the integration sum and update of this register is determined by the register DECFILTER_MXCR. The register is updated together with DECFILTER_FINTVAL, only upon an integration output request.

31.4.12 Current Integer Value Register (DECFILTER_CINTVAL)

Address: 0h base + E8h offset = E8h

DECFILTER_CINTVAL field descriptions

Field	Description
0–31 SUM_VALUE	Integration Sum Value The SUM_VALUE[31:0] field holds an unsigned number representing the sum of filtered output values, continuously updated as the integration proceeds. The control of the integration sum is determined by the register DECFILTER_MXCR. NOTE: If the DECFILTER_MXCR bit SSAT=1, the integration sum is saturated, so that if the accumulation overflows DECFILTER_CINTVAL holds the value 0xFFFFFFFF for absolute integration (SSIG=0), or values 0x7FFFFFFF (positive saturation) and 0x80000000 (negative saturation) for signaled integration (SSIG=1). If SSAT=0, DECFILTER_FINTVAL holds the integration sum modulo 2¹⁷ (considering the 15-bit fractional part). NOTE: A read on this register automatically commands an update of the register DECFILTER_CINTCNT.

31.4.13 Current Integer Count Register (DECFILTER_CINTCNT)

Address: 0h base + ECh offset = ECh

DECFILTER_CINTCNT field descriptions

Field	Description
0–31 COUNT	Integration Count Value The COUNT field holds the count of filtered outputs integrated. The value is updated only when register DECFILTER_CINTVAL is read, to keep the coherency between the integration and count values.

31.5 Functional Description

31.5.1 Overview

Figure 31-2 shows the block diagram of the Decimation Filter. The Control Logic provides the control signals for all other sub-modules. The PSI data interface is subdivided into two sub-modules, transmitter and receiver, that are accessed by two PSI slave-bus interfaces. The bypass path is used when the filter is disabled and the incoming data can be transmitted back to the master block without being processed by the Filter algorithm. The Filter hardware is implemented in such a way that an IIR (1 x 4 poles) or FIR filter type can be implemented. The selection between the two types of filter algorithms is implemented by the Control Logic sub-block.

The Coefficient register file provides the digital filter coefficients. This block is a register bank with read/write access by the device slave-bus interface. The Filter TAP registers are also accessed through the device slave-bus line interface, providing additional debug capabilities to the Decimation Filter block. The MAC (Multiply Accumulate) sub-block executes the filter arithmetic operations controlled by the Control Logic. The MAC results are routed to the Filter TAP registers and to the output buffer when the result is a decimated filter sample.

31.5.2 Parallel Side Interface (PSI) sub-block description

This section describes the operation of the Parallel Side Interface (PSI) sub-block which is responsible for communication and data exchange between two master blocks (for instance, two eQADC blocks) and the Decimation Filter block. It is important to note that there are two PSI lines (PSI0 and PSI1) but there are only one internal input buffer and only one internal output buffer.

The decimation filter receives sample data from up to two master blocks. The sample data arrives along with the control bits. These control bits are decoded and the proper action is decided in the Control Logic sub-block. When the decimation filter finishes its processing and a result is available, the read request signal is issued to the selected master block. This data transfer request remains set until the result is read by the master block.

When using two or more decimation filter blocks in the device, the output of the second block is connected to the input data of the next block, and the output of the first block is connected to the read data input of the corresponding PSI master block.

31.5.3 Input Buffer Description

The decimation filter receives data samples for filtering from two master blocks (e.g. two eQADCs) using the dual PSI interface, or from the CPU using the device slave bus interface. The data source is selected by the ISEL bit of the module configuration register DECFILTER_MCR. When ISEL selects the PSI interfaces, the user can send data from any of the two master blocks because both are enabled. However, it is necessary to consider the characteristics of the PSI interface itself as described below.

When the device slave bus interface is selected and DMA operation is chosen (DECFILTER_MCR bit DSEL=1), the input data request signal is asserted when the input buffer is empty. When DMA operation is not chosen (DSEL=0) in standalone or PSI output mixed modes, the logic asserts an input interrupt request and the input buffer waits for data from the device slave bus interface.

Input buffer filling is flagged by the DECFILTER_MSR bit IDF. The IDF flag remains set, even after the input data has been consumed and the buffer is free, until it is cleared by software.

Input buffer overrun is detected and flagged by the DECFILTER_MSR bit IVR. The idle (BSY=0) Decimation Filter is able to receive two consecutive input writes without input overrun. For more details, see [Input Buffer Overrun](#).

Note

There is no buffer / control to separate or select data from each PSI interface. The user should know which PSI is being served by the filter module to avoid undesired overrun caused by the two PSI inputs.

When the selected input source is any PSI master block, the PSI master may send timestamp data after related sample data for filtering. The timestamp is sent back to the PSI following the respective filter output, using the same request mechanism. As the decimation filter takes several clock cycles to process a sample, the timestamp is copied into an internal timestamp register until the filtered output is sent out, therefore freeing the input buffer for yet another sample data.

When the input buffer is loaded with a sample data coming from any PSI interface and enhanced debug monitor enabled is enabled (DECFILTER_MCR bits ISEL=0, EDME=1), input DMA or interrupt requests are asserted, so that the PSI input samples can be monitored from the device Sky-Blueslave-bus interface. These interrupt or DMA requests result in input read accesses from the DECFILTER_IB register, unlike write

accesses needed when the same requests are made and the device slave-bus interface is selected for input (ISEL=1). Only the sample data input (not timestamps), can be monitored in this way. See also [Enhanced Debug Monitor Description](#).

Soft reset clears the input buffer indication flags and any data write/read request that was generated in any mode.

31.5.3.1 Input Buffer Overrun

An input overrun occurs when the input buffer is holding input data and new data is received by the filter. See [Input Buffer Description](#) for details of the input buffer.

The input buffer overrun can occur only when the input is enabled (DECFILTER_MCR bit IDIS=0) , and in the following cases:

- When the input buffer has sample data to be processed but the filter is busy and another input (data or timestamp) is received.
- When the input buffer has a timestamp, the internal timestamp register is loaded and the next input data is received.
- When the two PSI interfaces try to write the input buffer at the same time.

As an example of the input data sequence, assume that the filter is enabled and not busy, and all registers are empty. Then a word of sample data is received followed by a timestamp and another word of sample data. No input overrun occurs in this case, because the first sample is immediately transferred to the tap input register, the timestamp is immediately transferred to the internal timestamp storage register, and the second sample can be held in the input buffer until the end of the processing of the sample data by the filter. The input overrun may occur if more input is received before the end of the processing, or if the filter is busy at the beginning of the received sequence.

When the filter is in bypass/disable mode (DECFILTER_MCR field FTYPE=00), the data from the input buffer is transferred to the output buffer, if it is not already full. If the output buffer is full, the input buffer is loaded, and another word of input data is sent, then an input overrun occurs.

Note

Configuring ISEL=1, MIXM=1 and FTYPE=00 (bypass), writes to the DECFILTER_IB are routed directly to the PSI output.

31.5.4 Output Buffer Description

The decimation filter has an output buffer to send filtering results to a master block using any PSI, or to the CPU using the device slave-bus, as selected through the DECFILTER_MCR bits ISEL and MIXM bits.

Note

There is only one output buffer to serve the two PSI outputs. The PSI output selection is controlled by the PSI input field RPSI or by the bit field PSIOSEL in the DEC_FILTER_IB register.

Filtering of prefill inputs do not update the output buffer, so the flag ODF is not set.

When filter types IIR and FIR are selected and the input source is any PSI master block (normal or PSI input mixed modes), the output buffer receives data from the MAC sub-block or from the timestamp storage register. The result from the MAC is written immediately after the processing if the decimation is enabled. However, the timestamp data is enabled to be written in the output buffer only when the output buffer is empty, the decimation count is reached, and the corresponding data was also ready to be transmitted. When a new word of data is available in the output buffer, a read request signal is sent to a master block. The master block has to send the corresponding read commands to clear the read request signal. In this configuration, the core can always read the output buffer. The flag ODF is set when the buffer is updated.

When in filter operation mode with input from the device slave-bus (ISEL=1), only sample data is processed by the filter, as there is no way to input timestamps. When the filter result from the MAC is ready, this is immediately written to the output buffer when the decimation count is reached. The flag ODF is set when the buffer is updated. It also generates a DMA read request if DSEL=1 in standalone or PSI input mixed modes .

When the filter is bypassed (FTYPE=00), and a PSI is selected as output (normal mode or PSI output mixed mode), the data written into the input buffer waits until the output buffer is empty before passing the data. This is needed because the master block takes some clock cycles to send the read commands to the decimation filter after the read request signal is asserted. When the filter is bypassed and the device slave-bus is selected as output (standalone mode or PSI input mixed mode), the data written into the input buffer is immediately written into the output buffer. The flag ODF is set when the buffer is updated and a DMA read request is asserted if DSEL=1.

Soft reset clears the output buffer, as well as any data read request generated in any mode.

31.5.4.1 Output Buffer Overrun

An output overrun occurs when the output buffer is holding output data (sample or timestamp) that has not been read is overwritten with another word of data (sample or timestamp).

Output overruns are flagged by the DECFILTER_MSR bit OVR, if the output buffer is updated when not empty. The output buffer empty condition depends on the mode and output selection as follows:

- If PSI0 or PSI1 is selected as output (normal mode or PSI output mixed mode), the output buffer is considered empty when the last output has been read.
- If cascade mode is selected, the output buffer is considered empty if the last output request was acknowledged.
- If the device slave-bus is selected (standalone or PSI input mixed mode) for output and DMA is selected (DSEL=1), the output buffer is considered empty if the last output has been read.
- If the device slave-bus is selected (standalone or PSI input mixed mode) for output and DMA is not selected (DSEL=0), the output buffer is considered empty when the ODF flag is negated.

Note

When the device slave-bus is selected (standalone or PSI input mixed mode) for output and DMA is not selected (DSEL=0), the ODF flag must be cleared to avoid overrun, even if its corresponding interrupt is not used (ODEN=0).

Note

The normal use is to receive the data stream from one specific PSI and transmit the results using one specific PSI. Input and output timing care are necessary to avoid output overrun when output results are sent to both PSI alternately.

Prefill inputs do not cause IIR or FIR output overrun in standalone, normal, and cascade tail modes, but can cause overruns in cascade head or middle configurations (see [Cascade mode](#)).

When bypass is selected, the output overrun does not occur because the data written into the input buffer is written into the output buffer only when this buffer is empty, but an input overrun may still occur (see [Input Buffer Overrun](#)).

31.5.4.2 Triggered Output Result Description

The posting of a filter output, either to a PSI interface or to the device slave-bus can be controlled by an additional input trigger signal (see [Decimation trigger signal](#)). It allows the decimation to be controlled by another circuit, instead of the internal decimation counter.

Triggered output operation is enabled by the bit TORE in the configuration register DECFILTER_MCR. When triggered output is enabled, the decimation count configured by DECFILTER_MCR field DEC_COUNTER is ignored. The decimation filter detects the rising edge or the falling edge of the trigger signal as selected by the configuration field TMODE in the DECFILTER_MCR register. When the corresponding edge is detected, the output buffer is enabled to receive the next filter result. This means if a filtering process is occurring, the output buffer read request is only set when the filtering ends and a new result is available.

Note

This mode is not affected by the prefill sample indication then a result is pulled into the output buffer when TORE is enabled and a trigger is detected. Therefore, the initialization phase of the digital filter need to be controlled by the timing of asserting the TORE bit or by discarding the initial sampled results.

Note

The time interval between two consecutive trigger events should be greater than 60 clock cycles. This is necessary to avoid possible trigger overruns.

The input trigger signal can also be used as a simple filtered output enable: in this trigger mode, when the input trigger signal is asserted, every filtered output is posted to the output buffer; no output is posted when the signal is negated. This trigger mode and the assertion polarity (active 0 or 1) of the input trigger signal is also defined in the DECFILTER_MCR field TMODE.

31.5.5 Bypass Configuration Description

Bypass operation is configured by setting the field FTYPE[1:0] of module configuration register DECFILTER_MCR to 00. In this case, the input sample and tag are sent to the output with no change. This behavior is independent of the ISEL/MIXM setting. The following applies to the bypass configuration:

- flush is ignored
- prefill is ignored
- trigger or counted decimation is ignored
- BSY bit is not set
- the input and output flags are set

Note

Bypass must not be configured in cascade mode (see [Cascade mode description](#)).

31.5.6 IIR and FIR Filter

This section describes the IIR filters implemented in the Decimation Filter block. [Figure 31-33](#) shows the filters functional diagrams. The figure shows a IIR filter of fourth order (4poles). The filter topology, not the hardware, is represented. The hardware implementation is based on a MAC unit controlled by an FSM which implements the filter algorithm.

Figure 31-33. 1 x 4 Poles IIR Filter Functional Diagram

The difference equation for the IIR filter of [Figure 31-33](#) can be written as:

$$y(n) = \sum_{i=0}^N B_i x(n-i) + \sum_{j=1}^M A_j y(n-j)$$

Figure 31-34. Eqn-1

where $x(n)$ is the filter input at time n , $y(n)$ is the filter output at time n , N is the number of feed-forward filter coefficients minus one, B_i are the feed-forward filter coefficients, M is the number of feed-back filter coefficients, and A_j are the feedback filter coefficients.

Figure 31-34 can be written as:

$$y(n) = S \left\{ \sum_{i=0}^N \frac{B_i}{S} x(n-i) + \sum_{j=1}^M \frac{A_j}{S} y(n-j) \right\}$$

Figure 31-35. Eqn-2

Where all the coefficients are scaled down by S . The block diagram for Figure 31-35 is shown in Figure 31-36 in a fourth-order IIR filter implementation where the coefficients A_j and B_i are called *coefficient n* , where $n=0-8$.

**Figure 31-36. Fourth Order IIR Filter Implementation Block Diagram**

The fourth order IIR filter is implemented with a FIR section followed by an IIR section. If the FIR type filter mode is selected, the IIR section is converted into an FIR section. In this case the order of the FIR filter is twice the IIR filter order, since all the TAP and coefficient registers are allocated for the FIR section. The Filter configuration paths are shown in Figure 31-37. Multiplexer A controls the *bypass* filter path and multiplexer B controls/selects the filter mode of operation, to either IIR mode or FIR mode. The

selection is controlled by the FTYPE[1:0] bits in the Filter Module Configuration register. The order of the filter can be controlled by setting the appropriate *filter coefficients* to zero.

Figure 31-37. Filter Configuration Paths (FIR or 1x4Poles IIR)

31.5.6.1 Rounding

The Decimation Filter performs rounding operations in two different locations, as shown in Figure 31-37 :

- to obtain the filter output result with 16 bits
- to obtain the IIR feedback result to be stored in tap4 registers with 24 bits

The rounding mechanism implements the Convergent Rounding methodology (also known as round-to-nearest even number), which makes the decision on rounding up or down based on the value of the lower portion of data to be rounded (LS_WORD). The rounding up/down condition is equal to the traditional rounding except when the

LS_WORD has the format { 1000...00 }. In this particular case, the rounding procedure is like the example of Figure 31-38. If the MS_WORD is odd, the value is rounded up. Otherwise the value is rounded down.

Figure 31-38. Convergent Rounding Methodology

31.5.6.2 Saturation

Filter output saturation occurs when an overflow or underflow condition of the filter is detected by dedicated logic, and if it is enabled by the SAT control bit of the configuration register DECFILTER_MCR. In this condition, the filter output is set to a saturated value equal to the maximum or minimum value that can be represented by the 16-bit output port. Also, for the IIR filter an equivalent logic is used to assert the saturation for the 24-bit feedback result.

31.5.7 Filter Prefill Control Description

A prefill indicates that the input data should be accepted by the Decimation Filter, but no decimated output should be generated while the control field indicates prefill. Therefore the prefill function is used in the beginning of the filter operation to initialize and stabilize the Decimation Filter without generating decimated samples. In addition, the prefill does not operate when the filter is in bypass (FTYPE=0b00).

When ISEL=0, the M_CTRL[1:0] field in the PSI bus data, input and output controls the prefill. When ISEL=1, it is controlled by the PREFILL field in the DECFILTER_IB register. The prefill control is usually activated only in a certain number of words of sample data in the beginning of the input data sequence.

When the prefill control is set, the decimation filter block operates as follows:

- Input data is processed normally by the digital filter and tap values are updated.
- The decimation counter is maintained in reset value.
- The output buffer is not updated and no output interrupt or read request is generated.
- The accompanying timestamp for the identified prefill conversion data is not bypassed.
- The overflow detector/flag operates normally and the error interrupt request is set if enabled.

In Cascade Mode, prefill control is ignored in all cascaded filters except the Tail one: the prefill samples are filtered, decimated and forwarded to the next block with the prefill indication. The Tail block takes the samples with prefill indication, filter them and discard the result.

Note

The combined decimation count of the cascade combo may not be reset after the last prefill sample. Unlike in a single (non-cascaded) filter, the number of non-prefill inputs until an output comes out depends on the number of past prefill inputs.

31.5.8 Timestamp Data Transmission

The timestamp information is identified by the master block using the M_CTRL[1:0] bit field of the PSI bus data, input and output. For timestamp data, the input data and tag values that come with M_CTRL[1:0] bits set to 0b10 are sent back to the master block without changing. However, some additional conditions are considered:

- The timestamp is additional information that accompanies a sample conversion data. The PSI master block sends the decimation filter the conversion data with control bits for either prefill or filter operation. This data may optionally be followed by the corresponding timestamp data. When the corresponding conversion data is marked for prefill, the timestamp data is not sent to the output buffer. This occurs because the filter result is not sent to the output buffer.
- Similarly, when the filter is decimating the results, the timestamp is only sent to the output buffer if the corresponding received conversion data has generated a filter output that is selected by the decimation counter to be sent to the output buffer. Other received timestamps that come with data not selected by the decimator are discarded.

- Sending two consecutive words of timestamp data is not allowed: there must be at least one conversion data between two timestamp inputs. In normal operation, the filter should receive only one timestamp for each word of conversion data to be filtered.
- Timestamps are not allowed in PSI Input Mixed Mode.
- When both PSI are sending data / timestamp to the same decimation filter, the user should control the timing between the two PSIs to avoid loss of information and erroneous mixing of data and timestamp.

31.5.9 Flush Command Description

The flush signal is used by the Decimation Filter to execute a partial reset of the filter. This is useful when the same filter is used on a new set of data samples after finishing the filtering of another set of data.

When the flush control is detected, all filter TAPs are cleared and the DEC_COUNTER[3:0] field in the status register DECFILTER_MSR is reset.

The flush function does not clear the Coefficient registers file in the Decimation Filter, thus it is not required to re-write these registers after a flush. The integrator accumulator and sample count are not cleared either. The output buffer also keeps the last result and may be retrieved until the next output is posted.

The flush control precedes the input data to be filtered. Therefore, the corresponding sample data is processed by the block after the flush. When ISEL=0, the field M_FLUSH in the PSI bus data, input and output is processed. When ISEL=1, the field FLUSH in the DECFILTER_IB register is processed. Note that a word of valid sample data can be available at the same time the flush signal is asserted. In this case the flush is executed and the sample is processed after the flush.

When ISEL=0, flush bit M_FLUSH must not be asserted when the input data is a timestamp (M_CTRL=10).

When the filter is disabled by the FTYPE[1:0] control bit field, the flush command is not executed.

Note

In Cascade Mode, the flush command is forwarded to the next cascaded block together with the output, after the decimation count. Therefore it is possible that, in a given moment, the taps of a cascaded block are zeroed after a flush input, while the following ones still retain the old values.

31.5.10 Soft-Reset Command Description

The Soft-Reset command is requested through the self-negated bit SRES of the DECFILTER_MCR register and provides the CPU with the capability to initialize the Decimation Filter through the slave-bus interface. The procedure below must be performed for a software reset when the filter is active:

1. Disable filter inputs, writing DECFIL_MCR bit IDIS = 1.
2. Poll the register DECFIL_MSR until the bit BSY is 0.
3. Repeat the step 2 polling; this is necessary to cover the case when a sample is left in the input buffer.
4. Write DECFILTER_MCR bit SRES = 1.

After the software reset is issued, all internal Filter TAP registers, the decimation counter, the integrator outputs (except DECFILTER_CINTCNT), and the state machine are put in the initial state. The status register DECFILTER_MSR is also cleared. The Coefficient registers are not affected by the SRES. In case there is some filter processing, the filter process is aborted and the last sample is discarded. In addition, data in the input buffer waiting to be processed, and data in the output buffer waiting to be read, are discarded (the requests of service are cleared). The software reset command has high priority and the BSY bit is set during its operation.

The configuration registers DECFILTER_MXCR and DECFILTER_MCR are also not affected by a soft reset, except the bit SRES that is self-negated and is always read as zero.

When in debug or freeze mode, the soft reset is executed but the filter remains in debug or freeze mode.

Note

It is recommended to clear the IBIE bit before a software reset, especially if ISEL changes, in order to avoid unwanted interrupt requests.

Note

DMA transfers must not be active during soft reset. Data loss can occur.

31.5.11 Interrupts Requests Description

31.5.11.1 Block Interrupt Request

There are several interrupt request events that can be enabled using the module configuration register `DECFILTER_MCR`. Basically, the interrupt request can be issued under any of the following conditions:

- when a word of input data is received
- when a word of output data is available
- when an error has occurred.

The input data flag `IDF` is set when a word of data is received from the CPU when in standalone mode, or when a word of data is received from any PSI when it is not in standalone mode (normal mode). It is not used to generate the read or write requests (as defined in [Input Buffer Interrupt Request](#)) when `DSEL=0`.

Output data is available and its flag (`ODF`) is set when the input data sample is processed by the filter and the decimation counter matches the decimation rate value. It is not used to generate the read requests (as defined in [Output Buffer Interrupt Request](#)) when `DSEL=0`.

An error event in the decimation filter block is defined as one of these events:

- Overflow in the filter, flagged by `OVF`
- Overrun in the decimation filter input, flagged by `IVR`
- Overrun in the decimation filter output, flagged by `OVR`
- Overrun in enhanced debug monitor, flagged by `DIVR`
- Integrator overrun, flagged by `SVR`
- Integrator value exception, flagged by `SSE`
- Integrator count exception, flagged by `SCE`

An overflow occurs when the two's-complement result value from the MAC accumulator is out of the range of values that can be stored in tap register 4 (IIR) or in the output register.

An input overrun occurs when the input buffer is holding a word of input data and one more word of data is received by the filter. See [Input Buffer Overrun](#), for more details.

An output overrun occurs when a new word of data is sent to the output buffer but the previous word of data has not been handled yet. See [Output Buffer Overrun](#), for more details.

These flags can be set by the PSI events, however they are only cleared by:

- the CPU, or
- by the soft reset command in the DEC_FILTER_MCR, or
- by the clear flag registers in the DEC_FILTER_MSR register.

31.5.11.2 Input Buffer Interrupt Request

This interrupt is enabled by the register IBIE in the DECFILTER_MCR register and is asserted only when DSEL=0. This request is flagged in the DECFILTER_MSR by field IBIF.

In standalone and PSI output mixed modes, the input buffer interrupt request is asserted when the input buffer is available to receive a conversion sample and DMA operation is not selected (DSEL=0), meaning the block is requesting data to be written into the input buffer. The interrupt request is cleared when the CPU writes a "1" in field IBIC of the DECFILTER_MSR register, or by the soft reset command.

When in normal, cascade or PSI input mixed modes with enhanced debug enabled (ISEL=0 and EDME=1, DSEL=0), the input sample data can be read by the CPU when this interrupt request is asserted. The interrupt is asserted just when a new word of sample data is supplied to the filter sub-block to be processed. As this filter register is overwritten by the next word of sample data, an input read overrun event can occur (the DIVR bit in DECFILTER_MSR register is asserted) if the interrupt request is not cleared before, or at the same time as, the new sample arrives to set the interrupt. This DIVR bit is cleared by the DIVRC bit in the status register DECFILTER_MSR. However, in enhanced debug monitoring, the set condition has higher priority than the clear. This means that if the set condition and the clear bit IBIC occur at the same time, the interrupt remains asserted.

31.5.11.3 Output Buffer Interrupt Request

This interrupt is enabled by the register OBIE in the DECFILTER_MCR register and is asserted only when DSEL=0. This request is also indicated in the field OBIF of the DECFILTER_MSR register.

When in standalone mode, the output buffer can be read by the CPU with the DMA disabled. The output buffer interrupt request is asserted when the output buffer receives a new result from the filter sub-block. This means the block is requesting data to be read by the CPU.

The output buffer interrupt request can also be asserted due to an integrator result being ready, as flagged by the DECFILTER_MXSR bit SDF, when the DECFILTER_MCR bit SDIE=1. Note that both the filter output and integrator share the same interrupt source.

This interrupt request is cleared when a "1" is written in the bit OBIC and/or bit SDFC of the DECFILTER_MXSR register, or by the soft reset command.

31.5.12 DMA Requests Description

The DMA function for input and output buffers is enabled using DSEL=1 in the DECFILTER_MCR register. The DMA function for integrator result is described in another section.

31.5.12.1 Input Buffer DMA Request

This DMA request is enabled by the ISEL and DSEL bits in the DECFILTER_MCR register.

When in standalone mode, the input buffer can be written by the DMA. The input buffer DMA request is asserted when the input buffer is available to receive a conversion sample (it is not holding a word of data). This DMA request is cleared when an input data word is written in the input buffer. Therefore, the DMA request is always cleared before it is asserted again.

When in normal mode with enhanced debug enabled (ISEL=0 and EDME=1, DSEL=1), the input sample data can be read by the DMA when this DMA request is asserted. The request is asserted when a new word of sample data is written into the input buffer to be processed. As this filter register is overwritten by the next word of sample data, a DMA read overrun event can occur (the DIVR bit in DECFILTER_MSR register is asserted) if

the DMA request is not cleared before, or at the same time as, a new sample arrives to set the DMA request. This DIVR bit is cleared by the DIVRC bit in the status register DECFILTER_MSR or by soft reset.

This DMA request is cleared when the DMA transfer is complete or by soft reset.

31.5.12.2 Output Buffer DMA Request

This DMA request is enabled by the ISEL, MIXM and DSEL bits in the DECFILTER_MCR register.

When in standalone mode, the output buffer can be read using the DMA. The output buffer DMA request is asserted when the output buffer receives a new result from the internal filter sub-block. This DMA request is cleared when the output buffer is read by the processor.

The output buffer DMA request is also asserted when an integrator output is ready, if DECFILTER_MXCR bit SDMAE=1 and the filter output is directed to a PSI interface (ISEL=MIXM).

The DMA request is also cleared by soft reset.

31.5.13 Freeze Mode Description

The freeze mode operation is asserted using the FREN enable bit and FRZ bit in the DEC_FILTER_MCR register or by the modules debug input .

It is not possible to enter freeze mode when the module is disabled by the configuration bit MDIS.

In case of a freeze mode request during the processing of an input sample, the current processing is finished and then the module enters freeze mode.

Access to input and output buffers remain operational in freeze, as well as their related flags.

Note

For cascaded blocks (see [Cascade mode description](#)), it is recommended to freeze only the Head block. If it is really necessary to freeze all the blocks, it is recommended that they

are frozen sequentially starting from the Head block towards the Tail one. Unfreezing is recommended to be done sequentially from the Tail block towards the Head one.

31.5.14 Enhanced Debug Monitor Description

This feature is enabled by the EDME bit in the configuration register DECFILTER_MCR. The monitoring operation works either in normal or cascade modes, when the sample data is supplied by a master block through the PSI slave-bus interfaces (ISEL=0) or another cascaded block (see [Cascade mode description](#)). The Enhanced Debug Monitor feature makes the input sample data also available in the DECFILTER_EDID register. A DMA or interrupt request (selected by DSEL) indicates a new input was fed and DECFILTER_EDID was updated. The input is processed normally by the filter.

An Enhanced Debug Input Data Register (DECFILTER_EDID) overrun can occur if a sample is not read by the CPU or DMA before overwritten by a new sample. The overrun is indicated in a separate flag DIVR in the status register DECFILTER_MSR. If the ERREN bit is set in the DECFILTER_MCR configuration register, this overrun asserts the module interrupt request.

31.5.15 Integrator

The hardware sample integrator accumulates the filter output values for determined periods.

31.5.15.1 Integrator Inputs

The integrator can be fed either by raw or decimated filter outputs, selected by the DECFILTER_MXCR bit SISEL (see [Module Extended Config Register \(DECFILTER_MXCR\)](#)). The accumulated input value taken can be the filtered sample "as is" (signaled), or its absolute value, depending on the DECFILTER_MXCR register bit SSIG.

Note

The integrator accumulates input samples when bypass is selected.

31.5.15.2 Integrator Outputs

The integrator output is either:

- the 32-bit, fixed point unsigned accumulation of the absolute values from the filter output, when the integrator is configured for absolute operation (DECFILTER_MXCR bit SSIG=0). This resolution allows a minimum of 131071 samples to be integrated before an overflow occurs in absolute operation, or 65536 samples in signed operation.
- the 32-bit, fixed point signed two's complement accumulation of the signed values from the filter output, when the integrator is configured for signed operation (SSIG=1).

The fractional part of the accumulation is 15 bits wide in both cases.

An accumulation overflow is flagged by the DECFILTER_MXSR bit SSOVF. The accumulator can overflow in either of the ways below, selected through the DECFILTER_MXCR bit SSAT:

- saturated accumulation (SSAT=1), so that an overflow results in the value of 0xFFFFFFFF for absolute value accumulation (SSIG=0), or 0x7FFFFFFF (positive) and 0x80000000 (negative) for signaled accumulation (SSIG=1).
- non-saturated accumulation (SSAT=0), so that an overflow results in the modulo 2^{17} accumulation value. This operation is only allowed in absolute accumulation (SSIG=0).

The integrator output value becomes available in register DECFILTER_FINTVAL (see [Final Integer Value Register \(DECFILTER_FINTVAL\)](#)) when an integrator output request is issued. The integrator output request can be issued in the following ways:

- by hardware, controlled by an external signal; the enabling and the selection of the signal request modes is done through the DECFILTER_MXCR field SRQSEL (see [Module Extended Config Register \(DECFILTER_MXCR\)](#));
- by software, writing 1 to the DECFILTER_MXCR bit SRQ;

The SSOVF flag is asserted upon an integrator output request, based on the overflow state of the internal accumulator. This internal overflow state is cleared upon an output request, just after SSOVF is asserted, or upon an integrator reset (see [Integrator Reset](#)). The internal overflow state is also cleared by writing SSOVFC to 1, but only in saturated accumulation. Therefore, a non-saturated overflow that occurs before an SSOVF clear is still flagged in the next output request.

The integrator output request also updates the register `DECFILTER_FINTCNT`, which holds the number of samples accumulated into the register `DECFILTER_FINTVAL`. This internal accumulated sample counter can operate either in a saturated or "wrapped" count mode, as selected by the `DECFILTER_MXCR` bit `SCSAT`. In both cases, the counter overflow is flagged by the `DECFILTER_MXSR` bit `SCOVF`.

The `SCOVF` flag is asserted upon an integrator output request, based on the overflow state of the internal counter. This internal overflow state is negated upon an output request, just after `SCOVF` is asserted, or upon an integrator reset (see [Integrator Reset](#)). The internal overflow state is also negated by writing `SCOVFC` to 1, but only in saturated count. Therefore, a non-saturated overflow that occurs before an `SCOVF` clear is still flagged in the next output request.

An integrator output update can also issue a DMA or interrupt request. The interrupt and DMA requests are the same ones used for the filter output buffer (see [Output Buffer Interrupt Request](#) and [Output Buffer DMA Request](#)). The `DECFILTER_MCR` bit `SDIE` is used to enable integrator interrupts, and the `DECFILTER_MXCR` bit `SDMAE` enables the DMA integrator requests. The integrator DMA request uses the same signal as the filter output DMA request, so one must never use any configuration that allows both the integrator and filter output to make DMA requests.

Integrator output updates are flagged by the `DECFILTER_MXSR` bit `SDF`. The integrator overrun is detected in the same way as a filter output buffer overrun, and is flagged by `DECFILTER_MXSR` bit `SVR`. An integrator overrun also generates an error interrupt if the `DECFILTER_MCR` bit `ERREN`=1 (see [Output Buffer Overrun](#)).

Registers `DECFILTER_CINTVAL` and `DECFILTER_CINTCNT` provide a way to poll intermediate integration values and sample counts, respectively (see [Current Integer Value Register \(DECFILTER_CINTVAL\)](#) and [Current Integer Count Register \(DECFILTER_CINTCNT\)](#)). `DECFILTER_CINTVAL` is updated whenever the integrator is reset or a new sample is accumulated. `DECFILTER_CINTCNT` is updated only when `DECFILTER_CINTVAL` is read, so that coherency between the value and count values is guaranteed. Therefore, the read access order of that pair of registers must be `DECFILTER_CINTVAL` first, followed by `DECFILTER_CINTCNT`.

Note

The flags `SSOVF` and `SCOVF` can also be asserted when `DECFILTER_CINTVAL` is read. The `SSOVF` and `SCOVF` set and clearing rules apply for the `DECFILTER_CINTVAL` read the same way as for an integrator output request.

31.5.15.3 Integrator Reset

The integration value is reset to the value of zero, in the following ways:

- by hardware: on hardware reset, or controlled by an external signal; the enabling and the selection of the zero signal modes is done through the DECFILTER_MXCR field SZROSEL (see [Module Extended Config Register \(DECFILTER_MXCR\)](#));
- by software: on software reset, or writing 1 to the DECFILTER_MXCR bit SZRO;

The integrator reset also zeroes the internal counter of accumulated samples and the internal overflow state (but not SSOVF and SCOVF). Software and hardware resets reset all integrator registers immediately. Integrator zero command from external signal or by software (SZRO) affects the integrator registers and flags as follows:

- DECFILTER_CINTVAL resets immediately;
- DECFILTER_CINTCNT does not reset immediately; it is updated only upon a DECFILTER_CINTVAL read, loaded with the number of integrated samples occurred after the reset;
- DECFILTER_FINTVAL and DECFILTER_FINTCNT do not reset immediately; being updated only upon a new output request (see [Integrator Outputs](#)); if a integrator software zero command (through SZRO bit) and an integrator output request (through SRQ bit) are made at the same time, the registers DECFILTER_FINTVAL and DECFILTER_FINTCNT are updated with the last internal values before reset; the same applies to simultaneous integrator zero command and output request by hardware signal;
- the SSOVF and SCOVF flags do not negate; however, the internal overflow states which assert SSOVF and SCOVF do reset immediately, so that the next output update (either by hardware request, software request or DECFILTER_CINTVAL read) before an overflow does not assert SSOVF/SCOVF.

Note

The integrator reset does not depend on the integrator enabling (see [Integrator Enabling and Halting](#)).

31.5.15.4 Integrator Enabling and Halting

Two mechanisms, enabling and halting, drive the integrator accumulation, allowing it to be controlled by a combination of two distinct sources, both software, both hardware, or one hardware and other software. Values are accumulated when the integrator is enabled and not halted. The integrator halt and enable states can be controlled in the following ways:

- by hardware, through external signals ; the enabling and the selection of the signal request modes is done through the DECFILTER_MXCR fields SENSEL and SHLTSEL, respectively (see [Module Extended Config Register \(DECFILTER_MXCR\)](#));
- by software, through the same DECFILTER_MXCR fields SENSEL and SHLTSEL. Note that these fields are in different bytes, so that two distinct, concurrent software tasks can avoid coherency problems by changing the fields using byte read-modify-write accesses.

Note

Enabling and halting does not affect output requests or integrator reset.

31.5.15.5 Integrator Exceptions

Integrator may run into exception states due to overflow, either of the accumulated value or the sample counter. Exceptions are flagged by the DECFILTER_MXSR bits SSE, for sum value exception, and SCE, for counter exception. These flags generate an error interrupt, if it is enabled (see [Block Interrupt Request](#)).

The accumulator exception condition depends on whether it operates in saturated mode or not, as follows:

- In Saturated operation (DECFILTER_MXCR bit SSAT=1): a sum exception occurs (SSE=1) whenever an overflow is flagged; SSE asserts together with SSOVF.

- In Non-saturated operation (DECFILTER_MXCR bit SSAT=0): a sum exception occurs (SSE=1) when an overflow is flagged and the DECFILTER_MXSR bit SSOVF is already set to 1.
- In Non-saturated operation, an accumulator exception also occurs if the accumulator overflows twice without any update of the final integrator value DECFILTER_FINTVAL or the current integrator counter DECFILTER_CINTCNT (by a read to the DECFILTER_CINTVAL register), neither an integrator reset occurs. The SSOVF flag does not assert in this situation.

Note

The SSOVF flag can only be asserted upon a hardware request, a software request, or when DECFILTER_CINTVAL is read, based on the internal accumulator overflow state.

Similarly, the sample counter exception condition depends on whether it operates in saturated mode or not, as follows:

- In Saturated operation (DECFILTER_MXCR bit SCSAT=1): a counter exception occurs (SCE=1) whenever an overflow is flagged; SCE asserts together with SCOVF.
- In Non-saturated operation (DECFILTER_MXCR bit SCSAT=0): a counter exception occurs (SCE=1) when an overflow is flagged and the DECFILTER_MXSR bit SCOVF is already set to 1.
- In Non-saturated operation, a counter exception also occurs if the counter overflows twice without any update of the final count DECFILTER_FINTCNT or the current integrator counter DECFILTER_CINTCNT (by a read to the DECFILTER_CINTVAL register), neither an integration reset occurs. The SCOVF flag does not assert in this situation.

Note

The SCOVF flag can only be asserted upon a hardware request, a software request, or when DECFILTER_CINTVAL is read (also updating DECFILTER_CINTCNT), based on the internal counter overflow state.

31.5.16 Cascade mode description

The cascade mode is defined as a configuration mode of the decimation filter to work together with other ones in a chain arrangement. All blocks in the arrangement, hereafter called a **cascade combo**, are configured to operate in cascade mode by the CASCD[1:0] field in the DECFILTER_MCR register. [Figure 31-39](#) shows an example of cascade combo:

- The figure shows PSI being used for both data input and output, but cascade can also work in standalone or mixed modes.
- The left most block, named Head receives the raw data to be filtered from a PSI master block (or from the device slave-bus interface in standalone/PSI output modes). The head type is configured using CASCD[1:0] = 01 in the configuration register DECFILTER_MCR.
- The right most block, named Tail, is the last filter block in the chain. It sends the output result back to a PSI master block (or to the device slave-bus interface in standalone/PSI output modes). This type of cascaded block is configured using CASCD[1:0] = 10.
- The blocks in between, named Middle, do not exchange data (receive / transmit) with a PSI master the device slave-bus, only with other decimation filter blocks. This type of block is configured by setting CASCD[1:0] = 11. Middle blocks are optional in a cascaded combo: two blocks, one Head block feeding a Tail one, can be used in cascade.

Note

The values passed between cascaded blocks can be monitored using Enhanced Debug Monitor (see [Enhanced Debug Monitor Description](#)).

- Each decimation filter block has one cascade-in and one cascade-out ports, besides the PSI connections used in normal mode. The arrows show how they are physically connected. The bold arrows show the connections used in cascade mode.
- The block configurations as Head, Tail or Middle must respect their physical connections such that all the following apply:
 - a Head block feeds a Middle or Tail one
 - a Middle block feeds another Middle block or a Tail one
 - Tail feeds no other block, and Head is fed by no other block.

- As a consequence of the conditions above, there must be one and only one Head block and one and only one Tail block in a cascade combo.
- A group of physically chained blocks can form more than one cascade combo. For instance, [Figure 31-40](#) shows the same physical chain, but now with blocks 1 and 2 configured as Head and Tail, respectively, forming one combo. The remaining blocks form another combo starting with block 3 (Head), and ending with block N (Tail). Note that the chain-in inputs of blocks from block 3 on are used to carry output data from the first cascaded combo (Tail block 2) to a PSI master block.
- Blocks not used in a cascaded chain can be used normally, isolated (DEFILTER_MCR field CASCD[1:0] = 00), as exemplified in [Figure 31-41](#).
- The optional connection show from block N to block 1 in [Figure 31-39](#) allows block N to be configured as Head or Middle, feeding block 1 configured as Middle or Tail, yielding more flexibility, as in the last example of [Figure 31-41](#).

Figure 31-39. Cascade Mode Chain Structure

The input to a cascaded configuration is selected by the DECFILTER_MCR bit ISEL of the Head block. The output target of the cascaded blocks is selected by the DECFILTER_MCR bit ISEL of the Tail block, with the same values used for input selection (ISEL=0 for PSI, ISEL=1 for device slave-bus). DECFILTER_MCR bit MIXM must be written 0 for all cascaded blocks.

Figure 31-40. Multiple Cascade Mode Chain Structure

(arrows show just the physical cascading order)

Figure 31-41. Examples of mixed Cascaded and single blocks

31.5.16.1 Cascade Freeze, Stop, and Configuration Change Procedures

To change a block configuration mode to or from cascade mode, the following safe procedures must be observed:

- To modify a cascade combo, either to single or any other cascade combo combination, all the cascade combo blocks must have their inputs disabled (using DECFILTER_MCR bit IDIS), in order, from the Head to the Tail block. After a block IDIS bit has been set to 1 (one), one must wait for its DECFILTER_MSR bit BSY to be 0 (zero) before disabling the input of the next block in the sequence.
- Each block in a new cascade combo must be configured with its input disabled. When the mode configuration is done, the combo blocks must have their inputs enabled in order, from the Tail towards the Head block.
- A single block must also be reconfigured the same way, to or from a cascade combo configuration: first disabling its input, and then waiting for a non-busy state before writing DECFILTER_MCR field CASCD.

To take cascade combo blocks to or from freeze or low power modes, a similar procedure must be used:

- Take the Head to freeze or low-power first, wait for DECFILTER_MSR bit BSY=0, and repeat the procedure for the other blocks in the chain in sequence, towards the Tail block.
- Take the blocks out of freeze or low-power modes in the inverse sequence, from Tail to Head.

31.5.17 Return PSI (RPSI) and PSI Output Selector (PSIOSEL)

This block can be connected to two master blocks through two separated Parallel Side Interfaces - PSI0 and PSI1. The input data can come from any of these PSIs and can also come from the deviceslave-bus by DMA or interrupt request. And the filter output result can be sent to any of these PSIs or can be read by the deviceslave-bus by DMA or interrupt request.

The input data can come from PSI0 or PSI1. The PSI data bus structure is presented in [Parallel Side Interface \(PSI\) sub-block description](#)," and it contains the bit field RPSI that defines which PSI output should send the filter result back to its master block. This means the filter result correspondent to some sample data from a PSI input can be sent to any PSI output by the received RPSI value. For example, when the input data comes from PSI1 with RPSI=0 (=1) the filter result is sent back by using PSI1 (PSI0) by asserting the read request signal .

In case of PSI output mixed mode, the input data is supplied by writes to the DEC_FILTER_IB register and the output PSI is directly selected by the bit field PSIOSEL. This is different from RPSI because the sample data does not come from a PSI. For example, when the input data comes with PSIOSEL=0 (=1) the filter result is sent back by using PSI0 (PSI1) by asserting the read request signal .

31.6 Initialization Information

Following are some simple initialization steps to be done before using the decimation filter block. These steps assume that the user has already calculated the filter coefficients using a filter design tool.

31.6.1 Initialization Procedure

The sequence of steps for the block initialization is as follows:

1. Program the configuration registers `DECFILTER_MCR` and `DECFILTER_MXCR` as desired for your application.
2. Write all filter coefficient registers `DECFILTER_COEFn` with the previously calculated values.
3. Enable the filter input, writing `DECFILTER_MCR` bit `IDIS=0`.
4. Run a soft-reset cycle if necessary.
5. The module is ready to receive data from `PSI0/PSI1` or from the device slave-bus interface.

31.7 Application Information

31.7.1 eQADC IP as the PSI Master Block

The system block diagram for the eQADC application is shown in [Figure 31-42](#). In this case, the Decimation Filter receives conversion results generated by one eQADC block using `PSI0` interface. These results can be generated from several different ADC setup configurations which are identified by a specific eQADC Control address within a Conversion command. Conversion commands with Register Address set to zero use the standard configuration setup. The samples generated by the standard configuration setup are sent to one of the local eQADC RFIFO buffers. The samples generated by the Alternate Configurations can be sent to the internal RFIFO or to the eQADC dedicated slave-bus interface (Parallel Side Interface `PSI`) to communicate with the external Decimation Filter IP block or any other block that can communicate with this interface. A bit field in the Alternate Configuration Control Register selects the Internal RFIFO or this slave-bus interface as the destination for the conversion result.

The eQADC can send either conversion data or timestamp data. The conversion data is filtered by the decimation filter and the timestamp is bypassed and sent back to the eQADC.

In the eQADC application, the `TAG` field is used to address the appropriate RFIFO in the eQADC block. In this case, only addresses 0–5 are used since there are only six RFIFOS available in the eQADC block.

Figure 31-42. Decimation Filter/eQADC interface

31.8 Filter Example Simulation

The decimation filter block operation was checked in a Verilog simulation using calculated filter coefficient values and noisy input data. The expected output values and the RMS error were then calculated.

31.8.1 Coefficients Calculation

The coefficients were calculated using a digital filter design tool. We have supplied some hypothetical filter parameters to the tool and obtained the filter coefficients. The input parameters are:

- Filter characteristics: elliptic/low pass
- Filter type: 4th order IIR
- Input sample rate: 800k sample/s
- Passband edge: 100 kHz

- Stopband edge: 150 kHz
- Passband attenuation: ≤ 1 dB

The software tool gives the IIR filter coefficients in the Z-transform format expressed by Figure 31-43 :

$$\frac{Y(s)}{X(s)} = \frac{B_0 + B_1s + B_2s^2 + B_3s^3 + B_4s^4}{A_0 + A_1s + A_2s^2 + A_3s^3 + A_4s^4}$$

Figure 31-43. Eqn-3

The coefficient results in fixed point decimal representation are shown in Table 31-36.

Table 31-36. Coefficient Values Given by SPW Digital Filter Design Tool

Coefficient	Decimal Value	Coefficient	Decimal Value
B0	0.0221455	A0	1.0
B1	0.00445582948893748	A1	-2.69772868375858
B2	0.0318517846509088	A2	3.234056294853
B3	0.00445582948893748	A3	-1.92028561712454
B4	0.0221455	A4	0.47939080709495

Comparing Figure 31-35 with Figure 31-43, we obtain the relationship between the calculated values of coefficients and the values to be loaded in the DECFILTER_COEFn registers. Note that A0=1 in both cases and that the coefficients A1 to A4 in Figure 31-43 has the opposite signal from Figure 31-35.

See Table 31-37 below to obtain the coefficients. A scale factor of eight is used, being the smallest divider factor to have all coefficient values in the range ($-1 \leq \text{Coef} < +1$).

Table 31-37. Coefficient Values for Decimation Filter

SCALE	S=1	S=8	
COEFn	Decimal Value	Decimal Value	Hexadecimal Values (24 bits)
Coef0 = B0/S	0.0221455	0.00276815891266	0x005AB5
Coef1 = B1/S	0.00445582948893748	0.00055694580078	0x001240
Coef2 = B2/S	0.0318517846509088	0.00398147106171	0x008277
Coef3 = B3/S	0.00445582948893748	0.00055694580078	0x001240
Coef4 = B4/S	0.0221455	0.00276815891266	0x005AB5
Coef5 = -A1/S	2.69772868375858	0.33721613883972	0x2B29E6
Coef6 = -A2/S	-3.234056294853	-0.40425717830658	0xCC414E
Coef7 = -A3/S	1.92028561712454	0.24003565311432	0x1EB97D
Coef8 = -A4/S	-0.47939080709495	-0.05992400646210	0xF8546A

31.8.2 Input Data Calculation

The 24-bit words of input data are samples of a sum of two tones: one tone of 30kHz and another tone of 250kHz. The samples were calculated at the rate of 800k samples per second. The tones have the same amplitude and it is assured that the resultant amplitude is smaller than 1 so as to obtain samples in the range $(-1 \leq \text{sample} < +1)$. It is supposed the input data are signed values in the two's complement format in the range $(-1 \leq \text{sample} < +1)$.

31.8.3 Filter Results

The decimation filter was simulated using the calculated coefficients and the input data samples. A scaling factor of eight in the configuration register `DECFILTER_MCR`, and no decimation factor, were used to obtain the maximum of output results from the filter.

The theoretical expected values from this filter were also calculated, and these results were compared with those from the decimation filter. The resultant RMS error when considering about 500 samples was about -97 dB.

Chapter 32

Temperature Sensor (TSENS)

32.1 Chip-specific Temperature Sensor information

This chip has two instances of the Temperature Sensor.

32.1.1 Temperature Sensor programming control

The control and status registers for the Temperature Sensor are implemented in the PMC digital interface.

32.1.2 Accessing TSC parameters

The Temperature Sensor Calibration (TSC) parameters, including TSCA and TSCB, are used to calculate device temperature.

See the UTEST flash memory map for the specific locations of the TSC parameter values.

32.1.3 Temperature name alignment

The Temperature Sensor modules and Power Management Controller (PMC) module use different terminology to refer to the same temperature points. The following table aligns the terminology.

Table 32-1. Temperature Sensor and PMC temperature terminology

Temperature	Temperature Sensor name	PMC name
-40°C	Low temperature	Temperature 0
150°C	High temperature	Temperature 2

32.2 Introduction

The device includes two on-chip temperature sensors. The temperature sensor module monitors device temperature and delivers one analog output signal and two digital output signals each (under- and over-temperature flags). The analog output consists of a voltage signal directly proportional to the internal junction temperature. The analog output is connected to an input channel of an ADC on the device (see the ADC details for the channel number). The internal junction temperature must be calculated by software based on the sampled temperature sensor voltage; sampled bandgap reference voltage, which comes from another module; and calibration parameter values stored in internal flash memory. The two digital outputs, connected to the PMC module, are used to signal under- and over-temperature operating conditions.

The digital outputs signal when the junction temperature drifts below the low temperature threshold or above the high temperature threshold. These signals notify the device to take action to appropriately adjust the device temperature in response to an out-of-specification low or high temperature operating condition. Calibration parameter values associated with the temperature threshold detection feature are determined and stored in internal flash memory during production testing at the factory.

32.3 Functional Description

The temperature sensor generates one analog output voltage, $V_{TSENS}(T)$, which is proportional to the absolute current junction temperature of the device, and two digital outputs that signal whether the junction temperature has reached either a pre-set low temperature threshold or a pre-set high temperature threshold.

An on-chip ADC module is used to convert the analog output voltage, as well as the bandgap reference voltage, into a digital representation. These values, along with parameter values stored in on-chip flash memory, are used by software to calculate the device junction temperature.

32.3.1 Temperature threshold detection (digital output generation)

Temperature threshold trimming values are adjusted through calibration during factory test and stored in on-chip flash memory. While enabled, if a new trimming value is loaded into the Temperature Sensor module, it may take up to 1 microsecond for the digital outputs to be updated to reflect the new trimming condition.

When the temperature threshold detection feature is enabled, the temperature sensor monitors the internal junction temperature of the chip and asserts a signal if any of the following temperature thresholds are crossed.

- The low temperature digital output signals if the junction temperature falls below the low temperature threshold (-40°C).
- The high temperature digital output signals if the junction temperature rises above the high temperature threshold (150°C).

The threshold detection circuit is calibrated with respect to the factory-test temperatures: the low temperature threshold is trimmed to match the cold insertion test temperature (nominally equal to -40°C), and the high temperature threshold is trimmed to match the hot insertion test temperature (nominally equal to 150°C). In other words, the thresholds are not trimmed to absolute values of temperature but to the specific temperatures for which the device is validated during factory test.

Hysteresis is applied whenever outputs transition to a logic level low in order to eliminate spurious toggling. Digital output behavior is illustrated on [Figure 32-1](#).

Figure 32-1. Digital output behavior with temperature

32.3.2 Linear temperature sensor (analog output generation)

When analog output generation is enabled, the temperature sensor outputs a voltage proportional to the internal junction temperature of the chip. This analog voltage signal is converted into a digital code by an on-chip ADC. The temperature value is obtained from a linear voltage-temperature relation with coefficients adjusted by calibration parameters extracted during factory test and programmed into flash memory.

32.4 Temperature formula

The system chain that translates device junction temperature into a digital variable is composed of the temperature sensor, a bandgap reference voltage source and the on-chip ADC. Both analog output voltages of the temperature sensor and the bandgap reference voltage source must be converted by the ADC into digital codes to obtain the device junction temperature. The temperature formula shown in [Figure 32-2](#) is used to calculate internal device junction temperature.

$$T = (232 + TSCA \times 2^{-6}) \times \frac{V_{TSENS\_CODE}(T)}{V_{BG\_CODE}(T)} - (273 + TSCB \times 2^{-4}) [^{\circ}\text{C}]$$

Where:

$$TSCA = \left(\frac{T_{HIGH} - T_{LOW}}{V_{TSENS\_CODE}(T_{HIGH}) - V_{TSENS\_CODE}(T_{LOW})} \times V_{BG\_CODE}(T_{FINAL}) - 232 \right) \times 2^6$$

$$TSCB = \left(\frac{T_{HIGH} - T_{LOW}}{V_{TSENS\_CODE}(T_{HIGH}) - V_{TSENS\_CODE}(T_{LOW})} \times V_{TSENS\_CODE}(T_{LOW}) - T_{LOW} - 273 \right) \times 2^4$$

$$V_{TSENS\_CODE}(T_{LOW}) = \frac{V_{TSENS}(T_{LOW})}{V_{ref0}} \times 2^{12}$$

$$V_{TSENS\_CODE}(T_{HIGH}) = \frac{V_{TSENS}(T_{HIGH})}{V_{ref0}} \times 2^{12}$$

$$V_{BG\_CODE}(T_{FINAL}) = \frac{V_{BG}(T_{FINAL})}{V_{ref0}} \times 2^{12}$$

$$V_{BG\_CODE}(T) = \frac{V_{BG}(T)}{V_{ref}} \times 2^{12}$$

$$V_{TSENS\_CODE}(T) = \frac{V_{TSENS}(T)}{V_{ref}} \times 2^{12}$$

Notes:

- TSCA and TSCB are 16-bit signed integer constants stored in flash memory during factory test and calibration
- $V_{TSENS}(T)$ is the temperature sensor output sampled by the ADC
- $V_{BG}(T)$ is the bandgap reference voltage sampled by the ADC at temperature T
- V_{ref} is the ADC reference voltage in normal usage of the device
- V_{ref0} is the ADC reference voltage during factory calibration
- T_{LOW} is the low temperature factory calibration temperature
- T_{HIGH} is the hot temperature factory calibration temperature
- T_{FINAL} is the final insertion factory calibration temperature

Figure 32-2. Temperature formula

Parameters TSCA and TSCB are 16-bit signed integer constants stored during factory test and calibration that need to be used in the temperature formula to calculate device junction temperature. The values for TSCA and TSCB translate into positive or negative shifts of the linear relation coefficients that compensate for manufacturing process variation. [Figure 32-2](#) shows how parameters TSCA and TSCB are calculated in terms of the actual variables measured during factory calibration.

32.5 Calculating device temperature

Software must perform the following steps in order to calculate device temperature.

Calculating device temperature

1. Measure the bandgap reference voltage using the on-chip ADC module and calculate $V_{BG\_CODE}(T)$ according to the formula shown in [Figure 32-2](#).
2. Measure the temperature sensor output voltage using the on-chip ADC module and calculate $V_{TSENS\_CODE}(T)$ according to the formula shown in [Figure 32-2](#).
3. Retrieve parameters TSCA and TSCB from flash memory.
4. Calculate T according to the formula shown in [Figure 32-2](#).

Note

Temperature Formula may be calculated using signed 32-bit (integer) operations showing negligible precision loss.

Chapter 33

System Timer Module (STM)

33.1 Chip-specific STM information

This chip has one instance of the STM.

33.2 Introduction

This section provides an overview, list of features, and modes of operation for the STM.

33.2.1 Overview

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel. The counter is driven by the system clock divided by an 8-bit prescale value (1 to 256).

33.2.2 Features

The STM has the following features:

- One 32-bit up counter with 8-bit prescaler
- Four 32-bit compare channels
- Independent interrupt source for each channel
- Counter can be stopped in debug mode

33.2.3 Modes of operation

The STM supports two device modes of operation: normal and debug. When the STM is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the STM_CR register. If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run.

33.3 External signal description

The STM does not have any external interface signals.

33.4 Memory map and registers

The STM programming model includes a group of 32-bit registers—a module control register, a counter value register, and three registers for each channel.

The STM registers can only be accessed using 32-bit (word) accesses. Attempted references using a different size or to a reserved address generates a bus error termination.

STM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
0	STM Control Register (STM_CR)	32	R/W	0000_0000h	33.4.1/1347
4	STM Count Register (STM_CNT)	32	R/W	0000_0000h	33.4.2/1348
10	STM Channel Control Register (STM_CCR0)	32	R/W	0000_0000h	33.4.3/1348
14	STM Channel Interrupt Register (STM_CIR0)	32	w1c	0000_0000h	33.4.4/1349
18	STM Channel Compare Register (STM_CMP0)	32	R/W	0000_0000h	33.4.5/1349
20	STM Channel Control Register (STM_CCR1)	32	R/W	0000_0000h	33.4.3/1348
24	STM Channel Interrupt Register (STM_CIR1)	32	w1c	0000_0000h	33.4.4/1349

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

STM_CMP_n field descriptions

Field	Description
0–31 CMP	Compare value for channel <i>n</i> . If the STM_CCR _n [CEN] bit is set and the STM_CMP _n register matches the STM_CNT register, a channel interrupt request is generated and the STM_CIR _n [CIF] bit is set.

STM_CMPn field descriptions (continued)

Field	Description

33.5 Functional description

The STM has one 32-bit up counter (STM_CNT) that is used as the time base for all channels. When enabled, the counter increments at the system clock frequency divided by a prescale value. The STM_CR[CPS] field sets the divider to any value in the range from 1 to 256. The counter is enabled with the STM_CR[TEN] bit. When enabled in normal mode, the counter continuously increments. When enabled in debug mode, the counter operation is controlled by the STM_CR[FRZ] bit. When the STM_CR[FRZ] bit is set, the counter is stopped in debug mode; otherwise, it continues to run in debug mode. The counter rolls over at 0xFFFF_FFFF to 0x0000_0000 with no restrictions at this boundary.

The STM has four identical compare channels. Each channel includes a channel control register (STM_CCRn), a channel interrupt register (STM_CIRn), and a channel compare register (STM_CMPn). The channel is enabled by setting the STM_CCRn[CEN] bit. When enabled, the channel will set the STM_CIRn[CIF] bit and generate an interrupt request when the channel compare register matches the timer counter. The interrupt request is cleared by writing 1 to the STM_CIRn[CIF] bit. A write of 0 to the STM_CIRn[CIF] bit has no effect.

NOTE

The STM counter does not advance when the system clock is stopped.

Chapter 34

Software Watchdog Timer (SWT)

34.1 Chip-specific SWT information

This chip has two instances of the SWT module: SWT_A and SWT_B.

34.1.1 SWT register reset values

The following table identifies chip-specific reset values of SWT registers.

Table 34-1. Chip-specific SWT register reset values

Register	SWT_A	SWT_B
CR	FF00_010Bh ¹	FF00_010Ah
TO	0005_FCD0h	0005_FCD0h

1. This value is present after a hardware reset and before the BAM executes. The BAM code (RCHW) might change it before application code executes. See [Reset Configuration Half Word \(RCHW\)](#) for more information.

34.1.2 SWT time-out events and invalid accesses: configuring reset and interrupt requests

To configure the results of SWT time-out events and invalid accesses for an SWT that is enabled (SWT_CR[WEN] is 1):

- Program these [SWT Control Register \(SWT_CR\)](#) fields:

- **ITR** determines when the outcome of a time-out event is a reset request or an interrupt request.
- **RIA** determines when the outcome of an invalid access is a reset request or a bus error.
- Program FCCU reactions to the non-critical faults (NCFs) that are associated with these reset and interrupt requests.

See [FCCU fault inputs](#) for the default reaction to each NCF.

CAUTION

For any NCF that receives an SWT reset request: If the default FCCU reaction is no reset but the intended application requires a reset, configure the FCCU's reaction to be a reset.

The following table shows the NCFs to which the SWT generates reset and interrupt requests for time-out events.

Table 34-2. Routing of SWT reset and interrupt requests for time-out events

SWT instance	SWT_CR[ITR] is 0	SWT_CR[ITR] is 1	
	Any time-out generates reset request to	Initial time-out generates interrupt request to	Second consecutive time-out generates reset request to
SWT_A	NCF[14]	IRQ[8] and NCF[16]	NCF[14]
SWT_B	NCF[15]	IRQ[501]	NCF[15]

The following table shows the NCFs to which the SWT can generate reset requests for invalid accesses.

Table 34-3. Routing of SWT reset requests for invalid accesses

SWT instance	SWT_CR[RIA] is 0	SWT_CR[RIA] is 1
SWT_A	Invalid access generates bus error	Invalid access generates reset request to NCF[14]
SWT_B	Invalid access generates bus error	Invalid access generates reset request to NCF[15]

34.2 Introduction

This section provides an overview, list of features, and modes of operation for the SWT.

34.2.1 Overview

The Software Watchdog Timer (SWT) is a peripheral module that can prevent system lockup in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. When enabled, the SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified time-out period. If this servicing action does not occur before the timer expires, the SWT generates an interrupt or hardware reset request. The SWT can be configured to generate a reset request or interrupt on an initial time-out. The SWT always generates a reset request on a second consecutive time-out.

34.2.2 Features

The SWT has the following features:

- 32-bit time-out register to set the time-out period
- Programmable selection of system or oscillator clock, for timer operation
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits
- Reset configuration inputs allow timer to be enabled out of reset

34.2.3 Modes of operation

The SWT supports three device modes of operation: normal, debug and stop. When the SWT is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the SWT_CR. If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run. In stop mode, operation of the counter is controlled by the STP bit in the SWT_CR. If the STP bit is set, the counter is stopped in stop mode, otherwise it continues to run.

34.3 External signal description

The SWT module does not have any external interface signals.

34.4 Memory Map and Registers

The SWT programming model has seven 32-bit registers. The programming model can be accessed using only 32-bit (word) accesses.

Any of the following attempted accesses are invalid:

- References using non-32-bit access sizes
- Writes to read-only registers
- Writes of incorrect values to SWT_SR when the SWT is enabled
- Accesses to reserved addresses
- Accesses by masters without permission

For an enabled SWT, an invalid access generates a reset request if SWT_CR[RIA] is 1. An invalid access generates a bus error if SWT_CR[RIA] is 0.

If either HLK or SLK in SWT_CR is 1, then the SWT_CR, SWT_TO, SWT_WN, and SWT_SK registers are read-only.

SWT memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
0	SWT Control Register (SWT_CR)	32	R/W	See section	34.4.1/1355

34.4.3 SWT Time-out Register (SWT_TO)

NOTE

The reset value of this register is implementation specific. See the chip-specific SWT information.

The SWT Time-out (SWT_TO) register contains the 32-bit time-out period. This register is read-only if either SWT_CR[HLK] or SWT_CR[SLK] is 1.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- The reset value of this register is implementation specific. See the chip-specific SWT information.

SWT_TO field descriptions

Field	Description
0–31 WTO	Watchdog time-out period in clock cycles. An internal 32-bit down counter is loaded with this value or 0x100, whichever is greater, when the service sequence is written or when the SWT is enabled.

34.4.4 SWT Window Register (SWT_WN)

The SWT Window (SWT_WN) register contains the 32-bit window start value. This register is cleared on reset. This register is read-only if either SWT_CR[HLK] or SWT_CR[SLK] is 1.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SWT_WN field descriptions

Field	Description
0–31 WST	Window Start Value When window mode is enabled, the service sequence can only be written when the internal down counter is less than this value.

34.4.5 SWT Service Register (SWT_SR)

The SWT Service (SWT_SR) register is the target for service operation writes used to reset the watchdog timer.

Address: 0h base + 10h offset = 10h

SWT_SR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 WSC	Watchdog Service Code This field is used to service the watchdog and to clear the Soft Lock bit (SWT_CR[SLK]). If the SWT_CR[SMD] field is 01b, two pseudorandom key values are written to service the watchdog; see Functional description for details. Otherwise, the sequence 0xA602 followed by 0xB480 is written to the WSC field. To clear the Soft Lock bit (SWT_CR[SLK]), the value 0xC520 followed by 0xD928 is written to the WSC field. When read, the WSC field always returns zero.

34.4.6 SWT Counter Output Register (SWT_CO)

The SWT Counter Output (SWT_CO) register is a read-only register that shows the value of the internal down counter when the SWT is disabled.

Address: 0h base + 14h offset = 14h

SWT_CO field descriptions

Field	Description
0–31 CNT	Watchdog Count When the watchdog is disabled (SWT_CR[WEN] is 0), this field shows the value of the internal down counter. When the watchdog is enabled (SWT_CR[WEN] is 1), this field is cleared (the value is

SWT_CO field descriptions (continued)

Field	Description
	0x0000_0000). Values in this field can lag behind the internal counter value for up to 6 system clock cycles plus 8 counter clock cycles. Therefore, the value read from this field immediately after disabling the watchdog may be higher than the actual value of the internal counter.

34.4.7 SWT Service Key Register (SWT_SK)

The SWT Service Key (SWT_SK) register holds the previous (or initial) service key value. This register is read-only if either SWT_CR[HLK] or SWT_CR[SLK] is 1.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																SK

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

SWT_SK field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 SK	Service Key This field is the previous (or initial) service key value used in keyed service mode. If SWT_CR[SMD] is 01b, the next key value to be written to the SWT_SR is $(17 \cdot SK + 3) \bmod 2^{16}$.

34.5 Functional description**34.5.1 Introduction**

The SWT is a 32-bit window watchdog timer designed to enable the system to recover in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. It includes:

- a control register (SWT_CR),
- an interrupt register (SWT_IR),
- a time-out register (SWT_TO),
- a window register (SWT_WN),
- a service register (SWT_SR),

- a counter output register (SWT_CO), and
- a service key register (SWT_SK).

Accesses to SWT registers occur with no peripheral bus wait states. (The peripheral bus bridge may add one or more system wait states.) However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system plus seven counter clock cycles.

34.5.1.1 SWT_CR register

The SWT_CR register includes bits to enable the timer, set configuration options, and lock configuration of the module. The watchdog is enabled by setting the SWT_CR[WEN] bit. The reset value of the SWT_CR[WEN] bit is device specific.³ If the reset value of this bit is 1, the watchdog starts operation automatically after reset is released. Some devices can be configured to clear this bit automatically during the boot process.

34.5.1.2 SWT_TO register

The SWT_TO register holds the watchdog time-out period in clock cycles unless the value is less than 0x100, in which case the time-out period is set to 0x100. When the SWT is enabled, the time-out period is loaded into an internal 32-bit down counter each time a valid service operation is performed. The SWT_CR[CSL] bit selects which clock (system or oscillator) is used to drive the down counter.

34.5.1.3 SWT_CO register

The SWT_CO register shows the value of the down counter when the watchdog is disabled. When the watchdog is enabled this register is cleared. The value shown in this register can lag behind the value in the internal counter for up to six system plus eight counter clock cycles.

The SWT_CO register can be used during a software self test of the SWT. For example, the SWT can be enabled and not serviced for a fixed period of time less than the time-out value. Then the SWT can be disabled (SWT_CR[WEN] cleared) and the value of the SWT_CO register read to determine if the internal down counter is working properly.

3. See the chip-specific SWT information.

34.5.2 Configuration locking

The configuration of the SWT can be locked through use of either a soft lock or a hard lock. In either case, when locked, the SWT_CR, SWT_TO, SWT_WN and SWT_SK registers are read-only.

34.5.2.1 Hard lock

The hard lock is enabled by setting the SWT_CR[HLK] bit, which can only be cleared by a reset.

34.5.2.2 Soft lock

The soft lock is enabled by setting the SWT_CR[SLK] bit and is cleared by writing the unlock sequence to the service register.

34.5.3 Unlock sequence

The unlock sequence is a write of 0xC520 followed by a write of 0xD928 to the SWT_SR[WSC] field. There is no timing requirement between the two writes. The unlock sequence logic ignores service sequence writes and recognizes the 0xC520, 0xD928 sequence regardless of previous writes. The unlock sequence can be written at any time and does not require the SWT_CR[WEN] bit to be set.

34.5.4 Servicing operations

When enabled, the SWT requires periodic execution of a servicing operation that is determined by the SWT_CR[SMD] field. Properly servicing the watchdog loads the internal down counter with the time-out period. The servicing modes are:

- fixed service sequence
- keyed service sequence

34.5.4.1 Fixed service sequence mode

If the SWT_CR[SMD] field is 00b, the fixed service sequence mode is selected, which requires writing 0xA602, then 0xB480 to the SWT_SR[WSC] field to service the watchdog. There is no timing requirement between the two writes and the service sequence logic ignores unlock sequence writes.

34.5.4.2 Keyed service sequence mode

If the SWT_CR[SMD] field is 01b, then the keyed service sequence mode is selected, which requires writing two pseudorandom keys to the SWT_SR[WSC] field to service the watchdog. The key values are determined by the pseudorandom key generator defined by the equation in the following figure. This algorithm will generate a sequence of 2^{16} different key values before repeating. The state of the key generator is held in the SWT_SK register. For example, if SWT_SK[SK] is 0x0100, then the service sequence keys are 0x1103, 0x2136. In this mode, each time a valid key is written to the SWT_SR register, the SWT_SK register is updated. So, after servicing the watchdog by writing 0x1103 and then 0x2136 to the SWT_SR[WSC] field, SWT_SK[SK] is 0x2136 and the next key sequence is 0x3499, 0x7E2C.

$$SK_{n+1} = (17 \times SK_n + 3) \bmod 2^{16}$$

Figure 34-8. Pseudorandom Key Generator

34.5.4.3 Window mode

If window mode is enabled (SWT_CR[WND] bit is 1), the service sequence must be applied in the last part of the time-out period defined by SWT_WN.

- The window is open when the down counter is less than the value in SWT_WN.
- Outside this window, service sequence writes are invalid accesses and generate a bus error or reset request depending on the value of SWT_CR[RIA].

For example, if SWT_TO is set to 5000 and SWT_WN is set to 1000, the service sequence must be applied in the last 20% of the time-out period.

Synchronization logic in the watchdog design slightly delays when the window opens. This delay could be up to 3 system clock cycles plus 4 counter clock cycles.

34.5.5 Time-out

The Interrupt Then Reset bit (SWT_CR[ITR]) controls the SWT's action taken when a time-out occurs.

- If the SWT_CR[ITR] bit is 0, the SWT generates a reset request immediately on any time-out.
- If the SWT_CR[ITR] bit is 1, an initial time-out causes the SWT to generate an interrupt and load the down counter with the time-out period.
 - The interrupt is indicated by the Time-out Interrupt Flag (SWT_IR[TIF]).
 - Clear the interrupt by writing 1 to SWT_IR[TIF].

If the service sequence is not written before the second consecutive time-out, the SWT generates a reset request.

34.5.6 Initialization

All registers should be initialized before setting the SWT_CR[WEN] bit to enable the watchdog. Registers can be initialized in any sequence.

Chapter 35

Periodic Interrupt Timer (PIT-RTI)

35.1 Chip-specific PIT information

This chip has one instance of the PIT.

PIT channels can be used to trigger periodic ADC conversions via EQADC Command FIFOs. For more information, see:

- [eQADC Command FIFO Trigger Source Registers \(SIU_ISEL4\) to eQADC Command FIFO Trigger Source Registers \(SIU_ISEL7\) and eQADC Advance Trigger Source Register \(SIU_ISEL9\)](#)
- [SIU Trigger Burst Generators \(TBG\)](#)

35.2 Introduction

The PIT module is an array of timers that can be used to raise interrupts and triggers. It includes a dedicated Real Time Interrupt Timer (RTI), which runs on a separate clock and can be used for system wakeup

35.2.1 Block diagram

The following figure shows the block diagram of the PIT-RTI module.

Figure 35-1. Block diagram of the PIT-RTI

NOTE

See the chip-specific PIT information for the number of PIT channels used in this MCU.

35.2.2 Features

The main features of this block are:

- One RTI (Real-Time Interrupt) timer to wakeup the CPU
- Ability of timers to generate trigger pulses
- Ability of timers to generate interrupts
- Maskable interrupts
- Option to raise RTI interrupt, even when the bus clock is switched off

- Power saving with a separate input clock for the RTI timer. All other timers share one common core clock.
- Independent timeout periods for each timer

35.3 Signal description

The PIT module has no external pins.

35.4 Memory map/register description

This section provides a detailed description of all registers accessible in the PIT_RTIC module.

- Reserved registers will read as 0, writes will have no effect.
- See the chip-specific PIT information for the number of PIT channels used in this MCU.
- The RTI registers should be programmed only when the RTI clock is running.

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

PIT_LTMR64H field descriptions

Field	Description
0–31 LTH	Life Timer value Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1.

35.4.3 PIT Lower Lifetime Timer Register (PIT_LTMR64L)

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. LTMR64H will have the value of CVAL1 at the time of the first access, LTMR64L will have the value of CVAL0 at the time of the first access, therefore the application does not need to worry about carry-over effects of the running counter.

Access: User read only

Address: 0h base + E4h offset = E4h

PIT_LTMR64L field descriptions

Field	Description
0–31 LTL	Life Timer value Shows the value of timer 0 at the time LTMR64H was last read. It will only update if LTMR64H is read.

35.4.4 Timer Load Value Register (PIT_RTI_LDVAL)

These registers select the timeout period for the timer interrupts.

In the case of the RTI, it will take several cycles until this value is synchronized into the RTI clock domain. For all other timers the value change is visible immediately. The synchronisation mechanism allows 0 wait states in this case.

Access: User read/write

Address: 0h base + F0h offset = F0h

PIT_RTI_LDVAL field descriptions

Field	Description
0–31 TSV	Timer Start Value Sets the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer; instead the value will be loaded after the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again. NOTE: The RTI timer must not be set to a value lower than 32 cycles, otherwise interrupts may be lost, as it takes several cycles to clear the RTI interrupt. For the other timers, this limit does not apply, however there will be practical limits, since the processor will require several cycles to service an interrupt.

35.4.5 Current Timer Value Register (PIT_RTI_CVAL)

These registers indicate the current timer position.

For the RTI timers, they show a value which is several cycles old, since it originates from a potentially different clock domain.

Access: User read only

Address: 0h base + F4h offset = F4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PIT_TCTRL_n field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 CHN	Chain Mode When activated, Timer n-1 needs to expire before timer n can decrement by 1. Timer 0 cannot be chained. The RTI timer cannot be chained. 0 Timer is not chained. 1 Timer is chained to previous timer. For example, for Channel 2, if this field is set, Timer 2 is chained to Timer 1.
30 TIE	Timer Interrupt Enable When an interrupt is pending, or, TFLG_n[TIF] is set, enabling the interrupt will immediately cause an interrupt event. To avoid this, the associated TFLG_n[TIF] must be cleared first. 0 Interrupt requests from Timer n are disabled. 1 Interrupt will be requested whenever TIF is set.
31 TEN	Timer Enable Enables or disables the timer.

Table continues on the next page...

PIT_TCTRLn field descriptions (continued)

Field	Description
0	Timer n is disabled.
1	Timer n is enabled.

35.4.11 Timer Flag Register (PIT_TFLGn)

These registers hold the PIT interrupt flags.

Access: User read/write

Address: 0h base + 10Ch offset + (16d × i), where i=0d to 3d

PIT_TFLGn field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TIF	Timer Interrupt Flag Sets to 1 at the end of the timer period. Writing 1 to this flag clears it. Writing 0 has no effect. If enabled, or, when TCTRLn[TIE] = 1, TIF causes an interrupt request. 0 Timeout has not yet occurred. 1 Timeout has occurred.

35.5 Functional description

This section provides the functional description of the module.

35.5.1 General operation

This section gives detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts. Each interrupt is available on a separate interrupt line. Additionally the RTI timer can be used to wake up the processor.

35.5.1.1 Timers / RTI

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start value again. Each time a timer reaches 0, it will generate a trigger pulse and set the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared. Since in the case of the RTI, clearing the interrupt crosses clock domains, a minimum load value of 32 must be maintained.

If desired, the current counter value of the timer can be read via the CVAL registers. The value of the RTI counter can be delayed considerably, as it is synchronized to the bus clock from the RTI clock domain.

The counter period can be restarted, by first disabling, and then enabling the timer with TCTRLn[TEN]. See the following figure.

Figure 35-29. Stopping and starting a timer

The counter period of a running timer can be modified, by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

Figure 35-30. Modifying running timer period

It is also possible to change the counter period without restarting the timer by writing LDVAL with the new load value. This value will then be loaded after the next trigger event. See the following figure.

Figure 35-31. Dynamically setting a new load value

35.5.1.2 Debug mode

In Debug mode, the timers will be frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

35.5.2 Interrupts

All the timers support interrupt generation. The RTI is typically used for system wakeup, but can be used for interrupt generation as well. See the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting TCTRLn[TIE]. TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

The PIT_RTI generates a real time interrupt when the selected interrupt time period elapses. The RTI interrupt is disabled locally by setting TCTCRLn[TIE] to zero. The real time interrupt flag (TIF) is set to 1 when a timeout occurs, and is cleared by writing a 1 to the corresponding TFLGn[TIF]. The flag will be set regardless whether the interrupt is enabled.

The RTI can be used for periodic wakeup from a low-power mode. It can also be used to generate a general-purpose interrupt.

35.5.3 Chained timers

When a timer has chain mode enabled, it will only count after the previous timer has expired. So if timer n-1 has counted down to 0, counter n will decrement the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

35.6 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- The RTI clock has a frequency of 10 MHz.
- The RTI creates a wakeup interrupt every 500 ms.
- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns and the 10 MHz frequency equates to a clock period of 100 ns. Therefore, the RTI timer needs to trigger every $500 \text{ ms} / 100 \text{ ns} = 5,000,000$ cycles. Timer 1 needs to trigger every $5.12 \text{ ms} / 20 \text{ ns} = 256,000$ cycles and Timer 3 every $30 \text{ ms} / 20 \text{ ns} = 1,500,000$ cycles. The value for the LDVAL register trigger is calculated as:

$\text{LDVAL trigger} = (\text{period} / \text{clock period}) - 1$

This means RTI LDVAL will be written with 004C4B3F hex; LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F respectively.

To generate the wakeup interrupt, the interrupt line must be enabled by writing 1 to the RTI TIE bit in the TCTRL register. To start the RTI, the TEN in the RTI TCTRL register must also be set.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// RTI
PIT_RTI_LDVAL = 0x004C4B3F; // setup RTI for 5000000 cycles
PIT_RTI_TCTRL = PIT_TIE; // let RTI generate interrupts
PIT_RTI_TCTRL |= PIT_TEN; // start RTI

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1

// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

35.7 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.
- Timers 1 and 2 are available.
- An interrupt shall be raised every 1 minute.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN]. TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 2
```

Example configuration for the lifetime timer

```
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2

// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

35.8 Example configuration for the lifetime timer

To configure the lifetime timer, channels 0 and 1 need to be chained together.

First the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, then the LDVAL registers need to be set to the maximum value.

The timer is a downcounter.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1

// Timer 0
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

To access the lifetime, read first LTMR64H and then LTMR64L.

```
current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;
```

Chapter 36

Enhanced Modular IO Subsystem (eMIOS)

36.1 Chip-specific eMIOS information

This has two eMIOS module instances: eMIOS_0 and eMIOS_1. The two modules are identical and located on different Peripheral Bridges.

36.1.1 eMIOS channels and counter buses

Each eMIOS module instance has 16 channels, for a total of 32 channels. The 32 channels are split across the two instances to support redundancy for safety applications.

The following table shows the mapping of the 32 eMIOS external balls to the instance channels.

Table 36-1. eMIOS channel mapping

eMIOS balls	Instance channels	
	eMIOS_0	eMIOS_1
0-7	0-7	—
8-15	—	0-7
16-23	16-23	—
24-31	—	16-23

For both module instances, each set of implemented channels drives a counter bus:

- Channels 0-7 drive counter bus B.
- Channels 16-23 drive counter bus D.

36.1.2 eMIOS unimplemented channels

For both module instances, channels 8-15 and 24-31 are not implemented. References to features and functionality related to these channels—including registers, register fields, and counter buses—do not apply to this chip.

36.1.3 eMIOS interaction with other modules

The eMIOS modules interface with eTPU, DSPI, and IGF modules.

36.1.3.1 eMIOS global time base synchronization with eTPU

The Global Time Base Enable (GTBE) signal output of the eMIOS module instances, which is controlled by the eMIOS's MCR[GTBE] field, is ORed together with the GTBE signal output from the two eTPU instances. The ORed signal is then fed back to the GTBE input of all eMIOS and eTPU instances.

These connections enable global time base synchronization through the following procedure:

1. Negate the GTBE field in all eMIOS and eTPU instances.
2. Configure eMIOS and eTPU channels.
3. Assert the GTBE field in one of the eMIOS or eTPU instances.

36.1.3.2 eMIOS and eTPU ODIS connections

The following table lists the Output Disable (ODIS) connections between eMIOS and eTPU modules. The eMIOS modules' Cn[ODISSL] fields for the applicable channels use these connections.

Table 36-2. eMIOS and eTPU ODIS connections

Source		Destination		Description
Instance	Pin	Instance	Pin	
EMIOS_0	emios_flag_out[16:19]	EMIOS_0	emios_odis[3:0]	Connection from EMIOS_0 Channel Flag Out numbers 16, 17, 18, 19 to EMIOS_0 ODIS bits 3, 2, 1, 0, respectively
EMIOS_1	emios_flag_out[16:19]	EMIOS_1	emios_odis[3:0]	Connection from EMIOS_1 Channel Flag Out numbers 16, 17, 18, 19 to EMIOS_1 ODIS bits 3, 2, 1, 0, respectively

Table continues on the next page...

Table 36-2. eMIOS and eTPU ODIS connections (continued)

Source		Destination		Description
Instance	Pin	Instance	Pin	
EMIOS_0	emios_flag_out[16:19]	ETPU_C	etpu_odis_1[3:0]	Connection from EMIOS_0 Channel Flag Out numbers 16, 17, 18, 19 to ETPU_C ODIS bits 3, 2, 1, 0, respectively
EMIOS_1	emios_flag_out[16:19]	ETPU_A	etpu_odis_1[3:0]	Connection from EMIOS_1 Channel Flag Out numbers 16, 17, 18, 19 to ETPU_A ODIS bits 3, 2, 1, 0, respectively
EMIOS_1	emios_flag_out[23:20]	ETPU_B	etpu_odis_2[3:0]	Connection from EMIOS_1 Channel Flag Out numbers 23, 22, 21, 20 to ETPU_B ODIS bits 3, 2, 1, 0, respectively

36.1.3.3 STAC server IDs

STAC server IDs are defined in [STAC server IDs](#).

36.1.3.4 eMIOS and DSPI connections

See [DSPI and eMIOS direct connections](#) and [DSPI connections with SIU, eTPU, and eMIOS modules](#).

36.1.3.5 eMIOS inputs with Glitch Filters

See [IGF interaction with other modules](#) for connections between eMIOS and Input Glitch Filters (IGFs).

36.1.3.6 eMIOS and eTPU signal passthrough from pins via IGFs

On this chip, the IGF modules mediate between some pins and the eMIOS and eTPU modules. After system reset, the IGF modules are in Configuration mode by default. This mode disables IGF output and prevents the signals from the pins from reaching the eMIOS and eTPU modules.

The signals affected by this situation appear in [IGF interaction with other modules](#).

To route an affected signal directly to an eMIOS or eTPU instance, program the applicable channel of the applicable IGF instance:

1. Ensure that IGF_MCRn[MDIS] is 0 and that the IGF channel is disabled: IGF_MCRn[FGEN] is 0.
2. Configure the rising and falling edges for bypass:
 - Rising edge: Write 00b to IGF_MCRn[RFM].
 - Falling edge: Write 00b to IGF_MCRn[FFM].
3. Enable the IGF channel: Write 1 to IGF_MCRn[FGEN].

At the end of this sequence, the programmed filter enters Normal mode and passes through the affected signal.

36.2 Introduction

36.2.1 Overview

The configurable enhanced Modular Input/Output Subsystem (eMIOS) provides functionality to generate or measure time events. Its overall architecture resembles that of the MIOS timer.

The predecessor MIOS timer block provides a framework in which a set of sublocks with different timer functions are assembled to attend to the specific needs of an SoC. The eMIOS builds on this concept by using a Unified Channel module that provides a superset of the functionality of all the individual MIOS channels, while also providing a consistent user interface. This allows more flexibility as each Unified Channel can be programmed for different functions in different applications of the SoC. In addition, eMIOS architecture allows the use of Dedicated Channels which perform specific functions not included in MIOS inheritance.

The block diagram of the configurable eMIOS block is shown below.

Figure 36-1. eMIOS full channel configuration using Unified Channels only (see Configuration section)

36.2.2 Features

The eMIOS has the following features:

- Up to 32 channels chosen among Unified or Dedicated Channels, not necessarily numbered in a continuous sequence. (See Configuration information)
- Data registers of either 8-, 16-, 24-, or 32-bit width. (See Configuration information)
- Counter buses B, C, D, and E can be driven by Unified Channels 0, 8, 16, and 24, respectively. (See Configuration information)
- Counter bus A can be driven by Unified Channel 23 or by the external shared timer bus(Red-Line Client).
- Each channel has its own timebase, alternative to the counter buses.
- One global prescaler
- One prescaler per channel (CP)
- Timebases shared through the counter buses
- One STAC Client (STAC)
- Control and status bits grouped in separated registers
- Synchronization among timebases
- Shadow FLAG register
- State of the Unified Channels can be frozen for debug purposes

36.2.3 Modes of operation

The Unified Channels can be configured to operate in the following modes:

- General-Purpose Input/Output (GPIO)
- Single-Action Input Capture (SAIC)
- Single-Action Output Compare (SAOC)
- Input Pulse-Width Measurement (IPWM)
- Input Period Measurement (IPM)
- Double-Action Output Compare (DAOC)
- Pulse/Edge Accumulation (PEA)
- Pulse/Edge Counting (PEC)
- Quadrature Decode (QDEC)
- Windowed Programmable Time Accumulation (WPTA)

- Modulus Counter (MC)
- Modulus Counter Buffered (MCB)
- Output Pulse-Width and Frequency Modulation (OPWFM)
- Output Pulse-Width and Frequency Modulation Buffered (OPWFMB)
- Center Aligned Output Pulse Width Modulation with Dead Time Insertion (OPWMC)
- Center Aligned Output Pulse Width Modulation with Dead Time Insertion Buffered (OPWMCB)
- Output Pulse-Width Modulation (OPWM)
- Output Pulse-Width Modulation Buffered (OPWMB)

These modes are described in [Unified Channel modes of operation](#).

Each channel can have a specific set of modes.

36.3 Memory map / register definition

36.3.1 Memory map

The overall address map organization is shown in the table below.

Whenever an access to either an absent register, absent channel, or reserved address space is performed, the transfer is terminated with an error.

Table 36-3. eMIOS Memory Map

eMIOS[n] Base Address	Description
0x000	Module Configuration register (EMIOSMCR)
0x003	
0x004	Global FLAG register (EMIOSGFLAG)
0x007	
0x008	Output Update Disable (EMIOSOUDIS)
0x00B	
0x00C	Reserved
0x00F	
0x01F	Reserved

Table continues on the next page...

Table 36-3. eMIOS Memory Map (continued)

eMIOS[n] Base Address	Description
0x020	Channel 0 to Channel 7
0x11F	
0x120	Channel 8 to Channel 15
0x21F	
0x220	Channel 16 to Channel 23
0x31F	
0x320	Channel 24 to Channel 31
0x41F	
0x420	Reserved
0xFFF	

36.3.1.1 Unified channel memory map

Addresses of Unified Channel registers are specified as offsets from the channel's base address, otherwise the eMIOS base address is used as reference.

The following table describes the Unified Channel memory map.

Table 36-4. Unified channel memory map

UC[n] Base Address	Description
UC[n]_BASE + 0x000	A register (EMIOSA[n])
UC[n]_BASE + 0x004	B register (EMIOSB[n])
UC[n]_BASE + 0x008	Counter register (EMIOSCNT[n])
UC[n]_BASE + 0x00C	Control register (EMIOSC[n])
UC[n]_BASE + 0x010	Status register (EMIOSS[n])
UC[n]_BASE + 0x014	Alternate A register (EMIOSALTA[n])
UC[n]_BASE + 0x018	Control 2 register (EMIOSC2[n])
UC[n]_BASE + 0x01C to UC[n]_BASE + 0x01F	Reserved

36.4 Control Memory Map and Registers

All control registers are 32 bits wide. This document illustrates the eMIOS with 24 Unified Channels and 24-bit wide data registers.

eMIOS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	eMIOS Module Configuration Register (eMIOS_MCR)	32	R/W	0000_0000h	36.4.1/1391
4	eMIOS Global FLAG Register (eMIOS_GFLAG)	32	R	0000_0000h	36.4.2/1393
8	eMIOS Output Update Disable register (eMIOS_OUDIS)	32	R/W	0000_0000h	36.4.3/1393

36.4.1 eMIOS Module Configuration Register (eMIOS_MCR)

The MCR register contains Global Control bits for the eMIOS block.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15		
R	Reserved	MDIS	FRZ	GTBE	ETB	GPREN	0								SRV			
W

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	GPRE								0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eMIOS_MCR field descriptions

Field	Description
0 Reserved	Reserved. This field is reserved. Only write this field with the reset value.
1 MDIS	Module Disable bit. Puts the eMIOS into low power mode. The MDIS bit stops the clock of the block, except the access to registers EMIOSMCR and EMIOSOUDIS. 0 Clock is running 1 Enter low power mode
2 FRZ	Freeze bit. This bit enables the eMIOS to freeze the registers of the Unified Channels when Debug Mode is requested at MCU level. Each Unified Channel should have FREN bit set in order to enter freeze state. While in Freeze state, the eMIOS continues to operate to allow the MCU access to the Unified Channels registers. The Unified Channel will remain frozen until the FRZ bit is written to zero or the MCU exits Debug mode or the Unified Channel FREN bit is cleared.

Table continues on the next page...

eMIOS_MCR field descriptions (continued)

Field	Description
	0 Exit freeze state 1 Stops Unified Channels operation when in Debug mode and the FREN bit is set in the EMIOSC[n] register
3 GTBE	Global Time Base Enable bit. The GTBE bit is used to export a Global Time Base Enable from the module and provide a method to start time bases of several blocks simultaneously. NOTE: The Global Time Base Enable input pin controls the internal counters. When asserted, Internal counters are enabled. When negated, Internal counters disabled. 0 Global Time Base Enable Out signal negated 1 Global Time Base Enable Out signal asserted
4 ETB	External Time Base bit The ETB bit selects the time base source that drives counter bus[A]. 0 Counter bus[A] assigned to Unified Channel. 1 Counter bus[A] assigned to STAC.
5 GPREN	Global Prescaler Enable bit. The GPREN bit enables the prescaler counter. 0 Prescaler disabled (no clock) and prescaler counter is cleared 1 Prescaler enabled
6–11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12–15 SRV	Server Time Slot bits. The SRV bits select the address of a specific STAC server to which the STAC is assigned.
16–23 GPRE	Global Prescaler bits. The GPRE[0:7] bits select the clock divider value for the global prescaler, as shown in the following table. GPRE values and corresponding divide ratio values are: 00000000 1 00000001 2 00000010 3 00000011 4 ----- - 11111110 255 11111111 256
24–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

36.4.2 eMIOS Global FLAG Register (eMIOS_GFLAG)

GFLAG is a read-only register that groups the FLAG bits from all channels. Each bit relates to one channel.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0								F23_F16								0								F7_F0							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eMIOS_GFLAG field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–15 F23_F16	Channel [n] mirrored FLAG bit. For Unified Channels these bits are mirrors of the FLAG bits in the EMIOSS[n] register.
16–23 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
24–31 F7_F0	Channel [n] mirrored FLAG bit. For Unified Channels these bits are mirrors of the FLAG bits in the EMIOSS[n] register.

36.4.3 eMIOS Output Update Disable register (eMIOS_OUDIS)

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0								OU23_OU16								0								OU7_OU0

eMIOS_OUDIS field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

eMIOS_OUDIS field descriptions (continued)

Field	Description
8–15 OU23_OU16	Channel [n] Output Update Disable bit. When running MC, MCB or an output mode, values are written to registers A2 and B2. OU[n] bits are used to disable transfers from registers A2 to A1 and B2 to B1. Each bit controls one channel. 0 Transfer enabled. Depending on the operation mode, transfer may occur immediately or in the next period. Unless stated otherwise, transfer occurs immediately. 1 Transfers disabled.
16–23 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
24–31 OU7_OU0	Channel [n] Output Update Disable bit. When running MC, MCB or an output mode, values are written to registers A2 and B2. OU[n] bits are used to disable transfers from registers A2 to A1 and B2 to B1. Each bit controls one channel. 0 Transfer enabled. Depending on the operation mode, transfer may occur immediately or in the next period. Unless stated otherwise, transfer occurs immediately. 1 Transfers disabled.

36.5 Unified Channels Memory Map and Registers

The Unified Channel registers are as follows:

eMIOS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
20	eMIOS UC A register n (eMIOS_A0)	32	R/W	0000_0000h	36.5.1/1397
24	eMIOS UC B register n (eMIOS_B0)	32	R/W	0000_0000h	36.5.2/1398
28	eMIOS CNT register n (eMIOS_CNT0)	32	R/W	0000_0000h	36.5.3/1399

36.5.1 eMIOS UC A register n (eMIOS_An)

This section describes the register for channels 0-7. For channels 16-23, see [eMIOS UC A register n \(eMIOS_An\)](#).

Address: 0h base + 20h offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0								A																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eMIOS_An field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–31 A	Depending on the mode of operation, internal registers A1[0:23] or A2[0:23], used for matches and captures, can be assigned to address EMIOS_An. Both A1 and A2 are cleared by reset. The table in the EMIOS_Bn register description summarizes the EMIOS_An writing and reading accesses for all operation modes. Values not listed are reserved. For more information, see the “UC Modes of Operation” section.

36.5.2 eMIOS UC B register n (eMIOS_Bn)

This section describes the register for channels 0-7. For channels 16-23, see [eMIOS UC B register n \(eMIOS_Bn\)](#).

Depending on the mode of operation, internal registers B1[0:23] or B2[0:23] can be assigned to address EMIOS_Bn. Both B1 and B2 are cleared by reset. The table below summarizes the EMIOS_Bn writing and reading accesses for all operation modes. Values not listed are reserved. For more information see the “UC Modes of Operation” section.

Depending on the channel configuration, it may have an EMIOS_B register or not. EMIOS_B register is required for the following modes: DAOC, IPM, IPWM, OPWM, OPWMB, OPWFM, OPWFMB, OPWMC, OPWMCB, MC, MCB, PEA, PEC, WPTA.

The following table summarizes the EMIOS_An, EMIOS_Bn, and EMIOS_ALTAn writing and reading accesses for all operation modes. Values not listed are reserved. For more information, see the “UC Modes of Operation” section.

Table 36-13. EMIOS_An, EMIOS_Bn and EMIOS_ALTAn values assignment

Operation mode	Register access					
	Write	Read	Write	Read	Alt write	Alt read
GPIO	A1, A2	A1	B1, B2	B1	A2	A2
SAIC ¹	–	A2	B2	B2	–	–
SAOC	A2	A1	B2	B2	–	–
IPWM	–	A2	–	B1	–	–
IPM	–	A2	–	B1	–	–
DAOC	A2	A1	B2	B1	–	–
PEA	A1	A2	–	B1	–	–
PEC	A1	A1	B1	B1	–	A2
QDEC	A1	A1	B2	B2	–	–
WPTA	A1	A1	B1	B1	–	A2

Table continues on the next page...

Table 36-13. EMIOS_An, EMIOS_Bn and EMIOS_ALTAn values assignment (continued)

Operation mode	Register access					
	Write	Read	Write	Read	Alt write	Alt read
MC	A2	A1	B2	B2	–	–
OPWFM	A2	A1	B2	B1	–	–
OPWMC	A2	A1	B2	B1	–	–
OPWM	A2	A1	B2	B1	–	–
OPWMT	A2	A1	B2	B1	A2	A2
MCB	A2	A1	B2	B1	–	–
OPWFMB	A2	A1	B2	B1	–	–
OPWMCB	A2	A1	B2	B1	–	–
OPWMB	A2	A1	B2	B1	–	–

1. In these modes, the register EMIOS_Bn is not used, but B2 can be accessed.

Address: 0h base + 24h offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eMIOS_Bn field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–31 B	See text above register figure.

1. In these modes, the register EMIOS_Bn is not used, but B2 can be accessed.

36.5.3 eMIOS CNT register n (eMIOS_CNTn)

This section describes the register for channels 0-7. For channels 16-23, see [eMIOS CNT register n \(eMIOS_CNTn\)](#).

When GPIO mode is selected or the channel is frozen, the EMIOS_CNTn register is read/write. For all others modes, the EMIOS_CNTn is a read-only register. When entering some operation modes, this register is automatically cleared (refer to the “UC Modes of Operation” section for details).

EMIOS_CNTn register is required for the following modes:

- OPWFM

Unified Channels Memory Map and Registers

- OPWFMB
- OPWMC
- OPWMCB
- PEA
- PEC
- WPTA
- QDEC
- MC
- MCB

For other modes, the internal counter is not used. Therefore, depending on the modes available in a channel, the internal counter may be absent.

Address: 0h base + 28h offset + (32d × i), where i=0d to 7d

eMIOS_CNTn field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–31 C	The C field contains the value of the internal counter.

36.5.4 eMIOS UC Control register n (eMIOS_Cn)

This section describes the register for channels 0-7. For channels 16-23, see [eMIOS UC Control register n \(eMIOS_Cn\)](#).

The UC Control register gathers several read/write control bits affecting the UC operation conditions.

NOTE

This register does not include a FORCMB bit for Channel Types A and C.

Address: 0h base + 2Ch offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R									0							0
W	FREN	ODIS	ODISSL		UCPRE		UCPREN	DMA			IF			FCK	FEN

R	0				0											
W			FORCMA	FORCMB		BSL		EDSEL	EDPOL							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eMIOS_Cn field descriptions

Field	Description						
0 FREN	Freeze Enable bit. The FREN bit, if set and validated by FRZ bit in EMIOS_MCR register allows the channel to enter freeze state, freezing all registers values when in debug mode and allowing the MCU to perform debug functions. 0 Normal operation 1 Freeze UC registers values						
1 ODIS	Output Disable bit. The ODIS bit allows disabling the output pin when running any of the output modes with the exception of GPIO mode. 0 The output pin operates normally 1 If the selected Output Disable Input signal is asserted, the output pin goes to EDPOL for OPWFMB and OPWMB modes and to the complement of EDPOL for other output modes, but the Unified Channel continues to operate normally, i.e., it continues to produce FLAG and matches. When the selected Output Disable Input signal is negated, the output pin operates normally.						
2–3 ODISSL	Output Disable select bits. The ODISSL[0:1] bits select one of the four output disable input signals, as shown in the following table. Table 36-23. UC ODISSL selection <table> <tr> <th>ODISSL[0:1]</th><th>input signal</th></tr> <tr> <td>00</td><td>Output Disable Input 0</td></tr> <tr> <td>01</td><td>Output Disable Input 1</td></tr> </table>	ODISSL[0:1]	input signal	00	Output Disable Input 0	01	Output Disable Input 1
ODISSL[0:1]	input signal						
00	Output Disable Input 0						
01	Output Disable Input 1						

Table continues on the next page...

	<table><tr><th>IF[0:3] ¹</th><th>Minimum input Pulse width [filter clock periods]</th></tr><tr><td>0100</td><td>08</td></tr><tr><td>1000</td><td>16</td></tr><tr><td>All others</td><td>Reserved</td></tr></table>	IF[0:3] ¹	Minimum input Pulse width [filter clock periods]	0100	08	1000	16	All others	Reserved
IF[0:3] ¹	Minimum input Pulse width [filter clock periods]								
0100	08								
1000	16								
All others	Reserved								
	1. Filter latency (the difference in time between the input and the response) is 3 clock edges. 2. The input signal is synchronized before arriving to the digital filter.								
13 FCK	Filter Clock select bit. The FCK bit selects the clock source for the programmable input filter. 0 Prescaled clock 1 eMIOS module clock								
14 FEN	FLAG Enable bit. The FEN bit allows the Unified Channel FLAG bit to generate an interrupt signal or a DMA request signal (the type of signal to be generated is defined by the DMA bit). 0 Disable (FLAG does not generate an interrupt request) 1 Enable (FLAG generates an interrupt request)								
15–17 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.								
18 FORCMA	Force Match A bit. For output modes, the FORCMA bit is equivalent to a successful comparison on comparator A (except that the FLAG bit is not set). This bit is cleared by reset and is always read as zero. This bit is valid for every output operation mode which uses comparator A, otherwise it has no effect. For input modes, the FORCMA bit is not used and writing to it has no effect. 0 Has no effect. 1 Force a match at comparator A								
19 FORCMB	Force Match B bit. For output modes, the FORCMB bit is equivalent to a successful comparison on comparator B (except that the FLAG bit is not set). This bit is cleared by reset and is always read as zero. This bit is valid for every output operation mode which uses comparator B, otherwise it has no effect. 0 Has not effect 1 Force a match at comparator B								
20 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.								
21–22 BSL	Bus Select bits.								

Table continues on the next page...

eMIOS_Cn field descriptions (continued)

Field	Description													
	The BSL[0:1] bits are used to select either one of the counter buses or the internal counter to be used by the Unified Channel , as shown in the following tables. Table 36-20. UC BSL bits <table> <tr> <th>BSL[0:1]</th><th>Selected bus¹</th></tr> <tr> <td>00</td><td>All channels: counter bus[A]</td></tr> <tr> <td rowspan="4">01</td><td>Channels 0 to 7: counter bus[B]</td></tr> <tr> <td>Channels 8 to 15: counter bus[C]</td></tr> <tr> <td>Channels 16 to 23: counter bus[D]</td></tr> <tr> <td>Channels 24 to 31: counter bus[E]</td></tr> <tr> <td>10</td><td>Reserved</td></tr> <tr> <td>11</td><td>All channels: internal counter</td></tr> </table> 1. Not all devices support all counter buses. See the Device Configuration chapter for details.	BSL[0:1]	Selected bus ¹	00	All channels: counter bus[A]	01	Channels 0 to 7: counter bus[B]	Channels 8 to 15: counter bus[C]	Channels 16 to 23: counter bus[D]	Channels 24 to 31: counter bus[E]	10	Reserved	11	All channels: internal counter
BSL[0:1]	Selected bus ¹													
00	All channels: counter bus[A]													
01	Channels 0 to 7: counter bus[B]													
	Channels 8 to 15: counter bus[C]													
	Channels 16 to 23: counter bus[D]													
	Channels 24 to 31: counter bus[E]													
10	Reserved													
11	All channels: internal counter													
23 EDSEL	Edge Selection bit. For input modes, the EDSEL bit selects whether the internal counter is triggered by both edges of a pulse or just by a single edge as defined by the EDPOL bit . When not shown in the mode of operation description, this bit has no effect. 0 – Single edge triggering defined by the EDPOL bit 1 – Both edges triggering{mts_ipi_slv_saic} For GPIO in mode, the EDSEL bit selects if a FLAG can be generated. 0 – A FLAG is generated as defined by the EDPOL bit 1 – No FLAG is generated For SAOC mode, the EDSEL bit selects the behavior of the output flip-flop at each match. 0 – The EDPOL value is transferred to the output flip-flop 1 – The output flip-flop is toggled													
24 EDPOL	Edge Polarity bit. For input modes (except QDEC mode), the EDPOL bit asserts which edge triggers either the internal counter or an input capture or a FLAG . When not shown in the mode of operation description, this bit has no effect. 0 – Trigger on a falling edge 1 – Trigger on a rising edge NOTE: UC[n-1] EDPOL bit selects which edge clocks the internal counter of UC[n] NOTE: In order to operate properly, EDPOL bit must contain the same value in UC[n] and UC[n-1] For output modes, the EDPOL bit is used to select the logic level on the output pin . 0 – A match on comparator A clears the output flip-flop, while a match on comparator B sets it 1 – A match on comparator A sets the output flip-flop, while a match on comparator B clears it													
25–31 MODE	Mode selection bits. The MODE bits select the mode of operation of the Unified Channel, as shown in the following table. Values not listed are reserved.

1. Not all modes of operation are supported. See the configuration information for details. 2. b = adjust parameters for the mode of operation. Refer to “UC Modes of Operation” section for details.		

1. Filter latency (the difference in time between the input and the response) is 3 clock edges.
2. The input signal is synchronized before arriving to the digital filter.
3. Not all devices support all counter buses. See the Device Configuration chapter for details.
4. Not all modes of operation are supported. See the configuration information for details.
5. b = adjust parameters for the mode of operation. Refer to “UC Modes of Operation” section for details.

36.5.5 eMIOS UC Status register n (eMIOS_Sn)

This section describes the register for channels 0-7. For channels 16-23, see [eMIOS UC Status register n \(eMIOS_Sn\)](#).

The UC Status register EMIOS_Sn gathers bits reflecting the status of the UC input/output signals and the overflow condition of the internal counter.

Address: 0h base + 30h offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	OVR	0														
W	w1c															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	OVFL	0												UCIN	UCOUT	FLAG
W	w1c															w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	*	0	0

* Notes:

- UCIN field: Reset value is undefined.

eMIOS_*Sn* field descriptions

Field	Description
0 OVR	Overflow bit. The OVR bit indicates that FLAG generation occurred when the FLAG bit was already set . The OVR bit can be cleared either by clearing the FLAG bit or by writing a 1 to the OVR bit. 0 Overflow has not occurred 1 Overflow has occurred
1–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16 OVFL	Overflow bit. The OVFL bit indicates that an overflow has occurred in the internal counter. The OVFL bit must be cleared by software writing a 1 to it. 0 No overflow 1 An overflow had occurred
17–28 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
29 UCIN	Unified Channel Input pin bit. The UCIN bit reflects the input pin state after being filtered and synchronized.
30 UCOUT	Unified Channel Output pin bit. The UCOUT bit reflects the output pin state .
31 FLAG	FLAG bit. The FLAG bit is set when an input capture or a match event in the comparators occurred. The FLAG bit must be cleared by writing a 1 to it.

Table continues on the next page...

eMIOS_Sn field descriptions (continued)

Field	Description
0	FLAG cleared
1	FLAG set event has occurred

36.5.6 eMIOS Alternate Address register n (eMIOS_ALTAn)

This section describes the register for channels 0-7. For channels 16-23, see [eMIOS Alternate Address register n \(eMIOS_ALTAn\)](#).

The eMIOS_ALTAn register provides an alternate address to access A2 channel registers in restricted modes (GPIO, PEC, WPTA) only. In modes where the function of eMIOS_ALTAn register is not specified, any write access is ignored and any read access returns unspecified data. If eMIOS_An register is used along with eMIOS_ALTAn, both A1 and A2 registers can be accessed in these modes. The table in the eMIOS_Bn register's description summarizes the EMIOS_ALTAn writing and reading accesses for all EMIOS_ALTAn operation modes. See the “General purpose Input/Output mode (GPIO) Mode” section, the “Pulse/Edge Counting (PEC) Mode” section, the “Windowed Programmable Time Accumulation (WPTA) Mode” section for a more detailed description of the use of eMIOS_ALTAn register.

Address: 0h base + 34h offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eMIOS_An field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–31 A	Depending on the mode of operation, internal registers A1[0:23] or A2[0:23], used for matches and captures, can be assigned to address EMIOs_An. Both A1 and A2 are cleared by reset. The table in the EMIOs_Bn register description summarizes the EMIOs_An writing and reading accesses for all operation modes. Values not listed are reserved. For more information, see the “UC Modes of Operation” section.

36.5.8 eMIOS UC B register n (eMIOS_Bn)

This section describes the register for channels 16-23. In all other respects, this register is identical to the register for channels 0-7. See that register's description: [eMIOS UC B register n \(eMIOS_Bn\)](#).

Address: 0h base + 224h offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eMIOS_Cn field descriptions

Field	Description
0 FREN	Freeze Enable bit. The FREN bit, if set and validated by FRZ bit in EMIOS_MCR register allows the channel to enter freeze state, freezing all registers values when in debug mode and allowing the MCU to perform debug functions. 0 Normal operation 1 Freeze UC registers values
1 ODIS	Output Disable bit. The ODIS bit allows disabling the output pin when running any of the output modes with the exception of GPIO mode.

Table continues on the next page...

eMIOS_Cn field descriptions (continued)

Field	Description										
0	The output pin operates normally										
1	If the selected Output Disable Input signal is asserted, the output pin goes to EDPOL for OPWFMB and OPWMB modes and to the complement of EDPOL for other output modes, but the Unified Channel continues to operate normally, i.e., it continues to produce FLAG and matches. When the selected Output Disable Input signal is negated, the output pin operates normally.										
2–3 ODISSL	Output Disable select bits. The ODISSL[0:1] bits select one of the four output disable input signals, as shown in the following table. Table 36-129. UC ODISSL selection <table> <tr> <th>ODISSL[0:1]</th><th>input signal</th></tr> <tr> <td>00</td><td>Output Disable Input 0</td></tr> <tr> <td>01</td><td>Output Disable Input 1</td></tr> <tr> <td>10</td><td>Output Disable Input 2</td></tr> <tr> <td>11</td><td>Output Disable Input 3</td></tr> </table>	ODISSL[0:1]	input signal	00	Output Disable Input 0	01	Output Disable Input 1	10	Output Disable Input 2	11	Output Disable Input 3
ODISSL[0:1]	input signal										
00	Output Disable Input 0										
01	Output Disable Input 1										
10	Output Disable Input 2										
11	Output Disable Input 3										
4–5 UCPRE	Prescaler bits. The UCPRE[0:1] bits select the clock divider value for the internal prescaler of Unified Channel, as shown in the following table. Table 36-128. UC Internal Prescaler clock divider <table> <tr> <th>UCPRE[0:1]</th><th>Divide ratio</th></tr> <tr> <td>00</td><td>1</td></tr> <tr> <td>01</td><td>2</td></tr> <tr> <td>10</td><td>3</td></tr> <tr> <td>11</td><td>4</td></tr> </table> NOTE: The UCPRE bits are mirrored in the two LSBs of the UCEXTPRE field in register EMIOS_Cn. Any write operations to UCPRE bits will affect the respective bits at EMIOS_C2n register.	UCPRE[0:1]	Divide ratio	00	1	01	2	10	3	11	4
UCPRE[0:1]	Divide ratio										
00	1										
01	2										
10	3										
11	4										
6 UCPREN	Prescaler Enable bit. The UCPREN bit enables the prescaler counter. 0 Prescaler disabled (no clock) 1 Prescaler enabled										
7 DMA	Direct Memory Access bit. The DMA bit selects if FLAG generation will be used as an interrupt or as a DMA request. 0 Flag/overflow assigned to Interrupt request. 1 Flag/overflow assigned to DMA request.										
8 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.										

Table continues on the next page...

eMIOS_Cn field descriptions (continued)

Field	Description														
9–12 IF	Input Filter bits. The IF[0:3] bits control the programmable input filter, selecting the minimum input pulse width that can pass through the filter, as shown in the following table. For output modes, these bits have no meaning. Table 36-127. UC Input Filter bits <table> <tr> <th>IF[0:3] ¹</th><th>Minimum input Pulse width [filter clock periods]</th></tr> <tr> <td>0000</td><td>bypassed²</td></tr> <tr> <td>0001</td><td>02</td></tr> <tr> <td>0010</td><td>04</td></tr> <tr> <td>0100</td><td>08</td></tr> <tr> <td>1000</td><td>16</td></tr> <tr> <td>All others</td><td>Reserved</td></tr> </table> 1. Filter latency (the difference in time between the input and the response) is 3 clock edges. 2. The input signal is synchronized before arriving to the digital filter.	IF[0:3] ¹	Minimum input Pulse width [filter clock periods]	0000	bypassed ²	0001	02	0010	04	0100	08	1000	16	All others	Reserved

0001	02														
0010	04														
0100	08														
1000	16														
All others	Reserved														
13 FCK	Filter Clock select bit. The FCK bit selects the clock source for the programmable input filter. 0 Prescaled clock 1 eMIOS module clock														
14 FEN	FLAG Enable bit. The FEN bit allows the Unified Channel FLAG bit to generate an interrupt signal or a DMA request signal (the type of signal to be generated is defined by the DMA bit). 0 Disable (FLAG does not generate an interrupt request) 1 Enable (FLAG generates an interrupt request)														
15–17 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.														
18 FORCMA	Force Match A bit. For output modes, the FORCMA bit is equivalent to a successful comparison on comparator A (except that the FLAG bit is not set). This bit is cleared by reset and is always read as zero. This bit is valid for every output operation mode which uses comparator A, otherwise it has no effect. For input modes, the FORCMA bit is not used and writing to it has no effect. 0 Has no effect. 1 Force a match at comparator A														
19 FORCMB	Force Match B bit. For output modes, the FORCMB bit is equivalent to a successful comparison on comparator B (except that the FLAG bit is not set). This bit is cleared by reset and is always read as zero. This bit is valid for every output operation mode which uses comparator B, otherwise it has no effect. 0 Has not effect 1 Force a match at comparator B

36.6 Functional Description

The eMIOS provides independent channels (Unified) that can be configured and accessed by a host MCU. Up to five time bases can be shared by the channels.

The eMIOS module is based on a multi-bus timer architecture in which several timer channels are used to drive counter buses that are shared among the channels. Up to five timebases can be shared by the channels through five counter buses (counter bus A or F, B, C, D and E) and each channel can generate its own timebase. There are five counter buses in the module: one global counter bus, shared by all channels and selectable among time bases A or F, and four local counter buses (B, C, D, and E), each one dedicated to a slice of 8 channels. Counter bus A is referred to as the global counter buse. Counter buses B, C, D, and E are the local counter buses.

The eMIOS counter buses are driven by channels in specific locations. Global counter bus A is driven by the channel in channel slot [23]. Counter buses B, C, D, and E are driven by channels in slots 0, 8, 16, and 24, respectively. Counter bus A or F drives all channels. Counter bus B drives channels in slots from 0 through 7. Counter bus C drives channels in slots from 8 through 15. Counter bus D drives channels in slots from 16 through 23. Counter bus E drives channels from 24 through 31.

The eMIOS block is reset asynchronously. All registers are cleared on reset.

The following figure shows an eMIOS block configured with a mix of Unified Channels. In this configuration example, each one of the channels can be driven by the respective local bus—B for the [7:0] slice and D for the [23:16] slice—or by the global counter bus A. Note that there are Unified Channels with no external pin associated. These channels are used to trigger internal SoC signals such as interrupt requests or DMA transfer requests. Since the channel flags are also connected to the block top-level pins, they can be used as trigger signals for other blocks at chip level.

Figure 36-113. eMIOS example configuration using Unified Channels

36.6.1 Unified Channel (UC)

Figure 36-114 shows the Unified Channel block diagram. Each Unified Channel consists of the following:

- A counter bus selector, which selects the timebase to be used by the channel for all timing functions
- A programmable clock prescaler
- Two double-buffered data registers, A and B, that allow up to two input capture and/or output compare events to occur before software intervention is needed
- Two comparators (equal only), A and B, that compare the selected counter bus with the value in the data registers
- An internal counter, which can be used as a local time base or to count input events
- Programmable input filter, which ensures that only valid pin transitions are received by channel
- Programmable input edge detector, which detects the rising, falling, or either edge
- An output flip-flop, which holds the logic level to be applied to the output pin
- eMIOS Status and Control register
- An Output Disable Input selector, which selects the Output Disable Input signal that will be used as output disable

Figure 36-114. Unified Channel block diagram

Figure 36-115 shows both the Unified Channel control and datapath block diagrams. The control sub-block is responsible for the generation of signals to control the multiplexers in the datapath sub-block. Each mode is implemented by a dedicated logic independent from others modes, thus allowing to optimize the logic by disabling the mode and therefore its associated logic. Targeting the logic optimization, a set of registers is shared by the modes thus providing sequential events to be stored.

The datapath block provides the channel A and B registers, the internal timebase and comparators. Multiplexers select the input of comparators and data for the registers inputs, thus configuring the datapath to implement the channel modes. The outputs of the A and B comparators are connected to the uc_ctrl control block.

Figure 36-115. Unified Channel control and datapath block diagrams

36.6.1.1 Unified Channel modes of operation

The mode of operation of the Unified Channel is determined by the mode select bits `MODE[0:6]` in the `EMIOS_C_n` register.

When entering an output mode (except for GPIO mode), the output flip-flop is set to the disabled state according to `EMIOSCn[ODIS]`.

As the internal counter, `EMIOSCNTn`, runs in all modes (except for GPIO mode) and can be used as a timebase if the resource is not used in the current mode.

In order to provide smooth waveform generation even when A and B registers are immediately changed, it is available with the MCB, OPWFMB, OPWMB and OPWFMB modes. In these modes, A and B registers are double buffered. They are presented in separate sections because there are several basic differences between these and each corresponding nonbuffered mode.

36.6.1.1.1 General-Purpose Input/Output (GPIO) mode

In GPIO mode, all input capture and output compare functions of the Unified Channel are disabled, and the internal counter (`EMIOSCNTn` register) is cleared and disabled. All control bits remain accessible. In order to prepare the UC for a new operation mode, writing to registers `EMIOSAn` or `EMIOSBn` stores the same value in registers `A1/A2` or `B1/B2`, respectively. Writing to the `EMIOSALTAn` register stores a value only in register `A2`.

`MODE[6]` bit selects between input (`MODE[6] = 0`) and output (`MODE[6] = 1`) modes.

When changing `MODE[0:6]`, the application software must first enter GPIO mode to reset the Unified Channel's internal functions properly. Failure to do this could lead to invalid and unexpected output compare or input capture results or the `FLAGs` being set incorrectly.

In GPIO input mode (`MODE[0:6] = 0000000`), `FLAG` generation is determined according to `EDPOL` and `EDSEL` bits and the input pin status can be determined by reading the `UCIN` bit.

In GPIO output mode (`MODE[0:6] = 0000001`), the Unified Channel is used as a single output port pin and the value of the `EDPOL` bit is permanently transferred to the output flip-flop.

36.6.1.1.2 Single Action Input Capture (SAIC) Mode

In SAIC mode (MODE[0:6]=0000010), when a triggering event occurs on the input pin, the value on the selected time base is captured into register A2. The FLAG bit is set along with the capture event to indicate that an input capture has occurred. Register EMIOSA[n] returns the value of register A2. As soon as the SAIC mode is entered coming out from GPIO mode the channel is ready to capture events. The events are captured as soon as they occur thus reading register A always returns the value of the latest captured event. Subsequent captures are enabled with no need of further reads from EMIOSA[n] register. The FLAG is set at any time a new event is captured.

The input capture is triggered by a rising, falling or either edges in the input pin, as configured by EDPOL and EDSEL bits in EMIOSC[n] register.

Figure 36-116 and Figure 36-117 show how the Unified Channel can be used for input capture.

Figure 36-116. Single Action Input Capture with rising edge triggering example

Figure 36-117. Single Action Input Capture with both edges triggering example

36.6.1.1.3 Single Action Output Compare (SAOC) Mode

In SAOC mode (MODE[0:6]=0000011) a match value is loaded in register A2 and then immediately transferred to register A1 to be compared with the selected time base. When a match occurs, the EDSEL bit selects whether the output flip-flop is toggled or the value

in EDPOL is transferred to it. Along with the match the FLAG bit is set to indicate that the output compare match has occurred. Writing to register EMIOSA[n] stores the value in register A2 and reading to register EMIOSA[n] returns the value of register A1.

An output compare match can be simulated in software by setting the FORCMA bit in EMIOSC[n] register. In this case, the FLAG bit is not set.

When SAOC mode is entered coming out from GPIO mode, the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

Counter bus can be either internal or external and is selected through BSL[0:1] bits.

Figure 36-118 and Figure 36-119 show how the Unified Channel can be used to perform a single output compare with EDPOL value being transferred to the output flip-flop and toggling the output flip-flop at each match, respectively. Note that once in SAOC mode the matches are enabled thus the desired match value on register A1 must be written before the mode is entered. A1 register can be updated at any time thus modifying the match value which will reflect in the output signal generated by the channel. Subsequent matches are enabled with no need of further writes to EMIOSA[n] register. The FLAG is set at the same time a match occurs (see Figure 36-120).

Note

The channel internal counter in SAOC mode is free-running. It starts counting as soon as the SAOC mode is entered.

Figure 36-118. SAOC example with EDPOL value being transferred to the output flip-flop

Figure 36-119. SAOC example toggling the output flip-flop

Note: 1. EMIOSA[n] <= A2

Figure 36-120. SAOC example with flag behavior

36.6.1.1.4 Input Pulse Width Measurement (IPWM) Mode

The IPWM mode (MODE[0:6]=0000100) allows the measurement of the width of a positive or negative pulse by capturing the leading edge on register B1 and the trailing edge on register A2. Successive captures are done on consecutive edges of opposite polarity. The leading edge sensitivity (i.e., pulse polarity) is selected by EDPOL bit in the EMIOSC[n] register. Registers EMIOSA[n] and EMIOSB[n] return the values in register A2 and B1, respectively.

The capture function of register A2 remains disabled until the first leading edge triggers the first input capture on register B2. When this leading edge is detected, the count value of the selected time base is latched into register B2; the FLAG bit is not set. When the trailing edge is detected, the count value of the selected time base is latched into register A2 and, at the same time, the FLAG bit is set and the content of register B2 is transferred to register B1 and to register A1.

If subsequent input capture events occur while the corresponding FLAG bit is set, registers A2, B1 and A1 will be updated with the latest captured values and the FLAG will remain set. Registers EMIOSA[n] and EMIOSB[n] return the value in registers A2 and B1, respectively.

In order to guarantee coherent access, reading EMIOSA[n] forces B1 be updated with the content of register A1. At the same time transfers between B2 and B1 are disabled until the next read of EMIOSB[n] register. Reading EMIOSB[n] register forces B1 be updated with A1 register content and re-enables transfers from B2 to B1, to take effect at the next trailing edge capture. Transfers from B2 to A1 are not blocked at any time.

The input pulse width is calculated by subtracting the value in B1 from A2.

The following figure shows how the Unified Channel can be used for input pulse width measurement.

Functional Description

Figure 36-121. Input Pulse Width Measurement example

The following figure shows the A1 and B1 updates when EMIOSA[n] and EMIOB[n] register reads occur. Note that A1 register has always coherent data related to A2 register. Note also that when EMIOSA[n] read is performed B1 register is loaded with A1 register content. This guarantee that the data in register B1 has always the coherent data related to the last EMIOSA[n] read. The B1 register updates remains locked until EMIOB[n] read occurs. If EMIOSA[n] read is performed B1 is updated with A1 register content even if B1 update is locked by a previous EMIOSA[n] read operation.

Figure 36-122. B1 and A1 updates at EMIOSA[n] and EMIOB[n] reads

Reading EMIOS_A_n followed by EMIOS_B_n always provides coherent data. If coherent data is not required for any reason, the sequence of reads should be inverted, therefore EMIOB[n] should be read prior to EMIOSA[n] register. Note that even in this case B1 register updates will be blocked after EMIOSA[n] read, thus a second EMIOB[n] is required in order to release B1 register updates.

36.6.1.1.5 Input Period Measurement (IPM) Mode

The IPM mode (MODE[0:6]=0000101) allows the measurement of the period of an input signal by capturing two consecutive rising edges or two consecutive falling edges. Successive input captures are done on consecutive edges of the same polarity. The edge polarity is defined by the EDPOL bit in the EMIOSC[n] register.

Note

The input signal must have at least four system clock cycles period in order to be properly captured by the synchronization logic at the channel input even if the input filter is in by-pass mode.

When the first edge of selected polarity is detected, the selected time base is latched into the registers A2 and B2, and the data previously held in register B2 is transferred to register B1. On this first capture the FLAG line is not set, and the values in registers B1 is meaningless. On the second and subsequent captures, the FLAG line is set and data in register B2 is transferred to register B1.

When the second edge of the same polarity is detected, the counter bus value is latched into registers A2 and B2, the data previously held in register B2 is transferred to data register B1 and to register A1. The FLAG bit is set to indicate the start and end points of a complete period have been captured. This sequence of events is repeated for each subsequent capture. Registers EMIOSA[n] and EMIOSB[n] return the values in register A2 and B1, respectively.

In order to allow coherent data, reading EMIOSA[n] forces A1 content be transferred to B1 register and disables transfers between B2 and B1. These transfers are disabled until the next read of the EMIOSB[n] register. Reading EMIOSB[n] register forces A1 content to be transferred to B1 and re-enables transfers from B2 to B1, to take effect at the next edge capture.

The input pulse period is calculated by subtracting the value in B1 from A2.

The following figure shows how the Unified Channel can be used for input period measurement.

Figure 36-123. Input Period Measurement example

Figure 36-124 describes the A1 and B1 register updates when EMIOSA[n] and EMIOSB[n] read operations are performed. When EMIOSA[n] read occurs the content of A1 is transferred to B1 thus providing coherent data in A2 and B1 registers. Transfers from B2 to B1 are then blocked until EMIOSB[n] is read. After EMIOSB[n] is read, register A1 content is transferred to register B1 and the transfers from B2 to B1 are re-enabled to occur at the transfer edges, which is the leading edge in the following example figure.

Figure 36-124. A1 and B1 updates at EMIOSA[n] and EMIOSB[n] reads

36.6.1.1.6 Double Action Output Compare (DAOC) Mode

In the DAOC mode, the leading and trailing edges of the variable pulse width output are generated by matches occurring on comparators A and B. There is no restriction concerning the order in which A and B matches occur.

When the DAOC mode is entered, coming out from GPIO mode both comparators are disabled and the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

Data written to A2 and B2 are transferred to A1 and B1, respectively, on the next system clock cycle if OU[n] bit of EMIOSOUDIS register is cleared (see [Figure 36-151](#)). The transfer is blocked if OU[n] bit is set. Comparator A is enabled only after the transfer to A1 register occurs and is disabled on the next A match. Comparator B is enabled only after the transfer to B1 register occurs and is disabled on the next B match. Comparators A and B are enabled and disabled independently.

The output flip-flop is set to the value of EDPOL when a match occurs on comparator A and to the complement of EDPOL when a match occurs on comparator B.

MODE[6] controls if the FLAG is set on both matches (MODE[0:6]=0000111) or just on the B match (MODE[0:6]=0000110). FLAG bit assertion depends on comparator enabling.

If subsequent enabled output compares occur on registers A1 and B1, pulses will continue to be generated, regardless of the state of the FLAG bit.

At any time, the FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a comparison event in comparator A or B, respectively. Note that the FLAG bit is not affected by these forced operations.

Note

If both registers (A1 and B1) are loaded with the same value, the B match prevails concerning the output pin state (output flip-flop is set to the complement of EDPOL), the FLAG bit is set and both comparators are disabled.

The following two tables show how the Unified Channel can be used to generate a single output pulse with FLAG bit being set on the second match or on both matches, respectively.

Notes: 1. EMIOA[n] = A1 (when reading)
 2. EMIOB[n] = B1 (when reading)
 A2 = A1 according to OU[n] bit
 B2 = B1 according to OU[n] bit

Figure 36-125. Double Action Output Compare with FLAG set on the second match, MODE[0] bit is 0

Notes: 1. EMIOA[n] = A1 (when reading)
 2. EMIOB[n] = B1 (when reading)
 A2 = A1 according to OU[n] bit
 B2 = B1 according to OU[n] bit

Figure 36-126. Double Action Output Compare with FLAG set on both matches, MODE[0] bit is 1

Figure 36-127. DAOC with transfer disabling example

36.6.1.1.7 Pulse/Edge Accumulation (PEA) Mode

The PEA mode returns the time taken to detect a desired number of input events. MODE[6] bit selects between continuous or single shot operation.

After writing to register A1, the internal counter is cleared on the first input event, ready to start counting input events and the selected timebase is latched into register B2. On the match between the internal counter and register A1, a counter bus capture is triggered to register A2 and B2. The data previously held in register B2 is transferred to register B1 and the FLAG bit is set to indicate that an event has occurred. The desired time interval can be determined by subtracting register B1 from A2. Registers EMIOSA[n] and EMIOSB[n] return the values in register A2 and B1, respectively.

As part of the coherency mechanism, reading EMIOSA[n] disables transfers from B2 to B1. These transfers are disabled until the next read of the EMIOS_B_n register. Reading the EMIOSB[n] register re-enables transfers from B2 to B1, to take effect at the next transfer event, as described above. ³

In order to have coherent data in continuous mode of operation the following steps should be performed, assuming FLAG is initially cleared:

3. If B1 was not updated due to B2 to B1 transfer being disabled after reading register EMIOS_A_n, further EMIOS_A_n] and EMIOS_B_n reads will not return coherent data until a new bus capture is triggered to registers A2 and B2. This capture event is indicated by the channel FLAG being asserted. If enabled, the FLAG also generates an interrupt.

Functional Description

1. Wait for FLAG assertion;
2. Read EMIOSA[n] register;
3. Read EMIOSB[n] register;
4. Clear FLAG bit;
5. Return to step 1.

Accumulation cycles may be lost if the read is not performed in a timely manner. Whenever Overrun bit is asserted it means that one or more cycles have been lost.

Triggering of the counter clock (input event) is done by a rising or falling edge or both edges on the input pin. The polarity of the triggering edge is selected by the EDSEL and EDPOL bits in EMIOS_C_n register.

For continuous operation mode (MODE[6] cleared, MODE[0:6]=0001000), the counter is cleared on the next input event after a FLAG generation and continues to operate as described above.

For single shot operation (MODE[6] set, MODE[0:6]=0001001), the counter is not cleared or incremented after a FLAG generation, until a new writing operation to register A is performed.

Figure 36-128 and Figure 36-129 show how the Unified Channel can be used for continuous and single shot pulse/edge accumulation mode.

Figure 36-128. Pulse/Edge Accumulation continuous mode example (MODE[6] bit is 0b)

Figure 36-129. Pulse/Edge Accumulation single-shot mode example (MODE[6] bit is 1b)

36.6.1.1.8 Pulse/Edge Counting (PEC) Mode

The PEC mode returns the amount of pulses or edges detected on the input for a desired time window. MODE[6] bit selects between continuous or single shot operation.

Triggering of the internal counter is done by a rising or falling edge or both edges on the input signal. The polarity and the triggering edge is selected by EDSEL and EDPOL bits in EMIOSC[n] register.

Register A1 holds the start time and register B1 holds the stop time for the time window. After writing to register A1, when a match occur between comparator A and the selected timebase, the internal counter is cleared and it is ready to start counting input events. When the time base matches comparator B, the internal counter is disabled and its content is transferred to register A2. At the same time the FLAG bit is set. Reading registers EMIOSCNT[n] or A2 returns the amount of detected pulses.

For continuous operation (MODE[6] cleared, MODE[0:6]=0001010), the next match between comparator A and the selected time base clears the internal counter and counting is enabled again. In order to guarantee coherent measurements when reading EMIOSCNT[n] after the FLAG is set, the software must check if the time base value is out of the time interval defined by registers A1 and B1. Alternatively register A2 always holds the latest available measurement providing coherent data at any time after the first FLAG had occurred. This register is addressed by the alternate address EMIOSALTA[n].

Functional Description

For single shot operation (MODE[6] set, MODE[0:6]=0001011), the next match between comparator A and the selected time base has no effect, until a new write to register A is performed. The EMIOSENT content is also transferred to register A2 when a match in the B comparator occurs.

Figure 36-130 and Figure 36-131 show how the Unified Channel can be used for continuous or single shot pulse/edge counting mode.

Figure 36-130. Pulse/Edge Counting continuous mode example

Figure 36-131. Pulse/Edge Counting single-shot mode example

36.6.1.1.9 Quadrature Decode (QDEC) Mode

Quadrature decode mode uses UC[n] operating in QDEC mode and the input programmable filter (IPF) from UC[n-1]. Note that UC[n-1] can be configured, at the same time, to an operation mode that does not use I/O pins, such as MC mode (modulus counter). The connection among the UCs is circular, i.e., when UC[0] is running in QDEC mode, the input programmable filter from UC[23] is being used, for the case of a 24-channel configuration.

This mode generates a FLAG every time the internal counter matches A1 register. The internal counter is automatically selected and is not cleared when entering this mode.

MODE[6] bit selects which type of encoder will be used: *count & direction* encoder or *phase_A and phase_B* encoders.

When operating with *count and direction* encoder (MODE[6] cleared), UC[n] input pin must be connected to the *direction* signal and UC[n-1] input pin must be connected to the *count* signal of the quadrature encoder. UC[n] EDPOL bit selects count direction according to *direction* signal and UC[n-1] EDPOL bit selects if the internal counter is clocked by the rising or falling edge of the *count* signal.

When operating with *phase_A and phase_B* encoder (MODE[6] set), UC[n] input pin must be connected to the *phase_A* signal and UC[n-1] input pin must be connected to the *phase_B* signal of the quadrature encoder. EDPOL bit selects the count direction according to the phase difference between *phase_A* and *phase_B* signals.

Figure 36-132 and Figure 36-133 show two Unified Channels configured to quadrature decode mode for *count & direction* encoder and *phase_A and phase_B* encoders, respectively.

Figure 36-132. Quadrature Decode mode example with *count and direction* encoder

Functional Description

Figure 36-133. Quadrature Decode mode example with *phase_A* and *phase_B* encoder

36.6.1.1.10 Windowed Programmable Time Accumulation (WPTA) Mode

The WPTA mode (MODE[0:6]=0001110) accumulates the sum of the total high time or low time of an input signal over a programmable interval (time window).

The prescaler bits UCPRE[0:1] in EMIOSC[n] register define the increment rate of the internal counter.

Register A1 holds the start time and register B1 holds the stop time of the programmable time interval. When a match occurs between register A and the selected timebase, the internal counter is cleared and it is ready to start counting. The internal counter is used as a time accumulator, i.e., it counts up when the input signal has the same polarity of EDPOL bit in EMIOSC[n] register and does not count otherwise. When a match occurs in comparator B, the internal counter is disabled regardless of the input signal polarity and the FLAG bit is set. At the same time the content of EMIOSCNT[n] is transferred to register A2. Reading registers EMIOSCNT[n] or A2 returns the high or low time of the input signal.

Note that EMIOSCNT[n] is stable only outside the time window defined from A1 to B1 matches, otherwise its content reflects a count in progress and not the final value. Alternatively to EMIOSCNT register A2 returns the latest available measurement. Since this register is updated only at comparator B matches it always contains stable and up-to-date data. In this mode this register is accessible through the alternate register address EMIOSALTA[n].

The following figure shows how the Unified Channel can be used to accumulate high time.

Figure 36-134. Windowed Programmable Time Accumulation example

36.6.1.1.11 Modulus Counter (MC) Mode

The MC mode can be used to provide a time base for a counter bus or as a general purpose timer.

MODE[6] bit selects internal or external clock source when cleared or set, respectively. When external clock is selected, the input signal pin is used as the source and the triggering polarity edge is selected by the EDPOL and EDSEL in the EMIOSC[n] register.

The internal counter counts up from the current value until it matches the value in register A1. Register B1 is cleared and is not accessible to the MCU. MODE[4] bit selects up mode or up/down mode, when cleared or set, respectively.

When in up count mode, a match between the internal counter and register A1 sets the FLAG and clears the internal counter. The timing of those events varies according to the MC mode setup as follows:

- Internal counter clearing on match start (MODE[0:6]=001000b)

- External clock is selected if MODE[0] is set. In this case the internal counter clears as soon as the match signal occurs. The channel FLAG is set at the same time the match occurs. Note that by having the internal counter cleared as soon as the match occurs and incremented at the next input event a shorter zero count is generated. See [Figure 36-164](#) and [Figure 36-165](#).
- Internal clock source is selected if MODE[0] is cleared. In this case the counter clears as soon as the match signal occurs. The channel FLAG is set at the same time the match occurs. At the next prescaler tick after the match the internal counter remains at zero and only resumes counting on the following tick. See [Figure 36-164](#) and [Figure 36-166](#).
- Internal counter clearing on match end (MODE[0:6]=001001b)
 - External clock is selected if MODE[0] is set. In this case the internal counter clears when the match signal is asserted and the input event occurs. The channel FLAG is set at the same time the counter is cleared. See [Figure 36-164](#) and [Figure 36-167](#).
 - Internal clock source is selected if MODE[0] is cleared. In this case the internal counter clears when the match signal is asserted and the prescaler tick occurs. The channel FLAG is set at the same time the counter is cleared. See [Figure 36-164](#) and [Figure 36-167](#).

Note

If internal clock source is selected and the prescaler of the internal counter is set to 1 the MC mode behaves the same way even in Clear on Match Start or Clear on Match End sub-modes.

When in up/down count mode (MODE[0:6]=00101bb), a match between the internal counter and register A1 sets the FLAG and changes the counter direction from increment to decrement. A match between register B1 and the internal counter changes the counter direction from decrement to increment and sets the FLAG only if MODE[5] bit is set.

Only values different than 0x0 must be written at A register. Loading 0x0 leads to unpredictable results.

Updates on register A or counter in MC mode may cause loss of match in the current cycle if the transfer occurs near the match. In this case, the counter may rollover and resume operation in the next cycle.

Register B2 has no effect in MC mode. Nevertheless, register B2 can be accessed for reads and writes by addressing EMIOB.

The following two figures show how the Unified Channel can be used as modulus counter in up mode and up/down mode, respectively.

Figure 36-135. Modulus Counter up mode example (MODE[4] bit is 0)

Figure 36-136. Modulus Counter up/down mode example (MODE[4] bit is 1)

36.6.1.1.12 Modulus Counter Buffered (MCB) Mode

The MCB mode provides a time base which can be shared with other channels through the internal counter buses. Register A1 is double buffered thus allowing smooth transitions between cycles when changing A2 register value on the fly. Register A1 is updated at the cycle boundary, which is defined as when the internal counter transitions to 0x1.

The internal counter values operates within a range from 0x1 up to register A1 value. If when entering MCB mode coming out from GPIO mode the internal counter value is not within that range then the A match will not occur causing the channel internal counter to wrap at the maximum counter value which is 0xff_ff for a 24-bit counter. After the counter wrap occurs it returns to 0x1 and resume normal MCB mode operation. Thus in order to avoid the counter wrap condition make sure its value is within the 0x1 to register A1 value range when the MCB mode is entered.

MODE[6] bit selects internal clock source if cleared or external if set. When external clock is selected the input channel pin is used as the channel clock source. The active edge of this clock is defined by EDPOL and EDSEL bits in the EMIOSC[n] channel register.

When entering in MCB mode, if up counter is selected by MODE[4]=0 (MODE[0:6]=101000b), the internal counter starts counting from its current value to up direction until A1 match occurs. The internal counter is set to 0x1 when its value matches A1 value and a clock tick occurs (either prescaled clock or input pin event).

If up/down counter is selected by setting MODE[4]=1, the counter changes direction at A1 match and counts down until it reaches the value 0x1. After it has reached 0x1 it is set to count in up direction again. Register B1 is used to generate a match in order to set the internal counter in up-count direction if up/down mode is selected. Register B1 cannot be changed while this mode is selected.

Note that differently from the MC mode, the MCB mode counts between 0x1 and A1 register value. Only values greater than 0x1 must be written at register A1. Loading values other than those leads to unpredictable results. The counter cycle period is equal to A1 value in up counter mode. If in up/down counter mode the period is defined by the expression: $(2 * A1) - 2$.

Figure 36-137 describes the counter cycle for several A1 values. Register A1 is loaded with A2 register value at the cycle boundary. Thus any value written to A2 register within cycle **n** will be updated to A1 at the next cycle boundary and therefore will be used on cycle **n+1**. The cycle boundary between cycle **n** and cycle **n+1** is defined as when the internal counter transitions from A1 value in cycle **n** to 0x1 in cycle **n+1**. Note that the FLAG is generated at the cycle boundary and has a synchronous operation, meaning that it is asserted one system clock cycle after the FLAG set event.

Figure 36-137. Modulus Counter Buffered (MCB) Up Count mode

Figure 36-138 describes the MCB in up/down counter mode (MODE[0:6]=10101bb). Register A1 is updated at the cycle boundary. If A2 is written in cycle *n*, this new value will be used in cycle *n+1* for A1 match. Flags are generated only at A1 match start if MODE[5] is 0. If MODE[5] is set to 1 flags are also generated at the cycle boundary.

Figure 36-138. Modulus Counter Buffered (MCB) Up/Down Mode

The figure below describes in more detail, the register A1 update process in up counter mode. The A1 load signal is generated at the last system clock period of a counter cycle. Thus, A1 is updated with A2 value at the same time that the counter (EMIOSCNT[n]) is loaded with 0x1. The load signal pulse has the duration of one system clock period. If A2 is written within cycle *n* its value is available at A1 at the first clock of cycle *n+1* and the new value is used for match at cycle *n+1*. The update disable bits OU[n] of EMIOSOUDIS register can be used to control the update of this register, thus allowing to delay the A1 register update for synchronization purposes.

Figure 36-139. MCB Mode Register A1 Update in Up Counter Mode

The figure below describes the register A1 update in up/down counter mode. Note that A2 can be written at any time within cycle **n** in order to be used in cycle **n+1**. Thus A1 receives this new value at the next cycle boundary. Note that the update disable bits **OU[n]** of **EMIOSOUDIS** register can be used to disable the update of register A1.

Figure 36-140. MCB Mode Register A1 Update in Up/Down Counter Mode

36.6.1.1.13 Output Pulse Width and Frequency Modulation (OPWFM) Mode

In this mode, duty cycle of output signal is the value defined in register A1 plus one and the period is the value defined in register B1 plus one. **MODE[6]** bit controls the transfer from register B2 to B1, which can be done either immediately (**MODE[6]** cleared, **MODE[0:6]=00110b0**), providing the fastest change in the duty cycle, or at every match of register A1 (**MODE[6]** set, **MODE[0:6]=00110b1**).

When OPWFM mode is entered, coming out from GPIO mode, the output flip-flop is set to the complement of the **EDPOL** bit in the **EMIOSC[n]** register.

The internal counter is automatically selected as a time base, therefore the BSL[0:1] bits in register EMIOSC[n] has no meaning. When a match on comparator A occurs, the output flip-flop is set to the value of the EDPOL bit. When a match occurs on comparator B, the output flip-flop is set to the complement of the EDPOL bit and the internal counter is cleared.

A FLAG can be generated at match B, when MODE[5] is cleared, or in both matches, when MODE[5] is set.

At any time, the FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on A or B respectively. Also, FORCMB clears the internal counter. Note that the FLAG bit is not set by the FORCMA or FORCMB operations.

If subsequent comparisons occur on comparators A and B, the PWFM pulses continue to be output, regardless of the state of the FLAG bit.

In order to achieve 100% duty cycle, both registers A1 and B1 must be set to the same value. When a simultaneous match occurs on comparators A and B, the output flip-flop is set to the value of EDPOL bit. 0% duty cycle is possible by writing 0x0 to register A. When a match occurs, the output flip-flop is set at every period to the complement of EDPOL bit. The transfer from register B2 to B1 is still controlled by MODE[6] bit.

Note

Writing 0x0 to A1 and B1 produces a duty cycle of 0%.

Figure 36-141 shows the Unified Channel running in OPWFM mode with immediate register update and Figure 36-142 shows the Unified Channel running in OPWFM mode with next period update.

Figure 36-141. OPWFM with immediate update (MODE[6] bit is 0b)

Figure 36-142. OPWFM with next period update (MODE[6] bit is 1b)

36.6.1.1.14 Output Pulse Width and Frequency Modulation Buffered (OPWFMB) Mode

This mode (MODE[0:6]=10110b0) provides waveforms with variable duty cycle and frequency. The internal channel counter is automatically selected as the time base when this mode is selected. Register A1 indicates the duty cycle and B1 register the frequency. Both registers A1 and B1 are double buffered to allow smooth signal generation when changing the registers values.. 0% and 100% duty cycles are supported.

At OPWFMB mode entry, the output flip-flop is set to the value of the EDPOL bit in the EMIOSC[n] register.

In order to provide smooth and consistent channel operation this mode differs substantially from the OPWFM mode. The main differences reside in the A1 and B1 registers update, on the delay from the A1 match to the output pin transition and on the range of the internal counter values which starts from 0x1 up to register B1 value.

When entering OPWFMB mode coming out of GPIO mode, the internal counter value is not within that range then the B match will not occur causing the channel internal counter to wrap at the maximum counter value which is 0xff_fff for a 24-bit counter. After the counter wrap occurs it returns to 0x1 and resume normal OPWFMB mode operation. Thus in order to avoid the counter wrap condition make sure its value is within the 0x1 to B1 register value range when the OPWFMB mode is entered.

When a match on comparator A occurs the output register is set to the value of EDPOL. When a match on comparator B occurs the output register is set to the complement of EDPOL. B1 match also causes the internal counter to transition to 0x1, thus restarting the counter cycle.

Only values greater than 0x1 are allowed to be written to register B1. Loading values other than those leads to unpredictable results.

Figure 36-143 describes the operation of the OPWFMB mode regarding output pin transitions and A1/B1 registers match events. Note that the output pin transition occurs when the A1 or B1 match signal is deasserted which is indicated by the A1 match negedge detection signal. If register A1 is set to 0x4 the output pin transitions 4 counter periods after the cycle had started, plus one system clock cycle. Note that in the example shown in Figure 36-143 the internal counter prescaler has a ratio of two.

Figure 36-143. OPWFMB A1 and B1 match to Output Register Delay

Figure 36-144 describes the generated output signal if A1 is set to 0x0. Since the counter does not reach zero in this mode, the channel internal logic infers a match as if A1=0x1 with the difference that in this case, the posedge of the match signal is used to trigger the output pin transition instead of the negedge used when A1=0x1. Note that A1 posedge match signal from cycle $n+1$ occurs at the same time as B1 negedge match signal from cycle n . This allows to use the A1 posedge match to mask the B1 negedge match when they occur at the same time. The result is that no transition occurs on the output flip-flop and a 0% duty cycle is generated.

Figure 36-144. OPWFMB Mode with A1 = 0 (0% duty cycle)

Figure 36-145 describes the timing for the A1 and B1 registers load. The A1 and B1 load use the same signal which is generated at the last system clock period of a counter cycle. Thus, A1 and B1 are updated respectively with A2 and B2 values at the same time that the counter (EMIOSCNT[n]) is loaded with 0x1. This event is defined as the cycle boundary. The load signal pulse has the duration of one system clock period. If A2 and B2 are written within cycle **n** their values are available at A1 and B1, respectively, at the first clock of cycle **n+1** and the new values are used for matches at cycle **n+1**. The update disable bits OU[n] of EMIOSOUDIS register can be used to control the update of these registers, thus allowing to delay the A1 and B1 registers update for synchronization purposes.

In Figure 36-145, it is assumed that both the channel and global prescalers are set to 0x1 (each divide ratio is two), meaning that the channel internal counter transitions at every four system clock cycles. FLAGS can be generated only on B1 matches when MODE[5] is cleared, or on both A1 and B1 matches when MODE[5] is set. Since B1 flag occurs at the cycle boundary, this flag can be used to indicate that A2 or B2 data written on cycle **n** were loaded to A1 or B1, respectively, thus generating matches in cycle **n+1**. Note that the FLAG has a synchronous operation, meaning that it is asserted one system clock cycle after the FLAG set event.

Figure 36-145. OPWFMB A1 and B1 Registers Update and Flags (MODE6] bit is 0b)

Figure 36-146 describes the operation of the Output Disable feature in OPWFMB mode. Differently from the OPWFM mode, the output disable forces the channel output flip-flop to EDPOL bit value. This functionality targets applications that use active high signals and a high to low transition at A1 match. In this case EDPOL should be set to 0. Note that both the channel and global prescalers are set to 0x0 (each divide ratio is one), meaning that the channel internal counter transitions at every system clock cycle.

Figure 36-146. OPWFMB Mode with Active Output Disable (MODE[6] bit is 1b)

Note that the output disable has a synchronous operation, meaning that the assertion of the Output Disable input pin causes the channel output flip-flop to transition to EDPOL at the next system clock cycle. If the Output Disable input is deasserted the output pin transition at the following A1 or B1 match.

In [Figure 36-146](#), it is assumed that the Output Disable input is enabled and selected for the Channel. Please, refer to UC Control Register (EMIOSCn) for a detailed description about the ODIS and ODISSL bits, respectively enable and selection of the Output Disable inputs.

The FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on comparators A or B respectively. Similarly to a B1 match FORCMB sets the internal counter to 0x1. The FLAG bit is not set by the FORCMA or FORCMB bits being asserted.

[Figure 36-147](#) describes the generation of 100% and 0% duty cycle signals. It is assumed EDPOL = 0 and the resultant prescaler value is 1. Initially, A1=0x8 and B1=0x8. In this case, B1 match has precedence over A1 match, thus the output flip-flop is set to the complement of EDPOL bit. This cycle corresponds to a 100% duty cycle signal. The same output signal can be generated for any A1 value greater or equal to B1.

Figure 36-147. OPWFMB Mode from 100% to 0% Duty Cycle

A 0% duty cycle signal is generated if A1=0x0 as shown in [Figure 36-147](#) cycle 9. In this case B1=0x8 match from cycle 8 occurs at the same time as the A1=0x0 match from cycle 9. Please, refer to [Figure 36-144](#) for a description of the A1 and B1 match generation. In this case A1 match has precedence over B1 match and the output signal transitions to EDPOL.

36.6.1.1.15 Center Aligned Output Pulse Width Modulation with Dead Time Insertion (OPWMC) Mode

This operation mode generates a center aligned PWM with dead time insertion in the leading (MODE[0:6]=00111b1) or trailing edge (MODE[0:6]=00111b0).

The selected counter bus must be running an up/down time base, as shown in the 'Modulus Counter up/down mode example' figure. BSL[0:1] bits select the time base. Register A1 contains the ideal duty cycle for the PWM signal and is compared with the selected time base. Register B1 contains the dead time value and is compared with the internal counter. For a leading edge dead time insertion, the output PWM duty cycle is equal to the difference between register A1 and register B1, and for a trailing edge dead time insertion, the output PWM duty cycle is equal to the sum of register A1 and register B1. Mode[6] bit selects between trailing and leading dead time insertion, respectively.

Note

The internal counter may be running in the internal prescaler ratio, while the selected time base may be running in a different prescaler ratio. The output signal may produce an unexpected output if the dead time interval is greater than the duty cycle of the PWM signal.

When OPWMC mode is entered, coming out from GPIO mode, the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

When operating with leading edge dead time insertion, the first match between A1 and the selected time base clears the internal counter and switches the selected time base to the internal counter. When a match occurs between register B1 and the selected time base, the output flip-flop is set to the value of the EDPOL bit and the time base is switched to the selected counter bus. In the next match between register A1 and the selected time base, the output flip-flop is set to the complement of the EDPOL bit. This sequence repeats continuously.

When operating with trailing edge dead time insertion, the first match between A1 and the selected time base sets the output flip-flop to the value of the EDPOL bit. In the next match between register A1 and the selected time base, the internal counter is cleared and the selected time base is switched to the internal counter. When a match occurs between register B1 and the selected time base, the output flip-flop is set to the complement of the EDPOL bit and the time base is switched to the selected counter bus. This sequence repeats continuously.

FLAG can be generated in the trailing edge of the output PWM signal when MODE[5] is cleared, or in both edges, when MODE[5] is set.

At any time, the FORCMA or FORCMB bits are equivalent to a successful comparison on comparator A or B with the exception that the FLAG bit is not set.

Note

When in freeze state, the FORCMA or FORCMB bits only allow the software to force the output flip-flop to the level corresponding of a match on A or B respectively.

If subsequent matches occur on comparators A and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

In order to achieve a duty cycle of 100%, both registers A1 and B1 must be set to the same value. When a simultaneous match occurs between the selected time base and registers A1 and B1, the output flip-flop is set to the value of EDPOL bit and the selected time base switches to the selected counter bus, allowing a new cycle to begin at any time, as previously described. 0% duty cycle is possible by writing 0x0 to register A. When a match occurs, the output flip-flop is set to the complement of EDPOL bit and the selected time base switches to the selected counter bus, allowing a new cycle to begin at any time, as previously described. In both cases, FLAG is generated regardless of MODE[6] bit.

Note

If A1 and B1 are set to the 0x0, a 0% duty cycle waveform is produced.

[Figure 36-148](#) and [Figure 36-149](#) show the Unified Channel running in OPWMC with leading and trailing dead time, respectively.

Figure 36-148. OPWMC with leading dead time insertion (MODE [6] bit is 1b)

Figure 36-149. OPWMC with trailing dead time insertion (MODE [6] bit is 0b)

36.6.1.1.16 Center Aligned Output Pulse Width Modulation with Dead Time Insertion Buffered (OPWMCB) Mode

This operation mode generates a center aligned PWM with dead time insertion to the leading (MODE[0:6]=10111b1) or trailing edge (MODE[0:6]=10111b0). A1 and B1 registers are double buffered to allow smooth output signal generation when changing A2 or B2 registers values.

BSL[0:1] bits select the time base. The time base selected for a channel configured to OPWMCB mode should be a channel configured to MCB Up/Down mode, as shown in [Figure 36-138](#). It is recommended to start the MCB channel time base after the OPWMCB mode is entered in order to avoid missing A matches at the very first duty cycle.

Register A1 contains the ideal duty cycle for the PWM signal and is compared with the selected time base.

Register B1 contains the dead time value and is compared against the internal counter. For a leading edge dead time insertion, the output PWM duty cycle is equal to the difference between register A1 and register B1, and for a trailing edge dead time insertion, the output PWM duty cycle is equal to the sum of register A1 and register B1. Mode[6] bit selects between trailing and leading dead time insertion, respectively.

Note

The internal counter runs in the internal prescaler ratio, while the selected time base may be running in a different prescaler ratio.

When OPWMCB mode is entered, coming out from GPIO mode, the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

The following basic steps summarize proper OPWMCB startup, assuming the channels are initially in GPIO mode:

1. *[global]* Disable Global Prescaler.
2. *[MCB channel]* Disable Channel Prescaler.
3. *[MCB channel]* Write 0x1 at internal counter.
4. *[MCB channel]* Set A register.
5. *[MCB channel]* Set channel to MCB Up mode.
6. *[MCB channel]* Set prescaler ratio.
7. *[MCB channel]* Enable Channel Prescaler.

8. [OPWMCB channel] Disable Channel Prescaler.
9. [OPWMCB channel] Set A register.
10. [OPWMCB channel] Set B register.
11. [OPWMCB channel] Select time base input through BSL[1:0] bits.
12. [OPWMCB channel] Enter OPWMCB mode.
13. [OPWMCB channel] Set prescaler ratio.
14. [OPWMCB channel] Enable Channel Prescaler.
15. [global] Enable Global Prescaler.

The following figure describes the load of A1 and B1 registers which occurs when the selected counter bus transitions from 0x2 to 0x1 . This event defines the cycle boundary. Note that values written to A2 or B2 within cycle **n** are loaded into A1 or B1 registers, respectively, and used to generate matches in cycle **n+1** .

Figure 36-150. OPWMCB A1 and B1 registers load

The OU[n] bit of EMIOSOUDIS register can be used to disable the A1 and B1 updates, thus allowing to synchronize the load on these registers with the load of A1 or B1 registers in others channels. Note that using the update disable bit A1 and B1 registers can be updated at the same counter cycle thus allowing to change both registers at the same time.

In this mode, A1 matches always sets the internal counter to 0x1 . When operating with leading edge dead time insertion the first A1 match sets the internal counter to 0x1. When a match occurs between register B1 and the internal time base, the output flip-flop is set

to the value of the EDPOL bit. In the following match between register A1 and the selected time base, the output flip-flop is set to the complement of the EDPOL bit. This sequence repeats continuously. The internal counter should not reach 0x0 as consequence of a rollover. In order to avoid it, the user should not write to EMIOSB register a value greater than twice the difference between external count up limit and EMIOSA value.

The following figure shows two cycles of a Center Aligned PWM signal. Note that both A1 and B1 register values are changing within the same cycle which allows to vary at the same time the duty cycle and dead time values.

Figure 36-151. OPWMCB with Lead Dead Time Insertion

When operating with trailing edge dead time insertion, the first match between A1 and the selected time base sets the output flip-flop to the value of the EDPOL bit and sets the internal counter to 0x1. In the second match between register A1 and the selected time base, the internal counter is set to 0x1 and B1 matches are enabled. When the match between register B1 and the selected time base occurs the output flip-flop is set to the complement of the EDPOL bit. This sequence repeats continuously.

Figure 36-152. OPWMCB with Trail Dead Time Insertion

A FLAG can be generated in the trailing edge of the output PWM signal when MODE[5] is cleared, or in both edges, when MODE[5] is set. If subsequent matches occur on comparators A and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

Note

In OPWMCB mode FORCMA and FORCMB do not have the same behavior as a regular match. Instead they force the output flip-flop to constant value which depends upon the selected dead time insertion mode, lead or trail and the value of the EDPOL bit.

FORCMA has different behaviors depending upon the selected dead time insertion mode, lead or trail. In lead dead time insertion FORCMA force a transition in the output flip-flop to the opposite of EDPOL. In trail dead time insertion the output flip-flop is forced to the value of EDPOL bit.

If FORCMB bit is set, the output flip-flop value depends upon the selected dead time insertion mode. In lead dead time insertion FORCMB forces the output flip-flop to transition to EDPOL bit value. In trail dead time insertion the output flip-flop is forced to the opposite of EDPOL bit value.

Note

FORCMA bit set does not set the internal time-base to 0x1 as a regular A1 match.

The FLAG bit is not set either in case of a FORCMA or FORCMB or even if both forces are issued at the same time.

Note

FORCMA and FORCMB have the same behavior even in Freeze or normal mode regarding the output pin transition.

When *FORCMA* is issued along with *FORCMB* the output flip-flop is set to the opposite of EDPOL bit value. This is equivalent of saying that *FORCMA* has precedence over *FORCMB* when lead dead time insertion is selected and *FORCMB* has precedence over *FORCMA* when trail dead time insertion is selected.

A duty cycle from 0% to 100% can be generated by setting appropriate values to A1 and B1 registers relatively to the period of the external time base. Setting A1=0x1 generates a 100% duty cycle waveform. Assuming EDPOL is set to one and OPWMCB mode with trail dead time insertion, 100% duty cycle signals can be generated if B1 occurs at or after the cycle boundary (external counter = 1). If A1 is greater than the maximum value of the selected counter bus period, then a 0% duty cycle is produced, only if the pin starts the current cycle in the opposite of EDPOL value. In case of 100% duty cycle, the transition from EDPOL to the opposite of EDPOL may be obtained by forcing pin, using FORCMA and/or FORCMB.

Note

If A1 is set to 0x1 at OPWMCB entry the 100% duty cycle may not be obtained in the very first PWM cycle due to the pin condition at mode entry.

Only values different than 0x0 are allowed to be written to A1 register. If 0x0 is loaded to A1, the results are unpredictable.

Note

A special case occurs when A1 is set to (external counter bus period)/2, which is the maximum value of the external counter. In this case the output flip-flop is constantly set to the EDPOL bit value.

The internal channel logic prevents matches from one cycle to propagate to the next cycle. In trail dead time insertion B1 match from cycle **n** could eventually cross the cycle boundary and occur in cycle **n+1**. In this case B1 match is masked out and does not cause the output flip-flop to transition. Therefore matches in cycle **n+1** are not affected by the late B1 matches from cycle **n**.

The following figure shows a 100% duty cycle output signal generated by setting $A1=0x4$ and $B1=0x3$. In this case, the trailing edge is positioned at the boundary of cycle $n+1$, which is actually considered to belong to cycle $n+2$ and therefore does not cause the output flip-flop to transition.

Figure 36-153. OPWMCB with 100% Duty Cycle ($A1=4$ and $B1=3$)

The output disable feature, if enabled, causes the output flip-flop to transition to the EDPOL inverted state. This feature allows an application to force the channel output pin to a "safe" state. The internal channel matches continue to occur even in this case, thus generating Flags. As soon as the output disable is deasserted, the channel output pin is again controlled by A1 and B1 matches. Note that this process is synchronous, meaning that the output channel pin transitions only on system clock edges.

It is important to notice that, such as in OPWMB and OPWFMB modes, the match signal used to set or clear the channel output flip-flop is generated on the deassertion of the channel combinational comparator output signal which compares the selected time base with A1 or B1 register values. Please refer to [Figure 36-143](#), which describes the delay from matches to output flip-flop transition in OPWFMB mode. The operation of OPWMCB mode is similar to OPWFMB regarding matches and output pin transition.

36.6.1.1.17 Output Pulse Width Modulation (OPWM) Mode

Registers A1 and B1 define the leading and trailing edges of the PWM output pulse, respectively. MODE[6] bit controls the transfer from register B2 to B1, which can be done either immediately (MODE[6] cleared, MODE[0:6]=01000b0), providing the fastest change in the duty cycle, or at every match of register A1 (MODE[6] set, MODE[0:6]=01000b1).

The value loaded in register A1 is compared with the value on the selected time base. When a match on comparator A occurs, the output flip-flop is set to the value of the EDPOL bit. When a match occurs on comparator B, the output flip-flop is set to the complement of the EDPOL bit.

A FLAG can be generated at match B, when MODE[5] is cleared, or in both matches, when MODE[5] is set.

At any time, the FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on A or B respectively. Note that FLAG bit is not set by the FORCMA and FORCMB operations.

If subsequent matches occur on comparators A and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

At OPWM mode entry the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

In order to achieve 100% duty cycle, both registers A1 and B1 must be set to the same value. When a simultaneous match on comparators A and B occur, the output flip-flop is set at every period to the value of EDPOL bit. 0% duty cycle is possible by writing 0x0 to register A. When a match occurs, the output flip-flop is set at every period to the complement of EDPOL bit. The transfer from register B2 to B1 is still controlled by the MODE[6] bit.

Note

If A1 and B1 are set to the 0x0, a 0% duty cycle waveform is produced.

[Figure 36-154](#) and [Figure 36-155](#) show the Unified Channel running in OPWM with immediate update and next period update, respectively.

Figure 36-154. PWM with immediate update (MODE[6] is 0b)

Figure 36-155. PWM with next period update (MODE[6] is 1b)

36.6.1.1.18 Output Pulse Width Modulation Buffered (OPWMB) Mode

OPWMB mode (MODE[0:6]=11000b0) is used to generate pulses with programmable leading and trailing edge placement. An external counter driven in MCB Up mode must be selected from one of the counter buses. A1 register value defines the first edge and B1 the second edge. The output signal polarity is defined by the EDPOL bit. If EDPOL is zero, a negative edge occurs when A1 matches the selected counter bus and a positive edge occurs when B1 matches the selected counter bus.

The A1 and B1 registers are double buffered and updated from A2 and B2, respectively, at the cycle boundary. The load operation is similar to the OPWFMB mode. Please refer to [Figure 36-145](#) for more information about A1 and B1 registers update.

FLAG can be generated at B1 matches, when MODE[5] is cleared, or in both A1 and B1 matches, when MODE[5] is set. If subsequent matches occur on comparators A and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on A1 or B1 respectively. The FLAG bit is not set by the FORCMA and FORCMB operations.

At OPWMB mode entry the output flip-flop is set to the value of the EDPOL bit in the EMIOSC[n] register.

Some rules applicable to the OPWMB mode are:

- B1 matches have precedence over A1 matches if they occur at the same time within the same counter cycle
- A1=0 match from cycle **n** has precedence over B1 match from cycle **n-1**
- A1 matches are masked out if they occur after B1 match within the same cycle
- Any value written to A2 or B2 on cycle **n** is loaded to A1 and B1 registers at the following cycle boundary (assuming OU[n] bit of EMIOSOUDIS register is not asserted). Thus the new values will be used for A1 and B1 matches in cycle **n+1**

The following figure describes the operation of the OPWMB mode regarding A1 and B1 matches and the transition of the channel output pin. In this example EDPOL is set to zero.

Figure 36-156. OPWMB Mode Matches and Flags

Note that the output pin transitions are based on the negedges of the A1 and B1 match signals. The figure above shows in cycle *n+1* the value of A1 register being set to zero. In this case the match posedge is used instead of the negedge to transition the output flip-flop.

The figure below describes the channel operation for 0% duty cycle. Note that the A1 match posedge signal occurs at the same time as the B1=0x8 negedge signal. In this case A1 match has precedence over B1 match, causing the output pin to remain at EDPOL bit value, thus generating a 0% duty cycle signal.

Functional Description

Figure 36-157. OPWMB Mode with 0% Duty Cycle

Figure 36-158 describes the operation of the OPWMB mode with the Output Disable signal being asserted. The Output Disable forces a transition in the output pin to the EDPOL bit value. After deasserted, the output disable allows the output pin to transition at the following A1 or B1 match. Note that the Output Disable does not modify the Flag bit behavior. Note that there is one system clock delay between the assertion of the output disable signal and the transition of the output pin to EDPOL.

Figure 36-158. OPWMB Mode with Active Output Disable (MODE[6] bit is 1b)

Figure 36-159 shows a waveform changing from 100% to 0% duty cycle. EDPOL in this case is zero. In this example, B1 is programmed to the same value as the period of the external selected time base.

Figure 36-159. OPWMB Mode from 100% to 0% Duty Cycle

In Figure 36-159, if B1 is set to a value lower than 0x8, it is not possible to achieve 0% duty cycle by only changing A1 register value. Since B1 matches have precedence over A1 matches the output pin transitions to the opposite of EDPOL bit at B1 match. Note also that if B1 is set to 0x9, for instance, B1 match does not occur, thus a 0% duty cycle signal is generated.

36.6.1.2 Input Programmable Filter (IPF)

The IPF ensures that only valid input pin transitions are received by the Unified Channel edge detector. A block diagram of the IPF is shown in [Figure 36-160](#).

The IPF is a 5-bit programmable up counter that is incremented by the selected clock source, according to bits IF[0:3] in EMIOSC[n] register.

Figure 36-160. Input Programmable Filter Submodule Diagram

The input signal is synchronized by system clock. When a state change occurs in this signal, the 5-bit counter starts counting up. As long as the new state is stable on the pin, the counter remains incrementing. If a counter overflow occurs, the new pin value is validated. In this case, it is transmitted as a pulse edge to the edge detector. If the opposite edge appears on the pin before validation (overflow), the counter is reset. At the next pin transition, the counter starts counting again. Any pulse that is shorter than a full range of the masked counter is regarded as a glitch and it is not passed on to the edge detector. A timing diagram of the input filter is shown in [Figure 36-161](#).

Figure 36-161. Input Programmable Filter Example (IF[0:3] is 0010b)

The filter is not disabled during either freeze state or negated GTBE input

36.6.1.3 Clock Prescaler (CP)

The CP divides the GCP output signal to generate a clock enable for the internal counter of the Unified Channels. The GCP output signal is prescaled by the value defined in the UCPRE[0:1] field description in the EMIOSC[n] register. The prescaler is enabled by setting the UCPREN bit in the EMIOSC[n] and can be stopped at any time by clearing this bit, thereby stopping the internal counter in the Unified Channel.

In order to ensure safe working and avoid glitches the following steps must be performed whenever any update in the prescaling rate is desired:

1. Write 0 at both GPREN bit in EMIOSMCR register and UCPREN bit in EMIOSC[n] register, thus disabling prescalers;
2. Write the desired value for prescaling rate at UCPRE[0:1] bits in EMIOSC[n] register;
3. Enable channel prescaler by writing 1 at UCPREN bit in EMIOSC[n] register;
4. Enable global prescaler by writing 1 at GPREN bit in EMIOSMCR register.

The prescaler is not disabled during either freeze state or negated GTBE input.

36.6.1.4 Effect of Freeze on the Unified Channel

When in debug mode, FRZ bit in the EMIOSMCR register and the FREN bit in the EMIOSC[n] are both set, the internal counter and Unified Channel capture and compare functions are halted. The UC is frozen in its current state.

During freeze, all registers are accessible. When the Unified Channel is operating in an output mode, the force match functions remain available, allowing the software to force the output to the desired level.

Note that for input modes, any input events that may occur while the channel is frozen are ignored.

When exiting debug mode or freeze enable bit is cleared (FRZ in the EMIOSMCR or FREN in the EMIOSC[n] register) the channel actions resume, but may be inconsistent until channel enters GPIO mode again.

36.6.2 IP Bus Interface Unit (BIU)

The BIU provides the interface between the Internal Interface Bus (IIB) and the Peripheral Bus, allowing communication among all submodules and this IP interface.

The BIU allows 8, 16 and 32 bits access. They are performed over a 32-bit data bus in a single cycle clock.

36.6.2.1 Effect of Freeze on the BIU

When the FRZ bit in the EMIOSMCR register is set and the module is in debug mode, the operation of BIU is not affected.

36.6.3 STAC Bus Client submodule

The STAC bus client provides one external time base, imported from the STAC bus, to the Unified Channels. [Figure 36-162](#) provides a block diagram for the module.

Figure 36-162. Block diagram

Bits SRV[0:3] in register EMIOSMCR selects the desired time slot of the STAC bus to be output. [Figure 36-163](#) shows a timing diagram for the REDC.

Figure 36-163. Timing diagram for the STAC bus and STAC output

Every time the selected time slot change, the STAC output is updated.

See the chip-specific eMIOS information for the STAC server IDs.

36.6.3.1 Effect of Freeze on the STAC bus

When the FRZ bit in the EMIOS_MCR register is set and the module is in debug mode, the operation of REDC submodule is not affected, i.e., there is no freeze function in this submodule.

36.6.4 Global Clock Prescaler Submodule (GCP)

The GCP divides the system clock to generate a clock for the CPs of the channels. The main clock signal is prescaled by the value defined in the Global Prescaler clock divider table within the eMIOS Module Configuration Register (EMIOSMCR) description according to the GPRE[0:7] bits in EMIOSMCR register. The global prescaler is enabled by setting the GPREN bit in the EMIOSMCR register and can be stopped at any time by clearing this bit, thereby stopping the internal counters in all the channels.

In order to ensure safe working and avoid glitches the following steps must be performed whenever any update in the prescaling rate is desired:

1. Write 0 at GPREN bit in EMIOSMCR register, thus disabling global prescaler;
2. Write the desired value for prescaling rate at GPRE[0:7] bits in EMIOSMCR register;
3. Enable global prescaler by writing 1 at GPREN bit in EMIOSMCR register.

The prescaler is not disabled during either freeze state or negated GTBE input.

36.6.4.1 Effect of Freeze on the GCP

When the FRZ bit in the EMIOSMCR register is set and the module is in debug mode, the operation of GCP submodule is not affected, i.e., there is no freeze function in this submodule.

36.7 Initialization/Application Information

On resetting the eMIOS, the Unified Channels enter GPIO input mode.

36.7.1 Considerations

Before changing an operating mode, the UC must be programmed to GPIO mode and EMIOSA[n] and EMIOSB[n] registers must be updated with the correct values for the next operating mode. Then the EMIOSC[n] register can be written with the new operating mode. If a UC is changed from one mode to another without performing this procedure, the first operation cycle of the selected time base can be random, i.e., matches

can occur in random time if the contents of EMIOSA[n] or EMIOSB[n] were not updated with the correct value before the time base matches the previous contents of EMIOSA[n] or EMIOSB[n].

When interrupts are enabled, the software must clear the FLAG bits before exiting the interrupt service routine.

36.7.2 Application Information

Correlated output signals can be generated by all output operation modes. Bits OU[n] of eMIOS_OUDIS register can be used to control the update of these output signals.

In order to guarantee that the internal counters of correlated channels are incremented in the same clock cycle, the internal prescalers must be set up before enabling the global prescaler. If the internal prescalers are set after enabling the global prescaler, the internal counters may increment in the same ratio, but at a different clock cycle.

It is recommended to drive Output Disable Input signals with the emios_flag_out signals of some UCs running in SAIC mode. When an output disable condition happens, the software interrupt routine must service the output channels before servicing the channels running SAIC. This procedure avoid glitches in the output pins.

36.7.2.1 Time Base Generation

For MC and OPWFM with internal clock source operation modes, the internal counter rate can be modified by configuring the clock prescaler ratio. [Figure 36-164](#) shows an example of a time base with prescaler ratio equal to one.

Note

MCB and OPWFMB modes have a different behavior.

PRE SCALED CLOCK RATIO = 1 (bypassed)

**Figure 36-164. Time base period when running in the fastest prescaler ratio**

If the prescaler ratio is greater than one or external clock is selected, the counter may behave in one of four different ways depending on the channel mode:

- If MC mode and Clear on Match Start and External Clock source are selected the internal counter behaves as described in [Figure 36-165](#).
- If MC mode and Clear on Match Start and Internal Clock source are selected the internal counter behaves as described in [Figure 36-166](#).
- If MC mode and Clear on Match End are selected the internal counter behaves as described in [Figure 36-167](#).
- If OPWFM mode is selected the internal counter behaves as described in [Figure 36-166](#). The internal counter clears at the start of the match signal, skips the next prescaled clock edge and then increments in the subsequent prescaled clock edge.

Note

MCB and OPWFMB modes have a different behavior.

**Figure 36-165. Time base generation with external clock and clear on match start**

PRESCALED CLOCK RATIO = 3

Note 1: When a match occurs, the first clock cycle is used to clear the internal counter, and only after a second edge of pre scaled clock the counter will start counting.

Figure 36-166. Time base generation with internal clock and clear on match start

Note 1: The match occurs only when the input event/prescaler clock enable is active. Then, the internal counter is immediately cleared.

Figure 36-167. Time base generation with clear on match end

36.7.2.2 Coherent Accesses

Reading the EMIOSA[n] register again in the same period of the last read of EMIOSB[n] register may lead to incoherent results. This will occur if the last read of EMIOSB[n] register occurred after a disabled B2 to B1 transfer.

36.7.2.3 Channel/Modes Initialization

The following basic steps summarize basic output mode startup, assuming the channels are initially in GPIO mode:

1. *[global]* Disable Global Prescaler.
2. *[timebase channel]* Disable Channel Prescaler.

3. *[timebase channel]* Write initial value at internal counter.
4. *[timebase channel]* Set A/B register.
5. *[timebase channel]* Set channel to MC(B) Up mode.
6. *[timebase channel]* Set prescaler ratio.
7. *[timebase channel]* Enable Channel Prescaler.
8. *[output channel]* Disable Channel Prescaler.
9. *[output channel]* Set A/B register.
10. *[output channel]* Select timebase input through BSL[1:0] bits.
11. *[output channel]* Enter output mode.
12. *[output channel]* Set prescaler ratio (same ratio as timebase channel).
13. *[output channel]* Enable Channel Prescaler.
14. *[global]* Enable Global Prescaler.
15. *[global]* Enable Global Time Base.

The timebase channel and the output channel may be the same for some applications such as in OPWFM(B) mode or whenever the output channel is intended to run the timebase itself.

At any time the flags can be configured.

Chapter 37

Enhanced Time Processing Unit (eTPU)

37.1 Chip-specific eTPU information

This chip contains three eTPU modules with the following configuration:

- 32 channels per eTPU module
- 36 KB code RAM total
- 9 KB parameter RAM total
- ETPU_A and ETPU_B share the same program and data (parameter RAM) space in a dual-engine configuration
 - Support for up to 200 MHz clock rate (provides 100 MHz instruction execution rate)
 - ECC support on parameter RAM and program space
 - Sizes of shared eTPU_A and eTPU_B memories:
 - SCM instruction memory address space: 24 KB code RAM
 - SDM data memory address space: 6 KB parameter RAM
 - No shared subsystem support and therefore no Shared Subsystem Integration registers (SSIRs)
- ETPU_C has private program and parameter RAM space in a single-engine configuration
 - Support for up to 200 MHz clock rate (provides 100 MHz instruction execution rate)
 - ECC support on parameter RAM and program space
 - Sizes of eTPU_C memories:
 - SCM instruction memory address space: 12 KB code RAM
 - SDM data memory address space: 3 KB parameter RAM
 - Supports REACM2 by [Shared Subsystems support](#)

See also this information:

- [eMIOS global time base synchronization with eTPU](#)

- [DSPI connections with SIU, eTPU, and eMIOS modules](#)
- [eMIOS and eTPU ODIS connections](#)

37.1.1 eTPU register field reset values

The following table lists chip-specific reset values for register fields of the eTPU instances.

Table 37-1. Chip-specific eTPU register field reset values

eTPU instance	Register field	Reset value	Notes
eTPU_A/B	eTPU_SCR_MCR[SCMSIZE]	01011b	The reset value of eTPU_SCR_MCR is 000B_0000h.
eTPU_A/B	eTPU_TBR_STAC_ENG1[SERVER_ID1]	0000b	This is consistent with eTPU_A TCR1 in Table 37-2 .
eTPU_A/B	eTPU_TBR_STAC_ENG1[SERVER_ID2]	0010b	This is consistent with eTPU_A TCR2 in Table 37-2 .
eTPU_A/B	eTPU_TBR_STAC_ENG2[SERVER_ID1]	0001b	This is consistent with eTPU_B TCR1 in Table 37-2 .
eTPU_A/B	eTPU_TBR_STAC_ENG2[SERVER_ID2]	0011b	This is consistent with eTPU_B TCR2 in Table 37-2 .
eTPU_C	eTPU_SCR_MCR[SCMSIZE]	00101b	The reset value of eTPU_SCR_MCR is 0005_0000h.
eTPU_C	eTPU_TBR_STAC_ENG1[SERVER_ID1]	0100b	This is consistent with eTPU_C TCR1 in Table 37-2 .
eTPU_C	eTPU_TBR_STAC_ENG1[SERVER_ID2]	0101b	This is consistent with eTPU_C TCR2 in Table 37-2 .
eTPU_C	eTPU_TBR_STAC_ENG2[SERVER_ID1]	—	eTPU_C does not have engine 2.
eTPU_C	eTPU_TBR_STAC_ENG2[SERVER_ID2]	—	eTPU_C does not have engine 2.

37.1.2 Access to eTPU registers in chip-level Stop mode

On this chip, if you attempt to access eTPU registers when the chip is in Stop mode (as defined in [Modes of operation](#)), you will receive a bus error.

NOTE

This Stop mode corresponds to the chip-level Stop mode. It is different from the eTPU Module Disable mode, also defined in [Modes of operation](#).

37.1.3 STAC server IDs

On this chip, an eTPU module can export the TCR1 and TCR2 timebases on the STAC bus to an eMIOS or eQADC module. See [STAC interface](#) for more information.

An eTPU module is able to export a timebase to an eMIOS or eQADC module when the eTPU timebase period is equal to or greater than 6 times the eTPU clock frequency, regardless of whether the clock ratio between the eTPU and eMIOS or eQADC is 1:1 or 2:1.

STAC server IDs are defined in the following table.

No more than 4 STAC servers must be enabled at any time.

Table 37-2. STAC server IDs

eTPU instance	Time base	Server ID
eTPU_A	TCR1	0
eTPU_A	TCR2	2
eTPU_B	TCR1	1
eTPU_B	TCR2	3
eTPU_C	TCR1	4
eTPU_C	TCR2	5

37.1.4 eTPU inputs with Glitch Filters

See [IGF interaction with other modules](#) for connections between eTPU and Input Glitch Filters (IGFs).

37.1.5 eMIOS and eTPU signal passthrough from pins via IGFs

On this chip, the IGF modules mediate between some pins and the eMIOS and eTPU modules. After system reset, the IGF modules are in Configuration mode by default. This mode disables IGF output and prevents the signals from the pins from reaching the eMIOS and eTPU modules.

The signals affected by this situation appear in [IGF interaction with other modules](#).

To route an affected signal directly to an eMIOS or eTPU instance, program the applicable channel of the applicable IGF instance:

1. Ensure that IGF_MCRn[MDIS] is 0 and that the IGF channel is disabled:
IGF_MCRn[FGEN] is 0.
2. Configure the rising and falling edges for bypass:

- Rising edge: Write 00b to IGF_MCRn[RFM].
- Falling edge: Write 00b to IGF_MCRn[FFM].

3. Enable the IGF channel: Write 1 to IGF_MCRn[FGEN].

At the end of this sequence, the programmed filter enters Normal mode and passes through the affected signal.

37.1.6 eTPU output disable channel groups

The output disable channel groups are defined in the following table. See [Table 36-2](#) for additional information.

Table 37-3. Output disable channel groups

Output disable signal	eTPU_A channels	eTPU_B channels	eTPU_C channels
ODIS_1(0)	0 to 7	–	0 to 7
ODIS_1(1)	8 to 15	–	8 to 15
ODIS_1(2)	16 to 23	–	16 to 23
ODIS_1(3)	24 to 31	–	24 to 31
ODIS_2(0)	–	0 to 7	–
ODIS_2(1)	–	8 to 15	–
ODIS_2(2)	–	16 to 23	–
ODIS_2(3)	–	24 to 31	–

37.1.7 Control of the eTPU Output Buffer Enable signal

On this chip, the eTPU Output Buffer Enable signal is controlled by the Pad Configuration Registers (PCRs) in the SIU. See [Table 8-3](#) and [Pad Configuration Register \(SIU_PCRn\)](#).

37.2 Device-specific Information

- Single (32 channels) or Dual (64 channels, dual core) Engine
- SCM size, error detection, error correction
- SDM size, error detection, error correction

- Nexus class 3 support
- GTBE is a logical OR with other modules (eMIOS, other eTPU)
- channel output buffers are controlled through the SIU, and cannot be controlled with microcode
- channels used to trigger the eQADC
- channels used to enable the Reaction Module modulation
- channels with DMA request
- TRC1, TRC2 STAC server IDs

37.3 Introduction

eTPU is an intelligent, semi-autonomous co-processor designed for timing control. Operating in parallel with the Host CPU, the eTPU processes instructions and real-time input events, performs output waveform generation, and accesses shared data without Host intervention. Consequently, for each timer event, the Host CPU setup and service times are minimized or eliminated.

High-level assembler, compiler and documentation allows customers to develop their own functions on the eTPU.

eTPU architecture aims at high resolution timing capabilities. From a system perspective, high resolution timing is limited by Host CPU overhead required for servicing timing tasks such as period measurement, pulse measurement, pulse width modulated waveform generation, etc. On the eTPU, high resolution timing is achieved by three main capabilities:

- Reduced latency: pin actions are immediate.
- Reduce or eliminate host interrupt service time.
- Double action channel capability reducing the channel request rate.

eTPU provides higher resolution than the Host CPU can achieve and creates no Host overhead for servicing timing tasks.

Latency is the interval from occurrence of an event to the start of event servicing. eTPU can service its own events without interrupting the Host. There are two types of timing events:

- Input pin transition.
- Selected Time Base match, i.e., a selected Time Base counter reached or exceeded a pre-programmed value.

Service time is the time spent servicing an event. In general, in microcontrollers the service time is constrained because the instruction set is not optimized for time function synthesis. The eTPU instruction set is optimized, so that time functions can be implemented with much fewer instructions than the Host CPU. Instructions execute faster, service time is reduced and program memory compacted.

Instructions executed by the eTPU are connected directly to the eTPU timing hardware and allow parallelism of hardware related actions.

37.3.1 Overview

The figure below shows a top-level eTPU block diagram. It displays a dual eTPU Engine configuration.

Figure 37-1. eTPU Block Diagram

eTPU Engine is responsible for processing input pin transitions and output pin waveform generation based on the **Time Bases**. Each eTPU Engine has its own microprocessor and dedicated hardware for processing signals on I/O pins and can also interface with external time bases through the STAC bus.

Both eTPU Engine CPUs, hereafter called **microengines**, fetch microinstructions from a **Shared Code Memory - SCM**.

Shared Data Memory - SDM - holds eTPU application parameters and work data. It is accessed by Host and both microengines.

Bus Interface Unit - BIU - allows Host to access eTPU registers, SCM and SDM.

Each I/O signal pair is associated with a dedicated **Channel**, which provides hardware for input signal processing and output signal generation, in relationship with selected Time Bases.

The eTPU, as a microprocessed subsystem, works much like a typical real-time system: it runs microengine code from instruction memory (SCM) to handle specific events, accessing data memory (SDM) for parameters, work data and application state info; events may originate from I/O Channels (due to pin transitions and/or time base matches), Host CPU requests or inter-channel requests; events that call for local eTPU processing activate the microengine by issuing a **Service Request**. The Service Request microcode may set an interrupt to the Host CPU. I/O channel events cannot directly interrupt the Host CPU.

Each Channel is associated with a **Function**, which defines its behavior: the Function is a software entity consisting, within the eTPU, of a set of microengine routines that attend to Service Requests. The Function routines are also responsible for Channel configuration. Function routines reside in SCM, which may contain several Functions. A Function may be assigned to several Channels, but a Channel can be associated with just one Function at a given moment. The association between Functions and Channels is defined by Host CPU, and is explained in detail in [Functions and threads](#).

eTPU hardware supplies resource sharing features that support concurrency:

- A hardware **Scheduler** dispatches the Service Request microengine routines based on a set of priorities defined by the Host CPU. Each Channel has its associated priority.
- A Service Request routine cannot be interrupted until it ends. This sequence of uninterrupted instruction execution is called a **Thread**.
- Channel-specific context (registers and flags) is automatically switched between the end of a Thread and the beginning of the next one.
- SDM arbitration, a dual-parameter coherency controller and semaphores can be used to ensure coherent access to eTPU data shared by both eTPU Engines and Host CPU.

37.3.1.1 eTPU Engine

Each eTPU Engine consists of all blocks that are duplicated in a dual eTPU configuration: two 24-bit time bases, 32 independent timer channels, a task scheduler, a microengine, and a Host interface. In addition, a 32-bit Shared Data Memory (SDM) is used for two eTPU Engines data storage and for passing information between the eTPU Engines and the Host CPU.

The following figure shows the block diagram for the eTPU Engine.

Figure 37-2. eTPU Engine Block Diagram

eTPU Engines 1 and 2 are sometimes called eTPU 1 and eTPU 2 for short throughout this chapter.

37.3.1.1.1 Time Bases

Two 24-bit counters TCR1 and TCR2 provide reference time bases for all match and input capture events. Prescalers for both time bases are controlled by the Host CPU through bit fields in the eTPU Engine configuration registers. The eTPU is able to export/import time to/from TCR1 or TCR2 in accordance to the STAC bus specification.

The clock for each of TCR1 and TCR2 clock can be independently derived from the eTPU clock or from an external input via the TCRCLK clock pin. In addition, the TCR2 timebase can be derived from special angle-clock hardware which enables implementing angle-based functions. This feature is added to support advanced angle based engine control applications.

For further details refer to [Time bases](#).

37.3.1.1.2 eTPU Timer Channels

Each eTPU Engine has 32 independent channels, each corresponding to an Input/Output signal pair. The channel time resolution is 24 bits, and are all identical.

Each channel consists of logic which supports two events and output controls. The event logic contains two 24-bit capture registers, two 24-bit match registers, greater-equal and equal-only comparators. Supporting two events enables many combinations of double action functions (for example the channel can handle two events with a single microcode service).

The channel configuration can be changed immediately by the microengine. Each channel can perform double capture, double match and other capture-match combinations. Channel modes available can do ordered or unordered match. Some modes are also provided that can block one match by the occurrence of the other. Service request can be generated on one or both of the match events.

Input signal can be separated from output signal in each channel. They can, optionally, be combined in a single I/O pin driver. An output buffer enable is controlled by the SIU (or SIUL). Digital filters are provided for the input signals, with distinct filtering modes available.

Each channel can use any time base or angle counter for either match or capture operation. For example, a match on TCR1 can capture the value of TCR2. The channels can request service from the microengine due to recognized pin transitions (input events) or timebase matches.

The eTPU channels also support the basic single-action operations found on TPU3 functionality with the exception that time resolution is 24-bits.

Channel configuration combinations:

- Single input capture, no match (TPU3 functionality)
- Single input capture with single match timeout (TPU3 functionality)
- Single input capture with double match timeout with several double match sub-modes
- Double input capture with single or double match timeout with several double match sub-modes
- Single output match (TPU3 functionality)

- Double output match with several double match sub-modes
- Input-dependent output generation

The double match functionality has various combinations for generation of service request and determining pin actions. For more details refer to [Enhanced Channels](#).

In addition to the predefined channel configurations above, the user can also program its own channel configuration, defining how input captures, matches and service-requests are related.

37.3.1.1.3 Host interface

The Host interface allows the Host CPU to control the operation of the eTPU. The Host CPU must initialize the eTPU by writing to the appropriate Host interface registers to assign a Function and priority to each channel. In addition, the Host writes to the Host Service Request and channel configuration registers to further define Function operation for each initialized channel. Refer to [Host interface](#) for a detailed description.

When the SCM is implemented by RAM, the Host must first initialize it with the proper microcode program prior to enabling any eTPU Function, and then enable eTPU access (which also disables Host access).

37.3.1.1.4 Shared Data Memory - SDM

The SDM works as data RAM which can be accessed by the Host CPU and up to two eTPU Engines. This memory is used for information transfer between the Host CPU and the eTPU, as data storage for the eTPU microcode program or for communication between the two eTPU Engines. SDM width is 32 bits, and is accessible by the Host as byte, 16-bit or 32-bit wide. eTPU can access it as full 32-bits, lower 24-bits or upper byte (8-bit).

The host can also access the SDM space mirrored in other area with Parameter Sign Extension (PSE). Parameter Sign Extension accesses differ from the usual host accesses to the original SDM area as follows:

- Writes are effective only to the lower 3 bytes of a word: the word's most significant byte is kept unaltered in SDM.
- Reads return the lower 3 bytes of a word sign-extended to 32 bits, i.e.: the most significant bit of the word's 2nd most significant byte is copied in all 8 bits of the most significant read byte.

Each eTPU channel can be associated with a variable number of parameters located in the SDM, according to its selected Function. In addition, the SDM can be fully shared between two eTPU Engines, enabling direct communication between them.

High flexibility of the SDM utilization is achieved as follows:

- Each channel has a programmable base address pointing to the address of its first parameter with two parameter granularity. This way the SDM can be partitioned according to the actual function needs.
- The microcode can access the first 128 parameters of the selected channel in channel relative access mode.
- Each Engine can access all the SDM address space in indirect addressing mode. Blocks of data are easily transferred using stack operation.
- Absolute addressing mode can access the first 256 parameters (TPU3 functionality), implementing a shared pool of parameters holding global variables.

In the Host address space each parameter occupies four bytes. eTPU usage of the upper byte is achieved by having a 32-bit P register which can access the upper byte, the lower 24 bits or all the 32 bits. The microcode can switch between access sizes at any time.

Each Function may require a different number of parameters. During the eTPU initialization the Host has to program channel base addresses, allocating proper parameters for each channel according to its selected Function.

37.3.1.1.5 Shared Subsystem Area

The Shared Subsystem (SSS) area is a memory map region used by both the host and the eTPU to access registers of the reaction channel, giving the user the option to control them by the host, the eTPU code, or a combination of both.

37.3.1.1.6 Scheduler

Out of reset, all channels are disabled. The Host CPU makes a channel active by assigning it one of three priorities: high, middle, or low. The Scheduler determines the order in which channels are serviced based on channel number and assigned priority. The priority mechanism, implemented in hardware, ensures that all requesting channels are serviced. For additional details refer to [Scheduler](#).

37.3.1.1.7 Microengine

eTPU microengine is a simple RISC implementation which performs each instruction in a microcycle of two eTPU clocks, while prefetching the next instruction through an instruction pipeline. Instruction execution time is constant unless it gets wait states from the SDM arbitration. Two eTPU Engines share code memory without having any performance degradation by interleaving their accesses (the Shared Code Memory has one-clock access time).

Instruction width is 32 bits. The microengine instruction set provides basic arithmetic and logic operations, flow control (jumps and subroutine calls), SDM access, and Channel configuration and control. The instruction formats are defined in such a way that allow particular combinations of two or three of these operations with unconflicting resources to be executed in parallel in the same microcycle.

Microengine has also an independent Multiply/Divide/MAC unit that performs these complex operations in parallel with other microengine instructions.

Channel functionality is tightly integrated to the instruction set through Channel Control operations and conditional Branch operations, which support jumps/calls on Channel-specific conditions. This allows quick and terse Channel configuration and control code, contributing to reduced service time.

Detailed description can be found in [Microengine](#).

37.3.1.1.8 Dual eTPU Engine System

A typical eTPU implementation includes two eTPU Engines sharing SDM and the same code in SCM.

The two eTPU Engines share the Bus Interface Unit (BIU) and the data memory (SDM) which enable Host-eTPU and eTPU Engine-Engine communication. The shared BIU includes coherency logic which supports dual parameter (8 bytes) coherency in transfers between Host and eTPU, using a temporary parameter area within the SDM. More details on this can be found on [Parameter sharing and coherency](#).

37.3.2 Features

The following sections show eTPU features and enhancements.

37.3.2.1 eTPU Feature Summary

The eTPU includes these distinctive features:

- up to 32 channels for each eTPU Engine, each channel is associated with an Input/Output signal pair.
 - enhanced input digital filters on the input pins for improved noise immunity. The eTPU digital filter can use 2 samples, 3 samples or work in continuous mode.
 - identical, orthogonal channels, except for channel 0: each channel can perform any time function. Each time function can be assigned to more than one channel at a given time, so each signal can have any functionality. Channel 0 has the same capabilities of the others, but can also work with special Angle Counter logic (see below).
 - Link Service Request allows activation of a Channel function by request of another channel, even between eTPU Engines.
 - Host Service Request allows activation of a Channel function by Host CPU request
 - each channel has an event mechanism which supports single and double action functionality in various combinations. It includes two 24-bit capture registers, two 24-bit match registers, 24-bit greater-equal and equal-only comparators.
- Two independent 24-bit time bases for channel synchronization:
 - first time base clocked by eTPU clock with programmable prescaler division from 1 to 512 (in steps of 2), or by output of second time base prescaler.
 - first time base can also be clocked by external signal with programmable prescaler division of 1 to 256.
 - second time base clocked by external signal with programmable prescaler division from 1 to 64.
 - second time base external clock source can be replaced by eTPU clock divided by 8.
 - both time bases can be exported or imported via Shared Time and Counter bus.
 - second time base counter can work as an Angle counter, enabling angle based applications to match angle instead of time.
 - second time base can also be used as a pulse accumulator gated by external signal.
- Event-Triggered RISC processor (microengine):
 - 3 stage pipeline implementation (fetch, decoding and execution), with separate instruction memory - SCM - and data memory - SDM (Harvard architecture)

- fixed-length instruction execution in one microcycle of two eTPU clocks
- interleaved SCM access in dual eTPU Engine avoids contention in time for instruction memory
- SCM address space of up to 16K positions (64 Kbytes) (see chip-specific eTPU information)
- SDM with interleaved access in dual eTPU Engine avoids contention for data memory
- SDM address space (both Engines) of up to 8 Kbytes (see chip-specific eTPU information)
- instruction set with embedded Channel support, including specialized Channel control subinstructions and conditional branching on Channel-specific flags.
- channel-oriented addressing: channel-bound address mode with Host configured Channel Base Address allows channel data isolation, independent of microengine application code.
- channel-bound data address space of up to 128 32-bit parameters (512 bytes)
- global parameter address mode allows access to common Channel data of up to 256 32-bit parameters (1024 bytes)
- support for indirect and stacked data access schemes.
- parallel execution of: data access, ALU, Channel control and flow control subinstructions in selected combinations.
- 32-bit microengine registers and 24-bit resolution ALU, with 1 microcycle addition and subtraction, absolute value, bitwise logical operations on 24-bit, 16-bit, or byte operands; single bit manipulation, shift and rotate operations, sign extension and conditional execution.
- additional 24-bit Multiply/MAC/Divide unit which supports all signed/unsigned Multiply/MAC combinations, and unsigned 24-bit Divide. The MAC/Divide unit works in parallel with the regular microcode commands.
- Resource sharing features support channel sharing of channel registers, memory and microengine time:
 - hardware Scheduler works as a "task management" unit, dispatching event service routines by predefined, Host-configured priority.

- automatic Channel context switch when a "task switch" occurs, i.e., one Function Thread ends and another begins to service a request from other Channel: Channel-specific registers, flags and parameter base address are automatically loaded for the next serviced channel.
- individual channel priority setting in 3 levels: high, middle and low.
- Scheduler priority scheme allows calculation of worst case latency for event servicing and ensures servicing all channels by preventing permanent blockage.
- SDM shared between Host CPU and both eTPU Engines, supporting communication either between Channels and Host or inter-channel.
- hardware implementation of 4 Semaphores supports resource sharing between both eTPU Engines.
- Hardware semaphores directly supported by the microengine instruction set.
- dual parameter coherency hardware support allows atomic (to host) access to 2 parameters by microengine(s) in back-to-back accesses.
- coherent dual-parameter controller allows atomic (to microengines) accesses to 2 parameters by the host.
- Development support features:
 - Nexus class 3 debug support (optional, associated with the eTPU-Nexus Block NDEDI).
 - Software breakpoints.
 - Debug interface supporting single-step execution, forced microinstruction execution, Hardware breakpoints and watchpoints on several conditions.
- Safety support features:
 - SCM (code memory) continuous signature-check built-in self test (MISC - Multiple Input Signature Calculator), runs concurrently with eTPU normal operation.
 - See [eTPU Plus Enhancements over eTPU](#) for additional safety features.

37.3.2.2 eTPU Enhancements over TPU3

- 32 orthogonal channels with enhanced functionality. Full support for double action with double match and double transition sub-mode combinations.

- Input and Output features separated in channel logic and microinstructions, allowing input and output signals to be processed separately or combined.
- Increased time resolution and execution unit to 24 bits.
- Increased linear code memory, shared by two eTPU Engines, configurable up to 16K positions (64 KB).
- Increased SDM address range (8 KB each Engine) and width (32 bits per parameter). The SDM can be dynamically allocated to support variable number of parameters for each channel. Each channel can have access to at least 256 parameters.
- The SDM is fully shared by two eTPU Engines (SDM), supporting direct inter-engine communication with the help of hardware semaphores.
- Enhanced arithmetic operations, including add/subtract with carry, absolute value, multiple shift and rotate, conditional execution with variable operand widths.
- Enhanced logic operations, including bitwise operations (and, or, xor) and bit manipulation, with conditional execution. Support for read-modify-write of any bit in the SDM.
- Hardware for Multiply/MAC/Divide, running in parallel to execution of other operations. The 24-bit divide result is available after 13 other unrelated instructions. Multiplication supports any data width of both operands (8, 16 or 24 bits), signed or unsigned. A 24x24 Multiply/MAC result is available after four other unrelated instructions. A 24x8 Multiply/MAC result is available after one other unrelated instruction.
- Supports export/import of time bases from other sources through the real time bus (STAC - Shared Time and Counter bus). This internal bus is used for sharing real time data between multiple peripherals.
- Contains angle clock hardware, supported by microcode, which can provide a 24-bit angle bus instead of time bus. This feature enables the eTPU to run angle based engine control applications.
- More interrupt types. Each eTPU channel can generate a data transfer request interrupt, in addition to regular interrupts, and one global exception interrupt. Data Transfer requests can be used either as interrupt sources or DMA requests. This feature takes advantage of DMA peripherals which off-load the Host. Interrupt Overflow status is also provided.
- Improved visibility to the Host (pin states, time bases, serviced channel).

- An edge case of priority inversion on TPU3 Scheduler was resolved.
- Supports channel link requests between eTPU Engines.

37.3.2.3 eTPU Plus Enhancements over eTPU

eTPU Plus features include the enhancements below in addition to all eTPU features

- TCR1, channel logic and digital filters (both channel and TCRCLK) now have an option to run at divisions of full eTPU clock speed, besides eTPU clock / 2 (see [T2/T4 channel timing](#)).
- Channels support unordered transitions: transition B can now be detected before transition A. Related to this enhancement, TDLA and TDLB can now be independently negated by microcode (see [Channel Mode Logic and Event Flags](#))
- Channel logic can now work on full eTPU clock, allowing faster response with slow clocks (see [T2/T4 channel timing](#)).
- Added a new User Programmable Channel Mode: the blocking, enabling, service request and capture characteristics of this channel mode can be programmed via microcode (see [General Channel registers](#)).
- Microinstructions now provide an option to issue Interrupt and Data Transfer requests selected by CHAN. They can also be requested simultaneously at the same instruction (see [Channel Interrupt and Data Transfer Requests](#)).
- Channel Flags 0 and 1 can now be tested for branching, besides selecting the entry point (see [Branch Operations](#)).
- Channel digital filters can be bypassed, and can be clocked by full eTPU clock (see [Bypass Mode](#)).

Backward compatibility is maintained so that all legacy object code (both Host and microcode) runs on eTPU Plus without modification.

37.3.2.4 eTPU2 enhancements over eTPU Plus

eTPU2 features include the enhancements below in addition to all eTPU Plus enhancements and eTPU features.

- Scheduler priority-passing mechanism can now be disabled (see [Priority passing disabling](#)).
- New Watchdog mechanism kills threads over a programmable timeout (see [Watchdog](#)).
- New counter allows microengine load information collection for performance analysis (see [Idle Counter](#)).
- Channels 1 and 2 (besides channel 0) can now be selected to control the EAC (see the TBCR_ENG1 and TBCR_ENG2 eTPU Time Base Configuration Registers).
- Timebase prescalers are now reset when the GTBE input is negated, guaranteeing synchronization with eMIOS in all cases (see [GTBE - Global Time Base Enable](#)).
- New MISC flag indicates when an SCM signature calculation round is completed. This allows measuring of the average MISC scan period in a real application situation (see the eTPU Module Configuration Register - MCR).
- New channel TCCEA flag allows continuous capture even after TDLA is set, making it fully compatible with TPU behavior (see [TCCEA - Transition Continuous Capture Enable](#)).
- New branch condition PRSS tells the pin state at the time when a channel (match or transition) service request occurred (see [Pin Control Registers](#)).
- MRLEA/B can now be negated independently by microcode (see [Disable Matches](#)).
- New Engine Relative address mode allows a function to access SDM address space common to one engine, but distinct between engines (see Engine Relative Addressing Mode under [SDM Addressing Modes](#)).
- Memory error support for Code (SCM) and Data (SDM) memories: error detection, correction, and hardware-assisted soft-error fixing (see [Memory error support](#)).
- Sharing of microengine and host accesses to subsystem modules (for instance, the Reaction Module), allowing their control by the eTPU, the host, or both (see [Shared Subsystems support](#)).

Backward compatibility is maintained so legacy object code (both Host and microcode) runs on eTPU2 without modification.

37.3.2.5 eTPU2 Plus enhancements over eTPU2

eTPU2 Plus features include the enhancements listed below in addition to all eTPU features, eTPU Plus enhancements and eTPU2 enhancements.

- New Latency Monitor allows latency measurements, either for individual channels or channels combined in a single priority (High, Medium or Low).
- Watchdog can now be configured to disable thread forced ending and channel blocking, allowing it to monitor thread lengths with no interference on the application.

- EAC Angle Tick Generator can now be clocked by the TCR2 prescaler output, as an alternative to the TCR1 clock.
- EAC now supports up to 7 missing teeth on hardware.

Backward compatibility is maintained so legacy object code (both Host and microcode) runs on eTPU2 Plus without modification.

37.3.3 Modes of operation

eTPU can be seen as capable of working in the following modes:

- **User Configuration Mode**

User has the ability to program the eTPU Cores with User Time Functions, having access to the Shared Code Memory (SCM).

- **User Mode**

User does not access the eTPU Shared Code Memory:

- Use of predefined eTPU Functions
- No need for eTPU Core programming ability

- **Debug Mode**

User debugs eTPU code, accessing special Trace/Debug features via Nexus interface:

- hardware breakpoint/watchpoint setting
- access to internal registers
- single-step execution
- forced instruction execution
- software breakpoint insertion and removal.

- **Module Disable Mode**

eTPU Engine clocks are stopped through a register write to the MDIS field in [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#), saving power. Input sampling stops. eTPU Engines can be in Module Disable Mode independently. Module Disable Mode stops only the Engine clock, so that the Shared BIU, and Global

Channel registers can be accessed, and interrupts and DMAs can be cleared and enabled/disabled. An Engine only enters Module Disable Mode when any currently running thread is finished (see [Functions and threads](#)).

- **Stop Mode**

Stop Mode is entered when eTPU answers device stop request assertion with stop acknowledge. The definition of which clocks are stopped is made at the MCU level, which defines whether or not registers can be accessed, interrupts and DMA requests cleared.

These modes are loosely selected: there is no unique register field or signals to choose between them. Some features of one mode can be used with features of other mode(s). More on this subject can be found on [eTPU mode selection](#) below.

Note

Throughout this chapter, an engine is said to be "stopped" if it is either in Module Disable mode or Stop mode.

37.3.3.1 eTPU mode selection

User and User Configuration are the production operating modes, and differ from each other only in access to SCM. User programmability is only possible with a RAM SCM.

On chips where the SCM is implemented as a RAM, it can either be accessed directly from IP-Bus for code loading, or for software breakpoint setting. On chips with a ROM SCM, an internal SCM Emulation RAM may be used, depending on the specific MCU implementation, to replace ROM SCM for test or debug purposes. SCM Emulation RAM is selected in a MCU-specific way. For more details, see [SCM Emulation](#).

Debug Mode is characterized by the use of the debug interface features. Specifically, Nexus blocks provide Nexus class 3 debug features. For more information on debug features, refer to [Development support features](#).

Module Disable Mode is entered by setting the MDIS field in [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#). eTPU Engines can be individually stopped going into Module Disable Mode (there is one eTPU_SCR_ECR register for each Engine). Each engine can leave Module Disable Mode by writing MDIS=0 (which can only be done if VIS=0).

Stop Mode is activated by IP-Bus (device stop request). In this case, the eTPU waits for both eTPU Engines to enter in stop mode, and then asserts the stop acknowledge line. eTPU leaves Stop Mode when device stop request is negated, but only if VIS=0. If device stop request is negated and VIS=1, eTPU will leave Stop Mode as soon as VIS=0.

Note

An Engine can stay in Module Disable mode when it leaves Stop Mode if its bit MDIS=1, even if the other leaves it.

37.4 Detailed signal descriptions

Detailed signal descriptions are presented in the following sections.

37.4.1 eTPU channel output signals

Each channel output signal is associated with a channel. The microcode may affect the logic level of an output signal¹ by implementing one of two actions:

- Specify the logic level output to the signal when there is a match or a transition.
- Immediately force a logic level.

The output signal may also be forced to a logic level, independently of the output value from the channel logic, by one of the four (each Engine) output disable input signals (see [eTPU channel output disable signals](#)).

The output buffer enable signals are not used.

37.4.2 eTPU channel input signals

Each channel input signal is associated with a channel. The microcode can directly control the effect of the transition edge. Each channel can be programmed to sense a transition when a rising and/or falling edge is detected. The channel logic can also process two transition events, and relate these events to each other and to other programmed timer events. The edge sensitivities of the two transition events are configured independently by microcode. For further information refer to [Enhanced Channels](#) and [Transition Detection and Pin Action Control](#).

1. Note that the minimum pulse width is one microcycle (two eTPU clocks), and slow pads may not be able to transfer it on time. For generation of very short pulses the eTPU pads have to be programmed by the system integration for fast operation mode with the voltage levels defined for fast pad operation in the MCU technology.

Each channel input signal has an associated synchronizer made of two flip-flops sampling the signal on every other eTPU clock², followed by a digital filter. This digital filter can work in three sub-modes, whose purpose is to filter out noise pulses that have width less than a programmed value of eTPU clocks, preventing these transitions from being input to the transition detect logic. The synchronizer and digital filter are guaranteed to pass pulses that are greater than a programmed value. All channel input filters in one Engine work on the same mode and sampling clock. For more information on channel input filters, refer to [Enhanced Digital Filter - EDF](#). In one of the Angle Modes, the output of the digital filter of channel 0 is replaced by the output of TCRCLK signal digital filter (see [EAC - eTPU Angle Counter](#)).

37.4.3 Time Base Clock Signal — TCRCLK

TCRCLK is an input signal used to control the Time Bases TCR1 and TCR2. There is one independent TCRCLK input for each Engine. For pulse accumulator operations TCRCLK can be used as a gate for a counter based on the eTPU clock divided by eight. For Angle operations TCRCLK can be used to get the tooth transition indications in Angle Mode. Further details can be found on [Time bases](#) and [EAC - eTPU Angle Counter](#).

Like the channel input signals, the TCRCLK signal has an associated synchronizer followed by a digital filter. This digital filter can work in two sub-modes, whose purpose is to filter out noise pulses that have width less than a programmed value of eTPU clocks, preventing these transitions from being input to the transition detect logic. The synchronizer and digital filter are guaranteed to pass pulses that are greater than a programmed value. The clock and operation sub-mode of the TCRCLK filter is configured independently of the other channel input filters, through the TCRCF field in [eTPU Engine 1 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG2\)](#). For more information on filter sub-modes, see [TCRCLK digital filter](#). In one of the Angle Modes, the output of the digital filter of channel 0 is replaced with the output of TCRCLK signal digital filter (see [EAC - eTPU Angle Counter](#)).

37.4.4 eTPU channel output disable signals

Each of these 4 input signals are used to force the outputs of a group of 8 channels to an inactive level. When an ODIS input is active, all the channels in its group of 8 that have their fields ODIS=1 in [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2](#)

2. Sampled on the T4 microcycle phase, see [Microcycle and I/O timing](#).

(eTPU_CCCR_CnCR_ENG2) have their outputs forced to the opposite of the value specified in bit OPOL of the same register. Therefore, channels can be individually selected to be affected by the output disable signals, as well as their disabling forced polarity (see 'Pin State Input/Output Logic' figure in [Pin Control Registers](#)).

See the chip-specific eTPU information for details on the output channel disable group definition.

In a Dual-engine eTPU there are 8 output disable signals for the 64 channels.

37.5 Memory map/register definition

The guideline for the description of all bits and fields throughout the “Memory Map/ Register Definition” section is to provide only a brief explanation (without examples or method of use) of the features, since it will be used mainly as a reference for the reader that is studying the “Functional Description” section, where those features are explained in detail.

37.6 Memory map

The eTPU System simplified memory map is shown in [Table 37-4](#). Each of the register areas shown may have their own reserved address areas.

[Table 37-5](#) shows a detailed memory map. Offsets are relative to the eTPU Base address, which is MCU-dependent.

See the chip-specific eTPU information about accessing eTPU registers in chip-level Stop mode.

SCM unused area is decoded and returns a fixed opcode, determined by [eTPU SCM Off-range Data Register \(eTPU_SCR_SCMOFFDATAR\)](#).

Table 37-4. High-level memory map

eTPU_SCR_MCR field descriptions

Field	Description
0 GEC	Global Exception Clear. This write-only bit negates global exception request and clears global exception status bits SDMERR, SSAERR, SCMERR, WDTO1/2, MGE1/2, ILF1/2, LTO1/2, and SCMMISF. GEC works the same way with either one or both Engines in Module Disable Mode. 0 Keep Global Exception request and status bits SDMERR, SSAERR, SCMERR, WDTO1/2, ILF1/2, MGE1/2, LTO1/2, and SCMMISF as is. 1 Negate Global Exception, clear status bits SDMERR, SSAERR, SCMERR, WDTO1/2, ILF1/2, MGE1/2, LTO1/2, and SCMMISF.
1 SDMERR	SDM Read Error This flag indicates that an SDM non-correctable read error occurred on a microengine or host (including CDC) read, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0 No Global Exception pending because of SDM read error. 1 Global Exception requested by SDM read error is pending.
2 WDTO1	Watchdog 1 Timeout. Flag WDTO1 indicates that a Watchdog Timeout occurred in engine 1, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0 No Global Exception pending because of Watchdog timeout. 1 Global Exception requested by Watchdog timeout.
3 WDTO2	Watchdog 2 Timeout. Flag WDTO2 indicates that a Watchdog Timeout occurred in engine 2, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0 No Global Exception pending because of Watchdog timeout. 1 Global Exception requested by Watchdog timeout.
4 MGE1	Microcode Global Exception Engine 1. This bit indicates that a global exception was asserted by microcode executed on engine 1. The determination of the reason why the global exception was asserted is application dependent: it can be coded in an SDM status parameter, for instance. This bit is cleared by writing 1 to GEC. 0 No microcode-requested global exception pending. 1 Global exception requested by microcode is pending.
5 MGE2	Microcode Global Exception Engine 2. This bit indicates that a global exception was asserted by microcode executed on engine 2. The determination of the reason why the global exception was asserted is application dependent: it can be coded in an SDM status parameter, for instance. This bit is cleared by writing 1 to GEC. 0 No microcode-requested global exception pending. 1 Global exception requested by microcode is pending.
6 ILF1	Illegal Instruction Flag for Engine 1. The ILFA1 flag is set by the microengine to indicate that an illegal instruction was decoded in Engine 1. This bit is cleared by host writing 1 to GEC. See Illegal instructions for more details.

Table continues on the next page...

eTPU_SCR_MCR field descriptions (continued)

Field	Description
	0 Illegal Instruction not detected. 1 Illegal Instruction detected by Engine 1.
7 ILF2	Illegal Instruction Flag for Engine 2. The ILFA2 flag is set by the microengine to indicate that an illegal instruction was decoded in Engine 2. This bit is cleared by host writing 1 to GEC. See Illegal instructions for more details. 0 Illegal Instruction not detected. 1 Illegal Instruction detected by Engine 2.
8 SSAERR	Shared Subsystem Access Error. This flag indicates that a bus error occurred in an microengine access to the Shared Subsystem Area (see Shared Subsystems support). This bit is cleared by writing 1 to GEC. NOTE: Bus errors on host accesses to the Shared Subsystem Area do not set this bit neither asserts the Global Exception, but the bus error is propagated to the host CPU 0 No bus error returned on a microengine Shared Subsystem Area access. 1 Bus error returned on a microengine Shared Subsystem Area access.
9 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
10 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
11–15 SCMSIZE	SCM Size This read-only field holds the number of 2 KB SCM Blocks minus 1. For more information, see the MCU Reference Manual. See the chip-specific eTPU information for this field's reset value.
16 LTO1	Latency Timeout for Engine 1. The LTO1 flag indicates the latency measured by the Latency Monitor of Engine 1 surpassed the specified maximum. See Latency Monitor for details. This bit is cleared by writing 1 to GEC. 0 No latency timeout detected by Engine 1's Latency Monitor. 1 Latency timeout detected by Engine 1's Latency Monitors.
17 LTO2	Latency Timeout for Engine 2. The LTO2 flag indicates the latency measured by the Latency Monitor of Engine 2 surpassed the specified maximum. See Latency Monitor for details. This bit is cleared by writing 1 to GEC. 0 No latency timeout detected by Engine 2's Latency Monitor. 1 Latency timeout detected by Engine 2's Latency Monitors.
18–19 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

eTPU_SCR_MCR field descriptions (continued)

Field	Description
20 SCMMISC	SCM MISC Complete flag. Flag SCMMISC indicates that MISC has completed the evaluation of the SCM signature since reset or since the last time it was cleared. SCMMISC is cleared by writing 1 to it, and is not cleared when MISC is disabled (SCMMISEN=0). SCMMISC asserts at the end of the SCM memory scan, either if the signature matches or not. 0 MISC has not yet completed an SCM signature calculation and compare since the last time SCMMISC was cleared. 1 MISC completed at least one SCM signature calculation and compare since the last time SCMMISC was cleared.
21 SCMMISF	SCM MISC Flag. The SCMMISF bit is set by the SCM MISC (Multiple Input Signature Calculator) logic to indicate that the calculated signature does not match the expected value, at the end of a MISC iteration. See SCM Test - Multiple Input Signature Calculator for more details. This bit is cleared when Global Exception is cleared by writing 1 to GEC. 0 Signature mismatch not detected. 1 MISC has read entire SCM array and the expected signature in eTPU MISC Compare Register (eTPU_SCR_MISCCMPR) does not match the value calculated.
22 SCMMISEN	SCM MISC Enable. The SCMMISEN bit is used for enabling/disabling the operation of the MISC logic. SCMMISEN is readable and writable at any time. The MISC logic will only operate when this bit is set to 1. When the bit is reset, the MISC address counter is set to the initial SCM address. When enabled, the MISC will continuously cycle through the SCM addresses, reading each and calculating a CRC. In order to save power, the MISC can be disabled by clearing the SCMMISEN bit. See SCM Test - Multiple Input Signature Calculator for more details. SCMMISEN resets automatically when MISC logic detects an error, i.e., when SCMMISF transitions from 0 to 1, disabling the MISC operation. 0 MISC operation disabled. The MISC logic is reset to its initial state. 1 MISC operation enabled.
23 SCMERR	SCM Read Error. This flag indicates that an SCM non-correctable read error occurred on a host or microengine (including MISC) read, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0 No Global Exception pending because of SCM read error. 1 Global Exception requested by SCM read error is pending.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 VIS	SCM Visibility Bit. VIS bit turns SCM visible to the IP-Bus and resets MISC state (but SCMMISEN keeps its value). This bit is write protected when any of the Engines is not halted or stopped. When VIS=1, the MDIS bits in the eTPU Memory Error Support registers are write protected.

Table continues on the next page...

eTPU_SCR_MCR field descriptions (continued)

Field	Description
	0 SCM is not visible to the slave bus. Accessing SCM address space issues a bus error, writes are protected and reads are meaningless. 1 SCM is visible to the slave bus. MISC state is reset.
26–30 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
31 GTBE	Global Time Base Enable. GTBE enables time bases in both Engines, allowing them to be started synchronously. NOTE: Global Time Base Enable action may also depend on other blocks, as explained in GTBE - Global Time Base Enable . NOTE: When GTBE is turned off with Angle Mode enabled, the EAC must be reinitialized before GTBE is turned on again. The EAC reinitialization procedure is described in Restarting angle logic . 0 Time bases in both Engines are disabled to run. 1 Time bases in both Engines are enabled to run.

37.7.2 eTPU Coherent Dual-Parameter Controller Register (eTPU_SCR_CDCR)

This register configures and controls dual-parameter coherent transfers. For more information, see [Coherent Dual-parameter Controller \(CDC\)](#).

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R																
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R																
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_SCR_CDCR field descriptions

Field	Description
0 STS	Start Bit. This bit is set by the host in order to start the data transfer between the parameter buffer pointed by PBBASE and the target addresses selected by the concatenation of fields CTBASE and PARM0/1. The host receives wait-states until the data transfer is complete, when this bit is reset by the coherency logic (see Coherent Dual-parameter Controller (CDC)). Therefore, host always reads STS as 0. 0 Write does not start a coherent transfer. 1 Write starts a coherent transfer.
1–5 CTBASE	Channel Transfer Base. This field concatenates with fields PARM0 and PARM1 to determine the absolute word offset (from the SDM base) of the parameters to be transferred: Parameter 0 word address = {CTBASE, PARM0} + SDM base word address. Parameter 1 word address = {CTBASE, PARM1} + SDM base word address.
6–15 PBBASE	Parameter Buffer Base Address. This field points to the base address of the parameter buffer location, with granularity of 2 parameters (8 bytes). The host (byte) address of the first parameter in the buffer is PBBASE * 8 + SDM Base Byte Address. The microengine absolute (word) address of the first parameter in the buffer is PBBASE * 2.
16 PWIDTH	Parameter Width Selection. This bit selects the width of the parameters to be transferred between the PB and the target address. 0 Transfer 24-bit parameters. The upper byte remains unchanged in the destination address. 1 Transfer 32-bit parameters. All 32 bits of the parameters are written in the destination address.
17–23 PARM0	Channel Parameter number 0. The PARM0 and PARM1 fields in concatenation with CTBASE determine the word address offset (from the SDM base) of the parameters that are destination or source (defined by WR) of the coherent transfer. The word SDM address offset of the parameters are {CTBASE, PARM0/1}. NOTE: PARM0 and PARM1 allow non-contiguous parameters to be transferred coherently. The parameter pointed by {CTBASE, PARM0} is the first transferred.
24 WR	Read/Write selection. This bit selects the direction of the coherent data transfer. 0 Read operation. Data transfer is from the selected SDM address to the PB. 1 Write operation. Data transfer is from the PB to the selected SDM address.
25–31 PARM1	Channel Parameter number 1. The PARM0 and PARM1 fields in concatenation with CTBASE determine the word address offset (from the SDM base) of the parameters that are destination or source (defined by WR) of the coherent transfer. The word SDM address offset of the parameters are {CTBASE, PARM0/1}. NOTE: PARM0 and PARM1 allow non-contiguous parameters to be transferred coherently. The parameter pointed by {CTBASE, PARM0} is the first transferred.

37.7.3 eTPU MISC Compare Register (eTPU_SCR_MISCCMPR)

This register holds the 32-bit signature expected from the whole SCM array. This register must be written by the host with the 32-bit word to be compared against the calculated signature at the end of the MISC cycle. This register is global to both eTPU Engines. For more detail, see [SCM Test - Multiple Input Signature Calculator](#).

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eTPU_SCR_MISCCMPR field descriptions

Field	Description
0–31 ETPUMISCCMP	Expected Multiple Input Signature Register value. For details, see SCM Test - Multiple Input Signature Calculator .

37.7.4 eTPU SCM Off-range Data Register (eTPU_SCR_SCMOFFDATAR)

This register holds the 32-bit value returned when SCM array is accessed at non-implemented addresses, either by the Host or by the microengine. This register can be written by the host with the 32-bit instruction to be executed by the microengine to recover from runaway code. This register is global to both eTPU Engines. For more detail see [SCM Off-range data](#).

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- HLTF field: HLTF field reset value is 1 if, after a reset, the eTPU Nexus debug support is on and a breakpoint request is asserted. Otherwise the reset value is 0.
- MDIS field: Reset value is 0.

eTPU_SCR_ECR_ENG1 field descriptions

Field	Description
0 FEND	Force End. FEND assertion terminates any current running thread as if an END instruction have been executed (see Ending Current Thread - END).

Table continues on the next page...

eTPU_SCR_ECR_ENG1 field descriptions (continued)

Field	Description
	This bit is self-negating when the thread ends. NOTE: Only on rare occasions (e.g., during a long stall, see Microengine Stall) FEND can be read as 1, because it negates as soon as the end begins execution. Writing FEND = 1 is ignored and FEND stays 0 when the microengine is in TST, halted, stopped, or idle (no thread executing). 0 Normal operation. 1 Ends any ongoing thread.
1 MDIS	Module Disable Bit. When MDIS is set, the Engine shuts down its internal clocks, going into Module Disable Mode. TCR1 and TCR2 cease to increment, and input sampling stops. The Engine asserts the stop flag (STF) bit to indicate that it has stopped. However, the BIU continues to run, and the Host can access all registers except for the channel registers (see channel registers starting with eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_CnCR_ENG1)) NOTE: The Timebase registers can still be read with MDIS=1, but writes are ineffective and a Bus Error is issued. Global Channel Registers and SDM can be accessed normally. After MDIS is set, even before STF asserts, data read from the channel registers is not meaningful and writes are ineffective, issuing a Bus Error. When the MDIS bit is asserted while the microcode is executing, the eTPU will stop when the thread is complete. Stop completes on the next eTPU clock after the stop condition is valid. NOTE: Once MDIS is switched from 1 to 0 or vice versa, it must not write a different value until STF changes accordingly. The MDIS bit is write-protected when VIS=1. See Register Reset Values in the chip-specific eTPU information. 0 eTPU Engine runs. 1 Commands Engine to stop its clocks.
2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3 STF	Stop Flag Bit. Each Engine asserts its stop flag (STF) to indicate that it has stopped. Only then the host can assume that the Engine has actually stopped. The eTPU system is fully stopped when the STF bits of both eTPU Engines are asserted. In case of a stop request, the eTPU responds by acknowledging stop only after both eTPU 1 and eTPU 2 have been stopped. Engine only stops when any ongoing thread is complete also in this case. Summarizing Engine stop conditions, which STF reflects: STF_1 := (after stop completed) MDIS_1 device stop request. STF_2 := (after stop completed) MDIS_2 device stop request. STF_1 and STF_2 mean STF bit from engine 1 and STF bit from engine 2, respectively. See Register Reset Values in the chip-specific eTPU information.

Table continues on the next page...

eTPU_SCR_ECR_ENG2 field descriptions

Field	Description
0 FEND	Force End. FEND assertion terminates any current running thread as if an END instruction have been executed (see Ending Current Thread - END). This bit is self-negating when the thread ends. NOTE: Only on rare occasions (e.g., during a long stall, see Microengine Stall) FEND can be read as 1, because it negates as soon as the end begins execution. Writing FEND = 1 is ignored and FEND stays 0 when the microengine is in TST, halted, stopped, or idle (no thread executing). 0 Normal operation. 1 Ends any ongoing thread.
1 MDIS	Module Disable Bit. When MDIS is set, the Engine shuts down its internal clocks, going into Module Disable Mode. TCR1 and TCR2 cease to increment, and input sampling stops. The Engine asserts the stop flag (STF) bit to indicate that it has stopped. However, the BIU continues to run, and the Host can access all registers except for the channel registers (see channel registers starting with eTPU Channel Configuration-Control registers) NOTE: The Timebase registers can still be read with MDIS=1, but writes are ineffective and a Bus Error is issued. Global Channel Registers and SDM can be accessed normally. After MDIS is set, even before STF asserts, data read from the channel registers is not meaningful and writes are ineffective, issuing a Bus Error. When the MDIS bit is asserted while the microcode is executing, the eTPU will stop when the thread is complete. Stop completes on the next eTPU clock after the stop condition is valid. NOTE: Once MDIS is switched from 1 to 0 or vice versa, it must not write a different value until STF changes accordingly. The MDIS bit is write-protected when VIS=1. See Register Reset Values in the chip-specific eTPU information.

Table continues on the next page...

eTPU_SCR_ECR_ENG2 field descriptions (continued)

Field	Description
	0 eTPU Engine runs. 1 Commands Engine to stop its clocks.
2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3 STF	Stop Flag Bit. Each Engine asserts its stop flag (STF) to indicate that it has stopped. Only then the host can assume that the Engine has actually stopped. The eTPU system is fully stopped when the STF bits of both eTPU Engines are asserted. In case of IP-Bus stop, the eTPU system responds by acknowledging stop only after both eTPU 1 and eTPU 2 have been stopped. Engine only stops when any ongoing thread is complete also in this case. Summarizing Engine stop conditions, which STF reflects: STF_1 := (after stop completed) MDIS_1 device stop request. STF_2 := (after stop completed) MDIS_2 device stop request. STF_1 and STF_2 mean STF bit from engine 1 and STF bit from engine 2, respectively. See Register Reset Values in the chip-specific eTPU information. 0 Engine is operating. 1 Engine has stopped (after the local MDIS bit has been asserted, or after the IP-Bus stop line has been asserted).
4–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8 HLTF	Halt Mode Flag. If eTPU Engine entered halt state, this flag is asserted. The flag remains asserted while the microengine is in halt state, even during a single-step or forced instruction execution. See Development support features for further details about entering Halt Mode. 0 eTPU Engine is not halted. 1 eTPU Engine is halted.
9–11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12 FCSS	Filter Clock Source Selection Speeds up the filter clock source before the prescaler, allowing more input capture resolution at minimum prescaling. NOTE: FCSS=1 also makes the channel work on T2/T4 timing mode (see T2/T4 channel timing). 0 Use eTPU clock / 2 as EDF clock source before prescaler. 1 Use eTPU clock as EDF clock source before prescaler
13–15 FPSCK	Filter Prescaler Clock Control.

Table continues on the next page...

eTPU_SCR_ECR_ENG2 field descriptions (continued)

Field	Description																		
	FPSCCK controls the prescaling of the clocks used in digital filters for the channel input signals and TCRCLK input, as shown in the table below. Filtering can be controlled independently by each engine, but all input digital filters in the same engine have same clock prescaling. For more details, see Filter clock prescaler. A new value written to FPSCCK only becomes effective when the filter prescaler finishes the current count. Table 37-18. 37.8 Timebase memory map and registers

Time Base registers allows configuration and visibility of internally-generated time bases TCR1 and TCR2. There is one of each of these registers for each eTPU Engine.

NOTE

Writes to these registers issue bus error and are ineffective when MDIS=1. Reads are always allowed.

eTPU_TBR_TBCR_ENG1 field descriptions

Field	Description
0–2 TCR2CTL	TCR2 Clock/Gate Control.

Table continues on the next page...

eTPU_TBR_TBCR_ENG1 field descriptions (continued)

Field	Description																											
	These bits are part of the TCR2 clocking system (see Time bases). They determine the clock source for TCR2 before the prescaler. TCR2 can count on any detected edge of the TCRCLK signal or use it for gating eTPU clock divided by 8. After reset - TCRCLK signal rising edge is selected. TCR2 can also be clocked by the eTPU clock divided by 8. TCR2CTL also determines the TCRCLK edge selected for angle tooth detection in angle mode. See the following table. Table 37-24. TCR2 Clock Source <table><tr><th>TCR2CTL</th><th>AM = 0 TCR2 Clock before prescaler</th><th>AM > 0 Angle Tooth detection</th></tr><tr><td>000</td><td>Gated DIV8 clock (eTPU clock / 8). In this case, when the external TCRCLK signal is low, the DIV8 clock is blocked, preventing it from incrementing the TCR2 prescaler. When the external TCRCLK signal is high, TCR2 prescaler is incremented at the frequency of the eTPU clock divided by 8.</td><td>Do not use with AM > 0</td></tr><tr><td>001</td><td>Rise transition on TCRCLK signal increments the TCR2 prescaler.</td><td>Rising edge</td></tr><tr><td>010</td><td>Fall transition on TCRCLK signal increments the TCR2 prescaler.</td><td>Falling edge</td></tr><tr><td>011</td><td>Rise or Fall transition on TCRCLK signal increments the TCR2 prescaler.</td><td>Both edges</td></tr><tr><td>100</td><td>DIV8 clock (eTPU clock / 8)</td><td>Do not use with AM > 0</td></tr><tr><td>101</td><td>Do not use with AM=0</td><td>Do not use with AM > 0</td></tr><tr><td>110</td><td>Do not use with AM=0</td><td>No edge¹</td></tr><tr><td>111</td><td>TCR2 frozen, except as STAC client</td><td>Do not use with AM > 0</td></tr></table> 1. TCRCLK edges are not detected by the EAC logic, but they can still be detected by the channel 0 logic if AM=01.	TCR2CTL	AM = 0 TCR2 Clock before prescaler	AM > 0 Angle Tooth detection	000	Gated DIV8 clock (eTPU clock / 8). In this case, when the external TCRCLK signal is low, the DIV8 clock is blocked, preventing it from incrementing the TCR2 prescaler. When the external TCRCLK signal is high, TCR2 prescaler is incremented at the frequency of the eTPU clock divided by 8.	Do not use with AM > 0	001	Rise transition on TCRCLK signal increments the TCR2 prescaler.	Rising edge	010	Fall transition on TCRCLK signal increments the TCR2 prescaler.	Falling edge	011	Rise or Fall transition on TCRCLK signal increments the TCR2 prescaler. 01	Filter clock of the channels	Two sample																										
10	eTPU clock divided by 2	Integrator																										
11	Filter clock of the channels	Integrator																										
5–6 AM	Angle Mode Selection. This field enables the Enhanced Angle Counter logic to generate angle information (see EAC - eTPU Angle Counter), and also select the tooth signal input and the channel used to process it, as shown in the following table. When EAC is not disabled by AM and neither TCR1 nor TCR2 are STAC Clients, the EAC																											

Table continues on the next page...

eTPU_TBR_TBCR_ENG1 field descriptions (continued)

Field	Description																		
	(eTPU Angle Clock) hardware provides angle information to the channels using the TCR2 bus. When AM is reset (non-angle mode), the EAC operation is disabled, and its internal registers can be used as general purpose. For more information, see EAC - eTPU Angle Counter .																		
	Table 37-22. AM - Angle Mode Selection																		
	<table><tr><th>Value</th><th>TCR2 Value</th><th>Tooth signal</th><th>Tooth processing channel</th></tr><tr><td>00</td><td>Timebase (EAC operation disabled)</td><td colspan="2">Not applicable</td></tr><tr><td>01</td><td rowspan="3">Angle Ticks</td><td>TCRCLK input</td><td>0</td></tr><tr><td>10</td><td>Channel 1 input</td><td>1</td></tr><tr><td>11</td><td>Channel 2 input</td><td>2</td></tr></table>	Value	TCR2 Value	Tooth signal	Tooth processing channel	00	Timebase (EAC operation disabled)	Not applicable		01	Angle Ticks	TCRCLK input	0	10	Channel 1 input	1	11	Channel 2 input	2
	Value	TCR2 Value	Tooth signal	Tooth processing channel															
	00	Timebase (EAC operation disabled)	Not applicable																
	01	Angle Ticks	TCRCLK input	0															
	10		Channel 1 input	1															
	11		Channel 2 input	2															
	If TCR1 or TCR2 is a STAC Bus Client (see STAC interface), the EAC operation is not allowed, and AM must be set to 0.																		
	NOTE: Changing AM may cause unexpected transition detections on the channel selected by AM, depending on the channel mode and state (see Transition detection and Time Base Capture). If AM must be changed with GTBE=1, the recommended procedure is described in Restarting angle logic .																		
7 ATGC	Angle Tick Generator Clock. This bit selects the clock that provides the time interval unit for Angle Tick Generation. For details, see Generating the angle ticks . 0 TCR1 prescaler output provides time intervals for tick generation. 1 TCR2 prescaler output provides time intervals for tick generation.																		
8–9 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.																		
10–15 TCR2P	Timer Count Register 2 Prescaler Control. These bits are part of the TCR2 clocking system (see Time bases). TCR2 is clocked from the output of a prescaler. The prescaler divides its input by (TCR2P + 1) allowing frequency divisions from 1 to 64. The prescaler input is the eTPU clock divided by 8 (in gated or non-gated clock mode), or Internal Timebase input, or TCRCLK filtered input. This field has no effect on TCR2 in Angle Mode.																		
16–17 TCR1CTL	TCR1 Clock/Gate Control. TCR1CTL is part of the TCR1 clocking system (see Time bases). It determines, together with TCR1CS, the clock source for TCR1. TCR1 can count on detected rising edge of the TCRCLK signal, the eTPU clock, or the eTPU clock divided by 2 (see the table in the TCR1CS bit description). After reset TCRCLK signal is selected.																		
18 TCR1CS	TCR1 Clock Source TCR1CS provides the option to double the TCR1 incrementing speed, using eTPU clock as its clock source instead of eTPU clock / 2.																		

Table continues on the next page...

eTPU_TBR_TBCR_ENG1 field descriptions (continued)

Field	Description																					
	NOTE: If ATGC=0, the clock source of the EAC angle tick generator will still be an even division of eTPU clock if TCR1CS=1, obeying to the field TCR1P as if TCR1CS=0 (see Angle Tick Generator).																					
	Table 37-21. TCR1 Clock Source																					
	<table><tr><th>TCR1CTL</th><th>TCR1CS</th><th>TCR1 Clock before prescaler</th></tr><tr><td>00</td><td>0</td><td>Selects TCRCLK as clock source for the TCR1 prescaler.¹</td></tr><tr><td>01</td><td>0</td><td>Reserved</td></tr><tr><td>01</td><td>1</td><td>Reserved</td></tr><tr><td>10</td><td>0</td><td>Selects eTPU clock divided by 2 as clock source for the TCR1 prescaler.</td></tr><tr><td>10</td><td>1</td><td>Selects eTPU clock as clock source for the TCR1 prescaler.</td></tr><tr><td>11</td><td>0</td><td>TCR1 frozen, except as a STAC client</td></tr></table>	TCR1CTL	TCR1CS	TCR1 Clock before prescaler	00	0	Selects TCRCLK as clock source for the TCR1 prescaler. ¹	01	0	Reserved	01	1	Reserved	10	0	Selects eTPU clock divided by 2 as clock source for the TCR1 prescaler.	10	1	Selects eTPU clock as clock source for the TCR1 prescaler.	11	0	TCR1 frozen, except as a STAC client
	TCR1CTL	TCR1CS	TCR1 Clock before prescaler																			
	00	0	Selects TCRCLK as clock source for the TCR1 prescaler. ¹																			
	01	0	Reserved																			
	01	1	Reserved																			
	10	0	Selects eTPU clock divided by 2 as clock source for the TCR1 prescaler.																			
	10	1	Selects eTPU clock as clock source for the TCR1 prescaler.																			
	11	0	TCR1 frozen, except as a STAC client																			
1. This selection must not be used in Angle Mode.																						
0 Use eTPU clock / 2 as TCR1 clock source before the prescaler, if that clock source is selected by TCR1CTL.																						
1 Use eTPU clock as TCR1 clock source before the prescaler; can only be set in specific combinations with TCR1CTL, as shown in the table.																						
NOTE: TCR1CS=1 also makes the channel work on T2/T4 timing mode (see T2/T4 channel timing).																						
19–23 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.																					
24–31 TCR1P	Timer Count Register 1 Prescaler Control. TCR1 is clocked from the output of a prescaler. The input to the prescaler is the internal eTPU clock divided by 2, eTPU clock, or the output of TCRCLK filter. The prescaler divides this input by (TCR1P + 1) allowing frequency divisions from 1 up to 256.																					

1. TCRCLK edges are not detected by the EAC logic, but they can still be detected by the channel 0 logic if AM=01.

2. This selection must not be used in Angle Mode.

37.8.2 eTPU Engine 1 Time Base 1 (TCR1) Visibility Register (eTPU_TBR_TB1R_ENG1)

This register provides visibility of the TCR1 time base for host read access (see [Time bases](#)). This register is read-only. The value of the TCR1 time base shown can be driven by the TCR1 counter or imported from STAC bus, depending on the configuration set in [eTPU Engine 1 STAC Configuration Register \(eTPU_TBR_STAC_ENG1\)](#).

1. TCRCLK edges are not detected by the EAC logic, but they can still be detected by the channel 0 logic if AM=01.																												
3–4 TCRCF	TCRCLK Signal Filter Control. This field controls the TCRCLK digital filter (see TCRCLK digital filter , determining whether the TCRCLK signal input (after a synchronizer) is filtered with the same filter clock as the channel input signals (see Enhanced Digital Filter - EDF) or uses the eTPU clock divided by 2, and also whether the TCRCLK digital filter works in integrator mode or two sample mode (see the following table). Table 37-31. TCRCLK Filter Clock/Mode																											
	<table><tr><th>TCRCF</th><th>Filter Clock</th><th>Filter Mode</th></tr><tr><td>00</td><td>eTPU clock divided by 2</td><td>Two sample</td></tr><tr><td>01</td><td>Filter clock of the channels</td><td>Two sample</td></tr><tr><td>10</td><td>eTPU clock divided by 2</td><td>Integrator</td></tr><tr><td>11</td><td>Filter clock of the channels</td><td>Integrator</td></tr></table>	TCRCF	Filter Clock	Filter Mode	00	eTPU clock divided by 2	Two sample	01	Filter clock of the channels	Two sample	10	eTPU clock divided by 2	Integrator	11	Filter clock of the channels	Integrator												
TCRCF	Filter Clock	Filter Mode

01	Filter clock of the channels	Two sample																										
10	eTPU clock divided by 2	Integrator																										
11	Filter clock of the channels	Integrator																										
5–6 AM	Angle Mode Selection. This field enables the Enhanced Angle Counter logic to generate angle information (see EAC - eTPU Angle Counter), and also select the tooth signal input and the channel used to process it, as shown in the following table. When EAC is not disabled by AM and neither TCR1 nor TCR2 are STAC Clients, the EAC (eTPU Angle Clock) hardware provides angle information to the channels using the TCR2 bus. When AM																											

Table continues on the next page...

eTPU_TBR_TBCR_ENG2 field descriptions (continued)

Field	Description																		
	is reset (non-angle mode), the EAC operation is disabled, and its internal registers can be used as general purpose. For more information, see EAC - eTPU Angle Counter. Table 37-30. AM - Angle Mode Selection <table><tr><th>Value</th><th>TCR2 Value</th><th>Tooth signal</th><th>Tooth processing channel</th></tr><tr><td>00</td><td>Timebase (EAC operation disabled)</td><td colspan="2">Not applicable</td></tr><tr><td>01</td><td rowspan="3">Angle Ticks</td><td>TCRCLK input</td><td>0</td></tr><tr><td>10</td><td>Channel 1 input</td><td>1</td></tr><tr><td>11</td><td>Channel 2 input</td><td>2</td></tr></table> If TCR1 or TCR2 is a STAC Bus Client (see STAC interface), the EAC operation is not allowed, and AM must be set to 0. NOTE: Changing AM may cause unexpected transition detections on the channel selected by AM, depending on the channel mode and state (see Transition detection and Time Base Capture). If AM must be changed with GTBE=1, the recommended procedure is described in Restarting angle logic.	Value	TCR2 Value	Tooth signal	Tooth processing channel	00	Timebase (EAC operation disabled)	Not applicable		01	Angle Ticks	TCRCLK input	0	10	Channel 1 input	1	11	Channel 2 input	2
Value	TCR2 Value	Tooth signal	Tooth processing channel																
00	Timebase (EAC operation disabled)	Not applicable																	
01	Angle Ticks	TCRCLK input	0																
10		Channel 1 input	1																
11		Channel 2 input	2																
7 ATGC	Angle Tick Generator Clock. This bit selects the clock that provides the time interval unit for Angle Tick Generation. For details, see Generating the angle ticks. 0 TCR1 prescaler output provides time intervals for tick generation. 1 TCR2 prescaler output provides time intervals for tick generation.																		
8–9 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.																		
10–15 TCR2P	Timer Count Register 2 Prescaler Control. These bits are part of the TCR2 clocking system (see Time bases). TCR2 is clocked from the output of a prescaler. The prescaler divides its input by (TCR2P + 1) allowing frequency divisions from 1 to 64. The prescaler input is the eTPU clock divided by 8 (in gated or non-gated clock mode), or Internal Timebase input, or TCRCLK filtered input. This field has no effect on TCR2 in Angle Mode.																		
16–17 TCR1CTL	TCR1 Clock/Gate Control. TCR1CTL is part of the TCR1 clocking system (see Time bases). It determines, together with TCR1CS, the clock source for TCR1. TCR1 can count on detected rising edge of the TCRCLK signal, the eTPU clock, or the eTPU clock divided by 2 (see the table in the TCR1CS bit description). After reset TCRCLK signal is selected.																		
18 TCR1CS	TCR1 Clock Source TCR1CS provides the option to double the TCR1 incrementing speed, using eTPU clock as its clock source instead of eTPU clock / 2.																		

Table continues on the next page...

eTPU_TBR_TBCR_ENG2 field descriptions (continued)

Field	Description																					
	NOTE: If ATGC=0, the clock source of the EAC angle tick generator will still be an even division of eTPU clock if TCR1CS=1, obeying to the field TCR1P as if TCR1CS=0 (see Angle Tick Generator). Table 37-29. TCR1 Clock Source <table><tr><th>TCR1CTL</th><th>TCR1CS</th><th>TCR1 Clock before prescaler</th></tr><tr><td>00</td><td>0</td><td>Selects TCRCLK as clock source for the TCR1 prescaler.¹</td></tr><tr><td>01</td><td>0</td><td>Reserved</td></tr><tr><td>01</td><td>1</td><td>Reserved</td></tr><tr><td>10</td><td>0</td><td>Selects eTPU clock divided by 2 as clock source for the TCR1 prescaler.</td></tr><tr><td>10</td><td>1</td><td>Selects eTPU clock as clock source for the TCR1 prescaler.</td></tr><tr><td>11</td><td>0</td><td>TCR1 frozen, except as a STAC client</td></tr></table> 1. This selection must not be used in Angle Mode. 0 Use eTPU clock / 2 as TCR1 clock source before the prescaler, if that clock source is selected by TCR1CTL. 1 Use eTPU clock as TCR1 clock source before the prescaler; can only be set in specific combinations with TCR1CTL, as shown in the table. NOTE: TCR1CS=1 also makes the channel work on T2/T4 timing mode (see T2/T4 channel timing).	TCR1CTL	TCR1CS	TCR1 Clock before prescaler	00	0	Selects TCRCLK as clock source for the TCR1 prescaler. ¹	01	0	Reserved	01	1	Reserved	10	0	Selects eTPU clock divided by 2 as clock source for the TCR1 prescaler.	10	1	Selects eTPU clock as clock source for the TCR1 prescaler.	11	0	TCR1 frozen, except as a STAC client
TCR1CTL	TCR1CS	TCR1 Clock before prescaler																				
00	0	Selects TCRCLK as clock source for the TCR1 prescaler. ¹																				
01	0	Reserved																				
01	1	Reserved																				
10	0	Selects eTPU clock divided by 2 as clock source for the TCR1 prescaler.																				
10	1	Selects eTPU clock as clock source for the TCR1 prescaler.																				
11	0	TCR1 frozen, except as a STAC client																				
19–23 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.																					
24–31 TCR1P	Timer Count Register 1 Prescaler Control. TCR1 is clocked from the output of a prescaler. The input to the prescaler is the internal eTPU clock divided by 2, eTPU clock, or the output of TCRCLK filter. The prescaler divides this input by (TCR1P + 1) allowing frequency divisions from 1 up to 256.																					

1. TCRCLK edges are not detected by the EAC logic, but they can still be detected by the channel 0 logic if AM=01.

2. This selection must not be used in Angle Mode.

37.8.6 eTPU Engine 2 Time Base 1 (TCR1) Visibility Register (eTPU_TBR_TB1R_ENG2)

This register provides visibility of the TCR1 time base for host read access (see [Time bases](#)). This register is read-only. The value of the TCR1 time base shown can be driven by the TCR1 counter or imported from STAC bus, depending on the configuration set in [eTPU Engine 2 STAC Configuration Register \(eTPU_TBR_STAC_ENG2\)](#).

Address: 0h base + 44h offset = 44h

eTPU_TBR_TB1R_ENG2 field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–31 TCR1	TCR1 value. TCR1 value used on matches and captures. See Time bases .

37.8.7 eTPU Engine 2 Time Base 2 (TCR2) Visibility Register (eTPU_TBR_TB2R_ENG2)

This register provides visibility of the TCR2 time base for host read access (see [Time bases](#)). This register is read-only. The value of the TCR2 time base shown can be driven by the TCR2 counter or imported from the STAC bus, depending on Angle Mode and STAC configurations set in [eTPU Engine 2 STAC Configuration Register \(eTPU_TBR_STAC_ENG2\)](#).

Address: 0h base + 48h offset = 48h

eTPU_TBR_TB2R_ENG2 field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–31 TCR2	TCR2 value. TCR2 value used on matches and captures. See Time bases .

37.8.8 eTPU Engine 2 STAC Configuration Register (eTPU_TBR_STAC_ENG2)

This register configures the eTPU STAC bus operation as a STAC Server/Client module (see [STAC interface](#)).

Address: 0h base + 4Ch offset = 4Ch

eTPU_TBR_STAC_ENG2 field descriptions

Field	Description
0 REN1	TCR1 Resource Client/Server Operation Enable Bit. This bit enables Client/Server operation to eTPU STAC resources. REN1 enables TCR1 STAC bus operations. 0 Server/Client Operation for TCR1 is disabled. 1 Server/Client Operation for TCR1 is enabled.
1 RSC1	TCR1 Resource Server/Client Assignment Bits. This bit selects the eTPU data resource assignment to be used as Servers or Clients. For Server mode, MCU-dependent value determines the unique server address assigned to each TCR. See the chip-specific

Table continues on the next page...

eTPU_TBR_STAC_ENG2 field descriptions (continued)

Field	Description
	eTPU information for the STAC server IDs. For a Client mode, the SRV1 field determines the Server address to which the Client listens. NOTE: Resource identifies any parameter that changes along the time and can be exported / imported from other device. In eTPU context, a resource can be TCR1 or TCR2 (either Time or Angle values). NOTE: When TCR1 or TCR2 is configured as a STAC Bus Client (REN2 = 1, RSC2 = 0) the eTPU Angle Clock hardware cannot be used. NOTE: RSC1 must not be changed when the REN1 bit is asserted. 0 TCR1 Client operation. 1 TCR1 Server operation.
2–3 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
4–7 SERVER_ID1	STAC ID 1. STAC Server ID (read-only MCU-dependent values; see the chip-specific eTPU information for the STAC server IDs) used for TCR1 when STAC servers are used.
8–11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12–15 SRV1	TCR1 Resource Server. This bit selects the address of the specific STAC Server to which the local TCR1 listens when configured as a STAC Client. SRV1 selects the STAC Server of TCR1.
16 REN2	TCR2 Resource Client/Server Operation Enable Bit. This bit enables Client/Server operation to eTPU STAC resources. REN2 enables TCR2 STAC bus operations. 0 Server/Client Operation for resource 2 is disabled. 1 Server/Client Operation for resource 2 is enabled.
17 RSC2	TCR2 Resource Server/Client Assignment Bits. NOTE: Resource identifies any parameter that changes along the time and can be exported / imported from other device. In eTPU context, a resource can be TCR1 or TCR2 (either Time or Angle values). 0 Resource Client operation. 1 Resource Server operation.
18–19 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
20–23 SERVER_ID2	STAC ID 2.

Table continues on the next page...

eTPU_TBR_STAC_ENG2 field descriptions (continued)

Field	Description
	STAC Server ID (read-only MCU-dependent values; see the chip-specific eTPU information for the STAC server IDs) used for TCR2 when STAC servers are used.
24–27 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
28–31 SRV2	TCR2 Resource Server. This bit selects the address of the specific STAC Server to which the local TCR2 listens when configured as a STAC Client. SRV2 selects the Red Line STAC Server of TCR2.

37.9 Engine memory map and registers

This section gathers registers that are engine-related, other than [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#).

eTPU_ER memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
60	eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1)	32	R/W	0000_0000h	37.9.1/1532
68	eTPU Idle Register for Engine 1 (eTPU_ER_IDLER_ENG1)	32	R/W	Undefined	37.9.2/1534

eTPU_ER_WDTR_ENG1 field descriptions

Field	Description
0–1 WDM	Watchdog Mode. WDM selects the Watchdog operation mode. For more information on the Watchdog operation, see Watchdog. NOTE: Before a new mode is configured, all conditions below must apply: 1. All channels must be disabled (CPR =00). 2. No thread must be executing (eTPU Channel Service Status Register for Engine 1 (eTPU_GCR_CSSR_ENG1) reads 0). 3. The watchdog must be disabled (WDM=00). 00 Disabled 01 Reserved 10 Thread length 11 Busy length
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 WMO	Watchdog Monitor Operation. This bit enables the monitor operation of the watchdog, inhibiting the thread ending and channel disabling in case of a timeout. The Global Exception occurs on a watchdog timeout, independently of WMO. NOTE: WDSn, WDTO1, WDTO2, and the Global Exception always asserts in case of a watchdog timeout, independently of WMO. 0 Force the end of the running thread and disable the service channel in case of a timeout. 1 Do not force the end of the running thread, nor disable the service channel in case of a timeout.
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 WDCNT	Watchdog Count. This field indicates the maximum number of microcycles allowed for a thread (in thread length mode) or a sequence of threads (in busy length mode) before the current running thread is forced to end. For more information on Watchdog operation, see Watchdog. NOTE: The TST microcycles are also counted by the watchdog. NOTE: Fields WDCNT and WMO must not be changed when the watchdog is enabled.

37.9.2 eTPU Idle Register for Engine 1 (eTPU_ER_IDLER_ENG1)

This register counts the microcycles in which the microengine is idle (see [Idle Counter](#)

Address: 0h base + 68h offset = 68h

eTPU_LMR_LMnMR_ENG1 field descriptions

Field	Description
0–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16–30 LATENCY	Latency measurement. This read-only field holds the value of the greatest latency measured, in microcycles, since reset or the latest clear. When the value is greater than the maximum specified in MAXLAT and MAXLAT value is not zero, a Global Exception is issued and LTO1 (engine 1) or LTO2 (engine 2) is set. See Latency Monitor for the detailed latency measurement description. NOTE: When read, the LATENCY field is concatenated with the LTC bit (LSB) to form a 16-bit value. NOTE: Any latency measured above 0xFFFF is captured as 0xFFFF into the LATENCY+LTC field.
31 LTC	Latency measurement clear Writing a 1 to the LTC bit clears the LATENCY field. NOTE: When read, the LATENCY field is concatenated with the LTC bit (LSB) to form a 16-bit value. NOTE: The LATENCY value is not automatically cleared when the Latency Monitor is disabled. 0 Keep the LATENCY field value. 1 Clear the LATENCY field value.

37.10.3 eTPU Latency Monitor Configuration Register for Engine 2 (eTPU_LMR_LMnCR_ENG2)

This register configures the operation of individual latency monitors.

Address: 0h base + C0h offset + (8d × i), where i=0d to 5d

eTPU_MESR_MECR field descriptions

Field	Description
0 FME	Field Modification Enable. Negation of this bit disables the modification of all fields in the register, except MECIE, DRDIS, CRDIS and FME itself: Write accesses do not cause a bus error, regardless of FME state. 0 Fields cannot be modified during a write access, except MECIE, DRDIS, CRDIS and FME. 1 All fields can be modified during a write access.
1–14 Reserved	Reserved.

Table continues on the next page...

eTPU_MESR_MECR field descriptions (continued)

Field	Description
	This field is reserved. This read-only field is reserved and always has the value 0.
15 MECIE	Memory Error Correction Interrupt Enable. This bit enables the Memory Error Correction Interrupt (see Interrupt types and sources). 0 Memory Error Correction Interrupt disabled. 1 Memory Error Correction Interrupt enabled.
16 HDEIE	Host Data Error Injection Enable This bit enables error injection into the SDM host read path, including CDC transfers. The eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR) specifies the address where the error is injected, while eTPU Data Error Injection Data Pattern Register (eTPU_MESR_DEIDPR) and eTPU Data Error Injection Parity Pattern Register (eTPU_MESR_DEIPPR) define the bit flips on data and parity, respectively. NOTE: Data error injection is also performed when data error detection is disabled (DEDD=1). 0 SDM error injection disabled for host reads. 1 SDM error injection enabled for host reads.
17 MDEIE	Microengine(s) Data Error Injection Enable. This bit enables error injection into the SDM microengine read path. The eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR) specifies the address where the error is injected, while eTPU Data Error Injection Data Pattern Register (eTPU_MESR_DEIDPR) and eTPU Data Error Injection Parity Pattern Register (eTPU_MESR_DEIPPR) define the bit flips on data and parity, respectively. NOTE: Data error injection is also performed when data error detection is disabled (DEDD=1). 0 SDM error injection disabled for microengine reads. 1 SDM error injection enabled for microengine reads.
18–20 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
21 DTEND	Thread End on Data Non-correctable Error. This bit controls the behavior of the microengine when a non-correctable data error occurs. For more details, see Memory error support. NOTE: DTEND must only be changed when the engine is stopped or halted, or when all channels are disabled. 0 Thread continues on non-correctable data read access by the microengine. 1 Thread ends on non-correctable data read access by the microengine.
22 DRDIS	Data Error Report Disable. This bit disables the sampling of SDM error address, data and syndrome into the eTPU Memory Error Support Registers, and eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR). It does not, however, disable the setting of eTPU Memory Error Status Register (eTPU_MESR_MESR) bits DCERR and DNCERR.

Table continues on the next page...

eTPU_MESR_MECR field descriptions (continued)

Field	Description
	NOTE: To guarantee coherent reading of eTPU Data Error Report Address Register (eTPU_MESR_DERAR), eTPU Data Error Report Data Register (eTPU_MESR_DERDR), and eTPU Data Error Report Syndrome Register (eTPU_MESR_DESR), DRDIS must be asserted beforehand if SDM concurrent accesses can happen, by host or microengine. After the registers are read, DRDIS may be negated again to allow new samplings. 0 SDM error report sampling enabled. 1 SDM error report sampling disabled.
23 DEDD	Data Error Detection Disable. This bit disables SDM error detection. The disabled state turns ineffective any action due to error detection, including consequently error correction. 0 SDM error detection enabled. 1 SDM error detection disabled.
24 CEIE	Code Error Injection Enable. This bit enables error injection into the SCM read path, either on microengine accesses (see VIS =0) or host accesses (VIS = 1) eTPU Code Error Injection Address Register (eTPU_MESR_CEAR) specifies the address where the error is injected, while eTPU Code Error Injection Data Pattern Register (eTPU_MESR_CEDPR) and eTPU Code Error Injection Parity Pattern Register (eTPU_MESR_CIPPR) define the bit flips on data and parity, respectively. NOTE: Code error injection is also performed when code error detection is disabled (CEDD=1). 0 SCM error injection disabled. 1 SCM error injection enabled.
25–28 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
29 CTEND	Thread End on Code Non-correctable Error. This bit controls the behavior of the microengine when a non-correctable code error occurs. For more details, see Memory error support. NOTE: CTEND must only be changed when the engine is stopped or halted, or when all channels are disabled. 0 Thread continues on instruction fetch non-correctable error. 1 Thread ends on instruction fetch non-correctable error.
30 CRDIS	Code Error Report Disable. This bit disables the sampling of SCM error address, data and syndrome into the eTPU Code Error Report Address Register (eTPU_MESR_CERAR), eTPU Code Error Report Data Register (eTPU_MESR_CERDR), and eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR). It does not, however, disable the setting of CCERR and CNCERR in eTPU Memory Error Status Register (eTPU_MESR_MESR).

Table continues on the next page...

eTPU_MESR_MECR field descriptions (continued)

Field	Description
	NOTE: To guarantee coherent reading of eTPU Code Error Report Address Register (eTPU_MESR_CERAR), eTPU Code Error Report Data Register (eTPU_MESR_CERDR), and eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR), CRDIS must be asserted beforehand if SCM concurrent accesses can happen, by host or microengine. After the registers are read, CRDIS may be negated again to allow new samplings. 0 SCM error report sampling enabled. 1 SCM error report sampling disabled.
31 CEDD	Code Error Detection Disable. This bit disables SCM error detection. The disabled state turns ineffective any action due to error detection, including consequently error correction. 0 SCM error detection enabled. 1 SCM error detection disabled.

37.11.2 eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR)

This register holds the address where error is to be injected into the SDM read data path. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

NOTE

This register must only be modified when [HDEIE](#) and [MDEIE](#) are both negated.

Address: 0h base + 104h offset = 104h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eTPU_MESR_DEIDPR field descriptions

Field	Description
0–31 DFLIP	Data Flip bits. Each bit corresponds to a bit in the actual data read from the SDM address defined in eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by HDEIE and/or MDEIE in eTPU Memory Error Control Register (eTPU_MESR_MECR). For more information on error injection, see Error injection. 0 Read data bit is not inverted. 1 Read data bit is inverted.

37.11.4 eTPU Data Error Injection Parity Pattern Register (eTPU_MESR_DEIPPR)

This register is used to specify the bits in which error is injected into the SDM read parity path.

NOTE

This register must only be modified when [HDEIE](#) and [MDEIE](#) are both negated.

Address: 0h base + 10Ch offset = 10Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eTPU_MESR_DEIPPR field descriptions

Field	Description
0–2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3–7 PFLIP_19_15	Parity Flip bits. Each bit corresponds to a bit in the actual parity read from the SDM address defined in eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR) , specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by the HDEIE and/or MDEIE fields in eTPU Memory Error Control Register (eTPU_MESR_MECCR) . Bits PFLIP[19:15] corresponds to the parity bits for the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error injection . 0 Parity data bit is not inverted. 1 Parity data bit is inverted.
8–10 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
11–15 PFLIP_14_10	Parity Flip bits. Each bit corresponds to a bit in the actual parity read from the SDM address defined in eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR) , specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by the HDEIE and/or MDEIE fields in eTPU Memory Error Control Register (eTPU_MESR_MECCR) . Bits PFLIP[19:15] corresponds to the parity bits for the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error injection . 0 Parity data bit is not inverted. 1 Parity data bit is inverted.
16–18 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
19–23 PFLIP_9_5	Parity Flip bits. Each bit corresponds to a bit in the actual parity read from the SDM address defined in eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR) , specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by the HDEIE and/or MDEIE fields in eTPU Memory Error Control Register (eTPU_MESR_MECCR) . Bits PFLIP[19:15] corresponds to the parity bits for

Field	Description
	the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error injection . 0 Parity data bit is not inverted. 1 Parity data bit is inverted.
24–26 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–31 PFLIP_4_0	Parity Flip bits. Each bit corresponds to a bit in the actual parity read from the SDM address defined in eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR) , specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by the HDEIE and/or MDEIE fields in eTPU Memory Error Control Register (eTPU_MESR_MECCR) . Bits PFLIP[19:15] corresponds to the parity bits for the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error injection . 0 Parity data bit is not inverted. 1 Parity data bit is inverted.

37.11.5 eTPU Data Error Report Address Register (eTPU_MESR_DERAR)

This register holds the address where the last non-correctable error was detected from the SDM. It also captures the address of the last correctable error detected, as long as [DNCERR](#) is 0. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

Address: 0h base + 110h offset = 110h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	ERR_ACC	0	ERR_CHANNEL						0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	ERR_ADDR														0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_DERAR field descriptions

Field	Description
0–1 ERR_ACC	Error Access Source Indication. This two-bit field indicates the source of the access when the error occurred. 00 Host - direct access 01 Engine 1 10 Engine 2 11 CDC
2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3–7 ERR_CHANNEL	Error Channel Access Indication. This field holds the number of the channel being serviced (not necessarily CHAN) when the error occurred. Its content is meaningful only when the field ERR_ACC indicates Engine 1 or Engine 2.
8–17 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
18–29 ERR_ADDR	Error Address. ERR_ADDR holds the (word) address where the last captured SDM read error was detected. The last captured error is a non-correctable one if DNCERR =1, or a correctable one if DNCERR =0 and DCERR =1. The field is meaningless if both DNCERR and DCERR are 0. For more information on error detection, see Memory error support .
30–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

37.11.6 eTPU Data Error Report Data Register (eTPU_MESR_DERDR)

This register holds the data read with the last non-correctable error detected from the SDM. It also captures the data of the last correctable error read detection, as long as **DNCERR** is 0. In both cases, the data is captured after the error correction logic. The data is meaningless if both **DNCERR** and **DCERR** are 0. For more information on error detection, see [Memory error support](#).

NOTE

Data is sampled before the error correction logic.

Address: 0h base + 114h offset = 114h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

R	BE1	0							BE0	0						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_DERSR field descriptions

Field	Description
0 BE3	Byte Enable 3. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0 Byte was not selected for read, therefore its respective error report fields are not meaningful. 1 Byte was selected for read, and the error report for the respective byte is meaningful.
1–2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3–7 SYND3	Error Syndrome 3. SYND3 holds the syndrome of an error detected in the SDM read data path, as defined in Error Correction Code (ECC) and syndrome definition . The field is meaningless if both DNCERR and DCERR are 0. For more information on error detection, see Memory error support .

Table continues on the next page...

eTPU_MESR_DERSR field descriptions (continued)

Field	Description
	NOTE: Syndrome fields which have their respective BE bits negated are not meaningful.
8 BE2	Byte Enable 2. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0 Byte was not selected for read, therefore its respective error report fields are not meaningful. 1 Byte was selected for read, and the error report for the respective byte is meaningful.
9–10 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
11–15 SYND2	Error Syndrome 2. SYND2 holds the syndrome of an error detected in the SDM read data path, as defined in the “Error Correction Code (ECC) and Syndrome Definition” section. The field is meaningless if both DNCERR and DCERR are 0. For more information on error detection, see Memory error support. NOTE: Syndrome fields which have their respective BE bits negated are not meaningful.
16 BE1	Byte Enable 1. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0 Byte was not selected for read, therefore its respective error report fields are not meaningful. 1 Byte was selected for read, and the error report for the respective byte is meaningful.
17–18 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
19–23 SYND1	Error Syndrome 1. SYND1 holds the syndrome of an error detected in the SDM read data path, as defined in the “Error Correction Code (ECC) and Syndrome Definition” section. The field is meaningless if both DNCERR and DCERR are 0. For more information on error detection, see Memory error support. NOTE: Syndrome fields which have their respective BE bits negated are not meaningful.
24 BE0	Byte Enable 0. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0 Byte was not selected for read, therefore its respective error report fields are not meaningful. 1 Byte was selected for read, and the error report for the respective byte is meaningful.
25–26 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–31 SYND0	Error Syndrome 0.

Table continues on the next page...

eTPU_MESR_DERSR field descriptions (continued)

Field	Description
	SYND0 holds the syndrome of an error detected in the SDM read data path, as defined in the “Error Correction Code (ECC) and Syndrome Definition” section. The field is meaningless if both DNCERR and DCERR are 0. For more information on error detection, see Memory error support .
	NOTE: Syndrome fields which have their respective BE bits negated are not meaningful.

37.11.8 eTPU Memory Error Status Register (eTPU_MESR_MESR)

This register gathers status bits of both SCM and SDM error detection and correction support.

Address: 0h base + 120h offset = 120h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R																
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R																
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_MESR field descriptions

Field	Description
0 DCERR	Data Correctable Error flag. When read: 0.....No SDM correctable error occurred. 1.....An SDM correctable error occurred. Writing 1 to this bit clears the DCERR status flag. DCERR asserts even if DNCERR is asserted beforehand, but in this case the address and data of the erroneous access is not captured (see Memory Error Support memory map and registers and following sections). DCERR is cleared by writing a 1 to it. Assertion of this bit can also assert the Memory Error Correction Interrupt (see Interrupt types and sources). NOTE: A correctable error is not considered for flagging if accompanied of a non-correctable one. Therefore, if both correctable and non-correctable data errors occur on the same access (in distinct bytes), the DNCERR flag asserts, but not the DCERR flag.

Table continues on the next page...

eTPU_MESR_MESR field descriptions (continued)

Field	Description
	0 Do not clear DCERR flag. 1 Clears DCERR flag
1–6 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
7 DCOVR	Data Correctable Overrun flag. Writing 1 to this bit clears the DCOVR status flag. 0 Data correctable error occurred while DCOVR = 1. 1 No data correctable error occurred while DCOVR = 1. DCOVR asserts when an SDM correctable error occurs and the DCERR flag is already asserted. Assertion of this bit causes no interrupt. NOTE: A correctable error is not considered for flagging if accompanied by a non-correctable one. Therefore, if both correctable and non-correctable data errors occur on the same access (in distinct bytes), the DCOVR does not assert, even if DCERR is asserted. The DNCOVR flag, on the other hand, asserts if DNCERR is asserted.
8 CCERR	Code Error flag. When read: 0.....No SCM correctable error occurred. 1.....An SCM correctable error occurred. When written: 0.....Do not clear CCERR flag. 1.....Clears CCERR flag. The CCERR flag asserts even if CNCERR is asserted beforehand, but in this case the address and data of the erroneous access is not captured (see eTPU Code Error Report Address Register (eTPU_MESR_CERAR) and the following sections). CCERR is cleared by writing a 1 at the same position. Assertion of this bit can also assert the Memory Error Correction Interrupt (see Interrupt types and sources).
9–14 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
15 CCOVR	Code Correctable Overrun flag This bit asserts when an SCM correctable error occurs and the CCERR flag is already asserted. Assertion of this bit causes no interrupt. When read: 0.....No SCM correctable error overrun occurred. 1.....An SCM correctable error overrun occurred. Writing 1 to this bit clears the CCOVR status flag: 0 Do not clear CCOVR flag. 1 Clear CCOVR flag.

Table continues on the next page...

eTPU_MESR_MESR field descriptions (continued)

Field	Description
16 DNCERR	Data Non-Correctable Error flag DNCERR flags a non-correctable error. When read: 0.....No SDM non-correctable error occurred. 1.....An SDM non-correctable error occurred; registers eTPU Global Channel Registers are not updated by correctable error detections. DNCERR must be cleared (by writing a 1 to it) to allow correctable error updates to eTPU Data Error Report Address Register (eTPU_MESR_DERAR) and eTPU Data Error Report Data Register (eTPU_MESR_DERDR). 0 Do not clear DNCERR flag. 1 Clear DNCERR flag.
17–22 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
23 DNCOVR	Data Non-Correctable Overrun flag. DNCOVR asserts when an SDM non-correctable error occurs and the DNCERR flag is already asserted. Assertion of this bit causes no interrupt. When read: 0.....No SDM non-correctable error overrun occurred. 1.....An SDM non-correctable error overrun occurred. DNCOVR is cleared by writing a 1 to it. 0 Do not clear DNCOVR flag. 1 Clear DNCOVR flag.
24 CNCERR	Code Non-Correctable Error flag CNCERR flags a non-correctable error: When read: 0.....An SCM non-correctable error occurred; the eTPU Global Channel Registers are not updated by correctable error detections. 1.....an SCM non-correctable error occurred; eTPU Code Error Report Address Register (eTPU_MESR_CERAR) and eTPU Code Error Report Data Register (eTPU_MESR_CERDR) are not updated by correctable error detections. CNCERR must be cleared to allow correctable error updates to eTPU Code Error Report Address Register (eTPU_MESR_CERAR) and eTPU Code Error Report Data Register (eTPU_MESR_CERDR). CNCERR is cleared by writing a 1 to it. 0 Do not clear CNCERR flag. 1 Clear CNCERR flag.
25–30 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

eTPU_MESR_MESR field descriptions (continued)

Field	Description
31 CNCOVR	Code Non-Correctable Overrun flag. CNCOVR asserts when an SCM non-correctable error occurs and the CNCERR flag is already asserted. Assertion of this bit causes no interrupt. When read: 0.....an SCM non-correctable error overrun occurred. 1.....An SCM non-correctable error overrun occurred. When written: 0 Do not clear CNCOVR flag. 1 Clear CNCOVR flag.

37.11.9 eTPU Code Error Injection Address Register (eTPU_MESR_CEIAR)

This register holds the address where error is to be injected into the SCM read data path. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

NOTE

This register must only be modified when [CEIE](#) is negated.

Address: 0h base + 124h offset = 124h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																INJ_ADDR														0	
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

eTPU_MESR_CEIAR field descriptions

Field	Description
0–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16–29 INJ_ADDR	Injection Address. INJ_ADDR holds the (word) address where an error is injected in the SCM read data path, as specified by eTPU Code Error Injection Data Pattern Register (eTPU_MESR_CEI DPR) and eTPU Code Error Injection Parity Pattern Register (eTPU_MESR_CEI PPR). For more information on error injection, see Error injection.
30–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

37.11.10 eTPU Code Error Injection Data Pattern Register (eTPU_MESR_CEIDPR)

This register is used to specify the bits in which error is injected into the SCM read data path.

NOTE

This register must only be modified when [CEIE](#) is negated.

Address: 0h base + 128h offset = 128h

eTPU_MESR_CEIDPR field descriptions

Field	Description
0–31 DFLIP	Data Flip bits. Each bit corresponds to a bit in the actual data read from the SCM address defined in eTPU Code Error Injection Address Register (eTPU_MESR_CEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SCM error injection is enabled by CEIE. For more information on error injection, see Error injection. 0 Read data bit is not inverted. 1 Read data bit is inverted.

37.11.11 eTPU Code Error Injection Parity Pattern Register (eTPU_MESR_CEIPPR)

This register is used to specify the bits in which error is injected into the SCM read parity path.

NOTE

This register must only be modified when [CEIE](#) is negated.

Address: 0h base + 12Ch offset = 12Ch

eTPU_MESR_CEIPPR field descriptions

Field	Description
0–24 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
25–31 PFLIP	Parity Flip bits. Each bit corresponds to a bit in the actual parity/code read from the SCM address defined in eTPU Code Error Injection Address Register (eTPU_MESR_CEIAR) , specifying whether it should be inverted or not. The inversion only occurs if the SCM error injection is enabled by CEIE . For more information on error injection, see Error injection . 0 Parity data bit is not inverted. 1 Parity data bit is inverted.

37.11.12 eTPU Code Error Report Address Register (eTPU_MESR_CERAR)

This register holds the address where the last non-correctable error was detected from the SCM. It also captures the address of the last correctable error detected, as long as [CNCERR](#) is 0. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

Address: 0h base + 130h offset = 130h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	ERR_ACC		0	ERR_CHANNEL				0								
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_CERAR field descriptions

Field	Description
0–1 ERR_ACC	Error Access Source Indication. This two-bit field indicates the source of the access when the error occurred. 00 Host 01 Engine 1

Table continues on the next page...

eTPU_MESR_CERAR field descriptions (continued)

Field	Description
	10 Engine 2 11 MISC
2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3–7 ERR_CHANNEL	Error Channel Access Indication. This field holds the number of the channel being serviced (not necessarily CHAN) when the error occurred. Its content is meaningful only when the field ERR_ACC indicates Engine 1 or Engine 2.
8–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16–29 ERR_ADDR	Error Address. ERR_ADDR holds the (word) address where the last captured SCM read error was detected. The last captured error is a non-correctable one if CNCERR = 1, or a correctable one if CNCERR = 0 and CCERR = 1. The field is meaningless if both CNCERR and CCERR are 0. For more information on error detection, see Memory error support .
30–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

37.11.13 eTPU Code Error Report Data Register (eTPU_MESR_CERDR)

This register holds the data read with the last non-correctable error detected from the SCM. It also captures the data of the last correctable error read detection, as long as **CNCERR** is 0. In both cases, the data is captured after the error correction logic. The data may be meaningless if both **CNCERR** and **CCERR** are 0. For more information on error detection, see [Memory error support](#).

NOTE

CODE is sampled before the error correction logic.

Address: 0h base + 134h offset = 134h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eTPU_MESR_CEFR field descriptions

Field	Description															
0–1 CFIXM	Code Fix Mode. This field specifies the SCM MISC fix logic operation mode as shown in the table below. NOTE: The CFIXM field can only be changed to/from disabled mode. Table 37-100. CFIXM - Code Fix Mode <table><tr><th>Value</th><th>Mode</th><th>Description</th></tr><tr><td>00</td><td>Disabled</td><td>SCM error fix disabled.</td></tr><tr><td>01</td><td>Reserved</td><td>Reserved value, must not be used.</td></tr><tr><td>10</td><td>Reserved</td><td>Reserved value, must not be used.</td></tr><tr><td>11</td><td>Automatic</td><td>The MISC logic rewrites the code word value read (already fixed by the error correction mechanism) into the same address whenever it finds a correctable error.</td></tr></table>	Value	Mode	Description	00	Disabled	SCM error fix disabled.	01	Reserved	Reserved value, must not be used.	10	Reserved	Reserved value, must not be used.	11	Automatic	The MISC logic rewrites the code word value read (already fixed by the error correction mechanism) into the same address whenever it finds a correctable error.
Value	Mode	Description														
00	Disabled	SCM error fix disabled.														
01	Reserved	Reserved value, must not be used.														
10	Reserved	Reserved value, must not be used.														
11	Automatic	The MISC logic rewrites the code word value read (already fixed by the error correction mechanism) into the same address whenever it finds a correctable error.														
2–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.															
16–29 CFIX_ADDR	Code Fix Address. This field is used for hardware debug purposes. CFIX_ADDR may change its contents and must not be written in automatic mode. For more information on error detection and correction, see Memory error support.															
30–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.															

37.12 Global Channel memory map and registers

The registers in this section group, by type, the interrupt status and enable bits from all the channels. This organization eases management of all channels or groups of channels by a single interrupt handler routine. These bits, except the service and watchdog status, are mirrored in the individual channel registers, grouped by channel.

eTPU_GCR memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
200	eTPU Channel Interrupt Status Register for Engine 1 (eTPU_GCR_CISR_ENG1)	32	R/W	0000_0000h	37.12.1/1564

294	eTPU Channel Service Status Register for Engine 2 (eTPU_GCR_CSSR_ENG2)	32	R	0000_0000h	37.12.18/1574

37.12.1 eTPU Channel Interrupt Status Register for Engine 1 (eTPU_GCR_CISR_ENG1)

This register groups the host interrupt status from all channels. These bits are mirrored from the Channel Status Control register (see [eTPU Channel n Status Control Register for Engine 1 \(eTPU_CCCR_CnSCR_ENG1\)](#)) and the Host must write 1 to clear a status bit.

For details about interrupts, see [Interrupts and data transfer requests](#).

Address: 0h base + 200h offset = 200h

eTPU_GCR_CISR_ENG1 field descriptions

Field	Description
0–31 CISn	Channel n Interrupt Status. When read, each bit: 0.....Indicates that channel n has no pending interrupt to the CPU. 1.....Indicates that channel n has a pending interrupt to the CPU. When written: 0.....Keep interrupt status bit unaltered. 1.....Clear interrupt status bit.

37.12.2 eTPU Channel Interrupt Status Register for Engine 2 (eTPU_GCR_CISR_ENG2)

This register groups the host interrupt status from all channels. These bits are mirrored from the Channel Status Control register (see [eTPU Channel n Status Control Register for Engine 2 \(eTPU_CCCR_CnSCR_ENG2\)](#)) and the Host must write 1 to clear a status bit.

For details about interrupts, see [Interrupts and data transfer requests](#).

Address: 0h base + 204h offset = 204h

eTPU_GCR_CISR_ENG2 field descriptions

Field	Description
0–31 CISn	Channel n Interrupt Status. When read, each bit: 0.....Indicates that channel n has no pending interrupt to the CPU. 1.....Indicates that channel n has a pending interrupt to the CPU. When written: 0.....Keep interrupt status bit unaltered. 1.....Clear interrupt status bit.

37.12.3 eTPU Channel Data Transfer Request Status Register for Engine 1 (eTPU_GCR_CDTRSR_ENG1)

This register groups data transfer request status from all channels. Their bits are mirrored from the Channel Status Control registers (see [eTPU Channel n Status Control Register for Engine 1 \(eTPU_CCCR_CnSCR_ENG1\)](#)) and Host must write 1 to clear a status bit.

For details about interrupts, see [Interrupts and data transfer requests](#).

Address: 0h base + 210h offset = 210h

eTPU_GCR_CDTRSR_ENG1 field descriptions

Field	Description
0–31 DTRSn	Channel n Data Transfer Request Status. These bits mimic the corresponding eTPU DMA requests. DTRSn can be cleared by software writing a 1 to it or by the assertion of corresponding DMA completion acknowledge line. When read: 0.....Indicates that channel n has no pending data transfer request. 1.....Indicates that channel x has a pending data transfer request. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.

37.12.4 eTPU Channel Data Transfer Request Status Register for Engine 2 (eTPU_GCR_CDTRSR_ENG2)

This register groups data transfer request status from all channels. These bits are mirrored from the Channel Status Control registers (see [eTPU Channel n Status Control Register for Engine 2 \(eTPU_CCCR_CnSCR_ENG2\)](#)) and Host must write 1 to clear a status bit.

For details about interrupts, see [Interrupts and data transfer requests](#).

eTPU_GCR_CDTRER_ENG1 field descriptions

Field	Description
0–31 DTREn	Channel n Data Transfer Request Enable. 0 Data Transfer request disabled for channel n. 1 Data Transfer request enabled for channel n.

37.12.12 eTPU Channel Data Transfer Request Enable Register for Engine 2 (eTPU_GCR_CDTRER_ENG2)

This register groups the data transfer request enable from all channels. These bits are mirrored from the Channel Status Control registers (see [eTPU Channel n Status Control Register for Engine 2 \(eTPU_CCCR_CnSCR_ENG2\)](#)).

For details about interrupts, see [Interrupts and data transfer requests](#).

Address: 0h base + 254h offset = 254h

eTPU_GCR_CDTRER_ENG2 field descriptions

Field	Description
0–31 DTREn	Channel n Data Transfer Request Enable. 0 Data Transfer request disabled for channel n. 1 Data Transfer request enabled for channel n.

37.12.13 eTPU Watchdog Status Register for Engine 1
(eTPU_GCR_WDSR_ENG1)

This register indicates the watchdog influence on each of the engine channels.

Address: 0h base + 260h offset = 260h

eTPU_GCR_WDSR_ENG1 field descriptions

Field	Description
0–31 WDSn	Channel n Watchdog Status. For details about Watchdog mechanism, see Watchdog . NOTE: The WDSn bits set in case of a watchdog timeout independently of WMO . When read: 0.....Watchdog did not expire during execution of a channel x thread since reset or last WDSn clear. 1.....Watchdog expired during execution of a channel n thread. When written: 0.....Keep watchdog status bit unaltered. 1.....Clear watchdog status bit.

37.12.14 eTPU Watchdog Status Register for Engine 2 (eTPU_GCR_WDSR_ENG2)

This register indicates the watchdog influence on each of the engine channels.

Address: 0h base + 264h offset = 264h

eTPU_GCR_WDSR_ENG2 field descriptions

Field	Description
0–31 WDSn	Channel n Watchdog Status. For details about Watchdog mechanism, see Watchdog. NOTE: The WDSn bits set in case of a watchdog timeout independently of WMO. When read: 0.....Watchdog did not expire during execution of a channel x thread since reset or last WDSn clear. 1.....Watchdog expired during execution of a channel n thread. When written: 0.....Keep watchdog status bit unaltered. 1.....Clear watchdog status bit.

37.12.15 eTPU Channel Pending Service Status Register for Engine 1 (eTPU_GCR_CPSSR_ENG1)

This register holds the status of the pending Channel Service Requests (see [Functions and threads](#)).

Address: 0h base + 280h offset = 280h

eTPU_GCR_CPSSR_ENG1 field descriptions

Field	Description
0–31 SRn	Pending Service Request n. Indicates a pending Service Request for channel n. Pending SR status is a logic OR of all service requests pending: if only HSR is active, SRn clears only at the end of the thread. SRn clear due to the other request sources is microcode dependent. NOTE: The pending service status bit for a channel is 1 when a Service Request is pending, even if the Channel is disabled (CPRn = 0). NOTE: There can be a delay of one clock between writing HSR greater than 0 in eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_CnHSRR_ENG1) of a channel and its respective bit being asserted in eTPU_GCR_CPSSR_ENG1. 0 No Service Request pending for channel n. 1 Pending Service Request for channel n.

37.12.16 eTPU Channel Pending Service Status Register for Engine 2 (eTPU_GCR_CPSSR_ENG2)

This register is a read-only register that holds the status of the pending Channel Service Requests (see [Functions and threads](#)).

Address: 0h base + 284h offset = 284h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_GCR_CPSSR_ENG2 field descriptions

Field	Description
0–31 SRn	Pending Service Request n. Indicates a pending Service Request for channel n. Pending SR status is a logic OR of all service requests pending: if only HSR is active, SRn clears only at the end of the thread. SRn clear due to the other request sources is microcode dependent. NOTE: The pending service status bit for a channel is 1 when a Service Request is pending, even if the Channel is disabled (CPRn = 0). NOTE: There can be a delay of one clock between writing HSR greater than 0 in eTPU Channel n Host Service Request Register for Engine 2 (eTPU_CCCR_CnHSRR_ENG2) of a channel and its respective bit being asserted in eTPU_GCR_CPSSR_ENG2. 0 No Service Request pending for channel n. 1 Pending Service Request for channel n.

37.12.17 eTPU Channel Service Status Register for Engine 1
(eTPU_GCR_CSSR_ENG1)

This register holds the current channel service status on whether it is being serviced or not (see [Functions and threads](#)). Only one bit may be asserted in this register at a given time. When no channel is being serviced, the register read value is 0x0000_0000. This register is read-only and can be read during normal eTPU operation for monitoring the scheduler activity.

NOTE

Channel Service Status does not always reflect decoding of the CHAN register (see [CHAN Register](#)), since the latter can be changed by the service thread microcode.

Address: 0h base + 290h offset = 290h

eTPU_GCR_CSSR_ENG1 field descriptions

Field	Description
0–31 SSn	Service Status n. Indicates that channel n is currently being serviced. It is updated at the 1st microcycle of a Time Slot Transition (see Time Slot Transition), or when the microengine ends the thread. 0 Channel n is not currently being serviced. 1 channel n is currently being serviced.

37.12.18 eTPU Channel Service Status Register for Engine 2
(eTPU_GCR_CSSR_ENG2)

This register holds the current channel service status on whether it is being serviced or not (see [Functions and threads](#)). Only one bit may be asserted in this register at a given time. When no channel is being serviced, the register read value is 0x0000_0000. This read-only register can be read during normal eTPU operation for monitoring the scheduler activity.

NOTE

Channel Service Status does not always reflect decoding of the CHAN register (see [CHAN Register](#)), since the latter can be changed by the service thread microcode.

Address: 0h base + 294h offset = 294h

eTPU_GCR_CSSR_ENG2 field descriptions

Field	Description
0–31 SSn	Service Status n. Indicates that channel n is currently being serviced. It is updated at the 1st microcycle of a Time Slot Transition (see Time Slot Transition), or when the microengine ends the thread. 0 Channel n is not currently being serviced. 1 channel n is currently being serviced.

37.13 Channel Configuration Control memory map and registers

Each channel has a group of 3 registers used to control, configure and check status of that channel as shown in the following table. This organization eases individual channel management.

Table 37-121. Channel registers structure

Channel offset	Register name
0x00	eTPU_CCCR_CnCR_ENGm - eTPU Channel Configuration Register
0x04	eTPU_CCCR_CnSCR_ENGm - eTPU Channel Status/Control Register
0x08	eTPU_CCCR_CnHSRR_ENGm - eTPU Channel Host Service Request Register
0x0C	Reserved

One contiguous area is used to map all channel registers of each eTPU engine as shown in the following table.

Table 37-122. Channel registers mMap

Offset	Registers structure
0x400	eTPU 1 Channel 0 Registers Structure
0x410	eTPU 1 Channel 1 Registers Structure
0x420	eTPU 1 Channel 2 Registers Structure
0x430	----
0x5E0	eTPU 1 Channel 30 Registers Structure
0x5F0	eTPU 1 Channel 31 Registers Structure
0x600	RESERVED
0x800	eTPU 2 Channel 0 Registers Structure
0x810	eTPU 2 Channel 1 Registers Structure
0x820	----
0x9E0	eTPU 2 Channel 30 Registers Structure
0x9F0	eTPU 2 Channel 31 Registers Structure
0xA00	RESERVED

There are 64 structures defined, one for each available channel in the eTPU System (32 for each Engine). The base address for the structure presented can be calculated by using the following equation:

$\text{Channel\_Register\_Base} = \text{eTPU\_Engine\_Channel\_Base} + (\text{channel\_number} * 0x10)$,
where:

- eTPU_Engine_Channel_Base = eTPU_Base + 0x400 for Engine 1.
- eTPU_Engine_Channel_Base = eTPU_Base + 0x800 for Engine 2.

eTPU_CCCR_CnCR_ENG1 field descriptions

Field	Description
0 CIE	Channel Interrupt Enable (see Channel Interrupt and Data Transfer Requests). This bit is mirrored from eTPU Channel Interrupt Enable Register for Engine 1 (eTPU_GCR_CIER_ENG1). 0 Disable interrupt for this channel. 1 Enable interrupt for this channel.
1 DTRE	Channel Data Transfer Request Enable (see Interrupts and data transfer requests). This bit is mirrored from eTPU Channel Data Transfer Request Enable Register for Engine 1 (eTPU_GCR_CDTRER_ENG1). 0 Disable data transfer request for this channel. 1 Enable data transfer request for this channel.
2–3 CPR	Channel Priority. This field defines the priority level for the channel, used by the Hardware Scheduler (see Scheduler). 00 Disabled 01 Low 10 Middle 11 High
4 T4DIS	T4 channel action Disable. This bit forces the channel to work on T2 timing mode, regardless of the FCSS and CDFC fields in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1), or of the TCR1CS field in eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1). For more details, see Channel timing modes. 0 Channel works either in T2 or T2/T4 timing modes, depending on the TCR1CS field in eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and the FCSS and CDFC fields in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1). 1 Channel works in T2 timing mode, regardless of the TCR1CS field in eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) or the FCSS and CDFC fields in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1).
5 SSMAE	Shared Subsystem Microengine Access Enable. This bit enables the microengine access to the Shared Subsystem Area (see Shared Subsystems support). When this bit is negated, DIOB address values pointing to the Shared Subsystem Area actually access SDM mirrors, in legacy mode. NOTE: SSMAE value must only be changed when the engine is either stopped or halted. 0 An SDM mirror is accessed when the Shared Subsystem Area is addressed by the microengine. 1 Enables microengine access to the Shared Subsystem Area.
6 ETPD	Entry Table Pin Direction. This bit selects which channel signal, input or output, is used in the Entry Point selection. The ETPD value has to be compatible with the function chosen for the channel, selected in the field CFS. For details about Entry Table and condition encoding schemes, see Entry Points.

Table continues on the next page...

eTPU_CCCR_CnCR_ENG1 field descriptions (continued)

Field	Description
	0 Use PSTI for Entry Point selection. 1 Use PSTO for Entry Point selection.
7 ETCS	Entry Table Condition Select. This bit determines the channel condition encoding scheme that selects, according to channel conditions, the Entry Point to be taken in an Entry Table. ETCS value has to be compatible with the function chosen for the channel, selected in field CFS. Two condition encoding schemes are available. For details about Entry Table and condition encoding schemes, see Entry Points . 0 Select Standard Entry Table Condition encoding scheme. 1 Select Alternate Entry Table Condition encoding scheme.
8–10 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
11–15 CFS	Channel Function Select. This field defines the function to be performed by the channel (see Functions and threads). The Function assigned to the channel has to be compatible with the channel condition encoding scheme, selected by field ETCS.
16 ODIS	Output Disable. This bit enables the channel to have its output forced to the value opposite to OPOL when the output disable input signal corresponding to the channel group that it belongs is active (see eTPU channel output disable signals and Figure 37-305). 0 Turns off the output disable feature for the channel. 1 Turns on the output disable feature for the channel.
17 OPOL	Output Polarity. Determines the output signal polarity. The activation of the output disable signal forces, when enabled by the ODIS bit, the channel output signal to the opposite of this polarity (see Figure 37-305). 0 Output active low (output disable drives output to high). 1 output active high (output disable drives output to low).
18–20 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
21–31 CPBA	Channel n Parameter Base Address. The value of this field times 8 specifies the SDM parameter base host (byte) address for channel n (2-parameter granularity; see SDM organization). As seen by the Host, the channel parameter base (byte) address is (without parameter sign extension) $eTPU\_Base + 0x8000 + CPBA * 8$ or (with parameter sign extension), $eTPU\_Base + 0xC000 + CPBA * 8$.

37.13.2 eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_CnSCR_ENG1)

This register gathers the interrupt status bits of the channel and the Function Mode definition (read-write). Bits CIS, CIOS and DTRS for each channel can be also accessed from [eTPU Channel Interrupt Status Register for Engine 1 \(eTPU_GCR_CISR_ENG1\)](#), [eTPU Channel Interrupt Overflow Status Register for Engine 1 \(eTPU_GCR_CIOSR_ENG1\)](#) and [eTPU Channel Data Transfer Request Status Register for Engine 1 \(eTPU_GCR_CDTRSR_ENG1\)](#). Host must write 1 to clear a status bit.

Address: 0h base + 404h offset + (16d × i), where i=0d to 31d

eTPU_CCCR_CnSCR_ENG1 field descriptions

Field	Description
0 CIS	Channel Interrupt Status. These bits are mirrored in eTPU Channel Interrupt Status Register for Engine 1 (eTPU_GCR_CISR_ENG1) . Also, see Channel Interrupt and Data Transfer Requests . When read: 0.....Channel has no pending interrupt to the Host CPU. 1.....Channel has a pending interrupt to the Host CPU. When written: 0.....Keep interrupt status bit unaltered.

Table continues on the next page...

eTPU_CCCR_CnSCR_ENG1 field descriptions (continued)

Field	Description
	1.....Clear interrupt status bit.
1 CIOS	Channel Interrupt Overflow Status. These bits are mirrored in eTPU Channel Interrupt Overflow Status Register for Engine 1 (eTPU_GCR_CIOSR_ENG1). Also, see Interrupt and Data Transfer Request overflow. When read: 0.....Interrupt overflow negated for this channel. 1.....Interrupt overflow asserted for this channel. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
2–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8 DTRS	Data Transfer Request Status. These bits are mirrored in eTPU Channel Data Transfer Request Status Register for Engine 1 (eTPU_GCR_CDTRSR_ENG1). Also, see Channel Interrupt and Data Transfer Requests. When read: 0.....Channel has no pending data transfer request. 1.....Channel has a pending data transfer request. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
9 DTROS	Data Transfer Request Overflow Status. These bits are mirrored in eTPU Channel Data Transfer Request Overflow Status Register for Engine 1 (eTPU_GCR_CDTROSR_ENG1). Also, see Interrupt and Data Transfer Request overflow. When read: 0.....Data transfer request overflow negated for this channel. 1.....Data transfer request overflow asserted for this channel. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
10–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16 IPS	Channel Input Pin State. This bit shows the current value of the filtered channel input signal state.
17 OPS	Channel Output Pin State.

Table continues on the next page...

eTPU_CCCR_CnSCR_ENG1 field descriptions (continued)

Field	Description
	This bit shows the current value driven in the channel output signal, including the effect of the external output disable feature (see eTPU channel output disable signals). If the channel input and output signals are connected to the same pad, OPS reflects the value driven to the pad. This is not necessarily the actual pad value, which drives the value in the bit IPS.
18 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
19–29 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
30–31 FM	Channel Function Mode. Each function uses this field for a specific configuration. These bits can be tested by microengine code (see Conditional/unconditional branch). These bits are equivalent to the TPU/TPU2/TPU3 Host Sequence (HSQ) bits.

37.13.3 eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_CnHSRR_ENG1)

This register is used by the Host to issue service requests to the channel.

Address: 0h base + 408h offset + (16d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

eTPU_CCCR_CnHSRR_ENG1 field descriptions

Field	Description
0–28 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
29–31 HSR	Host Service Request This field is used by the Host CPU to request service to the channel (see Host Service Requests). HSR value turns to 000 automatically at the end of microengine service for that channel, but only if the thread started due to an HSR. Host should write HSR greater than 0 only when HSR=0. Writing HSR=000 withdraws a pending request if scheduler did not begin to resolve the Entry Point yet, but it does not abort the service thread from that point on. For more details, see Entry Points and Host Service Requests . 000 No Host Service Request pending.

Table continues on the next page...

eTPU_CCCR_CnHSRR_ENG1 field descriptions (continued)

Field	Description
001	Function-dependent Host Service Request pending.
---	---
111	Function-dependent Host Service Request pending.

37.13.4 eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_CnCR_ENG2)

This register gathers configurations set individually per channel.

Address: 0h base + 800h offset + (16d × i), where i=0d to 31d

eTPU_CCCR_CnCR_ENG2 field descriptions

Field	Description
0 CIE	Channel Interrupt Enable (see Channel Interrupt and Data Transfer Requests). This bit is mirrored from eTPU Channel Interrupt Enable Register for Engine 2 (eTPU_GCR_CIER_ENG2) . 0 Disable interrupt for this channel. 1 Enable interrupt for this channel.
1 DTRE	Channel Data Transfer Request Enable (see Channel Interrupt and Data Transfer Requests). This bit is mirrored from eTPU Channel Data Transfer Request Enable Register for Engine 2 (eTPU_GCR_CDTRE_ENG2) . 0 Disable data transfer request for this channel. 1 Enable data transfer request for this channel.

Table continues on the next page...

eTPU_CCCR_CnCR_ENG2 field descriptions (continued)

Field	Description
2–3 CPR	Channel Priority. This field defines the priority level for the channel, used by the Hardware Scheduler (see Scheduler). 00 Disabled 01 Low 10 Middle 11 High
4 T4DIS	T4 channel action Disable. This bit forces the channel to work on T2 timing mode, regardless of the FCSS and CDFC fields in eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2), or of the TCR1CS field in eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2). For more details, see Channel timing modes. 0 Channel works either in T2 or T2/T4 timing modes, depending on the TCR1CS field in eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2) and the FCSS and CDFC fields in eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2). 1 Channel works in T2 timing mode, regardless of the TCR1CS field in eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2) or the FCSS and CDFC fields in eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2).
5 SSMAE	Shared Subsystem Microengine Access Enable. This bit enables the microengine access to the Shared Subsystem Area (see Shared Subsystems support). When this bit is negated, DIOB address values pointing to the Shared Subsystem Area actually access SDM mirrors, in legacy mode. NOTE: SSMAE value must only be changed when the engine is either stopped or halted. 0 An SDM mirror is accessed when the Shared Subsystem Area is addressed by the microengine. 1 Enables microengine access to the Shared Subsystem Area.
6 ETPD	Entry Table Pin Direction. This bit selects which channel signal, input or output, is used in the Entry Point selection. The ETPD value has to be compatible with the function chosen for the channel, selected in the field CFS. For details about Entry Table and condition encoding schemes, see Entry Points. 0 Use PSTI for Entry Point selection. 1 Use PSTO for Entry Point selection.
7 ETCS	Entry Table Condition Select. This bit determines the channel condition encoding scheme that selects, according to channel conditions, the Entry Point to be taken in an Entry Table. ETCS value has to be compatible with the function chosen for the channel, selected in field CFS. Two condition encoding schemes are available. For details about Entry Table and condition encoding schemes, see Entry Points. 0 Select Standard Entry Table Condition encoding scheme. 1 Select Alternate Entry Table Condition encoding scheme.
8–10 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

eTPU_CCCR_CnCR_ENG2 field descriptions (continued)

Field	Description
11–15 CFS	Channel Function Select. This field defines the function to be performed by the channel (see Functions and threads). The Function assigned to the channel has to be compatible with the channel condition encoding scheme, selected by field ETCS.
16 ODIS	Output Disable. This bit enables the channel to have its output forced to the value opposite to OPOL when the output disable input signal corresponding to the channel group that it belongs is active (see eTPU channel output disable signals and Figure 37-305). 0 Turns off the output disable feature for the channel. 1 Turns on the output disable feature for the channel.
17 OPOL	Output Polarity. Determines the output signal polarity. The activation of the output disable signal forces, when enabled by the ODIS bit, the channel output signal to the opposite of this polarity (see Figure 37-305). 0 Output active low (output disable drives output to high). 1 output active high (output disable drives output to low).
18–20 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
21–31 CPBA	Channel n Parameter Base Address. The value of this field times 8 specifies the SDM parameter base host (byte) address for channel n (2-parameter granularity; see SDM organization). As seen by the Host, the channel parameter base (byte) address is (without parameter sign extension) $eTPU\_Base + 0x8000 + CPBA * 8$ or (with parameter sign extension), $eTPU\_Base + 0xC000 + CPBA * 8$.

37.13.5 eTPU Channel n Status Control Register for Engine 2 (eTPU_CCCR_CnSCR_ENG2)

This register gathers the interrupt status bits of the channel and the Function Mode definition (read-write). Bits CIS, CIOS and DTRS for each channel can be also accessed from [eTPU Channel Interrupt Status Register for Engine 2 \(eTPU_GCR_CISR_ENG2\)](#), [eTPU Channel Interrupt Overflow Status Register for Engine 2 \(eTPU_GCR_CIOSR_ENG2\)](#) and [eTPU Channel Data Transfer Request Status Register for Engine 2 \(eTPU_GCR_CDTRSR_ENG2\)](#). Host must write 1 to clear a status bit.

Address: 0h base + 804h offset + (16d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

eTPU_CCCR_CnSCR_ENG2 field descriptions

Field	Description
0 CIS	Channel Interrupt Status. These bits are mirrored in eTPU Channel Interrupt Status Register for Engine 2 (eTPU_GCR_CISR_ENG2) . Also, see Channel Interrupt and Data Transfer Requests . When read: 0.....Channel has no pending interrupt to the Host CPU. 1.....Channel has a pending interrupt to the Host CPU. When written: 0.....Keep interrupt status bit unaltered.

Table continues on the next page...

eTPU_CCCR_CnSCR_ENG2 field descriptions (continued)

Field	Description
	1.....Clear interrupt status bit.
1 CIOS	Channel Interrupt Overflow Status. These bits are mirrored in eTPU Channel Interrupt Overflow Status Register for Engine 2 (eTPU_GCR_CIOSR_ENG2). Also, see Interrupt and Data Transfer Request overflow. When read: 0.....Interrupt overflow negated for this channel. 1.....Interrupt overflow asserted for this channel. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
2–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8 DTRS	Data Transfer Request Status. These bits are mirrored in eTPU Channel Interrupt Status Register for Engine 2 (eTPU_GCR_CISR_ENG2). Also, see Channel Interrupt and Data Transfer Requests. When read: 0.....Channel has no pending data transfer request. 1.....Channel has a pending data transfer request. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
9 DTROS	Data Transfer Request Overflow Status. These bits are mirrored in eTPU Channel Data Transfer Request Overflow Status Register for Engine 2 (eTPU_GCR_CDTROSR_ENG2). Also, see Channel Interrupt and Data Transfer Requests. When read: 0.....Data transfer request overflow negated for this channel. 1.....Data transfer request overflow asserted for this channel. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
10–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16 IPS	Channel Input Pin State. This bit shows the current value of the filtered channel input signal state.
17 OPS	Channel Output Pin State.

Table continues on the next page...

eTPU_CCCR_CnSCR_ENG2 field descriptions (continued)

Field	Description
	This bit shows the current value driven in the channel output signal, including the effect of the external output disable feature (see eTPU channel output disable signals). If the channel input and output signals are connected to the same pad, OPS reflects the value driven to the pad. This is not necessarily the actual pad value, which drives the value in the bit IPS.
18 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
19–29 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
30–31 FM	Channel Function Mode. Each function uses this field for a specific configuration. These bits can be tested by microengine code (see Conditional/unconditional branch). These bits are equivalent to the TPU/TPU2/TPU3 Host Sequence (HSQ) bits.

37.13.6 eTPU Channel n Host Service Request Register for Engine 2 (eTPU_CCCR_CnHSRR_ENG2)

This register is used by the Host to issue service requests to the channel.

Address: 0h base + 808h offset + (16d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eTPU_CCCR_CnHSRR_ENG2 field descriptions

Field	Description
0–28 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
29–31 HSR	Host Service Request This field is used by the Host CPU to request service to the channel (see Host Service Requests). HSR value turns to 000 automatically at the end of microengine service for that channel, but only if the thread started due to an HSR. Host should write HSR greater than 0 only when HSR=0. Writing HSR=000 withdraws a pending request if scheduler did not begin to resolve the Entry Point yet, but it does not abort the service thread from that point on. For more details, see Entry Points and Host Service Requests . 000 No Host Service Request pending.

Table continues on the next page...

eTPU_CCCR_CnHSRR_ENG2 field descriptions (continued)

Field	Description
001	Function-dependent Host Service Request pending.
---	---
111	Function-dependent Host Service Request pending.

37.14 Shared Subsystem Integration memory map and registers

Shared Subsystems Integration Registers configure aspects of how the shared modules interface with the eTPU. There is one integration register for each subsystem unit, which can be, depending on the specific subsystem, a whole IP module, a sub-module, or a channel within a module. For more details, see [Shared Subsystems support](#).

eTPU_SSIR memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

eTPU_SSIR_ETPUSSSIRn field descriptions

Field	Description
0–23 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
24–25 LENG	Link Engine. LENG specifies the engine that receives a Link Service Request when an interrupt is issued by the Shared Unit, or disables Shared Unit linking. The channel that receives the Link Service Request is specified in the LCHAN field. 00 Shared Unit Link Service Request disabled 01 Engine 1 receives Shared Unit Link Service Request 10 Engine 2 receives Shared Unit Link Service Request 11 Reserved
26 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–31 LCHAN	Link Channel. LCHAN specifies the channel linked when an interrupt is issued by the Shared Unit, if enabled in the LENG field. The field is meaningless if LENG disables Shared Unit linking. For more information on Link Service Requests, see Channel Link .

37.15 Functional description

37.15.1 Functions and threads

eTPU processing is event-driven, in the sense that eTPU microcode only runs to service a request from an event. Service Requests may result from the occurrence of any of the following events:

- Host CPU writing a non-zero value to the channel HSR (Host Service Request) field in [eTPU Channel n Host Service Request Register for Engine 1 \(eTPU_CCCR_CnHSRR_ENG1\)](#) and [eTPU Channel n Host Service Request Register for Engine 2 \(eTPU_CCCR_CnHSRR_ENG2\)](#).
- Occurrence of a time base match, an input signal transition, or a specific combination of them (depending on the Channel Mode currently configured).
- A Link Service Request.

A given event is always associated to only one Channel:

- There is one HSR register field for each Channel
- Each signal is associated with only one Channel, which has its own Match registers and independent mode configuration.
- Each Link Service Request can have only one Channel as a target.

Service Request processing is done by a set of microengine routines. A set of related routines that implement a specific channel application is called a **Function**. One or more Functions reside on SCM, limited only by the SCM space available, size of microcode Functions and the number of entry points available. Each Engine can be controlled by up to 32 Functions at a time.

A Function can be assigned to several channels, but only one Function can be assigned to a given Channel at a time. This is defined by the Host through the Channel Configuration Registers (see [Channel Configuration Control memory map and registers](#)).

The term **Thread** will be used hereafter to refer to a service routine of a Function, or its execution. A Thread is constructed of a specific number of microinstructions, typically the code necessary to calculate the next phase of waveform to be input to, or output from, a given channel. Once a Thread begins, its execution cannot be interrupted. A Thread normally finishes when an END microinstruction is executed.

A given Thread is selected and called by the Scheduler depending on the following:

- the type of event that generated the service request.

Functional description

- the Function assigned to the target channel.
- target channel pin state.
- the state of the channel logic.
- the priority assigned to the target channel, relative to the priorities of other channels with pending service requests

The mechanism to select a thread based on the channel Function and type of event is described in the [Entry Points](#).

The priority mechanism that determines the order of Thread execution amongst pending service requests is described in [Scheduler](#).

37.15.1.1 Entry Points

37.15.1.1.1 Entry Table

Each Thread has its **Entry Point**, which contains the SCM address of its first instruction, besides other information. For a complete Entry Point description, see [Entry Point format](#).

Once the Scheduler chooses a channel among pending Service Requests, the Entry Point is taken from an **Entry Table**, based on the Function assigned for the channel and other conditions. Entry Table layout is shown in the following figure.

Figure 37-291. Entry Table

The Entry Table is organized by Functions. Each Function can have up to 32 Entry Points of 16 bits each, corresponding to 32 possible Threads per Function. Each Entry Point location in the table corresponds to a combination of events and channel states (see [Entry Point address generation](#)). A single Thread can be associated to more than one combination, having its Entry Point repeated in the table. Each 32-bit word in the Entry Table holds two Entry Points.

Note that the Entry Table can be placed in any SCM address multiple of the Entry Table size, determined by the ETB field in [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#). However, it is recommended to place the Entry Table at the start of the SCM to get continuous code memory and to ease the eventual migration of the code from larger parts down to smaller ones without rearranging the binary image, but this is not a restriction. Unused Entry Points may be used for microcode, so this organization extends the microcode continuous area to the unused area of the Entry Table. For this purpose, Function numbers should be selected from 0 up to 31. If, for example, only 8 functions are implemented, only the Entry Table locations for Functions 0 to 7 are used, and the Entry Table locations for functions 8 to 31 can be used as microinstruction memory (adding extra continuous 1536 bytes for microprogram usage).

One way of implementing different sets of Functions is having more than one Entry Table, and configuring the eTPU with the appropriate one for the application by changing the ETB field in [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#). Note that the Engines can use different Entry Tables, with or without the same set of Functions.

37.15.1.1.2 Entry Point address generation

The Entry Point address within the Entry Table is determined by the Function assigned to the Channel, the state of the Channel, the type of event, and the condition encoding scheme. Together with the Entry Table base address, they form the Entry Point Address at the SCM, as shown in the following figure.

Figure 37-292. Entry Point Address (host address offset)

The type of event and channel state are coded in the Encoded Channel Conditions field C4-C0, according to one of two encoding schemes:

- Standard Entry Table Condition encoding scheme, shown in [Table 37-333](#), which privileges Host Service Requests.
- Alternate Entry Table Condition encoding scheme, shown in [Table 37-334](#), which focus on other events and state decoding.

The events that take part on condition encoding generate a Service Request, and have four origins:

1. Match Recognition (caused by greater/equal match, or equal-only, between the value TCR1/2 and the value stored in the channel match registers). eTPU channels support single and double match in various modes of match recognition; see [Match Recognition](#).
2. Transition Detect Service Request (channel input signal transition detection of a selected edge). The eTPU channels support single and double transition, which together with the double match options provide various modes of transition detection; see [Transition detection and Time Base Capture](#).

3. Channel Linking Service Request (microcode writing the channel number to the LINK register). Link service request allows one channel to activate another (see [Channel Link](#)). Links may also come from Shared Subsystem units (see [Shared Subsystems support](#)).
4. Host Service Request (Host writes a non-zero value to the HSR bits of the channel; see [Host Service Requests](#)).

Note

Even if a Transition or Match Service Request is inhibited (by channel mode/state or SRI), the Transition Detection and Match Recognition are taken into account for condition encoding. That is, the MRLA/B and TDLA/B flags are used, not their respective Service Requests.

Columns Host Request Bits, Link Request, MatchA/TransB, and MatchB/TransA determine the type of event. A non-zero value in these columns represents the recognition of the event, while "x" indicates that its recognition is irrelevant. Values 1 and 0 mean that event was recognized or not, respectively. Note that Match and Transition events may occur and not be recognized, and in this case it assumes value 0 for the condition encoding. The recognition of such an occurred event depends on the channel mode assigned and other conditions, as described in [Enhanced Channels](#).

The **Host Service Request Bits** column refers to the value written by the Host CPU to the Host Service Request Registers ([eTPU Channel n Host Service Request Register for Engine 1 \(eTPU_CCCR_CnHSRR_ENG1\)](#) and [eTPU Channel n Host Service Request Register for Engine 2 \(eTPU_CCCR_CnHSRR_ENG2\)](#)) of the Channel being serviced. Note that the bits on this row are coded (3-bit representation). If the value of HSR is not zero, then the Host actually requested service.

The **Link Request** column refers to the occurrence of a Channel Link or SSS Link requests.

The **MatchA/TransB** column refers to the recognition of either a Match event specified by MatchA channel register or the detection of a channel input signal event specified by the IPACB configuration register (see [Pin Control Registers](#)).

The **MatchB/TransA** column refers to the recognition of either a Match event specified by MatchB channel register or the detection of a channel input signal event specified by the IPACA configuration register (see [Pin Control Registers](#)).

For the channel input signal, MatchA and MatchB provide double timeout conditions which depend on the channel mode programming (see [Channel Modes](#)). If the channel is used for output only, there are no transition detections, so the MatchB/TransA column

represents only Match B, and MatchA/TransB column the Match A. In this case Match A and Match B are separated to give better state resolution in double match output functions. For more information about channel requests refer to [Enhanced Channels](#).

Besides those events, the following channel state conditions help to determine the Entry Point:

1. Channel Flags 0 and 1: these are channel-internal flags (not in SDM) associated with a channel. Their values are set by microcode (see [Channel flags operations](#)).
2. Input Pin state or Output Flip Flop: the state (0 or 1) of the channel input signal after the Enhanced Filter (see [Enhanced Digital Filter - EDF](#)), or the state driven to the output signal. Which one (input or output) is used is selected by the ETPD field in [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#).

The two Entry Table Condition encoding schemes combine events and state conditions differently, as detailed in the following sections.

37.15.1.1.3 Standard condition encoding scheme

In this scheme, shown in the following table, all 7 HSR combinations are used and other event type columns are marked "x" when HSR is non-zero, indicating that Host Service Request has priority over any other type of event. However, when an HSR service thread is called (entry numbers 0 to 9), other events may also have been recognized, and it is microcode responsibility to check them.

When HSR is 0, i.e., Host did not issue a Service Request to the channel, the other event conditions, the input signal state and channel flags determine the Entry Point. Note that channel flag 1 does not influence the encoding in this scheme.

Table 37-333. Standard channel condition encoding scheme

No.	Encoded channel conditions [C4-C0]	Host Service Request bits	Link request	MatchA/ TransB	MatchB/ TransA	In/output pin state ¹	Channel Flag1	Channel Flag0

31	11111	000	1	1	0	x	x	1
		Host Service Request						

1. The ETPD field in [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#) selects between input and output pin state.

37.15.1.1.4 Alternate condition encoding scheme

This scheme is shown in the following table. Because the HSR bits cannot be tested by microcode, only three distinct Host Service Request can be used:

1. HSR=010 or 011, which are coded into the same Entry Points (0 to 3)
2. HSR=100, 101 or 001, which are all coded into Entry Point 4

3. HSR=110 or 111, which are both coded into Entry Point 5

The remaining Entry Points use both channel flags for better state decoding, making this scheme better suited for Functions which need more states and/or faster state decoding, without needing many HSRs.

Table 37-334. Alternate channel condition encoding scheme

No.	Encoded channel conditions [C4-C0]	Host Service Request bits	Link request	MatchA/TransB	MatchB/TransA	In/Output pin state ¹	Channel Flag1	Channel Flag0

37.15.1.1.5 Entry Point format

Entry Point information includes a Preload-Parameter selection field, a Match Enable field, and the first microcode address of the thread. The Entry Point format is illustrated in the following figure.

**Figure 37-293. Entry Point format**

PP - Preload Parameter

PP indicates which pair of channel parameters are loaded into registers P and DIOB from the SDM prior to the execution of a thread. Preloading occurs during the time-slot transition period (see [Time Slot Transition](#)).

- 1 = microengine register P is preloaded from parameter 2 and DIOB from parameter 3.
- 0 = microengine register P is preloaded from parameter 0 and DIOB from parameter 1.

The parameter numbers are offsets from the channel parameter base address. For more info, see [Parameter Access](#).

ME - Match Enable

ME specifies whether match event recognitions are enabled or disabled for the thread associated with the entry point during the thread execution. If they are disabled, a match recognition can only occur after channel service. For more details refer to [Match Recognition](#).

- 1 = Matches are enabled during the thread.
- 0 = Matches are disabled during the thread.

The disabling of Match A/B recognition by MEF is dependent on IPACA/B configuration on the serviced channel (see [Pin Control Registers](#)). If IPACA=1xx, Match A is not disabled by ME=0. Likewise, IPACB=1xx overrides the effect of ME on Match B to "always on" If IPACA/B=0xx, Match A/B is disabled for two microcycles during TST (see [Time Slot Transition](#)) and is re-enabled when Entry Point is loaded, if ME=1. Note that if the comparator is in equal-only mode and the time base reaches the value of the Match register during the time that recognition is disabled (beginning of TST, plus whole thread if ME=0), the match recognition is lost. If the comparator is in greater-equal mode, the match event may be recognized after the disabling period if it satisfies the "greater-than" condition.

MICROCODE ADDRESS - Starting Microcode Address

This field specifies the microcode address on which the thread is to begin execution.

37.15.1.2 Time Slot Transition

The Time Slot Transition period (also called TST for short) is the interval between the servicing of two channels, during which all Channel-specific context is loaded for the new serviced Channel. The primary tasks completed during this period include:

- Set MEF for the TST wait-states, if any.
- Reset MEF for the first two microcycles (after eventual wait-states).
- Update of the CHAN register with the number of the new channel to be serviced.
- Parallel update of ERTA and ERTB from CaptureA and CaptureB registers of the new serviced channel.
- Sampling of the branch conditions of the new channel to be serviced into the branch logic (this means flags TDLA/B, MRLA/B, LSR, FM[1], FM[0], and PSS). The branch conditions are coherent with the timebase capture values sampled into ERTA/B (if MRLA/B, TDLA/B are set at the same time of the sampling, either both old flag state and capture values are sampled, or both new values are sampled).
- Formation of the entry point address.
- Copy the ME bit in the Entry Point into MEF.
- Access to the entry point location and getting the first microinstruction address.
- Preload of two parameters from the SDM into P (32 bits) and DIOB (24 bits).
- Fetch the first instruction of the thread to be executed for the new channel.
- Preset the RAR register value (see [RAR Register](#)).

The preload operation is 32-bit wide for P and 24-bit wide for DIOB. The P register is loaded with all the 32-bit parameter. The DIOB register is loaded with the lower 24-bits of the parameter. The microcode can switch at any time to access the lower 24-bits, upper byte, or all the 32-bits of any parameter in the SDM. Preload of P-DIOB pair of parameters is atomic with respect to Host and CDC accesses, and so are coherent with their dual-parameter coherent transfers. For more details see [Parameter sharing and coherency](#).

No instructions are executed at the Engine where the time slot transition period occurs, but the other Engine can execute normally. Match A/B is unconditionally disabled on the first two TST microcycles, if IPACA/B=0xx (respectively). During the rest of time slot transition, match recognition can be disabled or not, depending on IPACA/B field and ME. See [Match Recognition](#).

Time Slot Transition takes a minimum of 3 microcycles (6 eTPU clocks), which may be extended due to SDM arbitration wait-states for the first preload access (see [SDM arbitration](#)). When no wait-states are received ([Figure 37-294](#)), DIOB is preloaded twice, one for each PP value, and the correct value remains in DIOB when the Entry Point is loaded. [Figure 37-295](#) and [Figure 37-296](#) show the timing for one and two wait-states, respectively.

Registers B, C, D and SR are not altered by TST and keep their values from the previous thread. The values of registers A, MACL and MACH are not guaranteed at the thread start.

Figure 37-294. TST Timing - No Wait-states

Figure 37-295. TST Timing - 1 Wait-State

Figure 37-296. TST Timing - 2 Wait-states

For more information on Channel-specific registers and flags, refer to [Enhanced Channels](#). For more information on P, ERTA/B and DIOB registers refer to [Registers](#).

37.15.1.2.1 Thread gap

The MEF timing has changed from previous eTPU/eTPU2 versions, now being reset for two microcycles from the start of TST.¹² Therefore, two consecutive threads with ME=0 serving the same channel could block any match until the end of the second thread (see [Figure 37-294](#)). This could cause latency problems and also break compatibility with legacy code, so the thread transition logic was modified to introduce a one-microcycle gap between consecutive threads servicing the same channel, as shown in the following

12. the new MEF timing is found on all eTPU2 instances starting from the first version with Memory Error Support; all previous eTPU2 versions maintain the former MEF timing (see [Legacy Time Slot Transition Timing](#)).

figure. During the gap MEF is set to one, regardless of the previous or the next entry point ME field. The thread gap is inserted only between threads serving the same channel.

Figure 37-297. Thread gap

37.15.1.3 Thread ending

Threads can finish by either:

- an instruction with the END field active (see [Ending Current Thread - END](#)).
- a forced END by host writing to the FEND field in [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#).

- a forced END caused by Watchdog timeout (see [Watchdog](#)).
- a forced END caused by a non-correctable memory error (see [Memory error support](#)).

37.15.1.4 Watchdog

Each engine has a watchdog mechanism to prevent a thread or a sequence of threads from running too long, impacting the latency of the other channel services. The watchdog is configured through [eTPU Watchdog Timer Register for Engine 1](#) (`eTPU_ER_WDTR_ENG1`) and [eTPU Watchdog Timer Register for Engine 2](#) (`eTPU_ER_WDTR_ENG2`). When the watchdog is enabled, an internal counter increments on each microcycle when a thread is executing. If the count is greater than the value specified in the WDCNT field in [eTPU Watchdog Timer Register for Engine 1](#) (`eTPU_ER_WDTR_ENG1`) and [eTPU Watchdog Timer Register for Engine 2](#) (`eTPU_ER_WDTR_ENG2`) and a thread is still executing, the watchdog:

1. If the WMO field in [eTPU Watchdog Timer Register for Engine 1](#) (`eTPU_ER_WDTR_ENG1`) and [eTPU Watchdog Timer Register for Engine 2](#) (`eTPU_ER_WDTR_ENG2`) is negated, forces an END of the thread, allowing other channels to be serviced
2. Sets the WDS status bit of the serviced channel in [eTPU Watchdog Status Register for Engine 1](#) (`eTPU_GCR_WDSR_ENG1`) and [eTPU Watchdog Status Register for Engine 2](#) (`eTPU_GCR_WDSR_ENG2`).
3. If the WMO field in [eTPU Watchdog Timer Register for Engine 1](#) (`eTPU_ER_WDTR_ENG1`) and [eTPU Watchdog Timer Register for Engine 2](#) (`eTPU_ER_WDTR_ENG2`) is negated, the channel is disabled, not initiating any thread until its WDS bit is cleared (however, its CPR field in [eTPU Channel n Configuration Register for Engine 1](#) (`eTPU_CCCR_CnCR_ENG1`) and [eTPU Channel n Configuration Register for Engine 2](#) (`eTPU_CCCR_CnCR_ENG2`) is not changed).
4. Issues a Global Exception and sets [WDTO1](#) (engine 1) or [WDTO2](#) (engine 2), regardless of the WMO bit state.

If the WMO field in [eTPU Watchdog Timer Register for Engine 1](#) (`eTPU_ER_WDTR_ENG1`) and [eTPU Watchdog Timer Register for Engine 2](#) (`eTPU_ER_WDTR_ENG2`) is asserted, the watchdog can be used to monitor the execution time threshold of a thread or thread sequence without interfering with the eTPU code execution.

The watchdog can be configured in one of the following modes, defining how the internal watchdog count is reset:

- **Thread Length Mode:** the watchdog count is reset at the end of each thread.
- **Busy Length Mode:** the watchdog count is reset when the microengine goes idle. A sequence of threads, one right after another, keeps the count running. The counter is also reinitialized when a thread is forced to end, so that a new count begins if another TST initiates at the following microcycle.

The following applies to the watchdog mechanism:

- microcycles during TST and SDM access wait-states (on TST or instruction execution) are counted.
- if the watchdog count equals WDCNT in the last microinstruction (with SDM wait-states or not) of a thread servicing a channel, its WDS bit is not set.
- if the watchdog count expires (gets greater than WDCNT) during the TST, the thread is forced end on its first instruction.
- the watchdog count does not wrap, so that a thread (in thread length mode) or a thread sequence (in busy length mode) that lasts for more than the maximum value of WDCNT does get a forced end.

Note

Watchdog must not be enabled when the microengine enters halt mode.

The counter does not run when the engine is stopped, and resets when the watchdog is disabled.

37.15.2 Host interface

37.15.2.1 System configuration

System Configuration Registers are described in [System Configuration memory map and registers](#). Detailed explanation of the configured functionalities is found throughout [Functional description](#) and a specification for the initial configuration sequence is found in [Configuration sequence](#).

37.15.2.2 Interrupts and data transfer requests

37.15.2.2.1 Interrupt types and sources

Each one of the eTPU channels can be a source of two requests: **Channel Interrupt** request and **Data Transfer Request**. Channel Interrupts are targeted to a Host CPU. Data Transfer Requests may be targeted to a data transfer module (for example, a DMA controller). Interrupt and Data Transfer registers are used by the Host to enable interrupts and data transfer requests, indicate their status and service them. Interrupt and Data Transfer requests have the same sets of registers and external signals, and are handled in the same way. They differ only by the fact that Data Transfer Requests are also cleared by the assertion of respective DMA completion acknowledge line.

Note

Interrupt and Data Transfer requests can be cleared even when Engines are in Module Disable Mode, through the Global Channel Registers, and also DMA completion for Data Transfer requests.

Channel Interrupts and Data Transfer Requests can only be issued by eTPU microcode, through one of the Channel Control instruction fields (see [Channel Interrupt and Data Transfer Requests](#)).

Both Channel Interrupt and Data Transfer requests can be individually enabled for each channel.

eTPU Interrupt and Data Transfer Registers are mirrored in two organizations: grouped by Channel and grouped by type (interrupt status, interrupt enable, data transfer status, data transfer enable). This allows either "channel-oriented" or "bundled channel" Host interrupt service schemes, or a combination of them. For a detailed description, refer to the Channel Register Layout and Global Channel Registers sections.

eTPU can also assert a **Global Exception** interrupt indicating a global illegal state. There are six possible sources for a Global Exception:

- Execution of an illegal instruction by the microengine (see [Illegal instructions](#)). This Global Exception source is flagged by [ILF1](#) and [ILF2](#).
- An SCM signature mismatch detected by the Multiple Input Signature Calculator - MISC. See [SCM Test - Multiple Input Signature Calculator](#). This source is flagged by [SCMMISF](#).

- Microcode request, through microinstruction field CIRC (see [Channel Interrupt and Data Transfer Requests](#)). This Global Exception source is flagged by [MGE1](#) (Engine 1) and [MGE2](#) (Engine 2). The cause of this illegal state is application-dependent. The microcode may write an error code into the SDM to indicate the cause of the exception, for instance.
- A Watchdog timeout, flagged by [WDTO1](#) and [WDTO2](#) (see [Watchdog](#)).
- An SDM or SCM non-correctable error on a microengine or host access, flagged by [SDMERR](#) and [SCMERR](#), respectively (see [Memory error support](#)).
- Bus errors on microengine accesses to the Shared Subsystem Area, flagged by [SSAERR](#) (see [Shared Subsystems support](#)).
- The latency measured by any of either engine's Latency Monitors is greater than the specified maximum, flagged by [LTO1](#) (Engine 1) and [LTO2](#) (Engine 2) (see [Latency Monitor](#)).

Global Exceptions cannot be directly disabled within eTPU, except by disabling its sources (Memory Error, SSS, MISC and microcode), and it is cleared by writing 1 to [GEC](#). Clearing Global Exception clears all Global Exception source status bits (ILF1, ILF2, SCMMISF, MGE1, MGE2, SSAERR, SCMERR, SDMERR). If GEC is written 1 at the same time any of the sources issues a Global Exception, both the interrupt and the status bit of that source remains asserted. The assertion of Global Exception by one of the sources above does not prevent the others from asserting it too, so any number of them, in any combination, can be flagged.

Note

There can be a race between the clear of a Global Exception and occurrence of a new set condition, such that the set happens just before the clear and cannot be sensed by the Host. Therefore, Global Exception cannot be used as a normal interrupt source. It should only be used for emergency procedures.

Memory Error Correction support (see [Memory error support](#)) has a distinct interrupt source, which can activate on any correctable error occurrence, either to SCM or SDM accesses, but does not activate on non-correctable errors (which assert Global Exception instead). Memory Error Correction interrupt assert when it is enabled through [MECIE](#) (see [eTPU Memory Error Status Register \(eTPU_MESR_MESR\)](#)) and either DCERR or CCERR in [eTPU Memory Error Status Register \(eTPU_MESR_MESR\)](#) is asserted. The interrupt is negated when both DCERR and CCERR are negated, or MECIE is negated.

37.15.2.2.2 Interrupt and Data Transfer Request overflow

If a Channel Interrupt was issued, its status bit is still set, and microcode issues another Channel Interrupt, the Interrupt Overflow status bit is set for that channel. Interrupt Overflow status can be checked by the Host in the CIOS field of [eTPU Channel n Status Control Register for Engine 1 \(eTPU_CCCR_CnSCR_ENG1\)](#) and [eTPU Channel n Status Control Register for Engine 2 \(eTPU_CCCR_CnSCR_ENG2\)](#), mirrored in [eTPU Channel Interrupt Overflow Status Register for Engine 1 \(eTPU_GCR_CIOSR_ENG1\)](#) and [eTPU Channel Interrupt Overflow Status Register for Engine 2 \(eTPU_GCR_CIOSR_ENG2\)](#). Interrupt Overflow status is not cleared automatically when Interrupt Status is cleared. The same mechanism and respective registers ([eTPU Channel Data Transfer Request Overflow Status Register for Engine 1 \(eTPU_GCR_CDTROSR_ENG1\)](#) and [eTPU Channel Data Transfer Request Overflow Status Register for Engine 2 \(eTPU_GCR_CDTROSR_ENG2\)](#)) are available for Data Transfer Requests.

If interrupt is set and cleared at the same time, set prevails and overflow is not altered (keeps the same state as it was before, asserted or not).

Global Exception has no overflow status.

37.15.2.3 Parameter Access

37.15.2.3.1 Parameter Access Widths

From the Host side the SDM address space is mapped in bytes, and each 32-bit parameter occupies 4 contiguous, aligned bytes. The Host can read/write the SDM by 8-, 16-, or 32-bit accesses in aligned addresses.

In 32-bit access, Host can access all 32 bits or only the lower 24 bits with an automatic sign extension (see [Parameter Sign Extension area](#)).

37.15.2.3.2 Parameter Addresses and Endianness

To access parameter number xxx, eTPU Microengine(s) would select address xxx. The Host would add $(xxx * 4)$ to the SDM base address to access the same parameter. For example, parameter 0x101 is seen by the Host in $(SDM\ base\ address + 0x404)$. An example of SDM memory map is shown in [Figure 37-298](#). The Host can access the SDM with a 32-bit-wide bus cycle to a four-byte aligned address, 16-bit-wide bus cycle to a two-byte aligned address, or 8-bit wide bus cycle to any byte address.

The address of the 24-bit parameters and the most significant byte depends on the endianness of the MCU. For more details, see the [Endianness](#).

37.15.2.3.3 Parameter concurrency

Host accesses to parameters may occur in parallel with eTPU Microengine accesses. Readings taken from a group of parameters while they are being simultaneously updated may lack coherency. eTPU provides mechanisms to ensure parameter coherency in accesses from both Host side and Microengine side, including the use of a coherent dual-parameter transfer mechanism, described in detail on [Parameter sharing and coherency](#).

37.15.2.3.4 Parameter Sign Extension area

The SDM address space to the Host is mirrored in a Parameter Sign Extension (PSE) area (see [Table 37-4](#)). Accesses from the Host to the PSE area differ from accesses to the standard SDM address space as follows:

- **Writes:** the most significant byte of the parameters is not written, and the SDM retains the old byte value, regardless of the Host access size.
- **Reads:** the most significant bit of the 24-bit parameter (that is, the MSB of the second most significant 32-bit parameter byte) is repeated in the 8 most significant bits of the read value on all 32-bit reads and most significant 16- and 8-bit reads.

The same parameters written in the standard SDM address space are read from the PSE area with the same offsets, and vice-versa. See [Table 37-429](#) for a reference of the address offsets in big and little endian machines.

This feature relieves the Host from extending the signal of 24-bit eTPU parameters before calculations, and from read-modify-write accesses to modify 24-bit parameters at the SDM.

37.15.2.4 SDM organization

The SDM internal partition for channel allocation is dynamic and programmed in the Channel Registers (see [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#)).

The Host application is responsible for allocating a different parameter base address to each channel during the initial eTPU configuration, and to allocate enough parameters for the selected Function, with no unintentional overlapping between parameters of different functions.

Besides channel parameters, global areas may have to be allocated for parameters that are shared by more than one channel, in one or both Engines. Also, temporary parameter areas should be reserved to be used by the coherent parameter transfer mechanisms described in [Parameter sharing and coherency](#), if necessary. An SDM organization example is shown in the following figure.

Figure 37-298. SDM Organization Example (4 KB)

Single-engine eTPU or dual eTPU system may require less parameters than the maximum number provided by the SDM. Since the SDM partition is fully dynamic, there is no limitation of fixed channel addresses, and the reduced array can be fully utilized.

37.15.2.5 Host Service Requests

Host CPU can request immediate service from a channel by writing a non-zero value to the Host Service Request register field - HSR (see [eTPU Channel n Host Service Request Register for Engine 1 \(eTPU_CCCR_CnHSRR_ENG1\)](#) and [eTPU Channel n Host Service Request Register for Engine 2 \(eTPU_CCCR_CnHSRR_ENG2\)](#)). There is one HSR field for each channel, so that writing to it generates a Service Request to the respective channel only. A zero value in HSR means no Host Service Request is pending for the channel.

HSR value turns to 000 automatically at the end of microengine service for that channel, but only if the thread started due to an HSR.

The meaning of a non-zero HSR value depends on the Function assigned for the channel. These bits are part of the conditions which select the Function entry point, and cannot be tested by microcode. For more details, refer to [Entry Points](#).

If Host writes HSR=000 when a thread for the same channel is already running, the thread runs until the end and is not aborted. If Host writes HSR>000 when an HSR thread for the same channel is already running, HSR value resets at the end of the thread, and no new HSR will be pending. If HSR is written before its value is resolved by the scheduler during TST, the entry point will obey the new HSR value, and if this new value is 000, no service thread is executed for the HSR.

The scheduling of HSRs is completely asynchronous with Host accesses, and there is no race-free manner to change an HSR value before service thread execution, so generally the safe way is: write HSR>0 only when HSR=0. Error recovery or emergency host procedures may require one to safely abort service and reset channel state when an HSR is already pending or executing. In these cases, the procedure below should be followed:

1. Disable the channel, writing CPR=00 in [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#). That will prevent any pending HSR to be serviced.
2. Check if the channel is currently being serviced, reading its service status bit in [eTPU Channel Service Status Register for Engine 1 \(eTPU_GCR_CSSR_ENG1\)](#) and [eTPU Channel Service Status Register for Engine 2 \(eTPU_GCR_CSSR_ENG2\)](#). If

it is, wait for the time necessary to finish the service pending, or check again until $HSR == 0$, or channel service bit in [eTPU Channel Service Status Register for Engine 1 \(eTPU_GCR_CSSR_ENG1\)](#) and [eTPU Channel Service Status Register for Engine 2 \(eTPU_GCR_CSSR_ENG2\)](#) is cleared.

3. Write HSR with the error recover value. This value should, possibly combined with other host-defined flags in SDM or FM bits, initiate a channel reset or error recovery procedure.
4. Re-enable the channel, writing CPR value > 0 in [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#).

37.15.2.6 SCM access

Only Host can access SCM as data. Depending on the specific device, SCM may be implemented as a RAM or ROM. This determines Host accesses to the SCM as shown below.

37.15.2.6.1 SCM RAM implementations

When SCM is implemented as RAM, the Host may read or write to SCM by setting [VIS](#) = 1. If $VIS=0$ and Host tries to access SCM space, a bus error is issued, writes are ineffective and read data is meaningless. Both Engines must be stopped or halted to set $VIS=1$.

Note

It is necessary to turn [VIS](#) bit on to set software breakpoints (see [Software breakpoints](#)).

37.15.2.6.2 SCM low power

SCM turns off its internal clocks when both Engines are stopped (STF field in [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#) asserted), [VIS](#), and [MISC](#) is not enabled ($SCMMISEN=0$). The SCM clocks are automatically turned on if either one of the STF bits is negated or [VIS](#) turns to 1, or [SCMMISEN](#) turns to 1.

SCM clocks are not turned off if any of the Engines is not stopped, even if they are both halted.

The conditions for SCM Clocks and MISC activation are summarized in the following table.

Table 37-335. SCM clocks and MISC activation

STF in eTPU_SCR_ECR_ ENG1	STF in eTPU_SCR_ECR_ ENG2	VIS in eTPU_SCR_MCR	SCMMISEN in eTPU_SCR_MCR	SCM clocks	MISC
0	x	0 ¹	1	On	On
0	x	0 ¹	0	On	off
x	0	0 ¹	1	On	On
x	0	0 ¹	0	On	off
1	1	0	0	off	off
1	1	0	1	On	On
1 ²	1 ²	1	0	On	off
1 ²	1 ²	1	1	On	off ³
0	0	x	0	On	off
0	0	x	1	On	On

1. VIS cannot be written 1 if eTPU_SCR_ECR_ENG1[STF]=0 or eTPU_SCR_ECR_ENG2[STF]=0, and both HLTF bits are 0.
2. If VIS=1, neither MDIS can be written 0 nor the Engine leaves Stop Mode, regardless of device stop request.
3. MISC resets and stays so when VIS=1, restarting automatically when VIS goes 0 if SCMMISEN=1.

37.15.2.6.3 SCM Off-range data

When read accesses are made, either by the Host or by a microengine, to addresses above the limit corresponding to [SCMSIZE](#), the value read comes from [eTPU SCM Off-range Data Register \(eTPU_SCR_SCMOFFDATAR\)](#). The Host can program the register at initialization with an opcode value with operations that try to protect or recover the system from runaway code, for instance: terminate the thread, clear channel flags, disable match and transition service requests, issue an interrupt, jump to an error recovery procedure¹³. Writes to unimplemented addresses do not return error and can write on unspecified mirror addresses, so they should be avoided.

37.15.2.7 Bus error conditions

Follows a summary of the possible causes of bus errors on host accesses to the eTPU memory space:

- Read or write access to the SCM with [VIS](#) =0.

13. Only part of these suggested operations can be parallelized in a single instruction, see [Microinstruction formats](#).

- Read or write access to the channel registers with eTPU_SCR_ECR_ENG n bits MDIS=1, or bit STF=1 (see [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#)).
- Write access to the Time Base Registers with eTPU_SCR_ECR_ENG n bits MDIS=1, or bit STF=1 (see [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#)).
- Non-correctable errors in the SCM on reads of any size or writes less than 32-bits wide when CEDD =0.
- Non-correctable errors in the SDM on reads when DEDD =0.
- Accesses to the Shared Subsystem Area, when propagating a bus error issued by the attached subsystem.

37.15.3 Scheduler

Every Function is composed of one or more Threads. A Thread consists of a group of instructions that, once begins execution, cannot be interrupted by host or channel events. Each active channel intends to be serviced, being granted time for Thread execution. Since one microengine handles several channels operating concurrently, the Function threads must be executed serially.

The task of the Scheduler is to recognize and prioritize the channels needing service and to grant execution time to each channel. The time given to an individual Thread for execution or service is called a **Time Slot**. The duration of a time slot is determined by the number of instructions executed in the Thread plus SDM wait-states received, and varies in length.

At any time, an arbitrary number of channels can require service. To request service, channel logic, eTPU microcode or Host application notifies the Scheduler by issuing a Service Request.

37.15.3.1 Channel enabling and priority assignment

Every channel is assigned one of three priority levels - high, middle, or low - by the Host CPU, through the Channel Configuration Register field CPR (see [eTPU Channel \$n\$ Configuration Register for Engine 1 \(eTPU_CCCR_C \$n\$ CR_ENG1\)](#) and [eTPU Channel \$n\$](#)

[Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#)). These registers are also used to disable the channel, which is equivalent to assigning it a "null" priority. In this case, the Scheduler does not grant any of its Service Requests.

It is possible to change the channel priority level or disable it dynamically. If the Host disables a channel when it is currently being serviced, channel service thread will complete. This means that it is possible for the output level of a channel signal to change, or a Host interrupt occur, even after its priority register was written to "null". For instance, if an output transition is scheduled, the transition will occur even after the channel is disabled.

Service requests previously pending or that occur while a channel is disabled remain asserted while the channel is disabled, and are serviced if the channel is enabled again, in due time determined by the priority scheme and concurrent requests from other channels. Channels are disabled after reset, and it is recommended to configure a Host Service Request for initialization of a channel before that channel is enabled to active priority (see [Initialization/application information](#)).

37.15.3.2 Channel priority schemes

The Scheduler holds a Service Grant register with one bit for each channel. Once the Scheduler grants a time slot to channel, the Service Grant bit for that channel is asserted in the Service Grant register. When the Service Grant bit of a channel is set, the channel may request new service but is not serviced again before its Service Grant bit is cleared.

When all channels in a same priority level are serviced, their Service Grant bits are cleared at the end of the thread, one eTPU clock before the next serviced channel is calculated, according to the scheme below¹⁴:

- Clear all grant bits of priority High if all channels of that priority that are requesting have their grant bits in 1.
- Clear all grant bits of priority Medium if all channels of that priority that are requesting have their grant bits in 1.
- Clear all grant bits of priority Low if all channels of that priority that are requesting have their grant bits in 1.
- Clear all grant bits of disabled channels.

14. Grant bits are also cleared in the next clock, when the service channel is chosen, or when the microengine is idle, using the same scheme.

This scheme assures that no channel is left with its grant bit forever asserted (preventing it from being serviced again), even if the channel priorities are reassigned during the execution.

Priority level is determined based on the maximum latency desired for each channel. A channel having a Function that requires the most frequent or more immediate service should be allocated a high priority level.

The eTPU employs a **primary** and a **secondary priority scheme**. These two schemes ensure frequent servicing of high-demand Functions and ensure a minimum time allocation to all channels requesting service, regardless of their priority level. The primary scheme prioritizes requesting channels that have different priority levels; the secondary scheme prioritizes requesting channels that have the same priority level.

Initially, a channel requests service and is granted a time slot by the Scheduler: Service Grant bit is asserted. If only high-level channels constantly receive service first because of their priority level, middle- and low-level channels would only be serviced by default, i.e., if no high-level channels request service. To ensure that each priority level receives an opportunity for servicing, every time slot has a fixed priority level that the Scheduler honors first. Divided into sets of seven, time slots are numbered from one to seven. The figure below illustrates the numbered time slots in sets of seven (fields A and B) and identifies their assigned default priority level. The high level has more time slots than the middle and low levels. Out of every seven time slots available, four are assigned to honor high-level channels first, two are assigned to honor middle-level channels first, and one is assigned to honor low-level channels first. Only one request (in each Engine) is serviced per time slot. When no channel requests service and the microengine is idle the priority scheme is initialized to time slot one, to prevent priority inversion on the next request¹⁵.

15. Priority inversion would occur in the following situation: no channel is requesting service, and the current time slot is primarily assigned to a low-priority channel. If the Scheduler was not reset to time slot one and two channels requested service at the same time, one with high priority and the other with low priority, the channel to be serviced would be the low-priority channel.

Figure 37-299. Time Slot Priority levels

37.15.3.2.1 Primary Scheme - Priority Among Channels on Different Levels

Although time slot priority assignment is fixed, the servicing priority is not. The primary scheme acknowledges the priority level assigned to a time slot, granting service first to a channel having the same priority. In [Channel priority schemes](#), time slot one has a high-level assignment; therefore, a high-level channel requesting service is recognized first. However, if no high-level channel requests service, the Scheduler recognizes a requesting middle-level channel. If this level has no request, the Scheduler continues to the low-level. If no requests occur, the Scheduler truncates the seven state cycle and starts a new cycle at time slot one, waiting for the first request. Granting service to a different-level channel is called priority passing. The order of passing always gives the highest priority to the assigned level, and the second priority to the higher of the remaining requesting priority levels as shown in the following table.

Table 37-336. Priority Passing

Assigned Priority Level	Next Priority Level	Next Priority Level
High	Middle	Low
Middle	High	Low
Low	High	Middle

When priority is passed to another level, that level is serviced and the fixed-priority-level sequence is resumed with the next time slot.

Figure 37-300. Priority Passing Example

Examples of priority passing are shown in the above figure. Each cycle contains seven time slots (or less if no service request exist). In cycle B, no high-level or middle-level service requests are present before time slot three which is assigned by default to high-level priority. Thus, time slot three is passed to the low level. In cycle B there are also no middle-level service requests before time slot six, so it passes the priority to a requesting high-level channel. During time slot six no more high level requests are left, but two new middle-level requests arrive, and there are also three low level pending service requests. Thus, time slot seven of cycle B and time slot one of cycle C are passed to the middle-level which is the next priority level after high. Time slots two and three of cycle C are passed to the low level which contains the three remaining channel service requests. At time slot three of cycle C the last low level request is serviced, and the Scheduler passes to idle state. At this point the cycle C is truncated and the Scheduler passes to time slot one of cycle D.

37.15.3.2.2 Priority passing disabling

The priority passing scheme allows a case where a high priority channel loses to a lower priority one right after another lower priority has been serviced, exemplified in the Cycle D on [Figure 37-300](#). A middle priority channel wins time slot 1 due to priority passing from high to middle. While it is being serviced, two new service requests arrive, one high and one middle priority. The high priority request loses to the middle one on next time slot 2 by default priority assignment.

This priority inversion can be avoided by setting the SPPDIS field in the eTPU_SCR_ECR_ENG n registers (see [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#)), which disables the priority passing mechanism. When priority passing is disabled, at the end of the thread the slot number is incremented until a time slot that matches the priority of one of the requesting channel(s). The time slot advance takes no extra clocks. If no channel requests service, the time slot counter stays at time slot 1. The priority selection scheme with disabled priority passing is summarized in the following table.

Table 37-337. Priority Passing Disabling

At the end of time slot	servicing priority	if any request of priority	service it on time slot	else if any request of priority	service it on time slot	else if any request of priority	service it on time slot
1	High	Medium	2	High	3	Low	4
2	Medium	High	3	Low	4	Medium	6
3	High	Low	4	High	5	Medium	6
4	Low	High	5	Medium	6	Low	4
5	High	Medium	6	High	7	Low	4
6	Medium	High	7	Medium	2	Low	4
7	High	High	1	Medium	2	Low	4

An example of the priority passing disabling scheme is illustrated in the figure below. The sequence of service requests is the same as in the example of [Figure 37-300](#), and although the time slot incrementing differs, the priorities granted are the same for cycle B. Cycle C has one of the low priority channels serviced before the second middle one. Cycle D, however, no longer has the priority inversion.

In cycle B, after the time slot 2 only a low priority request remains, so the time slot count advances directly to 4, which has a low priority assigned. Time slot keeps on 4 for the next service, as only a low priority request remains also, and only time slot 4 is assigned to low. Two high priority services contend for the next time slot 5 (assigned to High). The second high priority channel is serviced on the next time slot, jumped to 7 because there is no middle request, ending cycle B. Cycle C starts with time slot 2, as there are no high priority requests and two middle and two low ones. After the first middle service, time slot count skips 3 assigned to high (no high requests), and services a low priority channel on time slot 4. It follows the same scheme until there are no other requests and cycle C is truncated, resetting the time slot counter to 1.

Cycle D begins with a middle request, jumping to time slot 2. During this service two requests arrive, one high and one middle. Unlike what happened with priority passing, the next serviced is the high priority channel, as the time slot increments to 3. The second middle priority channel request in cycle D is finally serviced next, on time slot 6.

Figure 37-301. Priority Passing Disabling Example

37.15.3.2.3 Secondary Scheme - Priority Among Channels on the Same Level

Because channels can randomly request service, channels having the same priority level will inevitably request service simultaneously. A secondary scheme prioritizes these requests. The Scheduler services channels on each of the three priority levels, beginning with the lowest numbered channel on that level.

37.15.3.2.4 Priority Scheme Example

The overall priority scheme simultaneously incorporates both primary and secondary schemes. Combining both schemes in the following example conveys their correlation.

1. One high-priority and one low priority channels request service, while the Scheduler is in time slot one. Having its service request bit asserted, a single high-level channel is granted the time slot, which has high-level priority (primary scheme) and its service grant bit is asserted. At the end of the thread, the service grant bit is negated (no more requests of high priority level channels).

2. The Scheduler proceeds to time slot two, which has middle-level priority; however, no middle-level channel is requesting service. Priority is passed to the high level, but no high-level channel is requesting service; therefore, priority is passed again, and service is granted to the single requesting low-level channel. Once serviced, this channel's grant bit is negated (no more low-level requests).
3. The Scheduler resumes with the fixed-priority sequence on time slot three; however, no channels are requesting service. The Scheduler returns to time slot one, waiting for requests.
4. Two high-level and two middle-level channels simultaneously request service. Being in time slot one which is assigned high priority, the Scheduler finds the lowest numbered high-level channel (secondary scheme) and selects it for service. This channel's service grant bit is asserted.
5. The Scheduler continues to time slot two, which has middle priority (primary scheme), and allocates the slot to the lowest numbered middle-level channel requesting service (secondary scheme). The Scheduler notes the still unserviced middle-level channel and proceeds to time slot three.
6. Time slot three is allocated for high priority. The slot is allocated to the remaining unserviced high-priority channel, and the channel's service grant bit is asserted. The Scheduler checks again at the end of the thread. All service grant bits of high-level requested channels are asserted; therefore, all high-priority channels that requested have been allocated execution time. Under this condition, all service grant bits of the high-level serviced channels are negated. The Scheduler proceeds to time slot four.
7. Time slot four is allocated for low-priority channel; however, no low-level channel is requesting service. Priority is passed to the high level, but no high-level channel is requesting service; therefore, priority is passed again, and service is granted to the remaining middle-level channel which requests service. This channel's service grant bit is asserted. The Scheduler checks again at the end of the thread. All grant bits of middle-level requested channels are asserted; therefore, all middle-priority channels have been allocated execution time. Under this condition, all service grant bits of the middle-level serviced channels are negated. The Scheduler proceeds to time slot five. Meanwhile a low priority channel requests service.
8. Time slot five is allocated for high-priority channels, but there are no more requests from high-priority or middle priority channels. The single low-level channel which required service is granted time slot five. Once serviced, the channel's service grant bit is asserted. Next, the service grant bit is negated (no more requests of low priority level channels).

9. The Scheduler resumes with the fixed-priority sequence on time slot six; however, no channels are requesting service. The Scheduler returns to time slot one and waits for requests.

37.15.3.3 Time slot latency

Latency is the amount of time between a service request and the beginning of service on that channel. The following factors affect latency:

- Number of active channels
- Number of channels on a priority level
- Number of available time slots on a priority level
- Number of microcycles required to execute a thread of a Function
- Number of SDM accesses during execution of a Function thread
- eTPU clock frequency

Each time slot may require a different number of microcycles, depending on the thread of a Function to be executed. This variation is shown in the figure below.

For more details on latency evaluation, see [Estimating Worst Case Latency](#).

Figure 37-302. Time-slot variation

37.15.4 Parameter sharing and coherency

SDM can be concurrently accessed by Host and Microengines (two in a Dual eTPU Engine system). In general, there is no guaranteed order by which a group of parameters is accessed, which may lead to a lack of internal consistency if two or more related parameters are read when only part of them is updated.

eTPU provides mechanisms to guarantee parameter coherency. The most generic mechanisms for Host-eTPU coherency, suitable for any number of parameters, are:

- the use of Transfer Service Thread mechanism.
- the mailbox (or "software semaphore") mechanism.

These mechanisms, described in [Multiple parameter coherency methods](#), use microcode to transfer parameters from temporary buffers in SDM to their definitive locations (or vice-versa). These methods have the disadvantage of wasting processing and code memory resources.

eTPU also provides a **Coherent Dual-parameter Controller - CDC** - mechanism. It is used by Host to coherently transfer pairs of parameters from/to a parameter buffer located on SDM to/from the locations on SDM where parameters are accessed directly by the channels. Coherency is guaranteed by SDM access arbitration. Although limited to two parameters only, it has lower latency and wastes no microengine resources¹⁶. CDC usage is described in [Coherent Dual-parameter Controller \(CDC\)](#).

For parameters shared by both Engines, eTPU provides **Hardware Semaphores**. Coherency is assured given the semaphores are used to prevent concurrent access to the changing parameters. Microengine can request semaphores using specific microinstructions (see [Semaphore Operations](#)). Hardware Semaphores are described in detail in [Hardware Semaphores](#).

Neither Host nor CDC have access to the hardware semaphores, but they can be combined with microcode transfer mechanisms if Host must coherently access parameters which are also shared by both Engines.

In order to ensure coherent access to a group of parameters by two or more contenders, **each contender must have atomic access** to the shared parameters. Atomicity conditions are discussed in [Host side atomic access](#) and [Microengine Side Atomic Accesses](#).

37.15.4.1 Host side atomic access

Host side atomic accesses can be achieved by either of following ways:

- For one parameter, the SDM should be accessed by 32-bit-wide data transfers to ensure coherency

16. A microengine access to the SDM in the moment CDC is performing the transfer may suffer a maximum of two wait-states.

- For two parameters only, using the Coherent Dual Parameter Controller.
- Indirectly, for any number of parameters, by requesting microcode to coherently access SDM in its behalf. The host side atomicity problem becomes, then, a microengine side atomicity problem. Some methods that use this approach to achieve coherency are described in [Multiple parameter coherency methods](#).

37.15.4.2 Microengine Side Atomic Accesses

37.15.4.2.1 Microengine Single Parameter Atomicity

SDM should be accessed by 32-bit-wide data transfers to ensure atomicity for 32-bit parameters. This applies either to Host-Microengine coherency or Microengine-Microengine coherency in a dual eTPU Engine system.

37.15.4.2.2 Microengine Dual Parameter Atomicity

Microengine has the ability to access two parameters coherently in back-to-back accesses, at random addresses: once it accesses SDM, it has priority over Host for another access in the next microcycle (see [SDM arbitration](#)). Note that it applies **only to Microengine-Host** coherency. For Microengine-Microengine coherency in a dual eTPU Engine system, one must use Hardware Semaphores (see [Hardware Semaphores](#)).

Microengine dual back-to-back accesses are guaranteed to be atomic in relation to Host slave accesses or Coherent Dual-parameter Controller, regardless of semaphore usage: Host or CDC accesses cannot break-up a back-to-back Microengine access, neither Microengine can break a CDC transfer, due to the SDM arbitration mechanism described in [SDM arbitration](#).

Atomicity is not guaranteed if microengine enters halt state in the middle of a back-to-back access (see [Microengine Halt State](#)): Host can access SDM while microengine is halted in the middle of a back-to-back access.

37.15.4.2.3 Microengine Side Multiple Atomicity

Hardware Semaphores must be used for Microengine-Microengine coherency (more than 1 parameter) since two or more accesses from one Microengine are not atomic with respect to the other.

For multiple Microengine-Host coherency, the software methods described in [Multiple parameter coherency methods](#), or similar ones, must be used. Some of these methods rely on the fact that parameter access of a thread is atomic in relation to another thread in the same Engine, since a thread cannot be suspended (preempted).

For 1 parameter coherent access, or dual parameter coherency between only one Microengine and Host, the alternatives shown in previous sections apply.

37.15.4.3 Coherent Dual-parameter Controller (CDC)

Dual-parameter coherency is supported by a Coherent Dual-parameter Controller hardware (CDC), which contends with microengine for SDM access. CDC atomically transfers, upon Host's command, two parameters from one area of the SDM to another. One area is a temporary (buffer) area, where the two parameters are directly read or written by the Host. This temporary area has to begin in an SDM address multiple of 2 words, and the two parameters must be sequential. The other area is the channel parameter area where the microcode normally accesses the parameters, usually with the channel relative address mode (see [SDM Addressing Modes](#)). In this area, the parameters transferred by CDC don't have to be sequential. A transfer from the temporary area to the channel area, when the Host sends data to the channel, is called a **write transfer**. Inversely, in a **read transfer** the parameters are copied from the channel area to the temporary area (channel to Host).

Coherency is guaranteed by the SDM access contention rules implemented in the SDM arbiter (see [SDM arbitration](#)). CDC transfers are coherent in respect to the two Engines, so the target parameters in the channel area may be shared by channels on them both. During CDC operation, the Host may suffer from 3 up to 11 eTPU clocks wait states¹⁷, and the Microengine(s) may suffer up to 2 microcycle wait-states¹⁸. CDC accesses are atomic with respect to Microengine(s) accesses to the SDM. Even when neither engine is in TST, CDC may suffer up to 4 eTPU clock internal wait-states from SDM arbiter, meaning 9 slave wait-states to Host, so that it does not break atomic back-to-back accesses from microengine(s). CDC also cannot break TST preload accesses. Host can initiate CDC back-to-back transfers: there is no need of idle slave cycles between two transfers.

-
- 17. The maximum number of Host wait states on CDC occurs when both microengines overlap their TSTs, delayed 3 eTPU clocks from each other.
 - 18. One microcycle takes two eTPU clocks. Microengines get wait-states in multiples of microcycles, while Host and CDC wait-states are multiples of eTPU clocks.

Note

SDM memory error detection and correction does not affect the number of wait-states to host due to CDC (see [Memory error support](#)).

CDC can be used to atomically fix SDM soft errors. For more details, see [Error fixing](#).

37.15.4.3.1 CDC programming

The Coherent Dual-parameter Controller Register (see [eTPU Coherent Dual-Parameter Controller Register \(eTPU_SCR_CDCR\)](#)) is used to configure and initiate CDC transfers between the temporary area and channel parameter area. Host asserts STS bit in order to start the data transfer. CDC then contends for the SDM and starts the transfer. When the data transfer is complete, STS returns to 0. Host receives wait-states for writing STS=1 while CDC contends for SDM and during the transfer. The write access ends when CDC finishes the transfer. Host receives wait-states during the CDC transfer. If Host writes [eTPU Coherent Dual-Parameter Controller Register \(eTPU_SCR_CDCR\)](#) with STS=0 or does not write the STS byte, the CDC transfer does not occur. CDC programming can be summarized as follows:

1. If it is a write transfer, i.e., from Host to channel, write the two parameters into temporary area.
2. Write **STS** =1 and the remaining CDC programming parameters: parameter width (32 or 24 bits, field PWIDTH), transfer direction (read or write, field WR), temporary parameter area base address (field PBBASE), and the absolute addresses of the parameters to be transferred (concatenation of the fields CTBASE and PARM0/1).
3. If it is a read transfer -- that is, from channel to host -- read the two parameters from the temporary area into Host memory/registers.

37.15.4.4 Hardware Semaphores

eTPU provides Hardware Semaphores accessible by the Microengine only. It is the responsibility of the application to ensure proper use of the semaphores (i.e., agree upon a specific semaphore and use it properly, to ensure coherency).

The eTPU microinstruction set has support for locking and freeing the semaphores, described in [Semaphore Operations](#), and this is the only way to access them.

There are four semaphores available, which reduces the amount of collisions by assigning unrelated data transfers to different semaphores. Semaphores are used for parameters which can be shared by channels in different Engines, and for Engine-to-Engine synchronization. Semaphores are also the only way to ensure coherent access to parameters shared between the two Microengines.

Attempting to lock one semaphore (even not successfully) frees the other locked by the same Engine, ensuring one can lock just one semaphore at a time. That prevents deadlock conditions between the two Engines.

Microcode END command or Engine being in idle state (no thread executing) automatically releases all semaphores from one Engine side, even if a semaphore lock is done in parallel. However, it is recommended to write the microcode in a way which locks semaphores for the shortest required period, and frees them without waiting for the END command, to improve the performance of the other microengine. Semaphores are free after reset. An Engine can only free a semaphore locked by itself.

Semaphore lock requests are always **non-blocking**, in the sense that they do not suspend the requester in case the semaphore is already locked. The semaphore status after the lock request - indicating if it was successfully locked or not - must be tested through the SMLCK microengine branch condition (see [Branch conditions](#)).

37.15.4.5 SDM arbitration

Up to four entities can access SDM:

- Two Microengines (in a dual eTPU Engine system)
- The Coherent Dual-parameter Controller (CDC)
- The Host CPU (direct memory-mapped access)

The following rules specify the access priorities for contended access. They keep compatibility with the TPU3 dual parameter access atomicity, but only between the microengine and CDC (not Host accesses through slave bus).

1. Microengine accesses from the two eTPU Engines are interleaved between each other, but not with Host or CDC accesses;
2. The eTPU microengine(s) gives priority for SDM accesses to either the Host CPU or the CDC under any of the following conditions:
 - a. The microengine has completed accessing the second parameter in a back-to-back SDM access¹⁹.

- b. The SDM was not accessed during the last arbitration slot for the microengine and the host does not lose the access to the other engine in the current arbitration slot²⁰
 - c. CDC is transferring data, after its first (read) access. Note that the CDC can be in middle of a data transfer of another pair of parameters, unrelated to the ones that microengine tries to access.
3. The eTPU microengine takes priority for SDM accesses under either of the following conditions:
- a. the Host CPU or CDC has done a data transfer during the last access arbitration slot for the engine²⁰. Also, the Host CPU does not hold a pending access against the other eTPU microengine.
 - b. the microengine is arbitrating for the access of its second parameter in a back-to-back access¹⁹. All pairs of back-to-back parameter accesses are coherent with respect to Host and CDC (not to the other microengine).

The direction (read or write) of any individual access by Host or microengine is irrelevant to the arbitration. The use of Normal or PSE SDM area by the Host is also irrelevant to the arbitration.

The first parameter preloading in a TST is considered first access by the arbiter, regardless of any access made at the END microinstruction of the previous thread, that is, the last access of a thread and the first preload are never considered a back-to-back access. On the other hand, the TST preload accesses are considered back-to-back and are, therefore, atomic with respect to Host or CDC.

Note

The Zero SDM operation (see [Zero SDM Operation](#)) is considered an SDM access for arbitration purposes both on writes and reads; the fact that read SDM data is discarded is irrelevant for arbitration.

19. If microengine tries to access the SDM in the following microcycles, the third and fourth consecutive accesses are considered the first and second of a new back-to-back dual access.

20. The microengine access slot is between its own T4 and T2 edges (see [Microcycle and I/O timing](#)).

37.15.5 Enhanced Channels

Enhanced Channels comprise hardware support for input digital signal processing and output signal generation. Each Channel is associated with one input and one output signal. Enhanced Channel logic is combined with Function microcode (and optionally Angle Mode logic) to implement Channel I/O functionality.

eTPU's Enhanced Channels are capable of **dual action**, meaning that each channel logic can handle two events at different times and/or cause two separated actions - these actions and events can be mutually dependent (with the first either blocking or enabling the other), or both independent, depending on the programmed **Channel Mode**.

Each Enhanced Channel contains event logic containing two **Event Register sets**, each set supporting one input and/or output action, the pair implementing dual action support. Each Event Register set contains two 24 bit registers: Match and Capture. The **Match register** holds the pending match value which is compared against one of the two time bases by an equal-only/greater-equal comparator. The **Capture register** captures one of the two time bases as a result of a Match or Transition detection. Service Requests are issued on particular combination of match and capture events, defined by the selected Channel Mode.

In the context of the eTPU channels, a **Match** is a comparison between a time base value and a channel Match register. If those two values are coincident, or the time base value is greater than the value of the Match register, a **Match Event occurs**. Depending on the channel mode of operation and current state of the channel logic, the match event may be recognized, i.e., change the state of the channel, or be ignored. A match event recognized by the channel logic is called a **Match Recognition**. Match Recognitions can cause, also depending on Channel Mode and current state, the channel to request service, configuring a **Match Service Request**.

eTPU uses two kinds of comparator to assert a Match Event: an **Equal comparator**, in which both the Match Register and the value of the selected time base must match exactly, and a **Greater-Equal comparator**. The Greater-Equal comparator considers any time base value between the range $[N : N+0x800000-1]$ as a valid match against the value of N in the Match Register, even when the value $N+0x800000-1$ wraps around the point of origin (0x0). See the following figure for an illustration of the matching values on a Greater-Equal comparator.

The second source of events for the eTPU channel is a **Transition** detected at the corresponding channel's input signal. Two distinct Transition detections can be programmed individually for each channel, allowing recognition of all possible combinations of edge detection. It is also possible to check the sampled state of an input

signal upon the occurrence of a Match: the sampling of the expected value is treated as a Transition, even if the input signal did not necessarily toggled at the time of the Match, or at any time at all.

Like Match Events, **Transitions Events** may or not be recognized by the channel logic. When they are, a **Transition Detection** occurs. As well as Match Recognitions, Transition Detections can issue a Channel Service Request, depending on Channel Mode and current state.

Transition Detections and Match Recognitions are sometimes simply called Transitions and Matches throughout this document, for short.

Input and output signals can be processed separately by the channel logic and microcode, and can also be combined such that Matches and Transitions are used to cause **output signal actions**. The output signals can also be directly controlled by microcode. Many event combinations are allowed for a channel, given the possibility of configuring pairs of matches and transitions for the dual action logic, where each event is able to block or enable the next one. There is a full set of Channel Modes described in [Channel Modes](#), exploring all the capabilities mentioned here.

Each channel has its own set of registers and flags. They are selected, and made accessible to the Microengine, according to the value written into the microengine **CHAN Register** that points to the desired channel . Every time the CHAN register is written, even if with the same previous value, a channel is selected and its flags and registers are updated. For further detail, see the Channel Selection Register-CHAN topic in the General Channel Registers section .

Figure 37-303. Greater-Equal Comparator

Beyond the request of services due to the signal and timing internal to each channel, one eTPU channel microcode can explicitly request service from another channel through the microengine **LINK Register**. A microcode write to the LINK Register asserts a service request to the channel whose number matches the contents of LINK. See [Channel Link](#) for a complete description of this mechanism.

These service requests originated in the eTPU Enhanced Channels (either time base match, input signal transition, or link service request) result in a call to the corresponding channel service routine, which is the sequence of microinstructions that is called a **Thread**. For further detail, see [Functions and threads](#).

In addition to Event Logic, each Channel has an Output Buffer Enable signal, controlled by microcode, and an Enhanced Digital Filter, which eliminates spurious glitches on input pin signal. See the chip-specific eTPU information for how the Output Buffer Enable signal is controlled.

A high level diagram of Channel logic and registers is shown in the following figure.

Figure 37-304. Channel logic block diagram

37.15.5.1 Channel registers and flags

Channel configuration and control registers can be divided in the following groups:

- **Host Configuration and Control registers**, which define channel Function and parameter allocation in SDM, input signal filtering, manage Host interrupts, and are used for Host Service Requests; they can only be accessed by Host, except for the Function Mode bits which can be also tested by microcode.
- **Event Registers**, which can only be accessed by eTPU Microengine, through dedicated Channel Control microinstruction operations (see [Channel Control and Configuration Microoperations](#)); these registers are directly used to implement channel functionality, and include channel event status latches which can be directly tested by Microengine branch instructions.
- **Pin Control registers**, which basically define pin state and transition polarity (but not input signal filtering); they are accessible only by dedicated Channel Control microinstruction operations.
- **Link registers**, which implement the channel link mechanism that allows one channel to request service to another one; they are accessible only by microinstruction operations.
- **General Channel registers**: CHAN, SRI, Flag0/1, PDCM, UDCM.

Most of those registers are channel exclusive, i.e., there is one copy of them for each channel. Microcode can access registers from only one channel at a time. The Channel Selection (CHAN) register (see [Channel Selection Register - CHAN](#)), accessible only by microcode, defines the channel whose registers are being accessed, with exception of link register and function mode. CHAN register assumes the value of the channel to be serviced at the beginning of TST.

The Service Request Inhibit - SRI - register controls the generation of Service Requests on matches and transitions, also affecting channel logic behavior. For a full description see [SRI - Match/Transition Service Request Inhibit Latch](#). Flag0/1 are used to select channel service threads based on channel software state. See [Flag1,Flag0 - Channel "state resolution" flags](#) for more details.

Host Configuration and Control registers are described in [Channel Configuration Control memory map and registers](#).

Time Base configuration is common to all channels, and described in [Time bases](#). Time Base selection for matches and captures, however, is individual to each channel, and is part of the Event Registers.

Link registers are described in [Channel Link](#).

The following sections describe the Event Registers and Pin Control registers.

37.15.5.1.1 ER - Event Registers

Each channel contains two identical Event Register sets, named ERA and ERB, corresponding to the two actions supported. Each Event Register set contains:

- a 24-bit Match register (Match A or Match B), which holds a match value. This value is compared against the selected match time base (TCR1 or TCR2).
- a 24-bit Capture register (CaptureA or CaptureB), which samples the selected capture time base (TCR1 or TCR2)
- a Time Base Selection register (TBSA or TBSB)
- a Match Recognition status flag (or latch) (MRLA or MRLB)
- a Match Recognition Enable latch (MRLEA or MRLEB)
- a Transition Detection flag (or latch) (TDLA or TDLB)
- a Transition Continuous Capture enable (TCCEA only)

ERA and ERB are associated with the first and second events in double action modes, not necessarily in that order. The order of Match events associated with ERA and ERB depends on the programmed channel mode, the MatchA and MatchB values, and the timebases selected by TBSA and TBSB. Similarly, the order of Transition events associated with ERA and ERB depends on the programmed channel mode, and the transition detection selected by IPACA and IPACB.

These registers are directly or indirectly accessed by the microcode. TBSA and TBSB registers are defined in [TBSA and TBSB - Time Base Selection Registers](#). The other registers are explained in [Match Recognition](#) and [Transition detection and Time Base Capture](#).

Access to the Event Registers is qualified by the channel currently selected by the microengine (i.e., the channel value currently in the CHAN register). During the channel transition period (automatic CHAN assignment), or whenever CHAN is written by microcode, Capture values of the new selected channel are sampled into Microengine registers ERTA and ERTB, therefore becoming visible to the microcode. At the same time, updated values of MRLA, MRLB, TDLA and TDLB are sampled into the branch logic, making the register values and the flags coherent with respect to each other and with the thread selected by the Scheduler. ²¹

21. The thread selected is determined by the Entry Point which, in turn, is determined partially by the channel latches. See [Entry Point address generation](#).

Note

The Function Mode bits are also sampled from the Host interface on Time Slot Transition, so that they remain constant to microengine even when Host changes them.

During service, the microcode can access updated values of the Event Registers of any channel by writing the channel number to CHAN. Writing CHAN with the same value (CHAN := CHAN) updates ERTA and ERTB with the new captured values, the branch logic with updated MRLA/B and TDLA/B flags. Writing CHAN with a different value does the same with the values from the newly selected channel.

Match values are also accessed through ERTA and ERTB Microengine registers, which are copied to/from the channel MatchA and MatchB registers by specific microinstruction operations.

Microcode writes to the flags and selections (MRLA/B, TDLA/B and TBSA/B) are immediately effective to the channel. The MRLA/B and TDLA/B branch conditions are also immediately reset when their correspondent flags are reset by microcode. Match registers are indirectly written by microcode through ERTA/B. MRLEA/B is unconditionally asserted when respective Match register is updated from ERTA/B, and its negation is immediate.

The following table summarizes Event Registers accesses.

Table 37-338. Event Registers microcode accesses

Register	Access type	Sampled from channel	Update to channel	Microcode fields ¹	Reset value ²
CaptureA, CaptureB	read through ERTA/B	to ERTA/B on CHAN assignment	no	T2ABD	n.a.
MatchA, MatchB	read and write through ERTA/B	to ERTA/B by microcode	from ERTA/B by microcode	ERWA, CMW, ERWB, T4ABS	n.a.
MRLEA, MRLEB	write to 0 (negate) directly; write to 1 (assert) upon MatchA/B update from ERTA/B	no	immediate	MRLE, ERWA, ERWB	0, 0
TBSA, TBSB	write only	no	immediate	TBSA, TBSB	000, 000
MRLA, MRLB	flag test on branch, write to 0 (negate) only	on CHAN assignment	immediate	BCC (test) MRLA, MRLB (reset)	0, 0
TDLA, TDLB	flag test on branch, write to 0 (negate) only	on CHAN assignment	immediate	BCC (test) TDL (reset)	0, 0
TCCEA	write only	no	immediate	MTD	0

1. See [Microinstruction Set](#).
2. n.a. means that value of the register is undetermined after reset.

37.15.5.1.1.1 MatchA and MatchB Registers

MatchA and MatchB registers hold a match value to be compared against the selected channel time base. A match value can only be written into the Match register by microcode, through ERTA/B microengine registers (see [Write Channel Match and UDCM Registers](#)). Microcode can also read the Match register as a special T4ABS source operation, when T4ABS=0101, and the source for T4ABS is selected from the second register set. In this operation, MatchA/B registers are copied into ERTA/B registers (see [Selecting sources and destination](#)). For more information on time base matches, see [Match Recognition](#).

37.15.5.1.1.2 CaptureA and CaptureB Registers

CaptureA and CaptureB registers capture the selected channel time base. CaptureA/B registers cannot be directly written or read by microcode. During the Time Slot Transition (TST) or during CHAN assignment, CaptureA/B registers are copied into ERTA/B microengine registers. For more information, see [Transition detection and Time Base Capture](#).

37.15.5.1.1.3 TBSA and TBSB - Time Base Selection Registers

TBSA/B are 3-bit registers which have the following effect on channel configuration:

- Selection of the timebase (TCR1 or TCR2) to be compared against the match values in MatchA and/or MatchB registers.
- Selection of the timebase (TCR1 or TCR2) to be captured in the CaptureA and/or CaptureB registers by a match or transition detection event.
- Selection of comparator mode to be used with MatchA and MatchB registers: equal-only or greater-equal.

After reset TBSA/B are 000. The following table shows values of TBSA and TBSB for configuration selection. Note that the time base selection for capture is independent of the time base selected for matches.

Table 37-339. TBSA/B Programming States

TBS bit	2	1	0
bit value	Comparator selection	Capture time base selection	Match time base selection
0	greater or equal	TCR1	TCR1
1	equal-only	TCR2	TCR2

TBSA/B are written through the microcode fields TBSA/B (see [Comparator and Time Base Selection](#)).

37.15.5.1.1.4 MRLA/B - Match Recognition Latches

See [MRLA/B - Match Recognition Latches](#).

37.15.5.1.1.5 MRLEA/B - Match Recognition Latch Enable

See [MRLEA/B - Match Recognition Latch Enable](#).

37.15.5.1.1.6 TDLA/B - Transition Detection Latch

See [TDLA/B - Transition Detect Latches](#).

37.15.5.1.1.7 TCCEA - Transition Continuous Capture Enable

See [TCCEA - Transition Continuous Capture Enable](#).

37.15.5.1.2 Pin Control Registers

Pin Control Registers are replicated one per channel, accessed only by microcode and qualified by the CHAN register in the same way as Event Registers.

The following table lists Pin Control Registers, explained in following subsections, and their accesses.

Table 37-340. Pin Control Registers microcode accesses

Register	Access type	Sampled from channel	Update to channel	Microcode fields ¹	Reset value
IPACA, IPACB	write only	no	immediate	IPACA, IPACB	000,000
OPACA, OPACB	write only	no	immediate	OPACA, OPACB	000,000
PSTI	flag test on branch	no	no	BCC	0

Table continues on the next page...

Table 37-340. Pin Control Registers microcode accesses (continued)

Register	Access type	Sampled from channel	Update to channel	Microcode fields ¹	Reset value
PSTO	flag test on branch, write	no	immediate	BCC (test) PSC, PSCS (set)	0
OBE ²	write only	no	immediate	TBSA values 1000,1001	0 (negated)
PSS	flag test on branch	on CHAN assignment	no	BCC	n.a. ³
PRSS	flag test on branch	on CHAN assignment	no	BCC	n.a. ⁴

1. See [Microinstruction Set](#).

2. Although this register exists for code compatibility reasons, OBE functionality is not available on this chip.

3. PSS is PSTI or PSTO sampled on CHAN assignments and at thread start.

4. PRSS is PSTI sampled on channel service request.

37.15.5.1.2.1 IPACA/B and OPACA/B - Input and Output Pin Action Control Registers

These registers determine the transition detections and output pin actions which takes place due to match or transition events. Each field is three bit wide. After reset, the IPACA/B and OPACA/B registers are set to 000. IPACA and IPACB registers are mutually independent and have identical encoding, and so do OPACA and OPACB. The table below shows IPAC and OPAC encoding. Note that transition detections are independent from the output actions, but some options of output actions are triggered by transition detections. Output actions can also be triggered by Matches. For a detailed definition of Transition Detections, see [Transition detection and Time Base Capture](#).

IPACA/B define the Transition events treated by channel logic. Although the name "transition" is generically used for the transition detections, IPAC options 100 and 101 do not really detect transitions: they actually sample the state of the input signal at the occurrence of the corresponding Match (Match A used for IPACA, Match B used for IPACB).

Table 37-341. IPACA/B and OPACA/B Encoding

Value	IPAC meaning	OPAC meaning
000	Do not detect transitions	Do not change output signal
001	Detect rising edge only	Match ¹ sets output signal high
010	Detect falling edge only	Match ¹ sets output signal low
011	Detect either edge	Match ¹ toggles output signal
100	Detect input signal = 0 on Match ¹	Transition sets output signal low
101	Detect input signal = 1 on Match ¹	Transition detection sets output signal high

Table continues on the next page...

Table 37-341. IPACA/B and OPACA/B Encoding (continued)

Value	IPAC meaning	OPAC meaning
110	reserved	Transition detection toggles output signal
111	n.a. ²	n.a. ²

1. Match A is used for IPACA/OPACA, and Match B for IPACB/OPACB.
2. On the microinstruction fields IPACA/B and OPACA/B this value is neutral, meaning that IPAC/OPAC register values are not changed.

37.15.5.1.2.2 Output Pin Control Logic and Pin State Output Register - PSTO

The output signal control logic uses OPACA/B, the Pre-defined Channel Mode (PDCM) and the User Defined Channel Mode (UDCM), and the microcode Pin State Control (PSC and PSCS) fields. It is responsible for setting the Pin State Output (PSTO) register to the specified logic value required by microcode, by input events, or by Match A and/or Match B events. The PSTO register stores the driven pin state determined by the Pin Control logic. The Output Buffer Enable signal, if used at MCU integration, must be set by microcode (using TBSA field) to make the pad propagate the PSTO register output to the actual pin.

PSTO register output also goes to the microengine branch logic, enabling branching on the driven pin state. PSTO is set to 0 on reset.

The PSC and PSCS microcode fields are used for setting the PSTO register to a fixed value, or to the value specified by the OPACA or OPACB microcode field, as shown in the following table.

Table 37-342. PSC and PSCS encoding

PSC	Output pin action
00	Force pin state according to OPACA (PSCS=0) or OPACB (PSCS=1).
01	Force pin high.
10	Force pin low.
11	Do not change pin state.

See [Channel Control and Configuration Microoperations](#) for details.

On occurrence of match recognitions or transition detections, the pin control logic sets PSTO value according to the event number (Match A/Transition A or Match B/Transition B) and the contents of OPACA/IPACA or OPACB/IPACB registers. There are cases in which two match or transition events may occur at the same time, each of them trying to force a different pin action. The resolution of the selected match event which sets the

value depends on the Pre-defined Channel Mode (PDCM) register and the User Defined Channel Mode (UDCM). For details refer to [Match/Transition Pin Action Conflict Resolution](#).

37.15.5.1.2.3 PSTI and PSS - Pin State Input and Pin Sampled State Registers

During the time slot transition period, or whenever the CHAN register is written by microcode, the filtered²² input signal PSTI or output signal PSTO (selected by the ETPD field in [eTPU Channel n Configuration Register for Engine 1](#) (eTPU_CCCR_CnCR_ENG1) and [eTPU Channel n Configuration Register for Engine 2](#) (eTPU_CCCR_CnCR_ENG2)) is sampled into the branch logic as the PSS flag (see [Table 37-411](#)). The microcode can then branch on either the currently driven (PSTO) or input (PSTI) pin state, or on sampled pin state (PSS, which is stable as long as CHAN does not change).

Note

If a transition occurs simultaneously (after the filter) with the CHAN assignment, PSS samples the new pin value. Therefore, if TDLA/B is cleared simultaneously with the assignment CHAN := CHAN, the occurrence of a transition at this very moment can still be tested with PSS.

37.15.5.1.2.4 PRSS - Pin Request Service Sample

Channel logic can, depending on its state and programmed mode, request service to the eTPU microengine (see [Functions and threads](#)). When the channel logic issues a service request, the filtered input signal PSTI is sampled into an internal channel flag PRSS. There is one such PRSS flag for each channel (see [Pin Control Registers](#)). Channel PRSS keeps its value until all its service request sources are cleared and until a new channel service request rises.

NOTE

Only channel service requests update PRSS. It is not updated by host service requests (HSRs) or by link service requests. Moreover, a channel service request updates PRSS even if the channel is disabled (its CPR set to 0, see [eTPU Channel n Configuration Register for Engine 1](#) (eTPU_CCCR_CnCR_ENG1) and [eTPU Channel n Configuration Register for Engine 2](#) (eTPU_CCCR_CnCR_ENG2)).

22. The filter can be bypassed.

Functional description

The channel PRSS flag is sampled into the branch logic as the PRSS flag (see [Table 37-411](#)) during the time slot transition period, or whenever the CHAN register is written by microcode.

37.15.5.1.2.5 OBE - Output Buffer Enable control latch

NOTE

Output Buffer Enable is not available on this chip.

OBE latch drives the Output Buffer Enable signal, which can be used to control the output signal pad driver. Channel output comes disabled from reset. If an Output Buffer Enable signal²³ from eTPU is used on MCU integration and a signal is desired to be output in a channel, OBE signal must be set by microcode. Microcode field TBSA is used to set/reset the Output Buffer Enable control when microcode field TBSA bit 3 is 1, according to the following table.

Table 37-343. TBSA Output Buffer control

microcode TBSA[2:0]	meaning when TBSA[3]=1
000	enable output buffer
001	disable output buffer
111	do nothing
other values	reserved

23. There is one independent OBE signal for each channel.

Figure 37-305. Pin State Input/Output Logic

37.15.5.1.3 General Channel registers

These registers control other aspects of channel logic. Except for CHAN, they are unique per channel. The following table summarizes the registers and access options.

Table 37-344. General Channel registers microcode access

Register	Access type	Sampled from channel	Update to channel	Microcode fields ¹	Reset value
CHAN	read/write	n.a. ²	n.a. ²	T4ABS, T4BBS, T2ABD	defaults to serviced channel at thread start

Table continues on the next page...

Table 37-344. General Channel registers microcode access (continued)

Register	Access type	Sampled from channel	Update to channel	Microcode fields ¹	Reset value
PDCM	write only	no	immediate	PDCM	1100 (sm_st)
UDCM	write only	no	from ERTA by microcode	CMW, ERWA	parameter value defined at integration
SRI	write only	no	immediate	MTD	1
Flag1, Flag0	branch flag test, write	no	immediate	BCC, FLC	0, 0

1. See [Microinstruction Set](#).
2. CHAN is common to all channels in the Engine.

37.15.5.1.3.1 Channel Selection Register - CHAN

CHAN is the register that holds the number of the channel that qualifies the context of most Channel Registers, including Pin Control and ER accesses, and is common to all channels in a same Engine.

When a thread starts to be executed, the contents of CHAN register is automatically updated on Time Slot transition to the number of the channel to be serviced. Serviced channel is constant during channel servicing, but the selected channel can be changed any time by microengine writing into CHAN register.

Some microinstructions are affected by the serviced channel instead of CHAN. These are:

- Conditional branch using LSR (see [LINK Register](#)) or Function Mode (see [eTPU Channel n Status Control Register for Engine 1 \(eTPU_CCCR_CnSCR_ENG1\)](#) and [eTPU Channel n Status Control Register for Engine 2 \(eTPU_CCCR_CnSCR_ENG2\)](#)).
- Negate channel flag LSR, Interrupt CPU and Data Transfer Request (see [Channel Interrupt and Data Transfer Requests](#)).

When CHAN register is written, accesses are qualified by the new CHAN register value from the instruction following CHAN assignment on, except CaptureA/B sampling into ERTA/B and Match register writing from ERTA/B (see [CHAN assignment, Read Match and ERWA/B](#)).

Writing CHAN (including with the same value, CHAN:= CHAN) updates ERTA and ERTB with the new captured values, the branch logic with updated MRLA/B and TDLA/B flags.

The following table shows the commands, flags and registers selected by the CHAN register value.

Table 37-345. CHAN-selected features

Feature used	Selected by CHAN
Channel-relative SDM access	YES
Branch using PSS, PRSS, PSTI and PSTO channel flags	YES
Branch using MRLA/B, TDLA/B, Flag0/1 ¹	YES
Branch on all other conditions ²	no
ERTA/B Value	YES
Configure (selected) channel	YES
Channel commands applied to: MRLA/B, TDLA/B, TBASA/B, IPACA/B, OPACA/B, PSC, PSCS, OBE, PDCM, MRLE, Flag0/1	YES
Channel command: set/reset SRI	YES
Channel command: write to Match registers (ERWA/B)	YES ³
Channel command: read Match registers into ERTA/B	YES
Clear LSR	no
Channel interrupts and data transfer requests (CIRC)	optionally

1. In TPU, these conditions retained the old values.

2. See [Branch Operations](#)

3. If write Match (ERWA/B) occurs at the same time of a CHAN assignment, the channel which is target of the write is the one selected by the new CHAN value. See [CHAN assignment](#), [Read Match](#) and [ERWA/B](#).

37.15.5.1.3.2 PDCM - Predefined Channel Mode

PDCM determines the channel mode assigned to the channel. Channel mode defines much of the channel logic behavior, specially how matches blocks and enables transitions and vice-versa, as well as occurrence of time base captures and service requests based on matches and transitions. For a complete description see [Channel Modes](#).

PDCM is a 4-bit register set by the microcode field of the same name (see [Predefined Channel Modes](#)), and cannot be read or tested in branch instructions. The table below relates the PDCM value with channel modes. The second column specifies the mnemonic used to reference the mode, introduced in [Channel Modes Overview](#). There is one PDCM for each channel, initialized with 1100 on reset.

PDCM is also used to select the User Programmable Channel Mode. If this selection is made, the channel behavior is defined by the settings of the UDCM register (see [UDCM - User Defined Channel Mode](#)).

Table 37-346. PDCM encoding

PDCM	Channel mode
0000	em_b_st

Table continues on the next page...

Table 37-346. PDCM encoding (continued)

PDCM	Channel mode
0001	em_b_dt
0010	em_nb_st
0011	em_nb_dt
0100	m2_st
0101	m2_dt
0110	bm_st
0111	bm_dt
1000	m2_o_st
1001	m2_o_dt
1010	User Defined Channel Mode
1011	reserved
1100	sm_st ¹
1101	sm_dt
1110	sm_st_e
1111	n.a. ²

1. This is the reset value, also compatible with TPU channel behavior.

2. This value is used as a neutral (do not change) value in the PDCM microinstruction field.

37.15.5.1.3.3 UDCM - User Defined Channel Mode

UDCM holds the control signals that define the channel logic behavior in terms of Match and Transition blocking and enabling, captures and service requests triggered by events. The register layout is defined in the figure below. The individual fields are defined in [Channel Mode Logic and Event Flags](#). There is one UDCM register for each channel, which can be independently programmed.

UDCM can only be written into the Match register by microcode, through ERTA/B microengine registers (see [Write Channel Match and UDCM Registers](#)).

13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSR	MCAP	M1ET	M1EM2	M1BM2	M2BM1	M2BT	T1BM1	T2BM1	TBM2	T1ET2	TSR	TCAP	

Figure 37-306. UDCM Register

37.15.5.1.3.4 SRI - Match/Transition Service Request Inhibit Latch

SRI blocks channel service requests due to the assertion of MRLA/B and/or TDLA/B. SRI does not affect recognition of Link Service Requests or Host Service Requests, neither MRLA/B or TDLA/B microcode branch tests nor Entry Table selection²⁴. SRI is asserted during reset and is controlled by microcode field MTD.

24. In TPU, SRI also blocked TDL and MDL branches and enabled any transition to capture time base.

To unburden the microengine, SRI asserted configures a channel "dumb" regarding the servicing of match and capture channel service requests. Even with SRI=1, TDLA/B and MRLA/B can still be asserted, and the level specified by the OPAC (Output Pin Action Control) registers will be output to the pin.

37.15.5.1.3.5 Flag1,Flag0 - Channel "state resolution" flags

Each channel has a pair of flags, simply called Flag0 and Flag1, that can be set/reset by microcode through microinstruction field FLC. FLC sets/resets Flag0/1 of the channel selected by CHAN. These flags can be tested by microcode, and are also used to resolve the microcode entry point for the channel service (see [Entry Points](#)). Flag0 and Flag1 are, so, typically used for fast state resolution. FLC microinstruction field also allows Flag1,Flag0 to be copied from selected bits of P register high byte, which is also meant to be used to hold application state. Flag0 and Flag1 are both zero out of reset.

37.15.5.2 Match Recognition

The match operation is performed every microcycle by comparing the channel MatchA and MatchB registers against the value of the TCR bus specified for each match. TCR1 or TCR2 bus is selected according to TBSA and TBSB fields. Both results have effect on the next clock cycle (see [Microcycle and I/O timing](#)).

A Match A/B event is qualified by a set of match enabling conditions to the Match Recognition Registers MRLA/B. To recognize the match, the following match enabling conditions are required:

- For IPACA/B=0xx, Match Enable Flag (MEF), qualified by the channel currently being serviced must be asserted. For IPACA/B =1xx, Match A/B is always enabled (even during Time Slot Transition - TST), regardless the state of the Match Enable Flag (MEF). See [MEF - Match Enable Flag](#) for the conditions of MEF assertion.
- Match Recognition Latch Enable 1/2 (MRLEA/B) is asserted. A match event recognition may only occur if its corresponding MRLEA/B bit is set, which only happens upon a write to a channel match register by the microcode, copied from ERTA/B. MRLEA/B is negated when the respective match occurs or, in some double match channel modes, when a match for the other Match register occurs. It ensures that the greater-equal comparison will not cause additional matches²⁵.
- In selected modes (see [Channel Modes](#)), the particular conditions of MRL and TDL flags of the other event, i.e:

25. Microcode can also negate MRLEA/B.

- MRLA, TDLA enable or block MRLB;
- MRLB, TDLB enable or block MRLA.
- The respective MRL is negated.
- In selected modes (see [Channel Modes](#)), the state of its respective TDL flag.

If the Match A and/or Match B conditions are met, the channel immediately forces the pin state if specified by the appropriate OPACA/B registers (Output Pin Action Control 1/2) and, in some cases, by IPACA/B registers. Refer to [IPACA/B and OPACA/B - Input and Output Pin Action Control Registers](#).

If both Match A and Match B events occur at the same time, with conflicting pin actions, the priority over the pin action is mode dependent. For further details on pin action resolution refer to [Match/Transition Pin Action Conflict Resolution](#).

37.15.5.2.1 MRLA/B - Match Recognition Latches

MRLA/B indicate the recognition of a match event detected by the comparator. They can be asserted either on T2 or T4 (see [Microcycle and I/O timing](#)). Assertion of MRLA/B issues a match Service Request in specific channel modes, depending on previous events and state of SRI. After reset MRLA and MRLB are both negated.

When MRLA or MRLB is asserted, it may change the output signal level according to the Input and Output Pin Action Control registers (refer to [IPACA/B and OPACA/B - Input and Output Pin Action Control Registers](#)). Assertion of MRLA/B causes a capture of one or two time bases, according to the selected mode capturing scheme (see [Transition detection and Time Base Capture](#))

A match recognition is self-blocking, regardless of Channel Mode: once MRLA (MRLB) has been asserted, it negates its associated MRLEA (MRLEB) register, preventing future match recognitions, until the associated match register is rewritten by microcode. The microcode has to enable new matches by updating the new match value in the MatchA (MatchB) register²⁶. In addition, assertion of MRLA/B can block its twin MRLB/A, depending on the channel mode. In some double match blocking channel modes, Match A/B event blocks the occurrence of Match B/A in a "first win" scheme.

It is the transition from 0 to 1 in MRL that causes the Match actions, except the service request: apart from MRLEA/B negation(s) and service request, no action due to a Match occurs if MRL was already set to 1, even if the other MRL assert conditions are satisfied. However, if a Match and a microoperation negating its corresponding MRL occur at the

26. Before that, microcode should also negate MRLA (MRLB), otherwise an old match may be recognized by the scheduler and serviced as a new one

same time, MRL negation by microcode overrides its assertion, but any dependable captures and pin action occurs anyway (if MRL was already negated before), and also the negation of MRLE(s) (the respective one and, in some channel modes, the other, regardless of MRL state before). Note that MRLE must have been set before (by writing a new Match value).

37.15.5.2.2 MEF - Match Enable Flag

MEF is a one-bit latch that is unique for all channels in an Engine.

MEF can selectively enable assertion of MRLA/B, depending on the IPACA/B field. For IPACA/B=0xx, MEF=1 enables assertion of MRLA/B for the scheduled channel during service. For IPACA/B=1xx, Match A/B is always enabled, regardless the state of the MEF, but it still depends on the other Match recognition conditions. Matches of channels not being serviced are never disabled by MEF.

MEF is not accessible by Microengine or Host. MEF is negated for two microcycles in the beginning of the time slot transition period. After two microcycles (plus wait-states) into TST, the ME bit in the entry point is copied to MEF to allow selective enabling of MRL for each thread (refer to [Time Slot Transition](#)). MEF is asserted unconditionally soon after a thread ends.

If a channel service needs to postpone a programmed match, MEF assures that microcode wins the race against match event after time slot transition (only for IPAC=0xx).

Note that a match event may be lost during the periods when MEF is negated only if:

- the match comparator is configured for "equal-only" behavior, and
- IPACA/B=0xx, and
- TCR increments at the rate of eTPU clock divided by 2 or faster.

When the comparator is configured as "greater-equal", the match event that occurred when MEF was negated may be recognized after MEF is asserted again, due to the "greater than" condition.

37.15.5.2.3 MRLEA/B - Match Recognition Latch Enable

MRLEA/B is negated upon the assertion of its respective MRLA/B. In blocking match channel modes it may also be negated together with the assertion of the twin MRLB/A. The MRLEA/B bits ensure that data captured due to the first match event will not be overwritten when MRLA/B is negated: due to greater-equal comparison, the match condition continues to be true, but should not cause another capture event.

In addition to negation by local match event, the microcode can negate both MRLEA and MRLEB, to block pending matches, and also MRLA/B, individually. This action will prevent future match events from the selected channel.

Writing the MatchA/B registers by microcode to schedule the next match values sets MRLEA and/or MRLEB and enables new matches. This setting overrides the MRLE negation conditions due to channel logic or microcode (see [Channel Modes](#)). By combining write to Match A/B with MRLEA/B negation microinstructions, the microcode can negate one MRLE while asserting the other.

Note

If the MRLE negation conditions continue after writing MatchA/B registers, the respective MRLE does not keep asserted. For instance, if MRL=1 and a match is programmed for a time value in the past during a thread with ME=1, then MRLE will be cleared soon after MatchA/B is written, even though a match does not occur (because MRL was already asserted, neither captures nor pin toggles occur).

When the match register is updated (with MRLE already asserted before) and field MRLA/B = 1 (no clear, see [Clear Transition/Match Event Registers](#)) and MRLA/B flag is zero, the eTPU behaves exactly as the TPU, that is: a match that comes concurrently with the rewrite of the match register, matching the old value, sets the MRL, as if the setting of the MRLE due to match register write had precedence over its clear by the match at that moment. After this simultaneous operation, the MRLE value stays at 1, and the captured time base value, if any, reflects the match value.

When the match register is updated (with MRLE already asserted before) and field MRLA/B = 0 (clear MRL, see [Clear Transition/Match Event Registers](#)) and MRLA/B flag is zero, the match captures will occur, the MRLA/B flag will keep negated, and MRLE will stay asserted. Special care must be taken when a match is reprogrammed on a channel running at T2/T4 timing, please see the details in the “T2/T4 Channel Timing” section.

37.15.5.3 Transition detection and Time Base Capture

Time Base Capture(s) occur when the value of a specified TCR is sampled into the CaptureA and/or CaptureB register. TBSA[1] and TBSB[1] select which TCR will be captured in CaptureA and CaptureB, respectively.

A capture event may occur due to either of the following events:

- The assertion condition of Match Recognition Latch (MRL), even if MRL is simultaneously negated by microcode
- The assertion condition of Transition Detection Latch (TDL), even if TDL is simultaneously negated by microcode.
- Any Transition Event specified by IPACA if both the Transition Detection Latch TDLA and Transition Continuous Capture Enable TCCEA are asserted.

A capture event occurs together with the assertion of MRL or TDL either on T2 or T4 positive edges, and captures the time-base value that caused the match, even if TCR1/2 increments concurrently with the assertion (see [Microcycle and I/O timing](#))²⁷. MRLA/B and TDLA may, depending on the channel mode, inhibit the capture of the second event's TCR into CaptureA/B. As a general rule, values captured by signal transitions are not overwritten by values captured by match events.

When the enable bit TCCEA is asserted, captures due to Transition Events also occur after TDLA is asserted. Those captures happen on transition events specified by IPACA, and the TCR value is saved into CaptureA register only.

The capturing scheme is defined by the Channel Mode programmed at register PDCM, or at register UDCM when User Defined Channel Mode is selected. For more information on mode-dependent capture schemes refer to [Channel Modes](#).

37.15.5.3.1 TDLA/B - Transition Detect Latches

TDLA/B indicate detection of specific transition occurrences on a channel input signal. TDLA and TDLB assertion causes service request in single and double transition predefined modes, respectively. TDLB assertion does not cause Service Request in single transition predefined modes, and TDLA assertion does not cause Service request in double transition predefined modes. In single transition channel predefined modes TDLB can be asserted on the second transition, but does not generate Service Request. Yet on predefined modes, TDLB assertion is enabled only if TDLA is asserted to detect an ordered input signal double transition. All the restrictions above, however, may be overridden by using the User Defined Channel Mode. The IPACA and IPACB registers indicate the programmed edges of the first and second detected transition, respectively.

The sampling of a determined value (0 or 1) on the input signal due the occurrence of a Match is also treated as a "transition", depending on IPACA/B programming (see [IPACA/B and OPACA/B - Input and Output Pin Action Control Registers](#)). When using a channel mode where the transition1 is initially blocked and IPACA is programmed to detect such "transitions", the occurrence of a Match A only unblocks the transition after

27. In TPU3, when TCR1 was counting at maximum rate of eTPU clock divided by 2, the next value was captured.

the sampling. It means that the transition on the first Match (IPACA configurations 100 and 101) is not effective on predefined modes where Transition A is enabled by Match A (m2_st, m2_dt, m2_o_st and m2_o_dt) or user-defined modes with UDCM bit M1ET asserted. A Transition A can still happen after the Match A, however, if MatchA register is reprogrammed without clearing MRLA.

TDLA/B assertion conditions initiates a capture event of one or both selected TCR buses. TDLA or TDLB transition event generates a Service Request, depending on channel mode, previous events and the state of SRI. For more information on service request scheme refer to [Entry Point address generation](#)" and [Channel Modes](#).

Assertion of TDLA/B occurs on either T2 or T4 positive edges. The capture event occurs on the same clock, and captures the time base value present when TDLA/B was asserted²⁸. TDLA and TDLB are negated during reset and may also be negated independently by microcode. TDLA/B is reset by no way other than reset and microcode.

It is the transition from 0 to 1 in TDL that causes the Transition actions: even if TDL assert conditions are satisfied, no action due to a Transition occurs if TDL was already set to 1. However, if a Transition and a microoperation negating TDLs occur at the same time and TDL was already negated, TDL negation by microcode overrides its assertion, but any dependable captures and pin action occurs anyway.

37.15.5.3.2 TCCEA - Transition Continuous Capture Enable

TCCEA enables capture from transitions after the TDLA flag is set. TCCEA is negated on reset, so that a capture occurs only when TDLA asserts. TCCEA can be set and reset by microcode only, through the instruction field MTD (see [Disable Match and Transition Service Requests](#)). It can only be set together with inhibiting of the channel service requests (SRI = 1)²⁹.

When TCCEA is asserted, the transition events specified by IPACA that occur after TDLA is set also cause captures, into the CaptureA register only. However, output actions related to transition events are still blocked by TDLA.

28. In TPU3, when TCR1 was counting at maximum rate of eTPU clock divided by 2, the next value was captured.

29. TCCEA provides compatibility with TPU when service request is inhibited.

37.15.5.4 Channel Modes

The Enhanced Channels support various modes of operation combining Match A/B recognition and transition detection events which set MRLA/B and TDLA/B. The channel mode is individually set for each channel by eTPU microcode, through the PDCM register (see [PDCM - Predefined Channel Mode](#)). The PDCM register selects among a set of 13 predefined channel modes, and also a user-defined channel mode.

The order in which events occur, combined with assigned channel mode, establish which following event detections are inhibited and/or enabled, as well as the actions taken: Time Base capture, flag setting (MRLA/B, TDLA/B), match disabling (MRLEA/B), output signal transition, and Service Request. Those channel mode characteristics are fixed in the predefined modes, but can be individually programmed in the user-defined channel mode.

A generic description of channel modes from the usage point of view can be found in [Channel Modes Overview](#). Each mode is named with a mnemonic acronym for terse reference. The individual programmed attributes of the user-programmable channel mode are also described.

The modes are used differently for input and output signals, as explained in [Predefined Channel Modes on Input Signal Processing](#) and [Channel Modes on Output Signal Generation](#). Modes also allow combining input processing and output generation in a single channel, as exemplified in [Combining Input and Output Signals](#).

[Channel Mode Logic and Event Flags](#) shows a structural definition of channel logic and its relation to channel modes. A dynamic, event-oriented view of each channel mode can be found in [Channel Mode Summary](#).

37.15.5.4.1 Channel Mode Logic and Event Flags

[Figure 37-307](#) shows a more detailed diagram of channel mode logic. The logic shown here is not necessarily identical to the actual channel logic implementation, but is equivalent with respect to conditions for event blocking, enabling, capture, and service requests.

Signals MSR, TSR, MCAP, TCAP, M1ET, M1EM2, M1BM2, M2BM1, M2BT, T1BM1, T2BM1, TBM2 and T1ET2 are decoded from programmed channel mode PDCM in predefined modes, and come directly from the UDCM register when user-defined mode is selected:

- TSR (1 bit) defines Service Requests issued by Transitions, as shown in [Table 37-348](#).
- MSR (2 bits) defines Service Requests issued by Matches, as shown in [Table 37-347](#).

Functional description

- TCAP (1 bit) defines time base captures caused by Transitions, as shown in [Table 37-348](#)
- MCAP (1bit) defines time base captures caused by Matches, as shown in [Table 37-349](#).
- M1ET, M1EM2, M1BM2, M2BM1, M2BT, T1BM1, T2BM1, TBM2, T1ET2 (1 bit each) define Match and Transition reciprocal blocking and enabling, as well as Transition ordering, as shown in [Table 37-350](#) and [Table 37-351](#).

[Table 37-352](#) shows the decoded values of those control signals for each predefined channel mode. The first column shows the mnemonic reference for the predefined channel modes described in the following sections.

Changing PDCM or the UDCM when user mode is selected may set or reset any of the channel flags, or issue captures and service requests, so it is advisable to switch channel modes only in a quiescent channel state, with channel flags MRLEA/B, TDLA/B, MRLA/B cleared. Furthermore, an event flag asserted in one mode may keep asserted after the mode programming change, even if the flag is impossible to be set in the new mode.

Table 37-347. MSR signals - Match Service Requests

value	MSR
00	issue no Service Requests on Matches
01	issue Service Request on Match B only
10	issue Service Request on 2nd ¹ Match
11	issue Service Request on both Matches

1. 2nd Match means the Match that happens after the 1st Match in time, either Match A or Match B.

Table 37-348. TCAP and TSR signals - Transition Captures and Service Requests

value	TCAP	TSR
0	1st ¹ Transition captures Time Bases corresponding to Transition A and Transition B ² Transition A captures corresponding Time Base if it is the second transition; Transition B captures corresponding Time Base if it is the second transition.	issue Service Request on the 1st ¹ Transition
1	Transition A captures corresponding Time Base. Transition B captures corresponding Time Base.	issue Service Request on the 2nd ³ Transition

1. 1st Transition means the Transition that happens first in time, either Transition A or Transition B.
2. Match capture(s) never overwrites a Transition capture. Transition captures can always overwrite a Match capture.
3. 2nd Transition means the Transition that happens second in time, either Transition A or Transition B

Table 37-349. MCAP signal - Match Capture

value	MCAP
0	Match A captures corresponding Time Base; Match B captures corresponding Time Base
1	either Match captures Time Bases corresponding to Match A and Match B ¹

1. Match capture(s) never overwrites a Transition capture. Transition captures can always overwrite a Match capture.

Table 37-350. TBM2 signal - Transition Blocks Match B

value	TBM2
0	Transition A Blocks Match B
1	Transition B Blocks Match B

Table 37-351. M1ET, M1EM2, M1BM2, M2BM1, M2BT signals

signal	active value meaning
M1ET (Match A Enable Transitions)	Transitions are initially blocked, and Match A enables Transitions
M1EM2 (Match A Enables Match B)	Match B is initially blocked ¹ , and Match A enables Match B
M1BM2 ² (Match A Blocks Match B)	Match B is initially enabled ¹ , and Match A blocks Match B ³
M2BM1 ² (Match B Blocks Match A)	Match A is initially enabled, and Match B blocks Match A ³
M2BT (Match B Blocks Transitions)	Match B blocks Transitions
T1BM1 (Transition A Blocks Match A)	Transition A blocks Match A
T2BM1 (Transition B Blocks Match A)	Transition B blocks Match A
T1ET2 (Transition A Enables Transition B)	Transition B is initially blocked, and Transition A enables Transition B

1. The initial condition of M1EM2 prevails over M1BM2, while M1BM2 blocking prevails over M1EM2 enabling, so that Match B stays always blocked when both M1BM2 and M1EM2 are active. This combination is used in single-match modes (sm_*).
2. Blocking of one Match by the other is done through MRLEs.
3. Matches always block themselves by resetting their own MRLEs (Match A always blocks Match A, Match B always blocks Match B)

1. signals TSR, TCAP and TBM2 replace the signal DTM used in previous eTPU versions.
2. bm_dt and sm_dt are exceptions in the match blocking logic by transitions. See [Both Match Request Modes \(bm_st, bm_dt\)](#) and [Single Match Modes \(sm_st, sm_dt\)](#).
3. sm_st_e is an exception in the capture scheme. See [Single Match Enhanced Mode \(sm_st_e\)](#).

Figure 37-307. Channel Mode Logic and Event Flags

37.15.5.4.2 Channel Modes Overview

The predefined channel modes are divided, according to the way they treat transitions, in two basic modes:

- **Single Transition Modes** (mnemonic suffix **_st**): in these modes the first transition (flagged in TDLA) issues a service request, and captures both time bases (selected by TBSA[1] and TBSB[1]) except on sm_st_e. The second transition (flagged in TDLB) does not issue a service request, but it captures time base selected by TBSB[1], except on sm_st_e.
- **Double Transition Modes** (mnemonic suffix **_dt**): in these modes the second transition (flagged in TDLB) issues a service request, and each transition captures its own selected time base (Transition A and Transition B capture time bases selected by TBSA[1] and TBSB[1], respectively).

In predefined modes, Transition B is always (but not only) enabled by Transition A, so that transitions are always ordered: TDLA is set on the first transition and TDLB on the second. Unordered transitions are possible with user-defined mode, when UDCM bit T1ET2=0. Matches are generally not ordered, except on specific ordered match modes m2_o_st and m2_o_dt. Match capture(s) never overwrites a Transition capture, while Transition captures can always overwrite a Match capture, either in predefined or user-defined modes.

The following general rules apply to both predefined and user-defined modes:

- Blocking of one Match by the other, when it occurs, is done through MRLEs.
- Matches always block themselves by resetting their own MRLEs (Match A always blocks Match A, Match B always blocks Match B).

Predefined modes differ mostly by the way matches affects and are affected by other matches and transitions, as explained in next sections. However, some general rules on Match blocking apply:

- Match B is blocked by first transition (TDLA) in single transition modes, and by second transition (TDLB) in double transition modes.
- Both Matches are blocked by first transition in single transition modes.

Note

The rules above and in following sections may be overruled by the state of the channel latches if they are set/reset by microcode or if channel mode is changed. Care must be taken

to change channel modes, and is advisable to reset channel flags MRLA/B, TDLA/B and MRLEA/B before writing PDCM, or to UDCM when user-defined mode is selected.

37.15.5.4.2.1 Either Match, Blocking Modes (em_b_st, em_b_dt)

In these modes the first match recognition that occurs blocks the other match recognition and generates a service request. They end up with one service request for two programmed match recognitions where only the first match recognition has an actual effect. If both match recognitions occur at the same time, both MRLA and MRLB are set, before the mutual blocking takes effect. The associated logic is shown in the following figure.

Figure 37-308. Either Match, Blocking Modes (em_b_st, em_b_dt)

37.15.5.4.2.2 Either Match, Non Blocking Modes (em_nb_st, em_nb_dt)

In these modes both match recognitions are independent and each of them generates service request. Each match recognition captures its related time base and does not block the other. The associated logic is shown in the following figure.

Figure 37-309. Either Match, Non Blocking Modes (em_nb_st, em_nb_dt)

37.15.5.4.2.3 Match B Request Modes (m2_st, m2_dt)

In these modes transitions are initially blocked, and are enabled by Match A. Match B recognition generates the match service request and disables Match A recognition. Each match recognition captures its own programmed timebase. In case of simultaneous match

recognition, both MRLA and MRLB are set, and OPACB register has priority over OPACA for selecting the pin action. The associated logic is shown in the following figure.

Figure 37-310. Match B Request Modes (m2_st, m2_dt)

37.15.5.4.2.4 Both Match Request Modes (bm_st, bm_dt)

In these modes, match service request is generated only after both match recognitions occurred. By definition this is a non-blocking match mode: match recognitions do not block each other, implementing a last-served scheme. Unlike other double transition

modes, bm_dt blocks Match A with Transition B (not with Transition A), so that the second transition blocks both matches. The associated logic is shown in the following figure.

37.15.5.4.2.5 Ordered Modes with Match B Request (m2_o_st, m2_o_dt)

These are ordered match modes on which Match A recognition must precede Match B recognition (ordered 1->2). Match A asserts MRLA and enables Match B and transitions. Match B asserts MRLB, generates a match service request, and blocks both transitions. The associated logic is shown in the following figure.

Figure 37-312. Ordered Modes with Match B Request (m2_o_st, m2_o_dt)

37.15.5.4.2.6 Single Match Modes (sm_st, sm_dt)

Single match modes support single or double transition with single match recognition. MRLB is never set, and MRLEB has no effect. The associated logic is shown in the following figure.

Figure 37-313. Single Match Modes (sm_st, sm_dt)

37.15.5.4.2.7 Single Match Enhanced Mode (sm_st_e)

This is an enhanced single transition and single capture mode, which provides non-filtered input captures in addition to the single capture, allowing one to measure the delay of the digital filter. In an output channel, it has the same functionality of sm_st (captures both time bases at once due to a match recognition). The associated logic is shown in the following figure.

Figure 37-314. Single Match Enhanced Mode (sm_st_e)

37.15.5.4.3 Predefined Channel Modes on Input Signal Processing

When processing an input signal, the predefined channel modes can be classified in the following primary mode groups:

- Single Transition, Single Match: em_b_st, sm_st, sm_st_e
- Single Transition, Double Match: em_nb_st, bm_st, m2_st, m2_o_st
- Double Transition, Single Match: em_b_dt, sm_dt
- Double Transition, Double Match: em_nb_dt, bm_dt, m2_dt, m2_o_dt

In single transition modes, TDLA assertion may capture both time bases at once, while in double transition modes each transition captures its related time base in its related capture register.

Double transition is always ordered, i.e TDLB is enabled by TDLA and generates the service request.

The channel logic supports various input modes with combinations of single/double transition and single/double match, explained in the following subsections.

37.15.5.4.3.1 Either Match, Blocking, Single Transition (em_b_st)

On an input signal, this mode provides double timeout mechanism on a programmed transition edge with two timebases. The signal transition blocks both pending matches, indicating that no timeout condition occurred. The two match recognitions block each other, giving good separation in the entry table as to which match recognition caused the first timeout condition, and generating only one service request. Either match performs timebase captures which do not overwrite captures by transitions.

37.15.5.4.3.2 Either Match, Blocking, Double Transition (em_b_dt)

In double transition mode each transition is related to one match recognition. TDLA assertion captures its related timebase, blocks Match A and enables TDLB. TDLB assertion blocks Match B, captures its related timebase and generates a service request. Match recognitions block each other, so if there is a match timeout condition on TDLA, only one match service request is generated. This mode is good for qualifying two signal transitions by match timeout mechanisms, with one service request. Note that although TDLA assertion does not block Match B recognition, the value captured in CaptureA by TDLA assertion is not overwritten by this recognition. The second transition blocks Match B. Either match performs timebase captures which do not overwrite captures by transitions.

37.15.5.4.3.3 Either Match, Non Blocking, Single Transition (em_nb_st)

On an input signal, this is a double timeout mechanism of independent match recognitions of two different timebases. The match recognitions do not block each other, such that the microcode can check if one or two match recognitions occurred before their related signal transition. The signal transition detection (by IPACA) asserts TDLA, blocks both matches, captures both time bases and generates a transition service request, indicating that none of the two timeout conditions occurred. Any combination can be easily resolved by microcode (for example, signal transition after Match A and before Match B, or signal transition after both Match A and Match B).

Another possible use of this mode is allocating one match recognition for transition timeout and the other for another non-critical timed task, adding functionality to a single channel. Since the transition detection blocks both match recognitions, the match recognition of the other timed task is based on the fact that the comparator checks greater-equal conditions. It may be delayed if it occurs in the period between the signal transition detection (which blocks it) and the time TDLA is negated by microcode. If matches are enabled during the service, the same code can check if the match recognition of the timed task occurred in this period, by negating TDLA and writing to the CHAN register its own value (in order to update the MRLA flag in the branch logic).

37.15.5.4.3.4 Either Match, Non Blocking, Double Transition (em_nb_dt)

In this mode each transition is related to one match recognition, and the match recognitions are independent of each other. This mode can be used to give independent timeout conditions for the first and the second signal transition recognitions, and call service in any case of any timeout condition.

The first transition detection programmed in IPACA sets TDLA, captures its related timebase, blocks Match A recognition and enables TDLB assertion. The second transition detection programmed in IPACB sets TDLB, blocks Match B recognition, captures its related timebase and generates a service request. Any match recognition that occurs captures its related time base and generates a match service request, independent on the other match recognition.

37.15.5.4.3.5 Match B Request, Single Transition (m2_st)

On an input signal, this mode provides an open window filter for a single signal transition. MRLA assertion opens the window, and enables transition detection on TDLA from this time on. MRLB assertion blocks Match A (by negating MRLEA), providing conditional window opening, because transitions are indirectly blocked. It also generates service request, but if it happens after Match A it does not block transitions, providing a non-blocking timeout mechanism for the estimated signal transition time (typically it indicates a missing transition, or mis-prediction of the transition time).

Transitions can be detected from the microcycle following MRLA assertion. The Transition A detection asserts TDLA, blocks both matches, captures both timebases and generates service request.

Using this mode, the channel can replace software open window filtering of qualified transitions with the channel hardware window. The window opening and timeout can be scheduled for any of the two time bases or combination of them. Typically, Match A will be used to open a prediction window, and Match B will be used as a timeout condition

which does not close the prediction window. This configuration improves noise immunity from early signal transitions, and reduces the probability for blocking late signal transitions due to timeout mis-prediction.

Using these conditions, the microcode can easily resolve the state:

- If TDLA and MRLA are asserted and MRLB negated, signal transition is in the expected range.
- If MRLA and MRLB are both asserted, and TDLA is asserted, the signal transition had a timeout condition due to Match B mis-prediction.
- If MRLB is asserted and TDLA negated, a timeout condition occurred, and the expected signal transition had not occurred yet.
- If MRLA is negated and MRLB is asserted, the conditional window did not open at all (for example: a time window is open only after a specific angle, otherwise it is not opened).

37.15.5.4.3.6 Match B Request, Double Transition (m2_dt)

This mode is used as an open window filter for two signal transitions. In this case the Match A recognition opens the window (unless Match B recognition occurred first), and Match B recognition blocks Match A and generates a match service request. It is similar to m2_st, but in this case, it is the second transition that blocks Match B. MRLB assertion is a global timeout condition for the two pulses. Like m2_st, MRLB can conditionally eliminate the window from opening.

Using the TDLA, TDLB, MRLA and MRLB conditions, the microcode can easily resolve the state, in a similar manner as m2_st, with additional information on the second transition (TDLB).

37.15.5.4.3.7 Both Match Request, Single Transition (bm_st)

On an input signal, this is a double timeout mechanism on two different time bases. Both match recognitions must occur before the signal transition to generate a match timeout service request. Assertion of TDLA blocks both Match A and Match B recognitions, and captures both time bases, indicating there was no double timeout condition from both time bases.

Using the same timebase implements two timeout conditions, the first only sets its related MRL and the second generates a service request. Using these flags allows the microcode to check if one or both match recognitions precede the signal transition.

37.15.5.4.3.8 Both Match Request, Double Transition (bm_dt)

In this mode the first transition detection does not block matches, since both match recognitions are required to generate a match service request. The second transition detection asserts TDLB, blocks Match A and Match B, captures its related timebase and generates transition service request. In this mode, a Match A recognition which occurs after the assertion of TDLA does not capture a new value in CaptureA, to preserve the actual signal transition time. Assertion of TDLA, however, always captures its related timebase.

This mode allows putting a double match timeout condition on the second transition. Typically, a pulse trailing edge timing can be checked against two time bases, to indicate if the pulse has not ended when both MRLA and MRLB are asserted. When a transition service request is generated by TDLB assertion, the state of MRLA and MRLB indicates which timeout condition occurred, if any.

37.15.5.4.3.9 Ordered Mode with Match B Request, Single Transition (m2_o_st)

On an input channel, this mode provides a closing window filter for a single signal transition. Match A assertion captures its programmed time base in CaptureA, opens the filter window (enables assertion of TDLA), and enables assertion of MRLB. Match B recognition captures its related timebase, closes the window (disables assertion of TDLA) and generates a service request. Due to Match A and Match B ordering, the window is opened for at least one microcycle. Match B recognition indicates a window timeout condition which blocks late signal transitions, outside the prediction window. Transition detection blocks both matches, indicating the transition occurred inside the estimated window. Transitions can be detected from the microcycle following MRLA assertion until the microcycle on which MRLB is asserted. When TDLA is asserted inside the window range it disables both matches, captures both time bases and generates a transition service request.

Using this mode, the channel can replace software window filtering of qualified transitions with the channel hardware window. The window opening and closing time can be scheduled for any of the two time bases or a combination of them.

37.15.5.4.3.10 Ordered Mode with Match B Request, Double Transition (m2_o_dt)

In this mode the channel logic implements a window filter for two detected signal transitions. MRLA assertion captures its related timebase and enables the assertion of both TDLA and TDLB. MRLB assertion captures its related timebase and disables the assertion of both TDLA and TDLB. Transitions can be detected from the microcycle following MRLA assertion until the microcycle on which MRLB is asserted. The first

signal transition (following MRLA assertion) asserts TDLA, captures its related timebase and enables assertion of TDLB. The second signal transition detection asserts TDLB, blocks Match B, captures its related timebase and generates the service request.

If both signal transitions occur inside the scheduled window, Match B recognition is blocked. If one or both signal transitions do not occur inside the scheduled window, Match B recognition generates a match service request and blocks further transition detections. The microcode can resolve the state using MRLA, MRLB, TDLA and TDLB, which affect the entry point selection.

37.15.5.4.3.11 Single Match Enhanced Mode (sm_st_e)

This is an enhanced single transition and single match channel mode which provides timing information of the digital filter delay.

The CaptureA register captures the timebase selected by TBSA due to transition detection specified by IPACA or match recognition, as in sm_st mode. Initially, the CaptureB register continuously captures the unfiltered IPACB-selected signal transitions from the digital filter input, directly from the signal synchronizer. When an IPACA-qualified, filtered transition detection occurs, TDLA is set, MRLA assertion is blocked, and, in addition, captures into CaptureB are also blocked. On service, CaptureA and CaptureB (copied into ERTA and ERTB) holds the time of the qualified transition detection (ERTA), and the time of the last signal transition at the input of the digital filter (ERTB). Subtracting the time in ERTB from the time in ERTA provides the delay of the digital filter.

In a quiet environment, the two captures provide the accurate delay of the digital filter in granularity of two eTPU clocks. In a noisy environment, false transitions may be detected at the input of the digital filter due to the noise, and the delay measurement may be reduced, especially if IPACB selects both edge detection. The microcode can do sanity checks on this value to recognize noise effects (for example: calculated delay is less than the minimum delay of the digital filter).

Note

In Channel 0, if eTPU_TBR_TBCR_ENG n [AM]=01 (Angle Mode), the unfiltered input comes from TCRCLK input and the filtered input comes from the TCRCLK filter output. The edge is selected by IPACA/B, and is independent of the edge selection by eTPU_TBR_TBCR_ENG n [TCR2CTL].

37.15.5.4.3.12 Single Match, Single Transition (sm_st)

In this mode the channel logic is functionally back-compatible to a TPU3 single action channel, but a match or transition detection captures at once both timebases. The mode recognizes a single transition with single match timeout. Either TDLA or MRLA generates service request and captures both timebases. Assertion of TDLA blocks future assertions of MRLA.

37.15.5.4.3.13 Single Match, Double Transition (sm_dt)

In this mode, the first transition detection asserts TDLA, captures a timebase in CaptureA and enables TDLB. The second signal transition asserts TDLB, blocks Match A, captures a timebase in CaptureB and generates a service request.

Match A (before TDLB) captures into CaptureB the timebase selected by TBSA, in order not to overwrite the captured value of TDLA.

This mode is used for scheduling one timeout condition on two input signal transitions (pulse timeout).

37.15.5.4.4 Channel Modes on Output Signal Generation

Since channel logic can generate output signal transitions based on Matches, the channel can be viewed as working in the following primary mode groups for signal generation:

- Single Match: em_b_st, sm_st, sm_st_e, em_b_dt, sm_dt
- Double Match: em_nb_st, bm_st, m2_st, m2_o_st, em_nb_dt, bm_dt, m2_dt, m2_o_dt

The channel logic supports various match channel modes with single/double match, as explained in the following subsections.

37.15.5.4.4.1 Either Match, Blocking Modes (em_b_st, em_b_dt)

On an output signal these modes are useful when using two different time bases to set a required signal transition. The first match condition which is met sets a required pin action, captures both time bases, blocks any effects of the other recognition, and generates a service request. Because the first match recognition blocks the other, the microcode can get good separation in the function entry table as to which match caused the timeout first, and both time bases are captured, enabling the microcode to compare one timebase to the other at the moment of the match recognition. These modes can be used for:

- Scheduling a required pin action to the first match recognition of two different time bases.
- Canceling a programmed pin action scheduled on one time base by match on another timebase (as a consequence of [Table 37-353](#)). Microcode has to set the OPAC register of the canceling match to no-action and the OPAC register of the other match to the required pin action which may be blocked. If Match A is the canceling match, it blocks the pin action also in case of two matches at the same time, since it has priority in this case. If Match B is the canceling match, it does not block the pin action in case of two matches at the same time.

37.15.5.4.4.2 Either Match, Non Blocking Modes (em_nb_st, em_nb_dt)

On an output signal these modes are useful in combination with the ME bit set on the entry point, to define an interlaced operation. For example, each match recognition can set a pin action, and the second pin action is not sensitive to microcode latency (ME bit asserted). Example for usage is PWM interlaced function on which the latency is determined by the period and not the duty cycle.

Another possibility is using one match for pin actions and the other match for an unrelated timed task without pin action (double the functionality of a single channel).

37.15.5.4.4.3 Match B Request Modes (m2_st, m2_dt)

On an output signal, these modes can generate narrow pulses or do conditional pin actions. A conditional pin action means that the pin state is changed only if the match recognitions occurred in the correct order, since the Match B recognition which generates the service request also has priority over the pin action and blocks future Match A recognitions.

Setting OPACA to a desired pin action and OPACB to no-action, and using different time bases for Match A and Match B defines a conditional OPACA pin action which can be blocked by Match B recognition. For example, setting Match A on time and Match B on angle can limit the pin action to a maximum angle value.

When pulses are generated, the service is requested at the trailing edge of the pulse, after MRLB is asserted.

37.15.5.4.4.4 Both Match Request Modes (bm_st, bm_dt)

On an output signal, each match recognition can affect the pin state, and capture its programmed time base. This way the pin action can be programmed separately for both match recognitions. For example, both match recognitions can negate the signal, and

service request is generated after both conditions are met. This mechanism can set two conditions to do a required pin action, and the first recognition changes the signal, but service is called only after both conditions occur.

When using the same time base, these modes can generate narrow pulses in any required order. For example, in a PWM function, when duty cycle is below 50% the function can get service on the low time and program the pulse to the required duty cycle of the high time. When duty cycle is equal or above 50%, the function can get service on the high time and program a negative pulse with the width of the required low time. To switch between the two states the function can program once the same transition time to MatchA and Match B with a required pin action, and on the next service program double match for the new state.

Another usage is generating a required pin action on one programmed time and service request later on another time, after the second match recognition occurs, or capturing some timebase on one time and generating a required signal transition and service request later.

37.15.5.4.4.5 Ordered Modes with Match B Request (m2_o_st, m2_o_dt)

The order of the match recognitions imply that OPACA register programmed pin action always precede the OPACB register pin action. Setting OPACA to no-action, based on the greater-equal comparator, enables using Match A on one time base to delay the signal effect of Match B on the other time base. This method implements a conditional pulse extension or conditional delay on signal transition.

These modes can also be used for deferred pulse generation with microcode service request after its trailing edge (if Match A condition comes after Match B condition). Another option is having Match A recognition associated with output pin actions and Match B recognition for a timed microcode task which has to be scheduled at a programmed time which may be delayed by the Match A pin action.

37.15.5.4.4.6 Single Match Modes (sm_st, sm_dt, sm_st_e)

There is no difference between plain and enhanced Single Match modes on an output signal.

In this mode the channel logic is functionally back-compatible to a TPU3 single match output channel. Match A recognition generates service request and sets the pin state according to OPACA register. It captures at once the timebase selected by TBSA in CaptureA and the timebase selected by TBSB in CaptureB.

37.15.5.4.4.7 Match/Transition Pin Action Conflict Resolution

In output signals, matches and/or transitions automatically cause pin actions defined by the OPACA/B and/or IPACA/B channel control registers (see [Pin Control Registers](#)). Simultaneous matches/transitions may be associated with different, possibly contradictory, pin actions. These conflicts are resolved according to the table below.

If an OPACA/B=000 (no action) prevails over non-zero OPAC according to the table below, then if Match A/Transition A and Match B/Transition B occur simultaneously, no output pin action occurs, that is: a match on the action logic with OPAC=000 inhibits simultaneous actions of the other OPAC, if prevailing according to the following table. That also applies when output actions are caused by inputs (OPAC=1xx).

Table 37-353. Simultaneous Match Pin Action Priority

Channel Mode	Priority
em_nb_st / em_nb_dt	OPACA
em_b_st / em_b_dt	OPACA
bm_st / bm_dt	OPACA
m2_st / m2_dt	OPACB
m2_o_st / m2_o_dt	in these modes there is no possibility of simultaneous matches
user-defined	OPACB if M2BM1 = 1 and M1BM2 = 0, OPACA otherwise

37.15.5.4.5 Combining Input and Output Signals

The processing of input signal can be combined with output signal generation. A detected input transition can trigger an output signal edge, even without microcode intervention, by using OPAC options 1xx.

The channel set-up examples below show these two capabilities combined (see the figure below).

The **first example** implements a fast (no microcode intervention) short-circuit protection feedback mechanism for driving high-current output devices. The signal after the high-current driver feeds back to the channel input. The input signal is normally delayed from the output signal by the device turn-on delay. After the channel output turns on, the channel logic must check if the driver output (connected to the channel input) follows the driven value after the maximum device turn-on delay. If it does not, the driver output is probably shorted, and the channel output must be turned off immediately to avoid damaging the device.

Match A causes the output to be driven high (for simplicity the output and input signals are shown as positive logic). It also causes a transition A, because IPACA=100 and the input is still low. Match B occurs after the expected driver delay, and causes a service request. If the output is shorted, a Transition B occurs on Match B because IPACB=100. This will cause the output to go low immediately, because OPACB=100.

In the **second example**, an output pulse is generated from an input transition without microcode intervention. Match A opens a window for transitions and also enables Match B. A rising edge on input sets output high. On Match B the window closes, and input signal is checked: if sampled high, the output resets; otherwise it stays high.

In the **third example**, a pulse is generated depending on the value sampled on the input signal at a predetermined time. Match A samples the input signal, causing a Transition. Low level on input sets output low, otherwise it stays high. Match B sets output high. In both cases a service request is issued (microcode intervention), at the beginning and at the end of the pulse (Match B), if required (SRI := 0).

Note

When IPAC = 1xx, a match event can cause simultaneously a Match recognition and a Transition detection. Depending on the Channel Mode, these Match and Transition may have conflicting effects on other Transition/Match blocking or enabling. In these cases, blocking always prevails over enabling, effective on the next microcycle.

Example 1: Short-circuit protection feedback

IPACA := 100; OPACA := 001; MatchA := output activate time;
 IPACB := 100; OPACB := 100; MatchB := MatchA + max. high-current driver turn-on delay;
 PDCM := bm_dt;

Example 2: Pulse generation on windowed input transition

IPACA := 001; OPACA := 101; MatchA := window open time;
 IPACB := 101; OPACB := 100; MatchB := window close time, input sampling;
 PDCM := m2_o_dt;

Example 3: Pulse generation on input sampling

IPACA := 100; OPACA := 100; MatchA := window open time, input sampling;
 IPACB := 000; OPACB := 001; MatchB := window close time = MatchA + pulse width;
 PDCM := em_nb_dt;

Figure 37-315. Input/Output combination

37.15.5.5 Channel Link

A channel can issue service requests to other channels through microcode, by assigning to the write-only microengine register LINK (refer to [LINK Register](#)) a value which specifies the target channel of the Link Service Request, as shown in the figure below.

Writing to the LINK register issues a link request to the target channel, setting its LSR flag. Each channel has its own LSR flag, which can be tested as a microcode branch condition (see [Conditional/unconditional branch](#)) and reset through the microcode field LSR (see [Clear Link Service Request](#)). The link branch condition samples, at the TST start, the value used to calculate the Entry Point.

Writing LINK with another channel target value in the same thread issues a Link Service Request to the new target, without negating the service request to the former one. This allows a channel to issue service requests to any number of channels, including itself. Neither LINK nor LSR microengine accesses are qualified by the CHAN register, i.e., they always access the serviced channel LINK and LSR, regardless of the value written in CHAN.

Channels can also receive link service requests from the Shared Subsystem Units (see [Shared Subsystems support](#)). These links are set by the interrupt signals from the shared subsystem and are level-sensitive, that is, they keep on requesting link service as long as the interrupt is active. Therefore, it is not enough to clear the link service request through the LSR instruction field: one must clear beforehand the respective shared subsystem unit interrupt source.

If microcode executes an instruction with field LSR=0 (clear Link Service Request), the link branch condition is cleared. However, the link service request itself is cleared only if no link from other channel was received by the serviced channel during the same thread³⁰. Note that this applies only to links that come from the other engine or the same channel: if only Shared Subsystem link was received during the thread, the link service is also cleared with field LSR=0. If microengine clears LSR of its channel and, simultaneously, Link Service Request is issued to the current serviced channel, the branch condition is cleared but the link service request remains pending.

Figure 37-316. Microengine LINK Register

30. That can only happen if the link service request came from the other Engine, or from the serviced channel itself.

A channel can issue Link Service Requests to channels in any of two Engines, determined by the LINK register field Engine Selection (2 bits), as shown in the following table. In a Single Engine eTPU, Link is ignored when sent to the other engine, or engine 2.

Table 37-354. LINK Engine Selection

Engine Selection	Description
00	this Engine
01	Engine 1
10 ¹	Engine 2
11 ¹	the other Engine

1. ignored in Single Engine eTPU.

There is no explicit hardware mechanism to allow the thread to identify the link service request source, but it can be done by a software protocol using SDM parameters. All links are negated on reset.

37.15.5.6 Enhanced Digital Filter - EDF

The EDF eliminates passing of signal transitions which are caused by noise. Its purpose is to eliminate false transition service requests caused by noise pulses which are shorter than a programmed width.

See the chip-specific eTPU information for connections between eTPU and input glitch filters.

The EDF has three modes of operations, selected by the CDFC field in [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#). These modes offer selections of trade-off between noise immunity and signal latency. CDFC also allows the filter to be bypassed. [Table 37-355](#) gives an example of minimum detected signal pulse and maximum filtered noise pulse in the three EDF operation modes. In Angle Mode, if AM=01, the EDF in channel 0 is replaced with the digital filter and synchronizer of the TCRCLK signal. In this mode, channel 0 works in combination with the Angle Counter logic, and their operation is fully synchronized.

Following subsections provide the functional description of the eTPU channel digital filter.

37.15.5.6.1 Two-Sample mode

In this mode the EDF works like the TPU2/3 digital filter. It uses the filter clock which is the eTPU clock divided by (2, 4, 8,..., 256) as a sampling clock. The filter clock is selected by the FPSCK field in [TPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#). The EDF compares two consecutive samples. If both samples have the same value, the input signal state is updated. Note that when the FPSCK field selects the eTPU clock divided by two, the EDF works like the TPU1 four-clock digital filter.

37.15.5.6.2 Three-Sample mode

In this mode, like in the TPU2/3 mode, the EDF uses the filter clock as a sampling clock. The EDF compares three consecutive samples. If all three samples have the same value, the input signal state is updated.

The Three-Sample mode gives more signal latency than the Two-Sample mode, but also better noise immunity and better ratio between minimum detected signal pulse to maximum filtered noise pulse. When a certain filter clock frequency is selected for Two-sample mode, double filter clock frequency can be selected to get better latency in Three-sample mode.

37.15.5.6.3 Continuous mode

In this mode the EDF compares all the values sampled at the rate of eTPU clock divided by two, between two consecutive filter clock pulses. If the signal is continuously stable for the entire digital filter clock period (i.e all the samples have the same signal value), the input signal state is updated.

This method gives the same latency and the same ratio between minimum detected signal pulse to maximum filtered noise pulse, as the Two-Sample mode, as long as there is no noise. Each sampled noise delays the signal transition detection by at least a whole digital filter clock period.

The Continuous mode gives the best noise immunity by comparing multiple samples of the noise. On the other hand, when a short noise pulse appears in the middle of the filter clock period at the same time of a real signal transition, the Continuous mode may reject a real signal transition and delay the response to the first filter clock period in which the signal is continuously stable. This may add to the latency and also to the minimum detected signal pulse in a noisy environment.

37.15.5.6.4 Bypass Mode

In bypass mode the signal that feeds the edge detection comes directly from the output of the synchronizer, not filtered. Bypass mode automatically makes the channel logic work in T2/T4 timing mode (see [Channel timing modes](#)).

37.15.5.6.5 Filter clock prescaler

Each channel configured as an input has an associated synchronizer followed by a digital filter connected to the signal that samples signal transitions. After reset, the digital filter filters out high and low pulse widths smaller than the period of two eTPU clocks with eTPU_SCR_ECR_ENG n field FCSS=0, or 1 eTPU clock with FCSS=1 (see [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#)), preventing these transitions from being input to the transition detect logic. For FPSCK=0 and FCSS=0, the synchronizer and digital filter are guaranteed to pass pulses that are as wide as or wider than four eTPU clocks, meaning a minimum period of 8 eTPU clocks. These figures are halved by setting FCSS=1. By changing the FPSCK field in [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#) the user can select a lower clock rate for the filter signal to define wider valid pulses and filter out wider noise pulses. The filter prescaler clock control is a division of the eTPU clock. To guarantee pulse detection by the digital filter, the pulse must cover at least the stated number of samples at the filter clock rate. For example, a two sample digital filter must sample two points in the pulse to detect it. The table below shows the minimum guaranteed detected pulse width and the maximum filtered noise pulse width. The table refers only to the digital filter operation. The external pulses may have to be wider (to ensure detection) or narrower (to ensure filtering) depending on the rise/fall delay differences in the MCU receivers and internal logic. Delays introduced by synchronizer, filter and edge detection logic are explained in [Input/Output Signal Delays](#).

The TCRCLK signal also has a synchronizer and a filter. The FCSS bit has no influence on the clock prescaler of the TCRCLK filter, which works like the channel filter with FCSS=0.

Table 37-355. Pulse widths and delays

Filter control (FPSCK)		Filter clock period ¹	Min. width guaranteed detected / max. width filtered (min. filter delay / max. filter delay) ¹	
FCSS = 0	FCSS = 1		Two-Sample or Continuous mode	Three-Sample or Integrator ² mode
not avail.	000	1	2 / 1 (2 / 3)	3 / 2 (3 / 4)
000 ³	001	2	4 / 2 (3 / 3)	6 / 4 (5 / 5)

Table continues on the next page...

Table 37-355. Pulse widths and delays (continued)

Filter control (FPSC)		Filter clock period ¹	Min. width guaranteed detected / max. width filtered (min. filter delay / max. filter delay) ¹	
FCSS = 0	FCSS = 1		Two-Sample or Continuous mode	Three-Sample or Integrator ² mode
001	010	4	8 / 4 (5 / 7)	12 / 8 (9 / 11)
010	011	8	16 / 8 (9 / 15)	24 / 16 (17 / 23)
011	100	16	32 / 16 (17 / 31)	48 / 32 (33 / 47)
100	101	32	64 / 32 (33 / 63)	96 / 64 (65 / 95)
101	110	64	128 / 64 (65 / 127)	192 / 128 (129 / 191)
110	111	128	256 / 128 (129 / 255)	384 / 256 (257 / 383)
111	not avail.	256	512 / 256 (257 / 511)	768 / 512 (513 / 767)

1. This table shows pulse widths and delays in number of periods of the eTPU clock.
2. Integrator mode is available for TCRCLK filtering only, see [TCRCLK digital filter](#).
3. These delays also apply to the TCRCLK filter when TCRCF selects eTPU clock/2 as filter clock.

Note

The TCRCLK filter is clocked as if FCSS=0, always dividing eTPU clock /2 using FPSC, regardless of the FCSS field.

37.15.5.7 Channel timing modes

Channels can work on two different timing schemes, defining the period of channel clocking, tied to T2 and T4 microengine phases, as explained in subsections below. Microengine T2 and T4 phases are shown in [Microcycle and I/O timing](#).

37.15.5.7.1 T2 channel timing

In T2 timing mode the channel event state can only be updated every two eTPU clocks (see [Figure 37-346](#)). Pin state, TDLs, MRLs and Capture registers are updated on the microengine's T2 clock phase. MRLE clears also happen on T2, but MRLE setting occurs on T4, together with the Match register write by microcode (see [Write Channel Match and UDCM Registers](#)).

Channels work in T2 timing mode when either the T4DIS field in [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#) is 1 or all the following conditions are true:

- The TCR1CS field in [eTPU Engine 1 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG2\)](#) is 0.
- The Enhanced Digital Filter is not configured as bypass (see [Enhanced Digital Filter - EDF](#)).
- The FCSS field in [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#) is 0 (see [Filter clock prescaler](#)).

37.15.5.7.2 T2/T4 channel timing

In T2/T4 timing mode the channel event state can be updated on any eTPU clock (see [Figure 37-347](#)). Pin state, TDLs, MRLs, MRLEs, and Capture registers are updated either on microengine's T2 or T4 clock phases. MRLE clears can happen on T2 or T4, but MRLE setting occurs on T4 only, together with the Match register write by microcode (see [Write Channel Match and UDCM Registers](#)).

Channels work in T2/T4 timing mode when the T4DIS field in [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#) is 0 and either one of the following conditions are true:

- The TCR1CS field in [eTPU Engine 1 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG2\)](#) is 1.
- The Enhanced Digital Filter is configured as bypass (see [Enhanced Digital Filter - EDF](#)).
- The FCSS field in [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#) (see [Filter clock prescaler](#)).

T2/T4 timing mode demands special care on channel microcode that reprograms a match in a thread with matches enabled (entry point ME=1, see the “Entry Points” section). When the match register is written and the MRLA/B flag(s) is(are) cleared in the same instruction, a match can occur after MRLA/B is cleared, together with the set of respective MRLE. In this case, both MRL and MRLE will be set, and a match service request will occur if enabled. However, the match happened on the old match value, not on the new (reprogrammed) one. In order to prevent this ambiguity to the code that services the match, it is advisable to clear the MRLE (besides MRL) together with the

match reprogramming, avoiding the match on the old value to occur while the new match value is being written. The set of the MRLE due to match reprogramming prevails over the MRLE clear, thus allowing the new programmed match to occur in the future.

A similar case occurs when a match is blocked by a transition, the blocking TDL is cleared and the blocked match is reprogrammed at the same instruction: in T2/T4 timing mode: a match can occur on the old match value. The solution is the same as the case above, that is, clear the respective MRLE in the same instruction.

37.15.6 Time bases

Each eTPU engine has two Time Counter Registers, TCR1 and TCR2. They provide 24-bit time bases, shared by all 32 channels. Any channel can use both time bases to:

- Match channel's internal registers MatchA or MatchB;
- Capture time base value to channel's internal registers, CaptureA and/or CaptureB, when a match recognition or an Input transition detection occurs. For more information on channel events refer to [Enhanced Channels](#).

The TCR1 and TCR2 counters are accessible by the microcode for read and write operations. Its current value is used for getting the current time, and the captured values are used for channel relative time calculations of future events. When they are written at the same time they are incremented from any clock source, the written value prevails.

TCR1 with `eTPU_TBR_TBCR_ENGn[TCR1CS]=0` and TCR2 values are updated in T2 and read in T4 (see [Microcycle and I/O timing](#)). TCR1 can also work at full-speed eTPU clock, and so be updated on both T2 and T4, when `eTPU_TBR_TBCR_ENGn[TCR1CS]=1`. Both TCR1 and TCR2 values can be imported from or exported to the STAC bus. When their values are imported (STAC Clients), these registers are written from the STAC bus and can only be read by microcode.

The TCR2 counters between the two Engines are out of phase by 1 eTPU clock, even when Time Bases are shared between them through STAC. It also applies to TCR1 counters if `eTPU_TBR_TBCR_ENGn[TCR1CS]=0`, but they can be in phase otherwise.

37.15.6.1 Timer Count Register 1 - TCR1

TCR1 can be used in the following modes:

- Internally Clocked Mode

- Externally Clocked Mode
- STAC Bus Client Mode

The host program can read TCR1 time base through eTPU Engine 1 Time Base 1 (TCR1) Visibility Register (eTPU_TBR_TB1R_ENG1) and eTPU Engine 2 Time Base 1 (TCR1) Visibility Register (eTPU_TBR_TB1R_ENG2).

The TCR1 bus runs through all the local engine channels. In channels which select TCR1 as MatchA and/or MatchB source, when its value is greater or equal to the programmed match value, a Match A and/or Match B event occurs on that channel. A recognized match event sets its related Match Recognition Latch 1 or 2, and according to the Predefined Channel Modes (PDCM) it may generate a channel service request. For details on eTPU channels see [Enhanced Channels](#).

37.15.6.1.1 Externally Clocked Mode

TCR1 can be driven externally by the TCRCLK input, after the digital filter. The TCR1 clock source is configured by the TCR1CTL bit, as shown in the following figure. For more information on clock source selection, see [eTPU Engine 1 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG2\)](#).

Figure 37-317. TCR1 clock selection

37.15.6.1.2 Internally Clocked Mode

TCR1 can be driven by the eTPU clock or eTPU clock divided by 2, before the prescaler. TCR1CTL can also be used to freeze TCR1 clock independently of TCR2 (unlike GTBE).

37.15.6.1.3 TCR1 clock prescaling

Any clock source selected by TCR1CTL is prescaled by a factor of 1 to 256, selected by the TCR1P field in [eTPU Engine 1 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG2\)](#). For more information on prescaler configuration see [eTPU Engine 1 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG2\)](#). The TCR1 Prescaler resets when the eTPU GTBE input is negated. After reset, it starts counting up to TCR1P when the eTPU GTBE input is asserted. When TCR1 increments (the eTPU GTBE input = 1), the prescaler starts a new count and the new TCR1P becomes effective. When TCR1 is written by microcode, the prescaler is reloaded with TCR1P and it becomes effective, if the eTPU GTBE input is asserted.

37.15.6.1.4 STAC Bus Client Mode

In this mode the TCR1 register is continuously updated from the STAC bus, and the clock selection and prescaling logic becomes ineffective. It is not writable by the microcode, and when read, it reflects the STAC bus imported value. The use of EAC is not allowed in client mode. This mode is configured through [eTPU Engine 1 STAC Configuration Register \(eTPU_TBR_STAC_ENG1\)](#) and [eTPU Engine 2 STAC Configuration Register \(eTPU_TBR_STAC_ENG2\)](#).

37.15.6.1.5 STAC Bus Server Mode

TCR1 bus can be exported to the STAC bus as a server, providing time information to other peripherals. This mode is configured through [eTPU Engine 1 STAC Configuration Register \(eTPU_TBR_STAC_ENG1\)](#) and [eTPU Engine 2 STAC Configuration Register \(eTPU_TBR_STAC_ENG2\)](#).

37.15.6.2 Timer Count Register 2 - TCR2

The TCR2 is a 24-bit counter which can be used in the following modes:

- Pin Transition Mode: Count the rise, fall or both transitions of TCRCLK signal.
- Angle Clock Mode: Count internal tooth angle in combination with the eTPU Angle Counter (EAC) hardware which implements an Angle PLL, and generates angle information to the channels. This mode is targeted for angle based applications.
- STAC (STAC) Bus Client Mode: TCR2 is driven by an external source (see [STAC Bus Client mode](#)).

- Gated Mode: Count with rate derived from the eTPU clock divided by eight. The TCRCLK signal is used to gate this count, enabling pulse accumulator operations.
- Internally Clocked Modes: TCR2 is driven by internal clock, with count rate of eTPU clock divided by eight.

All clock sources pass through a prescaler. In addition, the TCR2 count can be originated from the EAC which is a hardware angle clock and angle counter. Figure 37-318 shows the diagram for TCR2 clock control. When TCR2 is not driven by the EAC or STAC, the eTPU_TBR_TBCR_ENGn[TCR2CTL] field selects the clock source, also allowing TCR2 to be frozen independently of TCR1 (see eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2)). When in Angle Mode, TCR2CTL selects the TCRCLK edge sensitivity.

Figure 37-318. TCR2 clock control

The TCRCLK signal input is passed through a synchronizer and a programmable digital filter. In Angle Mode with AM=01, synchronizer and filter are also used in Channel 0, replacing its input synchronizer and filter, to get the same timing in the EAC and Channel 0. The TCRCLK synchronizer is an improved filter that provides best latency while maintaining proper noise filtering (see the field TCRCF in eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1))

The TCR2 bus runs through all the local engine channels. It transitions on clock T2 (see Microcycle and I/O timing). In channels which select TCR2 as MatchA and/or MatchB source, TCR2 value is compared against MatchA and/or MatchB registers. A recognized

match event sets its related Match Recognition Latch 1 or 2, and according to the Predefined Channel Modes (PDCM) it may generate a channel service request. For details on eTPU channels see [Enhanced Channels](#).

The TCR2 counter is accessible by the microcode for read and write operations. Its current value is used for getting the current counter value (representing signal transitions, time or angle), and the captured values are used for channel relative count calculations of future events. The TCR2 value is readable to the host through [eTPU Engine 1 Time Base 2 \(TCR2\) Visibility Register \(eTPU_TBR_TB2R_ENG1\)](#) and [eTPU Engine 2 Time Base 2 \(TCR2\) Visibility Register \(eTPU_TBR_TB2R_ENG2\)](#). When the TCR2 bus value is imported from the STAC bus (STAC client mode), TCR2 is not writable by the microcode, and read access from the microcode or from the host reflect the imported TCR2 value.

37.15.6.2.1 TCR2 clock prescaling

Except in Angle Mode, any clock source selected by TCR2CTL is prescaled by a factor of 1 to 64, selected by `eTPU_TBR_TBCR_ENGn[TCR2P]`. For more information on prescaler configuration, see [eTPU Engine 1 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG2\)](#). The TCR2 Prescaler resets when the eTPU GTBE input is negated. After reset, it starts counting up to TCR2P when the eTPU GTBE input is asserted. When TCR2 increments (the eTPU GTBE input = 1), the prescaler starts a new count and the new TCR2P becomes effective. When TCR2 is written by microcode, the prescaler is reloaded with TCR2P and it becomes effective, if the eTPU GTBE input is asserted.

The counter that divides the eTPU clock by 8 before the prescaler also resets when the eTPU GTBE input is negated, or when TCR2 is written by microcode.

In Angle Mode the TCR2 prescaler is not used to directly increment TCR2, but can be used, selected by programming `eTPU_TBR_TBCR_ENGn[ATGC]=1`, as a clock source for the EAC generation of the angle ticks which increments TCR2. In this case, the TCR2 prescaler input is eTPU clock/2, independently of TCR2CTL. See [Generating the angle ticks](#) for details.

37.15.6.2.2 TCR2 Gated mode

TCR2 Gated mode is selected in the `eTPU_TBR_TBCR_ENGn[TCR2CTL]` field. In this mode the TCRCLK signal enables or disables transfer of the eTPU clock divided by 8 to the TCR2 prescaler. By programming the prescaler, TCR2 can run at rates from eTPU clock divided by eight down to eTPU clock divided by 512, in steps of eight eTPU clock

divisions. For more information, see [eTPU Engine 1 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG2\)](#).

37.15.6.2.3 TCR2 Signal Transition modes

These modes are selected when `eTPU_TBR_TBCR_ENGn[TCR2CTL]` is set to rise, fall or "rise-and-fall". In these modes the TCRCLK signal is the TCR2 clock source, and its maximum transition rate depends on the TCRCLK digital filter mode of operation. The TCRCLK digital filter can be programmed to use the eTPU clock divided by two, or use the same filter clock of the channels, controlled by `eTPU_TBR_TBCR_ENGn[TCRCF]`. It contains an up-down counter which operates as a digital integrator, optimizing signal latency in the selected mode and clock rate.

When eTPU clock divided by two is selected, the synchronizer and the digital filter are guaranteed to pass pulses that are wider than four eTPU clocks (two filter clocks). Otherwise the TCRCLK is filtered with the same filter clock as the channel input signals. For details on TCRCLK and channels digital filter control, see [eTPU Engine 1 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG1\)](#), [eTPU Engine 2 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG2\)](#), and [Enhanced Digital Filter - EDF](#).

37.15.6.2.4 STAC Bus Client mode

In this mode the TCR2 register is continuously updated from the STAC bus, and the clock selection and prescaling logic becomes ineffective. It is not write accessible for the microcode, and when read, it reflects the STAC bus imported value. The use of EAC is not allowed in client mode. This mode is configured through [eTPU Engine 1 STAC Configuration Register \(eTPU_TBR_STAC_ENG1\)](#) and [eTPU Engine 2 STAC Configuration Register \(eTPU_TBR_STAC_ENG2\)](#).

37.15.6.2.5 STAC Bus Server mode

When TCR2 bus is exported to the STAC bus as a server, it can provide either time or angle bus to other peripherals, according to its operation mode. This mode is configured through [eTPU Engine 1 STAC Configuration Register \(eTPU_TBR_STAC_ENG1\)](#) and [eTPU Engine 2 STAC Configuration Register \(eTPU_TBR_STAC_ENG2\)](#). To provide sequential update of the STAC clients, the Angle tick rate must not be faster than the STAC programmed update rate. This requirement puts a limitation on the angle clock count rate on high rate mode. In this case the Angle and Angle Fraction accumulator (see [Angle Tick Generator](#) and [Figure 37-324](#)) are advanced at rate of eTPU clock divided by eight. Therefore, the STAC update rate for the Angle Bus must not be slower than eight eTPU clocks.

37.15.6.2.6 TCR2 bus in Angle Clock mode

In this mode the TCR2 counter operates as part of the eTPU Angle Counter (EAC). The TCR2 bus value reflects this angle representation in which it counts Angle Ticks. Angle Mode is selected when `eTPU_TBR_TBCR_ENGn[AM]=1`.

Note that when TCR2 works in Angle Mode, it does not count directly from the TCR2 clock input which indicates tooth signal transition. Its Angle counter is controlled by the Count Control and High Rate logic (see [Count Control and High Rate Logic](#)), which provides the interpolated pin position, and handle cases of missing tooth, acceleration, de-acceleration and mechanical corrections.

The EAC uses the TCRCLK signal to get the tooth transition indications. The `eTPU_TBR_TBCR_ENGn[TCR2CTL]` field has to be set for the appropriate tooth edge detection rise, fall, "rise-and-fall" or none. TCR2 count clock comes from the EAC control and not directly from the physical tooth. This way the EAC control processes the signal transitions and handles missing teeth and flywheel mechanical corrections. Note that when TCR2CTL selects "none" for tooth edge selection, the TCR2 is not necessarily frozen, but can still be incremented by the EAC logic.

In Angle Mode, eTPU channel 0, 1 or 2 operation is combined with the EAC operation. When channel 0 is selected for EAC operation, the TCRCLK digital filter is used both by the EAC and by channel 0 to get full synchronization between the two logics.

The eTPU Angle Counter (EAC) logic runs continuously and updates the TCR2 Angle counter, eliminating the microcode latency in updating the TCR2 value.

37.15.6.3 STAC interface

Both time bases TCR1 and TCR2 can be shared between the Engines and with other blocks in the same MCU. Each one of both eTPU engines can drive their time bases to the STAC (Shared Time and Count) bus, acting as a server, while any other block can capture the value into its resources and behave like a client. For further reference about the STAC bus operation see [eTPU Engine 1 STAC Configuration Register \(eTPU_TBR_STAC_ENG1\)](#) and [eTPU Engine 2 STAC Configuration Register \(eTPU_TBR_STAC_ENG2\)](#).

The eTPU can export to the STAC bus or import from the STAC bus the following internal resources:

- TCR1: Can be exported to or imported from the STAC bus. TCR1 can only be imported from STAC bus when the engine is not in Angle Mode. When TCR1 is imported from the STAC bus, it becomes read-only for the microcode and reflects the imported values. For details, see [Timer Count Register 1 - TCR1](#).
- TCR2: Can be exported to or imported from the STAC bus. TCR2 can only be imported from the STAC bus when engine is not in Angle Mode. When TCR2 is imported from the STAC bus, it becomes read-only for the microcode, and reflects the imported values. When exported to the STAC bus, TCR2 can work in either Angle Mode or as a free running counter associated with the TCRCLK signal. For details, see [EAC - eTPU Angle Counter](#).

Proper configuration of the following bits is necessary to determine what can drive the STAC bus: eTPU_TBR_TBCR_ENGn[AM] and eTPU_TBR_STAC_ENGn[REN2, RSC2], according to the following table.

Table 37-356. STAC bus and host read sources

AM (eTPU_TBR_TBCR_ENGn)	REN2, RSC2 (eTPU_TBR_STAC_ENGn)	TCR2 bus source (Host read of eTPU_TBR_TB2R_ENGn)	STAC bus driver
00	0x (disabled)	TCR2/Time	×
01, 10 or 11	0x (disabled)	TCR2/Angle	×
00	11 (Server)	TCR2/Time	TCR2/Time
01, 10 or 11	11 (Server)	TCR2/Angle	TCR2/Angle
01, 10 or 11	10 (Client)	not allowed ¹	

1. STAC client configuration in Angle Mode is also not allowed for TCR1.

Note that Angle Mode is not available for STAC bus clients: configuring both at the same time brings unspecified results and must be avoided. When TCR2 is a stand-alone counter or a STAC Bus server, the same value that is driven to the internal TCR2 bus is also exported to the STAC bus (either Time Count or Angle).

STAC bus configuration is provided by the eTPU_TBR_STAC_ENGn fields REN1/2 and RSC1/2. REN1/2 enable the STAC interface to interact with the resource (either TCR1 or TCR2 bus). RSC1/2 configure the resource (either TCR1 or TCR2 bus) as Server or Client.

Each time base / angle count resource from each engine receives a unique 4-bit hard-wired address that identifies it as a potential server. This address is used by the STAC Controller to coordinate which resource will drive the bus at a given STAC time-slot. For any time-slot there is a server driving the bus upon selection of the STAC Controller, and there may be a client linked to that server by the eTPU_TBR_STAC_ENGn fields bits SRV1/2 on each Engine. When the server address on the Red Line STAC bus matches

the value in SRV1/2, the client will load the STAC information into the appropriate resource. For information on eTPU STAC Bus configuration, see [eTPU Engine 1 STAC Configuration Register \(eTPU_TBR_STAC_ENG1\)](#) and [eTPU Engine 2 STAC Configuration Register \(eTPU_TBR_STAC_ENG2\)](#).

The eTPU does not include a STAC Controller module, which is instantiated once in the system integration.

Note

Setting a timebase as client of itself is not allowed.

37.15.6.4 GTBE - Global Time Base Enable

[GTBE](#) enables time bases in both engines, allowing them to be started synchronously. GTBE is divided in two block interface signals: the eTPU GTBE output and the eTPU GTBE input. GTBE bit sets the eTPU GTBE output, and the eTPU GTBE input enables time bases to start. The eTPU GTBE output signal can be used by MCU integration for synchronization between eTPU time bases and time bases from other modules. If [GTBE](#) must enable only the eTPU time bases, the eTPU GTBE output is simply connected to the eTPU GTBE input. These two cases are shown in the figure below. Synchronization logic can be as simple as an OR logic gate.

Once the eTPU GTBE input transitions to 1, the Engine 1 Time Bases start 1 eTPU clock earlier than Time Bases in Engine 2, except when TCRCLK is selected as clock source or TCR1 when eTPU_TBR_TBCR_ENG n [TCR1CS]=1. This happens independently of prescaler values as long as they are the same for both engines, because the prescalers also freeze when the eTPU GTBE input = 0. Microcode can always write to TCR1/2 registers, with either value of the eTPU GTBE input.

NOTE

The timebase prescalers are reset when the GTBE input is negated.

Figure 37-319. Time base synchronization

37.15.6.5 TCRCLK digital filter

The TCRCLK signal has an improved integrating digital filter with a 2-bit up-down counter. The counter counts up to 3 when a high signal level is detected, or down to 0 when a low level is detected. The signal state is updated to one when the counter stops at 3, or zero when the counter stops at 0. The `eTPU_TBR_TBCR_ENGn[TCRCF]` field (see [eTPU Engine 1 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG2\)](#)) determines whether the TCRCLK signal input (after a synchronizer) is filtered with the same filter clock as the channel input signals (see [Enhanced Digital Filter - EDF](#)) or uses the eTPU clock divided by 2, and also whether the TCRCLK digital filter works in integrator mode or the same two sample mode as the channel filters (see [Table 37-339](#)).

The TCRCLK filter delay and prescaling determines the minimum detectable TCRCLK pulse widths and, therefore, its maximum frequency, as shown in [Filter clock prescaler](#) and [Table 37-355](#). The TCRCLK signal delay from the module input to TCR1/TCR2 incrementing or detection in the EAC logic is explained in [Input/Output Signal Delays](#).

37.15.7 EAC - eTPU Angle Counter

37.15.7.1 General

The EAC logic contains a mechanism which follows the flywheel angle, based on the tooth rate. This hardware works in combination with the TCRCLK signal, the TCR2 counter and Channel 0, 1 or 2 (depending on the eTPU_TBR_TBCR_ENG n [AM] field) to generate angle information on the TCR2 bus which is passed to all the local engine channels. The EAC helps to implement a digital angle PLL (see [Figure 37-323](#)), which combines hardware with microcode processing at channel 0, 1 or 2. The angle measurement is based on history knowledge of the tooth period, for predicting the period of the next tooth. The tooth period is partitioned into a programmable number of **Angle Ticks**. The eTPU application will use the divider in the MAC/Divide unit to calculate an integer and a fraction part of the angle tick such that the full tooth period gets the correct programmed number of angle ticks with no accumulated error.

Each single tooth can be divided in angle ticks, up to 1024. In a 60 teeth flywheel, 128 Angle Ticks per tooth provide resolution of ~0.05 degrees per tick, which meets the accuracy requirement of 0.1 degrees in current automotive applications.

The measurement of one tooth in angle ticks is independent on engine RPM; it is the tooth period itself (and the corresponding tick period) that is re-calculated for each new tooth, based on the difference between the estimated tooth and the actual detection.

For these applications, one of the eTPU channels 0, 1 or 2 is dedicated to service the physical tooth detection. Channel 0 shares the same filtered input as the TCRCLK signal to get the same timing as the EAC. The TCRCLK edge detection is selected by the eTPU_TBR_TBCR_ENG n [TCR2CTL] field for the EAC, and by IPACA/B on channel 0, which must be set to detect the same edge(s). When channels 1 or 2 are selected to work with the EAC, IPACA/B is used to select the tooth signal edge detection for both the channel and the EAC, and the tooth signal that feeds the EAC is the same filtered input which feeds the channel.

Channel 0, 1 or 2 generates the signal transition service request, and can also be used for generation of a window filter on this transition, to qualify TCR2 clocks. For this purpose, the selected channel should be configured with double match window filtering mode (refer to [Channel Modes](#)). Depending on the channel mode set for the channel, Match A recognition opens the window, and Match B recognition may close it or leave it open. See [Angle Logic and Channel Modes](#) for details. Match B also generates a time-out service request. Its input signal transition comes from the tooth. The window can be defined by microcode to open at a predefined point inside the tooth period, and stay open for a desired percentage to the tooth period. The window can be measured in angle or time. This method improves the noise immunity by allowing transition detection only on an expected period, a feature which was software responsibility in previous TPU versions.

The EAC supports deceleration, acceleration, last tooth and missing tooth scenarios. The large range of angle ticks per tooth can be used to cover longer tick counts caused by one or more missing teeth, or to provide extra resolution for future application requirements. In case of a missing tooth, the EAC can be configured to insert a dummy tooth or to simply measure a longer tooth.

Figure 37-324 shows the block diagram of the Angle Counter system. TCR1 or TCR2 prescaler is used as a time base which measures the tooth period and is used for partitioning the period to angle ticks.

37.15.7.2 Angle Mode registers

In Angle Mode, the registers described below control eTPU angle operations. They are accessible only by microengine as source and destination registers in microinstructions. When eTPU is not in angle mode (eTPU_TBR_TBCR_ENGn[AM] field is negated), all Angle Mode registers can be used as general purpose registers.

37.15.7.2.1 TPR - Tooth Program Register

TPR provides configuration for the Angle Counter circuit. In this register, the microcode can properly adjust the tooth count (controlling last tooth, missing teeth, dummy tooth insertion, halt until tooth detection) and the number of angle ticks per tooth (field TICKS). Note that this register is sampled into a temporary register in the EAC logic when the High Rate Mode is detected (see High Rate Mode (Acceleration) and TPR Buffering), which means that changes to this register may take effect only for the next tooth.

See Count Control and High Rate Logic and to Special Cases of Missing Teeth and Last Tooth until Handling False Tooth Detection for a detailed explanation about the use of this register. The figure below provides a detailed description of TPR register.

Several conflict issues on TPR writes are explained in Special TPR write cases.

Figure 37-320. TPR

LAST —Last Tooth Indication
Asserted by microcode and negated when a tooth is detected or inserted via IPH.

Table continues on the next page...

1 = Last Tooth - reset TCR2 Counter at the end of the tooth tick count (after physical tooth or IPH=1) when MISSCNT=0.

0 = Not Last Tooth.

If the tooth is detected or inserted before the tooth tick count completes (going High Rate mode, see [High Rate Mode \(Acceleration\)](#)), LAST resets immediately, but TCR2 resets only when the tooth count completes and MISSCNT=0.

MISSCNT — Missing Tooth Counter

Decrement on each estimated tooth, stops at zero. Used for generation of up to 7 "Dummy Teeth" whenever it holds a non-zero value.

If the tooth is detected or inserted before the missing tooth tick count completes (going High Rate mode, see [High Rate Mode \(Acceleration\)](#)), MISSCNT resets immediately, but missing teeth count continues in High Rate mode (see [TPR Buffering](#)).

IPH — Insert Physical Tooth

This bit generates a dummy physical tooth which has the same effect as a real physical tooth, and resets itself subsequently. If EAC is in Halt mode, it switches back to Normal mode¹. If EAC is in Normal Mode, it switches to High Rate Mode. If Angle Logic is frozen by HOLD=1 (see below), it returns to the state it was at the freezing moment.

1 = Insert dummy physical tooth.

0 = No Operation.

Note: IPH reads as 1 in the next microinstruction after it is asserted, negating subsequently. However, it can be set twice in two consecutive microinstructions to generate two teeth and make the EAC go from Halt to Normal to High Rate Mode.

HOLD — Force EAC Hold

This bit forces the EAC to halt its operation in a special EAC freeze mode until a new physical tooth (a real one or emulated with IPH=1) is detected. Assertion of this bit immediately freezes the EAC in the middle of the tooth period. When a new physical tooth is detected, the bit is automatically negated by the EAC. The HOLD bit can be used for synchronizing the EAC tooth count, in case that a false physical tooth is detected due to noise.

1 = Force EAC to halt until detection of a physical tooth.

0 = Normal Operation.

TICKS — Angle Ticks Number in the Current Tooth

This field defines the number of angle ticks in the current physical tooth. It partitions the tooth period to the required number of angle ticks. The actual number of angle ticks in a tooth is (TICKS+1).

Note: In High Rate mode (see [High Rate Mode \(Acceleration\)](#)), TPR writes are immediately effective only for bits IPH and HOLD. All other fields changes are "buffered" and become effective when EAC leaves High Rate mode. See also [Special TPR write cases](#).

Note: Bits LAST, IPH and HOLD must not be asserted all at once

1. Missing a physical tooth naturally causes EAC to get into Halt mode.

37.15.7.2.2 TCR2 - Timer Counter 2

In Angle Mode, TCR2 (see the following figure) counts angle ticks instead of time.

Functional description

Figure 37-321. TCR2 in Angle Mode

This 24-bit free-running counter is used to generate an accumulated Angle Fraction value. It is updated by the Angle Tick Generator - refer to [Angle Tick Generator](#) for more details. Refer to [Count Control and High Rate Logic](#) for a detailed explanation about the use of this register in Angle Mode.

TCR2 provides continuous count of the angle in units of angle ticks. The Angle Tick Counter in TCR2 can be reset due to "Last Tooth" microcode indication. TCR2 Prescaling is disregarded in Angle Mode: physical tooth detection is done by EAC regardless of the value set in TCR2P.

37.15.7.2.3 TRR - Tick Rate Register

The exact period of the Angle Tick is programmed in the Tick Rate Register (see the figure below) by microcode. The TRR time unit depends on eTPU_TBR_TBCR_ENG n [ATGC] (see [Figure 37-324](#)):

- if ATGC=0, the TRR time unit is the period of TCR1 clocks taken as eTPU clocks divided by $2 \cdot (\text{TCR1P} + 1)$, even if TCR1CS=1 (see [eTPU Engine 1 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG2\)](#)).
- if ATGC=1, the TRR time unit is given by the eTPU clock divided by $2 \cdot (\text{TCR2P} + 1)$, using the TCR2 prescaler fed by eTPU clock/2 (independently of TCR1CS).

See [Calculating the Angle Tick Period Integer and Fraction](#) for a complete description about the mechanism to calculate the value to be written into this register.

Figure 37-322. TRR

INTEGER — The integer part of TCR1/TCR2 clocks in one Angle Tick.

This number, decremented by one, works as a down-counter preload value. A value of INTEGER=0 represents an integer of 32768. A new value written is reloaded into the counter (becoming effective) when a new tick starts or a tooth is detected or inserted via IPH.

FRACTION — Nine-bit fractional part of TCR1/TCR2 clocks in one angle tick.

The FRACTION value is accumulated in the EAC Fraction Accumulator, and whenever the result overflows (i.e., the accumulated fraction added up to an integer), the Tick Prescaler is halted for one TRR time unit.

Figure 37-323. EAC "PLL"

Figure 37-324. eTPU angle counter system

37.15.7.3 Acceleration and Deceleration

Acceleration and deceleration affect the new tooth period relative to the known period of the last tooth. Changes in tooth period may be extreme at very low engine RPM (such as cold start and warm start). The worst case of tooth period changes is caused during missing teeth, since there is more time for changes in angular velocity to be unnoticed by the EAC hardware. For example, on cold start (~20 RPM) there may be extreme acceleration: the ratio between a known tooth period before two missing teeth and the new tooth period after the missing teeth can be very high (up to a factor of 75). Acceleration and deceleration effects from tooth to tooth are less extreme as the engine climbs to high RPM.

In case of deceleration, the estimated tooth period ends before the actual tooth detection arrives. In this case, the EAC hardware waits at the end of the current tooth period, when it is said to be in **Halt mode**, until the real tooth indication is received, then continues with normal operation (**Normal mode**). See [Figure 37-323](#).

In case of acceleration, the actual tooth period is shorter than the estimated tooth period. As a result, a new physical tooth indication arrives before the end of the estimated tooth period. In this case the EAC closes the gap on **High Rate mode** by counting on eTPU clock divided by eight to the end of the tooth, advances to the next tooth, and switches back to normal operation mode. See [Figure 37-323](#).

The reason that the EAC does not jump directly to the next tooth is the need to provide sequential angle count throughout the whole tooth period, for channels or external STAC clients (if TCR2 is a STAC server) which compare angle in "equal" mode. These peripherals must get all the valid angle values in a sequential manner, to avoid missing angle matches.

TCR2 advancing from one tooth to another is a continuous count, and can be optionally reset at the end of the tooth. An estimated tooth is generated after the Tooth Tick Counter reaches the TICKS programmed value.

The EAC works continuously and switches automatically between Normal, Halt and High Rate modes. It relies on the microcode to calculate the estimated tooth period on every tooth, and to update the correct angle tick and tooth parameters in the EAC control registers. On high RPM, tooth period changes are reduced from tooth to tooth, and the EAC may follow the angle with good accuracy for several teeth without microcode intervention.

The EAC handles missing teeth by insertion of "dummy" teeth, or by enlarging the expected tooth period. It is a good practice to locate the flywheel missing teeth in non-critical angles, since a missing tooth may increase the angle measurement error (acceleration and deceleration is detected late).

37.15.7.4 Angle Tick Generator

The Angle Tick Generator is responsible for generating a programmed number of angle ticks in the tooth period. It generates the ticks in an average rate which ensures completion of the correct number of angle counts in the estimated period of the tooth, since the count of one tooth in angle ticks is independent on engine RPM. The main output of the Angle Tick Generator is the tick clock that feeds TCR2 in Angle Mode, as well as the internal Tooth Tick Counter (see [Figure 37-324](#)). The Tooth Tick Counter counts ticks within a tooth, from 0 up to TICKS, is controlled by the Angle Tick Generator logic and cannot be accessed by microcode. Refer to [Figure 37-325](#) for a generic presentation of the angle tick count and the measurement of a single tooth period.

37.15.7.4.1 Calculating the Angle Tick Period Integer and Fraction

On each tooth the microcode has to update the exact period of a single angle tick used for counting the internal angle in the tooth. The period of an angle tick is determined by the EAC configuration, see [Generating the angle ticks](#) for details.

The microcode can use the eTPU MAC Divider unit (see [MAC and Divide Unit \(MDU\)](#)) to divide the tooth period by the number of angle ticks per tooth, which is stored in the TICKS field of TPR (refer to [Angle Mode registers](#)). This division yields the integer part of the angle tick period and the remainder. Dividing again the remainder shifted left nine positions, by the number of angle ticks per tooth translates the remainder to a 9-bit fraction. The microcode concatenates the 15-bit integer and the 9-bit fraction to a 24-bit value and writes it to TRR. The new rate is effective immediately after the next Angle Tick is generated by the Angle Tick Generator³¹.

For high RPM, note that shifting the tooth period value nine positions to the left prior to the first divide operation would calculate, in one operation, the integer and the fraction. For example: On 60 teeth flywheel running at 1000 RPM, tooth period is 1 msec. If TCR1/TCR2 counts @25 MHz, it counts 25,000 times in a tooth, which can be represented by 15 bits. Therefore the tooth period can be shifted nine positions to the left prior to divide operation, and be represented with 24 bits.

Using shift left nine positions and one divide operation would get the result in MACL register (in MDU) which holds the integer and nine bits of the fraction:

```
Angle_Tick_Rate {Integer[14:0], Fraction[8:0]} = (ToothPeriod <<9) / Ticks
TRR = Angle_Tick_Rate {Integer[14:0], Fraction[8:0]}
```

31. In High-rate mode, the tick keeps being updated at the rate of eTPU clock/8 until it goes back to Normal mode, when the new TRR value is used.

NOTE

In the pseudocode above, the tooth period (ToothPeriod) is not, in general, the value of estimated tooth time. It is obtained by microcode by subtracting TCR1 values between two teeth detections, converted to TCR2 periods if ATGC=1. Its comparison with the estimated tooth time indicates acceleration (if minor) or deceleration (if greater) to the microcode.

On low RPM the initial tooth period, measured in TCR1/TCR2 counts, may be too big to be shifted nine positions to the left. For lower RPM (for example 500 RPM) the tooth period cannot be represented by 15 bits, and shifting it nine positions to the left would lose the MSB. In this case, two divide operations are required as follows: first divide the Tooth Period by the number of TICKS - the integer is stored in MACL and remainder in MACH. MACL is saved in another register. MACH is shifted 9 positions to the left and divided again by TICKS. In parallel with the second divide, the register which saved the original MACL is shifted left 9 positions. After the divide MACL contains the 9 bits fraction and the other register contains the 15-bit integer, shifted left nine times. The logical OR of the two registers is written to the TRR:

```
Angle_Tick_Rate {Integer[14:0]} = (ToothPeriod) / Ticks
Remainder[9:0] = (ToothPeriod) mod Ticks
Angle_Tick_Rate {Fraction[8:0]} = (Remainder[9:0] << 9) / Ticks
TRR = Angle_Tick_Rate {Integer[14:0], Fraction[8:0]} = (Integer[14:0] << 9) | Fraction[8:0]
```

Figure 37-325. Angle Ticks Generation

37.15.7.4.2 Generating the angle ticks

The integer part of TRR is preloaded to a prescaler, which counts in time intervals as follows (see [Figure 37-324](#)):

- If $\text{eTPU\_TBR\_TBCR\_ENGn[ATGC]}=0$, one unit of TCR1 clock period (if $\text{TCR1CS}=0$) or twice the TCR1 clock period (if $\text{TCR1CS}=1$)³², that is, $\text{eTPU clock period} \times 2 \times (\text{TCR1P}+1)$ (independently of TCR1CS).
- If $\text{ATGC}=1$, two units of the eTPU clock period multiplied by the TCR2 prescaler factor, that is, $\text{eTPU clock period} \times 2 \times (\text{TCR2P}+1)$.

When the down counter reaches zero, it generates an angle tick pulse to the Angle Counter Logic and a Load pulse to the Fraction Accumulator. It is then preloaded with most updated TRR integer part. Due to the Load pulse, the 9-bit fraction is accumulated in a 9-bit Fraction Accumulator. If a fraction overflow condition occurs (the 9-bit adder asserts carry out), the accumulator saves the lower 9 bits of the addition result, which is the remaining fractional part. The carry out bit indicates an accumulated integer "one" which means that the angle tick is early by one input clock. It halts the prescaler operation for one input clock to compensate the accumulated error generated by the integer prescaler. As a result, the average angle tick period takes into account both the integer and the fraction parts. The accuracy depends on the bit count of the fraction. Using 9-bit fraction part while the width of the field TICKS in register TPR is 10 bits provides accuracy of two LSB on a full scale ($\text{TICKS}=1023$) or one LSB on lower scale ($\text{TICKS} \leq 511$).

When the Tick Prescaler gets High Rate mode indication from the Angle Counter Logic, it generates angle ticks at a rate of eTPU clock divided by eight. In this case it does not generate Load pulses to the Fraction Accumulator, ignores its "hold" input and preloads internally to a fixed period of eight eTPU clocks. When High Rate mode is entered, the prescaler is preloaded to a period of eight eTPU clocks before its first angle tick generation, ensuring separation of at least eight eTPU clocks between the last Normal mode angle tick and the first High Rate mode angle tick. The fraction accumulator resets when the tick count advances to the next tooth, or when TRR is written by the microcode.

37.15.7.5 Count Control and High Rate Logic

The Count Control and High Rate Logic controls TCR2 operation in Angle Mode, using the angle ticks generated by the Angle Tick Generator. Count Control logic is responsible for advancing, holding and resetting the TCR2 and Tooth Tick Counter in the proper timing, such that the TCR2 time base will reflect the correct estimated angle. This logic also includes the Tooth Program Register (TPR, see [Angle Mode registers](#) for more information).

32. The EAC logic overall runs at a rate of eTPU clock divided by 2, therefore the tick generator takes the halved TCR1 clock when $\text{TCR1CS}=1$ and $\text{ATGC}=0$.

The Count Control and High Rate Logic handles deceleration, acceleration, missing teeth and last tooth. On High Rate (acceleration) it ensures that the angle bus scans all valid angle values in a rate which can be traced by the STAC bus. This operation enables external STAC clients (if TCR2 is a STAC server) or channels working in "equal-only" comparator mode to match the TCR2 exported angle information in "equal" mode, in an exact match.

Because the eTPU channels are capable of capturing either TCR1 or TCR2 due to signal transition, the microcode can get either the angle or time of the physical pin transition. Since the EAC channel (0, 1 or 2) is connected to the physical tooth, the microcode can get the EAC error in angle domain (tooth appears at the wrong angle) or time domain (physical tooth captured time into the EAC channel, relative to the estimated tooth time). Note that in angle mode, the transition detect logic of the channel 0, if selected as the EAC channel, is fed from the digital filter of the TCRCLK signal, and not from the channel 0 internal digital filter. This ensures synchronous operation of channel 0 and the EAC hardware.

Another feature of the eTPU channel, when working in Single Match And Single Transition Enhanced Mode (refer to [Single Match Enhanced Mode \(sm_st_e\)](#)), is capturing a single time base due to signal transition before and after the digital filter. This option allows subtracting the digital filter delay to get accurate signal transition timing on the channel. This way, the TCRCLK signal may be programmed with a slow and reliable digital filter, and get accurate time measurement of the digital filter delay.

To assert the end of the estimated tooth period the Count Control and High Rate logic compares the TICKS field in TPR (refer to [Angle Mode registers](#)) with the current value of the tooth tick counter. When the Tooth Tick value is greater or equal to TICKS, it determines the end of the estimated tooth period. On acceleration this event occurs during High Rate mode operation, after the arrival of a physical tooth. In deceleration, this event occurs during Normal Mode, before the arrival of a physical tooth. On constant angular velocity, this event appears together with the arrival of a physical tooth.

The following sections describe the operation of the Counter Control and High Rate logic.

37.15.7.5.1 Normal Mode

In Normal mode the Counter Control logic advances TCR2 and the Tooth Tick counter as if the engine has a constant speed during the tooth period. It receives the angle ticks from the Angle Tick Generator in an average rate which is determined by the Tooth Rate Register (TRR). This is the reset mode.

When the Tooth Tick Counter is about to reach the last value effectively stored in TPR field TICKS plus one, the hardware detects the end of the estimated tooth period. If the physical tooth and the estimated tooth arrive at the same time the EAC stays in Normal mode, the Tooth Tick Counter is reset, and TCR2 is incremented (depending on TPR bits LAST and MISSCNT). If the physical tooth and the estimated tooth do not arrive at the same time, either acceleration or deceleration is detected, and the EAC switches to the proper mode. See the figure below for a detailed diagram of Normal Mode behavior.

The microcode which services the EAC channel physical tooth transition may update TRR according to various conditions to give the best estimation of the current tooth period, according to the previous tooth period and other engine parameters.

Figure 37-326. Normal Mode

37.15.7.5.2 Halt Mode (Deceleration)

In case of deceleration, the Tooth Tick Counter reaches the TICKS value before the arrival of the next tooth. The Count Control logic does not reset neither advances TCR2 and Tooth Tick Counters. The Count Control logic halts TCR2 and Tooth Tick Counters at the end of the tooth, waiting for the physical tooth to arrive.

When the physical tooth is detected the EAC switches back to Normal Mode and releases TCR2 to count the angle ticks of the new tooth, also resetting the Tooth Tick Counter. Only then TCR2 may wrap to 0, if TPR bit LAST is asserted. See the figure below for a detailed diagram of Halt Mode behavior.

The microcode service caused by the physical tooth determines the deceleration, calculates the new tooth period and Angle Tick period and updates TRR. This operation slows the angle tick rate generated by the Angle Tick Generator on-the-fly, to the rate required for the new tooth period.

Since the microcode service is initiated by the physical tooth edge, microcode latency may introduce a small angle error caused by using the TRR value of the previous tooth at the beginning of the current tooth. On high RPM, deceleration is relatively small but the microcode latency may take a significant percentage of the tooth period. On low RPM microcode service latency takes little percentage of the tooth period, but there may be cases of extreme acceleration and deceleration. The microcode latency can be calculated knowing TCR1 value during the service time, and TCR1 value captured in the EAC channel due to the physical tooth pin transition. The duration of the Halt mode is obtained using the estimated tooth time.

Figure 37-327. Halt Mode - Deceleration

37.15.7.5.3 High Rate Mode (Acceleration)

In case of acceleration, the next tooth arrives before the Tooth Tick Counter reaches the TICKS value. In this case the High Rate logic is responsible for closing the gap and advancing the tooth on the correct timing. The High Rate mode operates as follows:

- When the acceleration is detected (physical tooth arrives before the Tooth Tick Counter reaches the TICKS value), the Count Control and High Rate logic switches to High Rate mode in which both the Tooth Tick Counter and TCR2 count at rate of

eTPU clock divided by eight, until the Tooth Tick Counter reaches the current TICKS value. To ensure correct operation, the TICKS value is sampled in the logic at the beginning of the mode.

- At this point, which represents the estimated tooth edge, the logic resets the Tooth Tick Counter and advances TCR2 (or resets it if LAST is asserted and MISSCNT = 0).
- The control logic switches back to Normal Mode, using the most updated TRR value as input to the Angle Tick Generator. The logic samples the updated TICKS value for the tooth estimation, last tooth indication and number of missing teeth from TPR.

In High Rate mode the angle ticks are provided at high speed until the end of the current tooth. This operation is required to scan all the valid angle values of the current tooth, in a rate which is not too high for the STAC bus continuous update, but much higher than the rate dictated by TRR.

EAC channel microcode, which services the physical tooth transition detection, can start its service either before High Rate mode operation is complete (the Tooth Tick Counter has not reached the TICKS value) or after the EAC switched back to Normal mode. Any physical teeth received while the EAC is in High Rate Mode does not alter the immediate EAC state, but it is still detected by the EAC channel logic and can, therefore, alter future EAC behavior (for instance, closing the tooth detection window - see [Angle Logic and Channel Modes](#)).

At the beginning of High Rate mode operation, the TPR value is preloaded into a temporary register in the Counter Control Logic, used for scanning all the valid values to the end of the current tooth, with its appropriate LAST and MISSCNT attributes. While the EAC is in High Rate mode operation, the effect of microcode update of TPR fields LAST, MISSCNT and TICKS is delayed to the next estimated tooth, after the High Rate mode operation is complete (see [Special TPR write cases](#)). This is because the current physical tooth represents the next estimated tooth. If the microcode updates this field after High Rate mode operation is complete, the current physical tooth and estimated tooth are the same, and the effect is immediate. Either in High-Rate mode or not, the value read by microengine is the same written, even if not yet effective, until the EAC resets LAST and/or IPH, or decrements MISSCNT. Typically the microcode service may occur during the High Rate mode on extreme acceleration situation at low RPM. Therefore, the microcode operations are always related to the real physical tooth. From the above it can be seen that the microcode updates of the TICKS field in TPR affect the end time of the current physical tooth. For correct operation, this field should be updated before the Tooth Tick Counter has reached either the old or the new TICKS value.

During High Rate mode operation, TRR is ignored and the Angle Tick Generator uses eTPU clock divided by eight. Therefore, the TRR update by microcode will take effect only after the EAC switches back to Normal mode. If microcode service occurs after the Tooth Tick Counter has been reset, the EAC is already back in Normal mode, and some angle ticks may have been counted at the rate of the previous tooth. In this case the new TRR value will have immediate effect on the angle tick period, and the microcode should take into consideration the delay from the physical tooth to the estimated tooth in calculation of the next tooth period. See the figure below for a detailed diagram of High Rate Mode behavior.

An angle error may be introduced by the duration of the High Rate mode. Also, the scheduler latency may introduce a small accumulated error by using TRR value of the previous estimated tooth at the beginning of the current tooth. After the estimated tooth has advanced, the duration of the High Rate mode operation is the actual delay from the physical tooth edge to the estimated tooth edge. This delay can be obtained by comparing the estimated tooth time with the EAC channel capture register which captured TCR1 on the physical pin transition.

Figure 37-328. High Rate Mode - Acceleration

37.15.7.6 Special Cases of Missing Teeth and Last Tooth

The EAC handles cases of up to three missing teeth and the last tooth in the engine cycle. The following paragraphs describe these functions.

37.15.7.6.1 Handling the Last Tooth

The microcode can set the TCR2 counter to work in engine periods (wrap-around count) or continuous angle measurement.

For periodic operation, during the last engine cycle tooth the EAC microcode has to set the LAST flag in TPR. As a result, when the tooth period is ended, the Counter Control Logic generates a reset command to both the Tooth Tick Counter and TCR2 instead of an advance command. The operation resets the TCR2 based angle count, indicating a new period of the engine cycle. This implementation provides an engine cycle based periodic angle measurement.

37.15.7.6.2 Handling Missing Teeth

The EAC can handle up to three missing teeth in two ways:

- Count the angle ticks relative to the last physical tooth. The microcode should update the TPR TICKS field to the number of angle ticks included in two, three or four teeth, according to the flywheel type (one, two or three missing teeth). EAC hardware works in its regular manner.
- Insert a "dummy" tooth instead of the missing tooth, at the estimated point in time. After the "dummy" tooth, the Angle Tick Counter is incremented as if there was a physical tooth. A "dummy" tooth can be inserted only during Normal or High Rate operation modes. The microcode inserts "dummy" teeth by writing to the MISSCNT field in TPR.

In the first option the missing tooth is not counted on the angle measurement. For example, a flywheel with 59 physical teeth and one missing tooth can be considered as 58 identical teeth numbered (0-57) and tooth number 58 has a double number of angle TICKS. In this case a 720 degrees engine cycle has 118 teeth. TCR2 reflects the real angle, since it counts angle ticks continuously.

In the second option, the missing teeth are counted as "regular" teeth by automatic insertion of "dummy" teeth. The microcode has to write a non-zero value to the MISSCNT field in TPR. This field is a 3-bit down counter which affects the operation of the Counter Control logic.

For example, a flywheel with 59 physical teeth (0-58) and one missing tooth (59) can be considered as 60 teeth numbered (0-59), all having the same number of angle ticks. The microcode has to write "001" to the MISSCNT bits during the period of tooth number 58 to indicate that next tooth (59) is missing.

When the Tooth Tick Counter reaches the TICKS value, TCR2 is incremented as if a physical tooth has been detected. In addition, the MISSCNT value initializes a "dummy tooth counter" which is decremented to indicate the number of left "dummy teeth" which still need to be generated. Because a dummy tooth was counted, EAC does not enter Halt Mode and Tooth Tick Counter continues incrementing in the absence of a physical tooth detection.

In case of extreme acceleration on very low RPM (cold start) there can be a situation that the first physical tooth after one or two missing teeth appears even before the "dummy" tooth is generated. Due to the acceleration the EAC switches to High Rate mode in order to run through all the valid angle values, including the dummy teeth. When the Tooth Tick Counter reaches the TICKS value on High Rate mode, and the "dummy tooth" down counter is not zero, the generated "dummy tooth" advances to the next tooth and decrements the "dummy tooth" counter, but does not switch the EAC back to Normal mode. The last "dummy tooth" decrements the counter to zero, indicating that no more dummy teeth are to be inserted, and the next tooth is an estimated physical tooth. The EAC continues at High Rate mode until the Tooth Tick Counter reaches the TICKS value again, then advances to the next tooth while switching back to Normal mode. When in High Rate mode, the TPR register does not reflect the MISSCNT downcounting, see [TPR Buffering](#) for details.

MISSCNT can be rewritten before it reaches 0, allowing it to count more than 7 missing teeth, as long as no physical tooth arrives between the first MISSCNT write and the rewrite.

37.15.7.6.3 Combining Missing Teeth and Last Tooth

The Last Tooth indication takes effect when there are no more missing teeth to be generated, i.e the "dummy tooth" counter value is zero. If, for example, the microcode sets the missing teeth counter to "10" (two missing teeth) and sets the LAST flag, the first and the second dummy teeth will increment TCR2, and the third estimated tooth, which correlates with the physical tooth (the first of the next cycle), will reset TCR2, because LAST was set. This scheme enables the microcode to define one or more missing teeth to be replaced by "dummy tooth" insertion, and the end of the engine cycle in one service request. It is assumed that the two missing teeth must come together in the same engine cycle, and not split between two engine cycles (either the missing teeth are both last in an engine cycle or both not last, but not last in one engine cycle and first in the next).

Figure 37-329. Missing Teeth and Last Tooth Combination

37.15.7.7 Handling Mechanical Tooth Correction

The EAC can handle tooth edge detection errors caused by flywheel mechanical errors. The eTPU application can hold a vector of tooth mechanical errors with one entry per tooth. This error can be measured in angle ticks which are independent of engine RPM. The TRR can be updated to the fixed period of any tooth, including its mechanical error.

Because TCR2 counts continuously, without being reset, the mechanical correction is transparent. Though the tooth has its own programmed TICKS value, TCR2 simply counts angle ticks, disregarding the boundary between two adjacent teeth.

37.15.7.8 Handling Mis-detected Tooth

When a physical tooth signal is missed by the engine sensor, the EAC may get into Halt mode at the end of the estimated tooth period, expecting the physical arrival. In this case, a Match timeout event of EAC channel will call service which detects extreme deceleration. The microcode can assert the IPH bit in TPR, to force the detection of the missed physical tooth. It can also calculate the accumulated angle bus error, and fix the next estimated tooth period, to close the gap.

37.15.7.9 Handling False Tooth Detection

Most of the false tooth detection, caused by noises on the engine tooth sensor, can be eliminated by the window blanking filtering, timed by EAC channel match recognitions. The EAC also provides means of fixing false detection of an additional tooth which passed the window filter. When such an event occurs, the EAC switched to High Rate

mode (advancing to the next tooth) and when the next physical tooth arrives, an extreme acceleration is detected: the EAC sees the remaining portion of the current tooth period as another tooth period. The microcode can detect the situation when the acceleration is not realistic, or when immediately after the detection of this extreme acceleration, the following tooth indicates extreme deceleration back to the original RPM.

When the microcode detects such a case, the Tooth Counter has been advanced by mistake to the next tooth. The microcode can set the HOLD bit in the TPR, forcing the EAC to freeze and wait for the next physical tooth to close the gap. When the next physical tooth arrives, HOLD is automatically negated and the EAC proceeds from that point to the remaining portion of the tooth period, in the same mode it was when HOLD bit was asserted.

37.15.7.10 Angle Logic and Channel Modes

The TCRCLK transition detection is qualified by a signal that comes from channel 0 (see [Figure 37-324](#)) and depends on the particular mode (PDCM) programmed for that channel. This configures a window for TCRCLK detection for the angle logic which is the same (except on High Rate mode, see [High Rate Mode \(Acceleration\)](#)) used to set the TDLA flag on single transition modes, and TDLB on double transition modes (see signals TSE1, TSE2 in [Figure 37-307](#)). The same applies when channels 1 or 2 are used to control EAC (see signals TS1, TS2 in [Figure 37-307](#)). As a consequence, the window depends on the channel mode as follows:

- on all modes, the window closes upon a tooth edge detection: TDLA asserted on single transition modes, TDLB asserted on double transition modes.
- on mode m2_st: the window opens on Match A (which enables Transition A) and does not close with Match B. If Match B comes before Match A, it blocks Match A and, hence, Transition A.
- on mode m2_o_st: the window opens on Match A (which enables Transition A) and closes on Match B. Match B is enabled by Match A, so it cannot come before.
- on all other Single Transition modes, the window is "always open", independently of matches.
- on mode m2_dt: the window opens on Transition A, which is enabled by Match A. The window does not close with Match B, but if it comes before Match A the later gets blocked and, hence, blocks Transitions. Match A is also a condition for the window, so the microcode closes it by clearing MRLA.

- on mode m2_o_dt: the window opens on Transition A, which is enabled by Match A. The window closes on Match B, which is enabled by Match A. Match A is also a condition for the window, so the microcode closes it by clearing MRLA.
- on all other Double Transition modes, the window opens on Transition A.

37.15.7.11 Restarting angle logic

It is not recommended to change the eTPU_TBR_TBCR_ENGn[AM] field while GTBE=1. However, if the angle logic must be restarted without interfering with the timebase count running on TCR1, the procedure below must be followed:

1. Program eTPU_TBR_TBCR_ENGn[AM]=00 and TCR2CTL=111 at once. That prevents TCR2 from incrementing while the angle logic is disabled. The angle logic state machine resets to Normal mode and the tick prescaler to the initial count with AM=00, but not the microengine registers TPR and TRR.
2. Start a thread to reconfigure the EAC. The thread must set the EAC controlling channel (0, 1 or 2) flags in a state, depending on the channel mode, that lets the channel tooth detection window open (see [Angle Logic and Channel Modes](#)). It can optionally write TCR2 with an angle preset value equivalent to the first tooth expected after restart. The thread must also set TPR bit HOLD=1. The TPR bit IPH must be 0.
3. After the thread is finished, program eTPU_TBR_TBCR_ENGn[AM]=01, 10 or 11, and TCR2CTL according to the desired tooth edge selection if AM=01.

The first tooth detected after this procedure restarts the TCR2 counting, unfreezing the Angle Mode logic into normal mode.

37.15.7.12 Special TPR write cases

This section describes how simultaneous modification of TPR fields are resolved, and how the effect of TPR writes depend on the EAC mode.

37.15.7.12.1 TPR Buffering

In High Rate mode (see [High Rate Mode \(Acceleration\)](#)), TPR writes are immediately effective only for bits IPH and HOLD. Writes to all other fields are "buffered" and become effective when EAC leaves High Rate mode. However, if TPR is written a

second time right after IPH is asserted in Normal mode, this second write behaves as if EAC is still in Normal mode. Only in the next microcycle (after execution of a nop, for instance) the TPR writes are buffered, acknowledging High Rate mode.

MISSCNT and LAST can be written any value during High Rate mode, and the value that prevails for the next tooth is the one sampled when EAC goes back to Normal mode (or the value written in Normal or Halt mode thereafter). If MISSCNT and/or LAST are not zero when High Rate mode begins, they are sampled into the internal EAC logic and are effective while High Rate lasts (missing teeth count continues, and TCR2 is reset at the end of High Rate if LAST=1). However, their values in TPR are reset when High Rate mode starts. After that and until the end of High Rate mode, the value read by microcode is the same written. This behavior prevents read-modify-writes to TPR from unwillingly rewriting LAST or MISSCNT.

37.15.7.12.2 IPH and LAST

If both IPH and LAST are asserted in the same microinstruction with HOLD=0, the EAC acts as if LAST was set first and then IPH right after, so that:

- in Normal mode, it goes to High Rate with LAST=1;
- in Halt mode, it goes to Normal Mode resetting LAST (and TCR2);
- in High Rate mode, IPH is ignored and LAST becomes effective in the next tooth (physical or inserted) after it goes back to Normal mode.

37.15.7.12.3 IPH and TICKS

Because of different results depending on the EAC mode at the time of TPR write, it is not advisable to write 1 to IPH and change TICKS at the same microinstruction. A consistent behavior is obtained if IPH is written first and TICKS on the second microinstruction after (for instance with a nop between them), making the new TICKS value valid for the next tooth regardless of the mode.

The mode-dependent behavior is (assuming HOLD=0):

- in Normal mode, the new TICKS value becomes valid before EAC goes High Rate due to the IPH;
- in Halt mode, the EAC goes to Normal mode, and new TICKS is valid for the next tooth;
- in High Rate mode, the new TICKS value is effective when EAC leaves High Rate mode, and IPH is ignored;

37.15.7.12.4 IPH and MISSCNT

If both IPH and MISSCNT are written non-zero values with HOLD=0:

- in Normal mode, at the next microcycle the EAC goes to High Rate mode, the MISSCNT field in TPR goes to 0, and the missing teeth are counted in High Rate mode.
- in Halt mode, the EAC goes to Normal mode for one microcycle and then, yet another microcycle later, goes to High Rate mode, counting the missing teeth. The TPR fields IPH and MISSCNT are zeroed on the transition from Normal to High Rate mode.
- in High Rate mode, IPH is ignored (resetting at the next microcycle) and MISSCNT is buffered (see [TPR Buffering](#)).

37.15.7.12.5 IPH and HOLD

If IPH and HOLD are asserted at once, IPH cancels the HOLD and both reset. The EAC is not frozen, regardless of the EAC mode (High Rate, Normal or Halt).

37.15.7.12.6 LAST and HOLD

If LAST and HOLD are written 1 at once, LAST asserts and EAC is frozen. Afterwards, when a physical tooth is detected or IPH is asserted, the EAC is unfrozen in the same state it was before, and LAST is kept asserted.

37.15.8 Microengine

Each eTPU engine has a microengine that fetches, decodes and executes microinstructions. The Microengine only works when there are service requests to be attended, otherwise it turns to idle state, controlled by Hardware Scheduler (see [Scheduler](#)).

Microcode is stored in Shared Code Memory (SCM) that is 32-bit wide. Microengine can access SCM using a different bus from the one used to access code memory, so that code and data can be accessed at the same time (Harvard Architecture).

Some of eTPU functionality can only be made through the microengine, like configuring channels and interrupting host. Microengine gives eTPU a high degree of flexibility, since any desired treatment for channel's events can be implemented; however, that

flexibility comes at the cost of channel service's latency. Latency is worsened when channels from a same eTPU engine contend for microengine service. In the figure below, a block diagram of microengine architecture is shown.

Follows a summary of Microengine features:

- P, DIOB, A, B, C, D, SR, RAR, LINK, CHAN, MACL, MACH, ERTA, ERTB, TCR1, TCR2, TPR, TRR registers are accessible by microcode.
- 24-bit ALU and Post-ALU shifter performs basic arithmetic and logical operations described in [ALU and Post-ALU Shifter](#).
- MDU (MAC/Divide Unit) performs integer MAC, multiply and divide operations.
- Fixed Microinstruction Size of 32bits.
- Fixed-length instruction execution (2 eTPU clocks)
- Static superscalar operation

Figure 37-330. Microengine Block Diagram

37.15.8.1 Registers

eTPU microengine accesses a total of 18 registers. Fourteen of them are special purpose (registers A, B, C and D are for general use). Special purpose registers except CHAN and LINK can also be used as general use if the operation that use their contents are not performed. Register description is intended to just introduce their functionalities and not to provide detailed explanation of it since it will be described in [Microinstruction Set](#). Registers less than 24 bits in size are right-justified.

None of the registers have guaranteed reset values. However, some are initialized just before the thread starts (see [Time Slot Transition](#)).

37.15.8.1.1 P Register

P register is the only one that is 32-bit wide. It can be used as source and destination for arithmetic/logical operation, and as source and destination for SDM read/write operations.

For P source/destination possibilities in ALU/MDU microoperations, see [Selecting sources and destination](#).

When P is used as SDM read/write operations source or destination there are only 3 possibilities of access: all 32 bits, lower 24 bits and upper 8 bits. SDM operations are explained in detail in [SDM Microoperations](#).

P is automatically loaded with one parameter before the thread starts (parameter preload). For more information see [Entry Point format](#) and [Time Slot Transition](#).

Upper 8 bits of P register can be used as application state, since these bits can be tested as branch conditions. P[31:24] is also used in dispatch microoperation (see [Dispatch Microoperation](#)), and bit pairs P[29:28], P[27:26], P[25:24] can be directly copied into Channel flags 1 and 0 using field FLC. Together with Entry Table Condition Encoding, it provides fast state resolution without code execution.

37.15.8.1.2 DIOB Register

DIOB is an abbreviation for Data Input/Output Buffer. DIOB is 24-bit wide and can be used as source and destination for arithmetic/logical operations as well as SDM data source and destination. DIOB only can be accessed as 24 bits, both in arithmetic/logical and SDM read/write operations. When using DIOB to perform an SDM access, only lower 24 bits of SDM will be accessible (SDM upper 8 bits always remains unchanged).

DIOB can also be used as SDM addressing register, when DIOB contents is used as absolute SDM address (14-bit wide). In this case DIOB can also be pre-decremented or post-incremented (see [Indirect Addressing Mode](#)).

DIOB is automatically loaded with one parameter before the thread starts (parameter preload). For more information see [Entry Point format](#) and [Time Slot Transition](#).

37.15.8.1.3 ERTA and ERTB Registers

ERTA/B registers are 24-bit wide and can be used as source or destination in arithmetic/logical operations. ERTA/B are the only source for channel's match registers write (see [Write Channel Match and UDCM Registers](#)). ERTA can also be the source for UDCM write.

When a thread starts to be executed, ERTA and ERTB are loaded with a copy of CaptureA and CaptureB registers respectively. ERTA/B can be used to receive a copy of MatchA and MatchB registers. ERTA/B are the only destination of MatchA/B read operation (see [Special T4ABS Source Operation: Read Match Registers](#)).

ERTA and ERTB also receive a copy of CaptureA and CaptureB registers when CHAN register is written (see [CHAN Register](#)). For more information about Capture and Match registers see [MatchA and MatchB Registers](#) and [CaptureA and CaptureB Registers](#).

37.15.8.1.4 SR register - Shift Register

SR is a 24-bit wide register that can be used as source and destination register for arithmetic/logical operations. SR can shift right its contents by 1 bit at time and, at the same time, receive in its bit 23 the lost bit of a shift-right operation in post-ALU shifter ([ALU and Post-ALU Shifter](#)), allowing SR to be used to perform 48-bit shift right (see [Shift Operations](#)).

37.15.8.1.5 MACH and MACL Registers

Both MACH and MACL are 24-bit registers, part of MAC/Divide unit (see [MAC and Divide Unit \(MDU\)](#)). They can be used as source and destination in most arithmetic/logic operations. When multiply or divide operations are used (multiply-accumulate included), MACH and MACL have special purpose and some restrictions apply, see [MAC and Divide Unit \(MDU\)](#) for more information.

37.15.8.1.6 LINK Register

Link Register is an 8-bit wide register and can be used only as destination in arithmetic operations. LINK is a write-only command register, which precludes its use as a source register for ALU operations. When LINK register is written, it issues a service request for the channel number and eTPU engine equal to the number written in LINK register (see [Functions and threads](#) and [Channel Link](#) for information about Link Service Request).

37.15.8.1.7 RAR Register

RAR is a 14-bit register and can be used as source and destination in arithmetic operations. RAR also receives the contents of PC register when a subroutine call is executed. The contents of RAR register is loaded into PC when a return from subroutine is executed. RAR is loaded with value 0x3FFF during TST. For more information about subroutine call and return see [Branch Operations](#) and [Return from subroutine](#) respectively.

37.15.8.1.8 CHAN Register

CHAN is a 5-bit register that can be used as source and destination in arithmetic operations. The contents of CHAN register affects the execution of many channel-related microinstructions, because its number indicates the **selected channel**. CHAN register must not be used to store temporary values in arithmetic operations. For more details, refer to [Channel Selection Register - CHAN](#).

37.15.8.1.9 Counter Registers: TCR1, TCR2, TPR and TRR

All these registers are 24-bit wide except TPR, which is a 16-bit register. They can be read or written in arithmetic/logical operations, and have special-purpose uses for time base and angle mode operations. For more information about those registers see [Time bases](#) and [EAC - eTPU Angle Counter](#).

37.15.8.1.10 General Purpose Registers: A, B, C and D

A, B, C and D are 24-bit general purpose registers, which can be used to store intermediate values and do not have other specific uses with any eTPU feature.

37.15.8.2 ALU and Post-ALU Shifter

The ALU executes 24-bit arithmetic and logical operations. ALU's output goes directly to a 1-bit shifter, called post-ALU shifter, so it is possible, for example, to add and shift using only one microinstruction.

In some microinstruction formats, it is not possible to specify the operation executed by ALU. In these cases ALU will always perform addition.

In formats which have the field ALUOP for ALU operation selection, all of them can be performed, including add/subtract using C (carry) flag as ALU's carry-in, bitwise AND/OR/NOT/XOR, and shift/rotate of 2, 4, 8 and 16 bits. See [ALU/MDU Operation Selection](#).

Subtraction, inversion, increment and decrement can be performed by combinations of source inversion and setting ALU's carry-in to 1.

ALU always performs 24-bit operations on its inputs, called **A-source** and **B-source**, and outputs a 24-bit result. 8-, and 16-bit inputs are zero padded to 24 bits. Likewise, ALU 24-bit output is always truncated to the destination register size.

37.15.8.2.1 ALU flags

Four flags - Carry, Negative, Overflow, Zero - described below, are related to ALU and post-ALU shift operations. Operation size and shifting affect flags generation logic. Operation size determines the result boundary to be used for flags generation. Operation size is determined by size of sources and destination (see [Flags Sampling Control](#)). For more information about flag generation, see [Flags Sampling Control](#). ALU flags can be used as branch condition (see [Conditional/unconditional branch](#)) or conditional ALU/MDU operation (see [Conditional ALU/MDU Operation Execution](#)).

Field CCS/CCSV in microinstructions can force **no update** of all flags. Not all flags are updated in all ALU operations: Overflow is updated only on addition and absolute value operations, Carry flag is updated in most ALU operations, and only Zero and Negative are updated in all ALU operations.

ALU flags are never updated when microinstruction starts an MDU operation, regardless of CCS/CCSV, but are updated normally afterwards, on ALU operations that are executed in parallel with an ongoing MDU operation (MDU has its own flags).

Note

Operation size can be smaller than destination register. For example: $0xFFFF + 0x0001$ (both 16-bit sources) stores $0x10000$ in a 24-bit register and sets Zero and Carry flags because operation size is 16 bits.

37.15.8.2.1.1 Carry flag (C)

In an unsigned addition without shifting, Carry flag is the ALU carry from bit 7 to 8, 15 to 16, or 23 to 24 on 8-, 16- and 24-bit operation sizes respectively. In an unsigned subtraction without shifting, Carry Flag represent the sign of ALU's result considering operation size (Carry Flag equal to 1 means a negative result).

Carry flag definition is operation-dependent. The Carry flag in add/subtraction with Post-ALU shift is defined in [Table 37-362](#). Find the definitions for other operations in the following sections.

37.15.8.2.1.2 Negative flag (N)

Negative flag indicates the sign of result based on the operation size, regardless of the operation performed, as shown in the following table.

Table 37-358. Negative (N) flag behavior

Operation size	Value
8 bits	$N = \text{result}[7]$
16 bits	$N = \text{result}[15]$
24 bits	$N = \text{result}[23]$

Note

The N flag may not reflect the sign of the value actually written into the destination register, if it does not have the same size of the operation (see [Flags Sampling Control](#)). This is always the case for registers RAR (14 bits) and CHAN (5 bits).

37.15.8.2.1.3 Overflow (V)

Overflow is updated only on addition (with or without carry) and absolute value operations. In signed operations, overflow flag indicates that the result of arithmetic operation (add or subtraction) can not be represented by a word of the size of the operation. Overflow flag behavior for addition is defined in the following table. Overflow flag for Absolute operation is explained in [Absolute Value operation](#). V Flag is calculated using ALU adder output (i.e., it is not affected by 1-bit shift/rotate operations).

Table 37-359. Overflow flag on addition - V

Op. size	Value ¹
8 bits	$(AS[7] \& BS[7] \& !\text{alu\_adder\_output}[7]) \vee (!AS[7] \& !BS[7] \& \text{alu\_adder\_output}[7])$
16 bits	$(AS[15] \& BS[15] \& !\text{alu\_adder\_output}[15]) \vee (!AS[15] \& !BS[15] \& \text{alu\_adder\_output}[15])$
24 bits	$(AS[23] \& BS[23] \& !\text{alu\_adder\_output}[23]) \vee (!AS[23] \& !BS[23] \& \text{alu\_adder\_output}[23])$

1. BS is taken after any inversion by the BINV field, but not added to the carry bit (CIN field)

NOTE

For V-flag definition on the absolute operation, see “Absolute Value Operation”.

37.15.8.2.1.4 Zero flag (Z)

Zero flag equal to 1 indicates that the result from the ALU, limited to the operation size, is zero, regardless of the operation performed, whether the result is written, or where it is written. It depends on the operation size, as shown in the following table.

Table 37-360. Zero flag - Z

Operation size	Value
8 bits	$Z = (\text{result}[7:0] == 0x00)$
16 bits	$Z = (\text{result}[15:0] == 0x0000)$
24 bits	$Z = (\text{result}[23:0] == 0x000000)$

37.15.8.2.2 ALU ADD operation with and without shifting

ADD operation is selected by ALUOP or ALUOPI fields and when none of them is available in a microinstruction format³³. Optionally, result can be shifted or rotated right by 1 bit, which is selected by SHF, ALUOP or ALUOPI fields. See [Microinstruction Set](#) for more details. The following table describes how CIN and BINV fields change ADD operation behavior.

Table 37-361. Types of ADD operations

BINV	CIN	Operation (adder output)
1	1	AS + BS
1	0	AS + BS + 1
0	0	AS - BS
0	1	AS - BS - 1

ALU adder output can be 1-bit shifted or 1-bit rotated right as follows:

Shift right:

```
if BINV==1
    result [23:0] = adder_output [24:1]
else
    result [23:0] = adder_output [24:1] xor 0x800000
endif
```

Shift left:

33. ALU operations only occur on formats where a destination field is found (T2ABD/T2D).

Functional description

```
result[23:1] = adder_output[22:0]
result[0]     = 0
```

Rotate right:

```
case (opsize/CCSV)
8-bit:
    result[6:0] = adder_output[7:1]
    result[7]   = adder_output[0]
    result[23:8] = adder_output[23:8]
16-bit:
    result[14:0] = adder_output[15:1]
    result[15]   = adder_output[0]
    result[23:16] = adder_output[23:16]
24-bit:
    result[22:0] = adder_output[23:1]
    result[23]   = adder_output[0]
```

Note

Only for the Post-ALU rotate right, the operation size is determined by the field CCSV (see [Flags Sampling Control](#)). For example: if CCSV=00, T4ABS=P (24-bits), T4BBS=A (24 bits), T2ABD=B (24 bits), and ALUOP="Add ROR", then B gets A+P with bits 7:0 rotated, even though the operation size is 24 bits.

The following table describes Carry flag behavior.

Table 37-362. Carry flag update on ADD operation

BINV ¹	Op. size	shift/rotate	Value
1	8 bits	none	adder carry from bit 7 to bit 8
1	16 bits	none	adder carry from bit 15 to bit 16
1	24 bits	none	alu_adder_output[24]
0	8 bits	none	!adder carry from bit 7 to bit 8
0	16 bits	none	!adder carry from bit 15 to bit 16
0	24 bits	none	!alu_adder_output[24]
0 or 1	8 bits	shift left	alu_adder_output[7]
0 or 1	16 bits	shift left	alu_adder_output[15]
0 or 1	24 bits	shift left	alu_adder_output[23]
0 or 1	x	shift right	alu_adder_output[0]
1	8 bits	rotate right	adder carry from bit 7 to bit 8
1	16 bits	rotate right	adder carry from bit 15 to bit 16
1	24 bits	rotate right	alu_adder_output[24]
0	8 bits	rotate right	!adder carry from bit 7 to bit 8
0	16 bits	rotate right	!adder carry from bit 15 to bit 16
0	24 bits	rotate right	!alu_adder_output[24]
except on max-constant generation (see Max Const Generation With T4BBS=111)			

1. BINV has no effect on carry-out when used to code max constant (see [Max Const Generation With T4BBS=111](#)).

Flags N and Z on shift are updated according to the result after shift. Flag V with shift is updated according to the ADD operation only, the same way as without shift.

37.15.8.2.3 ADC Operation

ADC operation is selected by the ALUOP field. CIN field is ignored when this operation is selected. The following table describes how BINV change ADC operation behavior.

Table 37-363. Types of ADC operations

BINV	CIN	Operation
1	x	AS + BS + C flag
0	x	AS - BS - C flag

Flags behave exactly the same way as for ADD operation without shift/rotate.

37.15.8.2.4 Bitwise Operations

Bitwise AND, OR and XOR are selected by ALUOP field. On these operations CIN field is ignored and BINV field inverts (bitwise NOT) BS. C and V Flags are never updated on these operations. The following table describes AND, OR and XOR bitwise operations.

Table 37-364. Types of Bitwise Operations

ALUOP	BINV	Operation
10000	1	AS BS
10000	0	AS (~BS)
10001	1	AS ^ BS
10001	0	AS ^ (~BS)
10010	1	AS & BS
10010	0	AS & (~BS)

37.15.8.2.5 Set Bit / Clear Bit Operations

These operations set or clear the AS bit determined by BS[4:0]. If the bit number resolves to a value greater than 23, no bit is set or cleared (i.e., result is equal to AS). On these operations CIN field is ignored and BINV field inverts (bitwise NOT) BS. C and V flags are never updated for set/clear bit operations. These operations **override** B-Source size to 8 bits.

set bit (BINV = 1):

Functional description

```
result = AS | (1 << BS)
```

clear bit (BINV = 1):

```
result = AS & ~(1 << BS)
```

set bit (BINV = 0):

```
result = AS | (1 << (31 - BS))
```

clear bit (BINV = 0):

```
result = AS & ~(1 << (31 - BS))
```

37.15.8.2.6 Exchange Bit

Exchange the AS bit determined by BS with C flag. If the bit number resolves to a value greater than 23, no exchange is performed (i.e., result is equal to AS and C flag is not updated). This operation **overrides** BS size to 8 bits. On this operation, CIN field is ignored and BINV field inverts (bitwise NOT) BS. V flag is never updated on exchange bit operation. C flag is always updated, regardless of CCSV, unless BS > 23.

Exchange Bit (BINV=1):

```
if BS <= 23
begin
    temp_C_flag = AS[BS]
    if C_flag == 1
        result = AS | (1 << BS)
    else
        result = AS & ~(1 << BS)
    C_flag = temp_C_flag
end
```

Exchange Bit (BINV = 0):

```
if (31 - BS) <= 23
begin
    temp_C_flag = AS[31 - BS]
    if C_flag == 1
        result = AS | (1 << (31 - BS))
    else
        result = AS & ~(1 << (31 - BS))
    C_flag = temp_C_flag
end
```

37.15.8.2.7 Multibit shift/rotate operations

These operations shift or rotate AS by 2, 4, 8 or 16 bits. Size of shift/rotate is determined by BS[1:0]. The following table describes the number of shifted/rotated bits depending on BS[1:0] value.

Table 37-365. Number of shifted/rotated bits for each BS[1:0] value

BS[1:0]	Bits shifted/rotated
0	2
1	4
2	8
3	16

Shift right is a logical operation (i.e., zeros are inserted on left). Multibit shift and rotate operations **overrides** BS size to 8 bits. The shifts and rotate operate on 24 bits, independently of the operation size.

V flag is never updated for multibit shift or rotate operations. Carry flag behavior is described in the following table. CIN is ignored in these operations, but BINV is effective.

Table 37-366. Carry flag value on multibit shift/rotate operations

ALUOP	BS[1:0]	C flag value ¹
11001 (shift left)	0	AS[22]
11001 (shift left)	1	AS[20]
11001 (shift left)	2	AS[16]
11001 (shift left)	3	AS[8]
11010 (shift right)	0	AS[1]
11010 (shift right)	1	AS[3]
11010 (shift right)	2	AS[7]
11010 (shift right)	3	AS[15]
11011 (rotate right)	0	AS[2]
11011 (rotate right)	1	AS[4]
11011 (rotate right)	2	AS[8]
11011 (rotate right)	3	AS[16]

1. CCS/CCSV can disable flag update on multibit shift/rotate, but the specified flag size in CCSV is ignored for the C flag.

37.15.8.2.8 Absolute Value operation

Absolute Value operation is selected by ALUOP field. On this operation, AS is interpreted as a signed number and its absolute value is the result. V and N flags are updated with the result signal determined by the operation size. AS bit 23 after size override and sign extension (if any, see [A-Source Size Override](#)), regardless of A-source register size, is used to check the operand signal and is copied to C-flag. Note that if AS is 8-bit or 16-bit, its sign is taken into account and copied to C only if sign-extension is performed. The following table summarizes flag updating for Absolute Value operation.

This operation is independent of B-source. Instruction fields T4BBS, BINV and CINV are ignored in this operation. The Absolute Value operation size is the minor between A-source size and Destination size.

Table 37-367. ALU flags in Absolute Value operation

operation size	V, N ¹	C	Z
8	alu_output[[7]	AS[23]	alu_output[7:0] == 0
16	alu_output[15]		alu_output[15:0] == 0
23	alu_output[23]		alu_output[23:0] == 0

1. V, N can be 1 on 8- and 16-bit Absolute Value, because the operand sign is always taken from bit 23. V, N can also be 1 in 23-bit Absolute Value (or 8-bit and 16-bit with sign extension), if the operand is 0x800000 (0x80, 0x8000).

37.15.8.3 MAC and Divide Unit (MDU)

MDU is an autonomous resource in the microengine which can carry out sequential multiply, multiply-accumulate, fractional multiplication and divide operations, selected through the microinstruction fields ALUOP or ALUOPI. The unit supports signed and unsigned multiply and fractional multiplication of any combination of 8, 16 or 24 bit operands ³⁴, and also signed and unsigned 24-bit multiply-accumulate. Divide operation is unsigned, and both operands are always 24-bit wide.

Depending on the size of operands and the type of operation, MDU can take more than one microcycle to execute the operation, but microengine continues to execute microinstructions in parallel. When the microcode issues an END command, any MDU executing operation terminate immediately and is left incomplete. When selecting an operation that uses MDU, the result is always placed in MACH and MACL registers, and the register selected as destination does not have its value changed ([Selecting sources and destination](#)). During calculations, MACH and MACL holds temporary values and should not be written, otherwise the result is unspecified. One must not start an MDU operation while MDU is already busy: the result is unspecified for both the ongoing operation and the started one.

MDU Operations update its own set of 5 flags, described in [MDU Flags](#). MDU operations never update C, N, V and Z flags. CIN and BINV microinstruction fields affect MDU operations according to the following table.

34. There is no distinct selection of 24-bit fractional multiplication, for it works exactly as a 24-bit ordinary multiplication.

Table 37-368. CIN and BINV with MDU Operations

B-source operand	BINV	CIN	Op. Performed
signed	1	1	AS mdu_op BS
	0	0	AS mdu_op (-BS)
	1	0	reserved
	0	1	reserved
unsigned ¹	1	1	AS mdu_op BS
	1	0	AS mdu_op (BS+1)
	0	x	reserved

1. includes the B-source (unsigned) in fmults (signed) operations.

37.15.8.3.1 Multiply and Multiply-Accumulate Operation Length

MDU needs 2 sources, A source and B source, to perform an operation. The time needed to perform a multiply or multiply-accumulate is:

- on 24-bit x 8 bit multiplies: 2 microcycles (one start-MDU plus one execution microcycle)
- on 24-bit x 16 bit multiplies: 3 microcycles (one start-MDU plus two execution microcycles)
- on 24 bit x 24 bit multiplies/macs: 4 microcycles (one start-MDU plus three execution microcycles)

An internal pipeline in MDU allows multiply-accumulate (or even non-fractional multiply) operations to start one microinstruction before a multiplication or multiply-accumulate (signed or unsigned) has been completed (e.g., one can start one multiply or multiply-accumulate once every three microinstructions). However, by doing that it is not possible to read the result in MACH and MACL (although the MDU flags can be tested), so this is intended to be used in a multiply-accumulate sequence. It is also allowed to mix different sizes in multiply/mac sequences.

Multiply-accumulate operations are similar to multiply operations, except that the contents of MACH and MACL registers are added to the multiplication result.

When multiply or multiply accumulate operations finish, MACL and MACH hold the least and the most significant 24-bit words, respectively.

37.15.8.3.2 Divide Operation Length

The divide operation is always unsigned. The division completes in 13 microcycles, meaning that after the start divide microinstruction, one has to wait for 12 microcycles and then read the result and the remainder in MACH and MACL registers. During the 12 execution microcycles, microengine can execute microinstructions unrelated to the MDU.

37.15.8.3.3 Signed Multiplication (mults)

MDU signed multiplication is defined as follows:

```
(signed) MACH,MACL = (signed) AS * (signed) BS
```

MC and MV flags are reset. MZ is set if result is 0, resets otherwise. MN is set if result is negative.

37.15.8.3.4 Unsigned Multiplication (multu)

MDU unsigned multiplication is defined as follows:

```
(unsigned) MACH|MACL = (unsigned) AS * (unsigned) BS
```

MC and MV flags are reset. MZ is set if result is 0, resets otherwise. MN is a copy of the most significant bit of result.

37.15.8.3.5 Signed Multiply-Accumulate (macs)

MDU signed multiply-accumulate is defined as follows:

```
(signed/unsigned) {MACH,MACL} += (signed) AS * (signed) BS
```

MC is not altered.

MV is set if result can not be represented by a 48-bit signed number. MACS never resets MV flag: it is left as is if no overflow occurs, or set it otherwise. This allows checking the overflow flag only once at the end of a series of multiply-accumulate operations in a scalar product calculation.

```
if (({MACH,MACL} += AS * BS < -247) || ({MACH,MACL} += AS * BS > 247 - 1))
    MV = 1
```

MZ is set if result is 0, resets otherwise. MN is a copy of the most significant bit of result.

Note that only 24-bit multiply-accumulate is available.

37.15.8.3.6 Unsigned Multiply-Accumulate (macu)

MDU Unsigned Multiply-Accumulate is defined as follows:

```
(signed/unsigned) {MACH,MACL} += (unsigned) AS * (unsigned) BS
```

MC is set if result can not be represented by a 48-bit unsigned non-negative number. MACU never resets MC flag: MC flag is left as is if no carry occurs, or set otherwise. This allows checking the carry flag only once at the end of a series of multiply-accumulate operations in a scalar product calculation.

```
if (({MACH,MACL} += AS * BS < 0) || ({MACH,MACL} += AS * BS > 248 - 1))
    MC = 1
```

MV is not altered.

MZ is set if result is 0, resets otherwise. MN is a copy of the most significant bit of result.

Note that only 24-bit multiply-accumulate is available.

37.15.8.3.7 Signed Fractional Multiplication (fmults)

MDU Signed Fractional Multiplication takes the B-Source as an **unsigned** 8- or 16-bit³⁵ fraction between 0 and $(2^8 - 1)/2^8$ (inclusive) for the 8-bit operation, or between 0 and $(2^{16}-1)/2^{16}$ (inclusive) for the 16-bit operation. Only A-Source is taken as a signed number. The value of B-Source is considered the unsigned numerator of a fraction with denominator 2^8 or 2^{16} for the 8- and 16-bit operations, respectively.

The integer part of the result is stored in MACH, and the fractional part in MACL. The result is signed, so that the concatenation of MACH and MACL form a 48-bit fixed point number with a 24-bit integer part, both for 8- and 16-bit operations. To calculate the unsigned numerator of the fractional part (with denominator 2^{24}) of the result, one must take the absolute value of MACL considering the signal of the result (not MACL alone), i.e.: if flag MN=1, invert MACL and add 1.

MDU flags are updated in the same way as in the Signed Multiplication.

37.15.8.3.8 Unsigned Fractional Multiplication (fmultu)

MDU Unsigned Fractional Multiplication takes both A-Source and B-Source as unsigned operands. B-Source is taken as an 8- or 16-bit³⁶ fraction between 0 and $(2^8 - 1)/2^8$ (inclusive) for the 8-bit operation, or between 0 and $(2^{16}-1)/2^{16}$ (inclusive) for the 16-bit operation. The value of B-Source is considered the numerator of a fraction with denominator 2^8 or 2^{16} for the 8- and 16-bit operations, respectively.

35. 24-bit fractional signed/unsigned multiplication is equivalent to mults/multu.

36. 24-bit fractional signed/unsigned multiplication is equivalent to mults/multu.

The integer part of the result is stored in MACH, and the fractional part in MACL. The fractional part in MACL is the numerator of a fraction with denominator 2^{24} . The concatenation of MACH and MACL form a 48-bit fixed point number with a 24-bit integer part, both for 8- and 16-bit operations.

MDU flags are updated in the same way as in the Unsigned Multiplication.

37.15.8.3.9 Unsigned Divide (div)

At the end of a divide operation MACL holds the result of the division, taking A-source as numerator and B-source as denominator, while MACH holds the remainder. If a divide by 0 is executed, MACL holds the maximum unsigned number (0xFFFFFFFF) as result and flag MV is set to indicate division by 0 (otherwise reset). The contents of MACH become indetermined.

MC flag is always reset.

MZ flag is set if MACL equals 0, and reset otherwise.

MN receives a copy of MACH bit 23 (msb from the remainder).

Note that signed division is not available.

37.15.8.3.10 MDU Flags

MDU has its own flags to indicate the result and status of an MDU operation. They are: MC, MZ, MV, MN and MB. All MDU flags are updated with the final result at the end of the operation, and do not change until the next operation finishes. Therefore it is possible to start a new MDU operation and test the flags of the previous one in parallel, except for mult/mac with 8-bit operand (takes only 1 microcycle).

37.15.8.3.10.1 MDU Negative Flag - MN

MN flag is always a copy of MACH bit 23 at the end of the operation, either in signed or unsigned ones. Note that MACH holds the rest of a division operation, which is always unsigned.

37.15.8.3.10.2 MDU Carry Flag - MC

MDU carry flag indicates if the result cannot be represented by a 48-bit number, in Signed and Unsigned Multiply Accumulates. It is reset in the other operations.

37.15.8.3.10.3 MDU Zero Flag - MZ

In multiply and multiply-accumulate operations, MDU zero flag is asserted if MACH and MACL are equal to zero at the end of an operation. In divide operations, zero flag is asserted if MACL (result) is equal to 0.

37.15.8.3.10.4 MDU Overflow Flag - MV

In multiply operations, MV flag is negated and keeps negated in the end, because the result of a multiplication can always fit in a 48-bit result (MACH and MACL concatenated). In a multiply-accumulate operation, MV is asserted if the result size is wider than 48 bits. MV flag work in both signed and unsigned operations.

In divide operations it is only asserted if a divide-by-zero operation was executed.

37.15.8.3.10.5 MDU Busy Flag (MB)

MB tests as true at the next microinstruction after the MDU start operation, and as false at the last microcycle of any MDU operation execution.

37.15.8.4 Branch conditions

Microengine allows conditional branch. There are five sets of flags that can be tested in a conditional branch: ALU flags, MDU flags, P flags, Channel flags, and Semaphore flag (flag SMLCK).

When a thread starts to be executed, the values in MDU and ALU flags are not initialized. ALU flags are described in [ALU flags](#), MDU flags are described in [MDU Flags](#). MDU and ALU flags are updated during execution of microinstructions.

P flags are actually the upper byte of P register, which optionally can work as user defined flags (see [P Register](#)).

Channel flags Flags0, Flag1, MRLA, MRLB, TDLA, TDLB, PSS, PRSS and PSTO are obtained from the selected channel (value in CHAN register), while channel flags, LSR, FM[0] and FM[1] are selected by the serviced channel, regardless of the CHAN value³⁷.

Flags TDLA/B, MRLA/B, LSR, FM and PSS, are sampled at the beginning of a thread. Flag PSS does not change during its execution while CHAN register is not written. When a write in CHAN register is performed, all flags except LSR and FM are updated according to the channel specified by CHAN value. Flags MRLA/B and TDLA/B are reset when their respective latches in channel are cleared by microcode.

37. Serviced channel does not change during execution of a thread, and it is the channel that requested a service (initial value of CHAN register when a thread starts).

Table 37-369. Channel flags as branch condition

Flag	Description	Service or selected channel
Flag0	State Resolution flag	reflects the selected channel (CHAN)
Flag1	State Resolution flag	reflects the selected channel (CHAN)
MRLA	Match A Recognition Latch	these flags reflect the selected channel (CHAN)see MRLA/B - Match Recognition Latches and TDLA/B - Transition Detect Latches for more information.
MRLB	Match B Recognition Latch	
TDLA	Transition A Detection Latch	
TDLB	Transition B Detection Latch	
LSR	Link Service Request	reflects the serviced channel.
PRSS	Input Pin state sampled at service request	reflects the selected channel (CHAN). Does not change if CHAN is not changed.
PSS	Sampled Input Pin State	reflects the selected channel (CHAN). Does not change if CHAN is not changed (see Pin Control Registers).
PSTI	Current Input Pin State.	reflects the selected channel (CHAN). Changes any time.
PSTO	Current Output Pin State	reflects the selected channel (CHAN). Changes any time.
FM	Function Mode Bits	reflects the Function Mode for serviced channel (see eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_CnSCR_ENG1) and eTPU Channel n Status Control Register for Engine 2 (eTPU_CCCR_CnSCR_ENG2))

Semaphore condition SMLCK always indicates if a semaphore is locked for the Engine, resolving as false before any lock attempt. For each trial, the SMLCK flag is updated. The SMLCK value set in one thread is not meaningful to the other. After a free, the SMLCK condition tests as false until a new lock attempt on the same thread.

Branch conditions are selected through instruction fields BCC and BCF (see [Conditional/unconditional branch](#)).

37.15.9 Microinstruction Set

Each microinstruction can execute up to 3 microoperations in parallel. Microinstructions are grouped into formats, and there are four types of microoperations:

- ALU/MDU Operations
- SDM Operations
- Channel Configuration/Control Operations
- Flow Control Operations

Each microinstruction format is defined by a set of microinstruction fields, which determine the operations, each belonging to one of the groups above (there may be several in one group). Complete microinstruction formats are shown in [Microinstruction formats](#).

Parallelism conflicts may arise when two operations are executed in the same microinstruction. These situations are explained in [Microinstruction Parallelism Issues](#).

37.15.9.1 SDM Microoperations

The access to SDM is made by providing an address and a register to perform a data transfer, except semaphore operations, which are also classified in the SDM group. Only P and DIOB registers can exchange data with SDM. Microengine always addresses SDM in 32-bit boundaries, for 8, 24, or 32 bit wide data.

Direction is determined by the field RW in all addressing modes: RW=0 selects read and RW=1 selects write.

37.15.9.1.1 SDM Addressing Modes

There are 4 addressing modes in eTPU:

- Absolute
- Selected Channel Relative
- Indirect
- Engine Relative

The addressing modes Absolute and Selected Channel Relative use immediate bits to form the physical address of SDM, which is identified in microinstruction as a field called AID. AID field can be 3-, 7-, or 8-bit wide depending on the addressing mode.

37.15.9.1.1.1 Absolute Addressing Mode

In Absolute addressing mode, the address range is 256 parameters, addressed by field AID, which in this mode is 8-bit wide. These parameters are located in SDM addresses from 0 to 255.

```
physical_address = AID[7:0]
```

37.15.9.1.1.2 Selected Channel Relative Addressing Mode

In Selected Channel Relative addressing mode, only the first 8 (with 3-bit AID) or 128 (with 7-bit AID) parameters of the selected channel are accessible, depending on the microinstruction format. Physical address is calculated using the channel parameter base address that is specified in the CPBA field of [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#). AID field is added to channel parameter base address to compose the physical address. The address equation is:

```
physical_address = selected_channel_parameter_base_address + AID[6:0], or
physical_address = selected_channel_parameter_base_address + AID[2:0]
```

37.15.9.1.1.3 Indirect Addressing Mode

In Indirect Addressing mode the physical address is taken from DIOB register. Only DIOB bits 14 to 2 are relevant. Since the SDM word address is shifted two bits up in DIOB, its contents hold the same parameter address value used by Host. The address equation for SDM access is:

```
physical_address = DIOB[13:2], or
physical_address = (truncated to 12 bits) (DIOB / 4)
```

Indirect addressing mode is used to access the Shared Subsystem Area when `eTPU_CCCR_CxCR_ENGn[SSMAE]=1` and DIOB addresses the 16 Kbytes just above the SDM range (DIOB bit 14 = 1). See [Shared Subsystems support](#) for more details. If `SSMAE=0`, accesses with DIOB bit 14 = 1 hit the same SDM addresses as with bit 14 = 0, providing full backwards compatibility with respect to DIOB contents.

Indirect addressing mode can have post-increment or pre-decrement on DIOB, allowing stack operations. See [DIOB stack operation](#) for more information.

37.15.9.1.1.4 Engine Relative Addressing Mode

In Engine Relative Addressing mode the physical address is the concatenation of the `eTPU_SCR_ECR_ENGn[ERBA]` field (see [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#)) with the 7-bit AID instruction field. This allows the same function microcode, when running on distinct engines, to access different address spaces, global to the engine only.

The SDM physical word address in Engine Relative Addressing mode is calculated as follows:

```
physical_address = (eTPU_SCR_ECR_ENGn[ERBA] << 7) + AID[6:0]
```

37.15.9.1.2 SDM source/destination registers

When performing an SDM operation, only DIOB or P can be used as data source or destination. P is 32-bit wide, and DIOB is 24-bit wide. Microinstruction field P/D (1 bit) is used to choose between P and DIOB as data the source or destination. When the P/D field is not available in microinstructions that support SDM access, the source/destination is P.

Table 37-370. SDM source/destination Register Selection

P/D	Meaning
0	P access
1	DIOB access

37.15.9.1.3 SDM Operation Size

When using DIOB register to perform SDM data transfers, the operation size is always 24-bit wide (lower 24 bits of SDM). When using P register, the operation size can be 8-, 24- or 32-bit wide, which is controlled by microcode RSIZ field (2 bits). RSIZ meaning is shown in the following table.

Table 37-371. SDM P access Size

RSIZ	P access	DIOB access
00	full 32-bit access (i.e. P[31:0]=SDM[addr] [31:0])	RESERVED
01	only upper 8 bits are transferred (i.e. P[31:24] = SDM[addr] [31:24])	RESERVED
10	only lower 24 bits are transferred (i.e. P[23:0] = SDM[addr] [23:0])	DIOB = SDM[addr] [23:0]
11	RESERVED	RESERVED

RSIZ is not available in all microinstructions that support SDM access. In microinstructions where RSIZ field is not available, SDM access will be 24 bits by default.

When performing a Zero SDM write operation (see [Zero SDM Operation](#)), RSIZ defines the size of operation regardless of the P/D field ([SDM source/destination registers](#)).

37.15.9.1.4 SDM access direction

RW field defines the direction of the access in the SDM. The access direction is summarized in the following table.

Table 37-372. SDM access direction

R/W	Meaning
0	read SDM parameter into P or DIOB registers
1	write SDM parameter from P or DIOB registers

37.15.9.1.5 Zero SDM Operation

Zero SDM operation is controlled by microcode field ZRO (1bit). When ZRO field is 0, the data portion written in SDM or in P/DIOB (SDM read) registers will always be 0x0. When performing a Zero SDM write operation, the RSIZ is relevant regardless of the P/D field (usually RSIZ is meaningful only for P/D = 0), which means that zero SDM write operation can be performed with 32, 24 or 8 bits according to SDM operation size. These conditions are summarized in the following table.

Table 37-373. Zero SDM Operation

ZRO	RW	P/D	Meaning
0	0	0	Clear P register. Size is determined by RSIZ field. See SDM Operation Size
0	0	1	Clear DIOB (all 24 bits), independently of RSIZ
0	1	x	Clear SDM parameter. Size is determined by RSIZ field. See SDM Operation Size
1	RW	P/D	Regular SDM operation

Note

When field STC is present, STC=11 also disables Zero SDM operation (see [Table 37-374](#)). The conflicts with DIOB operations (see [DIOB stack operation](#)) and ALU operations are resolved like a normal SDM operation (see [Table 37-415](#)).

Zero SDM read operations do check memory errors on the read data, however discarded. Zero SDM write operations normally update the ECC of the written data.

37.15.9.1.6 DIOB stack operation

SDM Indirect Addressing Mode (see [Indirect Addressing Mode](#)) is used if STC field (2 bits) exists in the microinstruction, controlling automatic increment/decrement of DIOB register, as shown in the following table, thus allowing stack operations. DIOB is incremented and decremented in word addresses, only from bits 15 downto 2, i.e.: the bits 23 to 16 and 1 to 0 are left untouched by STC pre-decrement and post-increment.

Table 37-374. DIOB Post-Increment / Pre-Decrement - STC

STC	Meaning
00	Post-Increment of DIOB
01	Pre-Decrement of DIOB
10	No Increment/Decrement (normal access)
11	No SDM Access ¹

1. Also disables Zero SDM operation.

37.15.9.1.7 Semaphore Operations

Semaphore lock and free operations are available through eTPU microcode. For more information about semaphores see [Hardware Semaphores](#). There are 2 microinstruction fields that control semaphore operations: FL (1 bit) and SMPR (2 bits). Serviced channel sees 4 semaphores, selected by field SMPR.

Table 37-375. Semaphore Operations Fields

Field	Meaning
FL	0 = free semaphore, 1 = lock semaphore
SMPR	semaphore number selector

When freeing a semaphore, the field SMPR has no meaning. This is because only one semaphore can be locked at a time by each engine, so when freeing a semaphore it is not necessary to specify its number.

Note

If microcode tries to lock a semaphore already locked for the same Engine, the semaphore continues locked for the Engine and the SMLCK branch condition resolves as true.

37.15.9.2 ALU/MDU Operations

ALU/MDU microoperations mostly comprises two sources, one destination and one operation. The operation is generally selected through fields ALUOP, ALUOPI or SHF. In formats where there is no operation selection field (ALUOP, ALUOPI or SHF), the operation performed is always addition; however, it is possible to perform subtraction, increment or decrement using fields BINV (see [B-Source Inversion](#)) and CIN (see [Carry-in Control](#)).

37.15.9.2.1 Source and Destination Register Set Selection

Microcode field T4ABS allows selection of a source from either one of two register sets, shown in [Table 37-379](#). The same applies to T2ABD, used for ALU destination selection with other two register sets, as shown in [Table 37-380](#). Microinstruction fields ABSE and ABDE control the register set selection for source and destination, respectively, when available at the format. In formats without ABSE/ABDE, the field T4BBS determines the register sets used by T2ABD and T4ABS, as shown in [Microinstructions without fields ABSE and ABDE](#).

37.15.9.2.1.1 Microinstructions With Fields ABSE and ABDE

In microinstructions where ABSE and ABDE fields are available (1 bit each), ABSE controls register set selection for T4ABS and ABDE controls register set selection for T2ABD. The following table shows the meaning of values for ABSE and ABDE fields.

Table 37-376. Register Set Selection by ABSE or ABDE

ABSE or ABDE	Register Set Selected
0	second
1	first

37.15.9.2.1.2 Microinstructions without fields ABSE and ABDE

When ABSE and ABDE are not available in a microinstruction format, register set is selected by T4BBS field. The following table explains how to select a register set either for T4ABS and T2ABD.

Table 37-377. Register set selection by T4BBS without ABSE and ABDE

T4BBS	Register set for T2ABD	Register set for T4ABS
0xx	first	first
100	second	second
101	second	first
110	first	second
111	first	first
none ¹	first	first

1. Refers to operations with immediate data as B-source, without ABSE and ABDE.

37.15.9.2.2 Selecting sources and destination

All ALU/MDU operations need 2 sources (called AS and BS) and 1 destination (called AD), except for some of those that use immediate data (see [Operations With Immediate Data](#)). Fields T4ABS (4 bits), ABSE (1 bit), T4BBS (3 bits) select sources, while T2ABD (4 bits) and ABDE (1 bit) select the destination. When MDU is used (multiply/divide), T2ABD destination selection is ignored and results are stored in MACH and MACL (see [MAC and Divide Unit \(MDU\)](#)). ABSE and ABDE are not available in some microinstruction formats that support ALU/MDU operations. However, in all formats where ABSE is available, ABDE is also available and vice-versa. The existence of ABSE/ABDE fields changes the meaning of T4BBS field, as shown in the table below. On instructions with immediate data, it is used as B-source (see [Operations With Immediate Data](#)).

All sources and destinations have a size associated to it, and these sizes are used to select flag sample position (see [Flags Sampling Control](#)). Sizes can be 8, 16 or 24 bits. Registers that are not exactly of one of these sizes are treated as the immediately upper size (e.g., CHAN[4:0] is an 8-bit source). See [Flags Sampling Control](#) for more information.

Some parallelism issues arise when selecting P, DIOB, ERTA or ERTB as destination registers, since they can be modified by other microoperations in the same microinstruction (see [Microinstruction Parallelism Issues](#) for details).

Table 37-378. B source selection - T4BBS

T4BBS	Meaning in microinstruction formats with ABSE/ABDE	Meaning in microinstruction formats without ABSE/ABDE ¹
000		BS[23:0] = P[23:0]
001		BS[23:0] = A[23:0]
010		BS[23:0] = SR[23:0]
011		BS[23:0] = DIOB[23:0]
100	reserved	BS = 0
101	reserved	BS = 0
110	reserved	BS = 0
111	BS=0, or Max const., if CIN=0 and BINV=0 (see Generating "max" constant).	

1. T4BBS also selects A-source and destination register set in this case, according to [Table 37-377](#).

T4ABS selects one source from 2 register sets, shown in the following table. ABSE and T4BBS control which set T4ABS field uses to select the source. For more information about how to select a register set for T4ABS and T2ABD see [Source and Destination Register Set Selection](#). All sources are zero-filled to 24 bits, unless sign-extension is specified (see [A-Source Size Override](#)).

Table 37-379. A source selection - T4ABS

T4ABS	First register set		Second register set	
	Selected register	Size	Selected Register	Size
0000	AS[7:0]=P[7:0]	8	AS[7:0]=0	8
0001	AS[7:0]=P[15:8]	8	AS[23:0]=C[23:0]	24
0010	AS[7:0]=P[31:24]	8	AS[15:0] = TPR[15:0]	16
0011	AS[23:0] = ERTB[23:0]	24	AS[23:0] = B[23:0]	24
0100	AS[23:0] = D[23:0]	24	AS[23:0] = TRR[23:0]	24
0101	AS[15:0] = P[15:0]	16	AS[7:0] = 0, read_match ¹	8
0110	AS[15:0] = P[31:16]	16	AS[13:0] = RAR[13:0]	16
0111	AS[7:0] = P[23:16]	8	AS[23:0] = MACH[23:0]	24
1000	AS[23:0] = P[23:0]	24	AS[23:0] = MACL[23:0]	24
1001	AS[23:0] = A[23:0]	24	AS[4:0]=CHAN[4:0]	8
1010	AS[23:0] = SR[23:0]	24	AS[14 :2] = CHAN_BASE ²	16
1011	AS[23:0] = DIOB[23:0]	24	AS[13:0] = ENGINE_BASE ³	16
1100	AS[23:0] = TCR1[23:0]	24	Reserved	-
1101	AS[23:0] = TCR2[23:0]	24	Reserved	-
1110	AS[23:0] = ERTA[23:0]	24	Reserved	-
1111	AS[23:0] = 0	24	Reserved	-

1. T4ABS=0101 with second register set also reads MatchA/B registers into ERTA/B (see [Special T4ABS Source Operation: Read Match Registers](#)).
2. CHAN_BASE is the selected channel's base SDM address in channel relative address mode (see [CHAN_BASE as a source](#)).
3. ENGINE_BASE is the eTPU_SCR_ECR_ENGn[ERBA] field shifted left 9 positions.

T2ABD selects the destination from 1 of 2 register sets, shown in the following table. ABDE and T4BBS control which set T2ABD field uses to select the destination.

Table 37-380. Destination selection - T2ABD

T2ABD	First register set		Second register set	
	Selected register	Size	Selected Register	Size
0000	A[23:0] = AD[23:0]	24	C[23:0] = AD[23:0]	24
0001	SR[23:0] = AD[23:0]	24	LINK[7:0] = AD[7:0]	8
0010	ERTA[23:0] = AD[23:0] ¹	24	TPR[15:0] = AD[15:0]	16
0011	ERTB[23:0] = AD[23:0] ²	24	B[23:0] = AD[23:0]	24
0100	DIOB[23:0] = AD[23:0]	24	CHAN[4:0] = AD[4:0]	8
0101	P[15:0] = AD[15:0]	16	D[23:0] = AD[23:0]	24
0110	P[31:16] = AD[15:0]	16	RAR[12:0] = AD[12:0]	16
0111	P[23:0] = AD[23:0]	24	MACH[23:0] = AD[23:0]	24
1000	TCR1[23:0] = AD[23:0]	24	MACL[23:0] = AD[23:0]	24
1001	TCR2[23:0] = AD[23:0]	24	Reserved	-
1010	P[31:24] = AD[7:0]	8	Reserved	-

Table continues on the next page...

Table 37-380. Destination selection - T2ABD (continued)

T2ABD	First register set		Second register set	
	Selected register	Size	Selected Register	Size
1011	P[23:16] = AD[7:0]	8	Reserved	-
1100	P[15:8] = AD[7:0]	8	Reserved	-
1101	P[7:0] = AD[7:0]	8	Reserved	-
1110	TRR[23:0] = AD[23:0]	24	Reserved	-
1111	no destination selected ³	24	Reserved	-

1. T2ABD=0010 with first register set also writes to MatchA or UDCM registers of the selected channel if field ERWA=0 (see [Write Channel Match and UDCM Registers](#)).
2. T2ABD=0011 with first register set also writes to MatchB register of the selected channel if field ERWB=0.
3. if no destination is selected, ALU flags are updated, although the result is lost.

37.15.9.2.2.1 Max Const Generation With T4BBS=111

When T4BBS = 111, BINV = 0, and CIN = 0, the value assigned to BS will be 0x800000, and not 0x0 as expected. See [Generating "max" constant](#) for detailed explanation about this.

37.15.9.2.2.2 Special T4ABS Source Operation: Read Match Registers

When T4ABS = 0101 and the source for T4ABS is selected from the second register set, the constant 0x00 is used as AS (8-bit size) and the following register transfer is performed in parallel as well: match registers of the selected channel (value in CHAN register) are copied to ERTA/ERTB registers, where ERTA receives the value of MatchA register and ERTB receives the value of MatchB register (see [ER - Event Registers](#)). Note that ALU destination can still be chosen by T2ABD in parallel. When ERTA or ERTB is selected by T2ABD, a parallelism issue arises (see [ALU Operations and Read Match Registers](#)).

37.15.9.2.2.3 CHAN_BASE as a source

Each channel has a parameter base address in SDM, which is configured in the CPBA field of [eTPU Channel n Configuration Register for Engine 1](#) (eTPU_CCCR_CnCR_ENG1) and [eTPU Channel n Configuration Register for Engine 2](#) (eTPU_CCCR_CnCR_ENG2). CHAN_BASE, which represents a parameter address (CPBA*2), can be used as A-source using T4ABS=1010 when T4ABS selects a source from the second register set. In this case, CHAN_BASE is loaded into AS[13:2] to form the byte address (AS[23:14]=0, AS[1:0]=0). For example, in Indirect addressing mode, where the destination register is DIOB, CHAN_BASE is loaded into DIOB[13:2], which is the parameter address, and DIOB[13:0] represents the byte address. CHAN_BASE is the base address of the selected channel (given by CHAN register).

37.15.9.2.3 Flags Sampling Control

This section explains how the flags Z (zero), C (carry), N (negative) and V (overflow) are updated in an ALU operation. When there are post-ALU shift operations, the ALU Carry Out is not directly sampled in Carry flag, but passed to the post-ALU shifter (see [Shift Operations](#)). Since the size of source operands in ALU operations is variable, flags can be sampled as an operation of 8, 16 or 24 bits wide. The operation size selection is automatic, based on defined sizes of sources and destination, using the equation:

```
operation_size = minor(size_of(destination), greater(size_of(A-Source),
size_of(B-Source)))
```

Operation size can also be shown with the following table:

Table 37-381. Operation Size Determination

A Source	B Source	Destination	Operation Size
x	x	8 bits	8 bits
8 bits	8 bits	x	8 bits
16 or 24 bits	x	16 bits	16 bits
16 bits	8 or 16 bits	24 bits	16 bits
8 or 16 bits	16 bits	24 bits	16 bits
24 bits	x	24 bits	24 bits
x	24 bits	24 bits	24 bits

Note

Whenever BS = (constant) 0, its size is considered 8 bits, and all 24 bits in B-bus are set to 0. Therefore, all operations with BS = (constant) 0 have their size determined by AS and Destination only.

CCS field (1 bit) controls whether flags will be updated or not ([Table 37-383](#)). When CCS bit exists in a microinstruction, the operation size will be used to sample flags. In some microinstructions CCS field is replaced by CCSV (2 bits, [Table 37-382](#)). Flag sampling according to CCSV can be set as defined by the operation size, or fixed as 8 or 16 bit operations.

Note

For the post-ALU rotate right operation, CCSV also determines the rotate size: whether 8-bit, 16-bit, or determined by the operation size.

Table 37-382. Flag Sampling Using CCSV field

CCSV	Meaning
00	sample flags as an 8 bit operation
01	sample flags as a 16 bit operation
10	sample flags as defined by operation size
11	do not sample flags

Table 37-383. Flag Sampling Using CCS field

CCS	Meaning
0	sample flags as defined by operation size
1	do not sample flags

When neither CCS nor CCSV are present in the microinstruction, flags are not sampled. CCS and CCSV do not affect the Carry update on Exchange Bit operation (see [Exchange Bit](#)), but does control the N and Z flags.

37.15.9.2.4 B-Source Inversion

The data selected as second source (T4BBS) can be inverted (bitwise boolean NOT) before operation. This is controlled by microinstruction field BINV (1 bit, in the following table). A zero value for BINV activates B-source inversion.

Table 37-384. B-Source Inversion - BINV

BINV	Meaning
0	invert B-source ¹
1	keep B-source bus unchanged

1. Except on max-constant selection, see [Generating "max" constant](#) .

BINV also selects between *adc* or *sbc* enhanced ALU operation, using inverted C flag as carry-in besides BS inversion for *sbc* . Note that BINV does not invert carry in fixed-carry operations (see [Table 37-385](#)).

When BINV = 0, T4BBS = 111 and CIN = 0, the value assigned to BS is 0x800000, instead of 0x0. See [Generating "max" constant](#) for more details.

37.15.9.2.5 Carry-in Control

CIN field (1 bit, [Table 37-385](#)) controls the carry-in for addition/subtraction operations. Functionality of CIN field depends on the arithmetic operation selected by ALUOP. When ALUOP is not available in microinstruction, the operation selected is *add*. For carry-in control in MDU operations, see the following table.

Table 37-385. ALU Carry-In Control

operation	CIN=0	CIN=1
<i>add</i> (addition)	carry-in used is 1 ¹	carry-in used is 0
<i>adc</i> (addition with carry) ²	carry-in used is C flag	
<i>sbcb</i> (subtraction with borrow) ³	carry-in used is inverted C flag	

1. Except on max-constant selection, see [Generating "max" constant](#).

2. Selected by ALUOP=11000 and BINV=1

3. Selected by ALUOP=11000 and BINV=0

37.15.9.2.5.1 Generating "max" constant

When T4BBS = 111, CIN = 0 and BINV = 0, BS is assigned to 0x800000 (called "max constant") instead of 0x000000. This is an exception for CIN and BINV fields: when "max constant" is selected, the carry in is 0 and B-source ("max constant" itself) is not inverted, neither the carry out.

"Max constant" is the value which, added to a time base value minus 1, gives the farthest wrapped time base value that satisfies a channel greater-equal comparison. See [Enhanced Channels](#) for more info.

37.15.9.2.6 Shift Operations

There are three types of shift operations: ALU, post-ALU and Shift Register. ALU shift operations are covered in [ALU/MDU Operation Selection](#). Post-ALU and Shift Register are covered in the following sections.

37.15.9.2.6.1 Shift Register Operations

SR can be used as a general purpose register and it can easily shift-right its contents, combined or not to post-ALU shift operations. If field SRC (1 bit) in microcode is 0, SR will shift its contents 1 bit to the right according to the algorithmic description below. SR shifting operation depends also on SHF or ALUOP fields. ALUOP and SHF never exist both on the same microinstruction format.

Table 37-386. Shift Register Control - SRC

SRC	Meaning
0	shift right SR 1 bit
1	no shift

SR Operation:

```

SR[22:0] = SR[23:1];
if SHF == "01" or ALUOP == "10110" then
    SR[23] = ALU_OUT[0];
else
    SR[23] = 0;
endif;

```

37.15.9.2.6.2 Post-ALU shift operations

Post-ALU shift can be selected by SHF field (2 bits) or by some specific ALUOP field values. SHF and ALUOP fields are never both available in the same microinstruction format. When selecting post-ALU shift operation using ALUOP field, ALU will always add the sources before shifting the result.

Table 37-387. Post-ALU shift operation

Post ALU operation	SHF ¹	ALUOP
shift left (1 bit)	00	10101
shift right (1 bit)	01	10110
rotate right (1 bit)	10	10111
no shift/rotate	11	any other ²

1. ALU performs AS+BS before shift/rotate for all SHF values.
2. Some ALUOP combinations perform shift/rotate, but not using the Post-ALU Shifter (see [Table 37-392](#))

Carry flag is only updated when CCS or CCSV fields allow it (see [Flags Sampling Control](#)). Algorithmic descriptions of post-ALU shift operations are presented in [ALU ADD operation with and without shifting](#).

37.15.9.2.7 Conditional ALU/MDU Operation Execution

The 3-bit field AS/CE allows conditional execution of arithmetic operation, as shown in the following table. The same field can also be used for overriding the size of A-Source (see [A-Source Size Override](#)).

Table 37-388. ALU/MDU Conditional Execution

AS/CE	Meaning
000	used for A-Source size override (see A-Source Size Override)
001	
010	execute if C = 1
011	execute if C = 0
100	execute if Z = 1
101	execute if Z = 0
110	execute if N = 1
111	execute unconditionally/no size override

Other operations not related to ALU/MDU in the same microinstruction are not affected by the AS/CE field.

If a conditional operation is selected, there is no A-Source size override; similarly, when size override for A-Source is selected, the ALU/MDU operation executes unconditionally.

When a conditional ALU/MDU operation is not executed:

- the destination register is not updated. If the destination is CHAN, no actions associated with CHAN assignment occur (see [Channel Selection Register - CHAN](#)).
- the ALU and MDU flags are not updated.
- MDU does not start any operation, i.e., MACH and MACL are not updated.
- SR does not shift.
- T4ABS-selected read-match does not occur.

37.15.9.2.8 A-Source Size Override

Some values if the AS/CE field are used for A-Source Size Override, as shown in the following table.

Table 37-389. A-Source Size Override

AS/CE	Meaning
000	A-source size override to 8 bits
001	A-source size override to 16 bits

Table continues on the next page...

Table 37-389. A-Source Size Override (continued)

AS/CE	Meaning
010	used for conditional execution (see Conditional ALU/MDU Operation Execution)
011	
100	
101	
110	
111	execute unconditionally/no size override

Register size override zero-pads an overridden source to 24-bits (if no sign extension is performed, see [A-source Sign Extension](#)) and affects operation size calculation. When register source is wider than size override, most significant bits of selected register are not used as A source (zeros are used instead). When size override is wider than selected register, register value is padded to zeros.

When size override is used with MDU operations, it affects only the operand values, but not the operation size: MDU operation size is fully determined by the operation definition (fields ALUOP, ALUOPI).

Table 37-390. AS/CE field A source size override functionality

Size Override	Size of Selected Register	AS Value ¹
8 bits	8 bits	reg[7:0]
8-bits	16 bits	reg[7:0]
8bits	24 bits	reg[7:0]
16 bits	8 bits	reg[15:0]
16 bits	16 bits	reg[15:0]
16 bits	24 bits	reg[15:0]

1. All values are zero-padded to 24 bits

37.15.9.2.9 A-source Sign Extension

The SEXT microinstruction field forces sign extension of A source according to the size of A operand, either overridden or not by AS/CE field, according to the following table. The sign is taken from the size-overridden value, not the original one.

Table 37-391. A source Sign Extension

SEXT	Meaning
0	extends sign of A source from its size to 24-bits
1	does not extend sign of A source

A-source sign is not extended in microinstructions without SEXT field, even if AS/CE field is present.

37.15.9.2.10 ALU/MDU Operation Selection

When field ALUOP is available in microinstruction, enhanced ALU operations shown in the following table can be performed, otherwise addition is performed. The ALU operations are defined in [ALU and Post-ALU Shifter](#). The MDU operations are defined in [MAC and Divide Unit \(MDU\)](#).

Table 37-392. ALU Operation Selection - ALUOP

ALUOP	Operation	Comment
00000	AS mults BS[7:0]	signed multiplication
00001	AS multu BS[7:0]	unsigned multiplication
00010	AS fmults BS[7:0]	signed fractional multiplication
00011	AS fmultu BS[7:0]	unsigned fractional multiplication
00100	AS mults BS[15:0]	signed multiplication
00101	AS multu BS[15:0]	unsigned multiplication
00110	AS fmults BS[15:0]	signed fractional multiplication
00111	AS fmultu BS[15:0]	unsigned fractional multiplication
01000	AS mults BS[23:0]	signed multiplication
01001	AS multu BS[23:0]	unsigned multiplication
01010	AS macs BS[23:0]	signed multiply-accumulate
01011	AS macu BS[23:0]	unsigned multiply-accumulate
01100	AS div BS[7:0]	unsigned division by 8-bit value
01101	AS div BS[15:0]	unsigned division by 16-bit value
01110	AS div BS [23:0]	unsigned division by 24-bit value
01111	n.a.	RESERVED
10000	AS[23:0] BS[23:0]	24 bit bitwise OR
10001	AS[23:0] ^ BS[23:0]	24 bit bitwise XOR
10010	AS[23:0] & BS[23:0]	24 bit bitwise AND
10011	abs(AS)	absolute value of AS
10100	AS + BS	arithmetic addition
10101	(AS + BS) shl 1	arithmetic addition with 1-bit post-ALU shift left. (Post-ALU shift operations)
10110	(AS + BS) shr 1	arithmetic addition with 1-bit post-ALU shift right (Post-ALU shift operations)
10111	(AS + BS) ror 1	arithmetic addition with 1-bit post-ALU rotate right (Post-ALU shift operations)
11000	AS adc/sbc BS ¹	addition/subtraction with C flag (Carry-in Control)
11001	AS shl (2 ^{^(BS[1:0]+1)})	AS is shifted left: 2 bits for BS=0; 4 for BS=1; 8 for BS=2; 16 for BS=3
11010	AS shr (2 ^{^(BS[1:0]+1)})	AS is shifted right: 2 bits for BS=0; 4 for BS=1; 8 for BS=2; 16 for BS=3
11011	AS ror (2 ^{^(BS[1:0]+1)})	AS is rotated right: 2 bits for BS=0; 4 for BS=1; 8 for BS=2; 16 for BS=3
11100	AS exch BS[4:0]	exchange C flag and AS bit determined by BS (Exchange Bit)
11101	AS setb BS[4:0]	set bit in AS determined by BS ²

Table continues on the next page...

Table 37-392. ALU Operation Selection - ALUOP (continued)

ALUOP	Operation	Comment
11110	AS clrb BS[4:0]	clear bit in AS determined by BS ³
11111	n.a.	RESERVED

1. Addition/Subtraction is selected by field BINV (see [B-Source Inversion](#))
2. In setb and clrb operations, the register that drives A source is not changed, unless selected as destination of the operation.
3. In setb and clrb operations, the register that drives A source is not changed, unless selected as destination of the operation.

37.15.9.2.11 Operations With Immediate Data

Immediate data can be used with some specific microinstruction formats. eTPU microcode allows 8-, 16- or 24-bit immediate data. Immediate data is loaded as B-source, so T4BBS field is not available. When using 24-bit immediate, an add is performed with A-source = 0 and flags are not updated. ALU operations are available with 8-bit immediate, although the field that selects ALU operation in this case is ALUOPI.

37.15.9.2.11.1 24-bit Immediate Destination

When using 24-bit immediate data, the destination register is selected by T2D field (2 bits), according to the following table.

Table 37-393. 24-bit Immediate Destination - T2D

T2D	Target Register
00	P[23:0]
01	A
10	SR
11	DIOB

37.15.9.2.11.2 Enhanced ALU Operations With Immediate Data

Enhanced operations with immediate data, selected by ALUOPI (5 bits) are allowed only with an 8 bit immediate operand (see the following table).

Table 37-394. ALU Operation Selection With Immediate Data - ALUOPI

ALUOPI	Operation	Comment
00000	AS mults #imm8	signed multiplication
00001	AS multu #imm8	unsigned multiplication
00010	AS fmults #imm8	signed fractional multiplication
00011	AS fmultu #imm8	unsigned fractional multiplication

Table continues on the next page...

Table 37-394. ALU Operation Selection With Immediate Data - ALUOPI (continued)

11100	AS exch #imm8[4:0]	exchange C flag and AS bit determined by #imm8[4:0] (see Exchange Bit)
11101	n.a.	reserved
11110	n.a.	reserved
11111	n.a.	reserved

37.15.9.3 Channel Control and Configuration Microoperations

Channel Control and Configuration fields set configuration values in the channel logic of the channel selected by the CHAN register, except fields LSR and CIRC.

37.15.9.3.1 Channel flags operations

Each channel has two associated hardware flags, called Channel Flag 0 and Channel Flag 1. Microcode field FLC (3 bits) allows them to be set or cleared, as shown in the following table. These flags can be tested by microcode as a branch condition, and may also influence in the Entry Point taken, allowing fast state decoding. For more details, see [Entry Points](#).

Table 37-395. P flags operation - FLC

FLC	Meaning
000	Clear flag0
001	Set flag0
010	Clear flag1
011	Set flag1
100	Copy flag1:flag0 from P[25:24]
101	Copy flag1:flag0 from P[27:26]
110	Copy flag1:flag0 from P[29:28]
111	No operation

37.15.9.3.2 Comparator and Time Base Selection

TBSA and TBSB fields (4-bit wide each) are used to configure the type of the comparator and the time bases used for match or capture (see the following tables). TBSA can also be used to control the Output Buffer Enable signal (See [Pin Control Registers](#)).

Table 37-396. Time Base Selection A - TBSA

TBSA[3] = 0	TBSA bit	2	1	0
	bitfield	Comparator selection	Capture selection	Match TB selection
	0	greater or equal	TCR1	TCR1
	1	equal-only	TCR2	TCR2
TBSA[3] = 1	action	2	1	0
	set OBE=1 ¹	0	0	0
	set OBE=0	0	0	1
	do nothing	1	1	1
	reserved	all other values		

1. Output Buffer Enable is not available on this chip.

Table 37-397. Time Base Selection B - TBSB

TBSB[3] = 0	TBSB bit	2	1	0
	bitfield	Comparator selection	Capture selection	Match TB selection
	0	greater or equal	TCR1	TCR1
	1	equal-only	TCR2	TCR2
TBSB[3] = 1	action	2	1	0
	do nothing	1	1	1
	reserved	all other values		

37.15.9.3.3 Transition Detection and Pin Action Control

IPACA/B and OPACA/B fields are used to configure transition detection sensitivity (for the channel input signal) or output pin action control (for the channel output signal), as defined in the table below. IPACA and IPACB have the same format, where IPACA is related to Match A and first transition detection, and IPACB to Match B and second transition detection. The same applies in analogue way to OPACA and OPACB.

For the output signal, configuring OPAC registers does not change the current signal state, but defines the action to be done when a match or transition detection occurs. See [Match Recognition](#) and [Channel Modes on Output Signal Generation](#) for more information.

IPACA/B=1xx also enables assertion of MRLA/B during Time Slot Transition. See [Match Recognition](#).

Table 37-398. Input and Output Pin Action Control - IPACA/B and OPACA/B

value	IPAC meaning	OPAC meaning
000	Do not detect transitions	Do not change output signal
001	Detect rising edge only	Match ¹ sets output signal high
010	Detect falling edge only	Match ¹ sets output signal low
011	Detect both edges	Match ¹ toggles output signal
100	Detect input signal = 0 on Match ¹	Transition detection sets output signal low
101	Detect input signal = 1 on Match ¹	Transition detection sets output signal high
110	reserved	Transition detection toggles output signal
111	do not change IPAC	do not change OPAC

1. Match A is used for IPACA/OPACA, and Match B for IPACB/OPACB.

37.15.9.3.4 Immediate Pin State Control

It is possible to change output signal state immediately by using PSC (2 bits) and PSCS (1 bit) fields.

Table 37-399. Immediate Pin State Control - PSC and PSCS

PSC	PSCS	Meaning
00	0	set signal as specified by OPACA (see Transition Detection and Pin Action Control)
00	1	set signal as specified by OPACB (see Transition Detection and Pin Action Control)
01	x	set signal high
10	x	set signal low
11	x	don't change signal state

37.15.9.3.5 Write Channel Match and UDCM Registers

Match registers can have their values changed using ERWA and ERWB fields (1 bit each). They also set their respective MRLE register (see [Match Recognition](#)).

ERWA can also be used to program the UDCM register (see [UDCM - User Defined Channel Mode](#)). The field CMW selects where the contents of ERTA is copied when ERWA is active (see the following table).

Table 37-400. Write MatchA/B - ERWA/B

Field	CM W	Value	Action
ERWA	1	0	write ERTA value in MatchA. Enable matches for MatchA register (MRLEA=1)
	0	0	write ERTA value into UDCM
	1	1	don't change UDCM, MatchA and MRLEA
	0	1	reserved
ERWB	1	0	write ERTB value in MatchB. Enable matches for MatchB register (set MRLEB=1)
	1	1	don't change MatchB and MRLEB
	0		
	0	0	reserved

If ERTA or ERTB is a destination of an ALU operation and, at the same time, the respective ERWA/B field is active, the new ERTA value is the one written into the MatchA/B register or the UDCM register.

37.15.9.3.6 Clear Transition/Match Event Registers

Flags MRLA, MRLB, TDLA and TDLB (see [ER - Event Registers](#)) indicate the state of matches and transitions detected in the selected channel, and it is possible to clear those flags using the microcode fields MRLA, MRLB (1 bit each) and TDL (1 or 2 bits, depending on the format). The flags cleared by these microcode fields are the actual channel flags, and also the ones sampled into the branch logic.

TDL can be one or two bits wide, depending on the microinstruction format (see [Microinstruction formats](#)). Two-bit TDL allows independent clearing of TDLA and/or TDLB. [Table 37-402](#) defines the two-bit TDL field.

Table 37-401. Clear Transition/Match Event Registers - MRLA/B, TDL

Field	Meaning
MRLA	0 = clear MRLA event register, 1 = don't change
MRLB	0 = clear MRLB event register, 1 = don't change
TDL (1 bit)	0 = clear TDLA and TDLB flags, 1 = don't change

Table 37-402. Independent TDLA/B clear - two-bit TDL

value	Meaning
0 0	clear TDLA
0 1	clear TDLB
1 0	clear both TDLA and TDLB
1 1	do not clear TDLA or TDLB

37.15.9.3.7 Disable Matches

Microcode field MRLE (1 bit) allows disabling matches on channel selected by CHAN register, for both MatchA and MatchB registers, by clearing their respective MRLE bits. Matches can be enabled for each Match register using ERWA and ERWB fields (see [Write Channel Match and UDCM Registers](#)).

Table 37-403. Disable Matches - MRLE

MRLE	Meaning
0	Disable matches for Match A and Match B
1	don't change match enabling

Some instruction formats have a two-bit MRLE field (see [Microinstruction formats](#)) which allows independent disabling of Matches 1 and 2, as shown in the following table.

Table 37-404. Two-bit MRLE

MRLE	Meaning
0 0	Disable Match A (clear MRLEA)
0 1	Disable both Matches (clear MRLEA and MRLEB)
1 0	Disable Match B (clear MRLEB)
1 1	nop

37.15.9.3.8 Disable Match and Transition Service Requests

Microcode field MTD (2 bits) disables match and transition service requests for the selected channel. MTD does not disable Link Service Request and Host Service Request. MTD sets or resets register SRI (for more details see [SRI - Match/Transition Service Request Inhibit Latch](#)) and TCCEA (see [TCCEA - Transition Continuous Capture Enable](#)) .

Table 37-405. Disable Match and Transition Service Request - MTD

MTD	Action on SRI	Action on TCCEA
00	SRI = 0: enable service requests for match and transition	TCCEA = 0: disable transition captures ¹ when TDLA = 1
01	SRI = 1: disable service requests for match and transition	
10	SRI = 1: disable service requests for match and transition	TCCEA = 1: enable transition captures ² when TDLA = 1
11	don't change	

1. Disables only captures on transition events specified by IPACA.

2. Enables only captures into CaptureA register, on transition events specified by IPACA.

37.15.9.3.9 Predefined Channel Modes

Microcode PDCM field (4 bits) defines the channel mode (see [Channel Modes](#)).

PDCM coding is shown in the table below. Note that PDCM bit 0 selects between Single Transition (PDCM[0]=0) and Double Transition (PDCM[0]=1) predefined modes.

PDCM is also used to select the user-defined channel mode, defined by the channel register UDCM (see [UDCM - User Defined Channel Mode](#)).

Table 37-406. Predefined Channel Modes

PDCM	Channel mode
0000	em_b_st
0001	em_b_dt
0010	em_nb_st
0011	em_nb_dt

37.15.9.3.10 Channel Interrupt and Data Transfer Requests

Microcode can issue Interrupt Requests, Data Transfer Requests and Global Exception through CIRC field. For more information see [Interrupts and data transfer requests](#).

Table 37-407. Channel and Data Transfer Requests - CIRC

CIRC	Meaning
000	Channel Interrupt Request from selected channel
001	Data Transfer Request from selected channel
010	Channel Interrupt and Data Transfer requests from selected channel
011	Channel Interrupt and Data Transfer requests from serviced channel
100	Channel Interrupt Request from service channel

Table continues on the next page...

Table 37-407. Channel and Data Transfer Requests - CIRC (continued)

CIRC	Meaning
101	Data Transfer Request from service channel
110	Global Exception
111	don't request interrupt

37.15.9.3.11 Clear Link Service Request

Microcode LSR field (1 bit) is used to clear the Link Service Request flag of the serviced channel (may not be the one selected by CHAN). The LSR branch condition is always cleared, but not the Link Service Request, if another channel link was received by the serviced channel during the executing thread. See [Channel Link](#) for more information.

Table 37-408. Link Service Request Negation Control - LSR

LSR	Meaning
0	clear Link Service Request (flag LSR)
1	don't change

37.15.9.4 Flow Control Microoperations

eTPU has *jump* and *call* microoperations to change microcode flow. Besides, eTPU has *dispatch jump* and *dispatch call* that can be used to implement a jump table. In *call* (or *dispatch call*) microoperation, the return address is saved in RAR register. If nested sub-routine calls are necessary, return address values have to be saved in a stack, usually implemented with DIOB register.

Flow Control microoperations are also provided to repeat a given microinstruction, to finish the current thread execution, and to halt the microengine.

37.15.9.4.1 Ending Current Thread - END

Microcode END field (1 bit) finishes current thread and allows other channels to be serviced. If END field is 0, the current instruction is completed and the thread is finished. END = 1 has no effect, and the next microinstruction is executed Any MDU operation (see [MAC and Divide Unit \(MDU\)](#)) that could be still pending when the thread is finished is left incomplete. END also releases any semaphore locked by the Engine.

37.15.9.4.2 Branch Operations

Branch operations can be **jump** or **call**. The target address of *jump* or *call* microoperations is always immediate and absolute. Branch microoperation is affected by FLS field (refer to [Flush Pipeline](#)).

37.15.9.4.2.1 Selecting Jump or Call Microoperations

The only difference between *jump* and *call* microoperations is that when a *call* is executed the value of PC or PC+1 (depending on flush, see [Flush Pipeline](#)) is saved in RAR register. The microcode field J/C (1 bit) selects whether *jump* or a *call* is executed, according to the following table.

Table 37-409. Jump / Call Selection - J/C

J/C	Meaning
0	jump
1	call

37.15.9.4.2.2 Branch Target Address

Microcode BAF field (14 bits) indicates the absolute address of a *jump/call target*.

37.15.9.4.2.3 Conditional/unconditional branch

Jump and *call* can be conditional or unconditional, depending on the BCC (6 bits) and BCF (1 bit) fields, as shown in [Table 37-410](#) and [Table 37-411](#). BCF determines whether branch is taken when condition specified by BCC is true or false. When a branch condition uses the channel flags, the channel context is related to the channel number written in CHAN register.

Table 37-410. Branch Condition Inversion - BCF

BCF	Meaning
0	branch if condition determined by BCC is false
1	branch if condition determined by BCC is true

Table 37-411. Branch Condition Selection - BCC

BCC	Meaning	BCC	Meaning
001110	Flag 0	001111	Flag 1
100000	V ALU flag	110000	PSS channel flag
100001	N ALU flag	110001	PRSS channel flag

Table continues on the next page...

Table 37-411. Branch Condition Selection - BCC (continued)

BCC	Meaning	BCC	Meaning
100010	C ALU flag	110010	"Less Than" ALU flag combination (signed) ¹
100011	Z ALU flag	110011	"Lower or Equal" ALU flag combination (unsigned) ²
100100	MV MDU flag	110100	P[24]
100101	MN MDU flag	110101	P[25]
100110	MC MDU flag	110110	P[26]
100111	MZ MDU flag	110111	P[27]
101000	TDLA channel flag	111000	P[28]
101001	TDLB channel flag	111001	P[29]
101010	MRLA channel flag	111010	P[30]
101011	MRLB channel flag	111011	P[31]
101100	LSR channel flag	111100	PSTO channel flag
101101	MB flag MDU flag	111101	PSTI channel flag
101110	FM[1] channel flag	111110	SMLCK semaphore flag
101111	FM[0] channel flag	111111	false
all other values reserved			

1. "less than" is a signed comparison, equal to the xor between ALU flags V and N; e.g., $0 < 0xFFFFFFFF$ tests as false ($0 < -1$).
2. "lower equal" is an unsigned comparison, equal to Z or C; e.g., $0 < 0xFFFFFFFF$ tests as true.

37.15.9.4.3 Dispatch Microoperation

Dispatch microoperation is an unconditional branch where the target address is always $PC + P[31:24]$ (unsigned). Dispatch is affected by FLS field (refer to [Flush Pipeline](#)). Dispatch microoperation is defined by R/D field (2 bits, see the following table). Field R/D can also be used to define return from sub-routine (see [Return from subroutine](#)).

Table 37-412. Return and Dispatch - R/D

R/D	Meaning
00	return from subroutine (see Return from subroutine)
01	dispatch jump
10	dispatch call
11	don't change microinstruction flow

37.15.9.4.4 Return from subroutine

When a subroutine *call* or a *dispatch call* microoperation is executed, the return address is saved in RAR register. To return from a subroutine a microoperation is available to load the contents of RAR register back to the PC. Fields R/D (2 bits) or RTN (1 bit, see the table below) can be used to return from subroutine. For R/D field, see [Table 37-412](#).

Return from subroutine microoperation is affected by FLS (see [Flush Pipeline](#)) when field R/D is used. Return execution through RTN always flushes the pipeline.

Table 37-413. Return from subroutine - RTN

RTN	Meaning
0	Return with pipeline flush
1	Do not return

37.15.9.4.5 Flush Pipeline

When a branch, dispatch or subroutine return microoperation is executed, the next microinstruction can be executed unconditionally before the flow change takes effect, since microengine has a three-stage pipeline. Executing the next microinstruction after a branch maximizes execution performance. This feature is controlled by field FLS (1 bit, see the table below). When FLS=0 the pipeline is flushed, so the next microinstruction placed after a branch is decoded as NOP if the branch is taken. If FLS=1, the microinstruction placed after the branch is executed, either if the branch is taken or not, as shown in the figure below.

Flush also controls which value is stored in RAR in a call: in case of no flush, it is the address of the branch/dispatch instruction + 2, even if RAR is the ALU destination of the instruction after the call; in case of a flush, it is the address of the instruction following branch/dispatch.

If a branch with no flush is followed by another branch with no flush, the instructions are executed in the following order:

1. first branch
2. second branch
3. first branch's destination instruction
4. second branch's destination instruction, and the flow proceeds normally from then on

The destination of the first branch must not be another flow changing instruction (branch, return or dispatch). Similar flows apply when returns or dispatches are used instead of branches. This scheme can be used to implement quick table look-ups with a dispatch replacing the first branch, for instance.

Table 37-414. Flush Pipeline - FLS

FLS	Meaning
0	flush pipeline when jump / call / dispatch jump / dispatch call / return is executed
1	do not flush pipeline when jump / call / dispatch jump / dispatch call / return is executed

Figure 37-331. Flush Pipeline

37.15.9.4.6 HALT microinstruction

HALT is a microinstruction provided to implement software breakpoints (see [Software breakpoints](#)). Note that HALT is coded as a microinstruction format, not a field (see [Microinstruction formats](#)). The execution of this instruction puts the microengine in halt state. For more information about the implications of microengine halt state, see [Microengine Halt State](#). HALT is valid only if software breakpoints are enabled at the Debug interface. If software breakpoints are not enabled, HALT executes as a NOP and is treated as an Illegal Instruction (see [Illegal instructions](#)).

37.15.9.4.7 NOP microinstruction

There is not a unique microinstruction with an assigned opcode to do No Operation. NOP microinstruction is achieved through any of the formats shown on [Microinstruction formats](#) where the user can assign to each individual field the corresponding value for "No Operation". However, to prevent future impacts of instruction changes on object code compatibility, the instruction value 0x4FFFFFFF should always be used for NOP.

37.15.9.5 Illegal instructions

An instruction is considered illegal if any reserved field value is used, including when the fields marked rsv in the instruction formats (see [Microinstruction formats](#)) are assigned value 0. A HALT instruction is exceptionally considered illegal when executed with software breakpoints disabled (see [HALT microinstruction](#)). Global Exception may be issued up to two microcycles after instruction fetch. The execution results of an illegal instruction on the microengine, channel logic or host interface are unspecified, except for the HALT case.

If the microengine decodes an illegal instruction, the following actions are taken:

- A Global Exception is issued.
- The ILF1/2 flags in [eTPU Module Configuration Register \(eTPU_SCR_MCR\)](#) are set to indicate this occurrence to the Host.
- A breakpoint occurs, if NDEDI is present and configured to do so (see the NDEDI details for more information).

37.15.9.6 Microinstruction Parallelism Issues

This section clarifies parallelism issues that arise when two non-commutative microoperations appear in the same microinstruction.

37.15.9.6.1 ALU Operations and Read Match Registers

ALU operations have only one destination register, but there is one case where source selection determines destination: read Match register in ERTA and ERTB registers. In this case if ALU destination is ERTA or ERTB a conflict arises. The ALU destination value overwrites the value read from the match registers.

37.15.9.6.2 ALU and SDM Operations

P and DIOB registers can be selected as destination by both ALU and SDM (read) microoperations in the same microinstruction. Since P and DIOB update from SDM data happens after P and DIOB update for ALU/MDU microoperations, the data read from SDM remains in P or DIOB after an operation when one of them is specified as destination for both ALU and SDM microoperations. In this case, the value loaded into P or DIOB is the one read from SDM. However, the ALU operation is executed and its flags are updated accordingly.

When P or DIOB is destination of an SDM read and also an ALU source at the same microinstruction, the value before the read is used for the ALU operation.

If DIOB is the ALU destination and P is loaded from SDM or vice-versa, no conflict occurs, and the result is the same as if operations occurred separately.

All the above also applies to Zero SDM operations.

When using P or DIOB as destination for ALU operations and also as source for a SDM write operation, the data written in SDM is the one calculated by ALU, which means it is possible to calculate a value and write it in an SDM address using only one microinstruction.

The old value of DIOB or the old value minus 4 (pre-decrement) is always used when DIOB is selected as address (indirect address mode), no matter if DIOB is selected as destination of either the SDM or ALU. For the value loaded into DIOB, refer to the following table.

Table 37-415. DIOB load from SDM and ALU

DIOB selected as SDM read destination?	DIOB selected as ALU destination?	DIOB load value
no	no	DIOB, --DIOB (pre-decrement), or DIOB++ (post-increment)
yes	no	SDM read data (post-inc and pre-dec ignored)
yes	yes	SDM read data (post-inc, pre-dec and ALU result ignored)
no	yes	ALU result (post-inc and pre-dec ignored)

When CHAN is the destination of an ALU operation in parallel with a channel-relative SDM access, the CHAN value used to calculate the address is the one before the ALU operation.

37.15.9.6.3 ERTA/B as ALU destination and ERWA/B

The value in ERTA and ERTB registers can be written in match registers of the selected channel by using fields ERWA and ERWB ([Write Channel Match and UDCM Registers](#)). If, at the same microinstruction, ERTA or ERTB is destination of an ALU/MDU microoperation, the value written in Match registers is the ALU/MDU result.

The same applies to UDCM when ERTA is the destination of an ALU operation and instruction fields ERWA and CMW are active .

If an ALU operation occurs in parallel with ERWA/B but ERTA/B are not the destination of an ALU/MDU operation, then UDCM and MatchA/B receives the ERTA/B value.

37.15.9.6.4 ERWA/B and MRLE

ERWA/B automatically sets the MRLEA/B channel latch, respectively (see [Write Channel Match and UDCM Registers](#)). Microinstruction fields ERWA/B independently sets MRLEA/B channel flags, regardless of MRLE.

37.15.9.6.5 CHAN assignment, Read Match and ERWA/B

When CHAN is a destination of an ALU operation it causes a read of the CaptureA/B register values into ERTA/B. The Capture registers loaded into ERTA/B are selected by the new CHAN value. The value of the CaptureA/B registers overwrites any read-match commanded simultaneously.

If CHAN assignment happens with an ERWA/B operation in the same instruction, the updated Match register(s) belong to the new selected channel.

37.15.9.6.6 Read Match and ERWA/B

If a read match operation is executed with ERWA/B in the same microinstruction, the MatchA/B registers receive the old values of ERTA/B, and the ERTA/B registers receive the old MatchA/B values simultaneously, i.e.: ERTA/B and MatchA/B swap their values.

If ERTA/B is the destination of an ALU operation at the same instruction, MatchA/B gets the ALU result (see [ERTA/B as ALU destination and ERWA/B](#)), but the ERTA/B not being written still receives the old MatchA/B values.

Note

Read match, ERWA/B and CHAN assignment can be active at the same instruction. Combining rules [CHAN assignment, Read Match and ERWA/B](#) and [Read Match and ERWA/B](#), the result is: ERTA/B receives the CaptureA/B values of the new CHAN value, and MatchA/B of the new channel receives the old ERTA/B value(s).

37.15.9.6.7 Stack accesses and ALU operations

Post-increment is ignored in a stack operation (field STC) if DIOB is loaded from SDM: DIOB keeps the value read from SDM. Pre-decrement is ignored in a stack operation (field STC) if DIOB is destination of an ALU operation, for DIOB load value, but not for DIOB as address. Post-increment/pre-decrement remains valid in all other situations. These rules can be summarized in the following equivalent C code, and in [Table 37-415](#).

```
DIOB = *DIOB[15:2];      // read without posinc/predec
*DIOB[15:2] = DIOB;      // write without posinc/predec
DIOB = * (--DIOB[15:2]); // read with predec
DIOB = *DIOB[15:2];      // read with posinc (ignored)
* (--DIOB[15:2]) = DIOB; // write with predec
*DIOB[15:2]++ = DIOB;    // write with posinc (value written is before
increment)
```

37.15.9.6.8 SRC and ALU/MDU operations

If operation SRC is active (field SRC = 0) and register SR is selected as destination of an ALU operation, the value of the ALU operation prevails over the shifted value.

The value of SR used as source in the ALU/MDU operation is the one before the shift.

37.15.9.6.9 Semaphore lock/free and SMLCK branch condition

When the SMLCK branch condition is tested at the same microinstruction of a semaphore lock or free, the condition is evaluated after the semaphore action (either free or lock) is taken.

37.15.9.6.10 Dispatch and SDM Read

When the most significant byte of P is read from SDM (read 8 msb bits or 32 bits) and a dispatch instruction is executed simultaneously, the dispatch target address is calculated upon the P value before the read.

37.15.9.6.11 CHAN Assignment, PSC/PSCS, and clear MRLEA/B, MRLA/B, TDLA/B

When clear MRLEs, MRLA/B or TDLs is done and a CHAN assignment is done at the same time, the flag selected by the old CHAN value is cleared in the channel, but the branch conditions receive the state of the flags selected by the new CHAN.

When a pin action is commanded through PCS/PSCS and a CHAN assignment is done simultaneously, the output signal affected is selected with the old CHAN value.

Flow Control Operations

NOTES:

¹ format E4 is deprecated; the same result can be obtained with format E1 with field STC=11

Figure 37-332. Microinstruction formats

All bits marked "rsvd" are reserved, and must be coded as 1.

37.15.10 Shared Subsystems support

Shared Subsystems support allows eTPU to control other modules, either independently or sharing control with the host. A notable example of shared subsystem is the Reaction Module (see the Reaction Module chapter for details), which is connected to the eTPU as shown in the figure below. The host CPU accesses the Reaction Module through the eTPU, which can also access the same registers.

When the SSMAE field in [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) or [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#) is 1, the eTPU channel's threads can control shared subsystems by accessing their registers, which are mapped onto the higher 16 Kbytes of the microcode data address space (byte addresses/DIOB values 0x4000 to 0x7FFF, equivalent to parameters 0x1000 to 0x1FFF), as shown in [Figure 37-334](#). The shared subsystem registers are accessible by microcode only with the indirect address mode (see [SDM Addressing Modes](#)).

When the SSMAE field in [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) or [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#) is 0, the channel's threads can access only the SDM, mirrored throughout the whole DIOB address range.

The same Shared Subsystem register address space is accessible by the host through the Shared Subsystem Area within the eTPU memory map (see [Figure 37-334](#) and [Memory map](#)), allowing shared control and/or supervision between the host and the eTPU. The arbitration mechanism between host and eTPU accesses is the same used for SDM accesses (see [SDM arbitration](#)). The CDC (see [Coherent Dual-parameter Controller \(CDC\)](#)) cannot be used for coherent transfers between SDM and the Shared Subsystem Area, or within the Shared Subsystem Area itself.

Note

The detailed register map within the Shared Subsystem Area depends on the subsystem module.

Bus errors coming from the Shared Subsystem cause a Global Exception and are flagged by the MCR[SSAERR] bit on microengine accesses only. In the case of host access, the bus error only propagates to the slave bus, which also issues a bus error.

A Shared Subsystem may be divided into submodules or channels, hereafter called **Shared Subsystem Units** (or **Shared Units** for short), which can be individually controlled by an eTPU function (see [Functions and threads](#))

A Shared Unit is logically linked with an eTPU channel through the eTPU_SSIR_ETPUSSSIR_n configuration³⁸. There is one eTPU_SSIR_ETPUSSSIR register for each Shared Unit to configure its interface with the eTPU (see [eTPU Shared](#)

[Subsystem n Integration Register \(eTPU_SSIR_ETPUSSSIR \$n\$ \)](#)). The Shared Unit uses the Link Service Request (LSR) mechanism to request service to the eTPU. The Link Service Request is targeted to the channel/engine configured in [LENG](#) and [LCHAN](#). The function assigned to this channel must be written to service the Shared Unit. The Shared Unit link service request may have the same source as an interrupt to the host.

Note

Shared Unit link service requests are level-sensitive to the eTPU. If it comes from an interrupt source, the link service request stays asserted as long as the interrupt is asserted and enabled, so the interrupt request must be cleared before the clear of the LSR flag in the link service request thread.

[LENG](#) can also be used by the host to disable Link Service Requests to the eTPU. The eTPU microcode can only disable LSRs from the Shared Unit through configuration specific to the Shared Unit itself.

Note that more than one Shared Unit can generate LSRs to the same eTPU channel, in which case the LSR source can be determined by microcode through the Shared Unit status register(s). An eTPU channel configured as a Shared Unit LSR target can also receive Link Service Requests from other eTPU channels or Shared Units. The same LSR service and flag behavior found in links between eTPU channels applies to Shared Unit links (see [Channel Link](#)).

The table below summarizes the mapping of Reaction Module resources into Shared Subsystem Support.

38. However, in the case of Reaction Module, the eTPU_SSIR_ETPUSSSIR n configuration does not determine which eTPU channel output enables the Reaction Channel modulation; this is defined in the Reaction Module configuration.

37.15.11 Development support features

Following sections describe several features available to support development. Most debug features are accessible through a separate debug bus, and are not available through registers in the standard eTPU memory map. The details of the access to this interface are MCU-dependent (see Debug Interface chapter). The microengines can also be put in halt state by a device-level debug request.

NOTE

The behavior of the debug support logic is not specified in the event of a non-correctable memory error on either SCM or SDM (see [Memory error support](#)).

37.15.11.1 Nexus Class 3 Support

NDEDI is an IP block designed to support Nexus functionality for the eTPU. It provides a Nexus class 3 or class 1 debug interface, depending on the MCU (see Configuration section). Nexus is a development support external interface defined by the **IEEE standard ISTO 5001-1999**. More details about it can be found in the NDEDI details.

Some of the next subsections describe debug features provided by the eTPU microengine debug support combined with the NDEDI block.

37.15.11.2 Microengine Halt State

Halt is a microengine state where it suspends execution during a thread, or does not start executing a scheduled thread from idle state. While Idle State is entered from END execution without any other scheduled thread, microengine enters Halt State by any of the following events:

- execution of the HALT microinstruction (software breakpoint).

- external halt request through the Debug Interface (includes Nexus breakpoint request via EVTI input pin - see [Nexus Class 3 Support](#)).
- the other Engine enters halt state and they are configured to halt simultaneously (bit HTWIN is asserted via Nexus Interface).
- System level device debug request assertion and NDEDI register NDEDIETPUx_DC field CBI=1. If same register's field CBT=1, microengine halts at the next time-slot boundary, if CBT=0 it halts immediately. As a particular case, microengines come halted out of reset if device debug request is asserted, since CBI reset value is 1. Microengine does not execute out of reset, either in halt (device debug request asserted) or idle state (device debug request negated), but halt enables several other features (see below).
- occurrence of any of the hardware breakpoint conditions. See [Hardware breakpoints](#) for details.
- execution of a single-step microinstruction: microengine returns to halt state after executing a single microinstruction while in halt state. See [Single-step Execution](#) and [Forced microinstruction execution](#) for details.

When microengine enters halt state, it automatically triggers the following actions:

- suspends input signal sampling and filters (respective Engine channels only), if NDEDI_ENGINEx_DC[PINS] = 1 at the Debug Interface.
- releases the SDM arbitration for Host or CDC accesses, no matter if microengine was halted in the middle of a dual parameter (back-to-back) access.
- stops TCR1/2 clocks of the respective Engine, if signal ndedi_stop_tcr is asserted at the Debug Interface.
- if the other Engine is also in halt state or stopped, allows turning the [eTPU Module Configuration Register \(eTPU_SCR_MCR\)](#) VIS bit to 1.

If all halt conditions are cleared when VIS=1, microengine(s) keep on halt state until VIS=0, when it automatically exits halt state, except on single-step (see [Single-step Execution](#)), so that single-step execution is ignored while VIS=1.

MDU continues executing until it finishes any ongoing operation even if microengine is in halt state, except when the halted instruction is an END.

There are two kinds of halt state, depending on the previous microengine state when halted:

1. **halt_idle**, if the engine was not executing a thread when halted; the engine cannot leave halt_idle to fetch instructions, so one cannot single-step or follow a program flow; it can, however, execute forced instructions (see [Forced microinstruction execution](#)).
2. **halt_exec**, if the engine was executing a thread when halted. The engine can single-step and continue a program flow from halt_exec.

When microengine exits halt state, any dependable action is suspended and, if exiting halt_exec, the instruction pointed by the PC is fetched, while the instruction already fetched before halt is executed. Note that both the PC and the prefetched instructions can be modified during halt state, with a forced execution of a branch instruction (see [Forced microinstruction execution](#)).

37.15.11.3 Hardware breakpoints

Microengine can enter halt state through a command from the Debug Interface, configuring a hardware breakpoint. Hardware breakpoints can halt the microengine on specific conditions, listed below. These conditions depend on NDEDI configuration (see the NDEDI details for more information).

- CHAN register assignment (only by microcode, not by time slot transition).
- SDM read and/or write to a given address and/or write data. The breakpoint is always qualified by the SDM address, but the following variations are allowed:
 - break on write only, read only, or read-and-write.
 - break on higher-byte write data value, lower 24-bit write value, full word (32-bit) write value, or regardless of data. Break on read data is not supported.
- PC (program counter) value.
- Beginning of a thread with a Host Service Request pending.
- Beginning of a thread with a Link Service Request pending.
- Beginning of a thread with a Match Service Request pending.
- Beginning of a thread with a Transition Service Request pending.
- End of a thread.
- Illegal instruction execution.

All these conditions can also be qualified by the value of the CHAN register.

NOTE

Data breakpoints are not supported on Shared Subsystem Area accesses (see [Shared Subsystems support](#)).

Hardware breakpoints halt the microengine before the halted instruction is executed, except on data breakpoints. Data breakpoints allow the instruction that performs the data access to be executed before the microengine is halted.

Note

Data breakpoints in eTPU versions before eTPU2 halt the breakpoint instruction before its execution in all cases, including data breakpoints.

On any of these conditions, halt of one microengine does not depend on the halt of the other, unless the other engine is configured to do so, via Nexus Interface. Occurrence of any of these conditions halts the microengine, i.e., the conditions are logically ORed together, and they can be individually enabled.

While in halt state, the microengine can also execute any forced microinstruction not in the normal program flow (see [Forced microinstruction execution](#)) or, if in halt_exec, in single-step (see [Single-step Execution](#)).

There are situations when requests for stopping an engine, breakpoint and service can occur simultaneously. Breakpoint requests always prevails over a stop request ([eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) or [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#) bit MDIS=1 or device debug request=1). When the eTPU is idle: stop request prevails over Service Request if there is not a hardware breakpoint request; a hardware breakpoint request leads to debug mode immediately if there is no Service Request, and after TST if there is Service Request (regardless of stop requests). The rules above are summarized in the the following table, showing the destination state of the microengine in each situation.

Table 37-417. Breakpoint, stop and service requests resolution from idle

Breakpoint request	MDIS	Service request	Final state
no	0	0	Idle
no	1	0	Stop
no	0	1	TST
no	1	1	Stop
Yes	0	0	Halt_idle
Yes	1	0	Halt_idle
Yes	0	1	TST ¹
Yes	1	1	TST ¹

1. Breaks after TST, if signal `ndedi_sync_break` is still asserted.

When a thread is ending, it goes to Idle or TST only if there is neither a hardware breakpoint request nor a request to stop ([eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) or [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#) bit MDIS=1 or device debug request=1). When thread is ending and there are simultaneous hardware breakpoint and stop (MDIS=1 or device debug request=1) requests, hardware breakpoint prevails and the engine enters Debug mode (Halt_idle state).

If the engine entered Debug mode after a thread finished (Halt_idle state) and a "go" command comes from the debug interface, the engine state machine goes to Idle and the rules above apply. It means that if a "go" is issued in Halt_idle state with MDIS=1, the engine goes to Idle for one microcycle and then stops (if MDIS or device debug request keeps asserted and there is no other breakpoint request).

Note

Hardware breakpoint requests are ignored for the first microinstruction executed when microengine leaves halt.

37.15.11.4 Hardware Watchpoints

Debug Interface allows watchpoints on the same conditions available for hardware breakpoints (see [Hardware breakpoints](#)).

Note

Data breakpoints are not supported on Shared Subsystem Area accesses (see [Shared Subsystems support](#)).

37.15.11.5 Software breakpoints

A software breakpoint occurs when microengine executes a HALT microinstruction. Any number of software breakpoints can be set in code, usually replacing an active microinstruction.

Like any other microinstruction, HALT increments the PC and pre-fetches the next instruction. So, before the halt state is suspended, if the original program flow must be followed, the original instruction at the HALT address must be executed, regardless if the software breakpoint is removed (replacing HALT by the original microinstruction) or not. Follows the procedure to resume execution from a software breakpoint:

1. restore the original instruction in SCM (replace HALT).
2. force a jump with flush to the original instruction (see [Forced microinstruction execution](#)).
3. if the software breakpoint must be kept: single-step and replace the original instruction with a HALT.
4. let the flow continue, issuing a GO command (leaving halt state).

Special care must be taken if HALT is followed by another HALT, and the second HALT is removed when microengine was halted by the first one. In this case, replacing the second HALT with the original microinstruction is not enough to remove the second breakpoint, because the second HALT was already prefetched and would be executed anyway when halt was suspended. The debugger must also do a forced execution of unconditional branch with flush to the original microinstruction address. That will clear the pipeline, replacing the prefetched instruction with a NOP, and load PC with the address of the removed breakpoint. So, when halt state is suspended, the original microinstruction will be fetched while NOP is executed, and program flow continues normally from then on.

Note

A HALT instruction placed after a no-flushing branch, dispatch or return may be a problem from the debugger application standpoint: after the HALT is executed, the eTPU debug interface informs the address of the branch/dispatch/return destination, and the debugger application has no direct way to identify which HALT instruction was executed, if multiple HALTs lead to the same address. This can be solved if the debug support block (NDEDI) has a register holding the address of the last instruction executed, otherwise one should forbid non-flushed HALT instructions. See the NDEDI details.

Software breakpoint setting and removal is possible only with SCM RAM implementations or ROM implementations with SCM RAM emulation (see [SCM Emulation](#)). There is only one way of inserting software breakpoints into SCM RAM: programming VIS=1 in [eTPU Module Configuration Register \(eTPU_SCR_MCR\)](#), and then accessing SCM as an ordinary RAM from the slave bus. This can be done only if both Engines are halted or stopped.

37.15.11.6 Single-step Execution

When microengine is already in halt_exec state, it can run the next microinstruction in the normal program flow and get back to halt state. PC is incremented, or assigned the BAF value in a branch with satisfied condition. Note that the executed instruction was already prefetched in the instruction pipeline, and a new microinstruction is fetched during its execution. The prefetched instruction may be cleared during halt state by the forced execution of a branch with flush (see [Forced microinstruction execution](#)), making single-step execute a NOP instead of the next instruction in the program flow.

Single-step execution is controlled by the debug interface, and is a feature available from Nexus if eTPU is connected to the NDEDI block (see NDEDI details).

The single-step execution of a NOP instruction can be useful to control input signal sampling and filtering, if NDEDI_ENGINEx_DC[PINS] = 1 at the Debug Interface (see NDEDI details). Single-step does not happen if VIS=1.

37.15.11.7 Forced microinstruction execution

When microengine is already in halt state (either halt_idle or halt_exec), it can run forced microinstructions through the debug interface. This feature is available from Nexus if eTPU is connected to the NDEDI block (see NDEDI details). The microinstruction, specified by the user, is not fetched from SCM and comes directly from the debug interface. MDU start commands issued by forced instructions are executed, and the MDU runs the operation until the end, independently of the halt state. The microinstruction field END is ignored.

During forced execution of any instruction except Branches, Returns and Dispatches, the PC does not change, and the prefetched instruction in the pipeline is bypassed, but not discarded. When halt state is suspended, the prefetched instruction is executed and the instruction pointed by the PC is prefetched in parallel (two-stage pipeline).

Forced execution of a Branch, Dispatch or Return loads the PC with the BAF field (if branch condition is satisfied), PC+P or RAR, respectively. If branch condition is not satisfied, PC value stays unaltered. The flush control (field FLS) also works, so that a successful forced branch with flush replaces the prefetched instruction with a NOP. So, to clear the instruction pipeline during halt, all one has to do is an unconditional branch to the desired address with flush. HALT instructions must not be executed as forced.

Forced operations that depend on the serviced channel are unspecified when executed in halt_idle and must be avoided.

Note

Forced instructions must not be commanded when [eTPU Module Configuration Register \(eTPU_SCR_MCR\)](#) field VIS=1.

37.15.11.8 Microengine Register Access

eTPU provides no direct access to microengine and channel registers from the slave bus or any other interface. However, these registers can be read and written in halt state by executing forced microinstructions (see [Forced microinstruction execution](#)). Immediate data microinstructions may be used to set register values. Some registers are not selectable for immediate data destination, so intermediary register(s) - notably P - may have to be used to carry the desired new value to the target register in two or more microinstructions. Usually the previous values of intermediary register(s) must be previously saved and restored after the whole operation.

Similar procedures apply for register reads: their contents must be dumped to SDM, where they can be read from the slave bus.

37.15.11.9 Microengine Flag Access

Microengine halt state allows reading the branch conditions flags through forced microinstructions or, more easily, through the NDEDI register NDEDI_ENGINEx_CFSR (see the NDEDI details). Flag conditions set by the user are seen by microengine for the next microinstruction execution. The flag set options are limited by the possibilities of forced microinstruction execution.

If the eTPU runs (not single-stepping) after exiting the halted state, the conditions modified during halt may remain only for the first microcycle after the halted state. After the first microcycle, branch conditions are altered only according to their regular update scheme.

37.15.11.10 Microengine Stall

Microengine can get into a stall state, attending a request from a debug interface signal assertion. The reason for a Stall request from NDEDI (or from any other debug support block) should be a temporary lack of resources, for instance queue full. During stall the microengine suspends execution, but all the other Engine logic continues operating: time

bases, angle logic, channel logic, input sampling and filters. Stall differs from Halt, not enabling any of the debug features that Halt enables (see [Microengine Halt State](#)). It also does not break an atomic microengine access, unlike halt.

The Microengine can be stalled when idle and from the moment TST ends, before executing the first thread microinstruction, until just before the last thread microinstruction is executed. Stall requests are ignored in any other occasions.

Microengines in a dual engine system can be independently stalled. If a forced end is issued when microengine is in stall coming from execution, the END is executed only when the microengine resumes execution from stall.

37.15.12 SCM Emulation

If SCM is implemented as ROM, an external RAM may be used to replace it, allowing code patching and software breakpoint setting for debugging purposes. SCM ROM replacement by Emulation RAM is MCU-dependent. The SCM may even be divided into a ROM part and a RAM part. In this case, both microengines can run code from both ROM and Emulation RAM. It is possible to make one Engine run code from RAM and the other from ROM, by using different Entry Tables. The SCM visibility conditions also apply to Emulation RAM.

All SCM implementations, either RAM, ROM or Emulation RAM, are external to the eTPU block. eTPU provides a signal to enable the switching between external SCM banks. The conditions for this switching are:

1. Both Engines stopped.
2. VIS bit = 0.

Note that these conditions also stop the clocks of the SCM interface and MISC logic.

37.15.13 Safety features

This section describes embedded safety features: MISC and memory error support.

The Multiple Input Signature Calculator - MISC - is an SCM test feature accessible through [eTPU Module Configuration Register \(eTPU_SCR_MCR\)](#) and [eTPU MISC Compare Register \(eTPU_SCR_MISCCMPR\)](#). MISC allows SCM test "on the fly", i.e., while eTPU is running, with no impact on eTPU functionality or performance.

Memory Error support features comprises SCM and SDM error detection, correction, report, and soft error.

37.15.13.1 SCM Test - Multiple Input Signature Calculator

The Multiple Input Signature Calculator (MISC) comprises special hardware that sequentially reads all SCM positions and calculates, in parallel, a 32-bit signature from a 32-input CRC signature calculator with the following polynomial:

$$1 + x^1 + x^2 + x^{22} + x^{31}$$

A complete description of the signature calculation procedure can be found in [MISC Algorithm](#).

Once started by the Host the MISC runs continuously, restarting after the completion of each cycle, when it sets [SCMMISC](#). The average time for a MISC calculation can be measured by checking SCMMISC state at regular intervals, incrementing a counter and clearing SCMMISC if it is set.

MISC accesses to the SCM array are executed if none of the engines is accessing the SCM, to avoid degradation of the microengine performance: it happens while no channel is being serviced. An ongoing MISC operation can be aborted by writing 0 to SCMMISEN.

The Host must load [eTPU MISC Compare Register \(eTPU_SCR_MISCCMPR\)](#) with the expected value to be found at the end of the MISC cycle, and then start the signature calculation by programming field SCMMISEN=1 in [eTPU Module Configuration Register \(eTPU_SCR_MCR\)](#). MISC zeroes the signature accumulator and starts reading SCM data and calculating the signature. After last SCM position is read, MISC compares the value in signature accumulator against the value in eTPU_SCR_MISCCMPR: if there is a mismatch MISC stops, a Global Exception is issued and [SCMMISF](#) assumes value 1. If no mismatch is found, MISC repeats the procedure automatically. When signature is being calculated, SCM address starts at the last SCM address and counts down to 0. The conditions for executing a MISC operation are (see also [Table 37-335](#)):

- Both microengines in idle state (no channel is being serviced) or stopped, in any combination (e.g., engine 1 idle with engine 2 stopped).
- [VIS](#) =0.
- [SCMMISEN](#) =1.

Note that MISC can run regardless of SCM implementation type (RAM or ROM).

If SCMMISEN=0 or VIS=1, the MISC logic stays at its initial state, with address counter pointing to the last SCM position and accumulator reset.

MISC can also be used to perform single-bit error fixes in the SCM. For more details, see [Error fixing](#).

37.15.13.2 Memory error support

Error Correction Code (ECC) support for SDM and SCM provides guaranteed single bit error correction and double bit error detection. Error detection and correction is performed on read accesses and on write accesses less than 32-bit wide to the SCM.

SDM ECC is calculated per byte, 5 bits wide each, totalling 20 ECC bits for each 32-bit word. That allows the ECC to be updated without a read-modify-write operation on writes of any size.

Error is not checked on bytes not selected on SDM read accesses, either by the Host, CDC or microengine. For instance, the most significant byte is not checked for errors on a microengine 24-bit read access.

Error detection also works for host accesses to the PSE area (see [Parameter Sign Extension area](#)). In this case, error is not detected in the most significant byte (bits 31:24). Also, because of sign extension, error is always detected on the bits 23:16, regardless if they are selected, whenever the most significant byte is read.

SCM ECC is 7 bits wide, comprising the whole 32-bit word. Read-modify-write is automatically made when 16-bit or 8-bit wide writes are made into the SCM in a host access. SCM errors are also detected on Entry Table accesses during TST (see [Time Slot Transition](#)) and on MISC accesses, which are considered microengine accesses with regards to interrupt generation and error reporting.

37.15.13.2.1 Error detection disabling

The error detection logic in SDM and SCM can be disabled by setting the [eTPU Memory Error Control Register \(eTPU_MESR_MECCR\)](#) bits DEDD and CEDD, respectively. The disabled state turns ineffective any action due to error detection, including error correction. Note that error detection is always enabled out of reset.

37.15.13.2.2 Memory error flags

SDM single (correctable) and non-correctable bit errors are flagged in [eTPU Memory Error Status Register \(eTPU_MESR_MESR\)](#) fields DCERR and DNCERR, respectively.

SCM correctable and non-correctable errors are flagged in the eTPU_MESR_MESR fields CCERR and CNCERR, respectively.

Double bit errors are guaranteed to be flagged, while three or more simultaneous bit errors in an SDM byte or SCM word are not. An error flagged as non-correctable can be in two or more bits.

Overflow flags DCOVR and CCOVR indicate, for SDM and SCM respectively, when a correctable error occurs when DCERR, CCERR are already asserted. Similarly, overflow flags DNCOVR/CNCOVR assert when a non-correctable error occurs when DNCERR/CNCERR are asserted already.

37.15.13.2.3 Memory error reports

The address, syndrome and data of a non-correctable SDM access can be sampled into [eTPU Data Error Report Address Register \(eTPU_MESR_DERAR\)](#), [eTPU Data Error Report Syndrome Register \(eTPU_MESR_DERSR\)](#), and [eTPU Data Error Report Data Register \(eTPU_MESR_DERDR\)](#), respectively. eTPU_MESR_DERAR also captures the SDM read access originator, whether the host, CDC, or specific eTPU channel service.

Similarly, non-correctable SCM accesses address, syndrome and data are stored in [eTPU Code Error Report Address Register \(eTPU_MESR_CERAR\)](#), [eTPU Code Error Report Syndrome Register \(eTPU_MESR_CERSR\)](#), and [eTPU Code Error Report Data Register \(eTPU_MESR_CERDR\)](#), respectively. eTPU_MESR_CERAR also captures the SCM read access originator, whether the host, MISC, or specific eTPU channel service. The occurrence of a non-correctable error overwrites the report register values from a correctable error, either on SDM (DCERR=1) or SCM (CCERR=1).

The last address, syndrome and data of a correctable SDM access can also be sampled into eTPU_MESR_DERAR, eTPU_MESR_DERSR, and eTPU_MESR_DERDR, but only if [DNCERR](#) is 0. That prevents access address, syndrome and data from a correctable error to overwrite the same information from a non-correctable access.

Similarly, the last address, syndrome and data from a correctable SCM access are stored in eTPU_MESR_CERAR, eTPU_MESR_CERSR, and eTPU_MESR_CERDR only if [CNCERR](#) is 0.

For either SDM or SCM, a new correctable error overwrites the report registers' values from an earlier correctable error, but report values from a non-correctable error are not overwritten, as long as bit DNCERR/CNCERR is asserted, neither by a new correctable error nor by a non-correctable one.

The sampling of SDM and SCM error report registers can be disabled through the eTPU_MESR_MECR fields DRDIS and CRDIS, respectively. When DRDIS (CRDIS) is asserted, the update of the SDM (SCM) error report registers is disabled, but not of

eTPU_MESR_MESR fields DCERR, DNCERR (CCERR, CNCERR). DRDIS, CRDIS must be set before reading the respective report registers to assure their coherent reading, preventing them to be updated between reads.

37.15.13.2.4 Error detection and wait-states

Microengine SDM accesses do not take any wait-state due to ECC support. Host SDM read accesses take two wait-states minimum³⁹ in MCUs with SDM ECC support, regardless if an error was detected or not, if the SDM error detection is enabled (eTPU Memory Error Control Register (eTPU_MESR_MECCR) field DEDD=0). Host SDM read accesses take a minimum of one wait-state if the SDM error detection is disabled (eTPU_MESR_MECCR[DEDD]=1). Host SDM write accesses take one wait-state minimum, regardless of ECC support presence or enabling.

Host SCM read accesses have two wait-states³⁹, regardless if an error was detected or not. Writes from the host to the SCM take one wait-state on 32-bit accesses, and one additional wait-state (two wait-states total³⁹ on 16-bit and 8-bit wide accesses. Those figures are not affected by the SCM error detection disabling (eTPU_MESR_MECCR[CEDD]).

37.15.13.2.5 Memory error interrupts

For **microengine accesses**, the Global Exception interrupt asserts whenever a non-correctable error is detected, either on SCM or SDM (see [Interrupts and data transfer requests](#)). These errors are flagged by eTPU Module Configuration Register (eTPU_SCR_MCR) fields SCMERR and SDMERR, respectively. Single bit errors are corrected and activate the Memory Error Correction Interrupt if it is enabled (see [Interrupt types and sources](#)), but do not generate Global Exceptions.

For **host accesses** a bus error is issued whenever a non-correctable error is detected, either on SCM or SDM (but not through the CDC) and it also generates a Global Exception. Single bit errors are corrected (if the error correction feature is available) and do not cause bus transfer errors, but assert the Memory Error Correction Interrupt if it is enabled (see [Interrupt types and sources](#)).

37.15.13.2.6 Effect of errors on microcode execution

Correctable errors, either on SCM or SDM, do not affect microcode execution if detection/correction is enabled.

The executing thread is affected by a non-correctable SDM error as follows:

39. One wait-state more, compared with eTPU versions before eTPU2 and previous eTPU2 without ECC support

- If **DTEND** = 1: on SDM errors due to a read operation, if the instruction is not also an END, the following instruction automatically executes an END, and its operations may be executed, totally or partially. On SDM errors during the TST preload, the thread automatically ends on the first instruction, if the error occurs on a preload parameter selected by the entry point bit PP (see Entry Point Format section.) The first instruction may be executed totally or partially. Data read into P or DIOB may be corrupted in either case.
- If **DTEND** = 0: the TST or thread continues the execution flow normally. Data read into P or DIOB may be corrupted in either case.

The executing thread is affected by a non-correctable SCM error as follows:

- If **CTEND** = 1: on SCM errors, the corrupted instruction is not executed, instead replaced by a simple END. Due to instruction prefetching, an error may be detected and yet not affect the thread execution. However, an error detected in a prefetched instruction may cause error report and global or memory error interrupts, even if not executed. If a non-correctable error occurs on the entry table read during TST (see Time Slot Transition section), the first instruction in the thread is replaced with a simple END, a global exception is issued and the reports and flags are normally updated.
- If **CTEND** = 0: the execution flow continues normally, and the results depend on the particular instruction corruption.

Table 37-418. Error support summary if CEDD = DEDD = 0

Action		SCM		SDM	
		single bit error	double bit error	single bit error	double bit error
Memory Error Correction Interrupt		Asserts	Not asserted	Asserts	Not asserted
Global Exception		Not asserted	Asserts	Not asserted	Asserts
Bus Error (host reads)		Not issued	Issued	Not issued	Issued
Thread	CTEND = 0	Normal execution	Potential erroneous execution ¹	Normal execution	see DTEND
	CTEND = 1		Terminates before erroneous execution ²		
	DTEND = 0		see CTEND		Potential erroneous execution
	DTEND = 1				Terminates after erroneous read ³
Code Error Report Registers	CNCERR = 0	Updates eTPU_MESR_CERAR, eTPU_MESR_CERSR, eTPU_MESR_CERDR		Not related	
	CNCERR = 1	eTPU_MESR_CERAR, eTPU_MESR_CERSR, eTPU_MESR_CERDR not updated			

Table continues on the next page...

Table 37-418. Error support summary if CEDD = DEDD = 0 (continued)

Action		SCM		SDM	
		single bit error	double bit error	single bit error	double bit error
Data Error Report Registers	DNCERR = 0	Not related		Updates eTPU_MESR_DERAR, eTPU_MESR_DERSR, eTPU_MESR_DERDR	
	DNCERR = 1			eTPU_MESR_DERAR, eTPU_MESR_DERSR, eTPU_MESR_DERDR not updated	

1. The thread executes correctly if the error is detected on an instruction fetched but not executed.
2. The erroneous instruction is not executed at all, and replaced by a simple END.
3. The instruction following the erroneous read may be executed totally or partially.

37.15.13.2.7 Error Correction Code (ECC) and syndrome definition

SDM ECC is composed of 5 Hsiao code⁴⁰ bits for each data byte. SCM ECC is composed of 7 Hsiao code bits for each 32-bit word.

Table 37-419 shows the encoding of the SDM syndrome and global parity fields as they read on eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR). There is one syndrome and one global parity for each byte in an SDM word, numbered SYND0 to SYND3 from the least to the most significant.

Table 37-419. SDM syndrome definition

SYNDn (hex)	Result	SYNDn (hex)	Result
0E	error on data bit 8n+7	10	error on code bit 8n+4
15	error on data bit 8n+6	08	error on code bit 8n+3
07	error on data bit 8n+5	04	error on code bit 8n+2
1A	error on data bit 8n+4	02	error on code bit 8n+1
19	error on data bit 8n+3	01	error on code bit 8n
13	error on data bit 8n+2		
16	error on data bit 8n+1	00	no error
1C	error on data bit 8n	any other	non-correctable error

The following table shows the definition of the SCM syndrome field as it reads on eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR).

40. Hsiao, M.Y.; A Class of Optimal Minimum Odd-weight-column SEC-DED Codes; IBM Journal of Research and Development http://ieeexplore.ieee.org/xpl/freeabs_all.jsp?arnumber=5391627

Table 37-420. SCM syndrome definition

SYND (hex)	Result	SYND (hex)	Result	SYND (hex)	Result
40	error on code bit 6	58	error on data bit 25	46	error on data bit 11
20	error on code bit 5	0B	error on data bit 24	4A	error on data bit 10
10	error on code bit 4	54	error on data bit 23	52	error on data bit 9
08	error on code bit 3	15	error on data bit 22	62	error on data bit 8
04	error on code bit 2	16	error on data bit 21	13	error on data bit 7
02	error on code bit 1	34	error on data bit 20	29	error on data bit 6
01	error on code bit 0	25	error on data bit 19	31	error on data bit 5
		26	error on data bit 18	43	error on data bit 4
49	error on data bit 31	64	error on data bit 17	45	error on data bit 3
0D	error on data bit 30	2C	error on data bit 16	19	error on data bit 2
0E	error on data bit 29	1A	error on data bit 15	51	error on data bit 1
38	error on data bit 28	23	error on data bit 14	61	error on data bit 0
4C	error on data bit 27	2A	error on data bit 13	00	no error
1C	error on data bit 26	32	error on data bit 12	any other	non-correctable error

37.15.13.2.8 Error injection

Errors can be injected into the SDM read data path through [eTPU Data Error Injection Address Register \(eTPU_MESR_DEIAR\)](#), [eTPU Data Error Injection Data Pattern Register \(eTPU_MESR_DEIDPR\)](#) and [eTPU Data Error Injection Parity Pattern Register \(eTPU_MESR_DEIPPR\)](#). They define bit flips on accesses at the specific address specified in eTPU_MESR_DEIAR.

SDM error injection is enabled independently for host and microengine accesses by the [eTPU Module Configuration Register \(eTPU_SCR_MCR\)](#) fields HDEIE and MDEIE, respectively. The user must program eTPU_MESR_DEIAR, eTPU_MESR_DEIDPR, and eTPU_MESR_DEIPPR with HDEIE=MDEIE=0, and only then enable error injection by setting HDEIE=1 and/or MDEIE=1 to avoid races (see [eTPU Memory Error Status Register \(eTPU_MESR_MESR\)](#)).

Similarly, SCM errors can be injected into the SCM read data path through [eTPU Code Error Injection Address Register \(eTPU_MESR_CEIAR\)](#), [eTPU Code Error Injection Data Pattern Register \(eTPU_MESR_CEIDPR\)](#) and [eTPU Code Error Injection Parity Pattern Register \(eTPU_MESR_CEIPPR\)](#), enabled by the [eTPU Module Configuration Register \(eTPU_SCR_MCR\)](#) field CEIE. Errors are injected on host accesses to the address specified in eTPU_MESR_CEIAR when **VIS** =1, or on microengine and MISC accesses when **VIS**=0 .

37.15.13.2.9 Error fixing

Single bit **soft errors** can be fixed by rewriting the right value, as corrected by the ECC logic, into the same address of the erroneous data. eTPU provides means to perform such fixes safely, coherently and concurrently with the normal operation.

SDM fixes can be done using the CDC (see [Coherent Dual-parameter Controller \(CDC\)](#)), limited to the lower 8 Kbytes of SDM. The Host application simply has to program a transfer with both origin and destination positions pointing to the address of the data to be fixed. Because the PBBASE field has an address granularity of 8 bytes, a word adjacent to the one to be fixed must also be rewritten. The CDC transfer is atomic, therefore the fix is done coherently and does not interfere with the application code or data flows.

SCM fixes can be done by programming [eTPU Code Error Fix Register \(eTPU_MESR_CEFR\)](#) (see [eTPU Code Error Report Syndrome Register \(eTPU_MESR_CERSR\)](#)). The fixes are performed by the MISC logic, which must be enabled (see [SCM Test - Multiple Input Signature Calculator](#)). The modes available, selected by [CFIXM](#), are:

- **Automatic Fix Mode (CFIXM=11)**: the MISC logic automatically rewrites the contents of an address whenever it finds a correctable error; the CFIXM field keeps its value if a fix is made.

37.15.14 Performance monitoring features

37.15.14.1 Idle Counter

The Idle Counters [eTPU Idle Register for Engine 1 \(eTPU_ER_IDLER_ENG1\)](#) and [eTPU Idle Register for Engine 2 \(eTPU_ER_IDLER_ENG2\)](#) continuously count microcycles in which the microengine is not busy with channel service. They can be used to measure the microengine utilization by rating the count measured during a period of time to the number of microcycles contained in the period. The Idle Counters do not count microcycles when the engine is stopped, or is in TST or halt states.

37.15.14.2 Latency Monitor

eTPU implements Latency Monitors to measure the time taken to service a request. Each Latency Monitor provides:

- The measure of the greatest latency found during actual thread executions, accessed from [eTPU Latency Monitor Measure Register for Engine 1](#) (eTPU_LMR_LMnMR_ENG1) and [eTPU Latency Monitor Measure Register for Engine 2](#) (eTPU_LMR_LMnMR_ENG2).
- A comparison between the measured latency and a threshold, determined through [eTPU Latency Monitor Measure Register for Engine 2](#) (eTPU_LMR_LMnMR_ENG2) and [eTPU Latency Monitor Configuration Register for Engine 2](#) (eTPU_LMR_LMnCR_ENG2).

Each Latency Monitor works independently in one of the following modes, selected with the LMM field in [eTPU Latency Monitor Configuration Register for Engine 1](#) (eTPU_LMR_LMnCR_ENG1) and [eTPU Latency Monitor Configuration Register for Engine 2](#) (eTPU_LMR_LMnCR_ENG2) :

- **Disabled mode:** no latency measures or actions are taken.
- **Channel mode:** monitors the latency of an individual channel.
- **Priority mode:** monitors the combined latency of all channels in a given priority level - High, Medium or Low (see [Scheduler](#)).

Channel and Priority modes are detailed in the subsections below. The following applies to both modes:

- After each latency measurement, the value measured is compared with the LATENCY value in [eTPU Latency Monitor Measure Register for Engine 1](#) (eTPU_LMR_LMnMR_ENG1) and [eTPU Latency Monitor Measure Register for Engine 2](#) (eTPU_LMR_LMnMR_ENG2). If the new measured value is greater, it replaces the old value in [eTPU Latency Monitor Measure Register for Engine 1](#) (eTPU_LMR_LMnMR_ENG1) and [eTPU Latency Monitor Measure Register for Engine 2](#) (eTPU_LMR_LMnMR_ENG2).
- After each latency measurement, the value measured is compared with the MAXLAT value in [eTPU Latency Monitor Configuration Register for Engine 1](#) (eTPU_LMR_LMnCR_ENG1) and [eTPU Latency Monitor Configuration Register for Engine 2](#) (eTPU_LMR_LMnCR_ENG2), and if the new measured value is greater:

- A Global Exception is issued.
- The [eTPU Module Configuration Register \(eTPU_SCR_MCR\)](#) flag LTO1 (engine 1) or LTO2 (engine 2) is set, independently of the LATENCY value in [eTPU Latency Monitor Measure Register for Engine 1 \(eTPU_LMR_LMnMR_ENG1\)](#) and [eTPU Latency Monitor Measure Register for Engine 2 \(eTPU_LMR_LMnMR_ENG2\)](#).

NOTE

The LATENCY value is updated even if MAXLAT=0.

NOTE

MAXLAT=0 just inhibits the assertion of the LTO1/2 flag and Global Exception due to the respective Latency Monitor. Other Latency Monitor instances with non-zero MAXLAT value may assert LTO1/2 and Global Exception.

37.15.14.2.1 Channel mode

When the Latency Monitor operates in Channel mode:

- Only the channel selected by the MONCHAN field in [eTPU Latency Monitor Configuration Register for Engine 1 \(eTPU_LMR_LMnCR_ENG1\)](#) and [eTPU Latency Monitor Configuration Register for Engine 2 \(eTPU_LMR_LMnCR_ENG2\)](#) is monitored.
- Any combination of Host Service Requests (HSR), Channel Service Requests and Link Service Requests can be selected for monitoring, based on the SRSEL field in [eTPU Latency Monitor Configuration Register for Engine 1 \(eTPU_LMR_LMnCR_ENG1\)](#) and [eTPU Latency Monitor Configuration Register for Engine 2 \(eTPU_LMR_LMnCR_ENG2\)](#).
- The latency is counted in microcycles, from the moment the logic OR of all the service requests selected by SRSEL asserts to the moment this logic OR negates.
- The latency count is interrupted when the channel is disabled, either by programming the CPR field in [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#) to 0, or by a watchdog timeout. Latency is counted until the channel is disabled and is not discarded; a new count can start from zero when the channel is re-enabled.

NOTE

If a selected service request type or a combination of them continues asserted during and after its service thread execution,

its latency counter will keep on running; this can happen, for instance, if either matches can service requests (e.g. channel modes `em_st/em_dt`), one match happens before the other is serviced, and only one of them is cleared. The Latency Monitor can, in cases like this, yield pessimistic measurements.

NOTE

The Latency Monitor in channel mode must be disabled before the channel it monitors is disabled.

37.15.14.2.2 Priority mode

When the Latency Monitor operates in Priority mode:

- Only the combination of channels assigned with the priority selected by the `SRSEL` field in [eTPU Latency Monitor Configuration Register for Engine 1](#) (`eTPU_LMR_LMnCR_ENG1`) and [eTPU Latency Monitor Configuration Register for Engine 2](#) (`eTPU_LMR_LMnCR_ENG2`) is monitored.
- The latency is measured in microcycles, starting from either of these two events, whichever happens first:
 - The logic OR of service requests of the selected priority transitions from 0 to 1 at a moment when all their grants are at state negated.
 - The grants of the selected priority are cleared by the scheduler at the end of the thread, and any of the service requests at the same priority is still active soon after the thread ends.
- The latency is measured until the grants of the selected priority are cleared by the scheduler, after the measurement started.

Note

A Latency Monitor in priority mode must be disabled before any of the channels in the selected priority is disabled, or any disabled channel is assigned with the selected priority.

37.15.14.3 Watchdog Monitor Operation

The watchdog mechanism can also be used to monitor, without interfering with the application execution, whether the execution time of any individual thread or a sequence of threads reaches a given limit. This can be achieved by asserting the WMO field in [eTPU Watchdog Timer Register for Engine 1 \(eTPU_ER_WDTR_ENG1\)](#) and [eTPU Watchdog Timer Register for Engine 2 \(eTPU_ER_WDTR_ENG2\)](#).

37.16 Initialization/application information

37.16.1 Configuration sequence

After initial power-on reset the eTPU remains in an idle state⁴¹, requiring initialization of several registers before any function can begin execution. Also, if the SCM is implemented in RAM, it should be initialized with the eTPU application code prior to configuring the eTPU. Configuration procedures are summarized as follows:

- If SCM is implemented as RAM, load the eTPU application code (see [SCM access](#)).
- Initialize SDM (optional if no ECC support available)
- Initialize the SCM MISC logic (optional, see [SCM Test - Multiple Input Signature Calculator](#)).
- Initialize Watchdog and Latency Monitors (optional).
- Initialize [eTPU Engine 1 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU_TBR_TBCR_ENG2\)](#) to set up:
 - TCR1 and TCR2 prescalers and clock sources.
 - Select digital filtering mode.
 - TCRCLK signal filter control.
 - Angle mode operation (if necessary).
- Initialize [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#) to set up:

41. Except when device debug request is asserted on power-on reset: in this case, the microengines wake-up in halt state.

- Entry table base.
- Filter prescaler clock control.
- Initialize eTPU Engine 1 STAC Configuration Register (eTPU_TBR_STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (eTPU_TBR_STAC_ENG2) if you need to set up TCR1/2 resource Client/Server operation.
- Write to eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_CnCR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_CnCR_ENG2) to choose the Function to be performed by each channel, and its parameter base address.
- Write to eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_CnSCR_ENG1) and eTPU Channel n Status Control Register for Engine 2 (eTPU_CCCR_CnSCR_ENG2) to choose among the possible variations within the function flow (FM bits).
- Write to SDM for parameter initialization of each configured channel.
- Write to eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (eTPU_ER_WDTR_ENG2) if you need to enable and set up the Watchdog(s) mode and timeout.
- Write to eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_CnHSRR_ENG1) and eTPU Channel n Host Service Request Register for Engine 2 (eTPU_CCCR_CnHSRR_ENG2) to initialize the active channels.
- Write to eTPU Channel Interrupt Enable Register for Engine 1 (eTPU_GCR_CIER_ENG1) and eTPU Channel Interrupt Enable Register for Engine 2 (eTPU_GCR_CIER_ENG2) if interrupts are to be enabled from the appropriate channels. Likewise for Data Transfer Requests (eTPU Channel Data Transfer Request Enable Register for Engine 1 (eTPU_GCR_CDTRER_ENG1) and eTPU Channel Data Transfer Request Enable Register for Engine 2 (eTPU_GCR_CDTRER_ENG2)). This can also be done through eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_CnCR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_CnCR_ENG2).
- Write to eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_CnCR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_CnCR_ENG2) to enable each channel by assigning it a high, middle, or low priority (CPR field).⁴¹

- Monitor [eTPU Channel n Host Service Request Register for Engine 1 \(eTPU_CCCR_CnHSRR_ENG1\)](#) and [eTPU Channel n Host Service Request Register for Engine 2 \(eTPU_CCCR_CnHSRR_ENG2\)](#) for completion of initialization.
- Write [GTBE](#) =1 to start TCR1/TCR2 time base counting at same time in both Engines (may be done before or never, depending on the particular application and use of Red Line bus).

See [Initialization Code Example](#).

37.16.2 Reset options

37.16.2.1 Hardware reset

Hardware reset is achieved by assertion of device synchronous reset. Both Engines and common logic is reset, and even the System Configuration and Global Channel registers assume their reset values.

Note

All eTPU input clocks must pulse during reset so that both engines are reset, even if they are in Module Disable or Stop mode.

37.16.2.2 Software reset

eTPU has no software reset. To abort infinite microcode loops, the Force END mechanism must be used (see field FEND in [eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#)).

37.16.3 Multiple parameter coherency methods

Follows a description of two methods for coherent transfer of multiple parameters between Host and eTPU. Both methods involve the use of two parameter areas: the Transfer Parameter Area (hereafter called TPA), which is the SDM area directly accessed by the Host for reads and writes, and the Permanent Parameter Area (hereafter called

PPA), which are the SDM positions where channel parameters are normally accessed by the Function microcode. Note that parameters in either TPA or PPA do not have to be in sequential addresses. TPAs and PPAs allocation are completely defined by the application, and there may be any number of them, independently of the channels.

The methods described here are not the only solutions for the coherent transfer problem, and both can coexist in eTPU and even used in combination. Also note that for transfers of a pair of parameters, the Coherent Dual-parameter Controller is faster and have less impact on both eTPU and Host performance. That said, the methods are:

- **Transfer Service:** a microengine thread transfers, upon Host Service Request, data from/to a TPA to/from a PPA. Coherency is guaranteed by the fact that a thread is atomic with respect to other threads in the same Engine, and so are its transfers. If parameters in PPA are shared by both Engines, hardware semaphores have to be used to access them.
- **Mailbox:** for Host to eTPU transfers, the microcode checks a flag, set by the host, indicating the existence of new parameter data in the TPA. It can, then, either access TPA data directly or copy it to the PPA. For eTPU to Host transfers, when microcode changes PPA, it copies them to the TPA and flags updated TPA data to Host, possibly using an Interrupt or a Data Transfer Request. The Mailbox flag is reset when data is copied: by the eTPU microcode, when it transfers TPA to PPA (possibly followed by an Interrupt); by the Host, when it reads data from the TPA. This indicates that TPA is free for another transfer.

Transfer Service has the advantage of separating the task of data transfer from the functional service thread that accesses the parameters, with less impact to the latter. Compared to the Mailbox method, however, it has bigger average latency, because the Transfer Service thread has to contend for a time slot to execute. This latency can be minimized if Transfer Service thread is assigned to a separate channel with higher priority, but even so it does not guarantee that PPA is updated before the next execution of the functional thread that uses it.

Mailbox method, on the other hand, makes the functional thread check for the existence of new data (Host to eTPU). It does not have to be responsible for the transfer, though: it may access the TPA directly, and a Transfer Service can then be used to copy data from TPA to PPA.

37.16.4 Programming Hints and Caveats

37.16.4.1 Atomic dual access after a call, return

A dual, back-to-back parameter access is not atomic after a call, a jump, or a return if they occurred in parallel with an odd SDM access. It is safer to make a pair of parameter accesses that must be coherent begin at the second instruction after a call/jump/return.

37.16.4.2 Resource polling

The use of polling while waiting for a condition or a resource (except semaphore lock) should be avoided in order not to hang the microengine in long loops. This general programming guideline is greatly enforced in eTPU, as a thread cannot be preempted for any reason. Safer polling, albeit with long and indeterministic latency, can be obtained if a thread issues a channel link to the serviced channel and terminates. The microengine is then free to other tasks, and the next poll happens at the next time the channel is serviced. This mechanism can be combined with finite (timed out) loops for better latency.

37.16.4.3 Changing channel function, parameter base, or entry table scheme

Channel function, parameter base address and entry table scheme are determined by the CFS, CPBA, and ETCS fields in [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#). They cannot be changed when the channel is enabled. If the channel is disabled first, one may still have service requests from the previous function, so before the channel is enabled again one must be sure that:

- the first thread executed in the new function is the initialization one.
- the initialization thread of the new function clears any previously pending service request.

Here is a safe procedure for function changing:

1. Disable the channel (in [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#), write CPR=00).
2. Change the function configuration (fields CFS and/or CPBA and/or ETCS in [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#)).

3. Request the initialization thread, writing [eTPU Channel n Host Service Request Register for Engine 1 \(eTPU_CCCR_CnHSRR_ENG1\)](#) and [eTPU Channel n Host Service Request Register for Engine 2 \(eTPU_CCCR_CnHSRR_ENG2\)](#) with the initialization HSR (channel still disabled).
4. enable the channel (in [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#) write $CPR > 0$); the initialization HSR is serviced before any other formerly pending service requests, clearing them.

37.16.4.4 Checking and Clearing Interrupts of a Stopped Engine

An Engine may be stopped with interrupts (or DMA requests) pending. This includes the case when the Engine's MDIS bit is set and a thread is still running: the thread will complete execution, possibly issuing an interrupt or DMA request before the engine stops, setting the STF bit.

As soon as the engine stops the channel registers become inaccessible, issuing bus errors when accessed. Interrupts and DMA requests can still be checked and cleared through the Global Channel Registers, though. DMA requests can also be cleared by the hardware handshaking with the DMA controller when the engine is stopped.

37.16.5 Estimating Worst Case Latency

Reliable systems are designed to work under worst-case conditions. This section explains how to estimate worst-case latency (WCL) for any eTPU function in any system. The appendix covers the following topics:

- Introduction to Worst-Case Latency
- Using Worst-Case Latency Estimates to Evaluate Performance
- Priority Scheme Details used in WCL Analyses
- First-Pass WCL Analysis
- Second-Pass WCL Analysis

The first-pass WCL analysis is based on a deterministic, generalized formula that is easy to apply. Because of the generalizations in the formula, the first analysis result is almost always much worse than the real worst case. If the desired system performance is within the limits of this first analysis, then no further analysis is required; the system is well

within the performance limits of the eTPU. If the desired system performance exceeds that indicated by the first analysis, the second-pass WCL analysis should be applied. The second-pass analysis is not a generalized formula, but rather uses specific system details for a realistic worst-case estimation.

37.16.5.1 Introduction to Worst-Case Latency

Note

The latency calculation and examples refer to old TPU functions such as PWM, DIO etc. These functions use single action channels which have single transition and single match functionality. They are not optimized for the eTPU hardware enhancement which support various double action modes. These examples are for reference only. New eTPU functions which are optimized for the new hardware will impose different latency calculations.

Worst-case latency for a channel is the longest amount of time that can elapse between the execution of any two function threads on that channel. For example, if in a particular system, channel 5 is running PWM, the worst-case latency for channel 5 is the longest possible time between the execution of two PWM threads. The worst case time includes the time the execution unit takes to execute threads for other active channels, and other delays described later in this section. Refer to the following figure.

Figure 37-335. Worst-Case Latency for PWM

Worst-case latency for a channel depends both on the function running on that channel and on the activity on other channels. Since the 32 eTPU channels must all share the same execution unit, execution speed of a particular function varies with each system. The PWM thread response is faster if there are no other active channels than if other

channels are also active. In addition, changing the priority scheme and channel number assignments can change performance for a function even if the same set of functions are still active.

Each function is divided into threads, as shown in the figure below (see also [Functions and threads](#)). The eTPU Microengine executes one thread of a function at a time. For example, the Microengine might execute thread 1 of PWM, then thread 3 of DIO, then thread 2 of PWM, then thread 2 of SM, and so on. The amount of time the eTPU Microengine grants a function to execute a thread varies with the number of microcode instructions in the thread.

Since there is only one eTPU Microengine (in each eTPU Engine), the eTPU cannot actually execute the software for multiple functions simultaneously. However, the hardware for each of the channels is independent. This means that, for example, all 32 channel signals can change thread at the same moment, provided that the function software sets up the channel hardware to do so beforehand.

With Host CPU code, the system designer assigns functions to channels and initializes the functions. After initialization, functions typically run without Host intervention, except for eTPU channel interrupts to the Host to give or receive information. Most functions can run continuously with periodic servicing from the eTPU Microengine. As required, the channels request service from the eTPU Microengine, and the eTPU Scheduler determines the order in which the channels are serviced. Worst-case latency for a channel can be derived from the details of the priority scheme that the scheduler uses (see [Scheduler](#)).

Figure 37-336. Function Threads

37.16.5.2 Using Worst-Case Latency estimates to evaluate performance

Once WCL is found for a channel, the user must determine how to use this number to analyze performance. To analyze the performance of a channel running the PWM function, for example, some information about what happens in each thread is necessary.

The following example refers to old TPU PWM function, which is not optimized to the eTPU enhanced hardware. For PWM, thread 1 is the initialization thread, and threads 2 and 3 are used during normal function execution. (PWM threads 4, 5, and 6 are for special modes and will be assumed to be unused on channel 5). Thread 2 writes a time into the channel 5 match register and performs other operations that will cause the channel 5 signal to go from low to high at the time indicated in the match register (match time). At match time, the signal goes high and channel 5 requests service from the eTPU Microengine to execute thread 3. Thread 3 writes a time into the channel 5 match register and performs other operations that will cause the channel 5 signal to go from high to low at match time. At match time, the signal goes low and channel 5 requests service from the eTPU Microengine to execute thread 2. A PWM wave is kept running on the system by the eTPU executing thread 2, then thread 3, then thread 2, then thread 3, and so on.

Since the definition of worse-case latency assumes a fully loaded running system, initialization threads are not part of worst-case calculations. For the channel 5 example, the two PWM threads in [Figure 37-335](#) are thus the two normal running threads, threads 2 and 3.

[Figure 37-335](#) does not define which thread is thread 2 and which is thread 3. Since the worst-case latency derived from the first-pass analysis is the worst case between any 2 threads (not counting initialization threads), it is safe to say that the worst-case latency shown in [Figure 37-336](#) represents both the worst-case high time and the worst-case low time.

Notice in [Figure 37-335](#) that worst-case latency is drawn from the end of the execution of the first PWM thread to the end of the execution of the next PWM thread. It is drawn from end to end because the microcode instructions that make up the threads control the channel hardware. To make sure that all the microcode instructions needed to change the pin thread have been executed, it is necessary to include the execution time of the second thread.

Thread information for each function is found in the programming notes for individual TPU functions. See NXP Programming Note TPUPN00/D, Using the TPU Function Library and TPU Emulation Mode, for a list of available programming notes. Similar documentation will be provided for the eTPU new functions.

37.16.5.3 Priority Scheme Details Used in WCL Analysis

The user assigns functions to channel numbers and gives each active channel a priority level of high, middle, or low. The Scheduler uses the channel number and channel priority level to determine the order in which to grant service.

The scheduler allocates time slots to specific priority levels of high, middle, or low. One function thread is executed in each time slot. The length of a time slot varies according to the length of the executing thread. When fully loaded, the scheduler always assigns time slots in a seven-slot sequence (see the following table). After a seven-slot sequence is completed, another seven-slot sequence begins (see [Figure 37-338](#)). Note that in eTPU, when no service request exists, the scheduler goes to thread 1, but WCL calculation considers full load.

Figure 37-337. Time-Slot Sequence

This sequence scheme gives higher-priority channels more service time than lower-priority channels. High-priority channels are allocated four of seven time slots, middle-priority channels are allocated two of seven time slots, and low-priority channels are allocated one of seven time slots.

Figure 37-338. Multiple Time-Slot Sequences

37.16.5.3.1 Priority Passing

If no channel of the priority level assigned to the time slot is requesting service, the eTPU scheduler can pass priority to other levels. If no high-level channel is requesting service during a high level time slot, a middle-level channel is granted service; or, if no middle level-channel is requesting service, a low-level channel is granted service. If no middle-level channel is requesting service during a middle-level time slot, a high-level channel is granted service; or, if no high-level channel is requesting service, a low-level channel is

granted service. If no low-level channel is requesting service during a low-level time slot, a high-level channel is granted service; or, if no high-level channel is requesting service, a middle-level channel is granted service. If no channel is requesting service, the time slot sequence is reset to state 1 and the scheduler idles until a request is received.

Priority passing is implemented in hardware and does not contribute to worst-case latency.

37.16.5.3.2 Time-slot transition

After each time slot, the eTPU must prepare for the next time slot. This preparation time between each time slot is called a time-slot transition. See [Time Slot Transition](#). Time-slot transitions can take from six up to ten eTPU clocks.

37.16.5.3.3 Channel Number Priority

If more than one channel of a priority level is requesting service, the lowest numbered channel is granted service first. For example, if channels 0, 5, and 9 are all high-level channels requesting service during a high time slot, channel 0 is granted service first. Continuing this example, if channel 0 requests service again immediately after being serviced, it is not serviced again until channels 5 and 9 are serviced. This scheme is implemented so that continuously-requesting low numbered channels do not take all the time on the eTPU execution unit and leave no time for other channels.

The scheduler uses registers to keep track of which channels have been serviced and which require servicing. Each channel has two register bit: a service request register (SRR) and a service grant register (SGR). The SRR is set when a channel requests service. After the channel has been granted service, the SGR is set and the SRR is cleared.

SGRs are not cleared individually by channel, but rather as priority level groups. The clearing of a group of SGRs begins a new cycle for that priority level. An SGR group is cleared on the condition that a channel of that priority level has just been serviced, and no other channel of that priority level is requesting service (has a set SRR) and has not been granted service (has a clear SGR).

For example, if a middle-priority channel has just been serviced (either in a middle-priority time slot or a high or low-priority time slot gained by priority passing), the SRRs and SGRs of all middle-priority channels are compared. If there is no middle-priority channel with its SRR set and SGR cleared, the scheduler clears all middle-level SGRs. If there is a middle-level channel with its SRR set and SGR cleared, the scheduler does not clear the SGR group, and the requesting middle-level channel is serviced on the next middle-level time slot (or possibly sooner by priority passing).

37.16.5.3.4 SDM Collision Rate

Most function threads read or write to the eTPU SDM at least once. Because both the eTPU Microengine and Host can access the SDM but not at the same time, the Microengine may suspend execution during the SDM access while waiting for the Host to finish accessing the SDM. At other times the Host may wait for the Microengine. Wait states can take up to two eTPU clocks, when the Host accesses the SDM directly, without using CDC. Microengine(s) wait-states must be added into the worst-case latency calculation. The system designer should estimate the percentage of SDM accesses in the system that will result in Microengine wait-states. This percentage is called the RAM collision rate (RCR). In each collision with direct Host accesses to the SDM the Microengine(s) wait for two eTPU clocks.

In eTPU the Coherent Dual-parameter Controller (CDC) may also access the SDM for atomic transfers of two parameters. eTPU Microengine may wait on this operation (if it is in service time) until the transfer is complete. CDC always transfers two parameters, making four consecutive accesses (read, write, read, write) of one eTPU clock each. The system designer should estimate the percentage of SDM accesses in the system that will result in a Microengine wait due to coherent transfer, and multiply it with the average number of eTPU clocks the Microengine waits for each transfer. This percentage is called Coherent Parameter Collision Rate (CPCR).

In addition, Microengine to Microengine multiple parameter coherent communication, using the hardware semaphores, may hold one Microengine which waits to lock the semaphore while the other Microengine is holding it. This waiting is due to a software loop, not hardware wait-states. Note that single parameter access of one Microengine does not affect the timing of the other Microengine due to SDM time interlace. This implies that single parameter Microengine to Microengine communication does not affect the performance. The Microengine which waits for the semaphore will loop until it is freed by the other Microengine. This time depends on the eTPU application. The system designer should estimate the percentage of Microengine to Microengine coherent parameter communication that will result in eTPU semaphore loops, and multiply it with the average number of eTPU clocks the Microengine loops for each such transfer. This percentage is called CCR (Communication Collision Rate).

A 100% collision rate for a system is the theoretical worst case. In many systems, however, the RCR, CPCR and CCR would be very low, sometimes even near 0%. This is because the eTPU is an independent processor capable of servicing most function needs, so that the Host rarely needs to access the eTPU SDM. Also coherent Microengine to Microengine communication of more than one parameter may be rare. To find a realistic

RCR, CPCR the system designer should evaluate the Host code and find the percentage of time it accesses the eTPU SDM with or without using the CDC. This percentage gives a good RCR and CPCR. The eTPU application provides a good estimation of CCR.

Note

The programming practice of polling a flag in the eTPU SDM causes a very high RCR and should be avoided in high-performance systems.

After the collision rate for a system is found, it can be applied to the WCL calculations for each channel. The system designer can use the collision percentage and the number of SDM accesses (with and without semaphores) to estimate the eTPU loop time for a function. Note that in old TPU functions CPCR and CCR are both zero.

The estimation of eTPU wait time is as follows:

Variables:

N1 = Number of simple RAM accesses in the longest thread

RCRWait = Maximal eTPU clocks wait time for simple RAM collision = 2

CPCRWait = Average eTPU clocks for Coherent Parameter Transfer (using CDC).

N2 = Number of eTPU-eTPU semaphore RAM accesses in the longest thread

CCRWait = Average eTPU clocks for Microengine-Microengine communication transfer.

Estimated Wait Time:

Function eTPU maximal wait time =

$$N1 * (RCR * RCRWait + CPCR * CPCRWait) + N2 * CCR * CCRWait$$

37.16.5.4 First-Pass Worst-Case Latency Analysis

Following is the first-pass calculation of worst-case latency for a channel. Remember that this analysis uses generalizations that usually produce a result much worse than the real worst case. If the worst-case result from the first analysis is too long for the desired performance, use the second analysis for a more realistic worst-case analysis.

37.16.5.4.1 Worst-case assumptions and formula

To estimate worst-case latency for a channel, assume this worst-case condition: the channel has just been serviced in a time slot of its priority level, and all other channels in the system are continuously requesting service and have cleared SGRs. The worst-case latency is the time from the end of the channel's service until the end of the channel's next service. See the following figure.

Figure 37-339. First-pass Worst-Case Latency

To estimate worst-case latency:

- Find the worst-case service time for each active channel.
- Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot.
- Add time for six-clock time-slot transitions.

37.16.5.4.1.1 Finding the Worst-Case Service Time for Each Active Channel

A table for eTPU functions should list the longest threads (not counting initialization threads) for the functions, and the number of eTPU SDM accesses in the longest thread (semaphored and non semaphored). These figures will be used for estimating Microengine wait time. The table below is an example for old TPU functions in which there are only simple SDM accesses. It does not take into consideration the CDC operation and Microengine to Microengine communication.

The worst-case service time for each channel is: (CPCR=CCR=0)

Longest thread + ((number of RAM accesses in longest thread+1) * RCR * 2 clocks).

Note that the formula adds 1 RAM accesses for the parameter preload that occurs during TST. There are actually three accesses during TST, but only the first one can receive wait-states.

Table 37-421. Longest Threads and RAM Accesses for old TPU Functions

Function	Longest Thread	RAM Accesses
DIO	10	4

Table continues on the next page...

Table 37-421. Longest Threads and RAM Accesses for old TPU Functions (continued)

Function	Longest Thread	RAM Accesses

Mode 1		
Mode 2		
Mode 3		

- Assumes one master and one slave. For each additional slave
 - Tab Add 32 clocks and 2 RAM accesses, and
 - Tab Add (STEP_RATE_CNT * two clocks)
- With one channel linked. Add two clocks for each additional channel linked.

37.16.5.4.1.2 Mapping the Channels for Each Time Slot

To determine when a channel will be serviced again, it is necessary to determine which other channels will be serviced first. Do this by assuming all channels are continuously requesting service and mapping the channels into the time-slot sequence.

37.16.5.4.1.3 Adding Time for Time-Slot Transitions

Add six eTPU clocks for time-slot transitions which occur after each time slot.

37.16.5.4.2 First-pass analysis Worst-Case Latency examples

The examples in this section assume the system configuration shown in the following table.

Table 37-422. System configuration example

Channel	Priority	Function ^{1, 2}
0	High	PWM (driving a DC motor)
1	Middle	PPWA (Mode 0, measuring the DC motor speed)
2	Low	DIO (Input)

1. 9% RAM Collision Rate (RCR)

2. CPU clock rate = 40 MHz, or 25 ns per clock period

37.16.5.4.2.1 Finding the WCL for PWM on Channel 0

The following shows how to find the WCL for PWM on channel 0.

1. Find the worst-case service time for each active channel.

a. Longest thread of PWM is 24 CPU clocks with four RAM accesses.

$24 + ((4 \text{ RAM accesses} + 1) * 0.09 * 2 \text{ CPU clock waits}) = 24.9 \text{ CPU clocks}$,
rounded up to 25 CPU clocks (since there are no partial clock periods)

Channel 0 worst-case service time = 25 CPU clocks.

b. Longest thread of PPWA in mode 0 is 44 CPU clocks with nine RAM accesses.

$44 + ((9 \text{ RAM accesses} + 1) * 0.09 * 2 \text{ CPU clock waits}) = 45.8 \text{ CPU clocks}$,
rounded up to 46 CPU clocks

Channel 1 worst-case service time = 46 CPU clocks.

c. Longest thread of DIO is ten CPU clocks with four RAM accesses.

$10 + ((4 \text{ RAM accesses} + 1) * 0.09 * 2 \text{ CPU clock waits}) = 10.9 \text{ CPU clocks}$,
rounded up to 11 CPU clocks

Channel 2 worst-case service time = 11 CPU clocks.

2. Assume channel 0 has just been serviced and that channels 1 and 2 are continuously requesting service. Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot. See the following figure.

Figure 37-340. Next Servicing for Channel 0

Channel 1 will be serviced in the middle-priority time slot before channel 0 is serviced again.

3. Add time for the six-clock CPU time-slot transitions. See the above figure and the following table.

A four-clock NOP occurs after each channel is serviced since there is one channel in each priority level, i.e., a new cycle for a priority level is started after each channel is serviced. Time-slot transitions occur after each time slot.

Table 37-423. Worst-Case Latency for Channel 0

Channel 0 worst-case service time	25 clocks
Channel 1 worst-case service time	46 clocks
Two 6-clock time-slot transitions	12 clocks
Total clocks	83 clocks

$83 \text{ clocks} * 25 \text{ ns/clock} = 2075 \text{ ns}$

Conclusion: in this system configuration PWM can run with a minimum high time or low time of 2075 ns.

Note that in double match eTPU system the PWM can be serviced once in each period, and there is no latency for minimum high time. The latency in eTPU PWM function will represent the minimum PWM period.

37.16.5.4.2.2 Finding the WCL for PPWA on Channel 1

The following shows how to find the WCL for PPWA on channel 1.

1. Find the worst-case service time for each active channel. See step 1 of previous example.
2. Assume channel 1 has just been serviced and that channels 0 and 2 are continuously requesting service. Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot. See the following figure.

Figure 37-341. Next Servicing for Channel 1

Channel 0 will be serviced twice and channel 2 once before channel 1 is serviced again.

3. Add time for the six-clock CPU time-slot transitions. See the above figure and the following table.

Table 37-424. Worst Case Latency for Channel 1

Two Channel 0 worst-case service times	50 clocks
Channel 1 worst-case service time	46 clocks
Channel 2 worst-case service time	11 clocks
Four 6-clock time-slot transitions	24 clocks
Total clocks	131 clocks

$131 \text{ clocks} * 25 \text{ ns/clock} = 3275 \text{ ns}$

Conclusion: in this system configuration PPWA can measure a period or pulse of minimum 3275 ns.

Note that PPWA function optimized for eTPU hardware can use double transition mode to measure very narrow pulses with one service after the second transition, and latency will affect only the minimum gap between two input pulses. Also the function threads would have more efficient coding.

37.16.5.4.2.3 Finding the WCL for DIO on Channel 2

The following shows how to find the WCL for DIO on channel 2.

- 1. Find the worst-case service time for each active channel. See step 1 of previous examples.
- 2. Assume channel 2 has just been serviced and that channels 0 and 1 are continuously requesting service. Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot. See the following figure.

Figure 37-342. Next Servicing for Channel 2

Channel 0 will be serviced four times and channel 1 twice before channel 2 is serviced again.

- 3. Add time for the ten-clock CPU time-slot transitions and the four-clock NOPs. See the above figure and the following figure.

Table 37-425. Worst Case Latency for Channel 2

Four Channel 0 worst-case service times	100 clocks
Two Channel 1 worst-case service time	92 clocks
Channel 2 worst-case service time	11 clocks
Seven 6-clock time-slot transitions	42 clocks
Total clocks	245 clocks

245 clocks * 25 ns/clock = 6125 ns

Conclusion: in this system configuration DIO can keep track of the input level at a minimum of every 6125 ns.

Note that DIO function optimized for eTPU hardware can use double transition mode to measure two pin transitions at a time and reduce the service time, improving the overall system performance and latency.

37.16.5.5 Second-Pass Worst-Case Latency Analysis

Following is an example of a second-pass analysis for calculating worst-case latency for a channel. The second-pass analysis is useful for higher-performance systems, since it gives a more realistic worst-case latency result than first-pass analysis.

This example uses a relatively simple system in order to illustrate the basic principles of second-pass analysis. For a more complex example of second-pass analysis, refer to Multiphase Motor Commutation TPU Function (COMM)(TPUPN09/ D).

37.16.5.5.1 Second-Pass Analysis Guidelines

Rather than use a fixed formula, a second-pass analysis relies on the application of the following guidelines.

1. The first-pass analysis makes the assumption that all channels in the system are continually requesting service. For many systems this is an unrealistic assumption. For example, if TCR1 is counting at a rate of 2 MHz (500 ns per count) and a channel is running the DIO function with a match rate of 20,000 TCR1 counts, the DIO will request service every 10 ms ($20,000 * 500 \text{ ns} = 10,000,000 \text{ ns}$ or 10 ms). It is therefore unrealistic to assume that the channel running this DIO function is continuously requesting service. Figure out a realistic service request rate for each channel. Time slots can then be mapped to each channel at the real rate of request.
2. If a function is active during system initialization but not during the high-speed running mode of the system, then that system does not need to be included in the high-speed worst-case latency calculations.
3. Use a realistic SDM collision rate.
4. Be careful when assigning functions priority levels and channel numbers. Decide which function or functions will be most difficult to make perform at the desired level. Assign those channels high priority and low channel numbers. Try different priority and channel assignments to see how it affects the system.
5. The seven-slot sequence of || H | M | H | L | H | M | H || is asymmetrical when put back-to-back with other seven-slot sequences. Note that in the following sequence there are two high-priority slots next to each other:

|| H | M | H | L | H | M | H ||| H | M | H | L | H | M | H ||

6. Make sure that when mapping out channels to the sequence, you choose a worst-case slot to start the mapping. For example, when estimating WCL for a high-priority channel, do not start the mapping in the last high-priority slot in a seven-slot sequence, as that is a best case for a high-priority channel since another high-priority time slot is next.
7. Instead of always using the longest thread in the function as the worst-case thread, evaluate the threads in the function that will be used in the system and use the appropriate worst-case threads. For example, in the preceding example of first-pass analysis, the PWM was shown to be able to achieve a high time and low time of 2475 ns under worst-case conditions. This was derived using the longest PWM thread of 24 CPU clocks. This longest thread is actually thread 2, the thread that is entered after the pin has just gone high. Thread 3, the thread that is entered after the pin has just gone low, requires only 2 CPU clocks. Therefore, in the first-pass example, the high time was correctly derived, but the low time is actually shorter than was estimated.

37.16.5.5.2 Second-pass analysis example

This example requires three 50% PWM waveforms: one 5 kHz (200 ms/period) and two 50 kHz (20 ms/period), each running DC motors. (Remember that the PWM function requests service from the eTPU after each high time and after each low time, so the eTPU must handle a request every 100 ms for the 5 kHz PWM and every 10 ms for the 50 MHz PWM.)

Note

This example uses square waves for simplicity. Notice that to use a PWM waveform in the typical way, in which the pulse is modulated, the pulse must not be modulated in a way that violates the worst-case latency requirements.

This example also uses one DIO channel monitoring a signal level every millisecond and one PPWA channel in mode 0 monitoring the speed of the 5-kHz DC motor. The PPWA must measure periods of 5 kHz (200 ms/period).

The CPU is interrupted by the channel running the PPWA function after measuring 200 periods (every 40 ms). The interrupt service routine performs an averaging of the period accumulation and checks it against a known parameter. The interrupt service time is so short and infrequent that it is a tiny fraction of total system time. The interrupt service routine contains no polling of the SDM. Therefore a realistic RCR = 0%.

37.16.5.5.2.1 First-Try System Configuration

Try a system configuration that seems likely to work. If it does not, change priority levels or channel numbers.

The 5 kHz and 50 kHz PWMs are the most time-critical functions. Those are assigned high priority. PPWA is assigned middle priority. The DIO is low performance and is assigned low priority. Refer to the following table.

Table 37-426. First-Try System Configuration

Channel	Priority	Function ^{1, 2}
0	High	PWM at 50 kHz (needs a 4-μs WCL)
1	High	PWM at 50 kHz (needs a 4-μs WCL)
2	High	PWM at 5 kHz (needs a 40-μs WCL)
8	Middle	PPWA at 5 kHz (needs a 80-μs WCL)
15	Low	DIO as input at rate of 1 ms

1. 0% RAM collision rate

2. CPU clock rate = 40 MHz, or 60 ns per clock period

With this system configuration, worst-case service time for each active channel is determined as follows:

1. Longest thread of PWM is 24 CPU clocks with four RAM accesses.

$$24 + ((4 \text{ RAM accesses} + 1) * 0 * 2 \text{ CPU clock waits}) = 24 \text{ CPU clocks}$$

Channels 0-2 worst-case service time = 24 CPU clocks.

2. Longest thread of PPWA in mode 0 is 44 CPU clocks with nine RAM accesses.

$$44 + ((9 \text{ RAM accesses} + 1) * 0 * 2 \text{ CPU clock waits}) = 44 \text{ CPU clocks}$$

Channel 8 worst-case service time = 44 CPU clocks.

3. Longest thread of DIO is ten CPU clocks with four RAM accesses.

$$10 + ((4 \text{ RAM accesses} + 1) * 0 * 2 \text{ CPU clock waits}) = 10 \text{ CPU clocks}$$

Channel 15 worst-case service time = 10 CPU clocks.

To find the WCL for channel 0, assume channel 0 has just finished service.

Map the channels in the H-M-H-L-H-M-H sequence. See the following figure.

Figure 37-343. Worst-Case Latency for Channel 0 (First Try)

Conclusion: with this system configuration, worst-case latencies for channels 0 and 1 are too high (WCL for channel 1 is the same as WCL for channel 0). Try a different system configuration.

37.16.5.5.2.2 Second-Try System Configuration

The second-try system configuration is shown in the following table.

Table 37-427. Second-Try System Configuration

Channel	Priority	Function ^{1, 2}
0	High	PWM at 50 kHz (needs a 4-μs WCL)
1	High	PWM at 50 kHz (needs a 4-μs WCL)
2	Middle	PWM at 5 kHz (needs a 40-μs WCL)
8	Middle	PPWA at 5 kHz (needs a 80-μs WCL)
15	Low	DIO as input at rate of 1 ms

- 1. 0% RAM collision rate
- 2. CPU clock rate = 40 MHz, or 60 ns per clock period

To find the WCL for channel 0, assume channel 0 has just finished service. Map the channels in the H-M-H-L-H-M-H sequence. See the following figure.

Figure 37-344. Worst-Case Latency for Channel 0 (Second Try)

Conclusion: with this system configuration, the WCL of both channel 0 and channel 1 is 3.85 ms, which is within the limit of 4 ms needed for a 50-kHz PWM.

Next, find the WCL for channel 2. Assume channel 2 has just finished service. Map the channels in the H-M-H-L-H-M-H sequence. See the following figure.

Figure 37-345. Worst-Case Latency for Channel 2

Conclusion: with this system configuration, the WCL for channels 2 and 8 is 4.7 ms, which is within the 40 and 80 ms WCL requirements.

Notice that channels 2 and 8 are well within their WCL requirements. The system could be reconfigured as shown in the following table to give channels 0 and 1 a larger margin while still keeping channels 2, 8 and 15 within their WCL requirements.

Table 37-428. Second-Try System with Channel 0 and 1 Reconfigured

Channel	Priority	Function ^{1, 2}
0	High	PWM at 50 kHz (needs a 10-μs WCL)
1	High	PWM at 50 kHz (needs a 10-μs WCL)
2	Middle	PWM at 5 kHz (needs a 40-μs WCL)
8	Low	PPWA at 5 kHz (needs a 80-μs WCL)
15	Low	DIO as input at rate of 1 ms

1. 0% RAM collision rate

2. CPU clock rate = 40 MHz, or 60 ns per clock period

37.16.6 Endianness

The following table shows the parameter addresses for big and little endian machines.

Table 37-429. Parameter Addresses and Endianness

Parameter	byte address offset (n = word address offset)	
	big endian	little endian
32-bit	4*n	
24-bit	4*n + 1	4*n
32-bit parameter's most significant byte	4*n	4*n + 3
24-bit parameter's most significant byte	4*n + 1	4*n + 2
least significant byte	4*n + 3	4*n

37.16.7 Memory Error Service Procedures

Follows separate procedures for correctable and non-correctable error interrupt service routines. It is assumed that the non-correctable error ISR has higher priority, and cannot be preempted by the correctable error ISR. For memory error support details, see [Memory error support](#).

Note

The memory error support hardware does not (and is not intended to) guarantee that no error occurred will go unreported. However, combined with the procedures below, the information loss is minimized to statistical irrelevance on most scenarios.

37.16.7.1 Non-correctable error service procedure

The basic procedure below can be followed in a Global Exception or a bus error machine check service routine. It handles the service for both SCM and SDM errors, as they are symmetrical at this level. However, a real implementation is likely to split the procedure in two, one for each memory.

1. Confirm/identify the error source, checking assertion of the [eTPU Module Configuration Register \(eTPU_SCR_MCR\)](#) fields SCMERR and SDMERR.
2. Save the state(s) of [eTPU Module Configuration Register \(eTPU_SCR_MCR\)](#) fields CRDIS/DRDIS.
3. Set the [eTPU Module Configuration Register \(eTPU_SCR_MCR\)](#) CRDIS/DRDIS=1 to disable further updates to the respective report registers, guaranteeing coherency.

4. Check whether the report registers were updated by a correctable or non-correctable error; to do this, check the [eTPU Code Error Report Syndrome Register \(eTPU_MESR_CERSR\)](#) syndrome (for SCM) and/or the [eTPU Data Error Report Syndrome Register \(eTPU_MESR_DERSR\)](#) syndromes (for SDM, only those with the respective BE flags asserted). If it is a correctable error report, skip the steps 5 and 6 for the respective memory.
5. Identify the error source (host, microengine or MISC/CDC) by checking the field ERR_ACC in the register(s) [eTPU Code Error Report Address Register \(eTPU_MESR_CERAR\)](#) and [eTPU Data Error Report Address Register \(eTPU_MESR_DERAR\)](#); take or schedule the appropriate application-dependent recover actions.
6. Update error statistics as needed; it may include recording the access source, address, data and syndrome from:
 - [eTPU Code Error Report Address Register \(eTPU_MESR_CERAR\)](#)
 - [eTPU Data Error Report Address Register \(eTPU_MESR_DERAR\)](#)
 - [eTPU Code Error Report Data Register \(eTPU_MESR_CERDR\)](#)
 - [eTPU Data Error Report Data Register \(eTPU_MESR_DERDR\)](#)
 - [eTPU Code Error Report Syndrome Register \(eTPU_MESR_CERSR\)](#)
 - [eTPU Data Error Report Syndrome Register \(eTPU_MESR_DERSR\)](#)
7. Save the status of non-correctable error overflows flagged in the [eTPU Memory Error Status Register \(eTPU_MESR_MESR\)](#) fields CNCOVR/DNCOVR.
8. Set the [eTPU Memory Error Control Register \(eTPU_MESR_MECR\)](#) fields CRDIS/DRDIS to the state(s) saved in the step 2. That assures the access coherency of a preempted Correctable Error Service Procedure (which may have set CRDIS/DRDIS before this procedure) is not disturbed.
9. Clear the [eTPU Memory Error Status Register \(eTPU_MESR_MESR\)](#) fields CNCOVR/DNCOVR and CNCERR/DNCERR at once, in a single write to eTPU_MESR_MESR.
10. Use the overrun status saved on step 7 to update the error statistics, as needed.
11. Check the other Global Exception flags in [eTPU Module Configuration Register \(eTPU_SCR_MCR\)](#); take or schedule the appropriate (application dependent) recover actions.
12. Clear the Global Exception, programming [GEC](#) =1.

37.16.7.2 Correctable error service procedure

The basic procedure below can be followed in a Memory Error Interrupt service routine (see [Interrupts and data transfer requests](#)). It handles the service for both SCM and SDM errors, as they are symmetrical at this level. However, a real implementation is likely to split the procedure in two, one for each memory.

1. Confirm/identify the error source, checking assertion of the [eTPU Memory Error Status Register \(eTPU_MESR_MESR\)](#) fields CCERR/DCERR.
2. Program the [eTPU Memory Error Control Register \(eTPU_MESR_MECR\)](#) fields CRDIS=1 and/or DRDIS=1, to disable further updates to the respective report registers, guaranteeing coherency.
3. Check whether the report registers were updated by a correctable or non-correctable error; to do this, check the [eTPU Code Error Report Syndrome Register \(eTPU_MESR_CERSR\)](#) syndrome (for SCM) and/or the [eTPU Data Error Report Syndrome Register \(eTPU_MESR_DERSR\)](#) syndromes (for SDM, only those with the respective BE flags asserted). If it is a non-correctable error report, skip the steps 4 and 5 for the respective memory.
4. Identify the error source (host, microengine or MISC/CDC) by checking the field ERR_ACC in [eTPU Code Error Report Address Register \(eTPU_MESR_CERAR\)](#) and [eTPU Data Error Report Address Register \(eTPU_MESR_DERAR\)](#); take or schedule the appropriate application-dependent recover actions, which may include soft-error fixing (see [Error fixing](#)).
5. Update error statistics as needed; it may include recording the access source, address, data and syndrome from:
 - [eTPU Code Error Report Address Register \(eTPU_MESR_CERAR\)](#)
 - [eTPU Data Error Report Address Register \(eTPU_MESR_DERAR\)](#)
 - [eTPU Code Error Report Data Register \(eTPU_MESR_CERDR\)](#)
 - [eTPU Data Error Report Data Register \(eTPU_MESR_DERDR\)](#)
 - [eTPU Code Error Report Syndrome Register \(eTPU_MESR_CERSR\)](#)
 - [eTPU Data Error Report Syndrome Register \(eTPU_MESR_DERSR\)](#)
6. Save the status of correctable error overflows flagged in the [eTPU Memory Error Status Register \(eTPU_MESR_MESR\)](#) fields CCOVR/DCOVR.
7. Program the [eTPU Memory Error Control Register \(eTPU_MESR_MECR\)](#) fields CRDIS/DRDIS=0.
8. Clear the [eTPU Memory Error Status Register \(eTPU_MESR_MESR\)](#) fields CCOVR/DCOVR and CCERR/DCERR at once, in a single write to [eTPU_MESR_MESR](#).

9. Use the saved overrun status to update the error statistics, as needed.

37.17 Appendices

37.17.1 Microcycle and I/O timing

37.17.1.1 Execution and channel timing

The following figure shows the main timings related to microinstruction execution when channels and timebases run on T2 timing.

Note: *TCR clock/prescaler selection = 1 x eTPU clock

Figure 37-346. Execution, timebase and channel T2 timing

Note: *TCR clock/prescaler selection = 4x eTPU clock

Figure 37-347. Execution, timebase and channel T2/T4 timing

The sequential occurrence of the four T states (T1-T4) constitutes a microcycle. Only T2 and T4 are taken as reference for timings, either internal or external. T2 and T4 have the timing of the positive eTPU clock pulses, and are used in most of the eTPU logic in an edge-triggered design style.

Two additional T states are derived from the eTPU clocks: $\overline{T2}$ and $\overline{T4}$. $\overline{T2}$ occurs when the eTPU loses SDM arbitration to a bus master. $\overline{T4}$ occurs in halt state (due to a breakpoint or device debug request assertion, for instance), or in stall state (due to an NDEDI queue full); see [Development support features](#) for more details.

$\overline{T2}$ and $\overline{T4}$ states are defined as microcycle timing states (not to be confounded with logic states) of one eTPU clock in which the T clocks continue to run, but the control signals associated with the clocks are unaffected. That is, no operation occurs during these states.

Both $\overline{T2}$ and $\overline{T4}$ states occur in multiples of two eTPU clocks to keep the microengine synchronized with the free running channels, which are unaffected and keep on working as in T2 and T4.

Thus, the eTPU has two types of timing states:

- $\overline{T2}$: hold execution for SDM access, from clock pulse T2 until one of the next T2 clock pulses of another microcycle.
- $\overline{T4}$: hold execution in debug mode or stall, from clock pulse T4 until one of the next T4 clock pulses of another microcycle.

The two following figures show the timing of $\overline{T2}$ and $\overline{T4}$ timing states, respectively.

Figure 37-348. $\overline{T2}$ timing

Figure 37-349. $\overline{T4}$ timing

37.17.1.2 Input/Output Signal Delays

The synchronizer, filter and edge detection logic delay the input signal transitions.

The Filter Delay varies with the filter clock ([eTPU Engine 1 Configuration Register \(eTPU_SCR_ECR_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU_SCR_ECR_ENG2\)](#) field FPSCK) and the filter mode used, as shown in the [Table 37-355](#). For any given transition, it depends on the phase of the filter clock when the input transition happens. In integration mode (TCRCLK filtering only), it also depends on the state of the integrator counter. The Total Delay is defined as the number of eTPU clock rising edges between the input transition and the setting of TDLA/B, TCR1/2 incrementing, or EAC tooth sensing (TCRCLK) in angle mode. The synchronizer delay is 2 or 3 eTPU clocks, depending on the phase of the synchronizer when the input transition happens. The edge detection takes 1 more eTPU clock. The total delays are, thus:

```

Min. Total Delay = Min. Synchronizer Delay + Min. Filter Delay + Edge Detection Delay
Min. Total Delay = 3 + Min. Filter Delay
Max. Total Delay = Max. Synchronizer Delay + Max. Filter Delay + Edge Detection Delay
Max. Total Delay = 4 + Max. Filter Delay

```

The channel filters can be bypassed, so nullifying the filter delays in the equations above.

See the chip-specific eTPU information for connections between eTPU and input glitch filters.

The channel output flip-flops drive the eTPU output signals directly, without any synchronous delays.

37.17.2 Channel Mode Summary

The initial state considered for all submodes is channel flags MRLEA and MRLEB asserted, MRLA, MRLB, TDLA and TDLB negated. From initial state one can follow the table below and verify how each submode behaves in a determined sequence of events. Note that the actions performed by an event type depend on all previous events following the initial state, for a given channel submode.

There are three columns for each event: one for event type, one for enable/disable actions and one for capture. **Event type** column can be matchA, matchB, transA and transB (for double transition modes). **Enable/disable actions** column (identified as "[blocks] (enables)" in column head) specifies which other events are enabled or disabled. Initially disabled events (specified in "**initially blocked**" column) are usually enabled by other events.

In double transition submodes, the first transition detected is always considered transA and the second is considered transB. This means that transA event actually enables the detection of transB event. This is not explicit in the table, since it is a general behavior for all double transition submodes.

A sequence of four events (two matches and two transitions) are necessary to describe the behavior of some channel submodes. When a determined sequence of events has less than four events, the other event columns are left blank.

Cells in an "**event type**" column that have light-grayed background indicate that a service request is generated. More than one event in the same event sequence can issue service request.

Note

The two tables below do not exhaust all possibilities of channel logic event sequences, because it does not account for possible microcode interventions. For instance, if matches are blocked

by first transition and microcode resets TDLA, the matches become enabled again, and from this point on the channel behaves as if the first transition had never occurred.

Table 37-430. Channel Mode Summary 1 of 2

Mode	Initially Blocked	1st Event			2nd Event

3. sm_st is compatible with TPU3 channel logic.
4. It is not possible to include all functionality of this submode in table.

37.17.3 MISC Algorithm

The MISC generator is based on the following polynomial:

$$G(x) = 1 + x^1 + x^2 + x^{22} + x^{31} \text{ (equivalent to feedback mask = 0x80400007)}$$

The MISC signature generation starts by clearing the MISC Accumulator value to 0 and preloading the MISC Counter with the highest SCM address. It then steps through each address decrementing the counter, reading 32 bit values and following the algorithm below:

```

If the least significant bit in MISC is 1 then
    MISC = MISC right shifted by 1 bit
    MISC = MISC XOR 0x80400007
else
    MISC = MISC right shifted by 1 bit
end if
MISC = MISC XOR RAM data

```

The code example below shows an excerpt of C code that calculates the MISC signature for a given array of data, based on the previous algorithm:

Appendices

```
#define SCM_size    (MAX_SCM_ADDRESS / 4)    /* last byte address - converted to 32-bit word */
#define POLY        0x80400007                /* G(x) = 1 + x1 + x2 + x22 + x31 */
/*****
FUNCTION : void calc_misc()
PURPOSE : This function calculates the MISC value.
INPUTS NOTES : none
RETURNS NOTES : MISC value
GENERAL NOTES : the array 'unsigned int data[]' represents the actual memory
                  array, organized in 32-bit words.
*****/
unsigned int calc_misc (void)
{
    int j; /* loop counter */
    unsigned int misc = 0;
    for (j = (SCM_size-1); j >= 0 ; j--) {    /* SCM_size has the number of 32-bit words in SCM
*/
        if (misc & 0x1) {
            misc >>= 1;
            misc ^= POLY;
        }
        else {
            misc >>= 1;
        }
        misc ^= data[j];                    /* data[j] is the actual 32-bit word taken from the SCM
array
*/
    }
    return (misc);                        /* final signature calculated */
};
```

The value calculated by this algorithm must be loaded into [eTPU MISC Compare Register \(eTPU_SCR_MISCCMPR\)](#) prior to activating the SCM MISC calculator in eTPU. Once the MISC calculator is activated (bit SCMMISEN in register [eTPU Module Configuration Register \(eTPU_SCR_MCR\)](#) is written to 1) eTPU itself will start this procedure⁴² reading the SCM whenever allowed by microengine. At the end of the cycle, when all the array has been read and the SCM signature is calculated, the Host CPU can be notified via Global Exception if the MISC Accumulator does not match the value in eTPU_SCR_MISCCMPR.

The average time taken by MISC to complete the signature of the whole SCM can be given by the formula:

$$\text{Average MISC period} = S / (4 * F * (1 - L))$$

where f is clock frequency, S is SCM size in bytes and L is eTPU load (as a percentage of execution clocks over a period of time, including TST clocks).

Further detail on MISC calculation can be found on [SCM Test - Multiple Input Signature Calculator](#). The application note **AN2192 - Detecting Errors in the Dual Port RAM (DPTRAM) Module** is also a good source of information (although it refers to TPU) on MISC signature.

42. eTPU MISC hardware is optimized to read 32-bit words from memory and to calculate this CRC in parallel, rather than shifting one bit at a time. The actual implementation inside eTPU, although bringing to the same results, does not match exactly the algorithm shown here.

Chapter 38

Reaction Module 2 (REACM2)

38.1 Chip-specific REACM2 information

This device contains one REACM2 module with 10 Reaction Channels. It is on the eTPU clock domain.

38.1.1 REACM2 interaction with other modules

The following figure shows the interaction of the Reaction Module 2 with other modules on the chip at a high level.

Figure 38-1. REACM2 interaction with other modules

- eTPU_C, a co-processor designed for timing control, has an interface with REACM2 that allows eTPU_C to read and write data to/from REACM2 and to read and write REACM2 registers.
- All accesses to REACM2 registers, including by the CPU, occur through eTPU_C.
- The REACM2 sends interrupt signals to both eTPU_C and INTC.
- Timer trigger inputs are multiplexed from eTPU_C, eTPU_A/B, and eMIOS_0/1.

- From its two internal ADCs (ADC0/1), eQADC_A sends ADC conversion results to the REACM2. See [Routing conversion results to REACM2 and DECFILTER modules](#) for details.
- The reaction channels' output is sent to output pins.

38.1.2 Timer inputs

The REACM2 timer input channels receive trigger input signals from eTPU or eMIOS. The timer input multiplexer is controlled by the SIU Reaction Module Trigger Selection Register (SIU_REACTSR).

Table 38-1. REACM2 timer inputs

REACM2 timer input channel	eTPU_A	eTPU_B	eTPU_C / eMIOS_0	eMIOS_0 / eMIOS_1
0	eTPU_A ch.10	eTPU_B ch.22	eTPU_C ch.13	eMIOS_0 ch.16
1	eTPU_A ch.11	eTPU_B ch.23	eTPU_C ch.14	eMIOS_0 ch.17

3	eTPU_A ch.13	eTPU_B ch.25	eTPU_C ch.16	eMIOS_0 ch.19
4	eTPU_A ch.14	eTPU_B ch.10	—	eMIOS_0 ch.0
5	eTPU_A ch.15	eTPU_B ch.11	—	eMIOS_0 ch.1
6	eTPU_A ch.16	eTPU_B ch.12	—	eMIOS_0 ch.2
7	eTPU_A ch.17	eTPU_B ch.13	—	eMIOS_0 ch.3
8	eTPU_A ch.18	eTPU_B ch.14	eTPU_C ch.28	eMIOS_1 ch.4
9	eTPU_A ch.19	eTPU_B ch.15	eTPU_C ch.29	eMIOS_1 ch.5
10	eTPU_A ch.20	eTPU_B ch.16	eTPU_C ch.30	eMIOS_1 ch.6
11	eTPU_A ch.21	eTPU_B ch.17	eTPU_C ch.31	eMIOS_1 ch.7
12	eTPU_A ch.22	eTPU_B ch.18	eMIOS_0 ch.4	eMIOS_1 ch.0
13	eTPU_A ch.23	eTPU_B ch.19	eMIOS_0 ch.5	eMIOS_1 ch.1
14	eTPU_A ch.24	eTPU_B ch.20	eMIOS_0 ch.6	eMIOS_1 ch.2
15	eTPU_A ch.25	eTPU_B ch.21	eMIOS_0 ch.7	eMIOS_1 ch.3

The timer input channel used by a Reaction Channel is determined by REACM2_CHRRn[CHIR].

38.1.3 REACM2 buffer overflow prevention

When two samples are feeding REACM2, the REACM2 buffer can overflow. The overflow can occur if two parallel conversions (ADC0/1 in EQADC_A) routed to REACM2 finish at approximately the same time.

To prevent the overflow, program the timing of the triggers (samples feeding REACM2) so they occur at least 6 REACM2 clock periods apart.

38.2 Introduction

The REACM2 is composed of 10 reaction channels. Each channel contains three outputs. Its main application is in the area of solenoid control for direct injection systems, valve control in automatic transmissions, and other current control applications. It is connected to the on-chip ADC which monitors the current on the solenoid or valve. Based on that the reaction channel generates an output signal that modulates the current circulating in the solenoid or valve. It is a cost-effective solution due to extensive sharing of several resources among channels and parameterized register banks for adequate dimensioning of resources and functionality.

38.2.1 Features

The REACM2 features include:

- Per channel architecture for independent output control
- Interface with on-chip ADC for fast response times
- Interfaced to timer modules
- Hardware connection with on-chip timer channels with channel routing capability
- Shared Modulation Control bank
- Dynamic timer allocation
- Three outputs per channel to support different driver architectures
- Flexibility to operate based on timing and threshold
- On-the-fly capture of ADC result reference for fast calibration
- Open and short circuit monitoring capability

38.2.2 Modes of Operation

Operation modes of this module are described below.

38.2.2.1 Programming Mode

After reset, the Reaction module is in the Programming mode. In this mode all channels are disabled and outputs are at logic zero. Note that this state does not necessarily mean that zero is the neutral state for the channel load, thus care must be taken in order to disconnect the channel from the load in this case.

In the programming mode the host CPU writes all module parameters including:

1. Modulation word data
2. Channel control data
3. Threshold data
4. Timer Bank data
5. Hold (on/off) Timer bank data
6. Timer router data
7. ADC router data
8. Period Shift Delay time
9. Period Generator timers

The last action to perform is to *enable* the channel. After that the channel is able to respond to timer signals and ADC data, thus able to perform modulation on the output pins. It is recommended to keep the timer signals inactive until all data to all reaction channels are programmed and all channels have been put in the *enabled* mode.

38.2.2.2 Low Power Mode

Coming out from reset all channels are in the disabled state. The channel may also be in low power mode depending on an instantiation parameter that configures the initial state of the MDIS in the Module Configuration Register. If MDIS=1 the module clock may be disabled, allowing for a low power state. The low power mode is controlled either by the MDIS bit or by a global stop signal. There is no explicit clock gating implemented in hardware within the Reaction Module. Reaction module clock gating is implemented in the SoC. Low power mode must be entered only when all channels are disabled by CHEN=00.

38.2.2.3 Channel Modes

After a channel is put in *enabled* mode that channel is also said to be in the *normal* mode of operation, which means it responds to timer signals from the timer inputs connected to the Reaction Module and also to ADC results received from the on-chip ADC module. Channel outputs are controlled in accordance with those inputs in order to perform an output modulation process. When performing a modulation the Reaction Channel is said to be in the *active state*. The Reaction Channel modes are described below in relation to the ability to execute a modulation:

- Disabled: the channel cannot execute modulation.
- Enabled: the channel is able to execute a modulation. It may be in the *Active* or *Inactive* states.
 - Inactive state: the channel is not executing a modulation.
 - Active state: the channel is executing a modulation.

38.2.2.4 Debug Mode

The Reaction Module Debug operation is defined by bits FRZ and FREN in the Module Configuration Register. In debug mode all Timers are freezed (halted), including the timers in the Shared Time Bank and Hold (on/off) timers. The module can enter debug mode in two different ways, either by software control or by the hardware debug input signal controlled by the chip logic. In both cases the Reaction Module enters debug mode only if enabled by the FREN bit:

- If both FREN and FRZ bits are set, the module enters debug mode.
- If FREN bit is set and a global debug signal is asserted, the module enters debug mode.

In debug mode, the channel outputs are held at HOD, LOD, or DOFF state, as determined by the channel current state. When resuming normal operation after exiting debug mode, the channel performs the read of the first Mod Word and the channel output is set to DOFF until the next timer control rising edge occurs.

MAXL flag is the only flag that operates in debug mode. All other flags retain the present state while the module is in debug mode. Note that the corresponding error flag in the Global Error Flag register is also set.

The ADC Input Sensor Input Register allows direct access for write to the TAG and ADC result values input to the Reaction Module. This software control may be used for module debug purposes.

38.2.3 Block Diagram

Figure 38-2 shows the on-chip connections of the reaction module. The ADC module is the source of data monitored from external sensors, usually voltage information, which is used by the reaction channel modulation to generate a PWM signal control signal in order to maintain the load current within a certain predefined boundary. eTPU is commonly used as the source for controlling the activation of a reaction channel. Alternatively eMIOS or PIT can be used to provide that control signal.

Figure 38-2. Reaction Module System Interconnection

The Reaction Module provides 10 channels with three outputs per channel. The channel outputs are programmed independently from each other. The outputs do not have a predefined ON or OFF state meaning as the definition of ON and OFF depends upon the application.

Figure 38-3 describes the interconnection between the reaction channel and the blocks in the Reaction Module. The indexes next to the blocks indicate the order in which each submodule executes an action during the modulation process. A simplified sequence of these steps is described as follows:

1. A new ADC result from the eQADC module is received, triggering one reaction channel
2. The triggered reaction channel generates the Modulation Word address based on the data programmed in the internal configuration register
3. A Modulation word is selected by the reaction channel
4. The selected Modulation word generates the address for the Threshold Bank
5. The Threshold bank selected data is compared against the incoming ADC result
6. The comparison result is sent back to the channel
7. The reaction channel executes modulation action and updates the channel output

In order to execute steps 1 through 7 the Reaction module takes five Module clock cycles.

The reaction channel sets the outputs according to HOD or LOD fields provided by the selected Modulation word.

Figure 38-3. Channel Interaction with internal submodules

Figure 38-4 shows the Reaction Module's internal architecture. The channels are controlled by a Modulation Control Word provided by the Modulation Control Bank submodule. The Modulation Word has information about the type of modulation to be executed as well as the addresses for the Threshold and Timer banks. The channel stores information such as the address of the modulation word and initial values for the output pins after the channel is *enabled*.

Note that the modulation process only initiates after the channel is moved to the *active* state. This process will be described in more detail in the following sections.

After the activation, the channel sets the outputs with a predefined value stored in the channel configuration register. Only after this initialization process the channel is ready to start a modulation process. Note that the channel only considers an ADC result as valid if it is within a window defined by the timer input, usually connected to the on-chip eTPU. The Reaction Channel can access more than one Modulation Word by incrementing the internal MODULATION_ADDR field in the channel configuration register. The original value of this field is preserved thus when a new modulation cycle is initiated the same modulation address value can be used.

Figure 38-4. Reaction Module Block Diagram

Timer channels, such as eTPU channel outputs, are connected to the Timer Channel Router. This submodule routes each timer channel to a reaction channel. Note that one timer channel can be routed to more than one reaction channel.

The modulation process initiates when an ADC result arrives and the time window is active. The ADC Router sends a trigger signal to all channels indicating that an ADC result is available. The channel address resolution is based on the TAG field received with the incoming ADC result. After decoding the TAG field the channel accesses the Modulation Word using the information stored in the channel configuration register.

The Threshold Bank submodule stores values to be used on the comparison with incoming ADC results. The address for the stored values is generated by the Modulation Control Bank. This address generation is actually executed in a two-step process since the Modulation Word is first addressed by the channel which then generates the address for the Threshold Bank. After having both inputs defined the Comparator generates the comparison result back to the channels.

The Hold timer bank address is also stored in the modulation word. The reaction channel uses that information for the modulation process which requires the output to remain ON or OFF during a certain amount of time. The Hold counter itself is located inside each channel.

The Period Delay generator provides timing signals for the channels operating in the threshold-period modulation mode. It provides period starting signal for each channel with a configurable constant delay between two consecutive channels.

38.3 Signal Description

The following table shows the chip level signals for the Reaction module.

Table 38-2. Signal Properties

Name	Function
RCHn_a	Output pin 'a' of Reaction Channel 'n'
RCHn_b	Output pin 'b' of Reaction Channel 'n'
RCHn_c	Output pin 'c' of Reaction Channel 'n'

38.3.1 REACM2_RCHn — REACM Channel (n) Output Pin a, b and c

Each Reaction Channel provides three outputs to be connected to device primary output PADs. These outputs can be configured as necessary in order to meet application requirements. Thus the active state as well as overall functionality are defined by the registers within the Reaction Module and the defined sequence of operation. The reset state for these outputs is zero.

38.4 Memory Map and Register Definition

This section provides a detailed description of all Reaction Module registers accessible to the end user.

The REACM2 is in the eTPU address space to allow the eTPU direct access to the registers.

NOTE

For reset value of the REACM2_MCR, refer to the section describing this register.

38.4.1 Module Configuration (REACM2_MCR)

The REACM2_MCR contains the control bits to configure the general operation of the Reaction Module.

Address: 0h base + 0h offset = 0h

REACM2_MCR field descriptions

Field	Description
0 OVRC	Overrun Detection Flag Clear The OVRC clears the OVR flag if "1" is written. This bit reads always as 0x0. If a set event occurs at the same time a flag clear is done, the set event has precedence over the clear thus the flag remains set. 0 No action 1 Clears OVR bit
1 MDIS	Module Disable The MDIS bit puts the Reaction Module in low power mode. Communication through the slave-bus Interface is ignored in this mode except writes to the REAC_MCR register which are allowed, except for the FRZ and FREN bits. The global debug signal state is not changed internally while in low power mode. 0 Normal Mode 1 Low Power Mode

Table continues on the next page...

REACM2_MCR field descriptions (continued)

Field	Description
2 FRZ	Freeze Control The FRZ bit controls the state of the Reaction Module regarding debug operation. If both FREN and FRZ bits are set the module enters debug mode. In this mode all time bases are halted and the outputs of channels are controlled solely by software. See section Debug Mode. This bit cannot be written if MDIS bit is set. 0 Normal Mode 1 Debug Mode
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 FREN	Freeze Enable The FREN bit enables the Reaction Module to enter debug mode. The debug mode is controlled either by the FRZ bit or by a global debug signal. This bit cannot be written if MDIS bit is set. 0 Debug Mode disabled 1 Debug Mode enable
5 TPREN	Timer Prescaler Enable The TPREN bit enables the Shared Timer Prescaler in the Reaction Module. 0 Prescaler Disabled 1 Prescaler Enabled
6 HPREN	Hold Timer Prescaler Enable The HPREN bit enables the Hold Prescaler in the Reaction Module. 0 Prescaler Disabled 1 Prescaler Enabled
7 GIEN	Global Interrupt Enable The GIEN bit enables the assertion of the global interrupt request to the CPU when any of the channel interrupts is set or when the OVR flag and its corresponding enable OVREN are both set. Note that this signal does not control the individual channel interrupt request. See section Global Interrupt and Channel Interrupt for more details. 0 Interrupt disabled 1 Interrupt enabled
8 OVREN	Overflow Detection Interrupt Enable The OVREN enables the OVR flag, when set, to generate a global interrupt request for the CPU. 0 Interrupt disabled 1 Interrupt enabled
9–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

38.4.2 Timer Configuration (REACM2_TCR)

The REACM2_TCR Timer Configuration Register contains the prescaler settings to configure the operation of the Reaction Module Hold Timer and Shared Timers. It is mandatory to change the value of the prescalers either when the prescalers are disabled by its control enable bits HPREN and TPREN in the Configuration Register or when the counters are not being used by any channel. Note that the prescalers are completely independent and thus modifying HPRE does not affect TPRES and vice-versa.

Address: 0h base + 4h offset = 4h

REACM2_TCR field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 HPRE	Hold Timer Prescaler The HPRE field defines the rate of the Hold Timers on each Reaction Channel. If its value is zero the prescaler is bypassed thus the Hold timer operates at the module clock rate. If HPRE = 0x01 the module operates at module clock divide by two and so forth up to HPRE = 0xFFFF which defines system clock divided by 4096.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 TPRE	Timer Prescaler The TPRES field defines the rate of the Timers on the Timer bank. If its value is zero the prescaler is bypassed thus the Timer operates at the module clock rate. If TPRES = 0x01 the Timer operates at module clock divide by two and so forth up to TPRES = 0xFF which defines module clock divided by 256 as the frequency of operation for the Timer.

38.4.3 Threshold Router Register (REACM2_THRR)

The Reaction Module Threshold Router Register routes the ADC result to the Threshold Bank. Since a TAG is assigned for each ADC result coming from the on-chip ADC module, this TAG is specified in this register and used for the routing process. The ADC result is written to the Threshold Value Bank as soon as it is received by the Reaction Module. Note that THRADC0 and THRADC1 TAG values may also be used by the Reaction Channels. In this case the results are routed to both, the channel and the Threshold Bank.

NOTE

Due to the timing in which these parallel events occur, if the channel uses the same Threshold Bank address in which the incoming ADC result was written to, this ADC result is used for the channel modulation being executed.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

REACM2_THRR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 WREN1	Write Enable Bit for THRADC1 The WREN1 write enable bit 1 controls if the ADC result having a TAG matching to THRADC1 field will be written into address one of the Threshold Bank 0 Do not write received ADC result to Threshold bank 1 Write received ADC result to Threshold bank address one
7 WREN0	Write Enable Bit for THRADC0 The WREN0 write enable bit 0 controls if the ADC result having a TAG matching to THRADC0 field will be written into address zero of the Threshold Bank 0 Do not write received ADC result to Threshold bank 1 Write received ADC result to Threshold bank address zero
8–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 THRADC1	ADC result Router value for Threshold Bank address one The THRADC1[3:0] field controls the routing from the received ADC result to the Threshold Bank address one. Any ADC result which TAG matching THRADC1 will be routed to Threshold Bank.
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 THRADC0	ADC result Router for Threshold Bank address zero

Table continues on the next page...

REACM2_THRR field descriptions (continued)

Field	Description
	The THRADC0[3:0] field controls the routing from the received ADC result to the Threshold Bank address zero. Any ADC result which TAG matching THRADC0 will be routed to Threshold Bank.

38.4.4 ADC Sensor Input Register (REACM2_SINR)

The Reaction Module ADC Sensor Input Register is used to monitor the ADC Interface (see section [ADC Interface](#)) and allows the software to define the ADC result and TAG values for the Reaction Module. Also ADC values captured through DMA directly from the ADC interface or after filtering can be transferred to the Reaction Module by the CPU. Writes to this register may overwrite data coming from the ADC interface thus it should be used when no ADC conversion has the Reaction Module as the target. Writing to this register triggers the Reaction Channel selected by the TAG value to execute a comparison and to evaluate an eventually new value for the channel outputs.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

REACM2_SINR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 ADC_TAG	TAG value The ADC_TAG[3:0] represents the TAG for the ADC conversion which is used by the Reaction Module to select the Reaction Channel to execute the modulation.
16–31 ADC_RESULT	ADC conversion result value The ADC_RESULT represents the value resulting from an ADC conversion. This value is used for the Reaction Channel Modulation process or for capturing by the Threshold Bank.

38.4.5 Period Generator Configuration Register (REACM2_PCR)

The Reaction Module Period Generator Configuration Register is used to setup the period pulse generator sub-block. See section [Period / Delay Generator](#). This configuration is necessary when running the modulation mode threshold/period.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

REACM2_PCR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 PERPRESC	Period prescaler rate value The PERPRESC field defines the rate of the prescaler to be used by the Period counter and Delay counter. If its value is 0, the rate is 1, and so forth up to PERPRESC= 0xFF which defines to divide the system clock by 256.
16–31 PER	Period time value The PER represents the value for the internal period generator counter. When it is configured to all 0, the counter is stopped. And if not all 0, the period time in clock cycles is given by multiplying (PER+1) by the prescaler value (PERPRESC+1).

38.4.6 Period Shift Delay Configuration Register (REACM2_PSCR)

The Reaction Module Period Shift Delay Configuration Register is used to configure the delay time between period pulses of two consecutive channels. See section [Period / Delay Generator](#). The delay multiplied by the number of channels must be less than or equal to the period.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0															DLY																
W

REACM2_PSCR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 DLY	Delay value between two consecutive channel period pulses The DLY represents the value to configure the shift delay between the period pulses of two consecutive reaction channels (for example, CH0 and CH1). The correct time depends on the prescaler counter. Also, if DLY=0 then the period pulses of all reaction channels occur at the same time. If DLY is not all 0, then the shift delay time in clock cycles is given by multiplying DLY with the prescaler (PERPRESC+1).

38.4.7 Global Error Flag Register (REACM2_GEFR)

The Reaction Module Global Error Flag Register helps the software in the resolution of error conditions signaled by the Reaction Channels. This allows a faster service in error handling. This register mirrors the Error Flag in the Channel Configuration and Status registers.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

REACM2_CHCRn field descriptions

Field	Description
0–1 CHEN	Channel Enable Bits The CHEN[1:0] bits control the activation of the Reaction Channel. Once changed from disabled, CHEN = 00, to any enabled state, the channel reads the first Modulation Word and initializes itself in order to be ready to execute a modulation as soon as a timer control window is detected or SWMC=1, if software modulation control is selected by CHEN= 11. NOTE: If CHEN is programed with 01 or 11 enabling a channel, and the eTPU time window is already active (or SWMC=1), the Reaction Channel disregards this window and waits until the next window activation in order to start the modulation process by moving to the active state. In order to start a modulation controlled by software, it is required to first write CHEN=11 and then to write SWMC=1 only after that. 00 Channel disabled, meaning that it does not execute any modulation even if a timer window is detected or SWMC is made active. In this mode DOFF field in the Channel Configuration register defines the state of the channel outputs. 01 Channel is enabled for timer control only, meaning that as soon as a timer window is detected a modulation sequence starts. 10 Reserved 11 Channel enabled for software control only, meaning that as soon as SWMC bit is set a modulation sequence starts.
2 SWMC	Software Modulation Control bit The SWMC, Software Modulation Control bit, if set, initiates the channel modulation. It is equivalent to the assertion of an eTPU channel connected to the Reaction module. To use this functionality it is required that CHEN[1:0] = 11.

Table continues on the next page...

REACM2_CHCR_n field descriptions (continued)

Field	Description
	0 Channel does not perform modulation 1 Channel executes modulation
3 MAXLEN	ADC result Maximum Limit Interrupt Enable bit The MAXLEN enables the MAXL flag, when set, to generate an interrupt request for the CPU. 0 Interrupt disabled 1 Interrupt enabled
4 OCDFEN	OCDF Interrupt Enable bit The OCDFEN bit enables the OCDF bit to issue an interrupt request. 0 OCDF interrupt disabled 1 OCDF interrupt enabled
5 SCDFEN	SCDF Interrupt Enable bit The SCDFEN bit enables the SCDF bit to issue an interrupt request. 0 SCDF interrupt disabled 1 SCDF interrupt enabled
6 TAEREN	TAER Interrupt Enable bit The TAEREN bit enables the TAER bit to issue an interrupt request. 0 TAER interrupt disabled 1 TAER interrupt enabled
7 SQEREN	Modulation Word Sequence Error Interrupt Enable The SQEREN bit enables the SQER flag to generate an interrupt request. 0 SQER interrupt disabled 1 SQER interrupt enabled
8 RAEREN	Resource Allocation Error Interrupt Enable The RAEREN bit enables the RAER flag to generate an interrupt request. 0 RAER interrupt disabled 1 RAER interrupt enabled
9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 CHOFF	Output Disable bit The CHOFF bit allows disabling the output pin. DOFF[2:0] field is used as disable state for the channel outputs. The output pins will set to DOFF value if CHOFF is asserted. Note that disabling the channel through CHOFF does not disable the channel operation. Only the channel outputs are forced to DOFF state. 0 Output Disable Disabled 1 Output Disable Enabled
11 SDCM	Short Detection Counting Mode

Table continues on the next page...

REACM2_CHCR_n field descriptions (continued)

Field	Description
	The SDCM bit configures the short detector to count one or two short detection events to set the SCDF field. 0 SCDF is set if two short detection events occur in a row 1 SCDF is set if a short detection occurs
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 DOFF	Drive Off Control field The DOFF[2:0] field defines the Reaction Channel output disabled state. This condition is achieved either when CHEN= 00, or after CHEN activation, or when Output is disabled by CHOFF in the Channel Configuration register. • DOFF[0] bit defines CH_n_a output pin value • DOFF[1] bit defines CH_n_b output pin value • DOFF[2] bit defines CH_n_c output pin value NOTE: It is possible to control the channel outputs directly through the software by writing to the DOFF bits. In this case the channel should be in the disabled state, CHEN=00. NOTE: If the DOFF value is changed just after the channel is enabled, it is not assured the new DOFF value is immediately used in the channel output.
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–23 BSB	Bank Support Bits The BSB[2:0] provides control for a banked mode operation of the Reaction Module. Each bit in this field controls the channel outputs chn_c, chn_b and chn_a respectively. When asserted the channel output implements a sharing function with the corresponding output of the subsequent channel.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 MODULATION_ ADDR	Address for Modulation Control Bank The MODULATION_ADDR field has the address of the Modulation Word in the Modulation Control Bank. This address is used as a base address for the first modulation word. The Reaction Channel can access subsequent words in the Modulation Control Bank by incrementing the Modulation Address field. Note that this field is not modified by the Reaction Channel in this process. NOTE: The number of subsequent words is limited to 15. Therefore the channel can handle a sequence with as many as 16 modulation words. NOTE: If a sequence advance is requested in the 16th modulation word, the channel returns back and accesses the first modulation word that is indicated by the address field MODULATION_ADDR on the REACM2_CHCR_n register.

38.4.9 Channel n Status Register (REACM2_CHSRn)

The Reaction Module Channel Status Register provides access to the channel flags and flag clear bits. It also provides access to the current values of the channel output being driven and the Modulation Word being accessed by the channel.

Address: 0h base + 104h offset + (16d × i), where i=0d to 9d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0		MODACT	MAXL	OCDF	SCDF	TAER	SQER	RAER	CHOUT			0			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0			0	0	0	0	0	0	0	MODULATION_POINTER					
W				MAXLC	OCDFC	SCDFC	TAERC	SQERC	RAERC							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

REACM2_CHSRn field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 MODACT	Modulation Active Flag The MODACT flag indicates that the channel is enabled and active thus executing a modulation cycle. 0 Channel is not active 1 Channel is active

Table continues on the next page...

REACM2_CHSR_n field descriptions (continued)

Field	Description
3 MAXL	ADC Maximum Limit Detection Flag The MAXL flag indicates that the ADC result which TAG is addressing this channel achieved or passed the maximum allowed limit specified in the ADCMAX register. This flag is set when the channel is in the active state (see section Channel Modes) or in debug mode. This bit is not set in the off time of the Threshold/Hold-off modulation mode. 0 Normal operation 1 ADC Maximum Limit Detected
4 OCDF	Open Circuit Detection Flag The OCDF flag indicates that an open circuit was detected in the channel load using the PWM monitored modulation, as described in Monitored Modulation. This Flag is set only if the channel is in the active state. 0 Normal operation 1 Open Circuit Detected
5 SCDF	Short Circuit Detection Flag The SCDF flag indicates that a short circuit was detected in the channel load using the PWM monitored modulation, as described in Monitored Modulation. This flag is set only if the channels are in the active state. 0 Normal Operation 1 Short Circuit Detected
6 TAER	Timer Allocation Error The Timer Allocation Error bit indicates that the channel tried to allocate a timer counter in the Shared Timer Bank without success. This situation is an indication that the Timer resources available in the module are not sufficient to execute the required functionality. This error indication is used during software development and should not occur during normal use of the module since it may result in incorrect operation. This flag is set only if the channel is in the active state. 0 No error occurred during timer allocation. 1 Error occurred during timer allocation
7 SQER	Modulation Word Sequence Error Flag The SQER bit indicates a Modulation Sequence error occurred, meaning that the time window which defines a modulation cycle ended in a premature modulation phase. The correct modulation phase for the time window to close is when SM field in the Modulation Word indicates no advance, or SM= 00. This Flag is set only if the channel is in the active state. 0 Modulation Sequence Error did not occur 1 Modulation Sequence Error occurred
8 RAER	Resource Allocation Error Flag The RAER bit indicates that a resource allocation error occurred. The possible allocation errors are: Modulation Control Word address is out of available range (including if the MODULATION_POINTER increments to an inexistent MCW address or wraps to 0x0), Threshold Value Bank address is out of available range, Hold Timer Bank address is out of available range, Shared Timer Bank address is out of available range, Channel Input Router points to an inexistent eTPU channel, and when the Hold timer is select for both modulation and sequence advance at the same time (i.e, SM=10 and MM=01). Note that the amount of hardware resources is configuration dependent thus may vary according to module

Table continues on the next page...

REACM2_CHSRn field descriptions (continued)

Field	Description
	parameterization in the SoC. This flag is intended to help on the debug of the Reaction Module during software development and can be set only if the channel is in the enabled state. NOTE: The condition that sets the RAER bit must be resolved prior to clear the bit, otherwise the bit can be set again. 0 No allocation error occurred 1 Allocation error occurred
9–11 CHOUT	Channel Output Monitoring bits The CHOUT[2:0] Channel Output Monitoring bits provides for the software the ability to monitor the output provided by the channel. This data is not buffered thus represents the channel output at the time the CPU read access is done. CHOUT[0] corresponds to the chn_a output, CHOUT[1] corresponds to the chn_b output and CHOUT[2] corresponds to the chn_c output pin. These bits are available independent of the channel mode or state.
12–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 MAXLC	ADC Maximum Limit Flag Clear The MAXLC clears the MAXL flag if "1" is written. This bit reads always as 0x0. If a set event occurs at the same time a flag clear is done, the set event has precedence over the clear thus the flag remains set. 0 No action 1 Clears MAXL bit
20 OCDFC	Open Circuit Detection Flag Clear The OCDFC clears the OCDF flag if "1" is written. This bit reads always as 0x0. If a set event occurs at the same time a flag clear is done, the set event has precedence over the clear thus the flag remains set. 0 No action 1 Clears OCDF bit
21 SCDFC	Short Circuit Detection Flag clear The SCDFC bit clears the SCDF flag if "1" is written. This bit is self negated thus read always as '0'. If a set event occurs at the same time a flag clear is done, the set event has precedence over the clear thus the flag remains set. 0 No action 1 Clears SCDF
22 TAERC	TAER Clear bit The TAERC bit clears the TAER bit if "1" is written. This bit is self-negated thus reads always as '0'. If a set event occurs at the same time a flag clear is done, the set event has precedence over the clear thus the flag remains set. 0 No action 1 Clears TAER
23 SQERC	Modulation Word Sequence Error Flag clear The SQERC bit clears the SQER flag in the Channel Status register. 0 SQER flag is not cleared 1 SQER flag is cleared

Table continues on the next page...

REACM2_CHSR_n field descriptions (continued)

Field	Description
24 RAERC	Resource Allocation Error Flag clear The RAERC bit clears the RAER flag in the Channel Status register. 0 RAER flag is not cleared 1 RAER flag is cleared
25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 MODULATION_ POINTER	Modulation bank address generated by the channel The MODULATION_POINTER[5:0] gives to the software the information of the current address being generated by the channel to access the Modulation Word. Note that the address increments from a base address stored in the channel, MODULATION_ADDR[5:0]. This register is not buffered thus represents the current address being generated.

38.4.10 Channel n Router Register (REACM2_CHRR_n)

The Reaction Module Channel Router Register controls the channel connection to external timers, such as eTPU and eMIOS and ADC result data. The channels have access to any 16 timer inputs and any ADC sample tag from 0 to 15. Note that this architecture allows several Reaction Channels to point to the same timer channel or to the same ADC result.

Address: 0h base + 108h offset + (16d × i), where i=0d to 9d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

REACM2_CHRR_n field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 ADCR	ADC result router field The ADCR[3:0] field selects which ADC result is used by the Reaction Channel for the modulation. The TAG[3:0] received along with the ADC result is used for comparison with the ADCR[3:0] field in order to define if the received result is used by the Reaction Channel.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 CHIR	Channel Input router field The CHIR field selects which eTPU channel is used by the Reaction Channel for the modulation.

38.4.11 Shared Timer Bank (REACM2_STBKn)

The Reaction Modulation Shared Timer Bank is a set of registers which define the values used by the Reaction Module Timer. The timer values are programmed by the Host CPU during the configuration of the Reaction Module. Modulation Word accessed by the Reaction Channel contains the address of a specific Timer value stored in the Shared Timer bank. By selecting a Timer value the Reaction Channel also selects and enables a counter. When this counter reaches the selected Timer value a time-out indication is generated for the Reaction Channel that initiated the counter. This event is used for example to indicate that a next Modulation Word should be used for the modulation.

Address: 0h base + 300h offset + (4d × i), where i=0d to 4d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																SHARED_TIMER															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

REACM2_STBKn field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 SHARED_TIMER	Timer Value The SHARED_TIMER value is one element of the Timer Register Bank. Up to 5 timer values can be stored within the Timer Bank. NOTE: When using the shared timer for sequence advance, the counted time (considering prescaler) must be greater than 64 clock cycles.

38.4.12 Hold Timer Bank (REACM2_HOTBKn)

The Reaction Module Hold Timer Bank is a set of registers that defines the values used by the Reaction Channels to measure hold time on certain modulation schemes. The timer values are programmed by software and addressed by the Reaction Channel based on the data read from a Modulation Word.

Address: 0h base + 380h offset + (4d × i), where i=0d to 4d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

REACM2_HOTBK n field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 HOLD_TIM	Hold Timer Value The HOLD_TIM value is one element of the Hold Timer Register Bank. Up to 5timer values can be stored within the Hold Timer Bank. NOTE: When using the hold timer for sequence advance, the counted time (considering prescaler) must greater than 64 clock cycles.

38.4.13 Threshold Bank (REACM2_THBK n)

The Reaction Module Threshold Bank holds the value to be used for comparison against results received from the ADC. Based on that comparison the Reaction Channel decides the Channel output value to be either HOD or LOD.

Address: 0h base + 400h offset + (4d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																THRESHOLD_VALUE															
W

REACM2_THBK n field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 THRESHOLD_VALUE	Threshold Value The THRESHOLD_VALUE unsigned value is one element of the Threshold register used for a threshold modulation. Up to 32timer values can be stored within the Threshold Bank.

38.4.14 ADC Result Maximum Limit Check (REACM2_ADCMAX)

The Reaction Module ADC Maximum Limit Check register holds the maximum expected value of the ADC result. If a value greater than or equal to ADC_MAX_LIMIT is received the MAXL bit in the corresponding Channel Status Register Error is asserted.

Address: 0h base + 600h offset = 600h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																ADC_MAX_LIMIT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

REACM2_ADCMAX field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 ADC_MAX_LIMIT	Maximum Limit allowed for the ADC result The ADC_MAX_LIMIT[15:0] value indicates the maximum expected value for the ADC result. The MAXL bit in the corresponding channel Status register is set in case a greater or equal value is received from the ADC. If set to zero no limit checking is performed, thus MAXL bit will not be set anyway. NOTE: ADC results are always considered unsigned unless specific note states the contrary. Since ADC received results can be 14-bit values a two bit sign extension must be performed before any comparison is executed.

38.4.15 Modulation Range Pulse Width (REACM2_RANGE_PWD)

The Reaction Module Range PulseWidth Detection Check register provides the value used to check if the PWM pulse width generated during the modulation process is larger than a maximum pulse width specified by (MIN_PWD + RANGE_PWD). The checking is performed by the channel logic during appropriate time intervals. See section [Monitored Modulation](#). This function is implemented by sharing the use of Reaction Channel Hold counter, thus if the Hold timer is used by the channel sequence mode, SM in the Channel Configuration register, this checking function is not active.

Address: 0h base + 680h offset = 680h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

REACM2_RANGE_PWD field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 RANGE_PWD	Range Pulse Width The RANGE_PWD[11:0] field defines the maximum pulse width allowed by the channel PWM generation. The checking is performed by the channel internal Hold Timer at appropriate times in the PWM modulation process. The maximum pulse is defined as (RANGE_PWD + MIN_PWD). See “REACM2 Minimum Pulse Width Check (REACM2_MIN_PWD)” for MIN_PWD description. If RANGE_PWD = 0x00 then no maximum pulse width checking is performed. NOTE: The RANGE_PWD value should be calculated considering the prescaler settings used for the HOLD counter. For a programmed (RANGE_PWD + MIN_PWD) value, a pulse narrower than or equal to (RANGE_PWD + MIN_PWD + 1) does not set the OCDF flag.

38.4.16 Modulation Minimum Pulse Width (REACM2_MIN_PWD)

The Reaction Module Minimum PulseWidth Check register provides the value used to check if the pulse width generated during the PWM modulation process on the channel outputs is shorter than a minimum pulse width specified by this register. The checking is performed by using the channel internal Hold timer during appropriate times on the channel operation when this counter is not being used for the hold modulation cycle.

Address: 0h base + 6C0h offset = 6C0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

REACM2_MIN_PWD field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 MIN_PWD	Minimum Pulse Width The MIN_PWD[11:0] field defines the minimum pulse width allowed by the channel PWM generation. The checking is performed by the channel hold timer. If MIN_PWD[11:0] = 0x00 then no checking is done even for maximum pulse width or minimum pulse width. NOTE: The MIN_PWD value should be calculated considering the prescaler settings used for the HOLD counter. For a programmed MIN_PWD value, a pulse wider than (MIN_PWD+1) does not set the SCDF flag.

38.4.17 Modulation Control Word Bank (REACM2_MWBK n)

The Reaction Module Control Word Bank is a set of registers that controls the Reaction Channel Modulation scheme. These registers are programmed by software and read by the Reaction Channels. All the information required by the Reaction Channels to perform a modulation is stored in these words. All channels have access to the same words thus sharing of Modulation Words among channels is possible in this architecture.

There are 32 modulation control words in this device.

Address: 0h base + 700h offset + (4d × i), where i=0d to 31d

REACM2_MWBK n field descriptions

Field	Description
0 LOOP	Loop Control Bit The LOOP Control bit indicates that the next Modulation Control Word accessed by the Reaction Channel when a Modulation Word address increment event occurs should be the one indicated by the Channel MODULATION_ADDR[5:0] register with no offset. 0 Increment to the next modulation word 1 Loop back to initial channel modulation word
1 IOSS	Initial Output State Selection The IOSS bit defines the state of the channel output pins when a modulation phase is started by the Reaction Channel. This bit is important in the Modulation Word first access. This first access occurs after the channel is enabled by CHEN bit field in the Channel Configuration register, or when the modulation phase advances, e.g. due to a timer event. This bit also defines the modulation initial behavior for some modulation modes. See Modulation Mode MM[1:0] field for more details. 0 LOD[2:0] is initially used for chn_c, chn_b and chn_a respectively 1 HOD[2:0] is initially used for chn_c, chn_b and chn_a respectively
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

REACM2_MWBK n field descriptions (continued)

Field	Description
3–4 MM	Modulation Mode The MM[1:0] Modulation Mode field indicates the type of the modulation that is executed by the channel while the IOSS bit determines the modulation mode initial state. The initial behavior of the modulation modes (or the threshold comparison level performed in threshold/Period modulation) is selected by the IOSS bit. 00 Modulation Type: threshold/threshold Modulation occurs between two threshold levels defined by THRESPT upper level threshold pointer and THRESPT +1 which corresponds to a lower level threshold pointer. IOSS selects the initial output state. Output ON state is defined by HOD (IOSS=1) and Output OFF state is defined by LOD (IOSS=0). 01 Modulation Type: threshold/Hold-off - IOSS="0": Modulation starts with channel outputs set to LOD for an amount of time defined by the hold timer. After that outputs are set to HOD until an upper threshold defined by THRESHPT is reached. - IOSS="1": Modulation starts with channel outputs set to HOD until an upper threshold defined by THRESHPT is reached. After that level is achieved outputs are set to LOD for an amount of time defined by the hold timer. 10 Modulation Type: Threshold/Hold-on - IOSS="0": Modulation starts with channel outputs set to LOD until a lower threshold defined by THRESHPT is reached. After that level is achieved outputs are set to HOD for an amount of time defined by the hold timer. - IOSS="1": Modulation starts with channel outputs set to HOD for an amount of time defined by the hold timer. After that outputs are set to LOD until a low threshold is reached. 11 - IOSS="0": Modulation Type: threshold-low/Period. In this modulation mode channel outputs starts in LOD and a low threshold comparison is performed. When the threshold level defined by THRESPT is achieved, the channel outputs state changes to HOD until the modulation period expires. - IOSS="1": Modulation Type: threshold-high/Period. In this modulation mode channel outputs starts in HOD and a high threshold comparison is performed. When the threshold level defined by THRESPT is achieved, the channel outputs state changes to LOD until the modulation period expires.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–7 SM	Sequencer Mode The SM[1:0] field defines the event that makes the channel address the next modulation word. This event can be a timer event or a threshold level event. Note that the channel does not necessarily increments the Modulation Word address thus the same Modulation Word is executed again in the new modulation sequence. NOTE: For time-out event selections, it is required the related time should be greater than 64 clock cycles. 00 Current modulation word is used, no advance is performed on any event. No timer is activated by this modulation word. 01 Advance to the next modulation word when a Timer time-out event is detected. The Timer is activated when the modulation word is accessed by the channel.

Table continues on the next page...

REACM2_MWBK n field descriptions (continued)

Field	Description
	10 Advance to the next modulation word when a Hold Timer time-out event is detected. The Hold timer is activated when the modulation word is accessed by the channel. This is only for MM=00 (THR-THR). 11 Advance to the next modulation word when a threshold level is achieved (greater or equal). The threshold level is defined by the THRESPT pointer.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–11 HOD	High Output Drive The HOD[2:0] field defines the values driven on the chn_c, chn_b and chn_a channel output pins, respectively, when the channel is at ON state.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 LOD	Low Output Drive The LOD[2:0] field defines the values driven on the chn_c, chn_b and chn_a channel output pins, respectively, when the channel is at OFF state.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–22 THRESPT	Threshold Pointer The THRESPT Threshold Pointer is the address of the Threshold Bank that holds values to be used for ADC result comparisons in the modulation process. This pointer has the resolution for a 16-bit data stored in the register described in section “REACM Threshold Bank Register (REACM_THBK)”.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–26 STPT	Shared Timer Pointer The STPT Shared Timer Pointer field is the pointer for the Shared Timer Bank. The Shared Timer is used as timer sequencer defining the advance of Modulation Words.
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 HDOFFTPT	Hold on/off Pointer The HDOFFTPT field is the address of the Hold timer value in the Hold Timer Bank that is used in the modulation cycle. Note that there are modulation sequences that does not require hold on/off measurement such as threshold/threshold modulations.

38.5 Functional Description

The following sections describe the Reaction Module functionality.

The Reaction Module is designed to allow a closed feedback loop control over the driver load currents. The load can be an injector for direct injection system or an electromagnetic actuator for robotized transmission. In both cases a solenoid is expected to be the actual load. The module architecture is based on shared resources sub-modules

that can be used by all 10 Reaction Channels. Please refer to [Figure 38-4](#) for details about the module architecture. The Reaction Module is composed of the following internal sub-modules:

- Reaction Channel
- Modulation Control Word Bank
- Shared Timer Bank
- Hold Time Bank
- Threshold Bank
- Period Pulse Generator

The following sections describe each one of these sub-modules and their combined operation.

38.5.1 Reaction Channel

The Reaction Channel is the core of the Reaction Module. Each channel controls three output pins and it is composed of a Control FSM which receives parameters to generate a modulated waveform as well as the timer control window usually provided by eTPU. The ADC interface sub-module indicates to the channel that a new ADC result is available. If *activated* by the eTPU channel, the Reaction Channel reads the Modulation Word which provides addresses for the Threshold Value bank, Shared Timer Bank and Hold Time Bank. The data provided by the Threshold Bank is compared with the incoming ADC result. Based on that comparison the Reaction Channel state machine selects the values for the output pin registers. The modulation only occurs if *activated* by the timer control signal, which can be generated by eTPU, or can be controlled by software by writing to the SWMC, software modulation control bit, in the Channel Configuration register. The MM and SM fields in the Modulation Word provide the Modulation Mode and Sequencer Mode control respectively. The following figure describes the internal architecture of the Reaction Channel and its interconnection with other sub-modules.

NOTE

The indexes corresponding to the register bit widths in the figure below will vary depending on the chip implementation. See the register descriptions for the correct bit width in your chip.

Figure 38-126. Reaction Channel Architecture Simplified Diagram

The addresses stored in the Modulation Word are pointers to timers and threshold banks. HOD and LOD provide the 3-bit field which controls the states, HIGH and LOW, respectively for the Reaction Channel output pins. The Reaction Channel FSM selects the values for the output pins as well as the load signal used to update those values. The modulation executed by the Reaction Channel is based on the feedback loop provided by the ADC results. These results are routed to one side of a comparator while the other comparator input receives the selected Threshold value from the threshold bank. The comparison result indicates for the Reaction Channel FSM if the output pin value should be defined either by HOD or by LOD. As a result a PWM is generated on the output pins. Note that since there are three independent outputs the PWM signal can be generated on any output or even on several outputs at the same time. Usually a PWM signal is generated in one of the outputs only, while the others outputs are used to control power supply switching, for example.

The preceding figure shows three waveforms at the right side of the figure. On the top there is the control signal from eTPU which defines the boundaries of the modulated waveform. In the middle there is the PWM waveform which is used to drive the power ON and OFF at the load, thus generating the third waveform which represents the current passing through the load.

NOTE

The modulation word sequence is limited to 16 words because the address value to the modulation control word bank can vary only from the configured initial value up to a maximum value given by (MODULATION_ADDR + 15).

38.5.2 Modulation Control Words Bank

The Modulation Control Word provides information about the modulation type to be performed and the addresses for several address banks. REACM2_MWBK_n describes the Modulation Word register and [Figure 38-127](#) describes the interfaces of this sub-module with some other sub-modules in the Reaction Module. The information stored in the Modulation Word are:

- Modulation control parameters for the Reaction Channel
- Threshold Value Register Bank address
- Hold time bank address
- Shared Timer bank address

All channels share the information stored in the Modulation Control Word Bank, which provides a size-effective implementation avoiding the duplication of information and allowing flexible implementation. The sharing of modulation control words allows several channels to execute the same modulation sequence.

The Modulation Control is designed to be used by all reaction channels as a centralized resource. However, only one channel is able to access the Modulation bank at a given time. Therefore, there is a priority in the selection of the channel that will have the access granted, but note that this condition does not occur too often since ADC results are provided for one channel at a time.

An arbiter in the Modulation Control Word bank selects one of the channels which are requesting access to a modulation word. The priority criteria is fixed and based on the channel number, considering Channel 0 the highest priority channel. The channel selected by the arbiter receives an acknowledge signal which indicates that channel was selected and therefore can access the modulation word.

Note

In order to avoid an initial delay when processing a timer window start event, the channel performs an speculative read operation of the first modulation word when it is enabled

(CHEN is configured). Therefore, when the modulation cycle is triggered by the timer window start event, all needed information for the modulation is already stored inside the channel.

Figure 38-127. Modulation Control Word Bank Interfaces

38.5.3 Shared Timer Bank

The Shared Timer bank is an innovative concept of dynamic timer allocation. Since the number of timers can be smaller than the number of channels in the Reaction Module, there is a possibility that all timers are allocated at a certain time. This architecture is based on the low probability of such scenario since the timer allocation is a sporadic event. The timers in the Shared Timer Bank are usually in IDLE state until they are allocated by a channel. Any timer can be allocated as soon as it is in IDLE. The shared timers work in conjunction with a timer bank which stores values to be used by the timing measurement.

The Shared Timer Bank block is composed of two sub-modules:

1. Four 16-bit counters.
2. A bank with five selectable 16-bit time values.

If there is an attempt to allocate more than existing timers then an error flag TAER (see [Figure 38-134](#)) is set and no timer is allocated by the requesting channel. As a general guideline the system should be dimensioned in such a way that the timer allocation is always possible.

Note

In case of an allocation error the channel forces DOFF to its output pin preventing any damage to occur to the actuator being controlled. This state will not change until TAER bit is cleared.

During the timer allocation the channel also provides the TIMERPT pointer which selects a timing value. The value pointed by TIMERPT is loaded into one of the 4 counters which counts down until reaching zero. At this time a time-out indication is sent to the requesting channel and the timer is deallocated, moving back to IDLE state.

In case of several timer activation requests being issued at the same time, the logic in the Timer Bank will prioritize giving higher priority to the channel with lower number, thus channel zero has higher priority than the others. No flags are set in case several requests are issued simultaneously unless there are more requests than the number of available timers. In this case the TAER error flag is set in the requesting channel status register. The following figure presents a block diagram of the Timer Bank.

Figure 38-128. Shared Timer Bank Block Diagram with 4 Timers

38.5.4 Hold Time Bank

The Hold Time Bank stores time values that are used by the hold-on/off periods during the modulation process. This bank is shared among all channels and is addressed based on the HDOFFPT pointer in the Modulation Control Word. The following figure shows a block diagram of this bank and its interconnections.

Figure 38-129. Hold Time Bank Block Diagram

The Modulation Control Word generates the address for the Hold Time bank which then generates the hold-on/off time value for the channels. The channel that addressed the Modulation Word captures the 12-bit value storing it in the channel Hold timer. In The preceding figure channel CH0 is requesting access to the Modulation Word thus receiving hold-on/off value from the Hold Time Bank. Each Reaction Channel has its own internal hold timer.

38.5.5 Threshold Bank and Comparator

The Threshold Bank and Comparator contains the threshold levels to be compared against the ADC results. This sub-module also performs the comparison between the ADC result and the selected threshold value.

The Threshold bank can be programmed with up-to 32 threshold values.

An ADC result received from the on-chip ADC is connected to the ADC router and then to the comparator (see the following figure). This result stays at the comparator input until the Reaction Channel and Modulation Control Word selects the address of the Threshold value. The THRESPT field in the Modulation Control Word sub-module is

used as the address for the Threshold Bank. Note that if Threshold-Threshold modulation mode is used two comparisons need to be executed with two different Threshold values. After the first comparison is made the THRESPT pointer is incremented and a new comparison is done:

- First comparison: $COMP = ADC\_DATA \geq THRESHOLD\_VALUE[THRESPT]$
- Second comparison: $COMP = ADC\_DATA \geq THRESHOLD\_VALUE[THRESPT + 1]$

The COMP, comparison result, is routed to the channel selected by the received TAG. Once receiving the comparison result the channel takes the appropriate actions in order to execute the modulation mode as defined by the Modulation Control Word.

Figure 38-130. Threshold Bank and Comparator Block Diagram

38.5.6 ADC Interface

The ADC Interface connects to the eQADC module through a Parallel Side Port (PSI). Please refer to the eQADC chapter for more information about this interface. The eQADC sends conversion results to the Reaction Module which are received by the ADC Interface sub-module. The ADC Interface is capable of distinguishing between ADC results, Time stamps and *Prefill* information from eQADC. Only ADC results with no *Prefill* are considered by the Reaction Module as valid ADC samples. The TAG value received with the conversion result indicates which channel the result is addressed to. The

ADC interface is also responsible to indicate for the selected Reaction Channel that a new ADC result is available. It is also possible to access the ADC Interface input buffer through the REACM_SINR register.

38.5.6.1 Input Buffer Overrun

The OVR flag indicates than an input buffer overrun occurred. This buffer is normally written by the ADC interface (PSI) but can be written also by the CPU using the REACM_SINR register.

The ADC Interface data (ADC_TAG and ADC_RESULT) should not be updated until all Reaction Channels (with ADCR = ADC_TAG) process the received data. The OVR flag is set in the case of an overrun condition occurs, indicating that at least one ADC data was lost (the input data that caused the overrun is lost).

The following situations can generate an input overrun:

- Two consecutive sample data are received from ADC or from CPU.
- ADC and CPU sending sample data at the same time (asynchronous events).
- Input buffer is holding a sample data that is being processed by some channel and a new sample is received from ADC or CPU (normal mode of operation).

Figure 38-131. ADC Interface Block Diagram

The maximum throughput supported by the Reaction Module depends upon the TAG of the incoming ADC data. If only one Reaction Channel is addressed by the ADC TAG then the maximum supported ADC data rate is 1 sample for each 5 clock cycles. If two Reaction Channels are addressed by the same ADC TAG, thus having the same CHRR

ADCR field and are active at the same time, the maximum supported ADC data rate is 1 sample for each 10 clock cycles. In general if (n) channels share the same TAG and are active at the same time the maximum supported ADC data rate is 5 x (n) clock cycles.

These limitations are related to the sharing of internal Reaction Module resources such as the Modulation Word bank. The ADC conversion data should remain stable in the ADC interface until it is used by all channels with matching TAG and CHRR ADCR fields.

Note that if all active channels have different CHRR ADCR fields, i.e. are assigned to different TAG, the maximum supported ADC rate is 5 clock cycles. If multiple channels have the same CHRR ADCR field but only one is active at a time, then the maximum supported ADC data rate is also 5 clock cycles.

38.5.6.2 On-the-fly ADC data Acquisition

The ADC Interface and the Threshold bank can operate in a learn mode, meaning that the received ADC result can be stored in the Threshold Bank and used for comparisons. This functionality allows the user to interactively calibrate the modulation levels or capture on-the-fly levels from the external application board for debug purposes. The THRR register is used for that purpose. See [Figure 38-128](#) for more details about the register architecture. [Figure 38-132](#) describes the main connections between the ADC interface and Threshold Bank sub-modules.

The routing of received ADC results to be stored in the Threshold Bank is independent from the routing of the same result to the Reaction Channels (see [Figure 38-135](#)). Thus the same ADC result can be used in a comparison and stored in the Threshold Bank.

Figure 38-132. ADC interface and Threshold Bank interconnections

38.5.7 Prescalers

The Prescalers provide internal system clock divided signals to be used by internal timers. There are 2 prescalers in the Reaction Module. A 12-bit prescaler HPRE[11:0] and an 8-bit prescaler TPRES[7:0]. Both are defined in the Timer Configuration register TCR. The HPRE[11:0] is dedicated to the Hold timers within the Reaction Channels. The TPRES[7:0] is used by the Shared Timer Bank counters. The HPRE[11:0] and TPRES[7:0] prescalers are enabled by HPREN and TPRES bits, respectively, in the Module Configuration register. Note that prescalers operate in a similar way regarding its activation. Once the prescaler is enabled by HPREN or TPRES bits in the Module Configuration Register it starts a new count sequence meaning that it is put in reset state and will generate the first prescaler tick after it reaches the programmed value defined by HPRE or TPRES fields.

38.5.8 Period / Delay Generator

This signal generator provides periodic pulses to support multi-channels operating in the threshold-period modulation modes (see [Threshold low/Period Mode](#) and [Threshold high/Period Mode](#)). There is an exclusive prescaler counter for period / delay counters. The modulation period is defined by the PER[15:0] bits in the Period Configuration register and supplied by internal period counter. This counter can be disabled if the field PER[15:0] is all 0.

Each channel receives a period pulse signal delayed from the others. The delay of the period signals between consecutive channels is defined by the field DLY[15:0] in the Period Shift Delay Configuration register. Channel 0 receives the period signal without delay. Channel 1 gets the channel 0 period signal delayed by DLY[15:0], channel 2 gets channel 1 signal delayed by the same amount, and so on. However, if the delay is zero, all period pulses occur at the same time.

Note

The correct period and delay times depend on the period prescaler setting.

The period pulses are generated for all available channels regardless if the threshold/period modulation mode is being executed. For instance, if channel 0 and 2 have Threshold/Period and channel 1 doesn't, the delay from 0 to 2 is "2 x DLY".

The following figure shows the architecture of the Period / Delay generator sub-block.

Figure 38-133. Period / Delay generator sub-block

38.5.9 Banked Mode Support

Banked Mode is a Reaction Module hardware configuration which allows the sharing of Reaction Channel output pins at the device I/O level. The banked mode architecture allows the stacking of up to four Reaction channels. The following figure shows the connection between two adjacent channels, CH0 and CH1. The CCR BSB bits are used to control the configuration of channel output logic. Thus if BSB[0] in Reaction Channel [0] is asserted to 1 and the channel is not in the active state, ch0_a output will be switched from CH[0] OUT[0] to CH[1] OUT[0]. If a channel is active, i.e. executing a modulation, it takes control over its outputs independent of BSB bits setting. The banked mode logic is extended to Reaction Channels CH[2] and CH[3] thus defining a group of 4 channels. For simplification the following figure shows only channels CH[0] and CH[1] logic.

Note

When CHEN=00 for CH0 (channel disabled), the BSB bits don't influence the channel output, which is driven by CH0's DOFF. Therefore, a banked injector driven by CH1 will have part of its controls off, even if CH1 is enabled.

To use BSB of CH0 in this case, an option is to program channel CH0 with CHEN=11 (channel enabled) and with SWMC=0 (modulation OFF).

Note

In case of using CH2 in banked mode with CH0, the intermediate channel CH1 should also be configured with CHEN different from 00.

Figure 38-134. Banked Mode showing stacking of channels [0] and [1]

The Banked Mode support hardware is implemented on groups of up to 4 channels. The groups are defined as CH[3:0], CH[7:4], and CH[9:8].

Table 38-125. Banked Mode groups

CH3 → CH2 → CH1 → CH0
CH7 → CH6 → CH5 → CH4
CH9 → CH8

Thus CH[3], CH[7], and CH[9] do not connect to the subsequent channel which are CH[4], CH[8], and CH[0] respectively.

38.6 Modulation Modes

This section describes the modulation modes provided by the Reaction Module.

38.6.1 Threshold/Threshold Mode

This mode is programmed by using $\text{REACM2\_MWBKx[MM]} = 00$. In this modulation mode the Reaction Channel tries to maintain the ADC results between two Threshold limits. The modulation actions are as follows:

- $\text{ADC result} \geq [\text{THRESPT}]$: The Reaction Channel turns the outputs off by loading $\text{LOD}[2:0]$ to the channel outputs.
- $\text{ADC result} < [\text{THRESPT} + 1]$: The Reaction Channel turns the outputs on by loading $\text{HOD}[2:0]$ to the channel outputs.
- $[\text{THRESPT}+1] \leq \text{ADC result} < [\text{THRESPT}]$: The Reaction Channel keeps the outputs unchanged.

The following figure indicates the threshold/threshold modulation mode.

Figure 38-135. Threshold/Threshold Modulation Mode

There can be overshoots or undershoots in the real application related to the threshold limits. This occurs due to following:

- Feedback values are periodically sampled thus can present gaps on the measured values. For example when the sampling has been executed the value may have already passed the range defined by the limits;
- There is a delay between the sampling of feedback value and the reaction of the Reaction Channel. This is mainly caused by the ADC conversion time and its maximum sampling frequency.

The short circuit and open circuit detection are performed by monitoring the width of the ON pulse. For more details refer to [Monitored Modulation](#).

38.6.2 Threshold/Hold-off Mode

This modulation mode is programmed by using $\text{REACM2\_MWBKx[MM]} = 01$. In this mode the output pins are driven with $\text{HOD}[2:0]$ until the ADC results matches or is greater than the programmed Threshold. The output controls are then driven with $\text{LOD}[2:0]$ for a fixed amount of time defined by the hold timer. The initial modulation behavior can be controlled by using the $\text{REACM2\_MWBKx[IOSS]}$ bit as follows:

- When $\text{REACM2\_MWBKx[IOSS]} = 0$, modulation starts with outputs driven with LOD until the hold timer expires.
- When $\text{REACM2\_MWBKx[IOSS]} = 1$, modulation starts with outputs driven with HOD until the upper threshold level is reached.

Note that the upper threshold limit and the hold timer pointers are indicated by the Modulation Word in the REACM2_MWBK register.

Note

It is considered that in hold-off time the ADC samples are not reliable, therefore no comparison for MAXL or for output definition are performed. If these comparisons are necessary, the Threshold / Threshold modulation mode can be used.

The short circuit and open circuit detection are performed by monitoring the width of the ON pulse. For more details refer to [Monitored Modulation](#)

Figure 38-136. Threshold/hold-off Modulation Mode

38.6.3 Threshold/Hold-on Mode

This modulation mode is programmed by using $\text{REACM2\_MWBKx[MM]} = 10$. In this mode the output pins are driven with $\text{LOD}[2:0]$ until the ADC results is smaller than the programmed Threshold. The output controls are then driven with $\text{HOD}[2:0]$ for a fixed

amount of time defined by the hold time. The exception for this defined ON time occurs if the value of an input sample surpasses the MAXL. In this case the output pins change to LOD[2:0] immediately.

The initial modulation behavior can be controlled by using the REACM2_MWBKx[IOSS] bit as follows:

- When REACM2_MWBKx[IOSS] = 0, modulation starts with outputs driven with LOD until the lower threshold level is reached.
- When REACM2_MWBKx[IOSS] = 1, modulation starts with outputs driven with HOD until the hold timer expires.

Note that the lower threshold limit and the hold timer pointers are indicated by the Modulation Word in the REACM2_MWBK registers.

The open circuit detection is performed by monitoring the minimum width of the OFF pulse. The short circuit is indicated by monitoring the ADC samples if the input sample surpasses the MAXL value. For more details refer to [Monitored Modulation](#).

Figure 38-137. Threshold/Hold-on modulation mode

38.6.4 Threshold low/Period Mode

This modulation mode is programmed by using REACM2_MWBKx[MM] = 11 and REACM2_MWBKx[IOSS] = 0. In this modulation mode channel outputs start with LOD[2:0] and a low threshold comparison is performed until the ADC result is smaller than the programmed threshold. When the threshold level defined by THRESPT is achieved, the channel outputs states change to HOD[2:0] until the modulation period expires. The exception for this defined event occurs if the value of an input sample surpasses the MAXL. In this case the output pins change to LOD[2:0] immediately. Note that the lower threshold limit is indicated by the Modulation Word in the REACM2_MWBK registers, but the period time is given by the Period / Delay generator sub-block.

The following figure indicates the threshold low/period modulation mode.

Figure 38-138. Threshold low/Period modulation mode

The open circuit detection is performed by monitoring the minimum width of the OFF pulse. The short circuit is indicated by monitoring the ADC samples if the input sample surpasses the MAXL value. For more details refer to [Monitored Modulation](#).

38.6.5 Threshold high/Period Mode

This modulation mode is programmed by using $\text{REACM2\_MWBKx[MM]} = 11$ and $\text{REACM2\_MWBKx[IOSS]} = 1$. In this modulation mode channel outputs starts with HOD[2:0] and a high threshold comparison is performed until the ADC results matches or is greater than or equal to the programmed threshold. When the threshold level defined by THRESPT is achieved, the channel outputs state change to LOD[2:0] until the modulation period expires. Note that the high threshold limit is indicated by the Modulation Word in the REACM2_MWBK registers, but the period time is given by the Period / Delay generator sub-block.

The following figure indicates the threshold high/period modulation mode.

Figure 38-139. Threshold high/Period modulation mode

The short circuit and open circuit detection are performed by monitoring the width of the ON pulse. For more details refer to [Monitored Modulation](#).

38.6.6 Limitations on the Modulation Process

This section describes the Channel limitations on the modulation process such as the width and distance between consecutive modulation pulses.

38.6.6.1 Minimum distance between consecutive Timer Control Pulses

The control signal generated by the external timer which controls the modulation process in a worst case scenario has a minimum distance of 40 system clock periods. This is required for the Reaction Channel state machine to properly re-start the modulation process and address the correct modulation word. The worst case scenario considers a Reaction Module with 10 channels and all channels being activated at the same time. If this minimum distance is violated the modulation on the second pulse will not be executed, meaning that the channel output will be defined by the DOFF field.

Note

No error flag is set if this violation occurs.

The following figure describes the channel behavior if the minimum time between two consecutive timer control pulse is violated.

Figure 38-140. Limitation on the OFF modulation timing

38.6.6.2 Minimum Timer Control Pulse Width

There is no limitation on the Timer Control pulse minimum width. The channel just finishes the modulation process when the pulse ends even if the Modulation Words did not complete the expected sequence. Thus if a modulation phase is designed to have four Modulation Words starting from word 0, and the Timer Pulse ends at the second word (word 1) then the modulation process finishes at this point in time. The channel output is set to DOFF one clock cycle after the Timer Pulse ends. And the flag SQER is set because the SM bit field for the second modulation word is not 00. This flag occurs to indicate that the modulation was ended before the last phase of the sequence that uses the modulation word 3 and has SM=00.

The following figure describes the channel behavior when an early end of the Timer Control pulse occurs. Note that the channel output is driven to DOFF which causes the modulation to end. Note that an early end of pulse only affects the current modulation cycle. Meaning that on the next modulation cycle the modulation word 0 is executed first and all subsequent words are executed in the appropriate sequence.

Note

In some applications the modulation runs continuously and the input timer control signal is not used as a modulation pulse control but only as an enabling signal. Therefore, if the modulation is turned off, the REACM2 can issue a Modulation Word Sequence Error by setting SQER flag. In this case, this SQER flag can be ignored (masked) without prejudice.

An option, if the application permits, is to disable the REACM2 channel (CHEN=00), thus avoiding unwanted SQER error.

Figure 38-141. Early end of Timer Control pulse

38.6.6.3 CHOFF behavior during modulation

The CHOFF, channel output disable bit in REACM2_CHCRn, is intended to disable the channel immediately before a modulation cycle had ended. This is important on error conditions detected by the software, thus setting the channel outputs to a safe state defined by DOFF. It is important to note that re-activating the channel by setting CHOFF=0 does not imply that the channel outputs immediately return to the state defined by HOD and LOD on the modulation word being executed. Instead, the HOD and LOD are driven to the channel outputs only when one of the following conditions occur:

- A sequence advance event (time-out or threshold, depending on SM)
- A new sample is received (no matter whether the comparison matches or not)
- A hold-on/off time-out
- A period pulse occurs for the related modulation mode

38.6.6.4 Module initialization

In order to properly execute the modulation process the Reaction Module must be initialized with a correct sequence. One alternative is described as follows:

1. Make sure eTPU channels are at zero, inactive state
2. Setup eQADC module
3. Program the Modulation Words
4. Program the Threshold Bank
5. Program the Shared Timer Bank
6. Program the Hold Time Bank
7. Program Timer Configuration register
8. Program the Module Configuration register
9. Program the Period Shift Delay Configuration register
10. Program the Period Generator Configuration register
11. Program the Channel Router register
12. Program the Channel Configuration register
13. Start eTPU channels

It is important to note that the channel activation, by setting CHEN=01, should be done after all other registers were configured and before the input timer control signals are active. Violating this order may lead to errors when the modulation cycle is executed by the channel.

Note

If a glitch is introduced in the input timer control pulse, the channel stops to modulate and does not operate during the pulse just after the glitch. The glitch value for wrong operation ranges from 1 system clock to about 5 times the number of channels.

38.6.6.5 Potential glitches on the reaction channel outputs

Reaction channels outputs are digital signals that are controlled by several events that are not synchronized to each other. Due to this nature, there are a few cases when a glitch can occur at the channel outputs. If the channels outputs are going to be used by systems that are very slow compared to the generated PWM, these cases of glitches are not a problem.

The known cases of potential glitches are listed below:

- At the end of a modulation phase when a new modulation word will be used, a glitch can occur if the output has just changed prior to the end of the phase and the IOSS of the next phase forces a value that is the opposite of the last value.
- At the end of the whole modulation when the modulation is going to be disabled by the timer channel, a glitch can occur if the output has just changed to HOD prior to the disabling.
- If the threshold / threshold modulation mode is used with SM set to threshold (high) mode, at the end of the phase the output is switched off to LOD. If the modulation word for the next modulation phase has IOSS set to 1, a LOW glitch is generated. This can be avoided by setting HOD=LOD in the described previous modulation phase.

38.7 Monitored Modulation

The modulation executed by the Reaction Channel can be monitored by measuring the width of the PWM ON pulse or the OFF state.

38.7.1 Monitoring the ON Pulse Width

The modulation executed by the Reaction Channel can be monitored by measuring the width of the PWM pulses provided by the channel. If the pulse becomes too narrow it means that the load impedance is probably too low, thus indicating a possible short circuit. If the PWM pulses become too wide it may indicate an open circuit on the solenoid. These criteria can be used for threshold-threshold, threshold-hold-off, and threshold high-period modulation modes.

The PWM pulse is considered to start (rising edge) in the following cases:

- in the start of the modulation phase with IOSS=1 (threshold-threshold, threshold-hold-off, or threshold high-period modulation modes);
- when the hold-off time is over in the threshold-hold-off modulation mode;
- when the received sample is lower than the threshold LOW value (threshold-threshold, or threshold-hold-off modulation modes);

The PWM pulse to be monitored ends (falling edge) when the input sample value surpasses the threshold HIGH in the above modulation modes.

NOTE

When modulation word progresses to new modulation phase the current pulse width monitoring is stopped and a new one is started if necessary. Therefore there is no pulse width extension nor narrow pulse occurrence due to modulation phase progress.

The short detection has an additional configuration to set the SCDF flag. The SCDF flag is set if a single detection event occurs (REACM2_CHCR register field SDCM=0) or if two short detection events occur in a row (SDCM=1). For simplicity, the following descriptions are for single short detection case.

The limits for narrow and wide pulses are defined by RANGE_PWD and MIN_PWD registers (see [Figure 38-140](#) and [Figure 38-141](#)). These values apply to all Reaction Channels. The PWM pulses are measured by the Hold timers within the Reaction Channels. This is possible only during idle periods of this timer, for example from the moment a hold-off time-out occurs until the maximum threshold is reached when HOD is being used for the channel output pins. During this period the hold counter is not used and thus it can measure pulse widths and compare them against pre-defined limits defined by RANGE_PWD and MIN_PWD registers, as shown in [Figure 38-142](#).

Note

Consider an uncertainty of (+1) in the value MIN_PWD and (MIN_PWD + RANGE_PWD) when calculating the pulse width limits. The Hold timer prescaler contributes to this uncertainty.

For a programmed MIN_PWD value, a pulse wider than (MIN_PWD+1) does not set the SCDF flag.

For a programmed (RANGE_PWD + MIN_PWD) value, a pulse narrower than or equal to (RANGE_PWD + MIN_PWD + 1) does not set the OCDF flag.

Figure 38-142. Fails detected by the pulse width monitoring

Figure 38-143 describes in more detail an open circuit detection using the Hold timer. Note that the Hold timer is used when the output is at the ON state, which means HOD is used to drive the outputs, thus hold-off functionally is not required at this moment. The Hold timer is loaded with MIN_PWD and starts counting. After a time-out occurs RANGE_PWD value is loaded and the Hold counter starts counting again. An open circuit is detected if the timer times-out on the second RANGE_PWD counting and the PWM pulse is still high, meaning that the outputs did not switch to LOD. In this case the OCDF flag is set in the Channel Status Register (REACM2_CHSR), of the corresponding channel.

Figure 38-143. Open Circuit detection using Hold timer

Figure 38-144 describes how the Hold timer detects a short circuit. The Hold timer is loaded with the MIN_PWD value and enabled. The condition indicating that a short circuit occurred is that the Hold timer is still running and LOD is loaded to the channel output pins. That means the PWM pulse is too narrow and a short circuit has occurred. In this case the SCDF flag is set in the Channel Status Register (REACM2_CHSR) of the corresponding channel.

Figure 38-144. Short Circuit detection using Hold timer

Note

In order to define RANGE_PWD value it is required to consider that the Hold timer already measured MIN_PWD, thus actually the maximum allowed pulse width = (MIN_PWD + RANGE_PWD). In other words, RANGE_PWD = (maximum allowed pulse width - MIN_PWD).

IF MIN_PWD = 0x00 or RANGE_PWD = 0x00 no pulse width is performed.

The CHSR SCDF flag does not set if the pulse was finished by disabling the modulation (i.e. eTPU channel=0 or SWMC=0) or by disabling the channel, CHEN=00, even if it ended shorter than MIN_PWD. However this flag can set in some situations that really indicates a short pulse detection but it is the result of some internal condition of the reaction module. The known situations are listed below:

- When a modulation phase with MM=01 (threshold / holdoff) starts with IOSS=1 with the previous modulation phase set to SM=11 (advance on threshold).

The CHSR OCDF flag only sets when the channel is enabled (CHEN not null) and the eTPU channel signal or SWMC is active too. However, the OCDF flag can set in some cases when the CHOFF bit is set. In this case, this OCDF flag should be disregarded because it is a false indication of the detector.

There can be a conflict of resource allocation if the Hold timer is used as the timer for the sequencer mode (SM=10) because it is not possible to have the detection of minimum and maximum pulse widths. This configuration is only allowed to be used with the threshold-threshold modulation mode but the monitor of short / open circuit is not enabled. The RAER flag will be set for any other modulation mode.

NOTE

An application case is to use SM=10 with threshold / threshold modulation mode and IOSS=0. The channel output starts OFF and the SM hold timer can be configured to have a time-out before the threshold low is reached. If the threshold low is reached before the SM time-out event, the channel switches to ON but the short / open detection is not started.

38.7.2 Monitoring the OFF State Width and the ADC Maximum Value

The modulation executed by the Reaction Channel can be monitored by measuring the width of the OFF states of the PWM waveforms provided by the channel. If the OFF state becomes too narrow it means that the load impedance is probably too high, thus indicating a possible open circuit. And if the sample value surpasses the `ADC_MAX_LIMIT` value a short circuit condition is detected. These criteria can be used for threshold-hold-on, and threshold low-period modulation modes.

The open detection event should occur twice in a row to set the OCDF flag. This condition helps to avoid false set of the open circuit detection flag. However a single sample that surpasses the `ADC_MAX_LIMIT` is sufficient to set the MAXL flag

The time limit for narrow OFF state is defined by `MIN_PWD` register. This value applies to all Reaction Channels. The PWM OFF states are measured by the Hold timers within the Reaction Channels. This is possible only during idle periods of this timer, for example from the moment a hold-on time-out occurs until the minimum threshold is reached when LOD is being used for the channel output pins. During these periods the hold counter is not used and thus it can measure the OFF states widths and compare them against the pre-defined limit defined by `MIN_PWD` register, as shown in the figure below.

Note

Consider an uncertainty of (+1) in the value `MIN_PWD` when calculating the OFF state width limit. The Hold timer prescaler contributes to this uncertainty..

For a programmed `MIN_PWD` value, a pulse wider than (`MIN_PWD+1`) is not an open circuit event to set the SCDF flag.

Figure 38-145. Fails detected by the OFF timing monitoring

The CHSR OCDF flag does not set if the OFF state was finished by disabling the modulation (i.e. eTPU channel=0 or SWMC=0) or by disabling the channel, CHEN=00, even if it ended shorter than MIN_PWD.

There can be a conflict of resource allocation if the Hold timer is used as the timer for the sequencer mode SM=10. In this case the RAER flag will be set to signal this conflict condition.

38.8 Reset Overview

The Reaction Module is reset whenever any MCU reset occurs. In order to re-initialize the Reaction Channels, the CHEN channel enable register should be used. Once disabled the channel output is set to DOFF state and the channel configuration can be changed safely. The disable/enable operation does not change the channel setup, thus the configuration registers remain at the state as before the channel was disabled. The Modulation Control word addressed by the channel after the enable bit is asserted is defined by the MODULATION ADDR field in the channel configuration register.

38.9 Reaction Module Interrupts

The Reaction Module issues one global interrupt signal and one interrupt signal per channel. If the Global interrupt signal is used, the resolution of the interrupt source needs to be performed by reading the Global Error Flag register to evaluate which channel issued the interrupt. After that the Channel Status register needs to be read to distinguish between the several interrupt sources by evaluating the flags: MAXL, OCDF, SCDF, TAER and SQER.

38.9.1 Interrupt sources

There are several sources of interrupts that indicates a faulty condition:

1. MAXL: maximum ADC result value was reached
2. OCDF: open circuit detected which indicates an open circuit, and thus, a potential malfunction in the circuitry controlled by the Reaction Module. Note that differently from the TAER, this flag does not indicate a faulty condition in the channel but in the circuit outside the SoC.
3. SCDF: short circuit detected which normally indicates a short circuit was detected on the off chip logic controlled by the reaction channel.
4. TAER: timer allocation error which indicates a required Timer resource was not allocated properly thus leading to faulty operation of the Reaction module.
5. SQER: sequencer error occurred meaning that the timer input signal was negated in a modulation phase with SM != 00.

38.9.2 Global Interrupt and Channel Interrupt

The following figure illustrates the relationship between the channel interrupts and the module global interrupt. The global interrupt summarizes the indication of error in the reaction module.

Figure 38-146. Channel Interrupt and Global Interrupt Diagram

38.10 Use cases

Figure 38-147 shows an example of the Reaction Module used to control an Injector solenoid. Note that this is a dual injector which is also called banked injector. Two Reaction channels are used to control this injector.

The injector Boost transistor on the top applies a higher voltage in order to minimize the time necessary for the injector to start injecting fuel. Transistors A and B control which injector is active in the injector bank. A sensor resistor is used to feed the current flowing through the solenoid back to the on-chip ADC. The current is sampled by the ADC and the result is sent to the Reaction Module, allowing closed loop control.

Note

This injector bank architecture does not allow both injectors to operate at the same time since the sensor in the feedback loop is shared by both injectors.

Figure 38-147. Boosted Banked Direct Injection with Passive Recirculation

Two eTPU channels are used to provide timing control signals, one for CH0 and one for CH1. The on-chip ADC monitors the sensor current periodically and sends the digitalized results to the Reaction Module. In a banked configuration as shown in this example one ADC channel is used to monitor both injectors current. Note that only one channel is *active* at a given time since the eTPU time windows are not *active* at the same time for both Reaction Channels. See [Figure 38-148](#) for more details.

Figure 38-148. eTPU CH0/1 Controlling Reaction CH0/1

There are several possible configurations for a banked mode application. The objective on those configurations is to share hardware resources such as Reaction Module channels, ADC monitor inputs and MCU pins, among others related to the Injector driver which is not covered in detail in this document.

[Figure 38-149](#) shows a more detailed diagram of the interconnection between the injector bank and the Reaction Module. Two reaction channels are used in this application. CH0 is used to control Injector A and CH1 is used to control Injector B. However, the Vboost/Vbatt selection is controlled by CH0 ch0_a output only since, when VBoost driver is switched off, Vbatt power source is applied to the injectors by the direct bias of the diode connecting Vbatt to the injector bank.

Figure 38-149. System Level Connection in a Banked Configuration

It is important to note that even if two reaction channels control different injectors they can share the data stored in the Modulation Word Control. In this case both channels should execute the same type of modulation and use the same threshold values. Note also that the data stored in the Threshold bank in this case is also shared between these channels. This is an important feature of the Reaction Module architecture since it allows the sharing of resources and therefore provides savings in size without compromising the module functionality.

Figure 38-150 shows an example of the required current levels through Injector A and B. In order to generate this waveform, the Reaction Module uses one Modulation Control Word for each one of the four phases of the waveform from A through D. In this example the Module should be configured in the following way:

1. Set the REACM2_CHRR0 CHIR[3:0]=0x0, thus routing eTPU channel 0 to Reaction Channel 0
2. Set the REACM2_CHRR1 CHIR[3:0]=0x1, thus routing eTPU channel 1 to Reaction Channel 1
3. Set the REACM2_CHRR0 ADCR[3:0]=0x0, thus routing ADC TAG 0 to Reaction Channel 0
4. Set the REACM2_CHRR1 ADCR[3:0]=0x0, thus routing ADC TAG 0 to Reaction Channel 1
5. Program Modulation Word Control bank according to [Figure 38-151](#)
6. Program Shared Timer Bank REACM2_STBK for addresses from 0 through 1 with timing intervals related to the duration of phases B and C respectively.
7. Program appropriate values in the Threshold Bank. Since threshold-threshold modulation is to be used in this example, 4 pairs of values should be provided for phases A,B,C and D respectively. Each pair corresponds to one address of the REACM2_THBK starting at address 0x0400.
8. Program configuration registers for both channels, REACM2_CHCR0/1. The parameters are DOFF[2:0] which defines the OFF state of the channel outputs and the MODULATION_ADDR = 0x0, which defines the address of the Modulation Control word. It is assumed that the Modulation Word zero is the first word to be accessed by both channels. Since 4 Modulation words will be used the addresses will be incremented by the Reaction Channel as needed, thus only the address for the first word is required. Note that MODULATION_ADDR=0x0 points to the first Modulation Word in the Modulation Word Bank.
9. Program the prescalers HPRE and TPRES in the REACM2_TCR register. Also enable the prescalers by setting the TPRES and HPRES bits in the REACM2_MCR register.
10. Enable channels CH0 and CH1 to start the modulation sequence by programming field CHEN=01 on REACM2_CHCR1/0 registers. At this time the Reaction channel CH0 accesses the Modulation Control word zero and switches to ON state as defined by the data stored in the HOD[2:0] field. Up to this point any activity in the eTPU channel or incoming ADC result is ignored by the Reaction module. After CHEN field is programmed, the reaction channels wait until a timer window is initiated by eTPU for the modulation process to start.

Figure 38-150. Modulation Phases1

The current through the injectors are initially zero since the reaction channel output is in the OFF state as configured by the DOFF[2:0] field. The eTPU timer window is at the OFF state as well. The modulation starts when the eTPU channel time window switches to ON state. Modulation *phase A* starts at this time as described in [Figure 38-150](#). The modulation word 0 is used. In this application this phase corresponds to the *Boosted Peak phase*. This process allows the fuel injection to start sooner because of the sharp edge of the current which is important for a precise control of the fuel to be injected. *Phase A* is setup to execute a Threshold-Threshold modulation but note that only *I0* value is used since the phase advances when a certain current is achieved. Below is a description of the bit fields in the Modulation word in order to execute the modulation described in *phase A*:

- LOOP=0
- The initial value should be HOD (IOSS=1)
- Threshold-Threshold modulation mode is obtained with MM=00
- This phase ends when the threshold value *I0* is achieved (SM=11)
- Necessary to have HOD=111 for boosted operation and sensor active. LOD setting is not important in this case since it is not used
- *I0* is read from Threshold Bank by using THRESPT=0x0 that points to address 0 of this bank

Use cases

- *I1* is read from Threshold Bank by using $(\text{THRESPT}+1) = 0x1$
- Hold timer is not used, therefore *HDOFFPT* can have any value (X).

At point b, *phase B* is initiated by the threshold being achieved from *phase A*. CH0 increments the Modulation Word address to *MODULATION_ADDR* = 0x1 and the second Modulation Word is read by the channel. As a result of the second Modulation Word decoding the *Vboost* voltage is disabled causing a *peak* modulation with *Vbatt*. The phase is called the *Peak Vbatt phase*. For *phase B* a Threshold-Threshold modulation is used with levels *I2* and *I3* during a period defined by *TB*. See [Figure 38-151](#)

A time-out event is received from the Shared Timer sub-module and a new Modulation Word is read. *Phase C* corresponds to the *re-circulation phase*. Energy from the injector is transferred back to the boost circuitry. In this phase the current cannot be measured because there is no current flowing through the sensor resistor. A Threshold-Threshold modulation mode is used. The Shared Timer is started at the beginning of this phase and *TC* delay is measured. The channel outputs are kept in the OFF state.

When the Shared Timer times out after *TC* delay the Modulation Word address is incremented, *MODULATION_ADDR* = 0x4 and the *Hold phase* is initiated. This phase is typically longer compared to the other phases and defines the amount of fuel that will be injected. Threshold-Threshold modulation mode is used between levels *I4* and *I5* and *Vbatt* is selected as the power supply. The phase ends based on the eTPU time window switching to *off* at point e. At this time the channel outputs are set to OFF and the channel points to *MODULATION_ADDR* = 0x0 which is the address of the first Modulation Word. Note that this address is not necessarily 0x0.

This modulation process is executed by a sequence of Modulation Words as described in [Figure 38-151](#).

38.10.1 Advancing Modulation Phase on a Threshold level

The Modulation Phase may be set to advance when a specific threshold value is reached. The use case for this scenario is described in the following figure. This functionality is used to assure a specific current level was achieved before the Reaction Channel advances to the next modulation phase, thus making sure that the solenoid had the fastest opening speed.

Figure 38-152. Advancing Modulation Phase on a Threshold level

In the example shown in the preceding figure the Modulation Word 0 has the field SM=11 meaning that it should advance if the ADC comparator, which compares ADC results and threshold values, is true. This means that the ADC result is greater or equal to the threshold value pointed by THRESPT Modulation Word 0 field. The advance from phase A to phase B in the preceding figure is described as follows:

- Initially at time *a* the Reaction Channel output is loaded with HOD[2:0] as indicated by IOSS value, both fields of modulation word 0.
- If ADC result $\geq$ [THRESPT] the Reaction Channel turns the outputs off by loading LOD[2:0] to the channel outputs and advance to the next modulation cycle at time *b*.

Note

The advance on threshold, SM=11, is intended to be used with IOSS=1, thus the advance occurs when the level from the ADC is greater or equal to the value pointed by THRESPT. IOSS=0 is a reserved value for this bit in this configuration and should not be used.

Note

In case of MM=01 (threshold/holdoff) on phase B, a glitch can occur in the beginning of this phase. To avoid this, on phase A it is necessary to set HOD=LOD. However, a false flag SCDF can be set at this time and should be discarded.

38.10.2 Controlling the LOOP function

The LOOP field in the Modulation Word controls the sequencing of Modulation Words to be executed by the channel. If LOOP = 1 and a phase is ended the next Modulation Word address returns to the initial modulation address programmed in the channel when the cycle was initiated. In this case a loop in the Modulation Bank is created. This loop ends when the cycle ends.

The following figure shows the sequence of Modulation Words within a Modulation Cycle if LOOP function is used. Note that an alternate modulated waveform is generated using only two Modulation Words, in this case Modulation Word 0 and Modulation Word 1.

Figure 38-153. LOOP function used within a Modulation Cycle

NOTE

Due to the limit of 16 words for a channel modulation, after the 16th modulation word accesses, the sequence advance is executed by returning back to the first word of the sequence even with LOOP=0.

38.10.3 Banked Mode

The following figure describes the interconnection of four channels controlling two injector banks. Note that two output pins are not connected since the boost control is shared between channels [0] and [1] and channels [2] and [3].

Figure 38-154. Four channels controlling two injector banks in banked mode.

Chapter 39

Input Glitch Filter (IGF)

39.1 Chip-specific IGF information

This chip has two instances of the IGF module: IGF_0 and IGF_1. They are in the eTPU clock domain. The two instances are located on different Peripheral Bridges.

39.1.1 IGF channels and internal prescalers

The two IGF module instances support a combined total of 76 channels. Some channels of the instances implement internal prescalers.

Each channel has a 24-bit counter. Each internal prescaler is 9 bits wide.

The following table identifies the number of channels of each instance, the specific channel numbers that implement an internal prescaler, and the group of specific channel numbers that can use each implemented internal prescaler.

Each group of channel numbers that is associated with one implemented prescaler is a filter cluster.

Table 39-1. IGF instance channels and internal prescalers

Instance	Channels supported	Channel number with prescaler	Filter cluster: channel numbers that use prescaler
IGF_0	30	0	0-29
IGF_1	46	0	0-31
		32	32-45

39.1.2 IGF internal prescaler selection

Channels in a filter cluster that do not implement their own internal prescaler must select an "external" prescaler. This selection means the channel uses the prescaler of the preceding channel in the filter cluster.

Within a filter cluster, to enable a channel x to use the cluster's internal prescaler:

1. For the channel that implements the cluster's internal prescaler, select the internal prescaler by ensuring that the channel's $\text{MCR}_n[\text{PSSEL}]$ field is 0.
2. For every channel between that channel and channel x , including channel x itself, select the "external" prescaler by setting the channel's $\text{MCR}_n[\text{PSSEL}]$ field to 1.

39.1.2.1 Example of internal prescaler selection

To select the applicable internal prescaler for IGF_0 channel 3:

1. Because IGF_0's channel 0 implements the cluster's internal prescaler, select the internal prescaler for channel 0 by ensuring that IGF_0's $\text{MCR}_0[\text{PSSEL}]$ field is 0.
2. Select the "external" prescaler for every channel between channel 0 and channel 3, including channel 3 itself:
 - a. Set IGF_0's $\text{MCR}_1[\text{PSSEL}]$ to 1.
 - b. Set IGF_0's $\text{MCR}_2[\text{PSSEL}]$ to 1.
 - c. Set IGF_0's $\text{MCR}_3[\text{PSSEL}]$ to 1.

39.1.2.2 Restriction on prescaler selection for IGF_1 channel 32

Do not set IGF_1's $\text{MCR}_{32}[\text{PSSEL}]$ field to 1.

This setting could cause timing failure for all IGF_1 channels.

39.1.3 IGF interaction with other modules

The IGF modules interface with eTPU and eMIOS modules.

The following table shows the mapping of IGF_0 channels.

Table 39-2. IGF_0 channel mapping

Filter channel	Primary function pin	Module
0	TCRCLKC	eTPU_C
1-15	ETPUC0-14	eTPU_C
16-19	EMIOS0_0-3 ¹	eMIOS_0
20-21	EMIOS0_6-7	eMIOS_0
22-29	EMIOS0_16-23	eMIOS_0

1. EMIOS0_4 and EMIOS0_5 do not have filters because the input channels are not connected directly from pads. They are connected from the DSPI_B module.

The following table shows the mapping of IGF_1 channels.

Table 39-3. IGF_1 channel mapping

Filter channel	Primary function pin	Module
0	TCRCLKA	eTPU_A
1-15	ETPUA0-14	eTPU_A
16	TCRCLKB	eTPU_B
17-31	ETPUB0-14	eTPU_B
32-37	EMIOS1_0-5 ¹	eMIOS_1
38-45	EMIOS1_16-23	eMIOS_1

1. EMIOS1_6 and EMIOS1_7 do not have filters because the input channels are not connected directly from pads. They are connected from the DSPI_D module.

39.1.4 STOP mode system requests for IGF_0 and IGF_1

As described in [STOP mode](#), a STOP mode system request can stop the IGF module instances.

This chip also has inter-module STOP mode system requests that affect IGF_0 and IGF_1 individually:

- IGF_0 automatically stops when eTPU_C and eMIOS_0 stop.
- IGF_1 automatically stops when eTPU_A/eTPU_B and eMIOS_1 stop.

39.2 Introduction

The Input Glitch Filter provides programmable glitch rejection filtering of digital input signals.

39.3 Block Diagram

The figure below is the block diagram for the Input Glitch Filter module.

Figure 39-1. Input Glitch Filter block diagram

39.4 Input Glitch Filter overview

The Input Glitch Filter receives an input signal usually from a device PAD. Signals generated externally to the device are affected by environmental noise or glitches. The signal level has to be evaluated with some criteria in order to remove the noise which could affect the measurements done over this signal, such as transition time, period and level.

In a typical application, the Input Glitch Filter interfaces with one or more timer peripherals.

The strategy to remove glitches from an input signal is to monitor the level of the signal during a wide time window thus the glitches can be evaluated and removed.

The input signal should be stable for a certain amount of time before it can be used as a trigger or by a timer input channel. This strategy implies a delay on detecting a transition in the signal.

There is another strategy which is based on removing the glitches by introducing a blanking period after an edge is detected. In this strategy there is no delay from the edge detection in the input signal to the filtered signal, in the filter output. The strategy also allows input signals with different filter periods to be measured at the same time.

39.4.1 Interaction with other peripherals

The figure below shows an example of how the Input Glitch Filter interacts with on-chip peripherals.

Figure 39-2. Input Glitch Filter application example

39.4.2 Mode of operation

The Input Glitch Filter has the following modes of operation:

- Configuration mode
- Normal mode
- Debug mode
- Low power mode

39.4.2.1 Configuration mode

The configuration mode is the initial mode of the Input Glitch filter after system reset is applied. The configuration mode is selected when FGEN = '0' in the MCR register. The filter parameters such as rising and falling thresholds can be programmed when the filter

is in configuration mode without disturbing the internal device logic since the filter output is kept at logic '0' state. Once FGEN is programmed with logic '1' the filter enters the normal operating mode and is able to initiate the filtering process.

NOTE

The MDIS bit in the MCR register, if set to logic '1', makes the filter transition to low power mode independent of FGEN bit settings. Thus, in order to enter the configuration mode MDIS bit needs to be at logic '0'.

39.4.2.2 Normal mode

The normal mode of operation is entered when MCR register FGEN = '1'. In this mode the filter implements one of the filter types:

- Bypass filter
- Windowing filter
- Integrating filter
- Integrating-hold filter

These filter types are described in the following sections. Before entering the normal mode, the filter parameters, such as rise and fall thresholds, need to be programmed in the appropriate registers, as well as the type needs to be defined in the corresponding register.

NOTE

In the normal mode it is still possible to change the filter parameters, such as rise and fall thresholds. See section [On-the-fly filter reconfiguration](#) for more details.

39.4.2.3 Debug mode

The debug mode is entered when the MCR FRZ bit is set and a system level debug request occurs. Once the debug mode is entered, the internal filter counter is halted and the debug functions controlled by the FBP, FOH, and FOL bits are enabled. The filter output is frozen and remains at the state it was immediately before the debug mode was entered. The FOH and FOL MCR bits can be used to force the filter output to logic '1' or '0', respectively. These bits are self-negating, thus they always read as zero.

By setting the MCR FBP bit, the filter input state is copied to the filter output, thus allowing to control the filter output based on the filter input state. The output is forced during one clock cycle. After that the filter output remains at the new forced state until it is changed again by using a debug control bit or if the filter returns to the normal mode of operation.

NOTE

The system level debug request occurs when a specific event, or a series of events, occurs in one of the device sub-modules and is interpreted by the device debug logic as a debug request. The Input Glitch Filter is not capable of generating an event that causes the assertion of the system level debug request.

39.4.2.4 Low power mode

The low power mode is controlled by the MDIS bit in the MCR register or by the STOP signal which is the system level low power control signal. When entering low power mode the filter output remains unchanged at the state it was just before the low power mode was entered. Since the Input Glitch Filter clocks are stopped in this mode, the internal counter remains inactive. The description of this mode is covered in the Low Power Mode section of this document.

39.5 Memory map

The Input Glitch Filter registers are implemented in 32-bit. 8-bit write operations are allowed. The coherency in case of 8-bit access must be provided by the application software since there is no coherence mechanism built into the hardware.

NOTE

RESERVED bit registers, when available for write operations, should be written always with logic '0'. Read access does not return meaningful data from RESERVED bit registers.

39.5.1 Module Configuration Register (IGF_MCRn)

The Module Configuration register (MCR) provides access to low power, debug, and filter control bits.

Address: 0h base + 0h offset + (64d × i), where i=0d to 45d

IGF_MCRn field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 MDIS	Module Disable The MDIS bit forces the filter to enter a low power state. After this bit is asserted the clock for the module is removed thus filter operation is not possible. The access to filter registers is allowed. 0 Input Glitch Filter is not in low power mode due to MDIS bit 1 Input Glitch Filter is in low power mode
2 FRZ	Freeze bit for debug operation The FRZ bit enables the Input Glitch Filter to enter freeze mode (debug mode) when a system level signal request the module enters freeze (debug) mode. Once in freeze mode the filter operation is disabled meaning that transitions on the input signal will not propagate through the filter output. The bypass FBP bit can be used by the software to force the filter output to be the same as the filter input. In this mode FOH and FOL also can be used to define the filter output state.

Table continues on the next page...

IGF_MCRn field descriptions (continued)

Field	Description
	0 Freeze mode disabled 1 Freeze mode enabled
3 FBP	Force Bypass This bit is self-negated thus is only read as zero. Writing 1 to this bit while in freeze mode forces the filter to bypass the value in the input to the filter output, thus allowing a software control on the filter. This bit is functional only in freeze mode. 0 no filter bypass 1 transfer input signal value to the filter output
4 FOH	Force filter output high If set, this bit forces the Input Glitch Filter output to '1'. This bit is functional only in debug mode. It is self-negated thus always read as zero. 0 no action 1 forces the filter output to '1'
5 FOL	Force filter output low If set this bit forces the Input Glitch Filter output to '0'. This bit is functional only in debug mode. It is self-negated thus always read as zero. 0 no action 1 forces the filter output to '0'
6–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 IMM	Immediate edge propagation control bit The IMM bit controls the propagation of an edge through the filter. If asserted, this bit defines that an edge at the filter input propagates through the filter output independent of the prescaler settings. In bypass mode the propagation delay is three system clock cycles. If negated, the signal propagation depends upon the prescaler settings. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN = 0 0 edge propagation depends on prescaler 1 edge propagation within three system clock cycles
23 PSSEL	Prescaler selection bit The PSSEL selects if the prescaler used by the Input Glitch Filter is from internal source (internal prescaler counter) or from external source. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0. 0 internal prescaler selected 1 external prescaler selected
24 POL	Output polarity bit This bit sets the polarity of the filter output to inverted or not inverted. The polarity control implemented by the POL bit is applied at the filter output stage thus also changing the reset state of the output, even if the filter is disabled by the FGEN bit. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0.

Table continues on the next page...

IGF_MCR_n field descriptions (continued)

Field	Description
	0 not inverted output 1 inverted output
25 FGEN	Filter global enable This control bit enables the filter operation, meaning that if the filter is enabled the filtering selected types are applied to the rising and falling edges of the input signal. If the filter is not enabled, then the filter output remains unchanged independent of the filter input signal. Note that the filter output state is affected by the POL bit when the filter is disabled. 0 filter is disabled: filter output keeps current state. 1 filter is enabled: filtering is applied to selected edges.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–28 FFM	Falling edge filter type selection This bit field selects the filter type for the filter input signal falling edge. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0. 00 bypass: edge is propagated to filter output without any filtering in three system clock cycles 01 windowing: windowing filter is selected for the falling edge 10 integrating: integrating filter is selected for the falling edge 11 integrating-hold: integrating-hold filter is selected for the falling edge
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 RFM	Rising edge filter type selection This bit field selects the filter type for the input signal rising edge. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0. 00 bypass: edge is propagated to filter output without any filtering in three system clock cycles 01 windowing: windowing filter is selected for the rising edge 10 integrating: integrating filter is selected for the rising edge 11 integrating-hold: integrating-hold filter is selected for the rising edge

39.5.2 Module Status Register (IGF_MSRn)

The Module status register (MSR) provides access to filter status bits and corresponding clear bits as well as access to the state of filter input and output signals.

Address: 0h base + 4h offset + (64d × i), where i=0d to 45d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

IGF_MSRn field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 WEDGE	Filter is active waiting for an edge This bit is set when the filter is enabled but the internal counter is not active. It indicates that the filter is waiting for an edge to occur at the filter input. It is set by the Input Glitch Filter hardware and cleared by the software by writing 1 to the bit. Since the intention of this bit is to capture the dynamic of the filter hardware, it should be cleared after the read thus being able to capture a new event. 0 Input Glitch Filter is disabled or the internal counter is active 1 Input Glitch Filter is waiting for an edge
27 FEDGE	Filter is active processing an edge This bit is set during the filter active state thus when the filter internal counter is counting, processing an edge in a filtering mode. It is cleared by the software by writing 1 to the bit. Since the intention of this bit is to capture the dynamic of the filter hardware, it should be cleared after the read thus being able to capture a new event. 0 Input Glitch Filter internal counter is not active 1 Input Glitch Filter internal counter is active

Table continues on the next page...

IGF_MSR_n field descriptions (continued)

Field	Description
28 RNDET	Rise noise detected bit This bit indicates that the filter filtered out noise in the input signal after a rising edge was detected. The criteria to set this bit is when a rising edge is detected thus starting the filter counter and before this edge pass through the filter (if filter is in integrating filter types) or during a window (if filter is in windowing filter types) another edge occurs in the input signal. This bit is set by a noise detection and cleared by the software by writing 1 to this bit. 0 noise was not detected 1 noise was detected after a rising edge
29 FNDET	Fall noise detected bit This bit indicates that the filter filtered out noise in the input signal after a falling edge was detected. The criteria to set this bit is when a falling edge is detected, thus starting the filter counter, and, if the filter is in integrating types, before this edge passes through the filter, or, in windowing types, when another edge occurs in the input signal during a window. This bit is set by a noise detection and cleared by the software by writing 1 to this bit. 0 noise was not detected 1 noise was detected after a falling edge
30 FLI	Filter input The FLI bit follows the state of the filter input value as captured by the filter input logic, which is affected by the IMM bit and prescaler settings.
31 FLO	Filter output The FLO bit follows the state of the filter output value considering the POL bit state.

39.5.3 Prescaler Register (IGF_PRESR_n)

The prescaler register (PRESR) provides access to the prescaler bits.

Address: 0h base + 10h offset + (2048d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

IGF_PRESR_n field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 FPRE	Filter prescaler The prescaler defines the rate of the filter counter FCOUNT. The filter counter clock rate is defined by the formula: Filter counter clock = module clock / (FPRE + 1).

39.5.4 Rising edge Threshold Register (IGF_RTHRn)

The Rising edge Threshold register (RTHR) provides access to the rising edge threshold bits.

Address: 0h base + 1Ch offset + (64d × i), where i=0d to 45d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0								RTH																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

IGF_RTHRn field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 RTH	Rising edge threshold This bit field defines the filter counter threshold when a rising edge occurs is being filtered.

39.5.5 Falling edge Threshold Register (IGF_FTTHR)

The Falling edge Threshold register (FTTHR) provides access to the falling edge threshold bits.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0								FTH																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

IGF_FTTHR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 FTH	Falling edge threshold This bit field defines the filter counter threshold when a falling edge is being filtered.

39.6 Functional description

The following sections describe the Input Glitch Filter module functionality.

39.6.1 Input double sampling

The filter input is double sampled for clock domain translation thus avoiding asynchronous signals to propagate through the filter internal logic. This stage is composed by two flip-flops connected back to back. The delay caused by this logic is therefore two clock cycles.

Note that due to the synchronous nature of the Input Glitch Filter design, if a glitch smaller than one clock cycle occurs at the filter input it will not propagate to the filter internal logic and thus will not propagate to the filter output. Also, if clock is not applied to the filter (i.e. in low power mode) any transition at the filter input will not propagate to the filter output.

39.6.2 Filter types

The Input Glitch Filter implements three main filter types:

- Windowing
- Integrating
- Integrating hold

These filter types can be selected for the rising and falling edges independently, thus allowing different filter types to be selected for different edges (i.e. rising edge filtered with windowing filter and falling edge filtered with integrating).

39.6.2.1 Windowing filter

This filter type detects an edge (positive or negative edge) at the filter input and then mask out detection of subsequent edges over a period of time, which is defined as the blanking period, thus effectively behaving as a high pass filter. After an edge is detected the level at the filter input is propagated to the filter output within three clock cycles. The delay is caused by the synchronization stage at the input and by the filter output register stage. During the blanking period any transition at the filter input is disregarded. After the blanking period has elapsed, the filter compares the input level state with the filter output state. In case they are different a transition is inferred and re-evaluate according to the filter type assigned to that transition (positive or negative edges). Since, in this example, the windowing filter type is programmed for both edges, the inferred negative edge is propagated to the filter output and another blanking period is initiated. The figure below describes the windowing filter type behavior.

Figure 39-148. Windowing filter type

39.6.2.2 Integrating filter

The integrating filter behaves like a low-pass filter, thus removing high frequency bursts from the input signal. The input and output signals are compared and if they are at different states an internal filter counter is enabled.

The direction of the counter (up or down counting) is defined by the states of the input and output filter signals as follows:

- Filter output is at the same state as the filter input: down-counting
- Filter output is at different state as the filter input: up-counting

The counter is compared with the rising or falling threshold register according to:

- Rising threshold register is selected if the rising edge is being filtered.
- Falling threshold register is selected if the falling edge is being filtered.

The filter output changes state to the same state as the filter input:

- If filter counter reaches the selected threshold for the edge being filtered.

The internal counter is disabled and cleared:

- If filter counter reaches the selected threshold for the edge being filtered.

The figure below describes an example of the Integrating filter type operation.

Figure 39-149. Integrating filter type

39.6.2.3 Integrating-hold filter

The integrating-hold filter type is similar to the integrating filter. The difference is the counter, which only counts in up direction instead of up-down in the integrating mode. In this filter configuration the input and output signals are compared and if they are at different states the filter counter is enabled. This counter is controlled by the state of the filter input and filter output signals as follows:

- Filter output is at the same state as the filter input: counter is in hold state (no-counting).
- Filter output is at different state as the filter input: counter is counting up.

The counter is compared with the rising or falling threshold register according to:

- Rising threshold register is selected if the rising edge is being filtered.
- Falling threshold register is selected if the falling edge is being filtered.

The filter output changes state to the same state as the filter input:

- If the filter counter reaches the selected threshold for the edge being filtered.

The internal counter is disabled and cleared:

- If the filter counter reaches the selected threshold for the edge being filtered.

The figure below shows an example of the Integrating-hold filter type operation.

Figure 39-150. Integrating-hold filter type

39.6.2.4 Bypass filter

In the bypass filter type, the Input Glitch Filter immediately propagates any transition on the filter input to the filter output. This filter type does not provide any protection against glitches in the input signal. It is intended to be used in situations where the input signal is already filtered, or it is a glitch free signal, or the filter output is connected to a module that already has filtering capabilities. The bypass filter type is independently selected for rising or falling edges. Thus rising edges may be not filtered by the bypass filter type while the falling edges are filtered by any of the available filter types.

The bypass filter presents a delay in the edge propagation through the filter that is caused by the double sampling at the filter input and by the output filter register. Therefore, the total delay is three clock cycles.

39.6.2.5 Combined filter

The Input Glitch Filter allows the combination of filter types for different edges, positive and negative. As an example, the rising edges may be filtered using the windowing filter while the falling edges are filtered with an integrating filter. This configuration of the Input Glitch Filter is provided for situations where the noise present in the rising edges is different from the noise in the falling edges. Another use case is when the delay requirements of the input signal is different for rising and falling edges.

The figure below shows the combined filter operation. The windowing filter type is applied to the rising edges. The integrating filter is used for the falling edges.

Figure 39-151. Combined filter type (windowing + integrating)

39.6.3 Application

This section describes several applications for the Input Glitch filter module.

39.6.3.1 Application use case 1: integrating filter

The integrating filter type is particularly useful in applications where glitches occur spuriously while the signal is expected to be in a steady state (either 1 or 0). Choosing correct up and down filter clock rates can ensure that the effects of spurious glitches can be completely eliminated, whilst minimizing propagation delays.

The application must be able to tolerate delays between the actual edge occurrence and the time that the signal is propagated through the filter logic. Because the delays are constants defined by the detection thresholds, application software may compensate for them, provided little or no noise occurs on the detected edge.

39.6.3.2 Application use case 2: windowing filter

The windowing filter type is particularly useful for removing noise bounce produced by a switch or sensor when its signal changes state. In this case, there is no propagation delay (except for the filter input synchronization logic and output register) between the filter input and filter output signals. This type of filter would not necessarily provide much immunity to spurious noise that occurred during the steady state portion of the signal. In

order to optimize the characteristics of this filter, the blanking period should be of the same magnitude as the expected input signal rate. Signals that change frequency can be accommodated by software by dynamically updating the blanking period.

39.6.3.3 Application use case 3: windowing filter

Safety applications may need to compare the inputs obtained from different input pins, but derived from a single external source. This form of redundancy may detect non-common mode faults that may occur in the portions of the SoC that route and process the incoming signal. Having two different instances of windowing filter used on each input pin will ensure that the signal edge timing for both input paths is equal. Applying different filter characteristics for each input path can enhance the ability to detect SoC fault conditions.

39.6.3.4 Application use case 4: combined filter

Some applications may have rising edge signals that exhibit different characteristics to falling edge signals which might require different filtering to optimize the filtering effect. For example the “first” rising edge may represent a true real time event with a fast slew rate that must be captured without delay, while the falling edge signal may have a slow slew rate with many noisy transitions. The Input Glitch Filter can apply, for example, a windowing filter on the rising edge to ensure no loss of real time information and an integrating filter on the falling edge to eliminate noise from being detected as a new rising transition.

39.6.3.5 Application use case 5: prescaler settings in windowing filter

The prescaler settings influence the timing for an edge to propagate through the filter. In windowing filter the IMM bit in the MCR register controls the way an edge is propagated through the filter. The figure below describes the windowing filter operation with regard to the IMM bit settings.

Figure 39-152. Input signal propagation through the filter in windowing filter type

If IMM = 0 then the input signal edges are propagated according to the prescaler ticks. If IMM = 1 then the input edges are propagated immediately (within 3 clock cycles) to the filter output.

39.6.3.6 Application use case 6: prescaler settings in bypass

The prescaler settings influence the timing for an input signal edge to propagate through the filter. In bypass, the IMM bit in the MCR register controls the way an edge is propagated through the filter. If IMM = 0, the prescaled clock is used to sample the input filter signal. The resolution the input signal is sampled is therefore related to the prescaler frequency. Glitches narrower than the prescaler period that are not aligned with the prescaler clock are not captured by the filter. If IMM = 1, the system clock is used to sample the filter input signal instead of the prescaled clock. In this case, the resolution of the sampled input signal is the system clock.

The figure below describes the filter input signal sampling behavior for IMM = 0 and IMM = 1.

Figure 39-153. Input signal propagation through the filter in bypass

39.6.4 Programming guidelines

The following generalized procedure may be used to configure the Input Glitch Filter Block:

1. Program the SoC pin mux logic to route an external signal to the input of the selected glitch filter.
2. Enable the destination module to receive the Input Glitch filter output.
3. Enable the clock source at the SoC level.
4. Program the Glitch Filter counter prescaler(s) to the desired rate.
5. Select the filter type for each edge using MCR[FFM] and MCR[RFM].
6. Clear any status bits if necessary.
7. Enable the filter using MCR[FGEN]

39.6.5 On-the-fly filter reconfiguration

The architecture of the Input Glitch Filter allows for on the fly reconfiguration of filter parameters such as rise and fall threshold values.

If a parameter is changed it influences the filter operation immediately after the new parameter value was written. The main problem when changing parameters, such as a threshold value, when the filter is enabled is that the filter counter could lose a match due to the parameter change. A great or equal comparator is used in the threshold match logic which allows correct filter operation when the threshold parameters are changed. The figure below shows an example of changing the rising edge parameter value. Note that in this case the match occurs immediately after the parameter is changed since the new parameter value is below the current counter value.

Figure 39-154. On-the-fly rising threshold parameter change

In the case shown in the figure above the match occurs immediately after the new rising threshold is programmed at 'A'.

NOTE

Note that when changing the threshold values the match may not occur when the counter is equal to the threshold value (the old or the new programmed value). Instead, the match may occur in between the old and new programmed thresholds when the threshold re-programming instant A is done when the counter is greater than the new value. This is a transitory effect which may occur when the threshold value is changed and should be considered by the application.

39.7 Power saving mode

The Input Glitch Filter implements power saving mode thus allowing to reduce power consumption when device inputs connected to the filter are not used or the filter is not necessary to be functioning in a specific SoC mode of operation.

39.7.1 STOP mode

There are two ways for the Input Glitch filter to enter low power mode:

- MDIS bit
- STOP mode system request

The MDIS control bit in the MCR register, when set, disables the filter logic by stopping the module clock signals and thus halting the internal filter counter which reduces the dynamic power consumption of the module. The MDIS bit provides a selective control of the low power operation of each one of the Input Glitch Filter instances in the device.

The STOP mode system request is similar to MDIS operation with exception that it applies to all Input Glitch Filter instances in the device. It does not need to be enabled by any control bit in the Input Glitch filter module. The low power mode in this case is controlled by the assertion of the STOP signal which is a system wide low power control signal.

Chapter 40

FlexCAN (CAN)

40.1 Chip-specific FlexCAN information

This chip has four FlexCAN modules.

Each FlexCAN instance supports 64 message buffers.

40.1.1 FlexCAN RAM

On this chip, each FlexCAN module instance has four 1.5 KB dedicated RAM blocks.

40.1.2 FlexCAN reset

The FlexCAN architecture has two sources of reset: one resets the entire FlexCAN system and the other resets only the Host Control Interface (CHI). This chip supports only the global reset, which is driven by the internal reset of the device.

40.1.3 CAN_MCR[SUPV] and access to FlexCAN registers

On this chip, regardless of the value of CAN_MCR[SUPV], all core accesses to FlexCAN registers occur in supervisor mode.

40.2 Introduction

The FlexCAN module is a communication controller implementing the CAN protocol according to the CAN 2.0 B protocol specification. A general block diagram is shown in the following figure, which describes the main subblocks implemented in the FlexCAN module, including one associated memory for storing message buffers, Receive (Rx)

Global Mask registers, Receive Individual Mask registers, Receive FIFO filters, and Receive FIFO ID filters. The functions of the submodules are described in subsequent sections.

Figure 40-1. FlexCAN block diagram

40.2.1 Overview

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific requirements of this field:

- Real-time processing
- Reliable operation in the EMI environment of a vehicle
- Cost-effectiveness
- Required bandwidth

The FlexCAN module is a full implementation of the CAN protocol specification, Version 2.0 B, which supports both standard and extended message frames. The message buffers are stored in an embedded RAM dedicated to the FlexCAN module. See the chip-specific FlexCAN information for the actual number of message buffers configured in the chip.

The CAN Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames
- Validating received messages
- Performing error handling

The Controller Host Interface (CHI) sub-module handles message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms.

The Bus Interface Unit (BIU) sub-module controls the access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs and test signals are accessed through the BIU.

40.2.2 FlexCAN module features

The FlexCAN module includes these distinctive legacy features:

- Full implementation of the CAN protocol specification, Version 2.0 B
 - Standard data and remote frames
 - Extended data and remote frames
 - Zero to eight bytes data length
 - Programmable bit rate up to 1 Mb/sec
 - Content-related addressing
- Compliant with the ISO 11898-1 standard
- Flexible mailboxes of zero to eight bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox
- Full-featured Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling
- Transmission abort capability
- Programmable clock source to the CAN Protocol Interface, either bus clock or crystal oscillator
- Unused structures space can be used as general purpose RAM space

- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes

New major features are also provided:

- Remote request frames may be handled automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- SYNCH bit available in Error in Status 1 register to inform that the module is synchronous with CAN bus
- CRC status for transmitted message
- Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- 100% backward compatibility with previous FlexCAN version
- Supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to 5 parity bits and the error correction mechanism assures that in this 13-bit word, errors in one bit can be corrected (corrected errors) and errors in 2 bits can be detected but not corrected (non-corrected errors).

40.2.3 Modes of operation

The FlexCAN module has these functional modes:

- Normal mode (User or Supervisor):

In Normal mode, the module operates receiving and/or transmitting message frames, errors are handled normally, and all CAN Protocol functions are enabled. User and Supervisor Modes differ in the access to some restricted control registers.

- Freeze mode:

Freeze mode is enabled when the FRZ bit in MCR is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when Debug mode is requested at chip level and MCR[FRZ_ACK] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See [Freeze mode](#) for more information.

- Listen-Only mode:

The module enters this mode when the LOM field in the Control 1 Register is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- Loop-Back mode:

The module enters this mode when the LPB field in the Control 1 Register is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

For low-power operation, the FlexCAN module has:

- Module Disable mode:

This low-power mode is entered when the MDIS bit in the MCR Register is asserted by the CPU and the LPM_ACK is asserted by the FlexCAN. When disabled, the module requests to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating the MDIS bit in the MCR register. See [Module Disable mode](#) for more information.

- Doze mode:

This low power mode is entered when the DOZE bit in MCR is asserted and Doze mode is requested at chip level and the LPM_ACK bit in the MCR Register is asserted by the FlexCAN. When in Doze mode, the module requests to disable the clocks to the CAN Protocol Engine and the CAN Controller-Host Interface submodules. Exit from this mode happens when the DOZE bit in MCR is negated, when the chip is removed from Doze mode. See [Doze mode](#) for more information.

- Stop mode:

This low power mode is entered when Stop mode is requested at chip level and the LPM_ACK bit in the MCR Register is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode happens when the Stop mode request is removed. See [Stop mode](#) for more information.

40.3 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

Table 40-1. FlexCAN signal descriptions

Signal	Description	I/O
CAN Rx	CAN Receive Pin	Input
CAN Tx	CAN Transmit Pin	Output

40.3.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

40.3.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

40.4 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the chip.

40.4.1 FlexCAN memory mapping

The complete memory map for a FlexCAN module is shown in the following table.

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address 0x0080.

Each individual register is identified by its complete name and the corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming the SUPV field in the MCR register. These registers are identified as S/U in the Access column of [Table 40-2](#).

Table 40-2. Register access and reset information

Register	Access type	Affected by hard reset	Affected by soft reset
Module Configuration Register (MCR)	S	Yes	Yes
Control 1 register (CTRL1)	S/U	Yes	No
Free Running Timer register (TIMER)	S/U	Yes	Yes
Rx Mailboxes Global Mask register (RXMGMASK)	S/U	No	No
Rx Buffer 14 Mask register (RX14MASK)	S/U	No	No
Rx Buffer 15 Mask register (RX15MASK)	S/U	No	No
Error Counter Register (ECR)	S/U	Yes	Yes
Error and Status 1 Register (ESR1)	S/U	Yes	Yes
Interrupt Masks 2 register (IMASK2)	S/U	Yes	Yes
Interrupt Masks 1 register (IMASK1)	S/U	Yes	Yes
Interrupt Flags 2 register (IFLAG2)	S/U	Yes	Yes
Interrupt Flags 1 register (IFLAG1)	S/U	Yes	Yes
Control 2 Register (CTRL2)	S/U	Yes	No

Table continues on the next page...

Table 40-2. Register access and reset information (continued)

Register	Access type	Affected by hard reset	Affected by soft reset
Error and Status 2 Register (ESR2)	S/U	Yes	Yes
CRC Register (CRCR)	S/U	Yes	Yes
Rx FIFO Global Mask register (RXFGMASK)	S/U	No	No
Rx FIFO Information Register (RXFIR)	S/U	No	No
Message buffers	S/U	No	No
Rx Individual Mask Registers	S/U	No	No
Memory Error Control Register (MECR)	S/U	Yes	Yes
Error Injection Address Register (ERRIAR)	S/U	Yes	Yes
Error Injection Data Pattern Register (ERRIDPR)	S/U	Yes	Yes
Error Injection Parity Pattern Register (ERRIPPR)	S/U	Yes	Yes
Error Report Address Register (RERRAR)	S/U	Yes	Yes
Error Report Data Register (RERRDR)	S/U	Yes	Yes
Error Report Syndrome Register (RERRSYNR)	S/U	Yes	Yes
Error Status Register (ERRSR)	S/U	Yes	Yes

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

This module's memory map includes sixty-four 128-bit message buffers (MBs) that occupy the range from offset 0x80 to 0x47F .

CAN memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (CAN_MCR)	32	R/W	5980_000Fh	40.4.2/1953

CAN_MCR field descriptions

Field	Description
0 MDIS	Module Disable This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface sub-modules. This is the only bit within this register not affected by soft reset. 0 Enable the FlexCAN module. 1 Disable the FlexCAN module.
1 FRZ	Freeze Enable The FRZ bit specifies the FlexCAN behavior when the HALT bit in the MCR Register is set or when Debug mode is requested at chip level . When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode.

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
	0 Not enabled to enter Freeze mode. 1 Enabled to enter Freeze mode.
2 RFEN	Rx FIFO Enable This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (0x80-0xDC) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which are used as Rx FIFO ID Filter Table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in the table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (in section "Arbitration and Matching Timing"). This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Rx FIFO not enabled. 1 Rx FIFO enabled.
3 HALT	Halt FlexCAN Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the Message Buffers and Control Register. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered while FlexCAN is in a low power mode. 0 No Freeze mode request. 1 Enters Freeze mode if the FRZ bit is asserted.
4 NOTRDY	FlexCAN Not Ready This read-only bit indicates that FlexCAN is either in Disable mode , Doze mode, Stop mode or Freeze mode. It is negated once FlexCAN has exited these modes. 0 FlexCAN module is either in Normal mode, Listen-Only mode or Loop-Back mode. 1 FlexCAN module is either in Disable mode , Doze mode, Stop mode or Freeze mode.
5 Reserved	This field is reserved. Always write 0 to this field.
6 SOFTTRST	Soft Reset When this bit is asserted, FlexCAN resets its internal state machines and some of the memory mapped registers. The following registers are reset: MCR (except the MDIS bit), TIMER , ECR, ESR1, ESR2, IMASK1, IMASK2, IFLAG1, IFLAG2 and CRCR. Configuration registers that control the interface to the CAN bus are not affected by soft reset. The following registers are unaffected: CTRL1, CTRL2, all RXIMR registers, RXMGMASK, RX14MASK, RX15MASK, RXFGMASK, RXFIR, all Message Buffers . The SOFTTRST bit can be asserted directly by the CPU when it writes to the MCR Register. Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTTRST bit remains asserted while reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed. Soft reset cannot be applied while clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied. 0 No reset request. 1 Resets the registers affected by soft reset.
7 FRZACK	Freeze Mode Acknowledge This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished.

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
	Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze Mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested while FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See Section "Freeze Mode". NOTE: FRZACK will be asserted within 178 CAN bits from the freeze mode request by the CPU, and negated within 2 CAN bits after the freeze mode request removal (see Section "Protocol Timing"). 0 FlexCAN not in Freeze mode, prescaler running. 1 FlexCAN in Freeze mode, prescaler stopped.
8 SUPV	Supervisor Mode This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the Access Type column of the module memory map. Reset value of this bit is 1, so the affected registers start with Supervisor access allowance only. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses. 1 FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location.
9 Reserved	This field is reserved. Always write 0 to this field.
10 WRNEN	Warning Interrupt Enable When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register. If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 TWRNINT and RWRNINT bits are zero, independent of the values in the error counters. 1 TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.
11 LPMACK	Low-Power Mode Acknowledge This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode, Doze mode, Stop mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode. NOTE: LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see Section "Protocol Timing"). 0 FlexCAN is not in a low-power mode. 1 FlexCAN is in a low-power mode.
12 Reserved	This field is reserved. Always write 0 to this field.
13 DOZE	Doze Mode Enable This bit defines whether FlexCAN is allowed to enter low-power mode when Doze mode is requested at chip level.

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
	0 FlexCAN is not enabled to enter low-power mode when Doze mode is requested. 1 FlexCAN is enabled to enter low-power mode when Doze mode is requested.
14 SRXDIS	Self Reception Disable This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Self reception enabled. 1 Self reception disabled.
15 IRMQ	Individual Rx Masking And Queue Enable This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with RXMGMASK, RX14MASK and RX15MASK, RXFGMASK. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY. 1 Individual Rx masking and queue feature are enabled.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 LPRIEN	Local Priority Enable This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Local Priority disabled. 1 Local Priority enabled.
19 AEN	Abort Enable This bit is supplied for backwards compatibility with legacy applications. When asserted, it enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. NOTE: When MCR[AEN] is asserted, only the abort mechanism (see Section "Transmission Abort Mechanism") must be used for updating Mailboxes configured for transmission. CAUTION: Writing the Abort code into Rx Mailboxes can cause unpredictable results when the MCR[AEN] is asserted. 0 Abort disabled. 1 Abort enabled.
20–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
22–23 IDAM	ID Acceptance Mode This 2-bit field identifies the format of the Rx FIFO ID Filter Table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Section "Rx FIFO Structure". This field can be written only in Freeze mode because it is blocked by hardware in other modes. 00 Format A: One full ID (standard and extended) per ID Filter Table element. 01 Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID Filter Table element. 10 Format C: Four partial 8-bit Standard IDs per ID Filter Table element. 11 Format D: All frames rejected.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 MAXMB	Number Of The Last Message Buffer This 7-bit field defines the number of the last Message Buffers that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Number of the last MB = MAXMB NOTE: MAXMB must be programmed with a value smaller than the parameter NUMBER_OF_MB, otherwise the number of the last effective Message Buffer will be: (NUMBER_OF_MB - 1) Additionally, the value of MAXMB must encompass the FIFO size defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (in Section "Arbitration and Matching Timing").

40.4.3 Control 1 register (CAN_CTRL1)

This register is defined for specific FlexCAN control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior and interrupt enabling (Bus-Off, Error, Warning). It also determines the Division Factor for the clock prescaler.

Address: 0h base + 4h offset = 4h

CAN_CTRL1 field descriptions

Field	Description
0–7 PRES DIV	Prescaler Division Factor This 8-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The Maximum value of this field is 0xFF, that gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Section "Protocol Timing". This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (PRES DIV + 1)
8–9 RJW	Resync Jump Width This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization. One time quantum is equal to the Sclock period. The valid programmable values are 0–3. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = RJW + 1.
10–12 PSEG1	Phase Segment 1 This 3-bit field defines the length of Phase Buffer Segment 1 in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) × Time-Quanta.
13–15 PSEG2	Phase Segment 2

Table continues on the next page...

CAN_CTRL1 field descriptions (continued)

Field	Description
	This 3-bit field defines the length of Phase Buffer Segment 2 in the bit time. The valid programmable values are 1–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time-Quanta.
16 BOFFMSK	Bus Off Mask This bit provides a mask for the Bus Off Interrupt. 0 Bus Off interrupt disabled. 1 Bus Off interrupt enabled.
17 ERRMSK	Error Mask This bit provides a mask for the Error Interrupt. 0 Error interrupt disabled. 1 Error interrupt enabled.
18 CLKSRC	CAN Engine Clock Source This bit selects the clock source to the CAN Protocol Engine (PE) to be either the peripheral clock (driven by the PLL) or the crystal oscillator clock. The selected clock is the one fed to the prescaler to generate the Serial Clock (Sclck). In order to guarantee reliable operation, this bit can be written only in Disable mode because it is blocked by hardware in other modes. See Section "Protocol Timing". 0 The CAN engine clock source is the oscillator clock. Under this condition, the oscillator clock frequency must be lower than the bus clock. 1 The CAN engine clock source is the peripheral clock.
19 LPB	Loop Back Mode This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. NOTE: In this mode, the MCR[SRXDIS] cannot be asserted because this will impede the self reception of a transmitted message. 0 Loop Back disabled. 1 Loop Back enabled.
20 TWRNMSK	Tx Warning Interrupt Mask This bit provides a mask for the Tx Warning Interrupt associated with the TWRNINT flag in the Error and Status Register. This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted. 0 Tx Warning Interrupt disabled. 1 Tx Warning Interrupt enabled.
21 RWRNMSK	Rx Warning Interrupt Mask

Table continues on the next page...

CAN_CTRL1 field descriptions (continued)

Field	Description
	This bit provides a mask for the Rx Warning Interrupt associated with the RWRNINT flag in the Error and Status Register. This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted. 0 Rx Warning Interrupt disabled. 1 Rx Warning Interrupt enabled.
22–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 SMP	CAN Bit Sampling This bit defines the sampling mode of CAN bits at the Rx input. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Just one sample is used to determine the bit value. 1 Three samples are used to determine the value of the received bit: the regular one (sample point) and 2 preceding samples; a majority rule is used.
25 BOFFREC	Bus Off Recovery This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be re-asserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery. 0 Automatic recovering from Bus Off state enabled, according to CAN Spec 2.0 part B. 1 Automatic recovering from Bus Off state disabled.
26 TSYN	Timer Sync This bit enables a mechanism that resets the free-running timer each time a message is received in Message Buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special “SYNC” message, that is, global network time. If the RFEN bit in MCR is set (Rx FIFO enabled), the first available Mailbox, according to CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Timer Sync feature disabled 1 Timer Sync feature enabled
27 LBUF	Lowest Buffer Transmitted First This bit defines the ordering mechanism for Message Buffer transmission. When asserted, the LPRIEN bit does not affect the priority arbitration. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Buffer with highest priority is transmitted first. 1 Lowest number buffer is transmitted first.
28 LOM	Listen-Only Mode This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters are frozen and the module operates in a CAN Error Passive mode. Only messages

Table continues on the next page...

CAN_CTRL1 field descriptions (continued)

Field	Description
	acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the REC, as if it was trying to acknowledge the message. Listen-Only mode acknowledgement can be obtained by the state of ESR1[FLTCNF] field which is Passive Error when Listen-Only mode is entered. There can be some delay between the Listen-Only mode request and acknowledge. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Listen-Only mode is deactivated. 1 FlexCAN module operates in Listen-Only mode.
29–31 PROPSEG	Propagation Segment This 3-bit field defines the length of the Propagation Segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = (PROPSEG + 1) × Time-Quanta. Time-Quantum = one Sclock period.

40.4.4 Free Running Timer (CAN_TIMER)

This register represents a 16-bit free running counter that can be read and written by the CPU. The timer starts from 0x0 after Reset, counts linearly to 0xFFFF, and wraps around.

The timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Doze, Stop, and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the Time Stamp entry in a message buffer after a successful reception or transmission of a message.

If bit CTRL1[TSYN] is asserted, the Timer is reset whenever a message is received in the first available Mailbox, according to CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the Timer is being reset by a reception in the first Mailbox, then the write value is discarded.

Reading this register affects the Mailbox Unlocking procedure; see Section "Mailbox Lock Mechanism".

Memory map/register definition

Address: 0h base + 8h offset = 8h

16–31 TIMER	Timer Value Contains the free-running counter value.

40.4.5 Rx Mailboxes Global Mask Register (CAN_RXMGMASK)

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When the MCR[IRMQ] bit is negated, RXMGMASK is always in effect.
- When the MCR[IRMQ] bit is asserted, RXMGMASK has no effect.

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

	1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1. RTR bit of the Incoming Frame. It is saved into an auxiliary MB called Rx Serial Message Buffer (Rx SMB). 2. If the CTRL2[EACEN] bit is negated, the RTR bit of Mailbox is never compared with the RTR bit of the incoming frame. 3. If the CTRL2[EACEN] bit is negated, the IDE bit of Mailbox is always compared with the IDE bit of the incoming frame. 0 The corresponding bit in the filter is "don't care." 1 The corresponding bit in the filter is checked.							

1. RTR bit of the Incoming Frame. It is saved into an auxiliary MB called Rx Serial Message Buffer (Rx SMB).
2. If the CTRL2[EACEN] bit is negated, the RTR bit of Mailbox is never compared with the RTR bit of the incoming frame.
3. If the CTRL2[EACEN] bit is negated, the IDE bit of Mailbox is always compared with the IDE bit of the incoming frame.

40.4.6 Rx 14 Mask register (CAN_RX14MASK)

This register is located in RAM.

RX14MASK is provided for legacy application support. When the MCR[IRMQ] bit is asserted, RX14MASK has no effect.

RX14MASK is used to mask the filter fields of Message Buffer 14.

This register can only be programmed while the module is in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_RX15MASK field descriptions

Field	Description
0–31 RX15M[31:0]	Rx Buffer 15 Mask Bits Each mask bit masks the corresponding Mailbox 15 filter field in the same way that RXMGMASK masks other Mailboxes' filters. See the description of the CAN_RXMGMASK register. 0 The corresponding bit in the filter is "don't care." 1 The corresponding bit in the filter is checked.

40.4.8 Error Counter (CAN_ECR)

This register has two 8-bit fields reflecting the value of two FlexCAN error counters: Transmit Error Counter (TXERRCNT field) and Receive Error Counter (RXERRCNT field). The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module. Both counters are read-only except in Freeze mode, where they can be written by the CPU.

FlexCAN responds to any bus state as described in the protocol, for example, transmit Error Active or Error Passive flag, delay its transmission start time (Error Passive) and avoid any influence on the bus when in Bus Off state.

The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT increases to be greater than or equal to 128, the FLTCONF field in the Error and Status Register is updated to reflect 'Error Passive' state.
- If the FlexCAN state is 'Error Passive', and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 while the other already satisfies this condition, the FLTCONF field in the Error and Status Register is updated to reflect 'Error Active' state.
- If the value of TXERRCNT increases to be greater than 255, the FLTCONF field in the Error and Status Register is updated to reflect 'Bus Off' state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in 'Bus Off' state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, the FLTCONF field in the Error and Status Register is updated to be 'Error Active' and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value.
- If during system start-up, only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to 'Error Passive' state, the TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the 'Bus Off' state.
- If the RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to 'Error Active' state.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_ECR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 RXERRCNT	Receive Error Counter

Table continues on the next page...

CAN_ECR field descriptions (continued)

Field	Description
24–31 TXERRCNT	Transmit Error Counter

40.4.9 Error and Status 1 register (CAN_ESR1)

This register reflects various error conditions and some general status of the device. It is also the source of interrupts to the CPU.

A CPU read operation clears the following fields to 0, so these fields report error conditions that occurred after the last time the CPU read this register: BIT1ERR, BIT0ERR, ACKERR, CRCERR, FRMERR, and STFERR. TXWRN, RXWRN, IDLE, TX, FLTCNF, and RX provide status information.

The following table shows the FlexCAN state variables and their meanings. Combinations not shown in the table are reserved.

SYNCH	IDLE	TX	RX	FlexCAN state
0	0	0	0	Not synchronized to CAN bus
1	1	x	x	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

Address: 0h base + 20h offset = 20h

CAN_ESR1 field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 SYNCH	CAN Synchronization Status This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. See the table in the overall CAN_ESR1 register description. 0 FlexCAN is not synchronized to the CAN bus. 1 FlexCAN is synchronized to the CAN bus.
14 TWRNINT	Tx Warning Interrupt Flag If the WRNEN bit in MCR is asserted, the TWRNINT bit is set when the TXWRN flag transitions from 0 to 1, meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control Register (TWRNMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when the WRNEN is set again. Writing 0 has no effect. This flag is not generated during Bus Off state. This bit is not updated during Freeze mode. 0 No such occurrence. 1 The Tx error counter transitioned from less than 96 to greater than or equal to 96.
15 RWRNINT	Rx Warning Interrupt Flag If the WRNEN bit in MCR is asserted, the RWRNINT bit is set when the RXWRN flag transitions from 0 to 1, meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control Register (RWRNMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when the WRNEN is set again. Writing 0 has no effect. This bit is not updated during Freeze mode. 0 No such occurrence. 1 The Rx error counter transitioned from less than 96 to greater than or equal to 96.
16 BIT1ERR	Bit1 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message.

Table continues on the next page...

CAN_ESR1 field descriptions (continued)

Field	Description
	NOTE: This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits. 0 No such occurrence. 1 At least one bit sent as recessive is received as dominant.
17 BIT0ERR	Bit0 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message. 0 No such occurrence. 1 At least one bit sent as dominant is received as recessive.
18 ACKERR	Acknowledge Error This bit indicates that an Acknowledge Error has been detected by the transmitter node, that is, a dominant bit has not been detected during the ACK SLOT. 0 No such occurrence. 1 An ACK error occurred since last read of this register.
19 CRCERR	Cyclic Redundancy Check Error This bit indicates that a CRC Error has been detected by the receiver node, that is, the calculated CRC is different from the received. 0 No such occurrence. 1 A CRC error occurred since last read of this register.
20 FRMERR	Form Error This bit indicates that a Form Error has been detected by the receiver node, that is, a fixed-form bit field contains at least one illegal bit. 0 No such occurrence. 1 A Form Error occurred since last read of this register.
21 STFERR	Stuffing Error This bit indicates that a Stuffing Error has been detected. 0 No such occurrence. 1 A Stuffing Error occurred since last read of this register.
22 TXWRN	TX Error Warning This bit indicates when repetitive errors are occurring during message transmission. This bit is not updated during Freeze mode. 0 No such occurrence. 1 TXERRCNT is greater than or equal to 96.
23 RXWRN	Rx Error Warning This bit indicates when repetitive errors are occurring during message reception. This bit is not updated during Freeze mode. 0 No such occurrence. 1 RXERRCNT is greater than or equal to 96.

Table continues on the next page...

CAN_ESR1 field descriptions (continued)

Field	Description
24 IDLE	This bit indicates when CAN bus is in IDLE state. See the table in the overall CAN_ESR1 register description. 0 No such occurrence. 1 CAN bus is now IDLE.
25 TX	FlexCAN In Transmission This bit indicates if FlexCAN is transmitting a message. See the table in the overall CAN_ESR1 register description. 0 FlexCAN is not transmitting a message. 1 FlexCAN is transmitting a message.
26–27 FLTCONF	Fault Confinement State This 2-bit field indicates the Confinement State of the FlexCAN module. If the LOM bit in the Control Register is asserted, after some delay that depends on the CAN bit timing the FLTCONF field will indicate “Error Passive”. The very same delay affects the way how FLTCONF reflects an update to ECR register by the CPU. It may be necessary up to one CAN bit time to get them coherent again. Because the Control Register is not affected by soft reset, the FLTCONF field will not be affected by soft reset if the LOM bit is asserted. 00 Error Active 01 Error Passive 1x Bus Off
28 RX	FlexCAN In Reception This bit indicates if FlexCAN is receiving a message. See the table in the overall CAN_ESR1 register description. 0 FlexCAN is not receiving a message. 1 FlexCAN is receiving a message.
29 BOFFINT	Bus Off Interrupt This bit is set when FlexCAN enters ‘Bus Off’ state. If the corresponding mask bit in the Control Register (BOFFMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 No such occurrence. 1 FlexCAN module entered Bus Off state.
30 ERRINT	Error Interrupt This bit indicates that at least one of the Error Bits (bits 15-10) is set. If the corresponding mask bit CTRL1[ERRMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 No such occurrence. 1 Indicates setting of any Error Bit in the Error and Status Register.
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

40.4.10 Interrupt Masks 2 register (CAN_IMASK2)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB63 to MB32. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG2 bit is set.

Address: 0h base + 24h offset = 24h

CAN_IMASK2 field descriptions

Field	Description
0–31 BUFHM	Buffer MB _i Mask Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB63 to MB32. NOTE: Setting or clearing a bit in the IMASK2 Register can assert or negate an interrupt request, if the corresponding IFLAG2 bit is set. 0 The corresponding buffer Interrupt is disabled. 1 The corresponding buffer Interrupt is enabled.

40.4.11 Interrupt Masks 1 register (CAN_IMASK1)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB31 to MB0. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG1 bit is set.

Address: 0h base + 28h offset = 28h

CAN_IMASK1 field descriptions

Field	Description
0–31 BUFLM	Buffer MB_i Mask Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB31 to MB0. NOTE: Setting or clearing a bit in the IMASK1 Register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set. 0 The corresponding buffer Interrupt is disabled. 1 The corresponding buffer Interrupt is enabled.

40.4.12 Interrupt Flags 2 register (CAN_IFLAG2)

This register defines the flags for the 32 Message Buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB] field, CPU must service the IFLAG2 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Address: 0h base + 2Ch offset = 2Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_IFLAG2 field descriptions

Field	Description
0–31 BUFHI	Buffer MB_i Interrupt Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB63 to MB32. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception. 1 The corresponding buffer has successfully completed transmission or reception.

40.4.13 Interrupt Flags 1 register (CAN_IFLAG1)

This register defines the flags for the 32 Message Buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When the bit MCR[RFEN] is set, the function of the 8 least significant interrupt flags BUF[7:0]I changes: BUF7I, BUF6I and BUF5I indicate operating conditions of the FIFO, and the BUF4TO0I field is reserved.

Before enabling the RFEN, the CPU must service the IFLAG bits asserted in the Rx FIFO region; see Section "Rx FIFO". Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When the RFEN bit is negated, the FIFO flags must be cleared. The same care must be taken when an RFFN value is selected extending Rx FIFO filters beyond MB7. For example, when RFFN is 0x8, the MB0-23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

Before updating MCR[MAXMB] field, CPU must service the IFLAG1 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

CAN_IFLAG1 field descriptions

Field	Description
0–23 BUF31TO8I	Buffer MB_i Interrupt Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB31 to MB8. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception. 1 The corresponding buffer has successfully completed transmission or reception.
24 BUF7I	Buffer MB7 Interrupt Or "Rx FIFO Overflow" When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB7. NOTE: This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. The BUF7I flag represents "Rx FIFO Overflow" when MCR[RFEN] is set. In this case, the flag indicates that a message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. 0 No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1 1 MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1
25 BUF6I	Buffer MB6 Interrupt Or "Rx FIFO Warning" When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB6. NOTE: This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. The BUF6I flag represents "Rx FIFO Warning" when MCR[RFEN] is set. In this case, the flag indicates when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. Note that if the flag is cleared while the number of unread messages is greater than 4, it does not assert again until the number of unread messages within the Rx FIFO is decreased to be equal to or less than 4. 0 No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1 1 MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1
26 BUF5I	Buffer MB5 Interrupt Or "Frames available in Rx FIFO" When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB5. NOTE: This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. The BUF5I flag represents "Frames available in Rx FIFO" when MCR[RFEN] is set. In this case, the flag indicates that at least one frame is available to be read from the Rx FIFO. 0 No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the FIFO, when MCR[RFEN]=1 1 MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Rx FIFO when MCR[RFEN]=1
27–30 BUF4TO1I	Buffer MB_i Interrupt Or "reserved" When the RFEN bit in the MCR is cleared (Rx FIFO disabled), these bits flag the interrupts for MB4 to MB1. NOTE: These flags are cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. The BUF4TO1I flags are reserved when MCR[RFEN] is set.

Table continues on the next page...

CAN_IFLAG1 field descriptions (continued)

Field	Description
	0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.
31 BUF0I	Buffer MB0 Interrupt Or "reserved" When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB0. NOTE: This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. The BUF0I flag is reserved when MCR[RFEN] is set. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.

40.4.14 Control 2 register (CAN_CTRL2)

This register contains control bits for CAN errors, FIFO features, and mode selection.

Address: 0h base + 34h offset = 34h

CAN_CTRL2 field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 ECRWRE	Error-correction Configuration Register Write Enable Enable that the MECCR register is updated. This bit is automatically set to 0 if the protocol described in the "Detection and Correction of Memory Errors" section is not followed. 0 Disable update. 1 Enable update.

Table continues on the next page...

CAN_CTRL2 field descriptions (continued)

Field	Description																																																																																										
3 WRMFRZ	Write-Access To Memory In Freeze Mode Enable unrestricted write access to FlexCAN memory in Freeze mode. This bit can only be written in Freeze mode and has no effect out of Freeze mode. 0 Maintain the write access restrictions. 1 Enable unrestricted write access to FlexCAN memory.																																																																																										
4–7 RFFN	Number Of Rx FIFO Filters This 4-bit field defines the number of Rx FIFO filters, as shown in the following table. The maximum selectable number of filters is determined by the chip. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field must not be programmed with values that make the number of Message Buffers occupied by Rx FIFO and ID Filter exceed the number of Mailboxes present, defined by MCR[MAXMB]. NOTE: Each group of eight filters occupies a memory space equivalent to two Message Buffers which means that the more filters are implemented the less Mailboxes will be available. Considering that the Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words which can be calculated as follows: $(\text{SETUP\_MB} - 6) \times 4$ where SETUP_MB is the least between NUMBER_OF_MB and MAXMB. The number of remaining Mailboxes available will be: $(\text{SETUP\_MB} - 8) - (\text{RFFN} \times 2)$ If the Number of Rx FIFO Filters programmed through RFFN exceeds the SETUP_MB value (memory space available) the exceeding ones will not be functional. <table><tr><th>RFFN[3:0]</th><th>Number of Rx FIFO filters</th><th>Message Buffers occupied by Rx FIFO and ID Filter Table</th><th>Remaining Available Mailboxes¹</th><th>Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks²</th><th>Rx FIFO ID Filter Table Elements Affected by Rx FIFO Global Mask²</th></tr><tr><td>0x0</td><td>8</td><td>MB 0-7</td><td>MB 8-63</td><td>Elements 0-7</td><td>none</td></tr><tr><td>0x1</td><td>16</td><td>MB 0-9</td><td>MB 10-63</td><td>Elements 0-9</td><td>Elements 10-15</td></tr><tr><td>0x2</td><td>24</td><td>MB 0-11</td><td>MB 12-63</td><td>Elements 0-11</td><td>Elements 12-23</td></tr><tr><td>0x3</td><td>32</td><td>MB 0-13</td><td>MB 14-63</td><td>Elements 0-13</td><td>Elements 14-31</td></tr><tr><td>0x4</td><td>40</td><td>MB 0-15</td><td>MB 16-63</td><td>Elements 0-15</td><td>Elements 16-39</td></tr><tr><td>0x5</td><td>48</td><td>MB 0-17</td><td>MB 18-63</td><td>Elements 0-17</td><td>Elements 18-47</td></tr><tr><td>0x6</td><td>56</td><td>MB 0-19</td><td>MB 20-63</td><td>Elements 0-19</td><td>Elements 20-55</td></tr><tr><td>0x7</td><td>64</td><td>MB 0-21</td><td>MB 22-63</td><td>Elements 0-21</td><td>Elements 22-63</td></tr><tr><td>0x8</td><td>72</td><td>MB 0-23</td><td>MB 24-63</td><td>Elements 0-23</td><td>Elements 24-71</td></tr><tr><td>0x9</td><td>80</td><td>MB 0-25</td><td>MB 26-63</td><td>Elements 0-25</td><td>Elements 26-79</td></tr><tr><td>0xA</td><td>88</td><td>MB 0-27</td><td>MB 28-63</td><td>Elements 0-27</td><td>Elements 28-87</td></tr><tr><td>0xB</td><td>96</td><td>MB 0-29</td><td>MB 30-63</td><td>Elements 0-29</td><td>Elements 30-95</td></tr><tr><td>0xC</td><td>104</td><td>MB 0-31</td><td>MB 32-63</td><td>Elements 0-31</td><td>Elements 32-103</td></tr><tr><td>0xD</td><td>112</td><td>MB 0-33</td><td>MB 34-63</td><td>Elements 0-31</td><td>Elements 32-111</td></tr></table>	RFFN[3:0]	Number of Rx FIFO filters	Message Buffers occupied by Rx FIFO and ID Filter Table	Remaining Available Mailboxes ¹	Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks ²	Rx FIFO ID Filter Table Elements Affected by Rx FIFO Global Mask ²	0x0	8	MB 0-7	MB 8-63	Elements 0-7	none	0x1	16	MB 0-9	MB 10-63	Elements 0-9	Elements 10-15	0x2	24	MB 0-11	MB 12-63	Elements 0-11	Elements 12-23	0x3	32	MB 0-13	MB 14-63	Elements 0-13	Elements 14-31	0x4	40	MB 0-15	MB 16-63	Elements 0-15	Elements 16-39	0x5	48	MB 0-17	MB 18-63	Elements 0-17	Elements 18-47	0x6	56	MB 0-19	MB 20-63	Elements 0-19	Elements 20-55	0x7	64	MB 0-21	MB 22-63	Elements 0-21	Elements 22-63	0x8	72	MB 0-23	MB 24-63	Elements 0-23	Elements 24-71	0x9	80	MB 0-25	MB 26-63	Elements 0-25	Elements 26-79	0xA	88	MB 0-27	MB 28-63	Elements 0-27	Elements 28-87	0xB	96	MB 0-29	MB 30-63	Elements 0-29	Elements 30-95	0xC	104	MB 0-31	MB 32-63	Elements 0-31	Elements 32-103	0xD	112	MB 0-33	MB 34-63	Elements 0-31	Elements 32-111

CAN_CTRL2 field descriptions (continued)

Field	Description					
	RFFN[3:0]	Number of Rx FIFO filters	Message Buffers occupied by Rx FIFO and ID Filter Table	Remaining Available Mailboxes ¹	Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks ²	Rx FIFO ID Filter Table Elements Affected by Rx FIFO Global Mask ²
	0xE	120	MB 0-35	MB 36-63	Elements 0-31	Elements 32-119
	0xF	128	MB 0-37	MB 38-63	Elements 0-31	Elements 32-127
	1. The number of the last remaining available mailboxes is defined by the least value between the parameter NUMBER_OF_MB minus 1 and the MCR[MAXMB] field. 2. If Rx Individual Mask Registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.					
8–12 TASD	Tx Arbitration Start Delay This 5-bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on CAN bus. This field can be written only in Freeze mode because it is blocked by hardware in other modes. This field is useful to optimize the transmit performance based on factors such as: peripheral/serial clock ratio, CAN bit timing and number of MBs. The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and CAN baud rate and inversely proportional to the peripheral clock frequency. The optimal arbitration timing is that in which the last MB is scanned right before the first bit of the Intermission field of a CAN frame. Therefore, if there are few MBs and the system/serial clock ratio is high and the CAN baud rate is low then the arbitration can be delayed and vice-versa. If TASD is 0 then the arbitration start is not delayed, thus the CPU has less time to configure a Tx MB for the next arbitration, but more time is reserved for arbitration. On the other hand, if TASD is 24 then the CPU can configure a Tx MB later and less time is reserved for arbitration. If too little time is reserved for arbitration the FlexCAN may be not able to find winner MBs in time to compete with other nodes for the CAN bus. If the arbitration ends too much time before the first bit of Intermission field then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is not the best to be transmitted. The optimal configuration for TASD can be calculated as: $TASD = 25 - \left\{ f_{CANCLK} \times [MAXMB + 3 - (RFEN \times 8) - (RFEN \times RFFN \times 2)] \times 2 \right\} / \left\{ f_{SYS} \times [1 + (PSEG1+1) + (PSEG2+1) + (PROPSEG+1)] \times (PRES DIV+1) \right\}$ where: • f_{CANCLK} is the Protocol Engine (PE) Clock (see section "Protocol Timing"), in Hz • f_{SYS} is the peripheral clock, in Hz • MAXMB is the value in CTRL1[MAXMB] field • RFEN is the value in CTRL1[RFEN] bit • RFFN is the value in CTRL2[RFFN] field • PSEG1 is the value in CTRL1[PSEG1] field • PSEG2 is the value in CTRL1[PSEG2] field • PROPSEG is the value in CTRL1[PROPSEG] field • PRES DIV is the value in CTRL1[PRES DIV] field					

Table continues on the next page...

CAN_CTRL2 field descriptions (continued)

Field	Description
	See Section "Arbitration process" and Section "Protocol Timing" for more details.
13 MRP	Mailboxes Reception Priority If this bit is set the matching process starts from the Mailboxes and if no match occurs the matching continues on the Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Matching starts from Rx FIFO and continues on Mailboxes. 1 Matching starts from Mailboxes and continues on Rx FIFO.
14 RRS	Remote Request Storing If this bit is asserted Remote Request Frame is submitted to a matching process and stored in the corresponding Message Buffer in the same fashion of a Data Frame. No automatic Remote Response Frame will be generated. If this bit is negated the Remote Request Frame is submitted to a matching process and an automatic Remote Response Frame is generated if a Message Buffer with CODE=0b1010 is found with the same ID. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Remote Response Frame is generated. 1 Remote Request Frame is stored.
15 EACEN	Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes This bit controls the comparison of IDE and RTR bits within Rx Mailboxes filters with their corresponding bits in the incoming frame by the matching process. This bit does not affect matching for Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Rx Mailbox filter's IDE bit is always compared and RTR is never compared despite mask bits. 1 Enables the comparison of both Rx Mailbox filter's IDE and RTR bit with their corresponding bits within the incoming frame. Mask bits do apply.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

1. The number of the last remaining available mailboxes is defined by the least value between the parameter NUMBER_OF_MB minus 1 and the MCR[MAXMB] field.
2. If Rx Individual Mask Registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.

40.4.15 Error and Status 2 register (CAN_ESR2)

This register reflects various interrupt flags and some general status.

Address: 0h base + 38h offset = 38h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0								LPTM							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	VPS	IMB	0												
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAN_ESR2 field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 LPTM	Lowest Priority Tx Mailbox If ESR2[VPS] is asserted, this field indicates the lowest number inactive Mailbox (see the IMB bit description). If there is no inactive Mailbox then the Mailbox indicated depends on CTRL1[LBUF] bit value. If CTRL1[LBUF] bit is negated then the Mailbox indicated is the one that has the greatest arbitration value (see the "Highest priority Mailbox first" section). If CTRL1[LBUF] bit is asserted then the Mailbox indicated is the highest number active Tx Mailbox. If a Tx Mailbox is being transmitted it is not considered in LPTM calculation. If ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its Mailbox number.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 VPS	Valid Priority Status This bit indicates whether IMB and LPTM contents are currently valid or not. VPS is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a Mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx arbitration process. If there is no inactive Mailbox and only one Tx Mailbox that is being transmitted then VPS is not asserted. VPS is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any Mailbox. NOTE: ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of a MB that is blocked by abort mechanism. When MCR[AEN] is asserted, the abort code write in C/S of a MB that is being transmitted (pending abort), or any write attempt into a Tx MB with IFLAG set is blocked. 0 Contents of IMB and LPTM are invalid. 1 Contents of IMB and LPTM are valid.
18 IMB	Inactive Mailbox If ESR2[VPS] is asserted, this bit indicates whether there is any inactive Mailbox (CODE field is either 0b1000 or 0b0000). This bit is asserted in the following cases:

Table continues on the next page...

CAN_ESR2 field descriptions (continued)

Field	Description
	- During arbitration, if an LPTM is found and it is inactive. - If IMB is not asserted and a frame is transmitted successfully. This bit is cleared in all start of arbitration (see Section "Arbitration process"). NOTE: LPTM mechanism have the following behavior: if an MB is successfully transmitted and ESR2[IMB]=0 (no inactive Mailbox), then ESR2[VPS] and ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into ESR2[LPTM]. 0 If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive Mailbox. 1 If ESR2[VPS] is asserted, there is at least one inactive Mailbox. LPTM content is the number of the first one.
19–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

40.4.16 CRC Register (CAN_CRCCR)

This register provides information about the CRC of transmitted messages.

Address: 0h base + 44h offset = 44h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0								MBCRC							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	TXCRC														
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAN_CRCCR field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 MBCRC	CRC Mailbox This field indicates the number of the Mailbox corresponding to the value in TXCRC field.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–31 TXCRC	CRC Transmitted This field indicates the CRC value of the last message transmitted. This field is updated at the same time the Tx Interrupt Flag is asserted.

40.4.17 Rx FIFO Global Mask register (CAN_RXFGMASK)

This register is located in RAM.

If Rx FIFO is enabled RXFGMASK is used to mask the Rx FIFO ID Filter Table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 48h offset = 48h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

C	-	-		-	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]																												

1. If MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

40.4.18 Rx FIFO Information Register (CAN_RXFIR)

RXFIR provides information on Rx FIFO.

This register is the port through which the CPU accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO as well as its output is updated whenever the output of the Rx FIFO is updated with the next message. See Section "Rx FIFO" for instructions on reading this register.

Address: 0h base + 4Ch offset = 4Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- x = Undefined at reset.

CAN_RXFIR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 IDHIT	Identifier Acceptance Filter Hit Indicator This field indicates which Identifier Acceptance Filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only while the IFLAG[BUF5I] is asserted.

40.4.19 Rx Individual Mask Registers (CAN_RXIMRn)

These registers are located in RAM.

RXIMR are used as acceptance masks for ID filtering in Rx MBs and the Rx FIFO. If the Rx FIFO is not enabled, one mask register is provided for each available Mailbox, providing ID masking capability on a per Mailbox basis.

When the Rx FIFO is enabled (MCR[RFEN] bit is asserted), up to 32 Rx Individual Mask Registers can apply to the Rx FIFO ID Filter Table elements on a one-to-one correspondence depending on the setting of CTRL2[RFFN].

Memory map/register definition

RXIMR can only be written by the CPU while the module is in Freeze mode; otherwise, they are blocked by hardware.

The Individual Rx Mask Registers are not affected by reset and must be explicitly initialized prior to any reception.

Address: 0h base + 880h offset + (4d × i), where i=0d to 63d

- * Notes:
- x = Undefined at reset.

CAN_RXIMRn field descriptions

Field	Description
0–31 MI[31:0]	Individual Mask Bits Each Individual Mask Bit masks the corresponding bit in both the Mailbox filter and Rx FIFO ID Filter Table element in distinct ways. For Mailbox filters, see the RXMGMASK register description. For Rx FIFO ID Filter Table elements, see the RXFGMASK register description. 0 The corresponding bit in the filter is "don't care." 1 The corresponding bit in the filter is checked.

40.4.20 Memory Error Control Register (CAN_MECR)

This register contains control bits for memory error detection and correction (ECC).

NOTE

When bit CTRL2[ECRWRE] is 0, this register is read-only and writes to this register result in bus transfer errors.

Address: 0h base + AE0h offset = AE0h

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_MECR field descriptions

Field	Description
0 ECRWRDIS	Error Configuration Register Write Disable Disables writes on this register. 0 Write is enabled. 1 Write is disabled.
1–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 HANCEI_MSK	Host Access With Non-Correctable Errors Interrupt Mask Enables the interrupt in case of non-correctable errors detected in memory reads issued by the host (CPU). 0 Interrupt is disabled. 1 Interrupt is enabled.
13 FANCEI_MSK	FlexCAN Access With Non-Correctable Errors Interrupt Mask Enables the interrupt in case of non-correctable errors detected in memory reads issued by the FlexCAN internal processes. 0 Interrupt is disabled. 1 Interrupt is enabled.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 CEI_MSK	Correctable Errors Interrupt Mask Enables the interrupt in case of correctable errors detected in memory reads issued by the host or FlexCAN internal processes. 0 Interrupt is disabled. 1 Interrupt is enabled.
16 HAERRIE	Host Access Error Injection Enable Enables the injection of errors only in memory reads issued by the host (CPU). 0 Injection is disabled. 1 Injection is enabled.
17 FAERRIE	FlexCAN Access Error Injection Enable Enables the injection of errors only in memory reads issued by the FlexCAN internal processes. 0 Injection is disabled. 1 Injection is enabled.

Table continues on the next page...

CAN_MECR field descriptions (continued)

Field	Description
18 EXTERRIE	Extended Error Injection Enable Memory accesses performed by internal FlexCAN processes are 64-bit. This bit extends the error injection on 32-bit memory accesses to the complementary 32-bit word using the same 32-bit error injection data and parity words. See Error Injection Data Pattern Register (FCERRIDPR) and Error Injection Parity Pattern Register (FCERRIPPR) 0 Error injection is applied only to the 32-bit word. 1 Error injection is applied to the 64-bit word.
19–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 RERRDIS	Error Report Disable Disables the update of the error report registers. The update of error-related flags and the generation of bus transfer errors are still active. NOTE: When reading the report registers, this bit must be cleared to assure coherence on the consecutive register reads. 0 Enable updates of the error report registers. 1 Disable updates of the error report registers.
23 ECCDIS	Error Correction Disable Disables completely the memory error detection and correction mechanism. Besides disabling the error report mechanism, it also stops the update of the error-related flags and generation of bus transfer errors. The parity bits continue being calculated and written into memory on write transactions. 0 Enable memory error correction. 1 Disable memory error correction.
24 NCEFAFRZ	Non-Correctable Errors In FlexCAN Access Put Device In Freeze Mode Determines the response when a non-correctable error is detected in a memory read performed by FlexCAN internal processes. In this case, entering Freeze mode prevents corrupted data from being treated as valid by FlexCAN internal processes. 0 Keep normal operation. 1 Put FlexCAN in Freeze mode (according to the "Freeze mode" section).
25–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

40.4.21 Error Injection Address Register (CAN_ERRIAR)

This register holds the address where error is to be injected.

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM:

RAM contents	Injection address	Memory map
FlexCAN Registers	Not mapped	-

Table continues on the next page...

RAM contents	Injection address	Memory map

Address: 0h base + AE4h offset = AE4h

CAN_ERRIR field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–31 INJADDR	Address Where Error Is To Be Injected The two least significant bits of this field always read as 0.

40.4.22 Error Injection Data Pattern Register (CAN_ERRIDPR)

Holds the error pattern to be injected in the data word read from memory.

Address: 0h base + AE8h offset = AE8h

CAN_ERRIDPR field descriptions

Field	Description
0–31 DFLIP	Data flip pattern Bits set to 1 in the flip pattern cause the corresponding data bit in the word read from memory to invert.

40.4.23 Error Injection Parity Pattern Register (CAN_ERRIPPR)

Holds the error pattern to be injected in parity bits read from memory along with data word.

Bits set to 1 in the flip pattern cause the corresponding parity bit in the word read from memory to invert.

Address: 0h base + AECh offset = AECh

CAN_ERRIPPR field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 PFLIP3	Parity Flip Pattern For Byte 3 (most significant)
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 PFLIP2	Parity Flip Pattern For Byte 2
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

Field	Description
19–23 PFLIP1	Parity Flip Pattern For Byte 1
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 PFLIP0	Parity Flip Pattern For Byte 0 (Least Significant)

40.4.24 Error Report Address Register (CAN_RERRAR)

Reports the address used for an access in which an error (correctable or non-correctable) was detected, and also reports the identification of the source of that access.

This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] non-0) are reported with the address aligned and data is reported in RERRDR accordingly shifted. In case of errors detected in accesses larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word in which the error was detected is reported. In case of errors detected in more than one 32-bit word, only the least significant address is reported.

Address: 0h base + AF0h offset = AF0h

CAN_RERRDR field descriptions

Field	Description
0–31 RDATA	Raw data word read from memory with error

40.4.26 Error Report Syndrome Register (CAN_RERRSYNR)

Holds the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYNDn field indicates the type of error and which bit in byte (n) is affected by the error. (SYND3 corresponds to the most significant byte in the data word read from memory; SYND0 corresponds to the least significant.)

Table 40-94. Syndrome Definition

SYNDn (hex)	Type	Bit affected
00	-	none (no error)
01	Code	0
02	Code	1
04	Code	2
07	Data	5
08	Code	3
0E	Data	7
10	Code	4
13	Data	2
15	Data	6
16	Data	1
19	Data	3
1A	Data	4
1C	Data	0
All others	-	Non-correctable error

Each BEn field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated (see the "Error Indication" section) and reported (see the "Error Reporting" section).

Memory map/register definition

Address: 0h base + AF8h offset = AF8h

CAN_ERRSR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 HANCEIF	Host Access With Non-Correctable Error Interrupt Flag Indicates that a non-correctable error was detected in a memory access initiated by Host. A bus transfer error is asserted for that access. If MECR[HANCEI_MSK] is set, the interrupt is asserted. 0 No non-correctable errors were detected in Host accesses so far. 1 A non-correctable error was detected in a Host access.
13 FANCEIF	FlexCAN Access With Non-Correctable Error Interrupt Flag

Table continues on the next page...

CAN_ERRSR field descriptions (continued)

Field	Description
	Indicates that a non-correctable error was detected in a memory access initiated by FlexCAN internal processes. If MECR[FANCEI_MSK] is set, the interrupt is asserted. 0 No non-correctable errors were detected in FlexCAN accesses so far. 1 A non-correctable error was detected in a FlexCAN access.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 CEIF	Correctable Error Interrupt Flag Indicates that a correctable error was detected in a memory access. If MECR[CEI_MSK] is set, the interrupt is asserted. 0 No correctable errors were detected so far. 1 A correctable error was detected.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 HANCEIOF	Host Access With Non-Correctable Error Interrupt Overrun Flag Indicates that a non-correctable error was detected in a memory access initiated by Host when HANCEIF was set. No interrupt is associated to this flag. (See the "Error Indication" section.) 0 No overrun on non-correctable errors in Host access 1 Overrun on non-correctable errors in Host access
29 FANCEIOF	FlexCAN Access With Non-Correctable Error Interrupt Overrun Flag Indicates that a non-correctable error was detected in a memory access initiated by FlexCAN internal processes when FANCEIF was set. No interrupt is associated to this flag. (See the "Error Indication" section.) 0 No overrun on non-correctable errors in FlexCAN access 1 Overrun on non-correctable errors in FlexCAN access
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 CEIOF	Correctable Error Interrupt Overrun Flag Indicates that a correctable error was detected in a memory access when CEIF was set. No interrupt is associated to this flag. (See the "Error Indication" section.) 0 No overrun on correctable errors 1 Overrun on correctable errors

40.4.28 Message buffer structure

The message buffer structure used by the FlexCAN module is represented in the following figure. Both Extended (29-bit identifier) and Standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16 bytes.

The memory area from 0x80 to 0x47F is used by the mailboxes.

Table 40-96. Message buffer structure

	0	1	2	3	4	7	8	9	10	11	12	13	14	15	16	23	24	31	
0x0					CODE			SRR	IDE	RTR	DLC				TIME STAMP				
0x4	PRIO			ID (Standard/Extended)										ID (Extended)					
0x8	Data Byte 0						Data Byte 1						Data Byte 2			Data Byte 3			
0xC	Data Byte 4						Data Byte 5						Data Byte 6			Data Byte 7			
					= Unimplemented or Reserved														

CODE — Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in [Table 40-97](#) and [Table 40-98](#). See [Functional description](#) for additional information.

Table 40-97. Message buffer code for Rx buffers

CODE description	Rx code BEFORE receive new frame	SRV ¹	Rx code AFTER successful reception ²	RRS ³	Comment
0b0000: INACTIVE — MB is not active.	INACTIVE	—	—	—	MB does not participate in the matching process.
0b0100: EMPTY — MB is active and empty.	EMPTY	—	FULL	—	When a frame is received successfully (after the Move-in process), the CODE field is automatically updated to FULL.

Table continues on the next page...

Table 40-97. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV ¹	Rx code AFTER successful reception ²	RRS ³	Comment
0b0010: FULL — MB is full.	FULL	Yes	FULL	—	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL. See Matching process for matching details related to FULL code.
		No	OVERRUN	—	If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. See Matching process for details about overrun behavior.
0b0110: OVERRUN — MB is being overwritten into a full buffer.	OVERRUN	Yes	FULL	—	If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB then the code returns to FULL.
		No	OVERRUN	—	If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. See Matching process for details about overrun behavior.

Table continues on the next page...

Table 40-97. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV ¹	Rx code AFTER successful reception ²	RRS ³	Comment
0b1010: RANSWER ⁴ — A frame was configured to recognize a Remote Request Frame and transmit a Response Frame in return.	RANSWER	—	TANSWER(0b1110)	0	A Remote Answer was configured to recognize a remote request frame received. After that an MB is set to transmit a response frame. The code is automatically changed to TANSWER (0b1110). See Matching process for details. If CTRL2[RRS] is negated, transmit a response frame whenever a remote request frame with the same ID is received.
		—	—	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0]=1b1: BUSY ⁵ — FlexCAN is updating the contents of the MB. The CPU must not access the MB.	BUSY ⁵	—	FULL	—	Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE.
		—	OVERRUN	—	

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See [Move-in](#) for details.
3. Remote Request Stored bit from CTRL2 register. See section "Control 2 Register (CTRL2)" for details.
4. Code 0b1010 is not considered Tx and an MB with this code should not be aborted.
5. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

Table 40-98. Message buffer code for Tx buffers

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
0b1000: INACTIVE — MB is not active	INACTIVE	—	—	MB does not participate in arbitration process.

Table continues on the next page...

Table 40-98. Message buffer code for Tx buffers (continued)

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
0b1001: ABORT — MB is aborted	ABORT	—	—	MB does not participate in arbitration process.
0b1100: DATA — MB is a Tx Data Frame (MB RTR must be 0)	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.
0b1100: REMOTE — MB is a Tx Remote Request Frame (MB RTR must be 1)	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.
0b1110: TANSWER — MB is a Tx Response Frame from an incoming Remote Request Frame	TANSWER	—	RANSWER	This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (0b1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See Matching process and Arbitration process for details.

SRR — Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

IDE — ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

RTR — Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See [Table 40-97](#), [Table 40-98](#), and the description of the RRS bit in Control 2 Register (CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

DLC — Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x8 through 0xF of the MB space (see the [Table 40-96](#)). In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see [Table 40-99](#)).

TIME STAMP — Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

PRI0 — Local priority

This 3-bit field is used only when LPRIO_EN bit is set in MCR, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See [Arbitration process](#).

ID — Frame Identifier

In standard frame format, only the 11 most significant bits (3 to 13) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

DATA BYTE 0–7 — Data Field

Up to eight bytes can be used for a data frame.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC as shown in the table below.

For Tx frames, the CPU prepares the data field to be transmitted within the frame.

Table 40-99. DATA BYTEs validity

DLC	Valid DATA BYTEs
0	none
1	DATA BYTE 0
2	DATA BYTE 0–1
3	DATA BYTE 0–2
4	DATA BYTE 0–3
5	DATA BYTE 0–4
6	DATA BYTE 0–5
7	DATA BYTE 0–6
8	DATA BYTE 0–7

40.4.29 Rx FIFO structure

When the MCR[RFEN] bit is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0–5) is used by the reception FIFO engine.

The region 0x80-0x8C contains the output of the FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 0x90-0xDC is reserved for internal use of the FIFO engine.

An additional memory area, which starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6–37) depending on the CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the FIFO.

Out of reset, the ID filter table flexible memory area defaults to 0xE0 and extends only to 0xFC, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Rx FIFO data structure.

Table 40-100. Rx FIFO structure

	0	3	7	8	9	10	11	12	13	14	15	16	23	24	31			
0x80					SRR	IDE	RTR	DLC				TIME STAMP						
0x84		ID standard								ID extended								
0x88	Data byte 0				Data byte 1								Data byte 2				Data byte 3	
0x8C	Data byte 4				Data byte 5								Data byte 6				Data byte 7	
0x90 to 0xDC	Reserved																	
0xE0	ID filter table element 0																	
0xE4	ID filter table element 1																	
0xE8 to 0x2D4	ID filter table elements 2 to 125																	
0x2D8	ID filter table element 126																	
0x2DC	ID filter table element 127																	
		= Unimplemented or reserved																

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See [Rx FIFO](#) for more information.

Table 40-101. ID table structure

Format	0	1	2	7	8	15	16	17	18	23	24	30	31
A	RTR	IDE	RXIDA (standard = 2–12, extended = 2–30)										
B	RTR	IDE	RXIDB_0 (standard = 2–12, extended = 2–15)				RTR	IDE	RXIDB_1 (standard = 18–28, extended = 18–31)				
C	RXIDC_0 (std/ext = 0–7)				RXIDC_1 (std/ext = 8–15)			RXIDC_2 (std/ext = 16–23)				RXIDC_3 (std/ext = 24–31)	
	= Unimplemented or Reserved												

RTR — Remote Frame

This bit specifies if Remote Frames are accepted into the FIFO if they match the target ID.

1 = Remote Frames can be accepted and data frames are rejected

0 = Remote Frames are rejected and data frames can be accepted

IDE — Extended Frame

Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

RXIDA — Rx Frame Identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (2 to 12) are used for frame identification. In the extended frame format, all bits are used.

RXIDB_0, RXIDB_1 — Rx Frame Identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (2 to 12 and 18 to 28) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3 — Rx Frame Identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

40.5 Functional description

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed by a set of Message Buffers (MB) that store configuration and control data, time stamp, message ID and data (see [Message buffer structure](#)). The memory corresponding to the first 38 MBs can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID Filter Table elements. Simultaneous reception through FIFO and mailbox is supported. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed on its ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range

of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A Message Buffer is said to be "active" at a given time if it can participate in both the Matching and Arbitration processes. An Rx MB with a 0b0000 code is inactive (refer to [Table 40-97](#)). Similarly, a Tx MB with a 0b1000 or 0b1001 code is also inactive (refer to [Table 40-98](#)).

40.5.1 Transmit process

To transmit a CAN frame, the CPU must prepare a Message Buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (0b1001) to the CODE field of the Control and Status word to request an abortion of the transmission. Wait for the corresponding IFLAG to be asserted by polling the IFLAG register or by the interrupt request if enabled by the respective IMASK. Then read back the CODE field to check if the transmission was aborted or transmitted (see [Transmission abort mechanism](#)). If backwards compatibility is desired (MCR[AEN] bit is negated), just write the INACTIVE code (0b1000) to the CODE field to inactivate the MB but then the pending frame may be transmitted without notification (see [Mailbox inactivation](#)).
3. Write the ID word.
4. Write the data bytes.
5. Write the DLC, Control, and CODE fields of the Control and Status word to activate the MB.

When the MB is activated, it will participate into the arbitration process and eventually be transmitted according to its priority. At the end of the successful transmission, the value of the Free Running Timer is written into the Time Stamp field, the CODE field in the Control and Status word is updated, the CRC Register is updated, a status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit. The new CODE field after transmission depends on the code that was used to activate the MB (see [Table 40-97](#) and [Table 40-98](#) in [Message buffer structure](#)).

When the Abort feature is enabled (MCR[AEN] is asserted), after the Interrupt Flag is asserted for a Mailbox configured as transmit buffer, the Mailbox is blocked, therefore the CPU is not able to update it until the Interrupt Flag is negated by CPU. This means that the CPU must clear the corresponding IFLAG before starting to prepare this MB for a new transmission or reception.

40.5.2 Arbitration process

The arbitration process scans the Mailboxes searching the Tx one that holds the message to be sent in the next opportunity. This Mailbox is called the *arbitration winner*.

The scan starts from the lowest number Mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the CTRL2[TASD] field value.
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When there is CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all Mailboxes before the CAN bus has reached the first bit of the Intermission field the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx Mailboxes at the end of the scan according to both CTRL1[LBUF] and MCR[LPRIOEN] bits settings.

40.5.2.1 Lowest-number Mailbox first

If CTRL1[LBUF] bit is asserted the first (lowest number) active Tx Mailbox found is the arbitration winner. MCR[LPRIOEN] bit has no effect when CTRL1[LBUF] is asserted.

40.5.2.2 Highest-priority Mailbox first

If CTRL1[LBUF] bit is negated, then the arbitration process searches the active Tx Mailbox with the highest priority, which means that this Mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the Mailbox. The highest-priority Tx Mailbox is the one that has the lowest arbitration value among all Tx Mailboxes.

If two or more Mailboxes have equivalent arbitration values, the Mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIOEN] bit setting.

40.5.2.2.1 Local Priority disabled

If MCR[LPRIOEN] bit is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the Local Priority is disabled.

Table 40-102. Composition of the arbitration value when Local Priority is disabled

Format	Mailbox Arbitration Value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

40.5.2.2.2 Local Priority enabled

If Local Priority is desired MCR[LPRIOEN] must be asserted. In this case the Mailbox PRIO field is included at the very left of the arbitration value (see the following table).

Table 40-103. Composition of the arbitration value when Local Priority is enabled

Format	Mailbox Arbitration Value (35 bits)					
Standard (IDE = 0)	PRI0 (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	PRI0 (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

As the PRI0 field is the most significant part of the arbitration value Mailboxes with low PRI0 values have higher priority than Mailboxes with high PRI0 values regardless the rest of their arbitration values.

Note that the PRI0 field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

40.5.2.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the corresponding MB is blocked (if the AEN bit in MCR is asserted). The write access is released in the following events:

- After the MB is transmitted
- FlexCAN enters in Freeze mode or Bus Off
- FlexCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules. FlexCAN transmits up to eight data bytes, even if the Data Length Code (DLC) field value is greater than that.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. T ASD value may be changed to optimize the arbitration start point.
- During CAN BusOff state from TX_ERR_CNT=124 to 128. T ASD value may be changed to optimize the arbitration start point.
- During C/S write by CPU in BusIdle. First C/S write starts arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after arbitration process has finished, then TX arbitration machine begins a new arbitration process.

- If there is a pending arbitration and BusIdle state starts then an arbitration process is triggered. In this case the first and second C/S write in BusIdle will not restart the arbitration process. It is possible that there is not enough time to finish arbitration in WaitForBusIdle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during BusIdle state. During this arbitration C/S write does not cause arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon Leave Freeze mode (first bit of the WaitForBusIdle state). If there is a re-synchronization during WaitForBusIdle arbitration process is restarted.

Arbitration process stops in the following situation:

- All Mailboxes were scanned
- A Tx active Mailbox is found in case of Lowest Buffer feature enabled
- Arbitration winner inactivation or abort during any arbitration process
- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or Overload flag in the bus
- Low Power or Freeze mode request in Idle state

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer
- Any C/S write if there is no Tx Arbitration process in progress
- Rx Match has just updated a Rx Code to Tx Code
- Entering Busoff state

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

40.5.3 Receive process

To be able to receive CAN frames into a Mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the Mailbox is active (either Tx or Rx) inactivate the Mailbox (see [Mailbox inactivation](#)), preferably with a safe inactivation (see [Transmission abort mechanism](#)).
2. Write the ID word
3. Write the EMPTY code (0b0100) to the CODE field of the Control and Status word to activate the Mailbox.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the Mailbox is updated by the *move-in* process (see [Move-in](#)) as follows:

1. The received Data field (8 bytes at most) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the Mailbox's Time Stamp field.
4. The received SRR, IDE, RTR, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see [Table 40-97](#) and [Table 40-98](#) in Section [Message buffer structure](#)).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for CPU servicing (read) the frame received in an Mailbox is using the following procedure:

1. Read the Control and Status word of that Mailbox.
2. Check if the BUSY bit is deasserted, indicating that the Mailbox is locked. Repeat step 1) while it is asserted. See [Mailbox lock mechanism](#).
3. Read the contents of the Mailbox. Once Mailbox is locked now, its contents won't be modified by FlexCAN Move-in processes. See [Move-in](#).
4. Acknowledge the proper flag at IFLAG registers.
5. Read the Free Running Timer. It is optional but recommended to unlock Mailbox as soon as possible and make it available for reception.

The CPU should synchronize to frame reception by the status flag bit for the specific Mailbox in one of the IFLAG Registers and not by the CODE field of that Mailbox. Polling the CODE field does not work because once a frame was received and the CPU

services the Mailbox (by reading the C/S word followed by unlocking the Mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in [Table 40-97](#). If the CPU tries to workaround this behavior by writing to the C/S word to force an EMPTY code after reading the Mailbox without a prior *safe inactivation*, a newly received frame matching the filter of that Mailbox may be lost.

CAUTION

In summary: never do polling by reading directly the C/S word of the Mailboxes. Instead, read the IFLAG registers.

Note that the received frame's Identifier field is always stored in the matching Mailbox, thus the contents of the ID field in an Mailbox may change if the match was due to masking. Note also that FlexCAN does receive frames transmitted by itself if there exists a matching Rx Mailbox, provided the MCR[SRXDIS] bit is not asserted. If the MCR[SRXDIS] bit is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching MB, and no interrupt flag or interrupt signal will be generated due to the frame reception.

To be able to receive CAN frames through the Rx FIFO, the CPU must enable and configure the Rx FIFO during Freeze mode (see [Rx FIFO](#)). Upon receiving the Frames Available in Rx FIFO interrupt (see the description of the IFLAG[BUF5I] "Frames available in Rx FIFO" bit in the IMASK1 register), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional – needed only if a mask was used for IDE and RTR bits)
2. Read the ID field (optional – needed only if a mask was used)
3. Read the Data field
4. Read the RXFIR register (optional)
5. Clear the Frames Available in Rx FIFO interrupt by writing 1 to IFLAG[BUF5I] bit (mandatory – releases the MB and allows the CPU to read the next Rx FIFO entry)

40.5.4 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between Mailboxes and FIFO filters. In any case, the matching starts from the lowest number Message Buffer toward the higher ones. If no match is

found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm will always look for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame

If a matching ID is found in the FIFO table or in one of the Mailboxes, the contents of the SMB will be transferred to the FIFO or to the matched Mailbox by the move-in process. If any CAN protocol error is detected then no match results will be transferred to the FIFO or to the matched Mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and active Rx Mailboxes (CODE is EMPTY, FULL, OVERRUN or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The SMB has the same structure of a Mailbox. The reception structures (Rx FIFO or Mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

Table 40-104. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EAC EN]	MB[IDE]	MB[RTR]	MB[ID ¹]	MB[CODE]
Mailbox	0	-	0	cmp ²	no_cmp ³	cmp_msk ⁴	EMPTY or FULL or OVERRUN
Mailbox	0	-	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	0	-	cmp	no_cmp	cmp	RANSWER
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	EMPTY or FULL or OVERRUN

Table continues on the next page...

Table 40-104. Matching architecture (continued)

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EAC EN]	MB[IDE]	MB[RTR]	MB[ID ¹]	MB[CODE]
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
FIFO ⁵	-	-	-	cmp_msk	cmp_msk	cmp_msk	-

1. For Mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on IDAM.
2. cmp: Compares the SMB contents with the MB contents regardless the masks.
3. no_cmp: The SMB contents are not compared with the MB contents
4. cmp_msk: Compares the SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

A reception structure is *free-to-receive* when any of the following conditions is satisfied:

- The CODE field of the Mailbox is EMPTY
- The CODE field of the Mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in [Mailbox lock mechanism](#))
- The CODE field of the Mailbox is either FULL or OVERRUN and an inactivation (see [Mailbox inactivation](#)) is performed
- The Rx FIFO is not full

The scan order for Mailboxes and Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for Mailboxes is affected by the MCR[IRMQ] bit. If it is negated the matching winner is the first matched Mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched Mailbox;
2. the last non free-to-receive matched Mailbox.

It is possible to select the priority of scan between Mailboxes and Rx FIFO by the CTRL2[MRP] bit.

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive then the Rx FIFO is the matching winner regardless of the scan for Mailboxes
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among Mailboxes as described above

If the selected priority is Mailboxes first:

Functional description

- If a free-to-receive matched Mailbox is found, it is the matching winner regardless the scan for Rx FIFO
- If no matched Mailbox is found, then the matching winner is searched in the scan for the Rx FIFO
- If both conditions above are not satisfied and a non free-to-receive matched Mailbox is found then the matching winner determination is conditioned by the MCR[IRMQ] bit:
 - If MCR[IRMQ] bit is negated the matching winner is the first matched Mailbox
 - If MCR[IRMQ] bit is asserted the matching winner is the Rx FIFO if it is a free-to-receive matched structure, otherwise the matching winner is the last non free-to-receive matched Mailbox

See the following table for a summary of matching possibilities.

Table 40-105. Matching possibilities and resulting reception structures

RFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
No FIFO, only MB, match is always MB first						
0	0	X ¹	None ²	- ³	None	Frame lost by no match
0	0	X	Free ⁴	-	FirstMB	
0	1	X	None	-	None	Frame lost by no match
0	1	X	Free	-	FirstMb	
0	1	X	NotFree	-	LastMB	Overrun
FIFO enabled, no match in FIFO is as if FIFO does not exist						
1	0	X	None	None ⁵	None	Frame lost by no match
1	0	X	Free	None	FirstMB	
1	1	X	None	None	None	Frame lost by no match
1	1	X	Free	None	FirstMb	
1	1	X	NotFree	None	LastMB	Overrun
FIFO enabled, Queue disabled						
1	0	0	X	NotFull ⁶	FIFO	
1	0	0	None	Full ⁷	None	Frame lost by FIFO full (FIFO Overflow)
1	0	0	Free	Full	FirstMB	
1	0	0	NotFree	Full	FirstMB	
1	0	1	None	NotFull	FIFO	
1	0	1	None	Full	None	Frame lost by FIFO full (FIFO Overflow)

Table continues on the next page...

Table 40-105. Matching possibilities and resulting reception structures (continued)

RFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
1	0	1	Free	X	FirstMB	
1	0	1	NotFree	X	FirstMb	Overrun
FIFO enabled, Queue enabled						
1	1	0	X	NotFull	FIFO	
1	1	0	None	Full	None	Frame lost by FIFO full (FIFO Overflow)
1	1	0	Free	Full	FirstMB	
1	1	0	NotFree	Full	LastMb	Overrun
1	1	1	None	NotFull	FIFO	
1	1	1	Free	X	FirstMB	
1	1	1	NotFree	NotFull	FIFO	
1	1	1	NotFree	Full	LastMb	Overrun

1. This is a don't care condition.
2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non-free-to-receive).
3. This is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO didn't exist (CTRL2[RFEN]=0).
6. Matched in FIFO "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

If a non-safe Mailbox inactivation (see [Mailbox inactivation](#)) occurs during matching process and the Mailbox inactivated is the temporary matching winner then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted, it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled and there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm will find the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm will find MB number 2 again, but it is not "free-to-receive", so it will keep looking and find MB number 5 and store the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages will be queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID Acceptance Masks. FlexCAN supports individual masking per MB. Refer to the description of the Rx Individual Mask Registers (RXIMRx). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is "don't care". Please note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (RXGMASK, RX14MASK, RX15MASK and RXFGMASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the MCR Register is negated.

40.5.5 Move process

There are two types of move process: move-in and move-out.

40.5.5.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to a Rx Mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see [Matching process](#)) and all of the following conditions are true:

- The CAN bus has reached or let past either:
 - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB
 - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB
- There is no ongoing matching process

- The destination Mailbox is not locked by the CPU
- There is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time both are performed and the newest substitutes the oldest.

The term *pending move-in* is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination Mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished
- There is a previous pending move-in to the same destination Mailbox
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and the self-reception is disabled (MCR[SRXDIS] bit is asserted)
- Any CAN protocol error is detected

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It only stays on hold waiting for exiting Freeze and Low-Power mode and to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. if the message is destined to the Rx FIFO, push IDHIT into the RXFIR FIFO;
2. reads the words DATA0-3 and DATA4-7 from the Rx SMB;
3. writes it in the words DATA0-3 and DATA4-7 of the Rx Mailbox;
4. reads the words Control/Status and ID from the Rx SMB;
5. writes it in the words Control/Status and ID of the Rx Mailbox, updating the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination Mailbox (see [Mailbox inactivation](#)) and in this case the Mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO Message Buffer, then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination Message Buffer is asserted while the move-in is being performed to alert the CPU that the Message Buffer content is temporarily incoherent.

40.5.5.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Section "Arbitration process"). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

40.5.6 Data coherence

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in [Transmit process](#) and [Receive process](#).

40.5.6.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] bit must be asserted
- The first CPU action must be the writing of abort code (0b1001) into the CODE field of the Control and Status word.

The active MBs configured as transmission must be aborted first and then they may be updated. If the abort code is written to a Mailbox that is currently being transmitted, or to a Mailbox that was already loaded into the SMB for transmission, the write operation is blocked and the MB is kept active, but the abort request is captured and kept pending until one of the following conditions are satisfied:

- The module loses the bus arbitration
- There is an error during the transmission
- The module is put into Freeze mode

- The module enters in BusOff state
- There is an overload frame

If none of the conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the IFLAG register, and an interrupt to the CPU is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. On the other hand, if one of the above conditions is reached, the frame is not transmitted; therefore, the abort code is written into the CODE field, the interrupt flag is set in the IFLAG, and an interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU just needs to read the abort code to make sure the active MB was *safely inactivated*. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

- CPU checks the corresponding IFLAG and clears it, if asserted.
- CPU writes 0b1001 into the CODE field of the C/S word.
- CPU waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.
- CPU reads the CODE field to check if the frame was either transmitted (CODE=0b1000) or aborted (CODE=0b1001).
- It is necessary to clear the corresponding IFLAG in order to allow the MB to be reconfigured.

40.5.6.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the Mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on Mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission Mailboxes must be performed just when MCR[AEN] bit is deasserted.

If a Mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See [Transmit process](#) and [Receive process](#) for more detailed instruction on how to inactivate and reactivate a Mailbox.

To inactivate a Mailbox, the CPU must update its CODE field to INACTIVE (either 0b0000 or 0b1000).

Because the user is not able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can lead to undesirable results:

- A frame in the bus that matches the filtering of the inactivated Rx Mailbox may be lost without notice, even if there are other Mailboxes with the same filter
- A frame containing the message within the inactivated Tx Mailbox may be transmitted without notice

In order to eliminate such risk and perform a *safe inactivation* the CPU must use the following mechanism along with the inactivation itself:

- For Tx Mailboxes, the Transmission Abort (see [Transmission abort mechanism](#))

The inactivation automatically unlocks the Mailbox (see [Mailbox lock mechanism](#)).

NOTE

Message Buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on the FIFO region by FlexCAN. CPU must maintain data coherency in the FIFO region when RFEN is asserted.

40.5.6.3 Mailbox lock mechanism

Other than Mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the Free Running Timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending-move and potentially may lose a received message. The MB locking is done to prevent a new frame to be written into the MB while the CPU is reading it.

NOTE

The locking mechanism applies only to Rx MBs that are not part of FIFO and have a code different than INACTIVE

(0b0000) or EMPTY¹ (0b0100). Also, Tx MBs can not be locked.

Suppose, for example, that the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no "free-to-receive" MBs, so it decides to override MB number 5. However, this MB is locked, so the new message can not be written there. It will remain in the SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

Note

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see Section "Free Running Timer Register (TIMER)"), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see [Modes of operation](#)) and it will take place only when the module resumes to Normal or Freeze modes.

1. In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

40.5.7 Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting the MCR[RFEN] bit. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature. The FIFO is 6-message deep. The memory region occupied by the FIFO structure (both Message Buffers and FIFO engine) is described in [Rx FIFO structure](#). The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a Message Buffer structure at the output of the FIFO.

The IFLAG[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the FIFO as a Message Buffer) and the RXFIR register and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and update the RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the FIFO is only valid whilst the IFLAG[BUF5I] is asserted.

The IFLAG[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

The IFLAG[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN] setting, that can be configured to one of the following formats (see also [Rx FIFO structure](#)):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

Note

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can be read by accessing the RXFIR register. The RXFIR[IDHIT] field refers to the message at the output of the FIFO and is valid while the IFLAG[BUF5I] flag is asserted. The RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (RXIMRx), according to the setting of CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If the IRMQ bit is negated, then the FIFO filter table is affected by RXFGMASK.

40.5.8 CAN protocol related features

This section describes the CAN protocol related features.

40.5.8.1 Remote frames

Remote frame is a special kind of frame. The user can program a mailbox to be a Remote Request Frame by writing the mailbox as Transmit with the RTR bit set to '1'. After the remote request frame is transmitted successfully, the mailbox becomes a Receive Message Buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on Remote Request Storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]) bits:

- If RRS is negated the frame's ID is compared to the IDs of the Transmit Message Buffers with the CODE field 0b1010. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame was received and matched a mailbox, this message buffer

immediately enters the internal arbitration process, but is considered as normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.

- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0b0100, 0b0010 or 0b0110. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the CPU. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote Request Frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

40.5.8.2 Overload frames

FlexCAN does transmit overload frames due to detection of following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

40.5.8.3 Time stamp

The value of the Free Running Timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of "move-in" in the TIME STAMP field, providing network behavior with respect to time.

The Free Running Timer can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in the description of the Control 1 Register (CTRL1).

40.5.8.4 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source bit CLKSRC in the CTRL1 Register defines whether the internal clock is connected to the output of a crystal oscillator (Oscillator Clock) or to the Peripheral Clock. In order to guarantee reliable operation, the clock source should be selected while the module is in Disable Mode (bit MDIS set in the Module Configuration Register).

Figure 40-92. CAN engine clocking scheme

The oscillator clock should be selected whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The oscillator clock has better jitter performance.

The FlexCAN module supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The Control Register has various fields used to control bit timing parameters: PRES DIV, PROPSEG, PSEG1, PSEG2 and RJW. See the description of the Control 1 Register (CTRL1).

The PRES DIV field controls a prescaler that generates the Serial Clock (Sclock), whose period defines the 'time quantum' used to compose the CAN waveform. A time quantum is the atomic unit of time handled by the CAN engine.

$$f_{Tq} = \frac{f_{CANCLK}}{(\text{Prescaler Value})}$$

A bit time is subdivided into three segments² (see [Figure 40-93](#) and [Table 40-106](#)):

- SYNC_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section

2. For further explanation of the underlying concepts, see ISO/DIS 11519–1, Section 10.3. See also the CAN 2.0A/B protocol specification for bit timing.

- Time Segment 1: This segment includes the Propagation Segment and the Phase Segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CTRL1 Register so that their sum (plus 2) is in the range of 4 to 16 time quanta
- Time Segment 2: This segment represents the Phase Segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CTRL1 Register (plus 1) to be 2 to 8 time quanta long

Figure 40-93. Segments within the bit time

Whenever CAN bit is used as a measure of duration (for example, MCR[FRZACK] and MCR[LPMACK]), the number of peripheral clocks in one CAN bit can be calculated as:

$$NCCP = \frac{f_{SYS} \times [1 + (PSEG1 + 1) + (PSEG2 + 1) + (PROPSEG + 1)] \times (PRES DIV + 1)}{f_{CANCLK}}$$

where:

- NCCP is the number of peripheral clocks in one CAN bit;
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure "CAN Engine Clocking Scheme"), in Hz;
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz;
- PSEG1 is the value in CTRL1[PSEG1] field;
- PSEG2 is the value in CTRL1[PSEG2] field;

- PROPSEG is the value in CTRL1[PROPSEG] field;
- PRESDIV is the value in CTRL1[PRESDIV] field.

For example, 180 CAN bits = 180 x NCCP peripheral clock periods.

Table 40-106. Time segment syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
Transmit Point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample Point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The following table gives an overview of the CAN compliant segment settings and the related parameter values.

Table 40-107. Bosch CAN 2.0B standard compliant bit time segment settings

Time segment 1	Time segment 2	Re-synchronization jump width
5 .. 10	2	1 .. 2
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

Note

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1). For bit time calculations, use an IPT (Information Processing Time) of 2, which is the value implemented in the FlexCAN module.

40.5.8.5 Arbitration and matching timing

During normal reception and transmission of frames, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

Figure 40-94. Matching and move-in time windows

Figure 40-95. Arbitration and move-out time windows

Figure 40-96. Arbitration at the end of bus off and move-out time windows

NOTE

The matching and arbitration timing shown in the preceding figures do not take into account the delay caused by the concurrent memory access due to the CPU or other internal FlexCAN sub-blocks.

When doing matching and arbitration, FlexCAN needs to scan the whole Message Buffer memory during the available time slot. In order to have sufficient time to do that, the following requirements must be observed:

- A valid CAN bit timing must be programmed, as indicated in [Table 40-107](#)
- The peripheral clock frequency can not be smaller than the oscillator clock frequency, see [Clock domains and restrictions](#)
- There must be a minimum ratio between the peripheral clock frequency and the CAN bit rate, as specified in the following table:

Table 40-108. Minimum ratio between peripheral clock frequency and CAN bit rate

Number of Message Buffers	RFEN	Minimum number of peripheral clocks per CAN bit
16 and 32	0	16
64	0	25
16	1	16
32	1	17
64	1	30

A direct consequence of the first requirement is that the minimum number of time quanta per CAN bit must be 8, therefore the oscillator clock frequency should be at least 8 times the CAN bit rate. The minimum frequency ratio specified in the preceding table can be achieved by choosing a high enough peripheral clock frequency when compared to the oscillator clock frequency, or by adjusting one or more of the bit timing parameters (PRES DIV, PROPSEG, PSEG1, PSEG2) contained in the Control 1 Register (CTRL1).

In case of synchronous operation (when the peripheral clock frequency is equal to the oscillator clock frequency), the number of peripheral clocks per CAN bit can be adjusted by selecting an adequate value for PRES DIV in order to meet the requirement in the preceding table. In case of asynchronous operation (the peripheral clock frequency greater than the oscillator clock frequency), the number of peripheral clocks per CAN bit can be adjusted by both PRES DIV and/or the frequency ratio.

As an example, taking the case of 64 MBs, if the oscillator and peripheral clock frequencies are equal and the CAN bit timing is programmed to have 8 time quanta per bit, then the prescaler factor (PRES DIV + 1) should be at least 2. For prescaler factor equal to one and CAN bit timing with 8 time quanta per bit, the ratio between peripheral and oscillator clock frequencies should be at least 2.

40.5.9 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The Bus Domain feeds the Control Host Interface (CHI) submodule and is derived from the peripheral clock.
- The Oscillator Domain feeds the CAN Protocol Engine (PE) submodule and is derived directly from a crystal oscillator clock, so that very low jitter performance can be achieved on the CAN bus.

When CTRL1[CLKSRC] bit is set, synchronous operation occurs because both domains are connected to the peripheral clock (creating a 1:1 ratio between the peripheral and oscillator domain clocks).

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the Bus Domain clock frequency must always be greater than the Oscillator Domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

40.5.10 Modes of operation details

The FlexCAN module has functional modes and low-power modes. See [Modes of operation](#) for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

CAUTION

“Permanent Dominant” failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a “Permanent Dominant”, the corresponding acknowledge can never be asserted.

40.5.10.1 Freeze mode

This mode is requested by the CPU through the assertion of the HALT bit in the MCR Register or when the chip is put into Debug mode. In both cases it is also necessary that the FRZ bit is asserted in the MCR Register and the module is not in a low-power mode. The acknowledgement is obtained through the assertion by the FlexCAN of FRZ_ACK bit in the same register. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off or Idle state
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.

- Ignores the Rx input pin and drives the Tx pin as recessive
- Stops the prescaler, thus halting all CAN protocol activities
- Grants write access to the Error Counters Register, which is read-only in other modes
- Sets the NOT_RDY and FRZ_ACK bits in MCR

After requesting Freeze mode, the user must wait for the FRZ_ACK bit to be asserted in MCR before executing any other action, otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory mapped registers are accessible, except for CTRL1[CLK_SRC] bit that can be read but cannot be written.

Exiting Freeze mode is done in one of the following ways:

- CPU negates the FRZ bit in the MCR Register
- The chip is removed from Debug Mode and/or the HALT bit is negated

The FRZ_ACK bit is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

40.5.10.2 Module Disable mode

This low power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of the MDIS bit in the MCR Register and the acknowledgement is obtained through the assertion by the FlexCAN of the LPM_ACK bit in the same register. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI sub-modules, sets the LPM_ACK bit and negates the FRZ_ACK bit.

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive

- Shuts down the clocks to the PE and CHI sub-modules
- Sets the NOTRDY and LPMACK bits in MCR

The Bus Interface Unit continues to operate, enabling the CPU to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Disable Mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPM_ACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

40.5.10.3 Doze mode

This is a system low power mode in which the CPU bus is kept alive and a global Doze mode request is sent to all peripherals asking them to enter low-power mode. When Doze mode is globally requested, the DOZE bit in MCR Register needs to have been asserted previously for Doze mode to be triggered. The acknowledgement is obtained through the assertion by the FlexCAN of the LPMACK bit in the same register. The CPU must only consider the FlexCAN in Doze mode when both request and acknowledgement conditions are satisfied.

If Doze mode is triggered during Freeze mode, FlexCAN requests to shut down the clocks to the PE and CHI sub-modules, sets the LPMACK bit and negates the FRZACK bit. If Doze Mode is triggered during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Shuts down the clocks to the PE and CHI sub-modules
- Sets the NOTRDY and LPMACK bits in MCR

The Bus Interface Unit continues to operate, enabling the CPU to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Doze Mode.

Exiting Doze mode is done in one of the following ways:

- CPU removing the Doze mode request
- CPU negating the DOZE bit of the MCR Register

40.5.10.4 Stop mode

This is a system low-power mode in which all chip clocks can be stopped for maximum power savings. The Stop mode is globally requested by the CPU and the acknowledgement is obtained through the assertion by the FlexCAN of a Stop Acknowledgement signal. The CPU must only consider the FlexCAN in Stop mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it sets the LPMACK bit, negates the FRZACK bit and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally.

If Stop mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Sets the NOTRDY and LPMACK bits in MCR
- Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Stop mode is exited when the CPU resumes the clocks and removes the Stop Mode request.

After the CAN protocol engine recognizes the negation of the Stop mode request, the FlexCAN negates the LPMACK bit. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up.

40.5.11 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Error, ECC Host Access Non-correctable Error, ECC FlexCAN Access Non-correctable Error, ECC Correctable Error, Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has assigned a flag bit in the IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes it to 1 (unless another interrupt is generated at the same time).

Note

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled ($\text{MCR}[\text{RFEN}] = 1$), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 7 of IFLAG1 becomes the "FIFO Overflow" flag; bit 6 becomes the FIFO Warning flag, bit 5 becomes the "Frames Available in FIFO flag," and bits 4-0 are unused. See the description of IFLAG1 for more information.

For a combined interrupt where multiple MB interrupt sources are ORed together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which MB or FIFO source caused the interrupt.

The interrupt sources for Bus Off, Error, Tx Warning, and Rx Warning generate interrupts like the MB interrupt sources, and they can be read from ESR1 and ESR2. The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in CTRL1.

The interrupt sources for ECC errors—Host Access with Non-correctable Interrupt Flag, FlexCAN Access with Non-correctable Interrupt Flag, and Correctable Error Interrupt Flag—can be read in ERRSR and the corresponding interrupts masks bits are located in MECR.

40.5.12 Bus interface

The CPU access to FlexCAN registers are subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in Table "Module Memory Map" in Supervisor Mode or with S only) results in access error.
- Read and write access to implemented reserved address space results in access error.
- Write access to positions whose bits are all currently read-only results in access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. Refer to register and bit descriptions for details.
- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power Mode results in access error.
- If MAXMB is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN is configured with 16 MBs, RFFN is 0x0, and MAXMB is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0x0080, and the space from 0x0080 to 0x008F is used by the one MB. The memory space from 0x0090 to 0x017F is available. The space between 0x0180 and 0x087F is reserved. The space from 0x0880 to 0x0883 is used by the one Individual Mask and the available memory in the Mask Registers space would be from 0x0884 to 0x08BF. From 0x08C0 through 0x09DF there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.

40.5.13 Detection and Correction of Memory Errors

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to 5 parity bits and the error correction mechanism assures that in this 13-bit word, errors in one bit can be corrected (corrected errors) and errors in 2 bits can be detected but not corrected (non-corrected errors). Errors in more than 2 bits may not be detected. When read, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

Memory errors are indicated to Host through status register (Error Status Register (ERRSR)) and bus transfer errors, and reported through report registers (Error Report Address Register (RERRAR), Error Report Data Register (RERRDR) and Error Report Syndrome Register (RERRSYNR)).

The error detection and correction mechanism can be activated or not, controlled by ECCDIS bit in Memory Error Control Register (MECR). When disabled, updates on indications and reporting registers are stopped, but the parity bits are still calculated and written along with data in memory write operations. It assures that memory has consistent parity bits associated to data.

NOTE

All FlexCAN memory must be initialized before starting its operation in order to have the parity bits in memory properly updated. The WRMFRZ bit in Control 2 Register (CTRL2) grants write access to all memory positions from 0x080 to 0xADF.

To avoid that critical error correction configuration be accidentally changed, this protocol must be followed to enable the update of the Memory Error Control Register (MECR):

1. By default, ECRWRE bit in Control 2 Register (CTRL2) is 0 and ECRWRDIS bit in Memory Error Control Register (MECR) is 1.
2. Set ECRWRE bit in Control 2 Register (CTRL2).
3. Clear ECRWRDIS bit.
4. All writes to Memory Error Control Register (MECR) must keep ECRWRDIS cleared.
5. After configuration is done, lock the Memory Error Control Register (MECR) by either setting ECRWRDIS or clearing ECRWRE.

40.5.13.1 Sources of the Memory Access

The FlexCAN memory can be accessed by 2 major sources (or requestors):

- by Host (CPU): largest word accessed is 32-bit wide
- by FlexCAN internal processes (Match, Arbitration, RxMove on reception, TxMove on transmission): largest word accessed is 64-bit wide

The way that non-correctable errors are indicated and reported depends on the source of access.

40.5.13.2 Error Indication

Memory errors are indicated by flags HANCEIF, FANCEIF, CEIF in the Error Status Register (ERRSR). Non-correctable errors detected in memory reads requested by Host are indicated separately than the ones detected in requests by FlexCAN internal processes. Corrected errors indication makes no distinction of the source of the access. There are 3 independent flags for these 3 cases, and each flag will raise an interrupt unless it is masked by mask bits in Memory Error Control Register (MECR). If both non-corrected and corrected errors are found in different bytes in the same read operation both flags are set.

The non-corrected error detected in Host accesses are also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If the flag bit HANCEIF is not masked, the same non-corrected error will raise a bus transfer error and an interrupt request.

Each indication flag has one Overrun flag in Error Status Register (ERRSR). The Overrun flags do not request interrupts. Overrun flags for non-correctable errors indicate that other errors of the same nature were detected after current error being treated, while overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated. This is the recommended handling sequence for error indication:

1. Get error report information from report registers
2. Use this information to take proper measures in the application
3. Clear the Interrupt flag
4. If the Overrun flag is active:
 - a. Alert application that at least one error could not be handled
 - b. Clear the Overrun flag

The FlexCAN internal processes can access memory in transactions larger than 32-bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in 2 or more 32-bit words the Interrupt and Overrun flags are set simultaneously.

40.5.13.3 Error Reporting

Report registers Error Report Address Register (RERRAR), Error Report Data Register (RERRDR) and Error Report Syndrome Register (RERRSYNR) provide detailed information about the address read, raw data and syndrome read with error and indicated by the flags described in the “Error Indication” section. The address, data and syndrome registers are updated simultaneously along with the error flags, according to these rules.

1. If any of the 2 non-corrected error flags is currently set, does not update the registers (preserve the old non-corrected error reporting)
2. Else (no error flag is currently set or only the corrected error flag is currently set), update the report registers according to the new error; or according to the most severe of new errors if non-corrected and corrected errors are simultaneously detected

Reporting of errors detected in accesses larger than 32-bit follows the semantic described in the “Error Indication” section and in the Error Report Address Register (RERRAR) description.

The address reported in RERRAR and defined in ERRIAR are not the same listed in the module memory map. How the reported addresses correspond to locations in the module memory map is shown in the Error Injection Address Register (ERRIAR) description.

Addresses reported when reading memory portions organized as FIFOs, such as the Rx FIFO Structure and the Rx FIFO Information Register (RXFIR), refer to the address of the element accessed in the FIFO, not to the FIFO base address.

To assure coherence of the error report registers it is necessary to turn off the report update by clearing the MECCR[RERRDIS] bit before reading the report registers.

40.5.13.4 Response to Errors

Correctable errors have no consequence on FlexCAN operation, once the corrected data is used by Host or FlexCAN internal processes. For host-initiated reads, a non-corrected error detected does not affect FlexCAN operation.

Non-corrected errors detected on memory reads requested by FlexCAN do not stop the FlexCAN processing and this may result in incorrect operation.

If a non-corrected error occurs during a reception process (Match or RxMove), an incorrect destination may be selected to store the incoming frame, a corrupted frame may be stored in the correct destination, or both. If a non-corrected error occurs during either

an Arbitration or a TxMove process, either a non-highest priority frame may be mistakenly selected to be transmitted or no frame may be transmitted at all, when $\text{MECR}[\text{NCEFAFRZ}] = 1$.

The error report registers can provide information to the application for a customized handling of these situations. If the delay of this handling is not accepted and $\text{MECR}[\text{NCEFAFRZ}] = 1$, the FlexCAN stops operation automatically and enters Freeze mode when these errors are detected. See the Memory Error Control Register (MECR) description for more details.

40.5.13.5 Error Injection

The error injection registers ERRIAR , ERRIDPR , and ERRIPPR are used to inject errors in memory reads in order to force errors and consequently update the indication and reporting registers. How the error injection addresses correspond to locations in the module memory map is shown in the ERRIAR description.

The injection is done by flipping the data and parity bits correspondent to the bits in 1 in ERRIDPR and ERRIPPR . Injection can be selected specifically for memory accesses requested by Host or by FlexCAN internal processes.

In case of accesses larger than 32-bits, the EXTERRIE bit in Memory Error Control Register (MECR) extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

NOTE

It is very unlikely, but error injection may correct a bit with error. This will not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, the HAERRIE and FAERRIE bits in Memory Error Control Register (MECR) must be cleared while configuring the memory injection registers.

40.6 Initialization/application information

This section provide instructions for initializing the FlexCAN module.

40.6.1 FlexCAN initialization sequence

The FlexCAN module may be reset as follows:

- Chip level hard reset, which resets all memory mapped registers asynchronously
- SOFTRST bit in MCR, which resets some of the memory mapped registers synchronously. See [Table 40-2](#) to see what registers are affected by soft reset.

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. The SOFTRST bit remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset can not be applied while clocks are shut down in a low power mode. The low power mode should be exited and the clocks resumed before applying soft reset.

The clock source (CLKSRC bit) should be selected while the module is in Disable mode. After the clock source is selected and the module is enabled (MDIS bit negated), FlexCAN automatically goes to Freeze mode. In Freeze mode, FlexCAN is unsynchronized to the CAN bus, the HALT and FRZ bits in MCR Register are set, the internal state machines are disabled and the FRZACK and NOTRDY bits in the MCR Register are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Note that the Message Buffers and the Rx Individual Mask Registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FlexCAN is put into Freeze mode; see [Freeze mode](#). The following is a generic initialization sequence applicable to the FlexCAN module:

- Initialize the Module Configuration Register
 - Enable the individual filtering per MB and reception queue features by setting the IRMQ bit
 - Enable the warning interrupts by setting the WRNEN bit
 - If required, disable frame self reception by setting the SRXDIS bit
 - Enable the Rx FIFO by setting the RFEN bit
 - Enable the abort mechanism by setting the AEN bit
 - Enable the local priority feature by setting the LPRIOEN bit
- Initialize the Control Register
 - Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW

- Determine the bit rate by programming the PRESDIV field
- Determine the internal arbitration mode (LBUF bit)
- Initialize the Message Buffers
 - The Control and Status word of all Message Buffers must be initialized
 - If Rx FIFO was enabled, the ID filter table must be initialized
 - Other entries in each Message Buffer should be initialized as required
- Initialize the Rx Individual Mask Registers
- When ECC is enabled, follow the initialization note in [Detection and Correction of Memory Errors](#)
- Set required interrupt mask bits in the IMASK Registers (for all MB interrupts) and in CTRL Register (for Bus Off and Error interrupts)
- Negate the HALT bit in MCR

Starting with the last event, FlexCAN attempts to synchronize to the CAN bus.

Chapter 41

Modular CAN (M_CAN)

41.1 Chip-specific M_CAN information

41.1.1 M_CAN Message RAM allocation

On this chip, each M_CAN instance can address 1216 words in the Message RAM.

As a result, the Message RAM shared by the two M_CAN instances supports 2432 words, or 9.5 KB.

41.1.2 Introduction

The M_CAN subsystem includes:

- Two M_CAN modules
- A Message RAM controller

The M_CAN subsystem block diagram is shown in the following figure.

Figure 41-1. M_CAN subsystem block diagram

41.1.3 Functional Description

41.1.3.1 Message RAM Controller

The Message RAM Controller has the arbiter for the accesses to the external Message RAM and the ECC (Error Code Correction) Controller for the external Message RAM data.

41.1.3.1.1 Message RAM Arbiter

The Message RAM Arbiter is a dynamic round robin arbiter that selects which request is sent to the external Message RAM. These requests are made by the CPU, M_CAN_0, or M_CAN_1.

This arbiter ensures:

- 50% bandwidth for CPU accesses to the external Message RAM. The CPU does not wait for more than one clock cycle to access the external Message RAM (see examples 1 and 3).
- 50% bandwidth is shared between M_CAN_0 and M_CAN_1 accesses to the external Message RAM. Each M_CAN waits at least one clock cycle to access the external Message RAM (see examples 1, 2, and 3).
- If there is no CPU request, all bandwidth is distributed to M_CAN_0 and M_CAN_1 (see example 2).
- If there are no M_CAN_0 and M_CAN_1 requests, all bandwidth is distributed to the CPU.
- If there are requests from only one M_CAN, the other M_CAN's bandwidth is distributed to the first M_CAN (see example 1).

The following examples illustrate the dynamic arbiter scheme.

- **Example 1:** The following figure shows who accesses the external Message RAM when only CPU and M_CAN_0 try to access to it.

- **Example 2:** The following figure shows who accesses the external Message RAM when only M_CAN_0 and M_CAN_1 try to access to it.

- **Example 3:** The following figure shows who accesses the external Message RAM when the CPU, M_CAN_0, and M_CAN_1 try to access to it.

The read or write accesses to the external Message RAM use two clock cycles. In the first clock cycle, the address is available, and in the second, the data is available.

The arbiter has a pseudo address pre-fetching mechanism that allows the data of the previous access to overlap with the address of the current access. The pseudo address pre-fetching scheme saves multiple clock cycles when there are multiples accesses to the external Message RAM.

41.1.3.1.2 ECC Controller

The ECC Controller provides Single Error Correction / Double Error Detection (SECEDED). It guarantees single bit error correction and double bit error detection (without correction). The SECEDED code is not guaranteed to detect more than two bits with error.

Each 32 data bits of the external Message RAM is associated with 7 ECC bits. If all these 39 bits are zero or one, then it is flagged as non-correctable error.

For writes to the external Message RAM, the ECC bits (7-bit) are calculated using the data bits (32-bit). The data bits plus ECC bits (39-bit) are written into the specified memory address. The error detection and correction are performed on the reads from the external Message RAM.

When an M_CAN accesses the external Message RAM, the ECC bits are calculated by the ECC Controller and they are sent to this M_CAN.

41.1.3.2 External Message RAM

The external Message RAM supports only 32-bit write and read accesses.

The CPU can access the external Message RAM through the M_CAN subsystem. In this case, the CPU can do 8/16/32-bit read accesses to the external Message RAM.

41.1.3.3 Transfer Error

The M_CAN subsystem does not report any transfer error.

41.1.4 External Signals

The M_CAN subsystem external signals are shown in the following table.

Table 41-1. M_CAN subsystem external signals

Signal name	Direction	Description
M_CAN_0_Rx	input	M_CAN_0 CAN Rx signal
M_CAN_0_Tx	output	M_CAN_0 CAN Tx signal
M_CAN_1_Rx	input	M_CAN_1 CAN Rx signal
M_CAN_1_Tx	output	M_CAN_1 CAN Tx signal

41.2 Overview

The M_CAN module is the new CAN Communication Controller IP-module that can be integrated as stand-alone device or as part of an ASIC. It is described in VHDL on RTL level, prepared for synthesis. The M_CAN performs communication according to ISO11898-1 (Bosch CAN specification 2.0 part A,B) and to Bosch CAN FD specification V1.0. Additional transceiver hardware is required for connection to the physical layer.

The message storage is intended to be a single- or dual-ported Message RAM outside of the module. It is connected to the M_CAN via the Generic Master Interface. Depending on the chosen ASIC integration, multiple M_CAN controllers can share the same Message RAM.

All functions concerning the handling of messages are implemented by the Rx Handler and the Tx Handler. The Rx Handler manages message acceptance filtering, the transfer of received messages from the CAN Core to the Message RAM as well as providing receive message status information. The Tx Handler is responsible for the transfer of transmit messages from the Message RAM to the CAN Core as well as providing transmit status information.

Acceptance filtering is implemented by a combination of up to 128 filter elements where each one can be configured as a range, as a bit mask, or as a dedicated ID filter.

The M_CAN can be connected to a wide range of Host CPUs via its 8/16/32-bit Generic Slave Interface. The M_CAN's clock domain concept allows the separation between the high precision CAN clock and the Host clock, which may be generated by an FM-PLL.

41.2.1 Features

The following are the features of M_CAN.

- Conforms with CAN protocol version 2.0 part A, B and ISO 11898-1

- CAN FD with up to 64 data bytes supported
- CAN Error Logging
- AUTOSAR support
- SAE J1939 support
- Improved acceptance filtering
- Two configurable Receive FIFOs
- Separate signalling on reception of High Priority Messages
- Up to 64 dedicated Receive Buffers
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO
- Configurable Transmit Queue
- Configurable Transmit Event FIFO
- Direct Message RAM access for Host CPU
- Multiple M_CANs may share the same Message RAM
- Programmable loop-back test mode
- Maskable module interrupts
- 8/16/32 bit Generic Slave Interface for connection customer-specific Host CPUs
- Two clock domains (CAN clock and Host clock)
- Power-down support
- Debug on CAN support

41.2.2 Block Diagram

Figure 41-2. M_CAN Block Diagram

- **CAN Core:** CAN Protocol Controller and Rx/Tx Shift Register. Handles all ISO 11898-1 protocol functions. Supports 11-bit and 29-bit identifiers.
- **Sync:** Synchronizes signals from the Host clock domain to the CAN clock domain and vice versa.
- **Clk:** Synchronizes reset signal to the Host clock domain and to the CAN clock domain.
- **Cfg and Ctrl:** CAN Core related configuration and control bits.
- **Interrupt and Timestamp:** Interrupt control and 16-bit CAN bit time counter for receive and transmit timestamp generation.
- **Tx Handler:** Controls the message transfer from the external Message RAM to the CAN Core. A maximum of 32 Tx Buffers can be configured for transmission. Tx buffers can be used as dedicated Tx Buffers, as Tx FIFO, part of a Tx Queue, or as a combination of them. A Tx Event FIFO stores Tx timestamps together with the corresponding Message ID. Transmit cancellation is also supported.

- **Rx Handler:** Controls the transfer of received messages from the CAN Core to the external Message RAM. The Rx Handler supports two Receive FIFOs, each of configurable size, and up to 64 dedicated Rx Buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx Buffer, in contrast to a Receive FIFO, is used to store only messages with a specific identifier. An Rx timestamp is stored together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs.
- Connects the M_CAN to a customer specific Host CPU. The Generic Slave Interface is capable to connect to an 8/16/32-bit bus to support a wide range of interconnection structures.
- **Generic Master Interface:** Connects the M_CAN access to an external 32-bit Message RAM. The maximum Message RAM size is 16 KB × 32-bit. A single M_CAN can use at most 4.25K × 32 bit.
- All flags from the Interrupt Register IR as well as selected internal status and control signals are routed to this interface. The interface is intended for connection of the M_CAN to a module-external interrupt unit or to other module-external components. The connection of these signals is optional.

41.2.3 Dual Clock Sources

To improve the EMC behavior, a spread spectrum clock can be used for the Host clock domain. Due to the high precision clocking requirements of the CAN Core, a separate clock without any modulation has to be provided as CAN clock.

Within the M_CAN module there is a synchronization mechanism implemented to ensure save data transfer between the two clock domains.

Note

In order to achieve a stable function of the M_CAN, the Host clock must always be faster than or equal to the CAN clock. Also, the modulation depth of a spread spectrum clock has to be regarded.

41.2.4 Dual Interrupt Lines

The module provides two interrupt lines. Interrupts can be routed either to M_CAN interrupt 0 or to M_CAN interrupt 1. By default all interrupts are routed to interrupt line M_CAN interrupt 0. By programming ILE[EINT0] and ILE[EINT1], the interrupt lines can be enabled or disabled separately.

41.3 Memory Map and Register Description

After hardware reset, the registers of the M_CAN hold the reset values listed in Table 1. Additionally the Bus_Off state is reset and the output M_CAN Tx is set to recessive (HIGH). The value 0x0001 (CCCR[INIT] = 1) in the CC Control Register enables software initialization. The M_CAN does not influence the CAN bus until the CPU resets CCCR[INIT] to 0.

The M_CAN module allocates an address space of 256 bytes. All registers are organized as 32-bit registers. The M_CAN is accessible by the Host CPU via the Generic Slave Interface using a data width of 8 bit (byte access), 16 bit (half-word access), or 32 bit (word access). Write access by the Host CPU to registers/bits marked with “P=Protected Write” is possible only with CCCR[CCE]=1 AND CCCR[INIT]=1. There is a delay from writing to a command register until the update of the related status register bits due to clock domain crossing.

CAUTION

In case the application software wants to access one of the reserved addresses in the M_CAN register map (read or write access), interrupt flag IR[ARA] is set, and if enable the interrupt is signalled via the assigned interrupt line (m_can_int0 or m_can_int1).

M_CAN memory map

M_CAN_ENDN field descriptions

Field	Description
0–31 ETV	Endianness Test Value The endianness test value is 0x87654321.

41.3.3 Data Bit Timing and Prescaler Register (M_CAN_DBTP)

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN bit time may be programmed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 m_can_cclk periods. $t_q = (DBRP + 1) \text{ mtq}$.

DTSEG1 is the sum of Prop_Seg and Phase_Seg1. DTSEG2 is Phase_Seg2.

Therefore the length of the bit time is (programmed values) $[DTSEG1 + DTSEG2 + 3] t_q$ or (functional values) $[Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2] t_q$.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

NOTE

With a M_CAN clock of 8 MHz, the reset value of 0x00000A33 configures the M_CAN for a data phase bit rate of 500 kBit/s.

NOTE

The bit rate configured for the CAN FD data phase via DBTP must be higher or equal to the bit rate configured for the arbitration phase via NBTP.

Address: 0h base + Ch offset = Ch

M_CAN_DBTP field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 TDC	Transceiver Delay Compensation NOTE: This field has Protected Write status. 0 Transceiver Delay Compensation disabled 1 Transceiver Delay Compensation enabled

Table continues on the next page...

M_CAN_DBTP field descriptions (continued)

Field	Description
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 DBRP	Data Bit Rate Prescaler NOTE: This field has Protected Write status. 0x0-0x1F The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Bit Rate Prescaler are 0 to 31. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 DTSEG1	Data time segment before sample point NOTE: This field has Protected Write status. 0x0-0x1F Valid values are 0 to 31. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
24–27 DTSEG2	Data time segment after sample point NOTE: This field has Protected Write status. 0x0-0xF Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
28–31 DSJW	Data (Re)Synchronization Jump Width NOTE: This field has Protected Write status. 0x0-0xF Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

41.3.4 Test Register (M_CAN_TEST)

Write access to the Test Register has to be enabled by setting bit CCCR[TEST] to 1. All Test Register functions are set to their reset values when bit CCCR[TEST] is reset.

Loop Back Mode and software control of pin M_CAN_Tx are hardware test modes. Programming of TX other than 00 may disturb the message transfer on the CAN bus.

Address: 0h base + 10h offset = 10h

Field	Description
	0 Reset value, Loopback mode is disabled
	1 Loopback mode is enabled (see Test Modes)
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

41.3.5 RAM Watchdog Register (M_CAN_RWD)

The RAM Watchdog monitors the READY output of the Message RAM. A Message RAM access via the M_CAN's Generic Master Interface starts the Message RAM Watchdog Counter with the value configured by RWD[WDC]. The counter is reloaded with RWD[WDC] when the Message RAM signals successful completion by activating its READY output. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag IR[WDI] is set. The RAM Watchdog Counter is clocked by the Host clock.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

M_CAN_CCCR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 NISO	Non ISO Operation If this bit is set, the M_CAN uses the CAN FD frame format as specified by the Bosch CAN FD Specification V1.0. NOTE: This field has Protected Write status. 0 CAN FD frame format according to ISO11898-1 1 CAN FD frame format according to Bosch CAN FD Specification V1.0
17 TXP	Transmit Pause If this bit is set, the M_CAN pauses for two CAN bit times before starting the next transmission after itself has successfully transmitted a frame (see Tx Handling). NOTE: This field has Protected Write status.

Table continues on the next page...

M_CAN_CCCR field descriptions (continued)

Field	Description
	0 Transmit pause disabled 1 Transmit pause enabled
18 EFBI	Edge Filtering during Bus Integration NOTE: This field has Protected Write status. 0 Edge filtering disabled 1 Two consecutive dominant tq required to detect an edge for hard synchronization
19 PHDX	Protocol Exception Handling Disable NOTE: When protocol exception handling is disabled, the M_CAN will transmit an error frame when it detects a protocol exception condition. This field has Protected Write status. 0 Protocol exception handling enabled 1 Protocol exception handling disabled
20–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 BRSE	Bit Rate Switch Enable NOTE: When CAN FD operation is disabled FDOE = 0, BRSE is not evaluated. This field has Protected Write status. 0 Bit rate switching for transmissions disabled 1 Bit rate switching for transmissions enabled
23 FDOE	FD Operation Enable NOTE: This field has Protected Write status. 0 FD operation disabled 1 FD operation enabled
24 TEST	Test Mode Enable NOTE: This field has Protected Write status. 0 Normal operation, register TEST holds reset values 1 Test Mode, write access to register TEST enabled
25 DAR	Disable Automatic Retransmission NOTE: This field has Protected Write status. 0 Automatic retransmission of messages not transmitted successfully enabled 1 Automatic retransmission disabled
26 MON	Bus Monitoring Mode

Table continues on the next page...

M_CAN_CCCR field descriptions (continued)

Field	Description
	Bit MON can only be set by the Host when both CCE and INIT are set to '1'. The bit can be reset by the Host at any time. NOTE: This field has Protected Write status. 0 Bus Monitoring Mode is disabled 1 Bus Monitoring Mode is enabled
27 CSR	Clock Stop Request 0 No clock stop is requested 1 Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle.
28 CSA	Clock Stop Acknowledge 0 No clock stop acknowledged 1 M_CAN may be set in power down by stopping M_CAN input clocks.
29 ASM	Restricted Operation Mode Bit ASM can only be set by the Host when both CCE and INIT are set to '1'. The bit can be reset by the Host at any time. For a description of the Restricted Operation Mode see Restricted Operation Mode. 0 Normal CAN operation 1 Restricted Operation Mode active
30 CCE	Configuration Change Enable NOTE: This field has Protected Write status. 0 The CPU has no write access to the protected configuration registers. 1 The CPU has write access to the protected configuration registers (while CCCR[INIT] = 1)
31 INIT	Initialization NOTE: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value. 0 Normal Operation 1 Initialization is started

41.3.7 Nominal Bit Timing and Prescaler Register (M_CAN_NBTP)

This register is only writable if its CCCR[CCE] and CCCR[INIT] are set. The CAN bit time may be programmed in the range of 4 to 385 time quanta. The CAN time quantum may be programmed in the range of 1 to 512 m_can_cclk periods. $tq = (NBRP + 1) mtq$.

NTSEG1 is the sum of Prop_Seg and Phase_Seg1. NTSEG2 is Phase_Seg2.

Memory Map and Register Description

Therefore the length of the bit time is (programmed values) $[NTSEG1 + NTSEG2 + 3] t_q$ or (functional values) $[Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2] t_q$.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

NOTE

With a CAN clock of 8 MHz, the reset value of 0x06000A03 configures the M_CAN for a bit rate of 500 kBit/s.

Address: 0h base + 1Ch offset = 1Ch

M_CAN_NBTP field descriptions

Field	Description
0–6 NSJW	Nominal (Re) Synchronization Jump Width NOTE: This field has Protected Write status. 0x00-0x7F Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
7–15 NBRP	Nominal Baud Rate Prescaler NOTE: This field has Protected Write status. 0x000-0x1FF The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Bit Rate Prescaler are 0 to 511. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
16–23 NTSEG1	Nominal Time segment before sample point NOTE: This field has Protected Write status. 0x01-0xFF Valid values are 1 to 255. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 NTSEG2	Nominal Time segment after sample point NOTE: This field has Protected Write status.

Table continues on the next page...

M_CAN_NBTP field descriptions (continued)

Field	Description
0x00-0x7F	Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

41.3.8 Timestamp Counter Configuration Register (M_CAN_TSCC)

For description of the Timestamp Counter see [Timestamp Generation](#)

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0												TCP				0														TSS	
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

M_CAN_TSCC field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 TCP	Timestamp Counter Prescaler NOTE: This field has Protected Write status. NOTE: With CAN FD, timestamp generation is not supported. 0x0-0xF Configures the timestamp and timeout counters time unit in multiples of CAN bit times [1...16]. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
16–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 TSS	Timestamp Select NOTE: This field has Protected Write status. 00 Timestamp counter value always 0x0000 01 Timestamp counter value incremented according to TCP 10 Reserved 11 Same as 00

41.3.9 Timestamp Counter Value Register (M_CAN_TSCV)

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

M_CAN_TSCV field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TSC	Timestamp Counter The internal Timestamp Counter value is captured on start of frame (both Rx and Tx). When TSCC[TSS] = 01, the Timestamp Counter is incremented in multiples of CAN bit times [1...16] depending on the configuration of TSCC[TCP]. A wrap around sets interrupt flag IR[TSW]. Write access resets the counter to zero. NOTE: A "wrap around" is a change of the Timestamp Counter value from non-zero to zero not caused by write access to TSCV.

41.3.10 Timeout Counter Configuration Register (M_CAN_TOCC)

See [Timeout Counter](#) for description of the Timeout Counter or for use of timeout function with CAN FD.

Address: 0h base + 28h offset = 28h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	TOP															
W																
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

M_CAN_TOCC field descriptions

Field	Description
0–15 TOP	Timeout Period Start value of the Timeout Counter (down-counter). Configures the Timeout Period. NOTE: This field has Protected Write status.
16–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 TOS	Timeout Select When operating in Continuous mode, a write to TOCV presets the counter to the value configured by TOCC[TOP] and continues down-counting. When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Down-counting is started when the first FIFO element is stored. NOTE: This field has Protected Write status. 00 Continuous operation 01 Timeout controlled by Tx Event FIFO 10 Timeout controlled by Rx FIFO 0 11 Timeout controlled by Rx FIFO 1
31 ETOC	Enable Timeout Counte NOTE: This field has Protected Write status. 0 Timeout Counter disabled 1 Timeout Counter enabled

41.3.11 Timeout Counter Value Register (M_CAN_TOCV)

Address: 0h base + 2Ch offset = 2Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																TOC															
W																	w1c															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	

M_CAN_TOCV field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TOC	Timeout Counter The Timeout Counter is decremented in multiples of CAN bit times [1...16] depending on the configuration of TSSC[TCP]. When decremented to zero, interrupt flag IR[TOO] is set and the Timeout Counter is stopped. Start and reset/restart conditions are configured via TOCC[TOS]

41.3.12 Error Counter Register (M_CAN_ECR)

NOTE

When CCCR[ASM] is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0								CEL								
W									CEL								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	RP	REC							TEC								
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

M_CAN_ECR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 CEL	CAN Error Logging The counter is incremented each time when a CAN protocol error causes the Transmit Error Counter or the Receive Error Counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag IR[ELO].
16 RP	Receive Error Passive 0 The Receive Error Counter is below the error passive level of 128 1 The Receive Error Counter has reached the error passive level of 128
17–23 REC	Receive Error Counter Actual state of the Receive Error Counter, values between 0 and 127.
24–31 TEC	Transmit Error Counter Actual state of the Transmit Error Counter, values between 0 and 255.

41.3.13 Protocol Status Register (M_CAN_PSR)

NOTE

When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in DLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error.

NOTE

The Bus_Off recovery sequence (see CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting CCCR[INIT].

1. If the device goes Bus_Off, it sets CCCR[INIT] and PSR[BO], stopping all bus activities.
2. After the user clears CCCR[INIT], the user must then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before normal CAN operation can resume.
 - During the waiting period, each time the device monitors a sequence of 11 recessive bits, a Bit0Error code (101b) is written to PSR[LEC].
 - These code writes enable the user to check readily whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence.
 - ECR[REC] is used to count these sequences.
3. After the observation of the 129 occurrences of Bus Idle, the device clears PSR[BO].

Address: 0h base + 44h offset = 44h

M_CAN_PSR field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 TDCV	Transmitter Delay Compensation Value 0x00-0x7F Position of the secondary sample point, defined by the sum of the measured delay from M_CAN Tx to M_CAN Rx and TDCR[TDCO]. The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 PXE	Protocol Exception Event NOTE: This field is reset by a read operation. 0 No protocol exception event occurred since last read access 1 Protocol exception event occurred
18 RFDF	Received a CAN FD Message This bit is set independent of acceptance filtering. NOTE: This field is reset by a read operation. 0 Since this bit was reset by the CPU, no CAN FD message has been received 1 Message in CAN FD format with FDF flag set has been received
19 RBRS	BRS flag of last received CAN FD Message This bit is set together with RFDF, independent of acceptance filtering. NOTE: This field is reset by a read operation. 0 Last received CAN FD message did not have its BRS flag set 1 Last received CAN FD message had its BRS flag set
20 RESI	ESI flag of last received CAN FD Message This bit is set together with RFDF, independent of acceptance filtering. NOTE: This field is reset by a read operation. 0 Last received CAN FD message did not have its ESI flag set 1 Last received CAN FD message had its ESI flag set
21–23 DLEC	Data Phase Last Error Code Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error. NOTE: This field is set by a read operation.
24 BO	Bus_Off Status 0 The M_CAN is not Bus_Off 1 The M_CAN is in Bus_Off state

Table continues on the next page...

M_CAN_PSR field descriptions (continued)

Field	Description
25 EW	Warning Status 0 Both error counters are below the Error_Warning limit of 96 1 At least one of error counter has reached the Error_Warning limit of 96
26 EP	Error Passive 0 The M_CAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 1 The M_CAN is in the Error_Passive state
27–28 ACT	Activity Monitors the module's CAN communication state. NOTE: ACT is set to 00 by a Protocol Exception Event. 00 Synchronizing - node is synchronizing on CAN communication 01 Idle - node is neither receiver nor transmitter 10 Receiver - node is operating as receiver 11 Transmitter - node is operating as transmitter
29–31 LEC	Last Error Code The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to 0 when a message has been transferred (reception or transmission) without error. NOTE: This field is set by a read operation. 000 Error: No error occurred since LEC has been reset by successful reception or transmission 001 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed 010 Form Error: A fixed format part of a received frame has the wrong format 011 AckError: The message transmitted by the M_CAN was not acknowledged by another node. 100 Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value 1), but the monitored bus value was dominant. 101 Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 110 CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data. 111 NoChange: Any read access to the Protocol Status Register re-initializes the LEC to 7. When the LEC shows the value 7, no CAN bus event was detected since the last CPU read access to the Protocol Status Register.

41.3.14 Transmitter Delay Compensation Register (M_CAN_TDCR)

Address: 0h base + 48h offset = 48h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

M_CAN_TDCR field descriptions

Field	Description
0–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–23 TDCO	Transmitter Delay Compensation Offset. NOTE This field has Protected Write status. 0x00-0x7F Offset value defining the distance between the measured delay from M_CAN Tx to M_CAN Rx and the secondary sample point. Valid values are 0 to 127 mtq.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 TDCF	Transmitter Delay Compensation Filter Window Length. NOTE This field has Protected Write status. 0x00-0x7F Defines the minimum value for the SSP position, dominant edges on M_CAN Rx that would result in an earlier SSP position are ignored for transmitter delay measurement. The feature is enabled when TDCF is configured to a value greater than TDCO. Valid values are 0 to 127 mtq.

41.3.15 Interrupt Register (M_CAN_IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. Aflag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect. Ahard reset will clear the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signalled.

Address: 0h base + 50h offset = 50h

M_CAN_IR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 ARA	Access to Reserved Address 0 No access to reserved address occurred 1 Access to reserved address occurred
3 PED	Protocol Error in Data Phase 0 No protocol error in data phase 1 Protocol error in data phase detected (PSR[DLEC] not equal to 0,7)
4 PEA	Protocol Error in Arbitration Phase 0 No protocol error in arbitration phase 1 Protocol error in arbitration phase detected (PSR[LEC] not equal to 0,7)
5 WDI	Watchdog Interrupt 0 No Message RAM Watchdog event occurred 1 Message RAM Watchdog event due to missing READY
6 BO	Bus_Off Status

Table continues on the next page...

M_CAN_IR field descriptions (continued)

Field	Description
	0 Bus_Off status unchanged 1 Bus_Off status changed
7 EW	Warning Status 0 Error_Warning status unchanged 1 Error_Warning status changed
8 EP	Error Passive 0 Error_Passive status unchanged 1 Error_Passive status changed
9 ELO	Error Logging Overflow 0 CAN Error Logging Counter did not overflow 1 Overflow of CAN Error Logging Counter occurred
10 BEU	Bit Error Uncorrected Message RAM bit error detected, uncorrected. Controlled by an external ECC logic attached to the Message RAM. An uncorrected Message RAM bit error sets CCCR[INIT] to 1. This is done to avoid transmission of corrupted data. 0 No bit error detected when reading from Message RAM 1 Bit error detected, uncorrected (e.g. parity logic)
11 BEC	Bit Error Corrected Message RAM bit error detected and corrected. Controlled by an external parity ECC logic attached to the Message RAM. 0 No bit error detected when reading from Message RAM 1 Bit error detected and corrected (e.g. ECC)
12 DRX	Message stored to Dedicated Rx Buffer The flag is set whenever a received message has been stored into a dedicated Rx Buffer. 0 No Rx Buffer updated 1 At least one received message stored into a Rx Buffer
13 TOO	Timeout Occurred 0 No timeout 1 Timeout reached
14 MRAF	Message RAM Access Failure The flag is set, when the Rx Handler - has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx Handler starts processing of the following message. - was not able to write a message to the Message RAM. In this case message storage is aborted. In both cases the FIFO put index is not updated resp. the New Data flag for a dedicated Rx Buffer is not set, a partly stored message is overwritten when the next message is stored to this location.

Table continues on the next page...

M_CAN_IR field descriptions (continued)

Field	Description
	The flag is also set when the Tx Handler was not able to read a message from the Message RAM in time. In this case message transmission is aborted. In case of a Tx Handler access failure the M_CAN is switched into Restricted Operation Mode (see Restricted Operation Mode). To leave Restricted Operation Mode, the CPU has to reset CCCR[ASM]. 0 No Message RAM access failure occurred 1 Message RAM access failure occurred
15 TSW	Timestamp Wraparound 0 No timestamp counter wrap-around 1 Timestamp counter wrapped around
16 TEFL	Tx Event FIFO Element Lost 0 No Tx Event FIFO element lost 1 Tx Event FIFO element lost, also set after write attempt to Tx Event FIFO of size zero
17 TEFF	Tx Event FIFO Full 0 Tx Event FIFO not full 1 Tx Event FIFO full
18 TEFW	Tx Event FIFO Watermark Reached 0 Tx Event FIFO fill level below watermark 1 Tx Event FIFO fill level reached watermark
19 TEFN	Tx Event FIFO New Entry 0 Tx Event FIFO unchanged 1 Tx Handler wrote Tx Event FIFO element
20 TFE	Tx FIFO Empty 0 Tx FIFO non-empty 1 Tx FIFO empty
21 TCF	Transmission Cancellation Finished 0 No transmission cancellation finished 1 Transmission cancellation finished
22 TC	Transmission Completed 0 Transmission not completed 1 Transmission completed
23 HPM	High Priority Message 0 No high priority message received 1 High priority message received
24 RF1L	Rx FIFO 1 Message Lost 0 No Rx FIFO 1 message lost 1 Rx FIFO 1 message lost, also set after write attempt to Rx FIFO 1 of size zero
25 RF1F	Rx FIFO 1 Full

Table continues on the next page...

41.3.17 Interrupt Line Select Register (M_CAN_ILS)

The Interrupt Line Select register assigns an interrupt generated by a specific interrupt flag from the Interrupt Register to one of the two module interrupt lines. For interrupt generation the respective interrupt line has to be enabled via ILE[EINT0] and ILE[EINT1]

0 = Interrupt assigned to interrupt line 0

1 = Interrupt assigned to interrupt line 1

Address: 0h base + 58h offset = 58h

M_CAN_RXF1A field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 F1AI	Rx FIFO 1 Acknowledge Index After the CPU has read a message or a sequence of messages from Rx FIFO 1 it has to write the buffer index of the last element read from Rx FIFO 1 to F1AI. This will set the Rx FIFO 1 Get Index RXF1S[F1GI] to F1AI + 1 and update the FIFO 1 Fill Level RXF1S[F1FL].

41.3.33 Rx Buffer / FIFO Element Size Configuration Register (M_CAN_RXESC)

Configures the number of data bytes belonging to an Rx Buffer / Rx FIFO element. Data field sizes >8 bytes are intended for CAN FD operation only.

NOTE

In case the data field size of an accepted CAN frame exceeds the data field size configured for the matching Rx Buffer or Rx FIFO, only the number of bytes as configured by RXESC are stored to the Rx Buffer resp. Rx FIFO element. The rest of the frame's data field is ignored.

2–7 TFQS	Transmit FIFO/Queue Size NOTE: This field has Protected Write status. 0 No Tx FIFO/Queue 1–32 Number of Tx Buffers used for Tx FIFO/Queue >32 Values greater than 32 are interpreted as 32
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

M_CAN_TXBC field descriptions (continued)

Field	Description
10–15 NDTB	Number of Dedicated Transmit Buffers NOTE: This field has Protected Write status. 0 No Dedicated Tx Buffers 1–32 Number of Dedicated Tx Buffers >32 Values greater than 32 are interpreted as 32
16–29 TBSA	Tx Buffers Start Address Start address of Tx Buffers section in Message RAM (32-bit word address, see Message RAM). NOTE: This field has Protected Write status.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

41.3.35 Tx FIFO/Queue Status Register (M_CAN_TXFQS)

The Tx FIFO/Queue status is related to the pending Tx requests listed in register TXBRP. Therefore the effect of Add/Cancellation requests may be delayed due to a running Tx scan (TXBRP not yet updated).

NOTE

In case of mixed configurations where dedicated Tx Buffers are combined with a Tx FIFO or a Tx Queue, the Put and Get Indices indicate the number of the Tx Buffer starting with the first dedicated Tx Buffers.

Example: For a configuration of 12 dedicated Tx Buffers and a Tx FIFO of 20 Buffers a Put Index of 15 points to the fourth buffer of the Tx FIFO.

Address: 0h base + C4h offset = C4h

M_CAN_TXBRP field descriptions

Field	Description
0–31 TRP	Transmission Request Pending Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR. TXBRP bits are set only for those Tx Buffers configured via TXBC. After a TXBRP bit has been set, a Tx scan (see Tx Handling) is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID). A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset. After a cancellation has been requested, a finished cancellation is signaled via TXBCF • after successful transmission together with the corresponding TXBTO bit • when the transmission has not yet been started at the point of cancellation • when the transmission has been aborted due to lost arbitration • when an error occurred during frame transmission

M_CAN_TXBRP field descriptions (continued)

Field	Description
	In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions.
0	No transmission request pending
1	Transmission request pending

41.3.38 Tx Buffer Add Request Register (M_CAN_TXBAR)**NOTE**

If an add request is applied for a Tx Buffer with pending transmission request (corresponding TXBRP bit already set), this add request is ignored.

Address: 0h base + D0h offset = D0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

M_CAN_TXEFS field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 TEFL	Tx Event FIFO Element Lost This bit is a copy of interrupt flag IR[TEFL]. When IR[TEFL] is reset, this bit is also reset. 0 No Tx Event FIFO element lost 1 Tx Event FIFO element lost, also set after write attempt to Tx Event FIFO of size zero
7 EFF	Event FIFO Full 0 Tx Event FIFO not full 1 Tx Event FIFO full
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 EFPI	Event FIFO Put Index Tx Event FIFO write index pointer, range 0 to 31.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 EFGI	Event FIFO Get Index Tx Event FIFO read index pointer, range 0 to 31.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 EFFL	Event FIFO Fill Level Number of elements stored in Tx Event FIFO, range 0 to 32.

41.3.46 Tx Event FIFO Acknowledge Register (M_CAN_TXEFA)

Address: 0h base + F8h offset = F8h

M_CAN_TXEFA field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 EFAI	Event FIFO Acknowledge Index After the CPU has read an element or a sequence of elements from the Tx Event FIFO it has to write the index of the last element read from Tx Event FIFO to EFAI. This will set the Tx Event FIFO Get Index TXEFS[EFGI] to EFAI + 1 and update the Event FIFO Fill Level TXEFS[EFFL].

41.4 Message RAM

For storage of Rx/Tx messages and for storage of the filter configuration a single- or dual-ported Message RAM has to be connected to the M_CAN module.

NOTE

In case the MessageRAMis equipped with parity or ECC functionality, it is recommended to initialize the Message RAM after hardware reset by writing e.g. 0x00000000 to each Message RAM word to create valid parity/ECC checksums. This avoids that reading from uninitialized Message RAM sections will activate interrupt IR[BEC] (Bit Error Corrected) or IR[BEU] (Bit Error Uncorrected).

The Message RAM has a width of 32 bits. In case parity checking or ECC is used a respective number of bits has to be added to each word.

When operated in CAN FD mode the required Message RAM size strongly depends on the element size configured for Rx FIFO0, Rx FIFO1, Rx Buffers, and Tx Buffers via RXESC[F0DS], RXESC[F1DS], RXESC[RBDS], and TXESC[TBDS].

The M_CAN module can be configured to allocate up to 4352 words in the Message RAM. For the actual amount of Message RAM on this chip, see the chip-specific M_CAN information.

It is not necessary to configure each of the sections listed in the following figure, and there is no restriction with respect to the sequence of the sections.

Figure 41-49. Message RAM configuration

When the M_CAN addresses the Message RAM it addresses 32-bit words, not single bytes. The configurable start addresses are 32-bit word addresses i.e. only bits 15 to 2 are evaluated, the two least significant bits are ignored.

NOTE

The M_CAN does not check for erroneous configuration of the Message RAM. Especially the configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully to avoid falsification or loss of data.

41.4.1 Rx Buffer and FIFO Element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of a Rx Buffer / FIFO element is shown in the following table. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register RXESC.

Table 41-49. Rx Buffer and FIFO Element

	31			24		23			16			15			8		7			0

Rn Bits 23:16	DBm-1[7:0]: Data Byte m-1
Rn Bits 15:8	DBm-2[7:0]: Data Byte m-2
Rn Bits 7:0	DBm-3[7:0]: Data Byte m-3

NOTE

Depending on the configuration of the element size (RXESC), between two and sixteen 32-bit words ($R_n = 3 \dots 17$) are used for storage of a CAN message's data field.

41.4.2 Tx Buffer Element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO / Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx Buffers and Tx FIFO / Tx Queue by evaluating the Tx Buffer configuration TXBC.TFQS and TXBC.NDTB. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register TXESC.

Table 41-51. Tx Buffer Element

	31	24	23	16	15	8	7	0
T0	ESI	XTD	RTR	ID[28:0]

Tn Bits 7:0	DBm-3[7:0]: Data Byte m-3

NOTE

Depending on the configuration of the element size (TXESC), between two and sixteen 32-bit words (Tn = 3 ..17) are used for storage of a CAN message's data field.

41.4.3 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from register TXEFS.

E1 Bits 15:0	TXTS[15:0]: Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC.TCP.

41.4.4 Standard Message ID Filter Element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address SIDFC[FLSSA] plus the index of the filter element (0...127).

Table 41-55. Standard Message ID Filter Element

	31	24	23	16	15	8	7	0

Table 41-58. Extended Message ID Filter Element Field Description

F0 Bits 31:29	EFEC[2:0]: Extended Filter Element Configuration All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = 100, 101, or 110 a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored
F0 Bits 28:0	EFID1[28:0]: Extended Filter ID 1 First ID of extended ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (see Extended Message ID Filtering) is used.
F1 Bits 31:30	EFT[1:0]: Extended Filter Type 00 Range filter from EFID1 to EFID2 (EFID2 >= EFID1) 01 Dual ID filter for EFID1 or EFID2 10 Classic filter: EFID1 = filter, EFID2 = mask 11 Range filter from EFID1 to EFID2 (EFID2 >= EFID1), XIDAM mask not applied
F1 Bits 28:0	EFID2[28:0]: Extended Filter ID 2 Overall, this bit field has a different meaning depending on the configuration of EFEC: EFEC = 001...110 Second ID of extended ID filter element EFEC = 111 Filter for Rx Buffers or for debug messages EFID2[10:9]: Decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00 Store message into an Rx Buffer 01 Debug Message A 10 Debug Message B 11 Debug Message C EFID2[8:6]: Is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one Host clock period in case the filter matches. EFID2[5:0]: Defines the offset to the Rx Buffer Start Address RXBC[RBSA] for storage of a matching message.

41.5 Functional Description

41.5.1 Operating Modes

41.5.1.1 Software Initialization

Software initialization is started by setting bit `CCCR[INIT]`, either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going `Bus_Off`. While `CCCR[INIT]` is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus output `M_CAN_Tx` is recessive (HIGH). The counters of the Error Management Logic EML are unchanged. Setting `CCCR[INIT]` does not change any configuration register. Resetting `CCCR[INIT]` finishes the software initialization. Afterwards the Bit Stream Processor BSP synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (= `Bus_Idle`) before it can take part in bus activities and start the message transfer.

Access to the `M_CAN` configuration registers is only enabled when both bits `CCCR[INIT]` and `CCCR[CCE]` are set (protected write).

`CCCR[CCE]` can only be set/reset while `CCCR[INIT] = 1`. `CCCR[CCE]` is automatically reset when `CCCR[INIT]` is reset.

The following registers are reset when `CCCR[CCE]` is set

- `HPMS` – High Priority Message Status
- `RXF0S` – Rx FIFO 0 Status
- `RXF1S` – Rx FIFO 1 Status
- `TXFQS` – Tx FIFO/Queue Status
- `TXBRP` – Tx Buffer Request Pending
- `TXBTO` – Tx Buffer Transmission Occurred
- `TXBCF` – Tx Buffer Cancellation Finished
- `TXEFS` – Tx Event FIFO Status

The Timeout Counter value `TOCV[TOC]` is preset to the value configured by `TOCC[TOP]` when `CCCR[CCE]` is set.

In addition the state machines of the Tx Handler and Rx Handler are held in idle state while $\text{CCCR}[\text{CCE}] = 1$.

The following registers are only writable while $\text{CCCR}[\text{CCE}] = 0$

- TXBAR – Tx Buffer Add Request
- TXBCR – Tx Buffer Cancellation Request

$\text{CCCR}[\text{TEST}]$ and $\text{CCCR}[\text{MON}]$ can only be set by the Host while $\text{CCCR}[\text{INIT}] = 1$ and $\text{CCCR}[\text{CCE}] = 1$. Both bits may be reset at any time. $\text{CCCR}[\text{DAR}]$ can only be set/reset while $\text{CCCR}[\text{INIT}] = 1$ and $\text{CCCR}[\text{CCE}] = 1$.

NOTE

In case the Message RAM is equipped with parity or ECC functionality, it is recommended to initialize the Message RAM after hardware reset by writing e.g. 0x00000000 to each Message RAM word to create valid parity/ECC checksums. This avoids that reading from uninitialized Message RAM sections will activate interrupt IR.BEC (Bit Error Corrected) or IR.BEU (Bit Error Uncorrected).

41.5.1.2 Normal Operation

Once the M_CAN is initialized and $\text{CCCR}.\text{INIT}$ is reset to zero, the M_CAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including Message ID and DLC are stored into a dedicated Rx Buffer or into Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated. Automated transmission on reception of remote frames is not implemented.

41.5.1.3 CAN FD Operation

There are two variants in the CAN FD frame transmission, first the CAN FD frame without bit rate switching. The second variant is the CAN FD frame where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame.

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers will now be decoded as FDF bit. FDF = recessive signifies a CAN FD frame, FDF = dominant signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF, res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. The coding of res = recessive is reserved for future expansion of the protocol. In case the M_CAN receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting bit PSR[PXE]. When Protocol Exception Handling is enabled (CCCR[PXHD] = 0), this causes the operation state to change from Receiver (PSR[ACT] = 10) to Integrating (PSR[ACT] = 00) at the next sample point. In case Protocol Exception Handling is disabled (CCCR[PXHD] = 1), the M_CAN will treat a recessive res bit as an form error and will respond with an error frame.

CAN FD operation is enabled by programming CCCR[FDOE]. In case CCCR[FDOE] = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via bit FDF in the respective Tx Buffer element. With CCCR[FDOE] = 0, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if bit FDF of a Tx Buffer element is set. CCCR[FDOE] and CCCR[BRSE] can only be changed while CCCR[INIT] and CCCR[CCE] are both set.

With CCCR[FDOE] = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format. With CCCR[FDOE] = 1 and CCCR[BRSE] = 0, only bit FDF of a Tx Buffer element is evaluated. With CCCR[FDOE] = 1 and CCCR[BRSE] = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.

- Wake-up messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

In the CAN FD format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to the following table.

Table 41-59. Coding of DLC in CAN FD

DLC	9	10	11	12	13	14	15
Number of data bytes	12	16	20	24	32	48	64

In CAN FD frames, the bit timing will be switched inside the frame, after the BRS (Bit Rate Switch) bit, if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the standard CAN bit timing is used as defined by the Bit Timing and Prescaler Register BTP. In the following CAN FD data phase, the fast CAN bit timing is used as defined by the Fast Bit Timing and Prescaler Register FBTP. The bit timing is switched back from the fast timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bit rate in the CAN FD data phase depends on the CAN clock frequency. Example: with a CAN clock frequency of 20 MHz and the shortest configurable bit time of 4 t_q , the bit rate in the data phase is 5 Mbit/s.

In both data frame formats, CAN FD long and CAN FD fast, the value of the bit ESI (Error Status Indicator) is determined by the transmitter's error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted recessive, else it is transmitted dominant.

41.5.1.4 Transmitter Delay Compensation

During the data phase of a CAN FD transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via pin M_CAN_Tx the M_CAN receives the transmitted data from its local CAN transceiver via M_CAN_Rx pin. The received data is delayed by the transmitter delay. In case this delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

In order to enable a data phase bit time that is even shorter than the transmitter delay, the delay compensation is introduced. Without transmitter delay compensation, the bit rate in the data phase of a CAN FD frame is limited by the transmitter delay.

41.5.1.4.1 Description

The M_CAN's protocol unit has implemented a delay compensation mechanism to compensate the transmitter delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver.

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the Secondary Sample Point SSP. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay, it is described in detail in the new ISO11898-1. It is enabled by setting bit DBTP[TDC].

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the M_CAN's transmit output M_CAN_Tx through the transceiver to the receive input M_CAN_Rx plus the transmitter delay compensation offset as configured by TDCR[TDCO]. The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (e.g. half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of mtq.

PSR[TDCV] shows the actual transmitter delay compensation value. PSR[TDCV] is cleared when CCCR[INIT] is set and is updated at each transmission of an FD frame while DBTP[TDC] is set.

The following boundary conditions have to be considered for the transmitter delay compensation implemented in the M_CAN:

- The sum of the measured delay from M_CAN_Tx to M_CAN_Rx and the configured transmitter delay compensation offset TDCR[TDCO] has to be less than 6 bit times in the data phase.
- The sum of the measured delay from M_CAN_Tx to M_CAN_Rx and the configured transmitter delay compensation offset TDCR[TDCO] has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

41.5.1.4.2 Transmitter delay compensation measurement

If transmitter delay compensation is enabled by programming $\text{DBTP}[\text{TDC}] = 1$, the measurement is started within each transmitted CAN FD frame at the falling edge of bit FDF to bit res. The measurement is stopped when this edge is seen at the receive input M_CAN_Rx of the transmitter. The resolution of this measurement is one mtq.

Figure 41-50. Transmitter delay measurement

To avoid that a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in a too early SSP position, the use of a transmitter delay compensation filter window can be enabled by programming $\text{TDCR}[\text{TDCF}]$. This defines a minimum value for the SSP position. Dominant edges on M_CAN_Rx, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least $\text{TDCR}[\text{TDCF}]$ AND M_CAN_Rx is low.

41.5.1.5 Restricted Operation Mode

In Restricted Operation Mode the node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters ($\text{ECR}[\text{REC}]$, $\text{ECR}[\text{TEC}]$) are frozen while Error Logging ($\text{ECR}[\text{CEL}]$) is active. The Host can set the M_CAN into Restricted Operation mode by setting bit $\text{CCCR}[\text{ASM}]$. The bit can only be set by the Host when both $\text{CCCR}[\text{CCE}]$ and $\text{CCCR}[\text{INIT}]$ are set to 1. The bit can be reset by the Host at any time.

Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset CCCR[ASM].

The Restricted Operation Mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

NOTE

The Restricted Operation Mode must not be combined with the Loop Back Mode (internal or external).

41.5.1.6 Bus Monitoring Mode

The M_CAN is set in Bus Monitoring Mode by programming CCCR.MON to one. In Bus Monitoring Mode (see ISO11898-1, 10.12 Bus monitoring), the M_CAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus. If the M_CAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the M_CAN monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode, register TXBRP is held in reset state.

The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. The following figure shows the connection of signals M_CAN Tx and Rx to the M_CAN in Bus Monitoring Mode.

Figure 41-51. Pin Control in Bus Monitoring Mode

41.5.1.7 Disabled Automatic Retransmission

According to the CAN Specification (see ISO11898-1, 6.3.3 Recovery Management), the M_CAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled. To support time-triggered communication as described in ISO 11898-1, chapter 9.2, the automatic retransmission may be disabled via CCCR[DAR].

41.5.1.7.1 Frame Transmission in DAR mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending bit TXBRP[TRPx] is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- Successful transmission:
 - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
 - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] not set
- Successful transmission in spite of cancellation:
 - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
 - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set
- Arbitration lost or frame transmission disturbed:
 - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] not set
 - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

41.5.1.8 Power Down (Sleep Mode)

The M_CAN can be set into power down mode controlled by CC Control Register CCCR[CSR].

When all pending transmission requests have completed, the M_CAN waits until bus idle state is detected. Then the M_CAN sets then CCCR[INIT] to one to prevent any further CAN transfers. Now the M_CAN acknowledges that it is ready for power down by

setting CCCR[CSA] to one. In this state, before the clocks are switched off, further register accesses can be made. A write access to CCCR[INIT] will have no effect. Now the module input clocks: CAN clock and Host clock may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting CC Control Register flag CCCR[CSR]. The M_CAN will acknowledge this by resetting output signal clock stop acknowledge and resetting CCCR[CSA]. Afterwards, the application can restart CAN communication by resetting bit CCCR[INIT].

41.5.1.9 Test Modes

To enable write access to register TEST, bit CCCR[TEST] has to be set to one. This allows the configuration of the test modes and test functions.

Four output functions are available for the CAN transmit pin M_CAN_Tx by programming TEST[TX]. Additionally to its default function – the serial data output – it can drive the CAN Sample Point signal to monitor the M_CAN's bit timing and it can drive constant dominant or recessive values. The actual value at pin M_CAN_Rx can be read from TEST[RX]. Both functions can be used to check the CAN bus' physical layer.

Due to the synchronization mechanism between CAN clock and Host clock domain, there may be a delay of several Host clock periods between writing to TEST[TX] until the new configuration is visible at output pin M_CAN_Tx. This applies also when reading input pin M_CAN_Rx via TEST[RX].

Note

Test modes should be used for production tests or self test only.
The software control for pin M_CAN_Tx interferes with all CAN protocol functions. It is not recommended to use test modes for application.

41.5.1.9.1 External Loopback Mode

The M_CAN can be set in External Loopback Mode by programming TEST[LBCK] to one. In Loopback Mode, the M_CAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into an Rx Buffer or an Rx FIFO. The following figure shows the connection of signals M_CAN_Tx and M_CAN_Rx to the M_CAN in External Loopback Mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the M_CAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in Loopback Mode. In this mode the M_CAN

performs an internal feedback from its Tx output to its Rx input. The actual value of the input pin M_CAN_Rx is disregarded by the M_CAN. The transmitted messages can be monitored at the pin M_CAN_Tx.

Figure 41-52. Pin Control in External Loopback Mode

41.5.1.9.2 Internal Loopback Mode

Internal Loopback Mode is entered by programming bits TEST[LBCK] and CCCR[MON] to one. This mode can be used for a "Hot Selftest", meaning the M_CAN can be tested without affecting a running CAN system connected to the pins M_CAN_Tx and M_CAN_Rx. In this mode pin M_CAN_Rx is disconnected from the M_CAN and pin M_CAN_Tx is held recessive. The following figure shows the connection of M_CAN_Tx and M_CAN_Rx to the M_CAN in case of Internal Loopback Mode.

Figure 41-53. Pin Control in Internal Loopback Mode

41.5.2 Timestamp Generation

For timestamp generation the M_CAN supplies a 16-bit wrap-around counter. A prescaler TSCC[TCP] can be configured to clock the counter in multiples of CAN bit times (1...16). The counter is readable via TSCV[TSC]. A write access to register TSCV resets the counter to zero. When the timestamp counter wraps around interrupt flag IR[TSW] is set.

On start of frame reception / transmission the counter value is captured and stored into the timestamp section of an Rx Buffer / Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element.

41.5.3 Timeout Counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO the M_CAN supplies a 16-bit Timeout Counter. It operates as down-counter and uses the same prescaler controlled by TSCC[TCP] as the Timestamp Counter. The Timeout Counter is configured via register TOCC. The actual counter value can be read from TOCV[TOC]. The Timeout Counter can only be started while CCCR[INIT] = 0. It is stopped when CCCR[INIT] = 1, e.g. when the M_CAN enters Bus_Off state.

The operation mode is selected by TOCC[TOS]. When operating in Continuous mode, the counter starts when CCCR[INIT] is reset. A write to TOCV presets the counter to the value configured by TOCC[TOP] and continues down-counting.

When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Down-counting is started when the first FIFO element is stored. Writing to TOCV has no effect.

When the counter reaches zero, interrupt flag IR[TOO] is set. In Continuous Mode, the counter is immediately restarted at TOCC[TOP].

Note

The clock signal for the Timeout Counter is derived from the CAN Core's sample point signal. Therefore the point in time where the Timeout Counter is decremented may vary due to the synchronization / re-synchronization mechanism of the CAN Core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

41.5.4 Rx Handling

The Rx Handler controls the acceptance filtering, the transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs, as well as the Rx FIFO's Put and Get Indices.

41.5.4.1 Acceptance filtering

The M_CAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to Rx Buffer or to Rx FIFO 0, 1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
 - Range filter (from - to)
 - Filter for one or two dedicated IDs
 - Classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled / disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global Filter Configuration (GFC)
- Standard ID Filter Configuration (SIDFC)
- Extended ID Filter Configuration (XIDFC)
- Extended ID AND Mask (XIDAM)

Depending on the configuration of the filter element (SFEC/EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx Buffer
- Store received frame in Rx Buffer and generate pulse at filter event pin

- Reject received frame
- Set High Priority Message interrupt flag IR.HPM
- Set High Priority Message interrupt flag IR.HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching Rx Buffer or Rx FIFO has been found, the Message Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If the CAN protocol controller has detected an error condition (e.g. CRC error), this message is discarded with the following impact on the affected Rx Buffer or Rx FIFO:

Rx Buffer

New Data flag of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data. For error type see PSR[LEC] respectively PSR[DLEC].

Rx FIFO

Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data. For error type see PSR[LEC] respectively PSR[DLEC]. In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in "Rx FIFO Overwrite Mode" section have to be considered.

Note

When an accepted message is written to one of the two Rx FIFOs, or into an Rx Buffer, the unmodified received identifier is stored independent of the filter(s) used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

41.5.4.1.1 Range Filter

The filter matches for all received frames with Message IDs in the range defined by SF1ID/SF2ID resp. EF1ID/EF2ID.

There are two possibilities when range filtering is used together with extended frames:

- EFT = "00": The Message ID of received frames is ANDed with the Extended ID AND Mask (XIDAM) before the range filter is applied
- EFT = "11": The Extended ID AND Mask (XIDAM) is not used for range filtering

41.5.4.1.2 Filter for Specific IDs

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SF1ID = SF2ID resp. EF1ID = EF2ID.

41.5.4.1.3 Classic Bit Mask Filter

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering SF1ID/EF1ID is used as Message ID filter, while SF2ID/EF2ID is used as filter mask.

A zero bit at the filter mask will mask out the corresponding bit position of the configured ID filter, e.g. the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering.

In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are zero, all Message IDs match.

41.5.4.1.4 Standard Message ID Filtering

The following figure shows the flow for standard Message ID (11-bit Identifier) filtering. The Standard Message ID Filter element is described in [Standard Message ID Filter Element](#).

Controlled by the Global Filter Configuration GFC and the Standard ID Filter Configuration SIDFC Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

Figure 41-54. Standard Message ID Filter Path

41.5.4.1.5 Extended Message ID Filtering

The figure below shows the flow for extended Message ID (29-bit Identifier) filtering. The Extended Message ID Filter element is described in [Extended Message ID Filter Element](#).

Controlled by the Global Filter Configuration GFC and the Extended ID Filter Configuration XIDFC Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

The Extended ID AND Mask XIDAM is ANDed with the received identifier before the filter list is executed.

Figure 41-55. Extended Message ID Filter Path

41.5.4.1.6 Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via registers RXF0C and RXF1C.

Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1 see [Acceptance filtering](#). The Rx FIFO element is described in [Rx Buffer and FIFO Element](#).

To avoid an Rx FIFO overflow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by RXFnC[FnWM], interrupt flag IR[RFnW] is set. When the Rx FIFO Put Index reaches the Rx FIFO Get Index an Rx FIFO Full condition is signalled by RXFnS[FnF]. In addition interrupt flag IR[RFnF] is set.

Figure 41-56. Rx FIFO Status

When reading from an Rx FIFO, Rx FIFO Get Index RXFnS[FnGI] x FIFO Element Size has to be added to the corresponding Rx FIFO start address RXFnC[FnSA].

Table 41-60. Rx Buffer / FIFO Element Size

RXESC.RBDS[2:0] RXESC.FnDS[2:0]	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

41.5.4.1.6.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is configured by $RXFnC[FnOM] = 0$. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached ($RXFnS[FnPI] = RXFnS[FnGI]$), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by $RXFnS[FnF] = 1$. In addition interrupt flag $IR[RFnF]$ is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signalled by $RXFnS[RFnL] = 1$. In addition interrupt flag $IR[RFnL]$ is set.

41.5.4.1.6.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by $RXFnC[FnOM] = 1$.

When an Rx FIFO full condition ($RXFnS[FnPI] = RXFnS[FnGI]$) is signalled by $RXFnS[FnF] = 1$, the next message accepted for the FIFO will overwrite the oldest FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (put index) while the CPU is reading from the Message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO. The following figure shows an offset of two with respect to the get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

Figure 41-57. Rx FIFO Overflow Handling

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index RXFnA[FnA]. This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (RXFnS[FnF] = 0).

41.5.4.1.7 Dedicated Rx Buffers

The M_CAN supports up to 64 dedicated Rx Buffers. The start address of the dedicated Rx Buffer section is configured via RXBC[RBSA].

For each Rx Buffer a Standard or Extended Message ID Filter Element with SFEC / EFEC = 111 and SFID2 / EFID2[10:9] = 00 has to be configured (see [Standard Message ID Filter Element](#) and [Extended Message ID Filter Element](#))

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag IR[DRX] (Message stored in Dedicated Rx Buffer) in the interrupt register is set.

Table 41-61. Example Filter Configuration for Rx buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register NDAT1,2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host by writing a 1 to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration

41.5.4.1.7.1 Rx Buffer Handling

- Reset interrupt flag IR[DRX]
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

41.5.4.1.8 Debug on CAN Support

Debug messages are stored into Rx Buffers. For debug handling three consecutive Rx buffers (e.g. #61, #62, #63) have to be used for storage of debug messages A, B, and C. The format is the same as for an Rx Buffer or an Rx FIFO element.

Advantage: Fixed start address for the DMA transfers (relative to RXBC[RBSA]), no additional configuration required.

For filtering of debug messages Standard / Extended Filter Elements with SFEC / EFEC = 111 have to be set up. Messages matching these filter elements are stored into the Rx Buffers addressed by SFID2 / EFID2[5:0].

After message C has been stored, the DMA request output m_can_dma_req is activated and the three messages can be read from the Message RAM under DMA control. The RAM words holding the debug messages will not be changed by the M_CAN while m_can_dma_req is activated. The behaviour is similar to that of an Rx Buffers with its New Data flag set.

After the DMA has completed the DMA unit sets m_can_dma_ack. This resets m_can_dma_req. Now the M_CAN is prepared to receive the next set of debug messages.

41.5.4.1.8.1 Filtering for Debug Messages

Filtering for debug messages is done by configuring one Standard / Extended Message ID Filter Element for each of the three debug messages. To enable a filter element to filter for debug messages SFEC / EFEC has to be programmed to 111. In this case fields SFID1 / SFID2 and EFID1 / EFID2 have a different meaning (see [Standard Message ID Filter Element](#) and [Extended Message ID Filter Element](#)). While SFID2 / EFID2[10:9] controls the debug message handling state machine, SFID2 / EFID2[5:0] controls the location for storage of a received debug message.

When a debug message is stored, neither the respective New Data flag nor IR[DRX] are set. The reception of debug messages can be monitored via RXF1S[DMS].

Table 41-62. Example Filter Configuration for Debug Messages

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message A	01	11 1101
1	ID debug message B	10	11 1110
2	ID debug message C	11	11 1111

41.5.4.1.8.2 Debug Message Handling

The debug message handling state machine assures that debug messages are stored to three consecutive Rx Buffers in correct order. In case of missing messages the process is restarted. The DMA request is activated only when all three debug messages A, B, C have been received in correct order.

The status of the debug message handling state machine is signaled via RXF1S[DMS].

Figure 41-58. Debug Message Handling State Machine

T0: reset m_can_dma_req output, enable reception of debug messages A, B, and C

T1: reception of debug message A

T2: reception of debug message A

T3: reception of debug message C

T4: reception of debug message B

T5: reception of debug messages A, B

T6: reception of debug message C

T7: DMA transfer completed

T8: reception of debug message A,B,C (message rejected)

41.5.5 Tx Handling

The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN Core, the Put and Get Indices, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The CAN mode for transmission (Classic CAN or CAN FD) can be configured separately for each Tx Buffer element. The Tx Buffer element is described in [Tx Buffer Element](#). The table below describes the possible configurations for frame transmission.

Table 41-63. Possible configurations for frame transmission

CCCR		Tx Buffer Element		Frame Transmission
BRSE	FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	FD without bit rate switching
1	1	1	1	FD with bit rate switching

Note

AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

The Tx Handler starts a Tx scan to check for the highest priority pending Tx request (Tx Buffer with lowest Message ID) when the Tx Buffer Request Pending register TXBRP is updated, or when a transmission has been started.

41.5.5.1 Transmit Pause

The transmit pause feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority should be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If, for example, CAN ECU-1 has the transmit pause feature enabled and is requested by its application software to transmit four messages, it will, after the first successful message transmission, wait for two CAN bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate with the next message of ECU-1. After having received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The transmit pause feature is controlled by bit CCCR.TXP. If the bit is set, the M_CAN will, each time it has successfully transmitted a message, pause for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is transmit pause disabled (CCCR[TXP] = 0).

This feature looses up burst transmissions coming from a single node and it protects against “babbling idiot” scenarios where the application program erroneously requests too many transmissions.

41.5.5.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU. Each Dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first.

If the data section has been updated, a transmission is requested by an Add Request via TXBAR[ARn]. The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM (see the following table). Therefore the start address of a Dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index (0...31) x Element Size to the Tx Buffer Start Address TXBC[TBSA].

Table 41-64. Tx Buffer / FIFO / Queue Element Size

TXESC.TBDS[2:0]	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

41.5.5.3 Tx FIFO

Tx FIFO operation is configured by programming TXBC[TFQM] to 0. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index TXFQS[TFGI]. After each transmission the Get Index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO. The M_CAN calculates the Tx FIFO Free Level TXFQS[TFFL] as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (TXFQS[TFQF] = 1) is signalled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing a 1 to the TXBAR bit related to the Tx Buffer referenced by the Tx FIFO's Put Index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx Buffers starting with the Put Index. The transmissions are then requested via TXBAR. The Put Index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level.

When a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (See [Table 41-64](#)). Therefore the start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index TXFQS.TFQPI (0...31) x Element Size to the Tx Buffer Start Address TXBC[TBSA].

41.5.5.4 Tx Queue

Tx Queue operation is configured by programming TXBC[TFQM] to 1. Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New messages have to be written to the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request cyclically increments the Put Index to the next free Tx Buffer. In case that the Tx Queue is full (TXFQS[TFQF] = 1), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use register TXBRP instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see [Table 41-64](#)). Therefore the start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index TXFQS[TFQPI] (0...31) x Element Size to the Tx Buffer Start Address TXBC[TBSA].

41.5.5.5 Mixed Dedicated Tx Buffers / Tx FIFO

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx FIFO. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Buffers assigned to the Tx FIFO is configured by TXBC[TFQS]. In case TXBC[TFQS] is programmed to zero, only Dedicated Tx Buffers are used.

Figure 41-59. Example of mixed Configuration Dedicated Tx Buffers / Tx FIFO

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by TXFS[TFGI])
- Buffer with lowest Message ID gets highest priority and is transmitted next

41.5.5.6 Mixed Dedicated Tx Buffers / Tx Queue

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx Queue. The number of Dedicated Tx Buffers is configured by TXBC.NDTB. The number of Tx Queue Buffers is configured by TXBC.TFQS. In case TXBC.TFQS is programmed to zero, only Dedicated Tx Buffers are used.

Figure 41-60. Example of mixed Configuration Dedicated Tx Buffers / Tx Queue

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

41.5.5.7 Transmit Cancellation

The M_CAN supports transmit cancellation. This feature is especially intended for gateway applications and AUTOSAR based applications. To cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer the Host has to write a 1 to the corresponding bit position (= number of Tx Buffer) of register TXBCR. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of register TXBCF to 1.

In case a transmit cancellation is requested while a transmission from a Tx Buffer is already ongoing, the corresponding TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding TXBTO and TXBCF bits are set. If the transmission was not successful, it is not repeated and only the corresponding TXBCF bit is set.

Note

In case a pending transmission is cancelled immediately before this transmission could have been started, there follows a short time window where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

41.5.5.8 Tx Event Handling

To support Tx event handling the M_CAN has implemented a Tx Event FIFO. After the M_CAN has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx Event FIFO element. To link a Tx event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

The Tx Event FIFO can be configured to a maximum of 32 elements. The Tx Event FIFO element is described in [Tx Event FIFO Element](#).

The purpose of the Tx Event FIFO is to decouple handling transmit status information from transmit message handling i.e. a Tx Buffer holds only the message to be transmitted, while the transmit status is stored separately in the Tx Event FIFO. This has the advantage, especially when operating a dynamically managed transmit queue, that a Tx Buffer can be used for a new message immediately after successful transmission. There is no need to save transmit status information from a Tx Buffer before overwriting that Tx Buffer.

When a Tx Event FIFO full condition is signalled by IR[TEFF], no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx Event FIFO is full, this event is discarded and interrupt flag IR[TEFL] is set.

To avoid a Tx Event FIFO overflow, the Tx Event FIFO watermark can be used. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by TXEFC[EFWM], interrupt flag IR[TEFW] is set.

When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index TXEFS[EFGI] has to be added to the Tx Event FIFO start address TXEFC[EFSA].

41.5.6 FIFO Acknowledge Handling

The Get Indices of Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see the registers RXF0A, RXF1A, and TXEFA). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

- When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index.
- When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFO's Get Index.

Due to the fact that the CPU has free access to the M_CAN's Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also alters the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

Note

The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The M_CAN does not check for erroneous values.

Chapter 42

Deserial Serial Peripheral Interface (DSPI)

42.1 Chip-specific DSPI information

This chip implements five instances of the DSPI module. Some feature details vary among the instances.

The following table summarizes the feature differences. The table does not list feature details that all instances share.

Table 42-1. DSPI instance feature differences

Feature	DSPI_A	DSPI_B	DSPI_C	DSPI_D	DSPI_E
Serialization mechanisms defined in the SIU chapter	Yes	Yes	Yes	Yes	No ¹
Serial Data In (SIN) signals	Yes	Yes	Yes	Yes	No
PISRs and bit muxes are implemented	Yes	Yes	Yes	Yes	No ²
Hardware Trigger (HT)	Yes	Yes	Yes	Yes	No
Clock and data signals (SCK and SOUT) are available on LVDS pairs to support microsecond bus functionality	No	No	Yes	Yes	No
Output serialization bits used	None	[15:0]	[15:0]	[15:4,1:0]	None

1. DSPI_E does not support serialization, except what is provided by the ASDR register.

2. The registers PSIR0, PSIR1, PSIR2, and PISR3 do not exist for DSPI_E.

42.1.1 DSPI and eMIOS direct connections

The following table shows direct connections between eMIOS and DSPI module instances.

Table 42-2. DSPI and eMIOS direct connections

Source	Destination	Description
DSPI_B	eMIOS_0	Connection from DSPI_B deserial data out bit 14 to eMIOS_0 input channel 5
DSPI_B	eMIOS_0	Connection from DSPI_B deserial data out bit 15 to eMIOS_0 input channel 4
DSPI_D	eMIOS_1	Connection from DSPI_D deserial data out bit 14 to eMIOS_1 input channel 7
DSPI_D	eMIOS_1	Connection from DSPI_D deserial data out bit 15 to eMIOS_1 input channel 6

42.1.2 DSPI connections with SIU, eTPU, and eMIOS modules

Some DSPI deserialized outputs can be used to trigger external interrupt requests via the External Interrupt Input Multiplexing sub-block in the SIU. See [External IRQ Input Select Register \(SIU_EIISR\)](#) for details.

DSPI_A, DSPI_B, DSPI_C, and DSPI_D connect via SIU registers to channels of eTPU and eMIOS modules as well as GPO data registers. See [Pin serialization for DSPI](#) for more information. The following table lists the applicable SIU registers for each DSPI instance.

Table 42-3. SIU registers for DSPI pin serialization

DSPI instance	SIU registers
DSPI_A	Mask-Output High Register (SIU_DSPIAH) Mask-Output Low Register (SIU_DSPIAL) Serialized Output Signal Selection Register for DSPI_A (SIU_ETPUBA) Serialized Output Signal Selection Register for DSPI_A (SIU_EMIOA) Serialized Output Signal Selection Register for DSPI_A (SIU_DSPIAHLA)
DSPI_B	Mask-Output High Register (SIU_DSPIBH) Mask-Output Low Register (SIU_DSPIBL) Serialized Output Signal Selection Register for DSPI_B (SIU_ETPUAB) Serialized Output Signal Selection Register for DSPI_B (SIU_EMIOB) Serialized Output Signal Selection Register for DSPI_B (SIU_DSPIBHLB)
DSPI_C	Mask-Output High Register (SIU_DSPICH) Mask-Output Low Register (SIU_DSPICL) Serialized Output Signal Selection Register for DSPI_C (SIU_ETPUAC) Serialized Output Signal Selection Register for DSPI_C (SIU_EMIOSC) Serialized Output Signal Selection Register for DSPI_C (SIU_DSPICHL) Serialized Output Signal Selection Register for DSPI_C (SIU_ETPUBC)

Table continues on the next page...

42.2 Introduction

The deserial serial peripheral interface (DSPI) module provides a synchronous serial bus for communication between a chip and an external peripheral device. The module supports chip pin count reduction through serialization and deserialization of chip internal signals transmitted over the DSPI serial link.

42.2.1 Block Diagram

The block diagram of this module is as follows:

Figure 42-1. DSPI Block Diagram

42.2.2 Features

The module supports the following features:

- Full-duplex, three-wire synchronous transfers
- Master mode
- Slave mode
- Data streaming operation in Slave mode with continuous slave selection
- Buffered transmit operation using the transmit first in first out (TX FIFO) with depth of 4 entries

- Buffered receive operation using the receive FIFO (RX FIFO) with depth of 4 entries
- Asynchronous clocking scheme for Register and Protocol Interfaces
- TX and RX FIFOs can be disabled individually for low-latency updates to SPI queues
- Visibility into TX and RX FIFOs for ease of debugging
- Programmable transfer attributes on a per-frame basis:
 - eight transfer attribute registers
 - Serial clock (SCK) with programmable polarity and phase
 - Various programmable delays
 - Programmable serial frame size: 4 to 32
 - SPI frames longer than 16 bits can be supported using the continuous selection format.
 - Continuously held chip select capability
 - Parity control
- 6 peripheral chip selects (PCSeS), expandable to 64 with external demultiplexer
- Deglitching support for up to 32 peripheral chip selects (PCSeS) with external demultiplexer
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
 - TX FIFO is not full (TFFF)
 - RX FIFO is not empty (RFDF)
- Interrupt conditions:
 - End of Queue reached (EOQF)
 - TX FIFO is not full (TFFF)
 - Transfer of current frame complete (TCF)
 - Attempt to transmit with an empty Transmit FIFO (TFUF)
 - RX FIFO is not empty (RFDF)
 - Frame received while Receive FIFO is full (RFOF)
 - SPI Parity Error (SPEF)

- Modified SPI transfer formats for communication with slower peripheral devices
- Power-saving architectural features:
 - Support for Stop mode

The DSPI also supports pin reduction through serialization and deserialization if enabled for the module.

- Two sources of serialized data:
 - The module memory-mapped register
 - Parallel Input signals
 - Programmable selection of source data on bit basis
- Deserialized data is provided as Parallel Output signals and as bits in a memory-mapped register
- Interrupt conditions:
 - Deserialized data matches pre-programmed pattern (DDIF)
 - DSI Parity Error (DPEF)
- Transfer initiation conditions:
 - Continuous
 - Edge sensitive hardware trigger
 - Change in data
- Pin serialization/deserialization with interleaved SPI frames for control and diagnostics
- Continuous serial communications clock

DSPI supports a combined SPI and DSI modes of operation known as the Combined Serial Interface (CSI). It also supports the downstream Micro Second Channel in the Timed Serial Bus (TSB) configuration.

TSB mode has the following features:

- Transmission of frames is done at frame boundaries
- Frames from SPI and DSI are identifiable by a bit transmitted at the start of each frame
- Separate interrupts for frame completion from SPI and DSI

42.2.3 Interface configurations

42.2.3.1 SPI configuration

The Serial Peripheral Interface (SPI) configuration allows the module to send and receive serial data. This configuration allows the module to operate as a basic SPI block with internal FIFOs supporting external queue operation. Transmitted data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the Receive FIFO and write transmit data to the Transmit FIFO.

For queued operations, the SPI queues can reside in system RAM, external to the module. Data transfers between the queues and the module FIFOs are accomplished by a DMA controller or host CPU. The following figure shows a system example with DMA, DSPI, and external queues in system RAM.

Figure 42-2. SPI with queues and DMA

42.2.3.2 DSI configuration

In the Deserial Serial Interface (DSI) configuration, DSPI serializes up to 32 parallel input signals or register bits. DSPI also deserializes the received data to parallel output signals or to a memory-mapped register. DSPI transfers the data using an SPI-like protocol.

Timed Serial Bus (TSB) mode provides the MicroSecond Channel (MSC) downstream support, serializing from 4 to 32 parallel input signals or register bits. For more information on TSB mode, see [Timed Serial Bus \(TSB\)](#).

42.2.3.3 CSI configuration

The Combined Serial Interface (CSI) configuration supports further configuration as follows:

- Normal: A combination of the SPI and DSI configurations. The DSPI interleaves DSI data frames with SPI data frames. Interleaving is done on the frame boundaries.
- TSB: Transmission of SPI data has higher priority than DSI data.

42.2.4 Modes of Operation

The module supports the following modes of operation that can be divided into two categories:

- Module-specific modes:
 - Master mode
 - Slave mode
 - Module Disable mode
- Chip-specific modes:
 - External Stop mode
 - Debug mode

The module enters module-specific modes when the host writes a module register. The chip-specific modes are controlled by signals external to the module. The chip-specific modes are modes that a chip may enter in parallel to the block-specific modes.

42.2.4.1 Master Mode

Master mode allows the module to initiate and control serial communication. In this mode, these signals are controlled by the module and configured as outputs:

- SCK
- PCS[x]

42.2.4.2 Slave Mode

Slave mode allows the module to communicate with SPI/DSI bus masters. In this mode, the module responds to externally controlled serial transfers. The SCK signal and the PCS[0]/ $\overline{\text{SS}}$ signals are configured as inputs and driven by an SPI bus master.

42.2.4.3 Module Disable Mode

The Module Disable mode can be used for chip power management. The clock to the non-memory mapped logic in the module can be stopped while in the Module Disable mode.

42.2.4.4 External Stop Mode

External Stop mode is used for chip power management. The module supports the Peripheral Bus Stop mode mechanism. When a request is made to enter External Stop mode, it acknowledges the request and completes the transfer that is in progress. When the module reaches the frame boundary, it signals that the protocol clock to the module may be shut off.

42.2.4.5 Debug Mode

Debug mode is used for system development and debugging. The MCR[FRZ] bit controls module behavior in the Debug mode:

- If the bit is set, the module stops all serial transfers, when the chip is in debug mode.
- If the bit is cleared, the chip debug mode has no effect on the module.

42.3 Module signal descriptions

This table describes the signals on the boundary of the module that may connect off chip (in alphabetical order).

Table 42-4. Module signal descriptions

Signal	Master mode	Slave mode	I/O
HT	Hardware Trigger	Hardware Trigger	I
PCS0/ $\overline{\text{SS}}$	Peripheral Chip Select 0 (O)	Slave Select (I)	I/O
PCS[1:3]	Peripheral Chip Selects 1–3	(Unused)	O
PCS4	Peripheral Chip Select 4	(Unused)	O

Table continues on the next page...

Table 42-4. Module signal descriptions (continued)

Signal	Master mode	Slave mode	I/O
PCS5/ $\overline{\text{PCSS}}$	Peripheral Chip Select 5 /Peripheral Chip Select Strobe	(Unused)	O
SCK	Serial Clock (O)	Serial Clock (I)	I/O
SIN	Serial Data In	Serial Data In	I
SOUT	Serial Data Out	Serial Data Out	O

42.3.1 HT—Hardware Trigger

Master mode: Hardware Trigger (I)—Honored only when the module is configured for the DSI or CSI configuration (MCR[DCONF]), hardware-trigger reception is enabled (DSICR0[TRRE] or TRIG[TRRE]), and the module is in the Running state (SR[TXRXS]). Receives hardware triggers that initiate data transfers. DSICR0[TPOL] specifies whether the module uses rising or falling edges of HT as hardware triggers.

Slave mode: Hardware Trigger (I)—Honored only when the module is configured for the DSI or CSI configuration (MCR[DCONF]), hardware-trigger reception is enabled (DSICR0[TRRE] or TRIG[TRRE]), and the module is in the Running state (SR[TXRXS]). DSICR0[TPOL] specifies whether the module uses rising or falling edges of HT as hardware triggers.

42.3.2 PCS0/ $\overline{\text{SS}}$ —Peripheral Chip Select/Slave Select

Master mode: Peripheral Chip Select 0 (O)—Selects an SPI slave to receive data transmitted from the module.

Slave mode: Slave Select (I)—Selects the module to receive data transmitted from an SPI master.

NOTE

Do not tie the DSPI slave select pin to ground. Otherwise, DSPI cannot function properly.

42.3.3 PCS1–PCS3—Peripheral Chip Selects 1–3

Master mode: Peripheral Chip Selects 1–3 (O)—Select an SPI slave to receive data transmitted by the module.

Slave mode: Unused

42.3.4 PCS4—Peripheral Chip Select 4

Master mode: Peripheral Chip Select 4 (O)—Selects an SPI slave to receive data transmitted by the module.

Slave mode: Unused

42.3.5 PCS5/ $\overline{\text{PCSS}}$ —Peripheral Chip Select 5/Peripheral Chip Select Strobe

Master mode:

- Peripheral Chip Select 5 (O)—Used only when the peripheral-chip-select strobe is disabled (MCR[PCSSE]). Selects an SPI slave to receive data transmitted by the module.
- Peripheral Chip Select Strobe (O)—Used only when the peripheral-chip-select strobe is enabled (MCR[PCSSE]). Strokes an off-module peripheral-chip-select demultiplexer, which decodes the module's PCS signals other than PCS5, preventing glitches on the demultiplexer outputs.

Slave mode: Unused

42.3.6 SCK—Serial Clock

Master mode: Serial Clock (O)—Supplies a clock signal from the module to SPI slaves.

Slave mode: Serial Clock (I)—Supplies a clock signal to the module from an SPI master.

42.3.7 SIN—Serial Input

Master mode: Serial Input (I)—Receives serial data.

Slave mode: Serial Input (I)—Receives serial data.

42.3.8 SOUT—Serial Output

Master mode: Serial Output (O)—Transmits serial data.

Slave mode: Serial Output (O)—Transmits serial data.

42.4 Memory Map/Register Definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Any Write access to the POPR and RXFRn also results in a transfer error.

NOTE

While the module is in the running state, do not write to these registers:

- PISRn
- DIMRn, DPIRn, and SSRn

42.4.1 Module Configuration Register (DSPI_MCR)

Contains bits to configure various attributes associated with the module operations. The HALT and MDIS bits can be changed at any time, but the effect takes place only on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed, while the module is in the Running state.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

DSPI_MCR field descriptions

Field	Description
0 MSTR	Master/Slave Mode Select Enables either Master mode (if supported) or Slave mode (if supported) operation. 0 Enables Slave mode 1 Enables Master mode
1 CONT_SCKE	Continuous SCK Enable Enables the Serial Communication Clock (SCK) to run continuously.

Table continues on the next page...

DSPI_MCR field descriptions (continued)

Field	Description
	0 Continuous SCK disabled. 1 Continuous SCK enabled.
2–3 DCONF	Interface Configuration Selects among the different interface configurations of the module. 00 SPI 01 DSI 10 CSI 11 Reserved
4 FRZ	Freeze Enables transfers to be stopped on the next frame boundary when the device enters Debug mode. 0 Do not halt serial transfers in Debug mode. 1 Halt serial transfers in Debug mode.
5 MTFE	Modified Transfer Format Enable Enables a modified transfer format to be used. 0 Modified SPI transfer format disabled. 1 Modified SPI transfer format enabled.
6 PCSSE	Peripheral Chip Select Strobe Enable Enables the PCS5/ $\overline{\text{PCSS}}$ to operate as a PCS Strobe output signal. 0 PCS5/ $\overline{\text{PCSS}}$ is used as the Peripheral Chip Select[5] signal. 1 PCS5/ $\overline{\text{PCSS}}$ is used as an active-low PCS Strobe signal.
7 ROOE	Receive FIFO Overflow Overwrite Enable In the RX FIFO overflow condition, configures the module to ignore the incoming serial data or overwrite existing data. If the RX FIFO is full and new data is received, the data from the transfer, generating the overflow, is ignored or shifted into the shift register. 0 Incoming data is ignored. 1 Incoming data is shifted into the shift register.
8–9 Reserved	Always write the reset value to this field. This field is reserved.
10–15 PCSIS	Peripheral Chip Select x Inactive State Determines the inactive state of PCSx. Refer to the chip-specific D SPI information for the number of PCS signals used in this chip. NOTE: The effect of this bit only takes place when module is enabled. Ensure that this bit is configured correctly before enabling the DSPI interface. 0 The inactive state of PCSx is low. 1 The inactive state of PCSx is high.
16 Reserved	This field is reserved.

Table continues on the next page...

DSPI_MCR field descriptions (continued)

Field	Description
17 MDIS	Module Disable Allows the clock to be stopped to the non-memory mapped logic in the module effectively putting it in a software-controlled power-saving state. The reset value of the MDIS bit is parameterized, with a default reset value of 0. When the module is used in Slave Mode, it is recommended to leave this bit 0, because a slave doesn't have control over master transactions. 0 Enables the module clocks. 1 Allows external logic to disable the module clocks.
18 DIS_TXF	Disable Transmit FIFO When the TX FIFO is disabled, the transmit part of the module operates as a simplified double-buffered SPI. This bit can be written only when the MDIS bit is cleared. 0 TX FIFO is enabled. 1 TX FIFO is disabled.
19 DIS_RXF	Disable Receive FIFO When the RX FIFO is disabled, the receive part of the module operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 RX FIFO is enabled. 1 RX FIFO is disabled.
20 CLR_TXF	Clear TX FIFO Flushes the TX FIFO. Writing a 1 to CLR_TXF clears the TX FIFO Counter. The CLR_TXF bit is always read as zero. 0 Do not clear the TX FIFO counter. 1 Clear the TX FIFO counter.
21 CLR_RXF	CLR_RXF Flushes the RX FIFO. Writing a 1 to CLR_RXF clears the RX Counter. The CLR_RXF bit is always read as zero. 0 Do not clear the RX FIFO counter. 1 Clear the RX FIFO counter.
22–23 SMPL_PT	Sample Point Controls when the module master samples SIN in Modified Transfer Format. This field is valid only when CPHA bit in CTARn[CPHA] is 0. 00 0 protocol clock cycles between SCK edge and SIN sample 01 1 protocol clock cycle between SCK edge and SIN sample 10 2 protocol clock cycles between SCK edge and SIN sample 11 Reserved
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 Reserved	This field is reserved.

Table continues on the next page...

DSPI_MCR field descriptions (continued)

Field	Description
30 PES	Parity Error Stop Controls SPI operation when a parity error is detected in a received SPI frame. 0 SPI frame transmission continues. 1 SPI frame transmission stops.
31 HALT	Halt The HALT bit starts and stops frame transfers. See Start and Stop of Module transfers 0 Start transfers. 1 Stop transfers.

42.4.2 Transfer Count Register (DSPI_TCR)

TCR contains a counter that indicates the number of SPI transfers made. The transfer counter is intended to assist in queue management. Do not write the TCR when the module is in the Running state.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DSPI_TCR field descriptions

Field	Description
0–15 SPI_TCNT	SPI Transfer Counter Counts the number of SPI transfers the module makes. The SPI_TCNT field increments every time the last bit of an SPI frame is transmitted. A value written to SPI_TCNT presets the counter to that value. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. The Transfer Counter wraps around; incrementing the counter past 65535 resets the counter to zero.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

42.4.3 Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTAR_n)

CTAR registers are used to define different transfer attributes. Do not write to the CTAR registers while the module is in the Running state.

In Master mode, the CTAR registers define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays. In slave mode, a subset of the bitfields in CTAR0 and CTAR1 are used to set the slave transfer attributes.

When the module is configured as a SPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the CTAR registers is used. When the module is configured as an SPI bus slave, it uses the CTAR0 register.

When the module is configured as a DSI master, the DSICTAS field in the DSI Configuration Register 0 (DSICR0), selects which of the CTAR register is used. When the module is configured as a DSI bus slave, the CTAR1 register is used.

In CSI Configuration, the transfer attributes are selected based on whether the current frame is SPI data or DSI data. SPI transfers in CSI Configuration follow the protocol described for SPI Configuration, and DSI transfers in CSI Configuration follow the protocol described for DSI Configuration. CSI Configuration is valid only in conjunction with master mode.

TSB mode sets some limitations on transfer attributes:

- Clock phase is forced to be CPHA = 1 and the CPHA bit setting has no effect.
- PCS lines are driven at the driving edge of the SCK clock together with SOUT, so PCS assertion and negation delays control is unavailable and PCSSCK, PASC, CSSCK and ASC fields have no effect.
- Delay after transfer can be set from 1 to 64 serial clocks with help of PDT and DT fields

Address: 0h base + Ch offset + (4d × i), where i=0d to 7d

DSPI_CTAR_n field descriptions

Field	Description																																								
0 DBR	Double Baud Rate Doubles the effective baud rate of the Serial Communications Clock (SCK). This field is used only in master mode. It effectively halves the Baud Rate division ratio, supporting faster frequencies, and odd division ratios for the Serial Communications Clock (SCK). When the DBR bit is set, the duty cycle of the Serial Communications Clock (SCK) depends on the value in the Baud Rate Prescaler and the Clock Phase bit as listed in the following table. See the BR field description for details on how to compute the baud rate. Table 42-11. DSPI SCK Duty Cycle <table><tr><th>DBR</th><th>CPHA</th><th>PBR</th><th>SCK Duty Cycle</th></tr><tr><td>0</td><td>any</td><td>any</td><td>50/50</td></tr><tr><td>1</td><td>0</td><td>00</td><td>50/50</td></tr><tr><td>1</td><td>0</td><td>01</td><td>33/66</td></tr><tr><td>1</td><td>0</td><td>10</td><td>40/60</td></tr><tr><td>1</td><td>0</td><td>11</td><td>43/57</td></tr><tr><td>1</td><td>1</td><td>00</td><td>50/50</td></tr><tr><td>1</td><td>1</td><td>01</td><td>66/33</td></tr><tr><td>1</td><td>1</td><td>10</td><td>60/40</td></tr><tr><td>1</td><td>1</td><td>11</td><td>57/43</td></tr></table> 0 The baud rate is computed normally with a 50/50 duty cycle. 1 The baud rate is doubled with the duty cycle depending on the Baud Rate Prescaler. 1	1	11	57/43																																						
1–4 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ value plus 1. Regardless of the transmission mode, the minimum valid frame size value is 4. There is a constraint on the minimum allowable Frame size, which depends on the ratio of the Register Read/Write clock to the Protocol clock. The minimum Frame size (FMSZ + 1) is determined by the following equation. Upper Ceiling must be applied for non-integer values. Minimum Frame Size = ((4 x f_p) + (3 x f_r)) / (n x f_r) f_p = Protocol clock frequency f_r = Register interface clock frequency n = (PBR x BR) / (1 + DBR) = Multiple of protocol clock required to get Baud (SCK) Clock However, the minimum frame size can never be less than 4. There is no constraint on the maximum programmable frame size. Also note that `fp` can be equal to, less than or greater than `fr` purely based on user requirement.																																								

Table continues on the next page...

DSPI_CTAR_n field descriptions (continued)

Field	Description
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock polarities. When the Continuous Selection Format is selected, switching between clock polarities without stopping the module can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge. NOTE: In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode or TSB mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 LSBFE	LSB First Specifies whether the LSB or MSB of the frame is transferred first. 0 Data is transferred MSB first. 1 Data is transferred LSB first.
8–9 PCSSCK	PCS to SCK Delay Prescaler Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. See the CSSCK field description for information on how to compute the PCS to SCK Delay. Refer PCS to SCK Delay (t_{CSC}) for more details. 00 PCS to SCK Prescaler value is 1. 01 PCS to SCK Prescaler value is 3. 10 PCS to SCK Prescaler value is 5. 11 PCS to SCK Prescaler value is 7.
10–11 PASC	After SCK Delay Prescaler Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. See the ASC field description for information on how to compute the After SCK Delay. In the TSB mode, the PASC field has no effect. Refer After SCK Delay (t_{ASC}) for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
12–13 PDT	Delay after Transfer Prescaler Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. The PDT field is only used in master mode. See

Table continues on the next page...

Field	Description																																		
	the DT field description for details on how to compute the Delay after Transfer. Refer Delay after Transfer (t_{DT}) for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.																																		
14–15 PBR	Baud Rate Prescaler Selects the prescaler value for the baud rate. This field is used only in master mode. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. See the BR field description for details on how to compute the baud rate. 00 Baud Rate Prescaler value is 2. 01 Baud Rate Prescaler value is 3. 10 Baud Rate Prescaler value is 5. 11 Baud Rate Prescaler value is 7.																																		
16–19 CSSCK	PCS to SCK Delay Scaler Selects the scaler value for the PCS to SCK delay. This field is used only in master mode. In the TSB mode the field has no effect. The PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{CSC} = (1/f_P) \times PCSSCK \times CSSCK.$ The following table lists the delay scaler values. Table 42-10. DSPI_CTAR_n field descriptions (continued)

Field	Description																												
	Refer PCS to SCK Delay (t_{CSC}) for more details.																												
20–23 ASC	After SCK Delay Scaler Selects the scaler value for the After SCK Delay. This field is used only in master mode. The After SCK Delay is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{ASC} = (1/f_P) \times PASC \times ASC$ See Delay Scaler Encoding table in CTAR_n[CSSCK] bit field description for scaler values. Refer After SCK Delay (t_{ASC}) for more details.																												
24–27 DT	Delay After Transfer Scaler Selects the Delay after Transfer Scaler. This field is used only in master mode. The Delay after Transfer is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In the Continuous Serial Communications Clock operation, the DT value is fixed to one SCK clock period, The Delay after Transfer is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{DT} = (1/f_P) \times PDT \times DT$ See Delay Scaler Encoding table in CTAR_n[CSSCK] bit field description for scaler values. In the TSB mode, the Delay after Transfer is equal to a number formed by concatenation of the PDT and DT fields plus 1 of the SCK clock periods. Refer Delay after Transfer (t_{DT}) for more details.																												
28–31 BR	Baud Rate Scaler Selects the scaler value for the baud rate. This field is used only in master mode. The prescaled protocol clock is divided by the Baud Rate Scaler to generate the frequency of the SCK. The baud rate is computed according to the following equation: $SCK \text{ baud rate} = (f_P / PBR) \times [(1+DBR)/BR]$ The following table lists the baud rate scaler values. Table 42-9. 42.4.4 Clock and Transfer Attributes Register (In Slave Mode) (DSPI_CTAR_n_SLAVE)

When the module is configured as an SPI bus slave, the CTAR0 register is used.

When the module is configured as a DSI master, the DSICTAS field in the DSI Configuration Register 0 (DSICR0), selects which of the CTAR register is used. When the module is configured as a DSI bus slave, the CTAR1 register is used.

Address: 0h base + Ch offset + (4d × i), where i=0d to 1d

DSPI_CTAR_n_SLAVE field descriptions

Field	Description
0–4 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ field value plus 1. Note that the minimum valid value of frame size is 4.
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK).

Table continues on the next page...

DSPI_CTARn_SLAVE field descriptions (continued)

Field	Description
	NOTE: In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode or TSB mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 PE	Parity Enable Enables parity bit transmission and reception for the frame. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of last data bit in frame, parity checked for received frame.
8 PP	Parity Polarity Controls polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.
9 Reserved	This field is reserved.
10–31 Reserved	This field is reserved.

42.4.5 Status Register (DSPI_SR)

SR contains status and flag bits. The bits reflect the status of the module and indicate the occurrence of events that can generate interrupt or DMA requests. Software can clear flag bits in the SR by writing a 1 to them. Writing a 0 to a flag bit has no effect. This register may not be writable in Module Disable mode due to the use of power saving mechanisms.

Address: 0h base + 2Ch offset = 2Ch

DSPI_SR field descriptions

Field	Description
0 TCF	Transfer Complete Flag Indicates that all bits in a frame have been shifted out. TCF remains set until it is cleared by writing a 1 to it. 0 Transfer not complete. 1 Transfer complete.

Table continues on the next page...

DSPI_SR field descriptions (continued)

Field	Description
1 TXRXS	TX and RX Status Reflects the run status of the module. 0 Transmit and receive operations are disabled (The module is in Stopped state). 1 Transmit and receive operations are enabled (The module is in Running state).
2 Reserved	This field is reserved.
3 EOQF	End of Queue Flag Indicates that the last entry in a queue has been transmitted when the module is in Master mode. The EOQF bit is set when the TX FIFO entry has the EOQ bit set in the command halfword and the end of the transfer is reached. The EOQF bit remains set until cleared by writing a 1 to it. When the EOQF bit is set, the TXRXS bit is automatically cleared. 0 EOQ is not set in the executing command. 1 EOQ is set in the executing SPI command.
4 TFUF	Transmit FIFO Underflow Flag Indicates an underflow condition in the TX FIFO. The transmit underflow condition is detected only for DSPI blocks operating in Slave mode and SPI configuration. TFUF is set when the TX FIFO of the module operating in SPI Slave mode is empty and an external SPI master initiates a transfer. The TFUF bit remains set until cleared by writing 1 to it. 0 No TX FIFO underflow. 1 TX FIFO underflow has occurred.
5 Reserved	This field is reserved.
6 TFFF	Transmit FIFO Fill Flag Indicates whether there is an available location to be filled in the FIFO. Either a DMA request or an interrupt indication can be used to add another entry to the FIFO. Note that this bit is set if at least one location is free in the FIFO. The TFFF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller to the TX FIFO full request. NOTE: The reset value of this bit is 0 when the module is disabled, (MCR[MDIS]=1). 0 TX FIFO is full. 1 TX FIFO is not full.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 DPEF	DSI Parity Error Flag Indicates that a DSI frame with parity error had been received. The bit remains set until it is cleared by writing a 1 to it. 0 No parity error. 1 Parity error has occurred.
10 SPEF	SPI Parity Error Flag

Table continues on the next page...

DSPI_SR field descriptions (continued)

Field	Description
	Indicates that a SPI frame with parity error had been received. The bit remains set until it is cleared by writing a 1 to it. 0 No parity error. 1 Parity error has occurred.
11 DDIF	DSI Data Received with Active Bits Indicates that a DSI frame had been received with bits selected by DIMR with active polarity, defined by the DPIR register. The bit remains set until it is cleared by writing a 1 to it. 0 No DSI data with active bits was received. 1 DSI data with active bits was received.
12 RFOF	Receive FIFO Overflow Flag Indicates an overflow condition in the RX FIFO. The field is set when the RX FIFO and shift register are full and a transfer is initiated. The bit remains set until it is cleared by writing a 1 to it. 0 No Rx FIFO overflow. 1 Rx FIFO overflow has occurred.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 RFDF	Receive FIFO Drain Flag Indicates whether there is an available location to be drained from the FIFO. Either a DMA request or an interrupt indication can be used to read from the FIFO. Note that this bit is set if at least one location can be read from the FIFO. The RFDF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty. 0 RX FIFO is empty. 1 RX FIFO is not empty.
15 Reserved	This field is reserved.
16–19 TXCTR	TX FIFO Counter Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the PUSHHR is written. The TXCTR is decremented every time an SPI command is executed and the SPI data is transferred to the shift register.
20–23 TXNXTPTR	Transmit Next Pointer Indicates which TX FIFO entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register.
24–27 RXCTR	RX FIFO Counter Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.
28–31 POPNXTPTR	Pop Next Pointer Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPNXTPTR is updated when the POPR is read.

42.4.6 DMA/Interrupt Request Select and Enable Register (DSPI_RSER)

RSER controls DMA and interrupt requests. Do not write to the RSER while the module is in the Running state.

Address: 0h base + 30h offset = 30h

DSPI_RSER field descriptions

Field	Description
0 TCF_RE	Transmission Complete Request Enable Enables TCF flag in the SR to generate an interrupt request. 0 TCF interrupt requests are disabled. 1 TCF interrupt requests are enabled.
1 Reserved	Always write the reset value to this field. This field is reserved.
2 Reserved	This field is reserved.
3 EOQF_RE	Finished Request Enable Enables the EOQF flag in the SR to generate an interrupt request. 0 EOQF interrupt requests are disabled. 1 EOQF interrupt requests are enabled.
4 TFUF_RE	Transmit FIFO Underflow Request Enable Enables the TFUF flag in the SR to generate an interrupt request.

Table continues on the next page...

DSPI_RSER field descriptions (continued)

Field	Description
	0 TFUF interrupt requests are disabled. 1 TFUF interrupt requests are enabled.
5 Reserved	This field is reserved.
6 TFFF_RE	Transmit FIFO Fill Request Enable Enables the TFFF flag in the SR to generate a request. The TFFF_DIRS bit selects between generating an interrupt request or a DMA request. 0 TFFF interrupts or DMA requests are disabled. 1 TFFF interrupts or DMA requests are enabled.
7 TFFF_DIRS	Transmit FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When SR[TFFF] and RSER[TFFF_RE] are set, this field selects between generating an interrupt request or a DMA request. 0 TFFF flag generates interrupt requests. 1 TFFF flag generates DMA requests.
8 Reserved	Always write the reset value to this field. This field is reserved.
9 DPEF_RE	DSI Parity Error Request Enable Enables the DPEF flag in the SR to generate an interrupt request. 0 DPEF interrupt requests are disabled. 1 DPEF interrupt requests are enabled.
10 SPEF_RE	SPI Parity Error Request Enable Enables the SPEF flag in the SR to generate an interrupt request. 0 SPEF interrupt requests are disabled. 1 SPEF interrupt requests are enabled.
11 DDIF_RE	DSI data received with active bits Request Enable Enables the SR[DDIF] flag to generate an interrupt request. 0 Disabled 1 Enabled
12 RFOF_RE	Receive FIFO Overflow Request Enable Enables the RFOF flag in the SR to generate an interrupt request. 0 RFOF interrupt requests are disabled. 1 RFOF interrupt requests are enabled.
13 Reserved	Always write the reset value to this field. This field is reserved.
14 RFDF_RE	Receive FIFO Drain Request Enable

Table continues on the next page...

DSPI_RSER field descriptions (continued)

Field	Description
	Enables the RFDF flag in the SR to generate a request. The RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 RFDF interrupt or DMA requests are disabled. 1 RFDF interrupt or DMA requests are enabled.
15 RFDF_DIRS	Receive FIFO Drain DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When the RFDF flag bit in the SR is set, and the RFDF_RE bit in the RSER is set, the RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 Interrupt request. 1 DMA request.
16 Reserved	Always write the reset value to this field. This field is reserved.
17 Reserved	Always write the reset value to this field. This field is reserved.
18–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

42.4.7 PUSH TX FIFO Register In Master Mode (DSPI_PUSHR)

Specifies data to be transferred to the TX FIFO and CMD FIFO. User must write 16-bits data into TXDATA field. An 8- or 16-bit write access to the TXDATA field transfers 16 bits of data bus to the TX FIFO. A write access to the command fields transfers the 16 bits of command information to the CMD FIFO. In Master mode, the register transfers 16 bits of data to the TX FIFO and 16 bits of command information to the CMD FIFO.

The TX FIFO and CMD FIFO must be filled simultaneously. In other words, you must perform write accesses to both the data and command fields for every PUSHR operation. Because both the TX FIFO and CMD FIFO are written to and read from simultaneously, they behave as a single 32 bit FIFO.

A read access of PUSHR returns the topmost TX FIFO and CMD FIFO entries concatenated.

When the module is disabled, writing to this register does not update the FIFO. Therefore, any reads performed while the module is disabled return the last PUSHR write performed while the module was still enabled.

Address: 0h base + 34h offset = 34h

DSPI_PUSHR field descriptions

Field	Description
0 CONT	Continuous Peripheral Chip Select Enable Selects a continuous selection format. The bit is used in SPI Master mode. The bit enables the selected PCS signals to remain asserted between transfers. 0 Return PCSn signals to their inactive state between transfers. 1 Keep PCSn signals asserted between transfers.
1–3 CTAS	Clock and Transfer Attributes Select Selects which CTAR to use in master mode to specify the transfer attributes for the associated SPI frame. In SPI Slave mode, CTAR0 is used. See the chip specific section for details to determine how many CTARs this device has. You should not program a value in this field for a register that is not present. 000 CTAR0 001 CTAR1 010 CTAR2 011 CTAR3 100 CTAR4 101 CTAR5 110 CTAR6 111 CTAR7
4 EOQ	End Of Queue Host software uses this bit to signal to the module that the current SPI transfer is the last in a queue. At the end of the transfer, the EOQF bit in the SR is set. 0 The SPI data is not the last data to transfer. 1 The SPI data is the last data to transfer.
5 CTCNT	Clear Transfer Counter Clears the TCNT field in the TCR register. The TCNT field is cleared before the module starts transmitting the current SPI frame. 0 Do not clear the TCR[TCNT] field. 1 Clear the TCR[TCNT] field.

Table continues on the next page...

DSPI_PUSHR field descriptions (continued)

Field	Description
6 PE	Parity Enable Enables parity bit transmission and parity reception check for the SPI frame. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame.
7 PP	Parity Polarity Controls the polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.
8–9 Reserved	Always write the reset value to this field. This field is reserved.
10–15 PCS	Select which PCS signals are to be asserted for the transfer. Refer to the chip-specific DSPI information for the number of PCS signals used in this chip. 0 Negate the PCS[x] signal. 1 Assert the PCS[x] signal.
16–31 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated SPI command.

42.4.8 PUSH TX FIFO Register In Slave Mode (DSPI_PUSHR_SLAVE)

Specifies data to be transferred to the TX FIFO in slave mode. An 8- or 16-bit write access to PUSHR transfers the 16-bit TXDATA field to the TX FIFO.

Address: 0h base + 34h offset = 34h

DSPI_PUSHR_SLAVE field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated SPI command.

42.4.9 POP RX FIFO Register (DSPI_POPR)

POPR is used to read the RX FIFO. Eight- or sixteen-bit read accesses to the POPR have the same effect on the RX FIFO as 32-bit read accesses. A write to this register will generate a Transfer Error.

Address: 0h base + 38h offset = 38h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_POPR field descriptions

Field	Description
0–31 RXDATA	Received Data Contains the SPI data from the RX FIFO entry to which the Pop Next Data Pointer points.

42.4.10 Transmit FIFO Registers (DSPI_TXFRn)

TXFRn registers provide visibility into the TX FIFO for debugging purposes. Each register is an entry in the TX FIFO. The registers are read-only and cannot be modified. Reading the TXFRx registers does not alter the state of the TX FIFO.

Address: 0h base + 3Ch offset + (4d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_TXFRn field descriptions

Field	Description
0–15 TXCMD_ TXDATA	Transmit Command or Transmit Data In Master mode the TXCMD field contains the command that sets the transfer attributes for the SPI data. In Slave mode, this field is reserved.
16–31 TXDATA	Transmit Data Contains the SPI data to be shifted out.

42.4.11 Receive FIFO Registers (DSPI_RXFRn)

RXFRn provide visibility into the RX FIFO for debugging purposes. Each register is an entry in the RX FIFO. The RXFR registers are read-only. Reading the RXFRx registers does not alter the state of the RX FIFO. The field MCR[MDIS] must be 0 when RXFR is read.

Address: 0h base + 7Ch offset + (4d × i), where i=0d to 3d

DSPI_RXFRn field descriptions

Field	Description
0–31 RXDATA	Receive Data Contains the received SPI data.

42.4.12 DSI Configuration Register 0 (DSPI_DSICR0)

Selects various attributes associated with the following configurations:

- DSI
- TSB

Do not write to the DSICR0 while the module is in the Running state.

Address: 0h base + BCh offset = BCh

DSPI_DSICR0 field descriptions

Field	Description
0 Reserved	This field is reserved.
1 FMSZ4	MSB of the frame size in master mode. If the bit is set, 16 is added to the frame size, as defined by the CTARn[FMSZ] field. The CTARx register is selected by the DSICTAS field.
2–7 Reserved	This field is reserved.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DSPI_DSICR0 field descriptions (continued)

Field	Description
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 TSBC	Timed Serial Bus Configuration. Enables the Timed Serial Bus interface configuration and allows t_{DT} to be programmable. 0 Timed Serial Bus Configuration disabled. 1 Timed Serial Bus Configuration enabled.
12 TXSS	Transmit Data Source Select. Selects the source of data to be serialized. The source can be either data from host software written to the DSI Alternate Serialization Data Register (ASDR0/1) or Parallel Input pin states latched into the DSI Serialization Data Register (SDR0/1). 0 Source of serialized data is the SDR. 1 Source of serialized data is the ASDR.
13 TPOL	Trigger Polarity Selects the active edge of the hardware trigger input signal (HT), initiating DSI frames transfer. 0 Falling edge initiates a transfer. 1 Rising edge initiates a transfer.
14 TRRE	Trigger Reception Enable Enables the module to initiate a DSI frames transfer with an external trigger signal. NOTE: When TRIG[ENABLE] is set, the TRRE bit is given by TRIG[TRRE] which overrides DSICR0[TRRE]. 0 Trigger signal reception disabled. 1 Trigger signal reception enabled.
15 CID	Change In Data Transfer Enable Enables a change in serialization data to initiate a DSI frames transfer in DSI and CSI configurations. When the CID bit is set, DSI frames are initiated when the current DSI data differs from the previous DSI data shifted out. NOTE: When TRIG[ENABLE] is set, the CID bit is given by TRIG[CID] which overrides DSICR0[CID].
16 DCONT	DSI Continuous Peripheral Chip Select Enable Enables the PCS signals to remain asserted between transfers. The DCONT bit affects the PCS signals only in DSI master mode. When the TSBC bit is set, DCONT has no effect. 0 Return Peripheral Chip Select signals to their inactive state after the transfer is complete. 1 Keep Peripheral Chip Select signals asserted after transfer is complete.
17–19 DSICTAS	DSI Clock and Transfer Attributes Select Selects the CTAR register to use to provide transfer attributes for DSI frames. The DSICTAS field is used in DSI master mode. In DSI slave mode, CTAR1 is always selected.
20 DMS	Data Match Stop If set, stops DSI frame transmissions if DDIF flag is set in the SR register.

Table continues on the next page...

DSPI_DSICR0 field descriptions (continued)

Field	Description
	0 DDIF flag does not have an effect on DSI frame transmissions. 1 DDIF flag stops DSI frame transmissions.
21 PES	Parity Error Stop If set, stops DSI operation if the parity error happened in the received DSI frame. 0 Parity error does not stop DSI frame transmissions. 1 Parity error stops all DSI frame transmissions.
22 PE	Parity Enable Enables parity bit transmission and parity reception check for the DSI frames. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame.
23 PP	Parity Polarity Controls the polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[DPEF] bit is set if in the received frame number of 1 bits is odd. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[DPEF] bit is set if in the received frame number of 1 bits is even.
24–31 DPCSx	DSI Peripheral Chip Select 0–7 Selects which of the PCS signals to assert during a DSI master mode transfer. 0 Negate PCS[x]. 1 Assert PCS[x].

42.4.13 DSI Serialization Data Register 0 (DSPI_SDR0)

SDR0 contains the states of the 32 LSB Parallel Input signals. The states of the Parallel Input signals are latched into the SDR0 on the rising edge of every bus clock. The SDR0 is read-only. When the TXSS bit in the DSICR0 is cleared, the data in the SDR0 is used as the source of the DSI frames.

Address: 0h base + C0h offset = C0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_SDR0 field descriptions

Field	Description
0–31 SER_DATA	Serialized Data Contains the signal states of the 32 LSB Parallel Input signals.

42.4.14 DSI Alternate Serialization Data Register 0 (DSPI_ASDR0)

ASDR0 is used by host software to write the 32 LSB of the data to be serialized. When the TXSS bit in the DSICR0 is set, the data in the ASDR0 is the source of the DSI frames. Writes to the ASDR0 take effect on the next frame boundary.

Address: 0h base + C4h offset = C4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_ASDR0 field descriptions

Field	Description
0–31 ASER_DATA	Alternate Serialized Data Holds the alternate 32 LSB of the data to be serialized.

42.4.15 DSI Transmit Comparison Register 0 (DSPI_COMPR0)

COMPR0 holds a copy of the 32 LSB of the last transmitted DSI data. COMPR0 is read-only. DSI data is transferred to this register as it is loaded into the TX Shift Register.

Address: 0h base + C8h offset = C8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_COMPR0 field descriptions

Field	Description
0–31 COMP_DATA	Compare Data

DSPI_COMPR0 field descriptions (continued)

Field	Description
	Holds the 32 LSB of the last serialized DSI data.

42.4.16 DSI Deserialization Data Register 0 (DSPI_DDR0)

DDR0 holds the 32 LSB signal states for the Parallel Output signals. DDR0 is read-only and host software can read data from incoming DSI frames.

Address: 0h base + CCh offset = CCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
