0–31 DESER_DATA	Deserialized Data Holds 32 LSB of deserialized data that is presented as signal states to the Parallel Output signals.

42.4.17 DSI Configuration Register 1 (DSPI_DSICR1)

Selects various attributes associated with the following configurations:

- DSI
- TSB

The user must not write to the DSICR1 while the module is in the Running state.

Address: 0h base + D0h offset = D0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

DSPI_DSICR1 field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 TSBCNT	Timed Serial Bus Operation Count When TSB is enabled (DSICR0[TSBC]), TSBCNT defines the length of the data frame. The length value can vary from 3 to 31 (00011b to 11111b). The length value specifies the number of data bits to be shifted out during a transfer in TSB mode. The number of data bits in the data frame is one more than the value in the TSBCNT field.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 DSE1	Data Select Enable 1 When the TBSC bit is set, the DSE1 bit controls insertion of the zero bit (Data Select) in the middle of the data frame. The insertion bit position is defined by the FMSZ field of CTARn register, selected by the DSICR0[DSICTAS] field. The TSBCNT field value must be greater than the position of insertion for proper operation of DSE1. 0 No Zero bit is inserted in the middle of the data frame. 1 Zero bit is inserted at the middle of the data frame. Total number of bits in the data frame is increased by 1.
15 DSE0	Data Select Enable 0 When the TBSC bit is set, the DSE1 bit controls insertion of the zero bit (Data Select) in the beginning of the DSI frame. 0 No Zero bit is inserted in the beginning of the frame. 1 Zero bit is inserted at the beginning of the data frame. Total number of bits in the data frame is increased by 1.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 DPCS1_x	DSI Peripheral Chip Select 0–7 Specifies the PCSs to assert for the second part of the DSI frame when operating in TSB configuration with dual receiver. DPCS1 selects the PCS signals to assert during the second part of the DSI frame. DPCS1 controls the assertions of PCS signals only in TSB mode. 0 Negate PCS[x]. 1 Assert PCS[x].

42.4.18 DSI Serialization Source Select Register 0 (DSPI_SSR0)

SSR0 is used to create a combined frame for transmission that contains bits from ASDR0 and SDR0. Each bit in the SSR0 register selects a corresponding bit to be serialized. When DSICR0[TXSS] is set, the SSR0 register value has no effect.

Address: 0h base + D4h offset = D4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_SSR0 field descriptions

Field	Description
0–31 SS	Source Select Select the serialization source for the 32 LSB of the DSI frame. Each SS bit selects data for a corresponded bit in the transmitted frame. 0 The bit in the transmitted frame is taken from the Parallel Input pin. 1 The bit in the transmitted frame is taken from the ASDR0 register

42.4.19 DSI Parallel Input Select Register 0 (DSPI_PISR0)

PISR0–3 select each data bit for the transmitted frame from 32 parallel input pins. Each Input Pin Select (IPS) field controls one bit in the transmitted frame. Each register contains control fields for 8 bits in the frame. The select field value is defined as a 4-bit signed integer number. The selected parallel input pin number is defined as a difference between the sum of the field number and the field value.

For example, if IPS16 is equal to the binary number 1111 (minus 1 decimal), then bit 16 in the frame is taken from parallel input pin number 15. When the IPS0 is equal to -1, then bit 0 in the frame is taken from parallel input 31. When the IPS0 is equal to +1, then bit 0 in the frame is taken from Parallel Input 1 and so on.

Note that PISR0–3 only preselect the Parallel Input pins. The final selection to the transmitted frame is made with the SSR0-1 register bits or the DSICR0[TXSS] bit.

1	If the received bit is 1, the SR[DDIF] bit is set.

42.5 Functional description

The module supports full-duplex, synchronous serial communications between chips and peripheral devices. The module can also be used to reduce the number of pins required for I/O by serializing and deserializing Parallel Input/Output signals. All communications are done with SPI-like protocol.

The module has the following configurations

- The SPI Configuration in which the module operates as a basic SPI or a queued SPI.
- DSI Configuration in which the module serializes and deserializes Parallel Input/Output signals or bits from memory-mapped registers
- When Master mode is enabled, the module also supports CSI Configuration, which combines the functionality of the SPI and DSI configurations.

The DCONF field in the Module Configuration Register (MCR) determines the module Configuration. See [Module Configuration Register \(DSPI_MCR\)](#) for the DSPI configuration values.

The CTAR_n registers hold clock and transfer attributes. The SPI configuration allows to select which CTAR to use on a frame by frame basis by setting a field in the SPI command.

The DSI configuration statically selects which CTAR to use. In CSI, Configuration priority logic determines if SPI data or DSI data is transferred and dictates what CTAR register is used for the data transfer. See [Clock and Transfer Attributes Register \(In Master Mode\) \(DSPI_CTAR_n\)](#) for information on the fields of CTAR registers.

Typical master to slave connections are shown in the following figure. When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave. The data that was in the master shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, the Transfer Control Flag(TCF) bit in the Shift Register(SR) is set to indicate a completed frame transfer.

Figure 42-45. Serial protocol overview

Generally, more than one slave device can be connected to the module master. 6 Peripheral Chip Select (PCS) signals of the module masters can be used to select which of the slaves to communicate with. Refer to the chip specific section for details on the number of PCS signals used in this chip.

The three DSPI configurations share transfer protocol and timing properties which are described independently of the configuration in [Transfer formats](#). The transfer rate and delay settings are described in [Module baud rate and clock delay generation](#).

42.5.1 Start and Stop of module transfers

The module has two operating states: Stopped and Running. Both the states are independent of it's configuration. The default state of the module is Stopped. In the Stopped state, no serial transfers are initiated in Master mode and no transfers are responded to in Slave mode. The Stopped state is also a safe state for writing the various configuration registers of the module without causing undetermined results. In the Running state serial transfers take place.

The TXRXS bit in the SR indicates the state of module. The bit is set if the module is in Running state.

The module starts or transitions to Running when all of the following conditions are true:

- SR[EOQF] bit is clear
- Chip is not in the Debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The module stops or transitions from Running to Stopped after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set

- Chip in the Debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from Running to Stopped occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

42.5.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The module is in SPI configuration when the DCONF field in the MCR is 0b00. The SPI frames can be 32 bits long. The host CPU or a DMA controller transfers the SPI data from the external to the module RAM queues to a TX FIFO buffer. The received data is stored in entries in the RX FIFO buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the module. The operation of FIFO buffers is described in the following sections:

- [Transmit First In First Out \(TX FIFO\) buffering mechanism](#)
- [Command First In First Out \(CMD FIFO\) Buffering Mechanism](#)
- [Receive First In First Out \(RX FIFO\) buffering mechanism](#)

The interrupt and DMA request conditions are described in [Interrupts/DMA requests](#).

The SPI configuration supports two block-specific modes—Master mode and Slave mode. In Master mode the module initiates and controls the transfer according to the fields of the executing SPI Command. In Slave mode, the module responds only to transfers initiated by a bus master external to it and the SPI command field space is reserved.

42.5.2.1 Master mode

In SPI Master mode, the module initiates the serial transfers by controlling the SCK and the PCS signals. The executing SPI Command determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See [PUSH TX FIFO Register In Master Mode \(DSPI_PUSHR\)](#) for details on the SPI command fields. The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the Serial Out (SOUT) pin. In SPI Master mode, each SPI frame to be transmitted has a command associated with it, allowing for transfer attribute control on a frame by frame basis.

42.5.2.2 Slave mode

In SPI Slave mode the module responds to transfers initiated by an SPI bus master. It does not initiate transfers. Certain transfer attributes such as clock polarity, clock phase, and frame size must be set for successful communication with an SPI master. The SPI Slave mode transfer attributes are set in the CTAR0. The data is shifted out with MSB first. Shifting out of LSB is not supported in this mode.

42.5.2.3 FIFO disable operation

The FIFO disable mechanisms allow SPI transfers without using the TX FIFO, CMD FIFO or RX FIFO. The module operates as a double-buffered simplified SPI when the FIFOs are disabled. The Transmit and Receive side of the FIFOs are disabled separately. Setting the MCR[DIS_TXF] bit disables the TX FIFO and CMD FIFO, and setting the MCR[DIS_RXF] bit disables the RX FIFO.

The FIFO disable mechanisms are transparent to the user and to host software. Transmit data and commands are written to the PUSHHR and received data is read from the POPR.

When the TX FIFO and CMD FIFO are disabled:

- SR[TFFF], SR[TFUF] and SR[TXCTR] behave as if there is a one-entry FIFO
- The contents of TXFRs, SR[TXNXTPTR] are undefined

Similarly, when the RX FIFO is disabled, the RFDF, RFOF, and RXCTR fields in the SR behave as if there is a one-entry FIFO, but the contents of the RXFR registers and POPNXTPTR are undefined.

42.5.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission. The TX FIFO holds 4 words, each consisting of SPI data. The number of entries in the TX FIFO is device-specific. SPI data is added to the TX FIFO by writing to the Data Field of module PUSH FIFO Register (PUSHHR). TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the module Status Register (SR) indicates the number of valid entries in the TX FIFO. The TXCTR is updated every time a 8- or 16-bit write takes place to PUSHHR[TXDATA] or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates the TX FIFO Entry that will be transmitted during the next transfer. The TXNXTPTR field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR number and it rolls over after reaching the maximum.

42.5.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO and CMD FIFO by writing to the PUSHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set. The TFFF bit is cleared when TX FIFO is full and the DMA controller indicates that a write to PUSHR is complete. Writing a '1' to the TFFF bit also clears it. The TFFF can generate a DMA request or an interrupt request. See [Transmit FIFO Fill Interrupt or DMA Request](#) for details.

The module ignores attempts to push data to a full TX FIFO, and the state of the TX FIFO does not change and no error condition is indicated.

42.5.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one. At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a '1' to the CLR_TXF bit in MCR.

If an external bus master initiates a transfer with a module slave while the slave's TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave's SR is set. See [Transmit FIFO Underflow Interrupt Request](#) for details.

42.5.2.5 Command First In First Out (CMD FIFO) Buffering Mechanism

The CMD FIFO functions as a buffer of SPI command used for SPI data transmission. The TX FIFO and CMD FIFO must be filled together, i.e. write enables should be given for both the Data and Command fields while performing a PUSHR operation.

The CMD FIFO holds 4 words, each representing SPI command fields. The number of entries in the CMD FIFO is device-specific. SPI Command is added to the CMD FIFO by writing to the command field of DSPI PUSH FIFO Register (PUSHR). CMD FIFO entries can only be removed from the CMD FIFO by being shifted out (to help transmit SPI data) or by flushing the CMD FIFO.

Every CMD FIFO entry has a corresponding single TX FIFO entry attached to it because both these FIFO's are filled simultaneously.

42.5.2.6 Receive First In First Out (RX FIFO) buffering mechanism

The RX FIFO functions as a buffer for data received on the SIN pin. The RX FIFO holds 4 received SPI data frames. The number of entries in the RX FIFO is device-specific. SPI data is added to the RX FIFO at the completion of a transfer when the received data in the shift register is transferred into the RX FIFO. SPI data are removed (popped) from the RX FIFO by reading the module POP RX FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the module's Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the SR points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in a number of 32-bit registers. For example, POPNXTPTR equal to two means that the RXFR2 contains the received SPI data that will be returned when the POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR number and it rolls over after reaching the maximum.

42.5.2.6.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register. While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time an SPI frame is transferred to the RX FIFO, the RX FIFO Counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the SR is set indicating an overflow condition. Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

42.5.2.6.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the module POP RX FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one. Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data, read from the empty RX FIFO, is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the SR is set. The RFDF bit is cleared when the RX_FIFO is empty and the DMA controller indicates that a read from POPR is complete or by writing a 1 to it.

42.5.3 Deserial Serial Interface (DSI) Configuration

The DSI Configuration supports pin count reduction by serializing Parallel Input signals or register bits and shifting them out in a SPI-like protocol. The timing and transfer protocol is described in [Transfer formats](#). The received serial frames are converted to a parallel form (deserialized) and placed on the Parallel Output signals or in the DSPI_DDR register. The various features of the DSI Configuration are set in DSPI DSI Configuration Registers (DSPI_DSICR0/1).

The DSI frames can be from 4 to 32 bits.

42.5.3.1 DSI Master Mode

In DSI master mode the DSPI initiates and controls the DSI transfers. The DSI master has different conditions that can initiate a transfer:

- Continuous
- Change in data
- Trigger signal
- Trigger signal combined with a change in data

These transfer initiation conditions are described in [DSI Transfer Initiation Control](#). Transfer attributes are set during initialization. The DSICTAS field in the DSPI_DSICR0 determines which of the DSPI_CTAR registers will control the transfer attributes.

42.5.3.2 Slave Mode

In DSI slave mode the DSPI responds to transfers initiated by a SPI or DSI bus master. In this mode the DSPI does not initiate DSI transfers. Certain transfer attributes such as clock polarity and phase must be set for successful communication with a DSI master. The DSI slave mode transfer attributes are set in the DSPI_CTAR1. The data is shifted out with MSB first.

42.5.3.3 DSI Serialization

In the DSI Configuration, up to 32 bits can be serialized using two different sources. The TXSS bit in the DSPI_DSICR0 selects between the DSPI DSI Serialization Data Register (DSPI_SDR0) and the DSPI DSI Alternate Serialization Data Register (DSPI_ASDR0) as the source of the serialized data. The DSPI_SDR0 holds the latest 32 Parallel Input signal values which is sampled at every rising edge of the bus clock. The DSPI_ASDR0 register is written by host software and used as an alternate source of serialized data.

The DSPI has to sample the inputs (from SDR0 or ASDR0) before it transmits a DSI frame. Due to the asynchronous clocking structure within DSPI, the sampled data (from SDR0 or ASDR0) must be synchronized into the Protocol Domain before being loaded into the Shift Register for transmission.

To prevent Clock Domain Crossing issues, inputs from SDR0 or ASDR0 should not change while they are being sampled into the Protocol Domain. This is ensured in the following manner for the ASDR0 inputs. The initial write performed on ASDR0 register will cause the 32-bit ASDR0 input to be latched into a temporary register which is then locked (further latching is prevented) until this data gets synchronized into the Protocol Domain. Once synchronized, the lock is removed and the next ASDR0 write will again trigger this process. If there was a write performed on ASDR0 while the lock was asserted, this will be taken into consideration as soon as the previous synchronization process completes and lock gets de-asserted. In case, multiple writes were performed on ASDR0 when lock was asserted, only the latest value will be considered for synchronization once the lock gets de-asserted.

The entire process explained above is also true for the SDR0 input, the only difference being that SDR0 inputs are delayed internally by a single Bus clock (register interface clock) to detect a change in the parallel input pins.

Once the synchronization process for a particular De-serial input begins, it takes up to 5 Bus clock (register interface clock) periods and 5 Protocol clock periods before the synchronization process for the next De-serial input can begin. Hence the writes performed on ASDR0 and SDR0 are constrained with this timing.

The DSPI_PISR0-3 registers allow to change relative position of the Parallel input pins in the transmitted frame. Each transmitted frame bit can be selected from 16 adjacent Parallel Inputs by writing IPSn fields. The IPSn field is treated as 4 bit integer number, representing numbers from -8 to 7. The Parallel Input pin number, selected by IPSn field is defined by the difference between the IPSn field number (n) and the IPSn field value. If the operation result is negative the number 32 should be added. If the result is higher than 32, 32 should be subtracted from the result.

For example, IPS0, set to minus 1 (binary 1111), preselects Parallel Input 1 to 0 position in the transmitted frame.

IPS6, set to 3 (binary 0011), preselects Parallel Input 3 to be bit number 6 in the transmitted frame. The value minus 2 (1110) preselects Parallel Input 8.

IPS31, set to minus 8 (binary 1000), preselects Parallel Input 7 to be bit number 31 in the transmitted frame.

Note

The Parallel Input pin state, to be transmitted, should be selected by TXSS or DSPI_SSR0 register and the frame size should be higher than the bit position in the preselected frame.

DSPI_SSR0 register provides additional way to create the frame for transmission. Each bit from this register is OR'd with the TXSS bit and controls individual transmitted bit source. This way, the transmitted frame can have any combination of the DSPI_SDR0 and DSPI_ASDR0 bits. This feature allows control SPI based devices, requiring control and data fields in the frame. Control field may come from DSPI_ASDR0 register, set by the device's CPU, while data field can be generated by device peripheral modules, like PWM timers.

A copy of the last DSI frame shifted out of the Shift Register is stored in the DSPI DSI Transmit Comparison Register (DSPI_COMPR0). This register provides added visibility for debugging and it serves as a reference for transfer initiation control. The following figure shows the DSI Serialization logic.

Figure 42-46. DSI Serialization Diagram

42.5.3.4 DSI Deserialization

When all bits in a DSI frame have been shifted in, the frame is copied to the DSPI DSI Deserialization Data Register (DSPI_DDR0). This register presents the deserialized data as Parallel Output signal values. DSPI_DDR0 is memory mapped to allow host software to read the deserialized data directly.

The received data is bit-wise compared to the value of the DSI Deserialized Data Polarity Interrupt Register (DSPI_DPIR0), bit-wise AND'ed with DSI Deserialized Interrupt Mask Register (DSPI_DIMR0) and the results OR'ed to produce DDIF flag in the DSPI_SR register; which in turn can cause DDI interrupt request or DMA request based on RSER[DDIF_RE] and RSER[DDIF_DIRS] bits and/or stop DSI frame transmissions if DSICR0[DMS] bit is set.

The following figure shows the DSI Deserialization logic.

Figure 42-47. DSI Deserialization Diagram

42.5.3.5 DSI Transfer Initiation Control

Data transfers for a DSPI in DSI configuration are initiated by a condition. The transfer initiation conditions are selected by the TRRE and CID bits in the DSPI_DSICR0. The following table lists the four transfer initiation conditions.

Table 42-75. DSI Data Transfer Initiation Control

DSPI_DSICR0 Bits		Transfer Initiation Control
TRRE	CID	
0	0	Continuous
0	1	Change in Data
1	0	Triggered
1	1	Triggered or Change in Data

42.5.3.5.1 Continuous Control

For Continuous Control a new DSI frame shifts out when the previous transfer cycle has completed and the Delay after Transfer (t_{DT}) has elapsed. This has no effect when DSPI is in Slave Mode.

42.5.3.5.2 Change In Data Control

For change in data control a transfer is initiated when the data to be serialized has changed since the transfer of the last DSI frame. A copy of the previously transferred DSI data is stored in DSPI_COMPR0. When the data selected for the transfer from the DSPI_SDR0 and DSPI_ASDR0 registers is different from the data in DSPI_COMPR0 a new DSI frame is transmitted.

NOTE

It is not advisable to configure a DSPI slave with the combination DSICR0[DCONT] = 1, DSICR0[CID] = 1 ; since the following statement then holds true.

Once slave select is asserted, there is a very small window (of up to t module clocks) after every SOF (Start of Frame) during which if a write on ASDR/SDR registers occur, the next frame to be transmitted would be loaded into the shift register. However, it is not feasible that such a write be initiated and completed within this short span of time; hence the data transmitted by DSPI slave would lag by one data frame.

42.5.3.5.3 Triggered Control

For Triggered Control initiation of a transfer is controlled by the Hardware Trigger signal (HT). The TPOL bit in the DSPI_DSICR0 selects the active edge of HT. For HT to have any affect, the TRRE bit in the DSPI_DSICR0 must be set.

42.5.3.5.4 Triggered or Change In Data Control

For Triggered or Change in Data Control, initiation of a transfer is controlled by the HT signal or by the detection of a change in data to be serialized.

42.5.4 Combined Serial Interface (CSI) Configuration

The CSI Configuration of the DSPI is used to support SPI and DSI functions on a frame by frame basis. CSI Configuration allows interleaving of DSI data frames from the parallel input signals with SPI data frames from the TX FIFO. The data returned from the bus slave is either used to drive the Parallel Output signals or it is stored in the RX FIFO. The CSI Configuration allows serialized data and configuration or diagnostic data to be transferred to a slave device using only one serial link. The DSPI is in CSI Configuration when the DCONF field in the DSPI_MCR is 0b10. The following figure shows an example of how a DSPI can be used with a deserializing peripheral that supports SPI control for control and diagnostic frames.

Figure 42-48. Example of System using DSPI in CSI Configuration

In CSI Configuration the DSPI transfers DSI data based on [DSI Transfer Initiation Control](#).

When SPI commands are in the TX FIFO, the SPI frames have priority over the DSI frames. When the TX FIFO or CMD FIFO is empty, DSI transfer resumes.

Two peripheral chip select signals indicate whether DSI data or SPI data is transmitted. The user must configure the DSPI so that the two CTAR registers associated with DSI data and SPI data assert different peripheral chip select signals denoted in the figure as PCSx and PCSy. The CSI Configuration is only supported in master mode.

Data returned from the external slave while a DSI frame is transferred is placed on the Parallel Output signals. Data returned from the external slave while a SPI frame is transferred is moved to the RX FIFO. The TX FIFO, CMD FIFO and RX FIFO are fully functional in CSI mode.

42.5.4.1 CSI Serialization

Serialization in the CSI configuration is similar to serialization in DSI Configuration. The transfer attributes for SPI frames are determined by the DSPI_CTAR register selected by the CTAS field in the SPI command halfword. The transfer attributes for the DSI frames are determined by the DSPI_CTAR register selected by the DSICTAS field in the DSPI_DSICR0.

The Parallel Inputs signal states are latched into the DSPI DSI Serialization Data Register (DSPI_SDR0) and serialized based on the transfer initiation control settings in the DSPI_DSICR0. When SPI frames are written to the TX FIFO (and when CMD FIFO is not empty) they have priority over DSI data from the DSPI_SDR and are transferred at the next frame boundary. A copy of the most recently transferred DSI frame is stored in DSPI_COMPR0. The Transfer Priority Logic selects the source of the serialized data and asserts the appropriate PCS signal.

Separate frame completion interrupts are available to indicate frame transmission completion from SPI and DSI frames.

42.5.4.2 CSI Deserialization

The deserialized frames in CSI Configuration go into the DSPI_DDR0 or the RX FIFO based on the transfer priority logic. When DSI frames are transferred the returned frames are deserialized and latched into the DSPI_DDR0. When SPI frames are transferred the returned frames are deserialized and written to the RX FIFO.

42.5.5 Module baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the protocol clock frequency by a prescaler and a scaler with the option for doubling the baud rate. The following figure shows conceptually how the SCK signal is generated.

Figure 42-49. Communications clock prescalers and scalers

42.5.5.1 Baud rate generator

The baud rate is the frequency of the SCK. The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR, and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. The following table shows an example of how to compute the baud rate.

Table 42-76. Baud rate computation example

f_p	PBR	Prescaler	BR	Scaler	DBR	Baud rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/s
20 MHz	0b00	2	0b0000	2	1	10 Mb/s

NOTE

The clock frequencies mentioned in the preceding table are given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

42.5.5.2 PCS to SCK Delay (t_{csc})

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. See [Figure 42-51](#) for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTAR_x registers select the PCS to SCK delay by the formula in the CSSCK field description. The following table shows an example of how to compute the PCS to SCK delay.

Table 42-77. PCS to SCK delay computation example

f_{sys}	PCSSCK	Prescaler	CSSCK	Scaler	PCS to SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 μs

PCSCSK and CSSCK fields have no effect in TSB configuration.

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

42.5.5.3 After SCK Delay (t_{Asc})

The After SCK Delay is the length of time between the last edge of SCK and the negation of PCS. See [Figure 42-51](#) and [Figure 42-52](#) for illustrations of the After SCK delay. The PASC and ASC fields in the CTAR_x registers select the After SCK Delay by the formula in the ASC field description. The following table shows an example of how to compute the After SCK delay.

Table 42-78. After SCK Delay computation example

f_p	PASC	Prescaler	ASC	Scaler	After SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 μs

PCASC and ASC fields have no effect in TSB configuration.

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

42.5.5.4 Delay after Transfer (t_{DT})

The Delay after Transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See [Figure 42-51](#) for an illustration of the Delay after Transfer. The PDT and DT fields in the CTARx registers select the Delay after Transfer by the formula in the DT field description. The following table shows an example of how to compute the Delay after Transfer.

Table 42-79. Delay after Transfer computation example

f_p	PDT	Prescaler	DT	Scaler	Delay after Transfer
100 MHz	0b01	3	0b1110	32768	0.98 ms

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

When in Non-Continuous Clock mode the t_{DT} delay is configured according to the equation specified in the CTAR[DT] field description. When in Continuous Clock mode and TSB is not enabled, the delay is fixed at 1 SCK period.

In TSB mode the Delay after Transfer is equal to a number formed by concatenation of PDT and DT fields plus 1 of the SCK clock periods. See detailed information on [Timed Serial Bus \(TSB\)](#)".

42.5.5.5 Peripheral Chip Select Strobe Enable ($\overline{PCSS}$)

The $\overline{PCSS}$ signal provides a delay to allow the PCS signals to settle after a transition occurs thereby avoiding glitches. When the Module is in Master mode and the PCSSE bit is set in the MCR, $\overline{PCSS}$ provides a signal for an external demultiplexer to decode peripheral chip selects other than PCS5 into glitch-free PCS signals. The following figure shows the timing of the $\overline{PCSS}$ signal relative to PCS signals.

Figure 42-50. Peripheral Chip Select Strobe timing

The delay between the assertion of the PCS signals and the assertion of $\overline{\text{PCSS}}$ is selected by the PCSSCK field in the CTAR based on the following formula:

$$t_{\text{PCSSCK}} = \frac{1}{f_{\text{P}}} \times \text{PCSSCK}$$

At the end of the transfer, the delay between $\overline{\text{PCSS}}$ negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

$$t_{\text{PASC}} = \frac{1}{f_{\text{P}}} \times \text{PASC}$$

The following table shows an example of how to compute the t_{pcssck} delay.

Table 42-80. Peripheral Chip Select Strobe Assert computation example

f_{P}	PCSSCK	Prescaler	Delay before Transfer
100 MHz	0b11	7	70.0 ns

The following table shows an example of how to compute the t_{pasc} delay.

Table 42-81. Peripheral Chip Select Strobe Negate computation example

f_{P}	PASC	Prescaler	Delay after Transfer
100 MHz	0b11	7	70.0 ns

The $\overline{\text{PCSS}}$ signal is not supported when Continuous Serial Communication SCK or TSB mode is enabled.

NOTE

The clock frequency mentioned in the preceding tables is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

42.5.6 Transfer formats

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In Master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTARn) select the polarity and phase of the serial clock, SCK.

- CPOL - Selects the idle state polarity of the SCK
- CPHA - Selects if the data on SOUT is valid before or on the first SCK edge

Even though the bus slave does not control the SCK signal, in Slave mode the values of CPOL and CPHA must be identical to the master device settings to ensure proper transmission. In SPI Slave mode, only CTAR0 is used. In DSI slave mode, only CTAR1 is used.

The module supports four different transfer formats:

- Classic SPI with CPHA=0
- Classic SPI with CPHA=1
- Modified Transfer Format with CPHA = 0
- Modified Transfer Format with CPHA = 1

A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The module can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the interface configurations, the module provides the option of keeping the PCS signals asserted between frames. See [Continuous Selection Format](#) for details.

42.5.6.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in following figure is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

Figure 42-51. Module transfer timing diagram (MTFE=0, CPHA=0, FMSZ=8)

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the t_{CSC} delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals. At the second edge of the SCK, the master and slave devices place their second data bit on their serial data output signals. For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signals. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

42.5.6.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in the following figure is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format, the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges.

Figure 42-52. Module transfer timing diagram (MTFE=0, CPHA=1, FMSZ=8)

The master initiates the transfer by asserting the PCS signal to the slave. After the t_{CSC} delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins. For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signal. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

42.5.6.3 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The DSPI in the slave mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The DSPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI_MCR[SMPL_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actual sample point is delayed by one protocol clock cycle automatically by the design.

The following timing diagrams illustrate the DSPI operation with MTFE=1. Timing delays shown are:

- T_{csc} - PCS to SCK assertion delay
- T_{acs} - After SCK PCS negation delay
- $T_{su_{ms}}$ - master SIN setup time
- $T_{hd_{ms}}$ - master SIN hold time
- $T_{vd_{sl}}$ - slave data output valid time, time between slave data output SCK driving edge and data becomes valid.
- $T_{su_{sl}}$ - data setup time on slave data input
- $T_{hd_{sl}}$ - data hold time on slave data input
- T_{sys} - protocol clock period.

The following figure shows the modified transfer format for CPHA = 0 and Fsys/Fsck = 4. Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behavior are shown.

- Signal, marked "SOUT of Ext Slave", presents regular SPI slave serial output.
- Signal, marked "SOUT of DSPI Slave", presents DSPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show DSPI SIN input as being driven by a regular external SPI slave, configured according DSPI master CPHA programming.

Note

In the following diagrams, f_{sys} represents the protocol clock frequency from which the Baud frequency f_{sck} is derived.

Figure 42-53. DSPI Modified Transfer Format (MTFE=1, CPHA=0, $f_{\text{sck}} = f_{\text{sys}}/4$)

Figure 42-54. DSPI Modified Transfer Format (MTFE=1, CPHA=0, $f_{\text{sck}} = f_{\text{sys}}/2$)

Figure 42-55. DSPI Modified Transfer Format (MTFE=1, CPHA=0, $f_{sck} = f_{sys}/3$)

42.5.6.4 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK. The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT signal on the odd numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. **The SCK to PCS delay and the After SCK delay must be greater or equal to half of the SCK period.**

NOTE

When MTFE=1 with continuous SCK enabled (MCR [CONT_SCKE] =1) in master mode, configure CTAR[LSBFE]=0 for correct operations while receiving unequal length frames. If PUSH[CONT] is also set for back to back frame transfer, also configure the frame size of the first frame as less than or equal to the frame size of the next frame. In this scenario, make sure that for all received frames, the bits are read equal to their respective frame sizes and any extra bits during POP operation are masked.

Figure 42-56. DSPI Modified Transfer Format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/2$)

Figure 42-57. DSPI Modified Transfer Format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/3$)

Figure 42-58. DSPI Modified Transfer Format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/4$)

42.5.6.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle both the following cases. The Continuous Selection Format is enabled for the SPI configuration by setting the CONT bit in the SPI command. Continuous Selection is enabled for the DSI Configuration by setting the DCONT bit in the DSICR0. The behavior of the PCS signals in the two configurations is identical so only SPI configuration will be described.

When the CONT bit = 0, the module drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select signals are selected by the PCSISn bits in the MCR. The following timing diagram is for two four-bit transfers with CPHA = 1 and CONT = 0.

Figure 42-59. Example of non-continuous format (CPHA=1, CONT=0)

When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers (t_{DT}) is not inserted between the transfers. The following figure shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

Figure 42-60. Example of continuous transfer (CPHA=1, CONT=1)

When using the module with continuous selection follow these rules:

- All transmit commands must have the same PCSn bits programming.
- The CTARs, selected by transmit commands, must be programmed with the same transfer attributes. Only FMSZ field can be programmed differently in these CTARs.

- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHHR[CONT] bit deasserted in Master mode and the user software must provide sufficient frames in the TX_FIFO to be sent out in Slave mode and the master deasserts the PCSn at end of transmission of the last frame.
- PUSHHR[CONT] and DSICR0[DCONT] must be deasserted before asserting MCR[HALT] in master mode. This will make sure that the PCSn signals are deasserted. Asserting MCR[HALT] during continuous transfer will cause the PCSn signals to remain asserted and hence Slave Device cannot transition from Running to Stopped state.

NOTE

User must fill the TX FIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TX FIFO becomes empty.

When operating in Slave mode, ensure that when the last entry in the TX FIFO is completely transmitted, that is, the corresponding TCF flag is asserted and TXFIFO is empty, the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

42.5.7 Continuous Serial Communications Clock

The module provides the option of generating a Continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT_SCKE bit in the MCR. Enabling this bit generates the Continuous SCK only if MCR[HALT] bit is low. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA=1. Clearing CPHA is ignored if the CONT_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the module is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- When the module is in DSI configuration, the CTAR specified by the DSICTAS field is used at all times.

- When the module is in CSI configuration, the CTAR selected by the DSICTAS field is used initially.
 - At the start of a SPI frame transfer, the CTAR specified by the CTAS value for the frame is used.
 - At the start of a DSI frame transfer, the CTAR specified by the DSICTAS field is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the module is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer (t_{DT}) is fixed to one SCK cycle. When TSB configuration is enabled the t_{DT} is programmable from 1 to 64 SCK cycles. The following figure is the timing diagram for Continuous SCK format with Continuous Selection disabled.

NOTE

In Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TX FIFO must be cleared using the MCR[CLR_TXF] field before initiating transfer.

Figure 42-61. Continuous SCK Timing Diagram (CONT=0)

If the CONT bit in the TX FIFO entry is set or the DCONT in DSICR0 is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with PCS asserted, but with no data being shifted out of SOUT, that is, SOUT pulled high. This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the TX FIFO.
- Continuous SCK with CONT bit set and entering Stopped state (refer to [Start and Stop of module transfers](#)).
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

The following figure shows timing diagram for Continuous SCK format with Continuous Selection enabled.

Figure 42-62. Continuous SCK timing diagram (CONT=1)

42.5.8 Slave Mode Operation Constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the module is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the $\overline{SS}$ signal is asserted and any time when transmit data is ready and $\overline{SS}$ signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programmed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR register.

If the $\overline{SS}$ negates before that last SCK edge, the data from shift register is lost.

42.5.9 Timed Serial Bus (TSB)

The DSPI can be programmed in Timed Serial Bus configuration by setting the TSBC bit in the DSPI_DSICR0 register. See DSPI DSI Configuration Register 0 (DSPI_DSICR0) for details.

TSB configuration provides the Micro Second Channel (MSC) downstream channel support.

The MSC upstream channel is not supported by the DSPI, but can be supported by any available Serial Communication Controller (SCI or UART) in the SoC.

The DSI Continuous Frame Selection Format is not supported by the TSB Mode (DSICR0[DCONT] bit cannot not be asserted).

To work in TSB mode the DSPI must be in master mode and in DSI (DCONF = 0b01) or CSI (DCONF = 0b10) configuration. Both Continuous and Non Continuous Serial Communication Clock (controlled by the DSPI_MCR[CONT_SCKE] bit) are supported in the TSB mode.

The following figure shows the signals used in the TSB interface.

In the TSB configuration the DSPI is able to send from 4 to 34 bits MSC data frames (4 to 32 serialized data bits and up to 2 Data Selection zero bits). The serialized data bits source can be either:

- the DSPI DSI Alternate Serialization Data Register (DSPI_ASDR0), written by the host software,
- Parallel Input pin states latched into the DSPI DSI Serialization Data Register (DSPI_SDR0).

DSPI_DSICR0 TXSS bit or DSPI_SSR0 register bits define the source of the data.

The Least Significant Bits of the DSPI_ASDR0 or DSPI_SDR0 registers are selected to be serialized if the data frame is set to less than 32 bits.

Figure 42-63. DSPI usage in the TSB Configuration

The PCS signals are driven together with SOUT. The t_{CSC} and t_{ASC} delays are not available. Delay after Transfer (DT) is set in SCK clock periods as a binary number formed by concatenation of the DSPI_CTARn PDT and DT fields plus one, allowing to set DT from 1 to 64 serial clock periods. DT field provides least significant bits and PDT field provides most significant bits of the Delay after Transfer.

Figure 42-64. TSB Downstream Frames

Above figure shows the two types of MSC downstream frames - command frame, and data frame.

The first transmitted bit, called the selection bit, determines the frame type:

- The selection bit "0" indicates a data frame
- The selection bit "1" indicates a command frame

Data frame may contain up to 2 selection bits to support two external slave devices, (so called dual receiver configuration) or no selection bits at all.

The command frame can be written by software, through SPI TX FIFO, using one or two FIFO entries with help of the CONT bit. The data frame consists of up to 32 bits from the SDR0 or ASDR0 registers and up to two selection bits (0). Number of data bits in the data frame is defined by the DSCICR1[TSBCNT] field.

The selection bit of the MSC command frames (1) can be implemented by software.

The selection bits in the data frames are enabled by DSPI_DSICR1 DSE0 and DSE1 bits. Each DSEn bit set increases the data frame size by one bit.

To comply with MSC specification, set DSPI_CTARn[LSBFE] to transmit least significant bit first.

Regardless the LSBFE bit setting, the Data Frame Selection Bits, if enabled, are always transmitted first, before corresponded data sub frames.

42.5.9.1 MSC Dual Receiver Support with PCS Switch Over

When in TSB mode it is possible to switch the set of PCS signals that are driven during the first part of the frame to a different set of PCS signals during the second part of the frame. The bit, at which this switch over occurs, is defined by FMSZ field of the DSPI_CTARn register, selected by DSICTAS field of the DSICR0 register.

Number of the bits, not including the Data Selection Bit, in the first part of the frame is equal to value of the FMSZ field plus one. During this part of the frame the PCS signal levels are controlled by DSPI_DSICR0 DPCSn bits, after that by DSPI_DSICR1 DPCS1_n bits.

The PCS switch over occurs at driving edge of the SCK clock output.

The second Data Selection Bit is inserted after the PCS switch over if enabled.

Data Frame with PCS switch over is shown in the following figure.

Figure 42-65. TSB Data Frame Format for MSC Dual Receiver Operation

42.5.10 Parity Generation and Check

The module can generate and check parity in the serial frame. The parity bit replaces the last transmitted bit in the frame. The parity is calculated for all transmitted data bits in frame, not including the last data bit that would be transmitted. The parity generation/control is done on frame basis. The registers field setting frame size defines the total

number of bits in the frame, including the parity bit. Thus, to transmit/receive the same number of data bits with parity check, increase the frame size by one versus the same data size frame without the parity check.

Parity can be selected as odd or even. Parity Errors in the received frame set Parity Error flags in the Status register. The Parity Error Interrupt Requests are generated if enabled. The module can be programmed to stop frame transmission in case of a frame reception with parity error.

42.5.10.1 Parity for SPI Frames

When the module is in the master mode the parity generation is controlled by PE and PP bits of the CMD FIFO entries (PUSHR). Setting the PE bit enables parity generation for transmitted SPI frames and parity check for received frames. PP bit defines polarity of the parity bit.

When continuous PCS selection is used to transmit SPI data, two parity generation scenarios are available:

- Generate/check parity for the whole frame
- Generate/check parity for each sub-frame separately.

To generate/check parity for the whole frame set PE bit only in the last command/TX FIFO entry, forming this frame (with the PUSHR register).

To generate/check parity for each sub-frame set PE bit in each command/TX FIFO entry, forming this frame.

If the parity error occurs for received SPI frame, the SR[SPEF] bit is set. If MCR[PES] bit is set, the module stops SPI frames transmission. To resume SPI operation clear the SR[SPEF] or the MCR[PES] bits.

In slave mode the parity is controlled by the PE and PP bits of the CTAR0 register similar to the master mode parity generation without continuous PCS selection.

42.5.10.2 Parity for DSI Frames

When DSPI is in Master Mode, parity generation is controlled by PE and PP bits of the DSPI_DSICR0 register similar to the SPI frames. The parity is calculated and checked for each DSI frame. DSPI_DSICR0[DCONT] bit has no effect on parity generation. In slave mode the parity is controlled by the PE and PP bits of the CTAR1 register.

If the parity error occurs for received DSI frame, the DSPI_SR[DPEF] bit is set. If DSPI_DSICR0[PES] bit is set, the DSPI stops DSI frames transmission. To resume DSI operation clear the DSPI_SR[DPEF] or the DSPI_DSICR0[PES] bits.

42.5.11 Interrupts/DMA requests

The module has several conditions that can generate only interrupt requests and two conditions that can generate interrupt or DMA requests. The following table lists these conditions.

Table 42-82. Interrupt and DMA request conditions

Condition	Flag	Interrupt	DMA
End of Queue (EOQ)	EOQF	Yes	-
TX FIFO Fill	TFFF	Yes	Yes
Transfer Complete	TCF	Yes	-
TX FIFO Underflow	TFUF	Yes	-
RX FIFO Drain	RFDF	Yes	Yes
RX FIFO Overflow	RFOF	Yes	-
SPI Parity Error	SPEF	Yes	-
DSI Parity Error	DPEF	Yes	-
DSI Deserialized Data Match	DDIF	Yes	-

Each condition has a flag bit in the module Status Register (SR) and a Request Enable bit in the DMA/Interrupt Request Select and Enable Register (RSER). Certain flags (as shown in above table) generate interrupt requests or DMA requests depending on configuration of RSER register.

42.5.11.1 End Of Queue interrupt request

The End Of Queue (EOQ) interrupt request indicates that the end of a transmit queue is reached. The module generates the interrupt request when EOQ interrupt requests are enabled (RSER[EOQF_RE]) and the EOQ bit in the executing SPI command is 1.

The module generates the interrupt request when the last bit of the SPI frame with EOQ bit set is transmitted.

42.5.11.2 Transmit FIFO Fill Interrupt or DMA Request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF_RE bit in the RSER is set. The TFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

NOTE

TFFF flag clears automatically when DMA is used to fill TX FIFO. Configure the DMA to fill only one FIFO location per transfer.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TX FIFO:

1. Wait until TFFF = 1.
2. Write data to PUSHR using CPU.
3. Clear TFFF by writing a 1 to its location. If TX FIFO is not full, this flag will not clear.

42.5.11.3 Transfer Complete Interrupt Request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF_RE bit is set in the RSER.

42.5.11.4 Transmit FIFO Underflow Interrupt Request

The Transmit FIFO Underflow Request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the module operating in Slave mode and SPI configuration. The TFUF bit is set when the TX FIFO of the module is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF_RE bit in the RSER is set, an interrupt request is generated.

42.5.11.5 Receive FIFO Drain Interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF_RE bit in the RSER is set. The RFDF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated. Configure the DMA to drain only one FIFO location per transfer.

42.5.11.6 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

42.5.11.7 SPI Frame Parity Error Interrupt Request

The SPI Frame Parity Error Flag indicates that a SPI frame with parity error had been received. The SPEF_RE bit in the RSER must be set for the interrupt request to be generated.

42.5.11.8 DSI Frame Parity Error Interrupt Request

The DSI Frame Parity Error Flag indicates that a DSI frame with parity error has been received. The DPEF_RE bit in the DSPI_RSER must be set for the interrupt request to be generated.

42.5.11.9 Deserialized Data Match Interrupt Request

The Deserialized Data Match Flag (DDIF) indicates that a DSI frame matches DSPI_DPIR0 data, masked with DSPI_DIMR0, had been received. The DDIF_RE bit in the DSPI_RSER must be set for the request to be generated.

42.5.12 Power saving features

The module supports following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory mapped logic

42.5.12.1 Stop mode (External Stop mode)

This module supports the Stop mode protocol. When a request is made to enter External Stop mode, the module acknowledges the request. If a serial transfer is in progress, then this module waits until it reaches the frame boundary before it is ready to have its clocks shut off. While the clocks are shut off, this module's memory-mapped logic is not accessible. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

42.5.12.2 Module Disable mode

Module Disable mode is a block-specific mode that the module can enter to save power. Host CPU can initiate the Module Disable mode by setting the MDIS bit in the MCR. The Module Disable mode can also be initiated by hardware.

When the MDIS bit is set, the module negates the Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, it is said to have entered Module Disable Mode. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. If implemented, the Clock Enable signal can stop the clock to the non-memory mapped logic. When Clock Enable is negated, the module is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different effect when the module is in the Module Disable mode. Reading the RX FIFO Pop Register does not change the state of the RX FIFO. Similarly, writing to the PUSH Register does not change the state of the TX FIFO or CMD FIFO. Clearing either of the FIFOs has no effect in the Module Disable mode. Changes to the DIS_TXF and DIS_RXF fields of the MCR have no effect in the Module Disable mode. In the Module Disable mode, all status bits and register flags in the module return the correct values when read, but writing to them has no effect. Writing to the TCR during Module Disable mode has no effect. Interrupt and DMA request signals cannot be cleared while in the Module Disable mode.

42.6 Initialization/application information

This section describes how to initialize the module.

42.6.1 How to manage queues

The queues are not part of the module, but it includes features in support of queue management. Queues are primarily supported in SPI configuration.

1. When module executes last command word from a queue, the EOQ bit in the command word is set to indicate it that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the module in the Stopped state. The TXRXS bit is cleared to indicate the Stopped state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO (and CMD FIFO) and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO (and CMD FIFO) by writing a 1 to the CLR_TXF bit in the MCR. Flush RX FIFO by writing a '1' to the CLR_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the module TX FIFO, (and CMD FIFO) and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

42.6.2 Switching Master and Slave mode

When changing modes in the module, follow the steps below to guarantee proper operation.

1. Halt it by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a 1 to the CLR_TXF and CLR_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable it by clearing MCR[HALT].

42.6.3 Initializing Module in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the module is enabled by clearing MCR[HALT]. It should be ensured that module Slave is enabled before enabling it's Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

42.6.4 Baud rate settings

The following table shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is cleared.

Table 42-83. Baud rate values (bps)

		Baud rate divider prescaler values			
		2	3	5	7
Baud Rate Scaler Values	2	25.0M	16.7M	10.0M	7.14M
	4	12.5M	8.33M	5.00M	3.57M
	6	8.33M	5.56M	3.33M	2.38M
	8	6.25M	4.17M	2.50M	1.79M
	16	3.12M	2.08M	1.25M	893k
	32	1.56M	1.04M	625k	446k
	64	781k	521k	312k	223k
	128	391k	260k	156k	112k
	256	195k	130k	78.1k	55.8k
	512	97.7k	65.1k	39.1k	27.9k
	1024	48.8k	32.6k	19.5k	14.0k
	2048	24.4k	16.3k	9.77k	6.98k
	4096	12.2k	8.14k	4.88k	3.49k
	8192	6.10k	4.07k	2.44k	1.74k
	16384	3.05k	2.04k	1.22k	872
	32768	1.53k	1.02k	610	436

42.6.5 Delay settings

The following table shows the values for the Delay after Transfer (t_{DT}) and CS to SCK Delay (T_{CSC}) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

NOTE

The clock frequency mentioned above is given as an example in this chapter. See the clocking chapter for the frequency used to drive this module in the device.

This table does not apply for TSB Continuous mode.

Table 42-84. Delay values

		Delay prescaler values			
		1	3	5	7
Delay scaler values	2	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns
	16	160.0 ns	480.0 ns	800.0 ns	1.1 μ s
	32	320.0 ns	960.0 ns	1.6 μ s	2.2 μ s
	64	640.0 ns	1.9 μ s	3.2 μ s	4.5 μ s
	128	1.3 μ s	3.8 μ s	6.4 μ s	9.0 μ s
	256	2.6 μ s	7.7 μ s	12.8 μ s	17.9 μ s
	512	5.1 μ s	15.4 μ s	25.6 μ s	35.8 μ s
	1024	10.2 μ s	30.7 μ s	51.2 μ s	71.7 μ s
	2048	20.5 μ s	61.4 μ s	102.4 μ s	143.4 μ s
	4096	41.0 μ s	122.9 μ s	204.8 μ s	286.7 μ s
	8192	81.9 μ s	245.8 μ s	409.6 μ s	573.4 μ s
	16384	163.8 μ s	491.5 μ s	819.2 μ s	1.1 ms
	32768	327.7 μ s	983.0 μ s	1.6 ms	2.3 ms
	65536	655.4 μ s	2.0 ms	3.3 ms	4.6 ms

42.6.6 Calculation of FIFO pointer addresses

Complete visibility of the FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and counter for each FIFO. The pointer to the first-in entry in each FIFO is memory mapped. For the TX FIFO the first-in pointer is the Transmit Next Pointer (TXNXTPTR). For the CMD FIFO the first-in pointer is the Command Next Pointer (CMDNXTPTR). For the RX FIFO the first-in pointer is the Pop Next Pointer (POPNXTPTR). The following figure illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts carry over. See [Transmit First In First Out \(TX FIFO\) buffering mechanism](#), [Command First In First Out \(CMD FIFO\) Buffering Mechanism](#) and [Receive First In First Out \(RX FIFO\) buffering mechanism](#) for details on the FIFO operation.

Figure 42-66. TX FIFO pointers and counter

42.6.6.1 Address Calculation for the First-in Entry and Last-in Entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBase} + (4 \times \text{TXNXTPTR})$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBase} + 4 \times (\text{TXCTR} + \text{TXNXTPTR} - 1) \bmod (\text{TXFIFOdepth})$$

TX FIFO Base - Base address of TX FIFO

TXCTR - TX FIFO Counter

TXNXTPTR - Transmit Next Pointer

TX FIFO Depth - Transmit FIFO depth, implementation specific

42.6.6.2 Address Calculation for the First-in Entry and Last-in Entry in the CMD FIFO

The memory address of the first-in entry in the CMD FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBase} + (4 \times \text{TXNXTPTR})$$

The memory address of the last-in entry in the CMD FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBase} + 4 \times (\text{TXCTR} + \text{TXNXTPTR} - 1) \bmod (\text{TXFIFOdepth})$$

CMD FIFO Base - Base address of CMD FIFO

CMDCTR - CMD FIFO Counter

CMDNXTPTR - Command Next Pointer

CMD FIFO Depth - Command FIFO depth, implementation specific

42.6.6.3 Address Calculation for the First-in Entry and Last-in Entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{RX FIFOBase} + (4 \times \text{POPNXTPTR})$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{RX FIFO Base} + 4 \times (\text{RXCTR} + \text{POPNXTPTR} - 1) \bmod (\text{RXFIFOdepth})$$

RX FIFO Base - Base address of RX FIFO

RXCTR - RX FIFO counter

POPNXTPTR - Pop Next Pointer

RX FIFO Depth - Receive FIFO depth, implementation specific

Chapter 43

Zipwire

43.1 Chip-specific Zipwire information

The following table provide the values for various Zipwire parameters as implemented in this device. Each parameter is given a variable name that is used in various sections of this chapter.

Table 43-1. Chip-specific parameters

Parameter		Variable name	Value
LFAST maximum baud rate		c	See the product Data Sheet
Bit time		d	$1/c$
XBAR frequency		x	PLAT_CLK
SIPI frequency		y	PLAT_CLK
No. of XBAR cycles		n	7
		m	6
SIPI address time	Read	z	$13/y + n/x$
	Write	v	$13/y + m/x$

43.2 Overview

The SIPI and LFAST modules work together as a single unit called Zipwire. The LFAST portion of the two modules allows for high speed inter-device communications. The SIPI allows memory to be shared between devices which have SIPI and LFAST communication modules.

The LFAST can operate in either slave or master mode configurations. The node running in master mode controls the serial link, but SIPI, in both master and slave modes, can act as both initiator and target for SIPI commands simultaneously. Please see the SIPI and LFAST chapters for detailed information on module configuration and functionality.

43.3 Introduction

Zipwire is a group of modules that allow one MCU to have a fast, low pin count, serial communication link directly into the memory mapped peripherals and/or memories of another MCU or smart ASIC. Zipwire is implemented in hardware so there is no CPU load for the initiator or target node. Zipwire supports 8-bit, 16-bit or 32-bit reads and writes to any 32-bit address at the target node.

Zipwire architecture is fully pipelined and support multiple outstanding commands to allow maximum use of the serial link bandwidth.

The serial link runs at a high speed using LVDS physical layer. One LVDS pair for Tx and another pair for Rx, with a separate LFAST reference clock for a total of five pins.

Zipwire also supports a streaming mode for the transfer of large blocks of data.

In streaming mode Zipwire has a high transfer rate.

43.4 Zipwire Block Diagram

[Figure 43-1](#) shows two MCUs with Zipwire connected using a five wire interface. Both MCUs support Target and Initiator modes of Zipwire. The SIPI Bus Master Interface is used for all Target mode transactions. The SIPI Register Interface is used for all Initiator Transactions and initial setup. The LFAST Register Interface is used for Initial Setup.

The diagram shows the LFAST reference clock coming from MCU B clock system. The Ref_Clock can come from either MCU. It is user configurable, but it must be the same clock that drives both LFAST modules.

Figure 43-1. Zipwire connection diagram

43.5 Architecture

Zipwire is composed of several modules and system resources. The physical layer is LVDS with common mode voltage and defined swing.

The transport layer is a protocol called LFAST. LFAST is an asynchronous protocol, using non-return to zero encoding. The LFAST protocol is composed of the following:

- A fixed 16-bit sync frame to allow the receiver to detect the optimal point to sample the incoming data.
- Followed by an 8-bit LFAST header, that defines the channel number and the size of the LFAST payload.
- Finally the payload, which can be between 8 and 288 bits.

The application layer protocol is called Serial Inter Processor Interface (SIPI). SIPI runs on top of LFAST and is fully encapsulated within the LFAST payload. SIPI uses four fixed sizes of LFAST payload in Zipwire:

- 32-bit
- 64-bit

- 96-bit
- 288-bit

The SIPI protocol implements a suite of commands initiated by one MCU, for reading and writing any 32-bit address location in another connected MCU. The SIPI protocol allows either or both MCUs to initiate commands. The protocol also supports interrupt requests from one MCU to the other.

The SIPI module implements both the initiator part of the protocol and the recipient part of the protocol. The module implements four SIPI Initiator channels that can run independently of each other and can run simultaneously. The SIPI module is a bus master on the low speed XBAR. As the target MCU for a command from the initiating MCU, SIPI can perform read and write accesses to any address location within the target MCU. The software running on the local MCU, should configure the system MPU to allow/deny memory accesses to MCU memory and resources as required.

The initiator part of the module is connected to the DMA controller and is able to generate DMA requests as a command is completed. This allows a series of read or write commands to be queued in the Initiator MCU and executed by DMA and SIPI without CPU intervention at either Initiator or Target MCU.

43.6 Zipwire interconnections

LFAST has the following connections:

- Tx and Rx configuration is controlled by LFAST Control registers.
- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers.
- Tx Data Port/Rx Data Port — Directly connected to the SIPI module. Allows received data to be efficiently transferred to SIPI and transmit data to be transferred from SIPI.
- Interrupt Request connections — Allows the module to flag to the CPU when it requires servicing.

SIPI has the following connections:

- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers and SIPI Interface Registers.

- DMA connections — Allows SIPI command sequences to be queues and initiated without CPU intervention.
- Crossbar master port — Allows SIPI to execute requested commands to read and write MCU address space.
- Tx Data Port/Rx Data Port — Directly connected to the LFAST module. Allows received data to be efficiently transferred from LFAST and transmit data to be transferred to LFAST.
- Interrupt Request connections — Allows the module to flag to the CPU when it requires servicing.

43.7 Zipwire performance

Two aspects of performance are considered:

- Bandwidth — The rate at which data can be read or written between two nodes. It assumes that read or write commands from the Initiator node, can be sent continuously at the highest speed the Target node can consume those commands.
- Latency — The time from the Initiator node sending a read or write command to the Initiator node receiving back the read data or write acknowledge.

43.7.1 Read performance

A Zipwire read operation consists of three stages:

- Initiator sends SIPI Read command to Target.
- Target parses the received command and runs a master bus cycle to read the data.
- Target sends the SIPI Read response back to the Initiator.

A SIPI Read command consists of:

- 16-bit header
- 32-bit read address
- 16-bit CRC
- 64 bits total

A SIPI Read response consists of:

- 16-bit header
- 32-bit read data
- 16-bit CRC
- 64 bits total

The SIPI message is encapsulated in a LFAST frame where the LFAST payload is the size of the SIPI message.

The LFAST frame consists of:

- 16-bit synchronisation header
- 8-bit header
- 64-bit payload
- 1-bit stop bit
- 89 bits total

LFAST Baud rate is c Mbaud which yields a bit time of d ns

Therefore, an 89-bit LFAST transmission of a SIPI 64-bit Read command or 64-bit Read response takes $89d$ ns.

The SIPI module takes thirteen system clock cycles to parse a command and create a Read response, plus the time to run the master bus cycle. The time to run the master bus cycle will vary depending on the memory being read.

Assumptions:

- Average of $n \times$ XBAR cycles to read different memories.
- XBAR clocked at x MHz
- SIPI clocked at y MHz

Therefore, time for SIPI to read an address location is:

$$(13 \times y \text{ MHz clocks}) + (n \times x \text{ MHz clocks}) = z \text{ ns}$$

43.7.1.1 Read bandwidth

The Zipwire target node has a three message deep receive FIFO and a three message deep transmit FIFO. So, the Target node can simultaneously be receiving a command, processing a command, and sending the Read response.

The time to transmit a command or response is less than the time to process the command. Therefore, the bandwidth is limited by the time to process the message.

$$\text{Read Bandwidth} = 4 \text{ bytes in } z \text{ ns} = 4 \times z \text{ MB/second}$$

43.7.1.2 Read latency

The latency is the time taken to send a Read command, process the command, and send a Read response.

$$\text{Read Latency} = 89d \text{ ns} + z \text{ ns} + 89d \text{ ns} = z + 178d \text{ ns}$$

43.7.2 Write performance

A Zipwire write operation consists of three stages:

- Initiator sends SIPI Write command to Target.
- Target parses the received command and runs a master bus cycle to write the data.
- Target sends the SIPI Write response back to the Initiator.

A SIPI Write command consists of:

- 16-bit header
- 32-bit write address
- 32-bit write data
- 16-bit CRC
- 96 bits total

A SIPI Write acknowledge consists of:

- 16-bit header

- 16-bit CRC
- 32 bits total

The SIPI message is encapsulated in an LFAST frame where the LFAST payload is the size of the SIPI message.

The LFAST frame consists of:

- 16-bit synchronisation header
- 8-bit header
- 96-bit payload (command) or 32-bit (acknowledge)
- 1-bit stop bit
- 121 bits total (command) or 57 bits (acknowledge)

LFAST Baud rate is c Mbaud which yields a bit time of d ns

Therefore, the time for an LFAST transmission is:

- 121-bit LFAST transmission of a SIPI 96-bit Write Command takes $121d$ ns
- 57-bit LFAST transmission of a SIPI 32-bit Write Acknowledge takes $57d$ ns

The SIPI module takes thirteen system clock cycles to parse a command and create a Write response, plus the time to run the master bus cycle. The time to run the master bus cycle will vary depending on the memory being written.

Assumptions:

- Average of $m \times$ XBAR cycles to write different memories.
- XBAR clocked at x MHz
- SIPI clocked at y MHz

Therefore, the time for SIPI to write an address location is:

$$(13 \times y \text{ MHz clocks}) + (m \times x \text{ MHz clocks}) = v \text{ ns}$$

43.7.2.1 Write bandwidth

The Zipwire target node has a three message deep receive FIFO and a three message deep transmit FIFO. So, the Target node can simultaneously be receiving a command, processing a command, and sending the Write Acknowledge response.

The time to transmit the command is longer than the time to process the command, or the time to transmit the Write Acknowledge. Therefore, the bandwidth is limited by the time to transmit the command.

Write Bandwidth = 4 bytes in ν ns = $4 \times \nu$ MB/second

43.7.2.2 Write latency

The latency is the time taken to send a Write command, process the command, and send a Write Acknowledge.

Write Latency = $121d$ ns + ν ns + $57d$ ns = $\nu + 178d$ ns

Chapter 44

Serial Interprocessor Interface (SIPI)

44.1 Chip-specific SIPI information

This chip has one instance of the SIPI module.

44.1.1 SIPI Chip ID

On this chip, the SIPI Chip ID is the same as the [JTAG ID](#).

44.2 Introduction

The Serial Interprocessor Interface (SIPI) is an application layer protocol which runs on top of the LFAST (LVDS Fast Asynchronous Serial Transmission) module. It is used by the local device to access the shared memory of a remote device. SIPI defines point-to-point full duplex communication between two devices, where LFAST works as a physical medium of communication between both the devices.

44.2.1 Scalability

The SIPI protocol is designed to provide a sophisticated, high bandwidth, multimaster, multi-channel memory interface between 2 devices using few interconnecting signals. But the protocol is designed in such a way that a subset of the protocol can be implemented, where die area is more important than features.

Main scalable features:

- Number of concurrent channels:

- Full Implementation = 4
- Minimum Implementation = 1
- Full implementation has a node both as Initiator and Target of commands. Minimum implementation either Initiator or Target.
- Full Implementation includes a block transfer feature, but this feature is optional.

The rest of this section describes a full implementation of SIPI which includes:

- Advanced High-Performance Bus (AHB-Lite) master interface
- Direct Memory Access (DMA) interface
- LFAST Tx/Rx (transmit/receive) interfaces along with Peripheral Bus Interface (IPS)

44.3 Overview

An instance of SIPI can act as initiator, or target or both. SIPI can access the shared memory directly through its AHB master interface or through its DMA interface. DMA interface is used when the node acts as an initiator while the AHB Master interface will be used when the node acts as target. SIPI has four channels, with one channel (Channel 2) having data streaming capability. Payload width for channel 0, 1 and 3 is 32 bits, and for channel 2 data widths can be 32 bits, or 256 bits when streaming. Any of these channels can be used for DMA access or bus interface access depending on the setting of the SIPI_CCR*n*. CRC encoder calculates the CRC on the command frame. Then the SIPI initiator appends the CRC to the end of the frame before transmission.

**Figure 44-2. SIPI module**

44.4 SIPI block diagram

¹ Finite State Machine

Figure 44-3. SIPI block diagram

44.5 Feature description

This section describes the features of the SIPI module.

44.5.1 Main features

- Point-to-point communication between two devices
- Full duplex communication
- Four channels, including one channel with data streaming capability

- Configurable DMA access for each channel
- CRC protection mechanism
- Timeout protection mechanism
- Fixed priority channel selection
- Data size up to 256 bits on streaming channel
- Common tag pool for assigning sequential transfer IDs to every new transfer
- AHB master interface which is used by target node to access shared memory
- Target node contains a set of nine 32-bit internal registers to store commands
- Up to two outstanding requests are supported at initiator

44.5.2 Standard features

- IPS bus interface (PBRIDGE)
- SPP DMA2x bus interface
- AHB Master Interface
- LFAST Tx/Rx interfaces
- Cyclic Redundancy Check error detection (CRC16)

44.6 SIPI operation from reset

When the SIPI module exits reset, it is operational and target mode is enabled without the need to configure the control registers.

44.7 Functional description

44.7.1 External signals

The SIPI has no chip external signals.

44.7.2 Frame format

All frames have the same general format:

- 16 bit header
- Address, Address and Data, or nothing
- 16-bit CRC

There are 2 main groups of command; read and write. Within those 2 groups are three read/write formats:

- 32-bit
- 16-bit
- 8-bit

Each command generates one of three different responses:

- Read data
- Write acknowledge
- Error

There is one additional command that requests the module ID from the Target node. The ID is a unique 32-bit ID that is specific to a particular device. It is normally the same as the JTAG ID. The sections below illustrate the four different frame formats that are used to implement all the commands and responses.

The number of frames depends on the data buffers (associated with every channel), the frame data is stored in data buffers at the initiator. Address and data are both transmitted in the same order in which they are stored.

44.7.2.1 Register read request

Figure 44-4. SIPI register read request

44.7.2.2 Register read response, ID request response

Figure 44-5. SIPI read response

44.7.2.3 Register write request

Figure 44-6. SIPI register write request

44.7.2.4 Trigger transfer, ID transfer, write acknowledge and streaming write acknowledge

Figure 44-7. SIPI write acknowledge

44.7.2.5 Streaming write request

Figure 44-8. Streaming write request format

NOTE

Direct write operations are used to set the streaming address.

Streaming data write is performed using the format shown in [Figure 44-8](#).

44.7.2.6 Header field

Header field contains 16 bits of configuration information. MSB will be transmitted first.

44.7.2.6.1 SIPI header coding

[Figure 44-9](#), [Table 44-1](#), [Figure 44-10](#), and [Table 44-2](#) show how the SIPI header bits are coded.

**Figure 44-9. SIPI header coding**

Table 44-1 shows the command coding for the bits[12:8] of the header.

Table 44-1. SIPI header command coding

b[12:8] (hex)	Command	Payload Size
00	Read 8 bits	64
01	Read 16 bits	64
02	Read 32 Bits	64
03	Reserved	—
04	Write 8 bits with ACK	96
05	Write 16 bits with ACK	96
06	Write 32 bits with ACK	96
07	Reserved	—
08	ACK – OK	32
09	ACK – Fault	32
0A	Read Answer – OK	64
0B	Reserved	—
0C	Trigger comm and with ACK	32
0D	Reserved	—
...	...	...
11	Reserved	—
12	ID Register Read Request	32
13	Reserved	—
...	...	...
16	Reserved	—
17	Stream Data with ACK (32 bytes)	288
18	Reserved	—
...	...	...
1F	Reserved	—

Figure 44-10 shows the channel number field in the header and Table 44-2 shows the channel number coding.

Figure 44-10. SIPI header channel field

Table 44-2. SIPI header channel number coding

SIPI channel name	Channel number coding in header(s)		Comment
	SIPI channel coding select field (SIPI_MCR[CHNSB])		
	Code table I (SIPI_MCR[CHNSB] = 1)	Code table II (SIPI_MCR[CHNSB] = 0)	
0 (Channel A)	000b	100b	In use
1 (Channel B)	001b	101b	In use
2 (Channel C)	010b	110b	In use
3 (Channel D)	011b	111b	In use
4 (Channel E)	100b	000b	Reserved
5 (Channel F)	101b	001b	Reserved
6 (Channel G)	110b	010b	Reserved
7 (Channel H)	111b	011b	Reserved

44.7.2.7 Address field

The address field is 32 bits wide with the MSB transmitted first.

44.7.2.8 Payload field

Table 44-3 shows the payload sizes of LFAST frames.

Table 44-3. Payload size of LFAST channel frame

LFAST Code	SIPI Code	LFAST Payload Size (bits)	LFAST Payload Size (bytes)
000b	—	8	1
001b	—	32	4
010b	010b	64	8
011b	011b	96	12
100b	100b	128	16

Table continues on the next page...

Table 44-3. Payload size of LFAST channel frame (continued)

LFAST Code	SIPI Code	LFAST Payload Size (bits)	LFAST Payload Size (bytes)
101b	101b	256	32
110b	110b	512	64
111b	111b	288	36

Table 44-4 shows the converted coding of LFAST for a given SIPI code.

Table 44-4. Converted coding of LFAST channel code for SIPI headers

LFAST Code	SIPI Code	Channel (hex) ¹
0100b	100b	A
0101b	101b	B
0110b	110b	C
0111b	111b	D
1000b	000b	E (not used by SIPI)
1001b	001b	F (not used by SIPI)
1010b	010b	G (not used by SIPI)
1011b	011b	H (not used by SIPI)

1. SIPI channel 0 sends all commands on LFAST channel A, commands received on LFAST channel A, are processed and the response sent back on LFAST channel A.
 SIPI channel 1 sends all commands on LFAST channel B, commands received on LFAST channel B, are processed and the response sent back on LFAST channel B.
 SIPI channel 2 sends all commands on LFAST channel C, commands received on LFAST channel C, are processed and the response sent back on LFAST channel C.
 SIPI channel 3 sends all commands on LFAST channel D, commands received on LFAST channel D, are processed and the response sent back on LFAST channel D.

44.7.2.9 CRC field

CRC field is 16 bits wide with calculation always enabled using CRC-16-CCITT syndrome ($x^{16} + x^{12} + x^5 + 1$). MSB is sent first in the data stream.

44.7.2.9.1 CRC field examples

44.7.2.9.1.1 Example 1 – 32 bit write on channel 1 with ID1

- Header = 260Ah
- Address = 1122_3344h
- Data = CCDD_EEFFh
- CRC = BF7Dh

44.7.2.9.1.2 Example 2 – 32 bit read on channel 2 with ID2

- Header = 420Ch
- Address = 89AB_CDEFh
- CRC = 6B80h

44.7.2.9.1.3 Example 3 – Event command on channel 3 with ID3

- Header = 6C0Eh
- CRC = B286h

44.8 Transfer types

This section describes the available transfer types of the SIPI module. The SIPI frame is inserted inside the payload of the LFAST frame as shown in the figures of the following examples.

44.8.1 Read transfer

A Read transfer can be of two types:

- Read Request Transfer (at initiator node)
- Read Response Transfer (at target node)

44.8.1.1 Register read request transfer

If there is a read request transfer, the initiator node will send header, address and CRC bits as shown in [Figure 44-11](#).

Figure 44-11. Read request transfer

44.8.2 Register read answer transfer

In response to a read request by the initiator node, the target node will send header, payload and CRC16. Data transfer could be in 8-bit, 16-bit or 32-bit modes (see [Figure 44-12](#)). In the case of 8-bit or 16-bit modes, copies of the SIPI data is sent in the payload (see [Figure 44-13](#)).

Figure 44-12. Read answer transfer

**Figure 44-13. Data allocation****Note**

- For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables.
 - Bits[1:0]:
 - 00 - byte 3 enabled (MSB)
 - 01 - byte 2 enabled
 - 10 - byte 1 enabled
 - 11 - byte 0 enabled (LSB)
- For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as halfword enable.
 - Bit[0]:
 - 0 - halfword 1 enabled (MSB)
 - 1 - halfword 0 enabled (LSB)

44.8.3 Register Write transfer

Register Write transfer can be of two types:

- Normal write transfer - channels 0, 1, 2 and 3
- Streaming data transfer - channel 2 only

A Register Write transfer can be done through Normal Write transfer on channels 0, 1, 2 and 3 (see [Normal write transfer](#)) as shown in [Figure 44-14](#).

Figure 44-14. Register write transfer (showing LFAST frame encapsulation)

44.8.3.1 Normal write transfer

A normal write transfer contains header, address, data (32-bit) and CRC as shown in [Figure 44-15](#).

Figure 44-15. Write transfer (LFAST frame encapsulation is not shown)

Note

- For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables.
 - Bits[1:0]:
 - 00 - byte 3 enabled (MSB)
 - 01 - byte 2 enabled
 - 10 - byte 1 enabled
 - 11 - byte 0 enabled (LSB)
- For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as half word enable.
 - Bit[0]:
 - 0 - half-word 1 enabled (MSB)
 - 1 - half-word 0 enabled (LSB)

44.8.3.2 Streaming write transfer

Streaming write transfer has 256 bits of payload.

44.8.3.2.1 Streaming write transfer with address

Setting the address is performed using a direct write transfer. The SIPI Maximum Count Register (SIPI_MAXCR) and SIPI Address Reload Register (SIPI_ARR) are written before the SIPI Address Count Register (SIPI_ACR). This is to avoid unwanted behavior of the SIPI attempting to access non-shared memory. This is only true for the very first streaming command, subsequent streaming command(s) may not need to write the SIPI_MAXCR and SIPI_ARR (see [SIPI Max Count Register \(SIPI_MAXCR\)](#), [SIPI Address Count Register \(SIPI_ACR\)](#) and [SIPI Address Reload Register \(SIPI_ARR\)](#)).

44.8.3.2.2 Streaming transfer with data

[Figure 44-16](#) shows the packet structure of the streaming transfer containing data.

Figure 44-16. Streaming transfer with data

44.8.4 Write Acknowledge transfer

A Write Acknowledge transfer contains only header and CRC bits (see [Write Acknowledge transfer](#)). The CRC bits are calculated on the header field.

Figure 44-17. Write Acknowledge transfer (LFAST encapsulation is not shown)

44.8.5 ID request response

44.8.5.1 ID request transfer

An ID request is transmitted by the initiator node as shown in [Figure 44-18](#).

Figure 44-18. ID request transfer (LFAST encapsulation is not shown)

44.8.5.2 ID request response transfer

An ID request response is transmitted by the target node as shown in [Figure 44-19](#).

Figure 44-19. ID request response transfer

Note

The ID request response contains the value of the CHIP ID in place of data.

44.9 Transfer API and flow charts

*Note: TC = Transmit Command

Figure 44-20. SIPI single register write API

Implement the following steps to generate a single Write Transfer Request (Figure 44-20):

1. Configure data and `SIPI_CCRn` at the initiator node.
2. Configure `SIPI_CARn` at the initiator node.

As soon as the channel address register (`SIPI_CARn`) is written and if `CCRn[CHEN] = 1`, the initiator SIPI will calculate the CRC on header, address and data field and will start transmitting data to LFAST.

3. Software polls the status register bits (`SIPI_CSRn`) to determine when the request completes, `SIPI_CSRn[ACKR] = 1`. An interrupt will be generated if the corresponding `SIPI_CIRn[ACKIE] = 1`.

On a single Write transfer request reception (Figure 44-21):

1. Target node will place the address, data and control information on its AHB master interface.
2. When the process is completed, the target node will generate an acknowledge frame and send it back to the LFAST.

Figure 44-21. SIPI Single Register Write API – Flow Chart

Figure 44-22. SIPI Multiple Register Write API

For multiple write transfer request generation (Figure 44-22):

1. Software will configure the Transfer Control Descriptor (TCD) of the DMA.
2. Software will write $\text{SIPI\_CCR}_n[\text{CHEN}] = 1$ and $\text{SIPI\_CCR}_n[\text{DAN}] = 1$.
3. SIPI will start copying data into the SIPI_CDR_n through its DMA interface, depending on the transfer count and data registers size. SIPI_CDR2_0 should be written with the MSB.
4. When the copying process is complete, initiator SIPI will calculate CRC on header, address and data field and start transmitting data to LFAST.
5. Software should poll the SIPI_CSR_n status register bits to determine if the request has completed. If $\text{SIPI\_CSR}_n[\text{ACKR}] = 1$, an interrupt will be generated (if the corresponding $\text{SIPI\_CIR}_n[\text{ACKIE}] = 1$).
6. If $\text{SIPI\_CCR}_n[\text{DEN}] = 1$, the SIPI request will transfer to the DMA controller. If not, the state machine goes idle.
7. Steps 4–7 will be repeated.

On Multiple Write transfer request reception (Figure 44-22):

1. Target node will place the address, data and control information on its AHB Master Interface.
2. When the process is completed, target node will generate an acknowledge frame and send it back to the LFAST.

Figure 44-23. SIPI Single Register Read API

For Single Read Transfer Request generation ([Figure 44-23](#)):

1. Software/DMA will configure SIPI_CCR_n and SIPI_CDR_n , with the last step by writing CAR_n .
2. As soon as SIPI_CAR is written, the initiator SIPI will calculate CRC of the header and address fields and start transmitting data to the LFAST.
3. Software should poll CSR_n to determine when the request has completed. If $\text{SIPI\_CSR}_n[\text{RAR}] = 1$, an interrupt will be generated (if $\text{SIPI\_CIR}_n[\text{RAIE}] = 1$). If $\text{SIPI\_CSR}_n[\text{RAR}]$ does not set then $\text{SIPI\_ERR}[\text{TOEN}] = 1$ which indicates a timeout has occurred.
4. If $\text{SIPI\_CSR}_n[\text{RAR}] = 1$ then software can read the data register, or can other necessary action if $\text{SIPI\_CSR}_n[\text{RAR}] = 0$.

On Single Read transfer request reception (Figure 44-23):

1. Target node will place the address and control information on its AHB Master Interface.
2. When the process is completed, target node will send read response back to LFAST.

Figure 44-24. SIPI multiple register read API

For multiple read transfer request generation (Figure 44-24):

1. Software/DMA will configure SIPI_CCR_n and SIPI_CDR_n, with the last step by writing SIPI_CAR_n.
2. As soon as channel address register is written, initiator SIPI will calculate CRC on the header and address fields, then starts transmitting data to the LFAST.
3. Software should poll SIPI_CSR_n to determine when the request has completed. If SIPI_CSR_n[RAR] = 1 and SIPI_CIR_n[RAIE] = 1 an interrupt will be generated. If SIPI_CSR_n[RAR] does not set, then SIPI_ERR[TOEn] = 1 which indicates a timeout.
4. Steps 2–3 will be repeated for multiple requests.

On Multiple Read transfer request reception (Figure 44-24):

1. Target node then will start reading data through its AHB interface.
2. When the transfer is completed/all data registers are full, it will calculate CRC and send the response frame back to LFAST.

NOTE

Read answer interrupt pins are also cleared by hardware in DMA transfers. This can lead the software in trouble where it tracks the requests by keep counting the number of times the interrupt was received and cleared.

Figure 44-25, Figure 44-26, Figure 44-27 and Figure 44-28 show the SIPI data streaming of data.

Figure 44-25. SIPI data stream model

Figure 44-26. SIPI data stream model - Initiator

Figure 44-27. SIPI data stream model - Target

Figure 44-28. SIPI data stream with acknowledge trigger

44.10 DMA programming sequence

The DMA programming sequence is as follows:

1. Software configures TCD (DMA data).
2. DMA transfers from RAM to SIPI registers.
3. SIPI starts transferring the data through LFAST Tx ports.
4. If an acknowledge or fault response is received, SIPI will repeat the process. If any error response is received, SIPI will move to an idle state. An interrupt will be flagged by SIPI, and software will take control of the SIPI.
5. When SIPI receives read response and LFAST's error flags are not asserted, it initiates a DMA request. In case the LFAST asserts error flag, SIPI moves to step 8.
6. When SIPI initiates DMA request, the DMA transfers data between SIPI and RAM.
7. If DMA transfer minor loop/major loop is complete, and the request is negated, ipd_request is negated.
8. If an error occurs:

- The SIPI generates an interrupt
- Software takes control of the SIPI

9. Steps 5 – 8 are repeated until the transfer is finished.

44.11 Modes of operation

SIPI has three operating modes:

- Initialization
- Normal
- Module Disable

After hardware reset the SIPI is in module disable mode, which helps reduce power consumption.

44.11.1 Initialization mode

To enter Initialization mode software writes SIPI_MCR[INIT]=1 (SIPI_MCR[MOEN] must be set before attempting to write SIPI_MCR[INIT]). To exit Initialization mode software writes SIPI_MCR[INIT]=0 (see [SIPI Module Configuration Register \(SIPI_MCR\)](#)).

Note

It is recommended that software checks the state of SIPI (SIPI_MCR[MOEN]) before setting SIPI_MCR[INIT].

44.11.2 Normal mode

Once software has completed initialization of SIPI (SIPI_MCR[INIT]=1), it can enter Normal mode by writing SIPI_MCR[INIT]=0. SIPI needs to be in Normal mode for all data transfers (see [SIPI Module Configuration Register \(SIPI_MCR\)](#)).

Note

SIPI must be enabled before attempting to write SIPI_MCR[INIT] (SIPI_MCR[MOEN]=1).

44.11.3 Module Disable (MD)

MD mode in the SIPI is used to help reduce power consumption. By default, SIPI is in Disable mode, SIPI_MCR[MOEN]=0, and is exited by writing SIPI_MCR[MOEN]=1 (see [SIPI Module Configuration Register \(SIPI_MCR\)](#)). Future SIPI Tx transfers are disabled in Module Disable mode. To disable Rx functionality, the Target Enable (TEN) bit field has to be deasserted, then the internal Rx state machine resets to initial state.

44.12 Errors

This section describes the potential errors that can occur during SIPI operation.

44.12.1 Timeout error

A timeout error is generated at the initiator node when the acknowledge/response is not received within the time configured in the corresponding CTOR_n[TOR] field setting (see [SIPI Channel Timeout Register 0 \(SIPI_CTOR0\)](#), [SIPI Channel Timeout Register 1 \(SIPI_CTOR1\)](#), [SIPI Channel Timeout Register 2 \(SIPI_CTOR2\)](#) and [SIPI Channel Timeout Register 3 \(SIPI_CTOR3\)](#)). A timeout error is indicated when ERR[TOEn]=1 (see [SIPI Error Register \(SIPI_ERR\)](#)).

Note

SIPI should not drop the response even after a timeout occurs. Software will poll both error and status flags after the transfer to see if there was a timeout error. If there was a timeout error the response received may then be discarded.

44.12.2 CRC error

A CRC error is generated at the target nodes when the CRC received with the frame does not match the calculated CRC, and the SR[GCRCE] is set (see [SIPI Status Register \(SIPI_SR\)](#)). An interrupt will be asserted if MCR[CRCIE]=1 (see [SIPI Module Configuration Register \(SIPI_MCR\)](#)).

Note

The target node will not send an acknowledge to the initiator node when a CRC error is generated. An interrupt will be generated on the target side if the corresponding interrupt

enable bit is set. The initiator node will detect a timeout and take necessary action.

44.12.3 Maximum count reached error

The maximum count reached error is only generated at the target node. It is generated when the value of the SIPI_ACR is equal to the SIPI_MAXCR (see [SIPI Max Count Register \(SIPI_MAXCR\)](#) and [SIPI Address Count Register \(SIPI_ACR\)](#)). When the maximum count is reached, SIPI_SR[MCR] = 1 (see [SIPI Status Register \(SIPI_SR\)](#)). An interrupt will be generated if SIPI_MCR[MCRIE] = 1 (see [SIPI Module Configuration Register \(SIPI_MCR\)](#)).

44.12.4 Transaction ID error

The Transaction ID (TID) error is always generated at the initiator node only. It is generated when header bits 15–13 do not match SIPI_CSR n [TID] (transaction ID bits, see [SIPI Channel Status Register 0 \(SIPI_CSR0\)](#), [SIPI Channel Status Register 1 \(SIPI_CSR1\)](#), [SIPI Channel Status Register 2 \(SIPI_CSR2\)](#), and [SIPI Channel Status Register 3 \(SIPI_CSR3\)](#)). SIPI_CSR n [TIDE] = 1 when a TID error is detected, and an interrupt will be generated if SIPI_CIR n [TIDIE] = 1 (see [SIPI Channel Interrupt Register 0 \(SIPI_CIR0\)](#), [SIPI Channel Interrupt Register 1 \(SIPI_CIR1\)](#), [SIPI Channel Interrupt Register 2 \(SIPI_CIR2\)](#), and [SIPI Channel Interrupt Register 3 \(SIPI_CIR3\)](#)).

44.12.5 Acknowledge error

An incorrect acknowledge is received only from the initiator. When the acknowledge received is incorrect, SIPI_ERR[ACKR n] will be set (see [SIPI Error Register \(SIPI_ERR\)](#)). An interrupt will be generated if SIPI_CIR n [WAIE]=1 (see [SIPI Channel Interrupt Register 0 \(SIPI_CIR0\)](#), [SIPI Channel Interrupt Register 1 \(SIPI_CIR1\)](#), [SIPI Channel Interrupt Register 2 \(SIPI_CIR2\)](#), and [SIPI Channel Interrupt Register 3 \(SIPI_CIR3\)](#)).

44.13 CRC calculation

Example: If header is AABBh, address is 1122_3344h and data is CCDD_EEFFh. Then CRC calculation will take place as follows:

- 1) The CRC seed is initialized by FFFF_FFFFh.

- 2) All the data will be mirrored before sending to CRC engine (for example, MSB will be sent as LSB).
- 3) So the header will be sent as DD55_0000h.
- 4) Address will be sent as 22CC_4488h.
- 5) Data will be sent as FF77_BB33h.

44.14 Interrupt logic

A description of the interrupt logic can be found in the following figure.

Figure 44-29. Interrupt description

44.15 SIPI control and status overview

The diagram below shows the relationship between transfers and the SIPI control and status registers.

Figure 44-30. SIPI control and status overview – Register transfer

44.16 Memory map and register definition

SIPI memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SIPI Channel Control Register 0 (SIPI_CCR0)	32	R/W	0000_0000h	44.16.1/ 2271

44.16.1 SIPI Channel Control Register 0 (SIPI_CCR0)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI_CSR0[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI_CSR0[CB] = 0).

PRIORITY SCHEDULING: The channel whose SIPI_CAR_n is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

NOTE

This register is only writable in Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSR_n[CB] = 1 (see [SIPI Channel Status Register 0 \(SIPI_CSR0\)](#)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CAR_n (see [SIPI Channel Address Register 0 \(SIPI_CAR0\)](#)).

Memory map and register definition

SIPI_CCR0 field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 TC	Send Trigger Command. A Trigger Command requires that only this bit to be set by software, the trigger does not depend on settings in SIPI_CAR0. 0 Trigger command not sent 1 Trigger command sent
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–25 WL	Word Length Transfer. For Streaming write, WL bits should be written 10. 00 8-bit 01 16-bit 10 32-bit 11 not used
26 CHEN	Channel Enable. If all channel enables are simultaneously written to enable the channels, channel 0 will be given the highest priority for transmission. For channels, the lowest channel number is given highest priority. 0 Channel is disabled 1 Channel is enabled
27 ST	Streaming Transfer. This bit is hard-coded to 0. It can only be written for channel 2 (SIPI_CCR2). This bit can only be written when the corresponding SIPI_CCRn[WRT] = 1. NOTE: Only transfers with channel 2 can write 1 to this bit. All other channels force SIPI_CCRn[ST] = 0. The SIPI_CCR2[WRT] and SIPI_CCR2[ST] bits must be set for streaming.

Table continues on the next page...

SIPI_CCR0 field descriptions (continued)

Field	Description
	0 Streaming transfer is disabled 1 Streaming transfer is enabled
28 IDT	ID Read Request Transfer. This request returns the value of the CHIP ID. NOTE: The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 ID read request not sent 1 ID read request sent
29 RRT	Read Request Transfer. NOTE: The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 Read request will not be sent 1 Read request transfer by the initiator. This bit can not be written if SIPI_CCR0[IDT] = 1.
30 WRT	Write Request Transfer. NOTE: The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 No write request will be sent 1 Write request transfer by the initiator. This bit can not be written if SIPI_CCR0[IDT] = 1 or SIPI_CCR0[RRT] = 1.
31 DEN	DMA Enable. When enabling DMA mode, this bit should be set by software. It will then be cleared by hardware after one major loop has completed. 0 Channel will be used for bus interface access. 1 Channel will be used for DMA access

44.16.2 SIPI Channel Status Register 0 (SIPI_CSR0)

CSR0 contains the status bits for the current transfer.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W

SIPI_CSR0 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 RAR	Read Answer Reception. 0 Read answer not received 1 Read answer received
25–27 TID	Transaction ID of transmitted frame. Transaction ID is a random number associated with every Tx frame to match the received response/ack with the command.
28 ACKR	Acknowledge Received. 0 Acknowledge not received 1 Acknowledge received
29 CB	Channel Busy. Indicates channel 0 status. 0 Channel 0 free 1 Channel 0 busy

Table continues on the next page...

SIPI_CSR0 field descriptions (continued)

Field	Description
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

44.16.3 SIPI Channel Interrupt Register 0 (SIPI_CIR0)

SIPI_CIR0 contains the interrupt enable bits for channel 0.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

29 TOIE	Timeout Error Interrupt Enabled. 0 Interrupt is disabled 1 Interrupt is enabled
30 TIDIE	Transaction ID Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
31 ACKIE	Acknowledge Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled

44.16.4 SIPI Channel Timeout Register 0 (SIPI_CTOR0)

SIPI_CTOR0 contains the timeout value for Tx requests.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																							TOR								
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	

SIPI_CTOR0 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 TOR	Timeout value for transmitted requests. Timeout counter runs on the prescaled peripheral clock. Prescaler is defined by SIPI_MCR[PRSCLR]. NOTE: Field can only be written during Initialization mode (SIPI_MCR[INIT] = 1).

44.16.5 SIPI Channel CRC Register 0 (SIPI_CCRC0)

SIPI_CCRCn is a read only which returns the CRC calculated value on the header, address and data bits.

Address: 0h base + 14h offset = 14h

SIPI_CCRC0 field descriptions

Field	Description
0–15 CRCI	Reflects received CRC value at initiator
16–31 CRCT	Reflects received CRC value at target

44.16.6 SIPI Channel Address Register 0 (SIPI_CAR0)

SIPI_CAR0 is the address target for data transmission.

Address: 0h base + 18h offset = 18h

SIPI_CAR0 field descriptions

Field	Description
0–31 CAR	These bits contain the address of the target node.

44.16.7 SIPI Channel Data Register 0 (SIPI_CDR0)

SIPI_CDR0 contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 1Ch offset = 1Ch

SIPI_CDR0 field descriptions

Field	Description
0–31 CDR	Data register bits. Contains the data that will be transmitted, or received.

44.16.8 SIPI Channel Control Register 1 (SIPI_CCR1)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI_CSR1[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI_CSR1[CB] = 0).

PRIORITY SCHEDULING: The channel whose SIPI_CAR_n is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

NOTE

This register is only writable in Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSR n [CB] = 1 (see [SIPI Channel Status Register 1 \(SIPI_CSR1\)](#)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CAR n (see [SIPI Channel Address Register 1 \(SIPI_CAR1\)](#)).

Address: 0h base + 20h offset = 20h

SIPI_CTOR1 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 TOR	Timeout value for transmitted requests. Timeout counter runs on the prescaled peripheral clock. Prescaler is defined by SIPI_MCR[PRSCLR]. NOTE: Field can only be written during Initialization mode (SIPI_MCR[INIT] = 1).

44.16.12 SIPI Channel CRC Register 1 (SIPI_CCRC1)

SIPI_CCRCn is a read only which returns the CRC calculated value on the header, address and data bits.

Address: 0h base + 34h offset = 34h

SIPI_CCRC1 field descriptions

Field	Description
0–15 CRCI	Reflects received CRC value at initiator
16–31 CRCT	Reflects received CRC value at target

44.16.13 SIPI Channel Address Register 1 (SIPI_CAR1)

SIPI_CAR1 is the address target for data transmission.

Address: 0h base + 38h offset = 38h

SIPI_CAR1 field descriptions

Field	Description
0–31 CAR	These bits contain the address of the target node.

44.16.14 SIPI Channel Data Register 1 (SIPI_CDR1)

SIPI_CDR1 contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 3Ch offset = 3Ch

SIPI_CDR1 field descriptions

Field	Description
0–31 CDR	Data register bits. Contains the data that will be transmitted, or received.

44.16.15 SIPI Channel Control Register 2 (SIPI_CCR2)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI_CSR2[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI_CSR2[CB] = 0).

PRIORITY SCHEDULING: The channel whose SIPI_CAR_n is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

NOTE

This register is only writable in Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSR n [CB] = 1 (see [SIPI Channel Status Register 2 \(SIPI_CSR2\)](#)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CAR n (see [SIPI Channel Address Register 2 \(SIPI_CAR2\)](#)).

Address: 0h base + 40h offset = 40h

SIPI_CCR2 field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 TC	Send Trigger Command. A Trigger Command requires that only this bit to be set by software, the trigger does not depend on settings in SIPI_CAR2. 0 Trigger command not sent 1 Trigger command sent

Table continues on the next page...

SIPI_CCR2 field descriptions (continued)

Field	Description
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–25 WL	Word Length Transfer. For Streaming write, WL bits should be written 10. 00 8-bit 01 16-bit 10 32-bit 11 not used
26 CHEN	Channel Enable. If all channel enables are simultaneously written to enable the channels, channel 0 will be given the highest priority for transmission. For channels, the lowest channel number is given highest priority. 0 Channel is disabled 1 Channel is enabled
27 ST	This bit is hard-coded to 0. It can only be written for channel 2 (SIPI_CCR2). This bit can only be written when the corresponding SIPI_CCRn[WRT] = 1. NOTE: Only transfers with channel 2 can write 1 to this bit. All other channels force SIPI_CCRn[ST] = 0. The SIPI_CCR2[WRT] and SIPI_CCR2[ST] bits must be set for streaming. 0 Streaming transfer is disabled 1 Streaming transfer is enabled
28 IDT	ID Read Request Transfer. This request returns the value of the CHIP ID. NOTE: The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 ID read request not sent 1 ID read request sent
29 RRT	Read Request Transfer. NOTE: The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 Read request will not be sent 1 Read request transfer by the initiator. This bit can not be written if SIPI_CCR2[IDT] = 1.
30 WRT	Write Request Transfer. NOTE: The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT

Table continues on the next page...

SIPI_CCR2 field descriptions (continued)

Field	Description
	0 No write request will be sent 1 Write request transfer by the initiator. This bit can not be written if SIPI_CCR2[IDT] = 1 or SIPI_CCR2[RRT] = 1.
31 DEN	DMA Enable. When enabling DMA mode, this bit should be set by software. It will then be cleared by hardware after one major loop has completed. 0 Channel will be used for bus interface access. 1 Channel will be used for DMA access

44.16.16 SIPI Channel Status Register 2 (SIPI_CSR2)

SIPI_CSR2 contains the status bits for the current transfer.

Address: 0h base + 44h offset = 44h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SIPI_CCRC2 field descriptions

Field	Description
0–15 CRCI	Reflects received CRC value at initiator
16–31 CRCT	Reflects received CRC value at target

44.16.20 SIPI Channel Address Register 2 (SIPI_CAR2)

SIPI_CAR2 is the address target for data transmission. For streaming operations this register is the start address.

Address: 0h base + 58h offset = 58h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SIPI_CAR2 field descriptions

Field	Description
0–31 CAR	These bits contain the address of the target node.

44.16.21 SIPI Channel Data Register 2 (SIPI_CDR2_n)

SIPI_CDR2_n contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 5Ch offset + (4d × i), where i=0d to 7d

SIPI_CDR2_n field descriptions

Field	Description
0–31 CDR2	Data register bits. Contains the data that will be transmitted, or received.

44.16.22 SIPI Channel Control Register 3 (SIPI CCR3)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, `SIPI_CSR3[CB]` = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, `SIPI_CSR3[CB]` = 0).

PRIORITY SCHEDULING: The channel whose SIPI_CAR_n is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

NOTE

This register is only writable in Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSR n [CB] = 1 (see [SIPI Channel Status Register 3 \(SIPI_CSR3\)](#)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CAR n (see [SIPI Channel Address Register 3 \(SIPI_CAR3\)](#)).

Address: 0h base + 7Ch offset = 7Ch

- INIT field: Can only be written when SIPI_MCR[MOEN] = 1.
- TEN field: Can only be written when SIPI_MCR[MOEN] = 1.
- CHNSB field: Can be written only once after reset.
- MCRIE field: Can only be written when SIPI_MCR[MOEN] = 1.
- CRCIE field: Can only be written when SIPI_MCR[MOEN] = 1.
- AID field: Can be written in initialization mode only (SIPI_MCR[INIT] = 1).

SIPI_MCR field descriptions

Field	Description
0 FRZ	Freeze Enable The FRZ bit specifies the SIPI behavior when Debug mode is requested at the MCU level. When FRZ is asserted, the SIPI is enabled to enter Freeze mode. Negation of this bit field causes SIPI to exit Freeze mode. NOTE: Can only be written when SIPI_MCR[MOEN] = 1. 0 Not enabled to enter Freeze mode 1 Enabled to enter Freeze mode
1 Reserved	This field is reserved. Important: Always write the default value to this field.
2 HALT	Halt Mode Enable Assertion of this bit puts SIPI into Freeze mode. No Rx or Tx is performed in the SIPI until this bit is cleared. If this bit is enabled in during Tx or Rx communications, the current activity will finish, then the SIPI will enter Freeze mode. NOTE: Can only be written when SIPI_MCR[MOEN] = 1. 0 No Freeze mode request 1 Enters Freeze mode if FRZ bit is asserted.
3–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 PRSCLR	Timeout counter prescaler The timeout counter runs on the prescaled system clock. Default value is 64 (040h). The allowed programmable values are (all other values are ignored): 040h 64 (default) 080h 128 100h 256 200h 512 400h 1024 NOTE: This field should be programmed by software during initialization mode, SIPI_MCR[INIT] = 1. Writes during other times are ignored. NOTE: Writes to SIPI_MCR[PRSCLR] can only be accomplished with 16-bit or 32-bit writes.
16–17 AID	Address Increment/Decrement These bits define the type of address change at the target node. NOTE: This bits should be programmed by software in initialization mode, SIPI_MCR[INIT] = 1. Writes during other times are ignored. 00 no change. address stays same 01 address increments by 4 10 address decrements by 4 11 not used
18–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

SIPI_MCR field descriptions (continued)

Field	Description
21 CRCIE	CRC Error Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
22 MCRIE	Max Count Reached Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
23–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 CHNSB	Channel coding select bit. 0 Code Table II (see Table 44-2) 1 Code Table I (see Table 44-2)
28 TEN	Target Enable Setting this bit enables the target functionality at SIPI. This bit can be read or written anytime. This bit is automatically negated by hardware when target detects an error in "streaming without ACK" mode. This bit has to be enabled for the transmission operations also.
29 INIT	Initialization Mode Setting this bit puts the module in initialization mode. This bit should be cleared by software. Most register bits are configured using this bit. The SIPI_MCR[MOEN] bit needs to be set first, and then the INIT bit can be set and both bits can't be enabled together. 0 Normal Mode 1 Initialization Mode
30 MOEN	Module Enable This bit should be set or cleared by software. When this bit is negated, future SIPI Tx transfers are disabled.
31 SR	Soft Reset Setting this bit clears all status and error registers, and FSMs are moved to idle state. This bit is automatically cleared by hardware once the reset operation is complete.

44.16.30 SIPI Status Register (SIPI_SR)

The SIPI_SR is the global status register of SIPI.

Address: 0h base + A0h offset = A0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	FRZACK	Reserved	Reserved													
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	Reserved					GCRCE	MCR	Reserved	TE				STATE			
W						w1c	w1c		w1c							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIPI_SR field descriptions

Field	Description
0 FRZACK	Freeze Mode Acknowledge. This read-only bit indicates that SIPI is in Freeze mode. The Freeze mode request cannot be granted until current transmission or reception processes have finished. The software can poll the FRZACK bit to find when the SIPI has actually entered Freeze mode. If Freeze mode is requested while SIPI is in any of the low power modes, then the FRZACK bit will only be set when the low power mode is exited.

Table continues on the next page...

SIPI_SR field descriptions (continued)

Field	Description
	0 SIPI not in Freeze mode 1 SIPI in Freeze mode
1 Reserved	This field is reserved.
2–20 Reserved	This field is reserved.
21 GCRCE	Global CRC Error Bit. 0 No CRC error 1 CRC error occurred
22 MCR	Maximum Count Reached. This bit will be set whenever SIPI_ACR[ADCNT] = SIPI_MAXCR[MXCNT]. An interrupt will be generated when this bit is set only if SIPI_MCR[MCRIE] = 1. This it should be cleared by software.
23 Reserved	This field is reserved.
24–27 TE	Trigger Event on Respective Channels. This field enables interrupts for target nodes. xxx1 TE0 = 1 - Channel 0 trigger event xx1x TE1 = 1 - Channel 1 trigger event x1xx TE2 = 1 - Channel 2 trigger event 1xxx TE3 = 1 - Channel 3 trigger event
28–31 STATE	These bits reflect the transmit state machine status. They can be polled for determination of state machine status. 0000 IDLE 0001 HEADER_AND_ADDRESS_FIELD 0010 HEADER_AND_DATA_FIELD 0011 HEADER_AND_CRC_FIELD 0100 ADDRESS_AND_CRC_FIELD 0101 ADDRESS_AND_DATA_FIELD 0110 DATA_AND_CRC_FIELD 0111 DATA_FIELD

44.16.31 SIPI Max Count Register (SIPI_MAXCR)

SIPI_MAXCR contains the maximum address count value at target node. It is programmed via direct write request through the initiator. This register can be read or written by software anytime.

Address: 0h base + A4h offset = A4h

SIPI_MAXCR field descriptions

Field	Description
0–29 MXCNT	This field contains the maximum address count value at the target node. It should be programmed via direct write request through the initiator.
30–31 Reserved	This field is reserved.

44.16.32 SIPI Address Reload Register (SIPI_ARR)

The SIPI_ARR contains the reload value for the address counter at the target node. It should be configured by direct write request from the initiator.

NOTE

This register is writeable only when SIPI_MCR[INIT] = 1.

Address: 0h base + A8h offset = A8h

Memory map and register definition

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	ADRLD														Reserved	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIPI_ARR field descriptions

Field	Description
0–29 ADRLD	ADRLD contains the reload value for the address counter at the target node. It should be configured by direct write request from the initiator.
30–31 Reserved	This field is reserved.

44.16.33 SIPI Address Count Register (SIPI_ACR)

This register reflects the count value of address counter at target node. It should be configured by direct write request from initiator. This register can be read/written by software anytime.

NOTE

SIPI_ARR, SIPI_ACR and SIPI_MAXCR will be configured by direct write operation through the initiator.

NOTE

When a streaming write command is received, the target will start the write operation from the address present in SIPI_ACR (address count register).

NOTE

After each 32-bit write has completed, SIPI_ACR[ADCNT] is compared against SIPI_MAXCR[MXCNT]. If they are equal, SIPI_ACR[ADCNT] is loaded with the value stored in SIPI_ARR[ADRLD]. If they are not equal, the SIPI_ACR[ADCNT] will increment by 4, decrement by 4 or remain the same (depending on configuration). In both cases, the SIPI_ACR[ADCNT] will contain the address at which the next streaming write will occur.

Address: 0h base + ACh offset = ACh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	ADCNT															
W

R	ADCNT														Reserved	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIPI_ACR field descriptions

Field	Description
0–29 ADCNT	Reflects the count value of address counter at target node. It should be configured by direct write request from the initiator. This register can be read/written by software anytime. At the end of the streaming operation, SIPI_ACR will point to the next address to be written.
30–31 Reserved	This field is reserved.

44.16.34 SIPI Error Register (SIPI_ERR)

This register contains the error bits for the last transaction(s) for all the channels. Communication errors are generated only for out of range address accesses, areas that are read only and where accesses do not lead to generation of transfer errors. Also, writing to read only registers will not generate errors.

Address: 0h base + B0h offset = B0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SIPI_ERR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 TOE3	Timeout Error for Channel 3. 0 Timeout error didn't occur 1 Timeout error occurred
6 TIDE3	Transaction ID Error for Channel 3. 0 Received transaction ID matched with the stored ID 1 Received transaction ID didn't match with the stored ID
7 ACKE3	Acknowledge Error for Channel 3. 0 Acknowledge received is correct. 1 Acknowledge received is not correct.
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 TOE2	Timeout Error for Channel 2. 0 Timeout error didn't occur 1 Timeout error occurred
14 TIDE2	Transaction ID Error for Channel 2. 0 Received transaction ID matched with the stored ID 1 Received transaction ID didn't match with the stored ID
15 ACKE2	Acknowledge Error for Channel 2. 0 Acknowledge received is correct 1 Acknowledge received is not correct
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 TOE1	Timeout Error for Channel 1. 0 Timeout error didn't occur 1 Timeout error occurred
22 TIDE1	Transaction ID Error for Channel 1. 0 Received transaction ID matched with the stored ID 1 Received transaction ID didn't match with the stored ID
23 ACKE1	Acknowledge Error for Channel 1. 0 Acknowledge received is correct 1 Acknowledge received is not correct
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 TOE0	Timeout Error for Channel 0. 0 Timeout error didn't occur 1 Timeout error occurred

Table continues on the next page...

SIPI_ERR field descriptions (continued)

Field	Description
30 TIDE0	Transaction ID Error for Channel 0. 0 Received transaction ID matched with the stored ID 1 Received transaction ID didn't match with the stored ID
31 ACKE0	Acknowledge Error for Channel 0. 0 Acknowledge received is correct. 1 Acknowledge received is not correct.

Chapter 45

LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications

45.1 Chip-specific LFAST information

This chip has one instance of the LFAST module.

45.2 Introduction

This chapter describes the specifications of the LFAST module, which implements the LVDS Fast Asynchronous Serial Transmission (LFAST) module. LFAST is used in dual mode (software configurable master/slave operation) for interprocessor communications.

45.3 Block diagram

The following figure depicts LFAST interaction with other modules on the device.

Figure 45-1. LFAST block diagram

45.4 External signals

LFAST is a five pin interface with the following signals :

- lfast_sysclk
 - Reference clock of the LFAST master and slave
- txdatap/txdatan
 - Differential transmit (Tx) interface pair
- rxdatap/rxdatan
 - Differential receive (Rx) interface pair

LFAST interface is an asynchronous high speed LVDS interface.

45.4.1 LFAST operating data rates

The change of data rate is controlled by the LFAST master by issuing appropriate Interface Control Logical Channel (ICLC) packets to the LFAST slave. Henceforth, the data rate 6.5 Mbps/5 Mbps ($\text{lfast\_sysclk} \div 4$ or $\text{lfast\_sysclk} \div 2$) is referred to as low data rate, and the high data rate is in the Data Sheet.

45.5 LFAST frame structure

A LFAST frame is made up of three fields:

- Sync pattern
- Header
- Payload

Sync pattern and header fields are of fixed length.

Sync pattern is used to synchronize incoming data stream in LFAST module.

Header field of the frame distinguishes various types of data and control transferred and also contains information about the length of the payload. The payload field is the actual data that is transferred across the channel. See [Figure 45-2](#) for details of the LFAST frame.

LFAST frame structure

Figure 45-2. LFAST frame structure

The same protocol is used on both transmit and receive interfaces for communications of data, control and status information. A synchronization pattern (16 bits) and header (8 bits) are present in every frame.

Figure 45-3. Serial frame structure

The frame structure is shown in [Figure 45-3](#) and consists of the following:

- **16-bit synchronization pattern:** Used for clock synchronization and pattern recognition. The frame synchronization code at the start of every frame is a unique reserved word that is used to identify whether the data received is the start of the frame and for synchronization (clock phase extraction) with the stream data. A synchronous sequence is used to give a high quality auto correlation. The LFAST 16-bit synchronization sequence = 1010_1000_0100_1011b = A84Bh.
- **Header - 3 MSB (b7 - b5):** Defines the payload size as shown in [Table 45-1](#) :

Table 45-1. Header payload sizes

b7-b5(bin)	Payload Size	Frame Size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	—	—
111	288	312

- **Header - (b4 - b1):** Defines the logical channel types, which indicate the type of payload that the frame carries. How the payload field of a frame is used for any other logical channel type is system side module specific except in the case of the interface control logical channel type and clear to send (CTS) frame.
- **Header - (b0):** CTS on the both LFAST master and slave devices.
- **Payload:** Content dependent upon frame type.
- **Bit after frame:** This bit determines entry into Sleep mode (1 = Sleep mode, 0 = normal mode)

45.6 Features

- Supports dual mode (register configurable Master/Slave).
- Supports asynchronous data transfer up to the maximum data rate shown in the product Data Sheet.
- Transmits and receives data, CTS, ICLC and unsolicited frames.
- Receives ICLC frames
- Provision of five interrupts for Tx and Rx channels.
- Supports processor controlled transfer of ICLC frame with 8-bit payload size to implement the data rate changes and test modes.
- Supports LFAST defined CTS controlled data transfer. No dependency between data transmission and reception unless CTS mode is enabled.
- Supports flow control using sliding window protocol.
- Provides configurable frame length for data frame with variable payload sizes of 32, 64, 96, 128, 256 or 288 bits.
- Provides transmit of data frame length with 96 bits of payload size and reception of data frame with 128 bits of payload size.
- Provides configurable frame length for unsolicited frame with variable payload sizes of 8, 32, 64, 96, 128, 256 or 288 bits.
- Supports PLL configuration (for example, feedback loop divider, etc.) through registers.
- Supports LVDS configuration through registers.
- Supports multiple loopback modes for checking the physical interface.
- Supports automatic ping response generation in slave mode.
- Supports for detection of unsupported channel number and unsupported payload size.

45.7 Memory map and register definition

All registers are 32 bits wide.

NOTE

Read/Write accesses to all unimplemented registers and write accesses to Read only register will return a Transfer Error.

LFAST memory map

* Notes:

- DRFRST field: Set by user software and then cleared by system hardware.
- CTSEN field: Only writable when MCR[DRFEN] = 0.
- MSEN field: Writable only once after the asynchronous reset.

LFAST_MCR field descriptions

Field	Description
0 MSEN	LFAST Master or Slave mode Enable. This bit selects either the LFAST master or slave functionality. 0 Enable the modules LFAST Slave functionality only. 1 Enable the modules LFAST Master functionality only.
1–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 IPGDBG	Control bit to enable support for IPG Debug mode. This mode is indicated by assertion of IPG debug mode signal. 0 IPG debug mode enable signal will be ignored. 1 IPG debug mode enable signal will not be ignored.
8–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 LSSEL	Selects the fraction of sysclk in Low Speed Select mode (see Slow speed clock for details). 0 Low Speed Mode in which the lfast_sysclk input is used to generate 4 phases of lfast_sysclk/2. 1 Low Speed Mode in which the lfast_sysclk input is used to generate 4 phases of lfast_sysclk/4.
16 DRFEN	LFAST Enable. This bit enables/disables the reception and transfer of LFAST device. 0 LFAST is immediately disabled. All current/pending requests are terminated and the Tx and Rx data FIFOs are flushed. If this bit is cleared in the middle of a transmit/receive operation, then that operation is terminated immediately and nothing is transmitted/received further. All the programmable

Table continues on the next page...

LFAST_MCR field descriptions (continued)

Field	Description
	registers retain their values and status registers are cleared to their reset values. Registers read/write operations can be performed through the IPS Bus. 1 LFAST is Enabled.
17 RXEN	LFAST Receiver Enable. This bit controls the reception of the frames and decoding on the LFAST device. This bit also disables the Rx LVDS Line Receiver (LR). 0 Receiver Interface is disabled. If this bit is cleared during a data transfer, the current frame is received and then the Rx block is disabled. After the Rx block is disabled, all new frames from LFAST peer device are ignored. System Side Module Rx interface isn't disabled by this bit. 1 Receiver Interface is Enabled.
18 TXEN	LFAST Transmitter Enable. This bit controls the transmission of frames from the LFAST device and disables the Tx LVDS LD. This bit can also be modified by LFAST slave H/W on reception of an ICLC command frame. This field can only be written in dual mode (LFAST_GSR[DUALMD] = 1). 0 LFAST transmitter Interface is disabled. No new request is accepted but ongoing request is served. 1 LFAST transmitter Interface is enabled. New requests are accepted.
19–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 TXARBD	Tx Arbiter Disable. This bit enables/disables the Tx block arbiter. Current frame transfer is completed, but new frame requests are ignored. 0 Enable Tx arbiter and framer. When enabled it takes all the frame request and services based on priority. 1 Disable Tx arbiter and framer. All frame requests are ignored.
28 CTSEN	CTS Enable. This bit defines the Push-Pull mode of the LFAST devices receiver. This bit is used to enable/disable CTS mode of the Tx block. This bit is only writable when MCR[DRFEN] = 0. 0 CTS mode is disabled. Indicates that the device is in Push mode. The CTS bit of frames transmitted is 1. The CTS bit doesn't represent the status of Rx FIFO. 1 CTS mode is enabled. The CTS bit of all transmit frames is set when the Rx FIFO empty space is on or above higher threshold, and cleared when the Rx FIFO empty space is on or below lower threshold.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 DRFRST	LFAST Soft Reset. This bit is automatically cleared after Reset.. 0 No Soft Reset 1 Soft Reset to LFAST is asserted. When set it causes a reset of the LFAST module; all the registers will be reset to their default values and all the FIFOs will be flushed.
31 DATAEN	DATA Frame Enable. This bit enables/disables the transmission and reception of data frames between the LFAST master and slave devices. 0 Data frame transmission and reception is disabled. Tx data frame requests are ignored by the transmitter. Frame with LCT of data frame is ignored by the receiver. 1 Data frame transmission and reception is enabled. Tx data frame requests are serviced by the transmitter. Frame with LCT of data frame is received and placed into the Rx data FIFO.

45.7.2 LFAST Speed Control Register (LFAST_SCR)

The SCR is used to configure the Rx and Tx data rate of the LFAST.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LFAST_SCR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 DRMD	Data Rate Controller mode. Defines the mode setting for LFAST slave device by S/W or LFAST master. 0 S/W controls the Data Rate controller mode. In LFAST Slave the ICLC frames for rate change have no affect on the Data rate. 1 In LFAST Slave the reception of ICLC frame for rate change sets appropriate speed mode. In LFAST Master the SCR[DRMD] should be 0.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 RDR	Receiver Data Rate. This bit defines the receiver data rate. For LFAST Master: - S/W should program this bit only after transmission of an ICLC frame changing the speed mode of the slaves Tx interface. For LFAST Slave: - When SCR[DRMD] = 1, the H/W programs this bit on reception of ICLC frame for changing speed mode of Slaves Rx interface. - The S/W can program this bit when SCR[DRMD] = 0. - This bit is cleared on MCR[DRFEN] negation. 0 Data rate of Rx block is low speed. 1 Data rate of Rx block is high speed.

Table continues on the next page...

LFAST_SCR field descriptions (continued)

Field	Description
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TDR	Transmit Data Rate. This bit defines the transmitter data rate. For LFAST Master: - S/W should program this bit only after transmission of an ICLC frame changing the speed mode of the slaves Rx interface. For LFAST Slave: - When SCR[DRMD] = 1, the H/W programs this bit on reception of ICLC frame for changing speed mode of Slaves Tx interface. - The S/W can program this bit when SCR[DRMD] = 0. - This bit is cleared on MCR[DRFEN] negation. 0 Data rate of Tx block is low speed. 1 Data rate of Tx block is high speed.

45.7.3 LFAST Correlator Control Register (LFAST_COCCR)

The COCCR is used to select the sampler data path and the number of bits of correlation to be used.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15			
R	SMPSEL								0						0				
W																			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0			
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31			
R	0												CORRTH						PHSEL
W																			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	0			

LFAST_COCCR field descriptions

Field	Description
0–7 SMPSEL	Sampler Data Path Selector (overrides the correlator selection). Defines the sampler data path to be activated at all the times. All the bits should be 0 (00h) for Sampler Data Path to be selected by the correlator. In Low Speed mode only Sampler Data Paths 0-3 are valid. This field can only be written when MCR[RXEN] = 0.

Table continues on the next page...

LFAST_COCR field descriptions (continued)

Field	Description
	00h Sampler Data Path selected by correlator 01h Sampler Data Path 0 selected 02h Sampler Data Path 1 selected 04h Sampler Data Path 2 selected 08h Sampler Data Path 3 selected 10h Sampler Data Path 4 selected 20h Sampler Data Path 5 selected 40h Sampler Data Path 6 selected others Sampler Data Path 7 selected
8–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–30 CORRTH	Correlator threshold level. Defines the correlation threshold level. This field can only be written when MCR[RXEN] = 0. 000 9 Bits of correlation 001 10 Bits of correlation ... 110 15 Bits of correlation 111 16 Bits of correlation
31 PHSSEL	Polyphase 8 or 4 phase selection. Defines the number of phases for the polyphase generator used. This bit is ignored in low speed mode since only 4 Phases are used in low speed mode. In High Speed mode phase 0, 2, 4 and 6 are used when 4 phase mode is selected. This field can only be written when MCR[RXEN] = 0 0 8 phases 1 4 phases

45.7.4 LFAST Test Mode Control Register (LFAST_TMCR)

The TMCR enables and configures the LFAST clock test and loopback modes.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0						CLKTST	LPON	0						LPMOD

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LFAST_TMCR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 CLKTST	Clock Test mode. S/W can define when the clock test mode is enabled. This bit can also be set and cleared by LFAST slave H/W on reception of an ICLC command. This field can only be written when MCR[DRFEN] = 1. 1 Clock Test mode enabled 0 Clock Test mode disabled
7 LPON	Loopback mode Logic Enable. S/W can define when the loopback logic is enabled. This bit can also be written by LFAST slave H/W on reception of an ICLC command. This field can only be written when MCR[DRFEN] = 1. 1 Loopback mode is enabled 0 Loopback mode is disabled
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 LPMOD	Loopback mode. Defines the type of loopback mode enabled. This field can only be written when TMCR[LPON] = 0. 000 Rx loopback 001 Rx LVDS loopback 010 Tx loopback without automatic frame generation 011 Tx loopback with automatic frame generation 100 Tx LVDS loopback (external) with automatic frame generation 101 Reserved

Table continues on the next page...

LFAST_TMCR field descriptions (continued)

Field	Description
	110 Reserved 111 Reserved
16–31 LPFRMTH	Loopback check mode valid pass frames threshold value. Defines the number of frames to verify before setting GCR[LPFPDV] when running in Automatic Loopback Frame mode. The loopback frame is considered pass when the payload is CBh, header is 13h and sync is valid. This mode is valid only when TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. This field can only be written when TMCR[LPON] = 0. 0000h Reserved.(Not to be used) 0001h Check 1 frame have correct sync, header and payload. ... FFFEh Check 65534 frames have correct sync, header and payload. FFFFh Check 65535 frames have correct sync, header and payload.

45.7.5 LFAST Auto Loopback Control Register (LFAST_ALCR)

Address: 0h base + 10h offset = 10h

LFAST_SLCR field descriptions

Field	Description
0–7 HSCNT	High Speed Sleep mode Exit Time. Defines 1/4 of the number of the high speed clock cycle wait after the negation of the LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of the Line Driver (LD) after negation of its sleep signal, and the wakeup time of the LR of the peer LFAST. This field can only be written when MCR[DRFEN] = 0. 00h 0 cycle 01h 1 cycle ...

Table continues on the next page...

LFAST_SLCR field descriptions (continued)

Field	Description
	12h 18 cycles (200 ns + 8 cycles of High speed clock) ... FEh 254 cycles FFh 255 cycles
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 LSCNT	Low Speed Sleep mode Exit Time. Defines 1/4 of the number of Low speed clock cycle wait after the negation of LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of LD after negation of LVDS LD sleep signal, and the wakeup time of the LR of the peer LFAST. This field can only be written when MCR[DRFEN] = 0. 0h 0 cycle 1h 1 cycle (200ns + 1 cycle of Low speed clock) ... Eh 14 cycles Fh 15 cycles
16–23 HWKCNT	Wake Up time for the LD. Defines the 1/4 of the number of High speed clock cycles used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from moving from Shutdown to Normal State in High speed mode. This field can only be written when MCR[DRFEN] = 0. 00h 0 cycles 01h 1 cycle ... 5Fh 95 cycles (1.18 μ s) ... FFh 255 cycles Maximum
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 LWKCNT	Wake Up time for the LD. Defines the 1/4 of the number Low speed clock used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from Shutdown to Normal State in Low speed mode. This field can only be written when MCR[DRFEN] = 0. 0h 0 cycle 1h 1 cycle 2h 2 cycles (1.18 μ s) ... Eh 14 cycles Fh 15 cycles

45.7.8 LFAST ICLC Control Register (LFAST_ICR)

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	Reserved								ICLCPLD							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LFAST_ICR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 ICLCSEQ	ICLC enabled. This bit should be set whenever the S/W is performing a series of ICLC frame transfers. This bit ensures only ICLC frame transmission request is serviced, other pending frames request are ignored. 0 Single ICLC frame transfer. 1 S/W is performing ICLC frame transfers. Only the ICLC frames will be scheduled during this period. All the other frames will be scheduled only after ICR[ICLCSEQ] = 0.
15 SNDICLC	ICLC frame request. This bit is set to initiate the transfer of ICLC frame by LFAST master. This bit should be set (ICR[SNDICLC] = 1) after writing the required ICLC payload to be transmitted in the ICLCPLD field of the register. This bit is self clearing, which will be cleared when ICLC frame transfer is complete. Set by user software and cleared by system hardware. 0 No Valid ICLC frame for transfer. 1 Valid ICLC frame for transfer.
16–23 Reserved	This field is reserved.
24–31 ICLCPLD	ICLC Payload. This field is used to program the payload of the ICLC frame to be transmitted. New ICLC payload should be set when ICR[SNDICLC] = 0. This field can only be written when ICR[SNDICLC] = 0 (see Table 45-53 for supported ICLC payloads).

45.7.9 LFAST Ping Control Register (LFAST_PICR)

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0														PNGREQ	
W

W																
Reset	1	0	0	0	0	0	0	0	1	1	0	0	1	0	1	0

LFAST_PICR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 PNGREQ	Ping Response Frame Request. This bit is set to initiate the transfer of Ping response frame. Cleared after transmission of Ping response frame. Set by user software and cleared by system hardware. This field can only be written when MCR[DRFEN] = 1. 1 Ping response frame transmission request is queued 0 No pending Ping response frame transmission request
16 PNGAUTO	Ping Response Enable. Defines when ping response should be automatically sent on reception of Ping ICLC frame from LFAST master. This field can only be written when MCR[DRFEN] = 0. 0 Ping response should not be automatically sent. 1 Ping response should be automatically sent.
17–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 PNGPYLD	LFAST Slave: Defines the LFAST slaves ping reply frame payload content. This field can only be written when MCR[DRFEN] = 0. LFAST Master: Defines the expected payload of ping response frame. Used for comparison with ping frame received.

45.7.10 LFAST Rx FIFO CTS Control Register (LFAST_RFCR)

Address: 0h base + 2Ch offset = 2Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LFAST_LCR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 SWWKLD	SW signal to take LVDS LD out of Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. NOTE: Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be taken out of sleep (provided no other source is trying to put it in sleep)
9 SWSLPLD	SW signal to put LVDS LD into Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. NOTE: Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be put in sleep

Table continues on the next page...

LFAST_LCR field descriptions (continued)

Field	Description
10 SWWKLR	SW signal to take LVDS LR out of Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. NOTE: Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be taken out of sleep (provided no other source is trying to put it in sleep)
11 SWSLPLR	SW signal to put LVDS LR into Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. NOTE: Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be put in sleep (provided no other source is trying to wake it up)
12 SWOFFLD	SW signal to turn OFF the LVDS LD. This field can only be written when LFAST_MCR[DRFEN] = 1. NOTE: Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be turned OFF(provided no other source is trying to turn the LD ON)
13 SWONLD	SW signal to turn ON the LVDS LD. This field can only be written when LFAST_MCR[DRFEN] = 1. NOTE: Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be turned ON
14 SWOFFLR	SW signal to turn OFF the LVDS LR. This field can only be written when LFAST_MCR[DRFEN] = 1. NOTE: Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be turned OFF (provided no other source is trying to turn the LR ON)
15 SWONLR	SW signal to turn ON the LVDS LR. This field can only be written when LFAST_MCR[DRFEN] = 1. NOTE: Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be turned ON
16 LVRXOFF	Indicates the value driven onto LVDS LR output when in shutdown mode
17 LVTXOE	LVDS LD output buffer enable. 0 LVDS LD output buffer enable is disabled. 1 LVDS LD output buffer enabled
18 TXCMUX	Tx and Clock Mux. The bit can be used to bring out PLL Phase 0 clock on Tx LVDS pad. 0 No effect 1 PLL Phase 0 clock will be brought out to Tx LVDS pad
19 LVRFEN	LVDS pad reference enable 0 LVDS reference pad disabled 1 LVDS reference pad enabled

Table continues on the next page...

LFAST_LCR field descriptions (continued)

Field	Description
20 LVLPEN	Tx LVDS internal loopback enable The bit is reflected by output signal <code>ipp_digrf_lvds_lpbk_en</code>. The internal loopback is not intended for board level functionality, so this feature should not be implemented. 0 Tx LVDS normal mode enabled 1 Tx LVDS internal loopback mode enabled
21–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 LVRXOP_TR	Used to enable or disable the on-chip receiver termination resistor in LFAST mode (applies to LVDS pad use for LFAST only): 0 Disable on-chip LFAST receiver termination 1 Enable on-chip LFAST receiver termination
27 Reserved	This field is reserved.
28 LVRXOP_BR	Used to set the bias current for the receiver in LFAST mode. It is recommended to always write 1 to this bit when using the LFAST interface. Writing 0 will allow for a small power savings during lower baud rates (applies to LVDS pad use for LFAST only): 0 Use for LFAST receiver baud rates less than the maximum baud rate. 1 Required for LFAST receiver maximum baud rate.
29 LVTXOP	Control signal for LFAST and Micro-Second Bus selection. 0 Micro-Second Bus selection 1 LFAST Bus selection
30 LVCKSS	LVDS Clock Sync Select This bit is used to adjust the LVDS data sampling to the duty cycle of the clock. It is recommended that a value of zero is used in all cases. A value of one is reserved for specific devices/revisions with different clock timing. 0 normal clock used to sample the LVDS data 1 adjusted clock used to sample the LVDS data
31 LVCKP	LVDS clock select. This bit is used for selecting use of direct pll clock or inverted pll clock in LVDS. 0 Direct pll clock to be used inside the LVDS 1 Inverted pll clock to be used inside the LVDS

45.7.16 LFAST Unsolicited Tx Control Register (LFAST_UNSTCR)

Address: 0h base + 44h offset = 44h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0														USNDRQ

LFAST_GSR field descriptions

Field	Description
0 DUALMD	Indicates the LFAST module is in Dual mode

Table continues on the next page...

LFAST_GSR field descriptions (continued)

Field	Description
	0 LFAST Module in Slave only mode 1 LFAST Module in Dual mode
1–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 LRMD	Indicates if the Rx Controller is idle/active and that the Rx clocks are enabled. In functional mode this will always be active. 0 Rx Controller is in Idle state 1 Rx Controller is active
14 LDSM	Transmit Interface Data Rate Status. Indicates the current speed rate of the Tx controller 0 Data rate of LOW speed mode 1 Data rate of HIGH speed mode
15 DRSM	Receive Interface Data Rate Status. Indicates the current speed rate of the Rx controller 0 Data rate of LOW speed mode 1 Data rate of HIGH speed mode
16–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LPTXDN	Auto loopback frame transmission count reached. The Count of frame is defined by LFAST_ALCR[LPFMCNT]. 0 Auto loopback frame transmission count not reached. 1 Auto loopback frame transmission count reached.
28 LPFPDV	Loopback frame pass threshold reached. 0 Pass frame threshold not reached. 1 Pass frame threshold achieved
29 LPCPDV	Valid payload received during loopback check mode. Indicates whether the Loop back frame received payload is CBh. 0 Payload received is not CBh 1 Payload received is CBh
30 LPCHDV	Valid header received during loopback check mode. Indicates whether the Loop back frame received header is 13h. 0 Header received is not 13h 1 Header received is 13h
31 LPCSDV	Valid synchronization received. 0 Valid Synchronization pattern not detected 1 Valid Synchronization pattern detected

45.7.19 LFAST Ping Status Register (LFAST_PISR)

Address: 0h base + 84h offset = 84h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LFAST_UNSRDR_n field descriptions

Field	Description
0–31 UNRXD	Unsolicited Receive Data. This represents 9 registers for Unsolicited received data. It is read only register. The first bit received as part of the payload will be stored at UNRXD8[31], second bit at UNRXD8[30], and so on. So the last bit will be stored at UNRXD0[0] in case of 288 bit payload.

45.8 Functional description**45.8.1 Startup procedure**

The LFAST requires a sequence of operations before it can be used for communication. The procedure to enable LFAST for proper operation is listed below.

45.8.1.1 LFAST master interface startup procedure

1. After reset the SLCR and RCDRCR are programmed according to the LVDS parameters in the device data sheet.

2. The PLLCR is programmed with configuration parameters for the PLL.
3. The LCR is programmed with configuration parameters of the LVDS.
4. Write MCR[MSEN] = 1. Then select LFAST modes by configuring MCR[CTSEN] and MCR[DATAEN].
5. Write MCR[DRFEN] = 1 to enable the LFAST.
6. Write MCR[RXEN] = 1 and MCR[TXEN] = 1 to negate the LD powerdown, LR disable and LR powerdown signals.
7. Write ICR[ICLCPLD] = 31h to enable the Slaves Tx Interface.
8. Write ICR[SNDICLC] = 1 and ICR[ICLCSEQ] = 1.
9. Write MCR[TXARBD] = 0.
10. The ICLC transmission is confirmed by verifying one of the following:
 - ICR[SNDICLC] = 0.
 - TISR[TXICLCF] = 1.
11. Write ICR[ICLCPLD] = 00h to check the LFAST slaves status.
12. Write ICR[SNDICLC] = 1.
13. The LFAST slave status is confirmed by occurrence of one of the following:
 - LFAST slave is enabled if RIISR[ICPSF] = 1. Proceed to step 14.
 - LFAST slave is disabled if RIISR[ICPFF] = 1. The LFAST master must wait and restart from Step 7.

Speed mode change:

14. Write PLLCR[SWPON] = 1 to enable the LFAST masters PLL.
15. Write ICLC start PLL frame, ICR[ICLCPLD] = 02h.
16. Write ICR[SNDICLC] = 1.
17. The ICLC transmission is confirmed by occurrence of one of the following:
 - ICR[SNDICLC] = 0.
 - TISR[TXICLCF] = 1.
18. To change LFAST masters Tx interface speed both of the following operations are performed:

Note

(The slaves Rx interface speed should be changed first.)

- Write ICR[ICLCPLD] = 10h for Tx data fast frame.
- Write ICR[SNDICLC] = 1.

19. Both of the following operations are performed to change the LFAST masters Rx interface speed:

Note

(The slaves Tx interface speed mode should be changed first)

- Write ICR[ICLCPLD] = 80h to select Rx data fast frame.
- Write ICR[SNDICLC] = 1.

20. The ICLC transmission is confirmed by the occurrence of one of the following:

- ICR[SNDICLC] = 0
- TISR[TXICLCF] = 1.

21. Write SCR[TDR] = 1 to change the LFAST masters Tx interface speed.

22. Write SCR[RDR] = 1 to change the LFAST masters Rx interface speed.

23. Write ICR[ICLCPLD] = 00h to confirm the change in speed of the LFAST slave. This frame should be written after waiting for the expected delay in the start of the PLL and speed mode change delay at the LFAST slave.

24. Write ICR[SNDICLC] = 1

25. Write MCR[TXARBD] = 1, after some delay to ensure the step 24 ICLC frame is send but no other frame is sent to arbitration.

26. The LFAST slaves speed mode is confirmed by the occurrence of the following:

- If RIISR[ICPSF] = 1. The LFAST slave is in High Speed mode.
- If RIISR[ICPFF] = 1. The LFAST slave is in Low Speed mode.

27. If RIISR[ICPSF] = 1, then all frame arbitration is enabled by both of the following operations:

- Write ICR[ICLCSEQ] = 0.
- Write MCR[TXARBD] = 0.

28. If RIISR[ICPFF] = 1 modifying the LFAST slaves speed needs to be repeated by:

- Write SCR[TDR] = 0 to return the Tx interface to Low Speed mode.
- Write MCR[TXARBD] = 0, to enable frame transmission.
- The operations from step 14 need to be executed again.

45.8.1.2 LFAST slave interface startup procedure

1. After reset the SLCR and RCDCCR are programed according to the LVDS datasheet.
2. The PLLCR is programed with the configuration parameters for the PLL.
3. The LCR is programed with the configuration parameters for the LVDS.
4. Write MCR[MSEN] = 0. Then select LFAST modes by configuring MCR[CTSEN] and MCR[DATAEN].
5. Write MCR[DRFEN] = 1 to enable the LFAST.
6. The LR is enabled by writing MCR[RXEN] = 1. This negates the LR disable signal and LR's power down signal.
7. The LD enable signal needs to be asserted. This is done when one of the following are true:
 - When an ICLC frame with payload 31h is received the H/W will write RIISR[ICTEF] = 1 and MCR[TXEN] = 1.
 - MCRMCR[TXEN] = 1.
8. After a write to MCR[TXARBD] = 0, a ping frame will be sent on one of the following conditions:
 - When PICR[PNGAUTO] = 1 and an ICLC frame with payload 00h frame is received. H/W writes [ICRPF] = 1.
 - PICR[PNGREQ] = 1.

Speed mode change:

9. The PLL will start when one of the following conditions is met:

- When an ICLC frame with payload 02h is received. H/W writes RIISR[IPONF] = 1.
- Write PLLCR[SWPON] = 1.

10. The speed of the Tx interface is changed on one of the following conditions:

- When SCR[DRMD] = 1 and an ICLC frame with payload 80h is received. H/W writes RIISR[ICTFF] = 1 and SCR[TDR] = 1.
- SCR[TDR] = 1, when SCR[DRMD] = 0.

11. The speed of the Rx interface is changed on one of the following conditions:

- When SCR[DRMD] = 1 and an ICLC frame with payload 10h is received. H/W writes RIISR[ICRFF] = 1 and SCR[RDR] = 1.
- SCR[RDR] = 1, when SCR[DRMD] = 0.

12. A Ping Frame is sent on one of the following conditions:

- When PICR[PNGAUTO] = 1 and an ICLC frame with payload 00h is received. H/W writes RIISR[ICRPF] = 1.
- Write PICR[PNGREQ] = 1.
- Write PICR[PNGREQ] = .

45.8.2 Line Receiver

This section describes the Line Receiver.

45.8.2.1 Introduction

The LR detects the voltage swing on the differential pair and converts it to a CMOS logic level that feeds the adaptive auto correlation block. The received data is sampled using the best of the 8 (default) or 4 (alternative setting) possible sampling edges from the high speed clock or 4 phases using the low speed clock. The sampling edge is chosen by checking which of the 8/4 Correlators provide the maximum correlation. If more than one sampling edge provides the maximum then the state machine will choose the sampling edge based on a defined selection algorithm.

After the correct sampling edge is chosen, the remaining unused sampling edges are turned off. Once the header is received the length of the frame (payload size) and logical channel definition can be obtained. The logical channel definition will determine the data

type of the payload and therefore will determine the destination for the payload. Decoding of the ICLC commands from the payload is required in order to extract the interface control, rate mode and PLL commands.

Figure 45-48 shows the block diagram of Uplink Controller.

Figure 45-48. Top Level Receive Controller

45.8.2.2 Edge detection and auto-correlation

The edge detection and auto correlation are described together, as the mode setting of the auto-correlation block impacts largely on whether the edge detection circuitry is used or not. The edge detection will be performed first if required before auto-correlation.

45.8.2.2.1 Auto-Correlation modes

This section describes the Auto-Correlation modes.

45.8.2.2.1.1 Hunt Correlation mode

On reset the Receive Controller will always come up in Hunt Correlation mode. In this mode all the Correlators are enabled and the Receive Controller is always hunting for the synchronization pattern. The phase enables (either 8 or 4) to the external clock control module are always high. There is no edge detection for the first bit of the synchronization pattern. Hunt Correlation mode is considered the safest mode as the Receive Controller is always checking for the synchronization pattern, but it is the mode that consumes the most power. In Hunt Correlation mode the correlation is performed over all 16 bits of the synchronization pattern.

Figure 45-49 shows the block diagram of Hunt Correlation mode.

Figure 45-49. Hunt Correlation mode

45.8.2.2.2 Edge Detection

The edge detector is disabled in Hunt Correlation mode.

45.8.2.2.3 Auto correlation

The data transmission between the 2 devices LD and LR is asynchronous in nature. Hence the Receive Controller does not have the knowledge about the correct clock phase to be used for extracting the data. The task of the auto correlation (or synchronization) scheme is to estimate the best clock phase (8 or 4) for extraction of data as shown in the following figure.

Figure 45-50. High Speed 8 Phase Selection

The objective of the auto correlation is to select the clock phase that occurs closest to the center of the eye diagram window. For 8 Phase clock alignment the worst case selection is when the clock edge is just after the LR output transition. The 8 clock phases will sample the correct value but the middle clock phases are the ideal selection. If one of the middle phases are selected then the minimum distance to the LR transition is 3 clock phases as shown in the following figure.

Figure 45-51. High Speed 8 Phase Clock Alignment Example

Each of the 8 high speed phases are 45 degrees separated. For 4 phases, whether high or low speed, the phases are 90 degrees separated but can have different phases enabled as shown in [Figure 45-52](#) and [Figure 45-53](#).

Figure 45-52. High Speed 4 Phase Clock Alignment Example

Figure 45-53. Low speed 4 phase clock alignment example

The auto correlation and selection of the correct clock phase starts after the edge detection finds a 0 to 1 transition. The high speed 8 or 4 phases from the PLL and the low speed 4 phases (generated inside the Clocking Module) are muxed inside the clocking module. The LFAST interface block will determine which phases are to be enabled and disabled. The only time the interface does not choose the phases is when the Clocking Module overrides the phase enables using COCR[SMPSEL].

The input data path can be sampled by different samplers depending on the configuration:

Functional description

- High speed 8-phases: Samplers 0,1,2,3,4,5,6,7
- High speed 4-phases: Samplers 0,2,4,6
- Low Speed 4-phases: Samplers 0,1,2,3

Each sampler block samples the data path with a different clock phase from the Clocking Module, and resamples it to a intermediate phase as shown in [Table 45-47](#), [Table 45-48](#), and [Table 45-49](#) before resampling it to Phase 0. The intermediate phase is used to make static timing between the initial phase and the final phase 0. The final phase, Phase 0 is chosen so all the clock trees after the sampler are clocked by the same clock.

Table 45-47. High speed 8 phase selection - sampling procedure

Samplers	InitialSample	Intermediate Sample	Final Sample
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Phase 4	Phase 2	Phase 0
5	Phase 5	Phase 2	Phase 0
6	Phase 6	Phase 4	Phase 0
7	Phase 7	Phase 4	Phase 0

Table 45-48. High speed 4 phase selection - sampling procedure

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Disabled	Disabled	Disabled
2	Phase 2	Phase 0	Phase 0
3	Disabled	Disabled	Disabled
4	Phase 4	Phase 2	Phase 0
5	Disabled	Disabled	Disabled
6	Phase 6	Phase 4	Phase 0
7	Disabled	Disabled	Disabled

For High speed 4 Phase selection, See [Table 45-48](#), Samplers 1, 3, 5, 7 are disabled. In the Phase Select algorithm Phase 1 is mapped to Phase0, Phase 3 is mapped to Phase 2, Phase 5 is mapped to Phase 4, Phase 7 is mapped to Phase 6 so it simplifies the algorithm and allows the algorithm to be the same independent of 4 or 8 Phases in high speed.

Table 45-49. Low speed 4 phase selection - sampling procedure

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0

Table continues on the next page...

Table 45-49. Low speed 4 phase selection - sampling procedure (continued)

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Disabled	Disabled	Disabled
5	Disabled	Disabled	Disabled
6	Disabled	Disabled	Disabled
7	Disabled	Disabled	Disabled

For low speed 4 Phase selection, See [Table 45-49](#), Samplers 4, 5, 6, 7 are disabled. The first four Samplers (0,1,2,3) of the low 4 phase speed selection algorithm are the same as the four samplers required for the high 8 phase speed. Therefore the same architecture can be used for both high speed and low speed with the other four data paths disabled for low speed.

45.8.2.2.4 Sampler block and phase enable and disable

There are 8 data sampler paths in total inside the auto correlation block, each data sampler has 3 sampling registers with the possibility of each register being clocked by a different phase (in example, Sampler 5 for high speed can have Phases 5, 2 and 0). Therefore, after the correct data sampler has been selected for either high or low speed, the block can turn off all the sampler paths except for one, therefore 3 out of 24 registers will remain enabled while the others are disabled, as shown in the following figure.

After correlation and the correct data sampler has been selected all the other data samplers whose initial phase does not match the select phase are disabled. The selected sampler will then keep the required phases needed enabled, this can be max 3 phases (for example, Sampler 5 has Phases 5, 2, 0) or min 1 phase (in example below, Sampler 0 has all Phase 0 content).

The end result is that the Rx Controller can disable the required number of unused sampler registers and disable any unnecessary phases from the Clocking Module by deasserting the respective phase enables.

Functional description

Figure 45-54. 8 Samplers, each Sampler has 3 Registers

In order to achieve the sampler and phase enable requirements each Sampler block will require the logic as shown in the following figure.

The Clock Gating Element resides inside the Clocking Module block. The interface will provide the enables to the Clocking Module and the Clocking Module will in return provide the individual clocks to the sampling registers.

Figure 45-55. Sampler 5 Logic

45.8.2.3 Header and Payload Extraction

Once the Phases/Samplers are chosen after Synchronization and Correlation the next part of the flow is the header extraction. The Receive Controller will output a 16 bit word, bit shifted every Phase 0 clock as shown in the [Figure 45-56](#).

Figure 45-56. Extracting Header and Payload from the 16-bit output from Auto correlation.

45.8.3 Transmit Controller

This section describes the Transmit Controller.

45.8.3.1 Introduction

The Transmit Controller uses Rx information, status information and error control data and codes them into the appropriate frame structure for transmission to the LD. This includes the synchronization and header, in preparation for the LD, which transmits the frame to peer LFAST IC at either low or high speed. The Transmit Controller creates a frame structure that is converted to a serial format for the LD.

An arbitration block will determine which message has higher priority data, unsolicited, ICLC, CTS, ping, and so on. The data frames are extracted from the FIFO controller, the unsolicited message from the register block, the CTS messages from the Receive Controller and the ping response from the register block.

The Tx interface has two speed modes:

- Low Speed
- Fast Speed

The Transmit Controller consists of the following blocks as shown in the following figure.

- Arbitrator
- Framer
- Request Clock Control

The arbitrator will grant access to the framer from the request that has the highest priority. The framer block will extract the payload data from the granted request source and build the frame (adding synchronization or header if required). The frame is fed into a PISO (Parallel In Serial Out) and eventually sent to the LD.

Figure 45-57. Transmit Controller Connections

45.8.3.2 Arbitration

The arbitration block prioritizes between requests from multiple sources like

- S/W programmable registers
- System side interface FIFO
- Rx interface controller

The level of priority for each request is shown in [Table 45-50](#)

Table 45-50. Priority Levels for the Transmit Controller

Request	LFAST MasterPriority	LFAST SlavePriority	Triggering Conditions (at least one of the listed)
LFAST interface enable	1	1	• LFAST interface enable is asserted • LFAST interface enable is negated
Tx Interface disabled	2	2	• MCR[DRFEN] = 0 • MCR[TXEN] = 0 • MCR[DRFRST] = 1 • MCR[TXARBD] = 1 • LFAST Slave: ICLC frame with payload for "Disable Rx interface" received
Tx Interface speedmode change	3	3	• SCR[TDR] is modified • LFAST Slave: ICLC frame with payload for changing Rx interface speed received
Loopback frame in Loopback mode	4	4	• TMCR[LPON] = 1Dig • RF Slave: ICLC frame with payload for loopback mode enable received Note: Valid only for following TMCR[LPMOD] settings: LPMOD[2:0] = 011b LPMOD[2:0] = 100b
ICLC frame request	5	-	• LFAST Master: ICR[SNDICLC] = 1 • LFAST Master: ICR[ICLCSEQ] = 1
Ping response request	-	5	• LFAST Slave: ICLC frame with payload for ping request received and PICR[PNGAUTO] = 1 • LFAST Slave: PICR[PNGREQ] = 1

Table continues on the next page...

Table 45-50. Priority Levels for the Transmit Controller (continued)

Request	LFAST MasterPriority	LFAST SlavePriority	Triggering Conditions (at least one of the listed)
Unsolicited frame request	6	6	- Last Frame with CTS = 1 received from the peer LFAST device - UNSTCR[USNDRQ] = 1
Data frame from Tx FIFO	7	7	- Tx FIFO contains one or more frames - Last Frame with CTS = 1 received from the peer LFAST device - MCR[DATAEN] = 1
CTSFrame	8	8	- MCR[CTSEN] = 1 - Rx FIFO reaches High/Low threshold, defined by TISR and no frame pending
Clock mode test	9	9	- TMCR[CLKTST] = 0 - LFAST Slave: ICLC frame with payload for clock test mode enable received

Once the arbitrator has granted access to a request, the Framer will commence building the frame. Any new requests for frame or data rate change will not be granted access until the framer has finished transmitting the current frame. If a data rate change request for the Tx interface is received while the Transmit controller is in the middle of sending a frame then the rate change request to the Clocking Module will be delayed. This allows for the frame to be completed before the change in speed mode. This prevents any speed mode change during the transmission of a frame. Once the speed mode request is sent to the Clocking Module by the Tx Interface Controller, it will then not allow any new requests to be processed for a specific time period defined by the bit field RCDCR[DRCNT].

45.8.3.3 Line Driver digital connections

45.8.3.3.1 Line Driver states

The LD has the following states:

- Shutdown

The LD enters the Shutdown state when the LD powerdown signal and the output buffer enable is high. In this state, the LD regulator is not supplying power and the LD outputs are connected to ground. Once LD powerdown signal is negated, a settling time is required before the LD may be used for communication. The settling time is defined by the SLCR[LWKCNT] and SLCR[HWKCNT] bitfields.

- Sleep

The LD enters in sleep state when the signal is asserted. In this state, the LD is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In the sleep state the LD outputs are connected to V_{cm} (common mode voltage). To exit from Sleep mode the LD sleep signal is negated. The LD is required to transmit a logic 0 level on the interface for a pre-defined minimum time. The minimum time is the summation of settling time of LD after negation of LD sleep signal and the wakeup time of the LR on the other side. This delay is programed in the SLCR[HSCNT] and SLCR[LSCNT] bitfields.

Figure 45-58. Example of Sleep mode

As shown in [Figure 45-58](#) before every normal mode burst on the txdatap line there is one guard bit period (minimum inter-frame gap) where a logic 0 will be transmitted.

- Normal

In the Normal state the LD is primed for transmission. The LD shall drive the interface as dictated by the input data bit that is supplied by a shift register under the control of a finite state machine. If the LD is not enabled, and the framer is activated,

and has a frame to transmit, an interrupt (TISR[TXIEF]) will be generated. The LD moves back to the shutdown state when the LFAST master sends an ICLC Rx data off command.

Table 45-51. Line Driver States

LD State	LFAST Master Triggers	LFAST Slave Triggers
Shutdown	• Programing LVDS[SWOFFLD] and LVDS[SWONLD] • Programing MCR[TXEN] and MCR[DRFEN]	• LFAST interface enable negation/assertion • Programing LVDS[SWOFFLD] and LVDS[SWONLD] • ICLC command from LFAST master • Programing MCR[TXEN] and MCR[DRFEN]
Sleep	• Programing LVDS[SWSLPLD] and LVDS[SWWKLD]	• No pending frame for transmission • Programing LVDS[SWSLPLD] and LVDS[SWWKLD]
Normal	Absence of above mentioned conditions	Absence of above mentioned conditions

45.8.4 CTS mode support

LFAST module supports flow control methods. The CTS (Clear to send) is a protocol defined method to ensure no loss of frame, due to Rx FIFO unavailability. The optimal use of bandwidth of LFAST, without losing frames, is ensured by proper programing of the Rx FIFO Lower threshold (RFCR[CTSMN]) and Higher threshold (RFCR[CTSMX]). The CTS is supported by both the LFAST Master and Slave.

CTS Transmission:

The LFAST device sends CTS information with each frame to the peer LFAST device.

If the CTS mode is enabled by write $MCR[CTSEN] = 1$ then:

- Sends CTS bit as 0 in LFAST frame (bit[0] of Header field) whenever the Rx FIFO reaches the higher threshold defined by the bitfield TISR[CTSMX]. This indicates that the LFAST device doesn't want the peer device to send data. The CTS bit of all frame are sent 0 untill the Rx FIFO pointer reaches the lower threshold, as described below.

Functional description

- Sends CTS bit as 1 in LFAST frame (bit[0] of Header field) whenever the Rx FIFO reaches the Lower threshold defined by the bitfield TISR[CTSMN]. This indicates that the LFAST device is ready to receive data from the peer device. The CTS bit of all frame are sent 1 untill the Rx FIFO pointer reaches the Higher threshold, as described above.
- The CTS bit can be sent through any type of frame (data, unsolicited or ICLC). When there are no frames available in LFAST to send to the peer device, a CTS frame is sent. In this frame, bit[4-1] of Header field are sent as 0011b and 8-bit payload of 0.

If the CTS mode is not enabled (for example, bit MCR[CTSEN] = 0) then:

- All the frame sent will have CTS bit as 1 in LFAST frame (bit[0] of Header field).

CTS Reception:

The reception of a LFAST frame with CTS bit 0 indicates that the peer device is not ready to receive data frames. The transmission of all pending data and unsolicited frames are postponed untill a frame with CTS bit 1 is received.

Figure 45-59. CTS generation

45.8.5 Frames supported

Table 45-52 provides the frames supported and their permissible payload sizes

Table 45-52. Frames supported by LFAST interfaces

Frame Type	LCT Code	Supported by 1. LFAST Master Tx2. LFAST Slave Rx	Supported by1. LFAST Slave Tx2. LFAST Master Rx	Payload Size (bits)
Data Frame	0100b – 1011b	YES	YES	32, 64, 96, 128, 256, 288
Unsolicited Frame	0001b	YES	YES	8, 32, 64, 96, 128, 256 and 288
ICLC Frame	0000b	YES	NO ¹	8
CTS Frame	0011b	YES	YES	8
Reserved	All others	—	—	—

1. Except the ICLC PING response frame.

If logical channel type (LCT) code other than the above mentioned are received then the interrupt flag $RISR[RXLCEF] = 1$. If the payload size received does not match any value in [Table 45-52](#) then the flag $RISR[RXSZF] = 1$. In both these error conditions the received frame is ignored. The S/W may have to take the necessary steps to recover from such an error.

45.8.6 Frame flow

Following sections describe Data Frame Flow, ICLC Flow and Rx Unsolicited Data Flow.

45.8.6.1 Data flow

LFAST supports the transfer of data between master and slave LFAST devices.

45.8.6.1.1 Data transmit

System Side Module is the initiator of all the Tx data frame to LFAST peer device. Data frame transmit is triggered whenever the Tx Data FIFO has at least one valid frame. The $MCR[DATAEN]$, $MCR[DRFEN]$ and $MCR[TXEN]$ bits, should be set to enable the transfer of Tx data.

If $MCR[DATAEN] = 0$, then the valid frames in the in Tx data FIFO will be ignored for transmission. The Payload Size and channel type of each frame is specified by the System Side Module interface during transfer of the frame to the LFAST interface. The frame header is stored in the Tx packet FIFO and the payload in the Tx data FIFO. Whenever the Tx FIFO has at least one frame then a data transmit request is made to the Tx arbiter of the LFAST. Tx block arbitrates the data transmit request and

schedules it depending on the priority of all the pending transmit requests. When data request is scheduled by Tx block, the required data is fetched from Tx data FIFO. The number of frames present in the Tx FIFO for transmission is indicated by the bitfield DFSR[TXFCNT].

45.8.6.1.1.1 Programing model for Tx data transmit

1. Program MCR[DATAEN] = 1, MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path of LFAST device
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR] bits.
3. Frame present in TX FIFO (Data and Packet FIFO) are sent.
4. TISR[TXDTF] = 1 after each frame transfer
5. CTS is set depending on the push/pull mode setting defined by MCR[CTSEN].

45.8.6.1.2 Data receive

LFAST master and slave supports reception of data frame. The received frame is determined to be of data frame type by decoding channel type field of the header present in the received frame. The MCR[DATAEN], MCR[RXEN] and MCR[DRFEN] bits should be set to enable the data frame reception. When MCR[DATAEN] = 0 the received data frames will be ignored and will not be placed in the Rx data FIFO.

The Rx data frames received by Rx block are stored in the Rx FIFO. Whenever the frame is received in the Rx FIFO the System Side Module is indicated by assertion of LFAST Rx FIFO ready signal. The frame size and the Channel type is passed to the LFAST. The frame boundaries are indicated by start of frame and end of frame signals. The number of unread frames in the Rx Data FIFO are indicated by DFSR[RXFCNT]. When Rx DATA FIFO is full and cannot accommodate current frame completely, then the remaining data of the Rx frame is discarded. In this case, UNSRSR[RXOF] = 1 and an interrupt is generated if the RIER[RXOFIE] = 1.

45.8.6.2 Unsolicited flow

45.8.6.2.1 Unsolicited frame transmit flow

The S/W is the initiator for unsolicited frames to the LFAST peer device. The unsolicited frame header and payload is programmed into the Unsolicited Data and Control registers. Once the Payload is programmed UNSTCR[USNDRQ] is set, generating a request for unsolicited frame transfer to the Tx arbiter.

45.8.6.2.1.1 Programing model for unsolicited frame transmit

1. Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 in the Mode Configuration Register (MCR) to enable the Tx path
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programming of SCR[TDR].
3. Read the UNSTCR[USNDRQ].
 - If UNSTCR[USNDRQ] = 1 then wait for either of the following:
 - UNSTCR[USNDRQ] = 0
 - TISR[TXUNSF] = 1
 - If UNSTCR[USNDRQ] = 0 then:
 - Program the unsolicited payload in UNSTDR0–UNSTDR8, and can be written up to a payload of frame of a maximum of 288 bits.
 - Program the unsolicited frame header in UNSTCR[UNSHDR].
 - Program UNSTCR[USNDRQ] = 1.
4. UNSTCR[USNDRQ] is cleared by the Tx Block after the frame transfer.
5. TISR[TXUNSF] = 1 when the frame is transmitted.
6. CTS is set depending on the Push-Pull mode setting defined by MCR[CTSEN].

45.8.6.2.2 Unsolicited frame receive flow

Whenever an Unsolicited frame is received from the peer device, the following steps are performed:

If UNSRSR[URXDV] = 0 then:

1. The payload size field of the header is first saved into the UNSRSR[URPCNT].
2. The payload is stored in the UNSTDR0–UNSTDR8.

3. UNSRSR[URXDV] = 1 and the RISR[RXUNSF] = 1 indicating the successful reception of the frame.

If UNSRSR[URXDV] = 1 then:

1. The current unsolicited frame is ignored.
2. RISR[RXUOF] = 1.

Typical steps by the processor after RISR[RXUNSF] = 1 is as follows:

1. The processor reads UNSRSR to get the payload size of the frame.
2. It then reads the complete frame by reading UNSRDR8–UNSRDR0 for the payload size as received in the frame.
3. Then it clears the interrupt (write RISR[RXUNSF] = 1) and also the UNSRSR[URXDV] bit.

45.8.6.3 ICLC flow

The ICLC (Interface Control Logical Channel) is a separate logical channel type, which is mainly meant for implementing the data rate change in the LFAST interface and initiating the test modes.

45.8.6.3.1 ICLC data transmit flow

Whenever the processor intends to transfer an ICLC frame to the LFAST slave then the following steps are to be followed.

1. Write the ICLC frame payload in the ICR[ICLCPLD] (see [Table 45-53](#) for payloads as defined by the standard).
2. Program ICR[SNDICLC] = 1 to initiate the ICLC frame transfer. This bit clears itself when the ICLC frame has been transmitted. The processor needs to poll this bit to make sure it is cleared before setting this bit again (even when ICR[ICLCSEQ] = 1).
3. TISR[TXICLCF] = 1 after the transfer of the ICLC frame.
4. CTS is set depending on the Push-Pull mode setting defined by MCR[CTSEN].

To determine whether the ICLC frame has been sent or not, either the ICR[SNDICLC] bit can be polled, or wait for TISR[TXICLCF] = 1.

Table 45-53. Supported ICLC Payloads

ICLC Code(hex)	ICLC Function
00	Ping Request from LFAST Master to LFAST Slave
01	Reserved
02	Start PLLIn preparation for High Speed mode
04	Stop PLL Fallback to low speed mode
08	Select TxData Slow (LFAST Slave Rx Interface)
10	Select TxData Fast (LFAST Slave Rx Interface)
20	Select RxData Slow (LFAST Slave Tx Interface)
40	Not Supported
80	Select RxData Fast (LFAST Slave Tx Interface)
31	Enable RxData Interface (LFAST Slave Tx Interface)
32	Disable RxData Interface (LFAST Slave Tx Interface)
34	Clock Test mode Send 101010... continuously using the currently configured clock rate (slow, fast);
FF	Turn payload loopback on
38	Turn Test mode (Loopback and Clock Test) off

Programing model for ICLC frame transmit:

1. Set the ICR[ICLCSEQ] bit (optional)
2. Write the ICLC frame payload in the ICR[ICLCPLD], corresponding to the desired Tx/Rx data rate change, as described in the [Table 45-53](#).
3. Write ICR[SNDICLC] = 1 to initiate the ICLC frame transfer.
4. LFAST master will schedule the ICLC transfer. Data present in ICR[ICLCPLD] is transmitted to the LFAST slave at the old Tx data rate. LFAST slave will configure its Tx/Rx interface data rate accordingly.
5. Reset the ICR[ICLCSEQ] to allow the scheduling of other types of frames, which will be sent at the new data rate.

When ICR[ICLCSEQ] = 0, though the ICLC frame transfer still has highest arbitration priority, other frames may be scheduled if no valid ICLC frame request exist.

Note

ICLC frame transmit will not trigger the internal data rate change of LFAST Master Tx/Rx interface. LFAST master Tx/Rx interface data rate will only be changed, when corresponding SCR[TDR] and SCR[RDR] bits are appropriately configured.

Processor requires to take care that no data frames are to be transmitted while data rate change is happening or ICLC is transmitting frames by setting ICR[ICLCSEQ] bit in [Table 45-53](#).

45.8.6.3.2 ICLC data receive flow

When the bits 4 to 1 of a receive frame are 0000b it indicates that the payload is an ICLC. ICLC payloads are always 8 bits.

The reception of an ICLC frame is indicated by an interrupt to the system. The ICLC status register RISR indicates the type of the ICLC frame received. The Rx block will decode and generate the appropriate signals. An invalid ICLC code besides the ones listed in [Table 45-53](#) will cause RISR[RXICF] = 1.

45.8.6.3.2.1 Ping request ICLC

The LFAST slaves ICLC decoder will decode the ping request and set RIISR[ICPRF]. The S/W can also write to PICR[PNGREQ] to indicate to the Tx block that a ping response frame needs to be transmitted. The PICR[PNGAUTO] indicates whether Tx block can respond automatically to the request by the LFAST master ICLC Ping Request frame. The Tx block will arbitrate the ping response frame request and send a ping frame with ping data defined by bitfield PICR[PNGPLYD]. Once the ping response frame has been sent the Tx block will set TISR[TXPNGF] and clear PICR[PNGREQ], if set.

45.8.6.3.2.2 LFAST Slaves RxData Interface Slow/Fast ICLC

The LFAST Slaves Rx Interface has two speed modes supported: slow (Low speed) and fast (High speed). The ICLC command will write RIISR[ICRSF] = 1 (Low speed) or RIISR[ICRFF] = 1 (High speed).

45.8.6.3.2.3 LFAST Slaves TxData Interface Slow/Fast ICLC

The LFAST slaves Tx Interface Controller has two speed modes: slow (Low speed), and fast (High speed). The ICLC command will write RIISR[ICTSF] = 1 (Low speed) or RIISR[ICTFF] = 1 (High speed).

45.8.6.3.2.4 Enable/Disable LFAST Slaves TxData Interface ICLC

The ICLC commands, Enable RxData Interface and Disable RxData Interface are decoded and the appropriate enable/disable signal sent to the Tx block Controller. These ICLC command writes RIISR[ICTEF] = 1 and RIISR[ICTDF] = 1. The ICLC Tx enable command will write MCR[TXEN] = 1.

No frames can be sent on the LFAST Slave Tx interface until the either LFAST master has enabled it via an ICLC frame or S/W programs MCR[TXEN] = 1.

45.8.6.3.2.5 Clock Test mode ICLC

This ICLC command is decoded, and then is used to write TMCR[CLKTST] = 1. This indicates to the Tx interface to output an alternating pattern of 1 and 0 at the currently configured clock rate. The Rx interface generates RIISR[ICCTF] = 1 on reception of this ICLC command.

The exit from this mode happens on reception of Test mode off ICLC command.

45.8.6.3.2.6 Loopback payload on ICLC

This ICLC command is decoded and TMCR[LPON] = 1 to indicate to the Tx Block that the received payload is to be sent back. The exit from this mode happens on reception of Test mode off ICLC command. The Rx interface causes RIISR[ICLPF] = 1 on reception of this ICLC command.

45.8.6.3.2.7 Test mode off ICLC

This ICLC command is decoded and TMCR[LPON] and TMCR[CLKTST] are cleared to indicate to the Tx block to exit from loopback mode or clock test mode.

Another option is for the payload loopback option to remain enabled until negated on the toggling of LFAST interface enable.

45.8.6.3.2.8 Ping response ICLC

The LFAST master considers any ICLC frame payload as ping response data. The LFAST masters Rx block will store the received ping data in PISR[RXPNGD] and match it with PICR[PNGPYLD]. RIISR[ICPSF] = 1 if the Ping received matches with the one stored in PICR[PNGPYLD], or RIISR[ICPFF] = 1.

45.8.6.4 CTS flow

45.8.6.4.1 CTS Tx flow

The CTS frame, if enabled by the S/W, indicates the status of the Receive Data FIFO. CTS frame is triggered whenever Rx Data FIFO reaches either the High/Low threshold and no data, ICLC or unsolicited frame is ready for transmission.

Programing model for CTS frame transmit:

- Program RFCR[CTSMX] and RFCR[CTSMN].
- Enable the CTS frame Transmission by programming MCR[CTSEN] = 1.
- Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path.
- The CTS bit sent with a valid frame (for example, data, ICLC and unsolicited) is 1 until the Rx Data FIFO reaches High Threshold.
- When the Rx Data FIFO reaches higher threshold and no valid frame (data, ICLC and unsolicited) is pending for transmission, then the CTS frame is triggered, with CTS bit of header = 0 and the status bit RISR[RXMXF] = 1.
- When the Rx Data FIFO reaches Low Threshold, due to system side reads and no valid frame (data, ICLC and unsolicited) is pending for transmission, then the CTS frame is triggered, with CTS bit of header = 1, and status bit RISR[RXMNF] = 1.

45.8.6.4.2 CTS Rx flow

Whenever a CTS frame header or any other frame with valid header is received with CTS bit = 0, then RISR[RXCTSF] = 1. The Tx Interface arbitration for unsolicited frame and data frame transmit request is turned off on reception of frame with CTS bit 0. The arbitration for unsolicited frame and data frame is enabled on reception of frame with CTS bit 1. Frame with LCT type CTS are not stored in the LFAST.

45.8.7 Test and Debug Support

The test and debug interface helps to debug the LFAST module. These signals can be brought out for ease of validation.

45.8.7.1 Loopback Test mode

The loopback function allows to verify the correct operation of the physical interface and the basic checks for the LFAST module without a peer device.

There are certain prerequisites before entering the Loopback mode:

- LD and LR should be turned on.
- Tx and Rx mode should be enabled.
- Interrupts needed for S/W should be enabled.
- Both Tx and Rx interface should be in same speed mode.
- For Automatic Test mode TMCR[LPFRMTH] should be programmed.

The LFAST module supports four loopback modes, defined by TMCR[LPMOD].

Table 45-54. Loopback modes

LPMOD[2:0]	Mode Selected
000	Rx Loopback (default)
001	Rx LVDS Loopback
010	Tx Loopback without Automatic frame generation
011	Tx Loopback with Automatic frame generation
100	Tx LVDS Loopback (external) with Automatic frame generation

The TMCR[LPON] bit controls the state of the loopback function, and the default setting is 0 (off). This can be written by S/W, or in the case of the LFAST slave, the TMCR[LPON] bit can be modified by the Rx interface controller on decoding of a valid ICLC loopback on or Test mode off commands. The LPMOD should not be changed when the LPON bit is set.

In all loopback modes, except Tx loopback without automatic frame generation, the decoding of frame and error flags is stopped. Only decoding of following is done:

- ICLC Turn Test mode Off frame.

- CTS bit of all frames.
- Automatic Loopback frame decoding (only in Automatic frame generation mode).

45.8.7.1.1 Rx Loopback mode

For Rx loopback mode the output of the LR is passed to the LD with manipulation via the Rx and Tx Interface controllers. CTS bit (Bit 0) of the header is guaranteed to be asserted when the incoming data from the other device is looped back. In Rx Loopback mode the Rx Interface controller operates in normal mode, decoding the frames (header, payloads). This allows the LFAST Master to control the Loopback mode on and off by sending ICLC commands.

Figure 45-60. Rx LoopBack mode

Entry to Rx Loopback mode:

1. S/W programs $\text{TMCR}[\text{LPMOD}] = 000\text{b}$.
2. Loopback can be turned on by either of the following methods:
 - S/W programs $\text{TMCR}[\text{LPON}] = 1$.
 - For Slave Only: - Reception of ICLC Frame with Payload FFh (Loopback mode on), from LFAST Master

Exit from Rx Loopback mode can be done by any of the following methods:

- S/W programs $\text{TMCR}[\text{LPON}] = 0$
- For LFAST Slave: - Transmission of ICLC Frame with payload 38h (Test mode off), from LFAST Master

The peer LFAST device is required to maintain at least 2-bit IFG between two Loopback frames in this mode.

45.8.7.1.2 Rx LVDS LoopBack mode

This loopback mode is provided to verify and characterize the LVDS pads. In this loopback mode the data received by LFAST on Rx LVDS input is loopback to Tx LVDS output, bypassing LFAST. For LVDS loopback the output of the LR is passed to the LD via "Rx LVDS LoopBack Mux". Bit 0 of the header cannot be guaranteed to be asserted when the incoming data from the other device is looped back. In this loopback, the Rx Interface Controller operates in normal mode, decoding the frames (header, payloads) but the Tx Interface Controller is ignored.

Figure 45-61. Rx LVDS LoopBack mode

Entry to Rx LVDS Loopback mode:

1. S/W programs $\text{TMCR}[\text{LPMOD}] = 001b$.
2. Loopback can be turned ON by either of the following methods:

- S/W writes $\text{TMCR}[\text{LPON}] = 1$.
- For Slave Only: - Reception of ICLC Frame with Payload = FFh (Loopback mode ON), from LFAST Master.

Exit from Rx LVDS Loopback mode can be done by any of the following methods:

- S/W programs $\text{TMCR}[\text{LPON}] = 0$.
- For LFAST Slave:
 - Transmission of ICLC frame with payload 38h (Test mode off), from LFAST Master.

45.8.7.1.3 Tx loopback mode without automatic frame generation

This loopback mode is provided to verify the LFAST functionality, if LVDS pads are not functional. In this loopback mode the data transmitted by LFAST on Tx LVDS output is loopbacked internally on Rx LVDS input, bypassing LVDS pads.

Figure 45-62. Tx LoopBack mode without automatic frame generation

Entry to Tx Loopback without Automatic frame generation mode:

1. S/W programs $\text{TMCR}[\text{LPMOD}] = 010b$.
2. Loopback can be turned on by either of the following methods:
 - S/W programs $\text{TMCR}[\text{LPON}] = 1$.
 - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback without Automatic frame generation mode can be done by any of the following methods:

- S/W programs $TMCR[LPON] = 0$.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off), from Tx interface (using unsolicited frame).

All frames and error flags are decoded in this mode.

45.8.7.1.4 Automatic frame generation

The LFAST module supports two Loopback modes where pre-defined frames are generated automatically by the Tx Interface and Rx Interface indicates its successful reception by dedicated signals and status registers. These modes are defined for BIST like check for the LFAST, with minimal S/W intervention.

The Control register used for these modes are:

- $ALCR[LPCNTEN]$ defines whether fixed number of auto loopback frames to be transmitted
- $ALCR[LPFMCNT]$ defines the number of loopback frames to be transmitted if $ALCR[LPCNTEN] = 1$.

The Status signals and register used for these modes are:

- $GSR[LPCSDV]$: Valid Synchronization received.
- $GSR[LPCHDV]$: Frame with Header of 13h received.
- $GSR[LPCPDV]$: Frame with Payload of CBh received.
- $GSR[LPTXDN]$: Number of Auto Loopback frame transmitted with valid Synchronization, Header (13h) and Payload (CBh) is equal to $ALCR[LPFMCNT]$.

Figure 45-63. Automatic Loopback Test status signal timings

The two Loopback with automatic frame generation modes are:

1. Tx Loopback with Automatic frame generation
2. Tx LVDS (external) with Automatic frame generation

45.8.7.1.4.1 Tx loopback mode with automatic frame generation

When TMCR[LPMOD] = 011b (Tx Loopback mode with Automatic frame generation) the frames are generated by the Tx Interface. This mode helps to validate the Tx and Rx Path with minimal intervention from the S/W. The frames generated have fixed header of 13h and payload of CBh. The successful reception of this frame is indicated by the status signals and registers.

TMCR[LPMOD] = Tx LOOPBACK with Automatic Frame generation

Figure 45-64. Tx LoopBack mode with automatic frame generation

Entry to Tx Loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 011b.
2. Loopback can be turned on by either of the following methods:
 - S/W programs TMCR[LPON] = 1.
 - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback with Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.

45.8.7.1.4.2 Tx LVDS loopback (external) mode with automatic frame generation

In this mode the LD/Tx Controller is used to test the LR/Rx Controller. The idea is to use a test frame (predefined) from the Tx Controller out through the LD, loopback completed on the DUT-board (LD connected to LR via a transmission line), back into the LR, synchronized and correlated in the Rx Controller and compared to what was sent in the Downlink controller.

Figure 45-65. Tx LVDS loopback (external) mode with automatic frame generation

Entry to Tx LVDS loopback with automatic frame generation mode:

1. S/W programs $\text{TMCR}[\text{LPMOD}] = 100\text{b}$.
2. Loopback can be turned on by either of the following methods:
 - S/W programs $\text{TMCR}[\text{LPON}] = 1$.
 - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx LVDS loopback with automatic frame generation mode can be done by the following method:

- S/W programs $\text{TMCR}[\text{LPON}] = 0$.

45.8.7.2 Clock test mode

The bit $\text{TMCR}[\text{CLKTST}]$ enables or disables the Clock Test mode of the LFAST module. In this mode the LFAST sends fixed pattern out on the LD at the current configured RxData clock rate. It is a RWM bitfield and the default setting is 0 (off). This bit can be set under one of the following conditions:

- S/W programs $\text{TMCR}[\text{CLKTST}]$.

The Tx Controller will send out a pattern of alternating 1 and 0 (pattern 101010...). This provides a divide by 2 test clock of the current Tx clock.

The Clock Test mode can be cancelled by either of the following methods:

- S/W programs $\text{TMCR}[\text{CLKTST}] = 0$.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off) from LFAST Master

In clock test mode the Tx Controller does not output any synchronization pattern or header, just a pattern of alternating 1's and 0's.

This mode doesn't affect the functionality of the Rx Interface.

45.8.8 Interrupts

The LFAST module generates five interrupts to the processor:

- Transmit complete interrupt
- Transmit exception interrupt
- Receive complete interrupt
- Receive exception interrupt
- ICLC receive interrupt

Each interrupt is asserted when any one of their status conditions is met.

45.8.8.1 Transmit complete interrupt

This interrupt indicates a transfer completion of a frame. This interrupt is asserted whenever any of the following bits are set in the TISR and also the corresponding mask bits are set in the TIER.

- TXDTF
- TXICLCF
- TXUNSF
- TXPNGF

Each of these bits can be individually maskable. So, those bits that are not required to generate an interrupt to the processor can be masked. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the TISR.

45.8.8.2 Transmit exception interrupt

This interrupt indicates occurrence of an exception condition in the Tx block. This interrupt is asserted whenever any of the following bits are set in the TISR along with the corresponding mask bits in the TIER.

- TXOVF
- TXIEF

Each of these bits can be individually masked. So, those bits that are not required to generate an interrupt to the processor can be masked. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the TISR.

Table 45-55. Recommended transmit exception handling

Exception	Recommendation
TXOVF	• MCR[TXEN] = 0 • The system level interfaces transmit is reseted and enabled again • For Slave: After reception of ICLC Ping Response Request the MCR[TXEN] may be set • For Master: The MCR[TXEN] should be set and an ICLC frame Ping Response Request should be sent
TXIEF	• The MCR[TXEN] should be set

45.8.8.3 Receive complete interrupt

This interrupt indicates a reception of a frame. This interrupt is asserted whenever any of the following bits is set in the RISR along with the corresponding interrupt enable bit is also set in the RIER.

- RXCTSF
- RXDF
- RXUNSF

Each of these bits are individually maskable. So, the bits that are not required to generate an interrupt to the processor can be masked by clearing its bit in the RIER. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the RISR.

45.8.8.4 Receive exception interrupt

This interrupt indicates occurrence of an exception condition in Rx block. This interrupt is asserted whenever any of the following bits is set in the RISR and corresponding enable mask bit is also set in the RIER.

- RXLCEF
- RXICF
- RXSZF
- RXUOF
- RXUFF
- RXMXF
- RXMNF
- RXOFF

Each of these bits are individually maskable. So, those bits that are not required to generate an interrupt to the processor can be masked by clearing the appropriate bit in the RIER. For details on the cause of assertion of each bit refer to the RISR description. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the RISR.

Table 45-56. Recommended receive exception handling mechanism

Exception	Recommendation
RXLCEF	The MCR[RXEN] may be set and cleared, as this exception can result in loss of subsequent packet
RXICF	No action required
RXSZF	The MCR[RXEN] may be set and cleared, as this exception can result in loss of subsequent packet
RXOFF	• The MCR[RXEN] may be cleared • The system level interfaces receive may be reset and enabled, as current transfer may be corrupted
RXUFF	No action required
RXMXF	The system level interfaces receive should be enabled, if not enabled
RXMNF	No action required
RXUNSF	No action required

45.8.8.5 ICLC receive interrupt

This interrupt indicates reception of a valid ICLC frame. This interrupt is asserted whenever any of the following bits is set in the RIISR along with the corresponding enable bit mask bit is set in the RIIER.

- ICPONF
- ICPOFF
- ICTSF
- ICTFF
- ICRSF
- ICRFF
- ICTEF
- ICTDF
- ICCTF
- ICLPF
- ICTOF
- ICPRF
- ICPSF
- ICPFF

Each of these bits are individually maskable. So those bits that are not required to generate an interrupt to the processor can be masked. For details on the cause of assertion of each bit, refer RIISR. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in RIISR.

45.9 Packet memory

The LFAST stores packet frames for transmission, and reads packet frames after reception. The transmitter has its own dedicated buffer and the receiver has its own dedicated buffer, and they are not shared between each other.

Table 45-57. Frames Supported by LFAST interfaces

Frame Type	Tx Buffer(in bits)	Rx Buffer(in bits)	Memory Type
Data Frame	38 × 32 max 6 packets	38 × 32 max 6 packets	FIFO
Unsolicited Frame	9 × 32 max 1 packet	9 × 32 max 1 packet	Registers UNSTD[8-0], UNSRDR[8-0]
ICLC Frame	1 × 7 max 1 packet ¹	1 × 8 max 1 packet ²	Registers ICR, PISR
CTS Frame	N/A	N/A	N/A

1. Only for MCR[MSEN] = 1

2. Only for ping response data when MCR[MSEN] = 1

45.10 Resets

The various blocks in LFAST are reset as described in the table below.

Table 45-58. Recommended receive exception handling mechanism

Reset	Blocks Reset
Asynchronous Hardware reset	Polarity: Active Low • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Register Space
DRFRST bit of Mode Configuration Register (MCR)	Polarity: Active High • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Register Space
DRFEN bit of Mode Configuration Register (MCR)	Polarity: Active Low • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Status Registers • SCR[RDR] and SCR[TDR] • TMCR[CLKTST] and TMCR[LPON] • ICR[ICLCSEQ] and ICR[SNDCILC] • PICR[PNGREQ] • UNSTCR[USNDRQ]

45.11 Clocks

The LFAST mainly works on three clocks:

- System Bus Clock used to program the registers.
- Protocol clock, which is either High Speed PLL clock or Low Speed clock depending on the speed mode, used for LFAST protocol operation.
- System Side Module clock, which is synchronous to the System Bus clock.

45.11.1 Clocking strategy

The following figure shows the clock domain in which each module functions. The PLL provides eight phases of the high speed clock to the Clock Muxing portion of the Clock Control Module. The Clock Module will then generate four phases of slow speed clock using both the edges of lfast_sysclk, muxes high speed and low speed clocks and provides a muxed clock to the Sampler Module.

Figure 45-66. LFAST module clock domains

45.11.2 Slow speed clock

45.11.2.1 External muxing

The Clock Control Module will receive `lfast_sysclk` from the clocking subsystem as shown in [Figure 45-67](#), [Figure 45-68](#) and [Figure 45-69](#).

Figure 45-67. External clock muxing of lfast_sysclk

All the reference clocks will be muxed first to provide lfast_sysclk to the module and then either div/2 or direct muxed clock will be used to generate 4 slow speed phases in the Clock Control Module of LFAST as shown in [Figure 45-67](#).

The lfast_sysclk could be either 20/26 MHz or 10/13 MHz. When lfast_sysclk is 20/26 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/4 when MCR[LSSEL] = 1. If lfast_sysclk is 20/26 MHz it needs to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in [Figure 45-68](#) (selected clock path shown in green).

Figure 45-68. External clock muxing of lfast_sysclk of 20/26 MHz

In this case, lfast_sysclk is 10/13 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/2 when MCR[LSSEL] = 0. If lfast_sysclk is 10/13 MHz then it does not need to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in Figure 45-69 (selected clock path selected shown in magenta).

Figure 45-69. External clock muxing of lfast_sysclk of 10 MHz

45.11.2.2 Slow Speed 4 phase generator

Clock control module will generate 4 phases of slow speed clock of frequency of 10/13 MHz. For instance, if `lfast_sysclk` is 10 MHz then 4 phases of 5 MHz will be generated. The following figure shows 4 phases getting generated using `lfast_sysclk`.

Figure 45-70. Slow speed 4 phases generation

45.11.3 Rx Controller Clocks

45.11.4 Clocking Module Requirements for High Speed Phases

The high speed phases are obtained from the PLL via the Clocking Module as shown in the following figure.

Figure 45-71. Clock enables and clock paths

The LFAST block will know which of the phases will be required for the different modes of operations. Therefore the LFAST block will provide enables and speed mode switches to the Clocking Module. The Clocking Module will use these signals to control the enables to the clock phases to reduce the power consumption.

The 8 phases of clocks signal are fed to the Clocking Module and muxed with the low speed phases. Depending on enables and data rate speed modes, the selected clocks are passed to the Sampler block and interface block.

COCR[PHSSEL] is connected to the Clocking Module, which selects whether 8 or 4 phases are selected for High Speed mode. It is only valid for high speed.

The routing of the 8 high speed phases to the interface is critical. Each clock phase will need to have the same routing track length from the PLL to the interface of Clocking Module. Each of the 8 high speed phases are separated by 45 degrees. This separation needs to be maintained from the phase generator to the interface.

45.11.5 Clock module requirements for low speed phases

45.11.5.1 Low speed

The low speed clock phases are generated in Clocking Module. These four phases are required to sample the data correctly at Low Speed mode. The LFAST block will provide the enable for the phases. The clock source for the low speed phases is SYSCLK. The Clocking Module block will need to generate the 4 phases of low speed clock 90 degrees apart.

Using the Low Speed mode on the interface allows the polyphase generation logic to be turned off and the requirement of high-speed-freq × 8 MHz clock from the PLL is not needed.

Table 45-59. Rx clocks summary

Rx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

45.11.6 Tx Controller Clocks

45.11.6.1 Clocking Module Requirements for Speed Phases

The low speed phase 0 clock is sourced from the lfast_sysclk and the high speed phase 0 clock is sourced from the PLL. See the following table.

Table 45-60. Tx clocks summary

Tx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

45.11.6.2 Transmit Clock Muxing

Figure 45-72. Transmit Clocks Muxing

The Tx phase 0 clock is enabled when all the resets are negated.

Chapter 46

Fast Ethernet Controller (FEC)

46.1 Chip-specific FEC information

This chip has one instance of the FEC module.

46.1.1 FEC interface selection

On this chip, the FEC can operate using MII-Lite or RMII interfaces.

46.1.2 FEC clocking

See [Ethernet clocking](#) for information about FEC clocking restrictions on this chip.

46.2 Introduction

The Fast Ethernet Controller (FEC) is a communication controller that supports 10 and 100 Mbps Ethernet/IEEE 802.3 networks. An external transceiver interface and transceiver function are required to complete the interface to the media. The FEC supports five different standard MAC-PHY (physical) interfaces for connection to an external Ethernet transceiver. The FEC supports the 10/100 Mbps MII, 10/100 Mbps MII-Lite, 10/100 Mbps reduced MII, and the 10 Mbps-only 7-wire interface.

46.2.1 Block diagram

[Figure 46-1](#) shows the block diagram of the FEC. The FEC is implemented with a combination of hardware and microcode. The off-chip (Ethernet) interfaces are compliant with industry and IEEE 802.3 standards.

NOTE

When MII-Lite is used on this chip, the FEC_TXER, FEC_RXER, FEC_COL, and FEC_CRX signals shown in [Figure 46-1](#) are not used.

Figure 46-1. FEC block diagram

The following table provides a brief description of the blocks in the previous figure.

Table 46-1. FEC sub-block descriptions

Block	Description
Control and status registers (CSR)	Provides global control (Ethernet reset and enable) and interrupt managing registers

Table continues on the next page...

Table 46-1. FEC sub-block descriptions (continued)

Block	Description
Descriptor controller	A RISC-based controller providing these functions in the FEC: • Initialization (those internal registers not initialized by you or hardware) • High-level control of the DMA channels (initiating DMA transfers) • Interpreting buffer descriptors • Address recognition for receive frames • Random number generation for transmit collision backoff timer
DMA block	Provides multiple channels allowing transmit data, transmit descriptor, receive data and receive descriptor accesses to all run independently Note: In this document, "DMA" refers to the DMA block within the FEC, and is not related to any other DMA controllers that may be present on the chip.
Media independent interface (MII)	Provides a serial channel for control/status communication with the external physical layer device (transceiver). This serial channel consists of: • The management data clock (FEC_MDC) • The management data input/output lines (FEC_MDIO) of the MII interface
Message information block (MIB)	Maintains counters for a variety of network events and statistics. It is not necessary for operation of the FEC, but provides valuable counters for network management. The counters supported are: • The RMON (RFC 1757) Ethernet Statistics group • Some of the IEEE 802.3 counters
RAM	Serves as the focal point of all data flow in the Fast Ethernet controller and divides into transmit and receive FIFOs. The FIFO boundaries are programmable using the FRSR register. User data flows to/from the DMA block from/to the receive/transmit FIFOs. Transmit data flows from the transmit FIFO into the transmit block. Receive data flows from the receive block into the receive FIFO.
Transmit and receive blocks	Provide the Ethernet MAC functionality (with some assist from microcode)

46.2.2 Features

The FEC incorporates the following features:

- Support for the following Ethernet physical interfaces:¹
 - 100-Mbps IEEE 802.3 MII
 - 10-Mbps IEEE 802.3 MII
 - 100-Mbps IEEE 802.3 MII-Lite

1. For interface selection options, see the chip-specific FEC information.

- 10-Mbps IEEE 802.3 MII-Lite
- 100-Mbps reduced media independent interface (RMII)
- 10-Mbps reduced media independent interface (RMII)
- 10-Mbps 7-wire interface (industry standard)
- IEEE 802.3 full duplex flow control
- Programmable max frame length supports IEEE 802.1 VLAN tags and priority
- Support for full-duplex operation (200 Mbps throughput) with a minimum internal bus clock rate of 50 MHz
- Support for half-duplex operation (100 Mbps throughput) with a minimum internal bus clock rate of 25 MHz
- Retransmission from transmit FIFO following a collision (no processor bus utilization)
- Automatic internal flushing of the receive FIFO for runts (collision fragments) and address recognition rejects (no processor bus utilization)
- Address recognition
 - Frames with broadcast address may be always accepted or always rejected
 - Exact match for single 48-bit individual (unicast) address
 - Hash (64-bit hash) check of individual (unicast) addresses
 - Hash (64-bit hash) check of group (multicast) addresses
 - Promiscuous mode

46.2.3 Clocking requirements

The FEC system clock frequency must be equal to or greater than the FEC protocol reference clock frequency (for example, 25 MHz system frequency for 100 Mbps protocol frequency). This requirement is true regardless of the reference selected by the application.

46.3 Modes of operation

This section describes the FEC operating modes.

46.3.1 Full and half duplex operation

Full duplex mode is for use on point-to-point links between switches or end node to switch. Half duplex mode works in connections between an end node and a repeater or between repeaters. TCR[FDEN] controls duplex mode selection.

When configured for full duplex mode, flow control may be enabled. For more details, see:

- The RFC_PAUSE and TFC_PAUSE fields in the TCR
- The RCR[FCE] field
- [Full duplex flow control](#)

46.3.2 Interface options

The following interface options are supported². A detailed discussion of the interface configurations is provided in [Network interface options](#).

46.3.2.1 10 Mbps and 100 Mbps MII interface

The IEEE 802.3 standard defines the media independent interface (MII) for 10/100 Mbps operation. The MAC-PHY interface may be configured to operate in MII mode by programming RCR[MII_MODE]=1.

The operation speed is determined by the FEC_TXCLK and FEC_RXCLK pins driven by the external transceiver. The transceiver auto-negotiates the speed or software controls it via the serial management interface (FEC_MDC/FEC_MDIO pins) to the transceiver. Refer to the MMFR and MSCR register descriptions, as well as the section on the MII, for a description of how to read and write registers in the transceiver via this interface.

46.3.2.2 10 Mbps and 100 Mbps MII-Lite interface

MII-Lite refers to MII without the following signals:

- FEC_COL
- FEC_CRs

2. For interface selection options, see the chip-specific FEC information.

Modes of operation

- FEC_RXER
- FEC_TXER

The MII-Lite connection is for PHYs that do not have all the MII pins and signals that are available for MII.

The following table provides additional information on the behavior of these signals when MII-Lite is used.

Table 46-2. MII signals not used in MII-Lite

Signal	Information
FEC_COL	This signal is asserted by the PHY when there has been a collision. With full-duplex links, this would always be low, so this signal's absence implies either that the link is full-duplex or that collisions are handled internally within the PHY. The signal is only asserted high on simultaneous Rx and Tx on half-duplex links. As this must be handled by the PHY if the signal is not available, it can be safely pulled low.
FEC CRS	Carrier sense is asserted high by the PHY to indicate that receive medium is non-idle. As in the case with the COL signal, this never occurs with full-duplex links. Again, it is recommended that this signal be pulled low using an external pulldown.
FEC_RXER	This signal is asserted high by the PHY to signal an error to the MAC. However, in these circumstances the PHY will deliberately corrupt the CRC of the incoming frame before passing to the MAC. This input to the FEC can therefore be pulled low and any RXER can be detected by a CRC error in the received frame where the CR bit is set in the receive buffer descriptor (RxBD).
FEC_TXER	This FEC output can be left unconfigured and unused. The signal was originally included for the test case in some PHY designs where the MAC layer in the FEC can demand that the PHY corrupt data during transmission. However, it is readily possible to do this within the MAC by setting the ABC (Append Bad CRC) bit in the transmit buffer descriptor (TxBD) for the frame being sent.

46.3.2.3 10 Mbps and 100 Mbps RMII interface

The reduced media independent interface (RMII) is a low-cost alternative to the IEEE802.3 MII standard. This interface provides the functionality of the MII interface on a total of 8 pins instead of 18. The RMII interface for 10/100 Ethernet MAC-PHY interface was defined by an industry consortium and is not currently included in the IEEE 802.3 standard. This functionality is selected as described in the chip configuration chapter, and is reflected in the read-only RCR[RMII_MODE] bit. The RCR[RMII_10T] bit determines the speed of operation. The reference clock for RMII is always 50 MHz, but this clock can be divided by 10 within the RCR register to support 10 Mbps operation. The PHY must be configured accordingly.

46.3.2.4 10 Mbps 7-wire interface operation

The FEC supports 7-wire interface used by many 10 Mbps Ethernet transceivers. The RCR[MII_MODE] bit controls this functionality. If this bit is cleared, MII mode is disabled and the 10 Mbps 7-wire mode is enabled.

46.3.3 Address recognition options

The address options supported are:

- Promiscuous
- Broadcast reject
- Individual address (hash or exact match)
- Multicast hash match

Address recognition options are discussed in detail in [Ethernet address recognition](#).

46.3.4 Internal loopback

Internal loopback mode is selected via RCR[LOOP]. Loopback mode is discussed in detail in [MII internal and external loopback](#).

46.4 External signal description

The following table describes the various FEC signals, as well as indicating which signals work in available modes.

Table 46-3. FEC signal descriptions

Signal name	MII	7-wire	RMII	Description
FEC_COL	X ¹	X	—	Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.
FEC_CRG	X ¹	—	—	Carrier sense. When asserted, indicates transmit or receive medium is not idle. In RMII mode, this signal is present on the FEC_RXDV pin.
FEC_MDC	X	—	X	Output clock provides a timing reference to the PHY for data transfers on the FEC_MDIO signal.
FEC_MDIO	X	—	X	Transfers control information between the external PHY and the media-access controller. Data is synchronous to FEC_MDC. This signal is an input after reset. When the FEC operates in 10Mbps 7-wire interface mode, this signal should be connected to VSS.

Table continues on the next page...

Table 46-3. FEC signal descriptions (continued)

Signal name	MII	7-wire	RMII	Description
FEC_RXCLK	X	X	—	Provides a timing reference for FEC_RXDV, FEC_RXD[3:0], and FEC_RXER.
FEC_RXDV	X	X	X	Asserting the FEC_RXDV input indicates PHY has valid nibbles present on the MII. FEC_RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Assertion of FEC_RXDV must start no later than the SFD and exclude any EOF. In RMII mode, this pin also generates the CRS signal.
FEC_RXD0	X	X	X	This pin contains the Ethernet input data transferred from PHY to the media-access controller when FEC_RXDV is asserted.
FEC_RXD1	X	—	X	This pin contains the Ethernet input data transferred from PHY to the media access controller when FEC_RXDV is asserted.
FEC_RXD[3:2]	X	—	—	These pins contain the Ethernet input data transferred from PHY to the media access controller when FEC_RXDV is asserted.
FEC_RXER	X ¹	—	X	When asserted with FEC_RXDV, indicates PHY detects an error in the current frame. When FEC_RXDV is not asserted, FEC_RXER has no effect.
FEC_TXCLK	X	X	X	Input clock which provides a timing reference for FEC_TXEN, FEC_TXD[3:0] and FEC_TXER. In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.
FEC_TXD0	X	X	X	The serial output Ethernet data and only valid during the assertion of FEC_TXEN.
FEC_TXD1	X	—	X	This pin contains the serial output Ethernet data and valid only during assertion of FEC_TXEN.
FEC_TXD[3:2]	X	—	—	These pins contain the serial output Ethernet data and valid only during assertion of FEC_TXEN.
FEC_TXEN	X	X	X	Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is negated before the first FEC_TXCLK following the final nibble of the frame.
FEC_TXER	X ¹	—	—	When asserted for one or more clock cycles while FEC_TXEN is also asserted, PHY sends one or more illegal symbols. FEC_TXER has no effect at 10 Mbps or when FEC_TXEN is negated.
Note: Interface selection is chip-specific; see the chapter that describes how modules are configured and connected.				

1. This signal is not available in the MII-Lite interface.

46.5 Memory map and register definition

The FEC is programmed by a combination of control/status registers (CSRs) and buffer descriptors. The CSRs control operation modes and extract global status information. The descriptors pass data buffers and related buffer information between the hardware and software.

Each FEC implementation requires a 1 KB memory map space, which is divided into two sections of 512 bytes each for:

- Control/status registers
- Event/statistic counters held in the MIB block

The following table defines the top-level memory map.

Table 46-4. FEC memory map

Address offset	Function
000h–1FFh	Control/status registers
200h–3FFh	MIB block counters

The following table shows the FEC register map. Any address offset not explicitly mentioned in this table is reserved. Do not modify the content of reserved fields. All accesses to and from the registers must be via 32-bit accesses. There is no support for accesses other than 32-bit. Accessing reserved or unimplemented register spaces in the FEC will not return transfer errors.

The MIB counters (shown in the following table) define the locations in the MIB RAM space where hardware-maintained counters reside. The counters are divided into two groups:

- RMON counters include the Ethernet statistics counters defined in RFC 1757
- Truncated frames counter (only frames with lengths up to 2047 bytes are supported)

The transmit and receive RMON counters are independent, which ensures accurate network statistics when operating in full duplex mode.

The included IEEE counters support the mandatory and recommended counter packages defined in Section 5 of ANSI/IEEE Std. 802.3 (1998 edition). The FEC supports IEEE Basic Package objects, but these do not require counters in the MIB block. In addition, some of the recommended package objects supported do not require MIB counters. Counters for transmit and receive full duplex flow control frames are also included.

46.5.1 Interrupt Event Register (FEC_EIR)

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

These interrupts can be divided into operational interrupts, transceiver/network error interrupts, and internal error interrupts. Interrupts which may occur in normal operation are GRA, TXF, TXB, RXF, RXB, and MII. Interrupts resulting from errors/problems detected in the network or transceiver are HBERR, BABR, BABT, LC, and RL. Interrupts resulting from internal errors are HBERR and UN.

Some of the error interrupts are independently counted in the MIB block counters:

- HBERR - IEEE_T_SQE
- BABR - RMON_R_OVERSIZE (good CRC), RMON_R_JAB (bad CRC)
- BABT - RMON_T_OVERSIZE (good CRC), RMON_T_JAB (bad CRC)
- LATE_COL - IEEE_T_LCOL
- COL_RETRY_LIM - IEEE_T_EXCOL
- XFIFO_UN - IEEE_T_MACERR

Software may choose to mask off these interrupts because these errors are visible to network management via the MIB counters.

FEC_EIR field descriptions

Field	Description
0 HBERR	Heartbeat error. Indicates TCR[HBC] is set and that the COL input was not asserted within the heartbeat window following a transmission.
1 BABR	Babbling receive error. Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
2 BABT	Babbling transmit error. Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused by a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.
3 GRA	Graceful stop complete. Indicates the graceful stop is complete. During graceful stop the transmitter is placed into a pause state after completion of the frame currently being transmitted. This bit is set by one of these conditions: • A graceful stop initiated by the setting of the TCR[GTS] bit is now complete. • A graceful stop initiated by the setting of the TCR[TFC_PAUSE] bit is now complete. • A graceful stop initiated by the reception of a valid full duplex flow control pause frame is now complete. See Full duplex flow control.
4 TXF	Transmit frame interrupt. Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.
5 TXB	Transmit buffer interrupt. Indicates a transmit buffer descriptor has been updated.
6 RXF	Receive frame interrupt. Indicates a frame has been received and the last corresponding buffer descriptor has been updated.
7 RXB	Receive buffer interrupt. Indicates a receive buffer descriptor not the last in the frame has been updated.
8 MII	MII interrupt. Indicates the MII has completed the data transfer requested.
9 EBERR	Ethernet bus error. Indicates a system bus error occurred when a DMA transaction is underway. When the EBERR bit is set, ECR[ETHER_EN] is cleared, halting frame processing by the FEC. When this occurs, software needs to ensure that the FIFO controller and DMA also soft reset.

Table continues on the next page...

FEC_EIR field descriptions (continued)

Field	Description
10 LC	Late collision. Indicates a collision occurred beyond the collision window (slot time) in half duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.
11 RL	Collision retry limit. Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half duplex mode.
12 UN	Transmit FIFO underrun. Indicates the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.
13–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.5.2 Interrupt Mask Register (FEC_EIMR)

The EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR bit (write 1 to clear) or a 0 is written to the EIMR bit.

Each bit in this register corresponds to an interrupt source defined by the EIR. The corresponding EIMR bit determines whether an interrupt condition can generate an interrupt. At every processor clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR bit reflects the state of the interrupt signal even if the corresponding EIMR bit is set.

Address: 0h base + 8h offset = 8h

	0 The interrupt source is masked. 1 The interrupt source is not masked.
13–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.5.3 Receive Descriptor Active Register (FEC_RDAR)

RDAR is a command register, written by the user, indicating the receive descriptor ring is updated (the driver produced empty receive buffers with the empty bit set).

When the register is written, the RDAR bit is set. This is independent of the data actually written by the user. When set, the FEC polls the receive descriptor ring and processes receive frames (if ECR[ETHER_EN] is also set). After the FEC polls a receive descriptor whose empty bit is not set, FEC clears the RDAR bit and ceases receive descriptor ring polling until the user sets the bit again, signifying that additional descriptors are placed into the receive descriptor ring.

The RDAR is cleared at reset and when ECR[ETHER_EN] is cleared.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0							RDAR	0							
W

FEC_RDAR field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Set to 1 when this register is written, regardless of the value written. Cleared by the FEC when no additional empty descriptors remain in the receive ring. Also cleared when ECR[ETHER_EN] is cleared.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.5.4 Transmit Descriptor Active Register (FEC_TDAR)

The TDAR is a command register which the user writes to indicate the transmit descriptor ring is updated (transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor).

When the register is written, the TDAR field is set. This value is independent of the data actually written by the user. When set, the FEC polls the transmit descriptor ring and processes transmit frames (provided ECR[ETHER_EN] is also set). After the FEC polls a transmit descriptor that is a ready bit not set, FEC clears the TDAR field and ceases transmit descriptor ring polling until the user sets the bit again, signifying additional descriptors are placed into the transmit descriptor ring.

The TDAR field is cleared when any of the following events occur:

- Chip reset
- When ECR[ETHER_EN] is cleared
- When ECR[RESET] is set

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

FEC_TDAR field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TDAR	Set to 1 when this register is written, regardless of the value written. Cleared by the FEC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHER_EN] is cleared.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.5.5 Ethernet Control Register (FEC_ECR)

ECR is a read/write user register, though hardware may alter fields in this register as well. The ECR enables/disables the FEC.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0				0	0	0									
W

4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 ETHER_EN	When this bit is set, FEC is enabled, and reception and transmission are possible. When this bit is cleared, reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame. The buffer descriptor(s) for an aborted transmit frame are not updated after clearing this bit. When ETHER_EN is cleared, the DMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. Hardware alters the ETHER_EN bit under the following conditions: • ECR[RESET] is set by software, in which case ETHER_EN is cleared. • An error condition causes the EIR[EBERR] bit to set, in which case ETHER_EN is cleared.
31 RESET	When this bit is set, the equivalent of a hardware reset is performed but it is local to the FEC. ECR[ETHER_EN] is cleared and all other FEC registers take their reset values. Also, any transmission/reception currently in progress is abruptly aborted. This bit is automatically cleared by hardware during the reset sequence. The reset sequence takes approximately eight internal bus clock cycles after this bit is set.

46.5.6 MII Management Frame Register (FEC_MMFR)

The MMFR is used to communicate with the attached MII compatible PHY device(s), providing read/write access to their MII registers. Performing a write to the MMFR causes a management frame to be sourced unless the MSCR is programmed to 0. If MSCR is cleared while MMFR is written and then MSCR is written with a non-zero value, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

The MMFR does not reset to any predefined value.

To perform a read or write operation on the MII Management Interface, write the MMFR. To generate a valid read or write management frame, ST field must be written with a 01 pattern, and the TA field must be written with a 10. If other patterns are written to these fields, a frame is generated, but does not comply with the IEEE 802.3 MII definition.

To generate an IEEE 802.3-compliant MII Management Interface write frame (write to a PHY register), write {01 01 PHYAD REGAD 10 DATA} to the MMFR. Writing this pattern causes the control logic to shift out the data in the MMFR following a preamble generated by the control state machine. During this time, contents of the MMFR register are altered as the contents are serially shifted and are unpredictable if read by the user. After the write management frame operation completes, the MII interrupt is generated. At this time, contents of the MMFR match the original value written.

To generate an MII management interface read frame (read a PHY register), write {01 10 PHYAD REGAD 10 XXXX} to the MMFR (the content of the DATA field is unimportant). Writing this pattern causes the control logic to shift out the data in the MMFR following a preamble generated by the control state machine. During this time, contents of the MMFR register are altered as the contents are serially shifted and are unpredictable if read by the user. After the read management frame operation completes, the MII interrupt is generated. At this time, the contents of the MMFR register match the original value written except for the DATA field whose contents are replaced by the value read from the PHY register.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the MII interrupt to avoid writing to the MMFR while frame generation is in progress.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- x = Undefined at reset.

FEC_MMFR field descriptions

Field	Description
0–1 ST	Start of frame delimiter. These bits must be programmed to 0b01 for a valid MII management frame.
2–3 OP	Operation code. 00 Write frame operation, but not MII compliant. 01 Write frame operation for a valid MII management frame. 10 Read frame operation for a valid MII management frame. 11 Read frame operation, but not MII compliant.
4–8 PA	PHY address. This field specifies one of up to 32 attached PHY devices.
9–13 RA	Register address. This field specifies one of up to 32 registers within the specified PHY device.
14–15 TA	Turn around. This field must be programmed to 10 to generate a valid MII management frame.
16–31 DATA	Management frame data. This is the field for data to be written to or read from the PHY register.

46.5.7 MII Speed Control Register (FEC_MSCR)

The MSCR:

- Provides control of the MII clock (FEC_MDC pin) frequency
- Allows a preamble drop on the MII management frame

The MII_SPEED field must be programmed with a value to provide an FEC_MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be set to 0 to turn off the FEC_MDC. The FEC_MDC generated has a 50% duty cycle except when MII_SPEED changes during operation (change takes effect following a rising or falling edge of FEC_MDC).

If the internal bus clock is 25 MHz, programming this register to 0000_0005h results in an FEC_MDC as stated the equation below.

$$25 \text{ MHz} \times \frac{1}{52} = 2.5 \text{ MHz}$$

Figure 46-9. FEC_MDC example

[Table 46-13](#) shows optimum values for MII_SPEED as a function of internal bus clock frequency.

Table 46-13. Programming examples for MSCR

Internal FEC clock frequency	MSCR[MII_SPEED]	FEC_MDC frequency
25 MHz	5h	2.50 MHz
33 MHz	7h	2.36 MHz
40 MHz	8h	2.50 MHz
50 MHz	Ah	2.50 MHz
66 MHz	Eh	2.36 MHz
80 MHz	10h	2.50 MHz
83 MHz	10h	2.59 MHz

Address: 0h base + 44h offset = 44h

FEC_MSCR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 DIS_PRE	Setting this bit causes the preamble (32 ones) not to be prepended to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY device(s) does not require it.
25–30 MII_SPEED	Controls the frequency of the MII management interface clock (FEC_MDC) relative to the internal bus clock. A value of 0 in this field turns off the FEC_MDC and leaves it in low voltage state. Any non-zero value results in the FEC_MDC frequency of $1/(\text{MII\_SPEED} \times 2)$ of the internal bus frequency.
31 Reserved	This field is reserved. Reserved

46.5.8 MIB Control Register (FEC_MIBC)

The MIBC is a read/write register controlling and observing the state of the MIB block. User software accesses this register if there is a need to disable the MIB block operation. For example, to clear all MIB counters in RAM:

1. Disable the MIB block

2. Clear all the MIB RAM locations
3. Enable the MIB block

The MIB_DIS bit is reset to 1. See the memory map for the locations of the MIB counters.

Address: 0h base + 64h offset = 64h

FEC_MIBC field descriptions

Field	Description
0 MIB_DIS	If MIB_DIS = 1, the MIB logic halts and not update any MIB counters.
1 MIB_IDLE	If MIB_IDLE = 1, the MIB block is not currently updating any MIB counters.
2–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.5.9 Receive Control Register (FEC_RCR)

RCR controls the operational mode of the receive block and must be written only when ECR[ETHER_EN] is cleared (initialization time).

Address: 0h base + 84h offset = 84h

FEC_RCR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 MAX_FL	Maximum frame length. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL causes the BABT interrupt to occur. Receive frames longer than MAX_FL causes the BABR interrupt to occur and sets the LG bit in the end of frame receive buffer descriptor.

Table continues on the next page...

FEC_RCR field descriptions (continued)

Field	Description
	The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 RMII_ECHO	RMII Echo. Enables RMII echo mode. RMII 2-bit receive data is processed through the RMII receive logic to the FEC and also routes through the RMII's transmit logic to become RMII 2-bit transmit data out. 0 Normal operation. 1 RMII echo mode enabled. NOTE: When RMII_ECHO is set, proper operation is guaranteed only when RMII_MODE = 1, RMII_LOOP = 0 and LOOP = 0.
21 RMII_LOOP	RMII loopback. Enables RMII loopback mode. Causes the MII transmit outputs from the Ethernet controller to loop back to the Ethernet controllers's MII receive inputs through the RMII transmit/receive logic. 0 Normal operation. 1 RMII loopback mode enabled. NOTE: When RMII_LOOP is set, proper operation is guaranteed only when RMII_MODE = 1, RMII_ECHO = 0, LOOP = 0, and TCR <i>n</i> [FDEN] = 1.
22 RMII_10T	RMII 10-Base T. Enables 10Mbps mode of the RMII. Determines the clock frequency of the clock source to the FEC logic to support 10/100Mbps operations. 0 100 Mbps operation. The 50 MHz RMII reference clock on FEC_TXCLK is sent to the RMII, while a divided-by-2 version (25 MHz) is sent to the FEC. 1 10 Mbps operation. The 50 MHz RMII reference clock on FEC_TXCLK is divided by 10 (5 MHz) and sent to the RMII, while a divided-by-20 version (2.5 MHz) is sent to the FEC.
23 RMII_MODE	RMII Mode. Indicates if the FEC is in RMII or MII/7-wire mode. See the chip configuration chapter for more details. NOTE: Interface selection is chip-specific; see the chapter that describes how modules are configured and connected. 0 FEC is in true MII mode. 1 FEC is in RMII mode.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 FCE	Flow control enable. If asserted, the receiver detects PAUSE frames. Upon PAUSE frame detection, the transmitter stops transmitting data frames for a given duration.
27 BC_REJ	Broadcast frame reject. If asserted, frames with DA (destination address) equal to FFFF_FFFF_FFFF are rejected unless the PROM bit is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the M (MISS) is set in the receive buffer descriptor.
28 PROM	Promiscuous mode. All frames are accepted regardless of address matching.
29 MII_MODE	Media independent interface mode. Selects the external interface mode for transmit and receive blocks. NOTE: Interface selection is chip-specific; see the chapter that describes how modules are configured and connected. 0 7-wire mode (used only for serial 10 Mbps) 1 MII or RMII mode as indicated by the RMII_MODE bit

Table continues on the next page...

FEC_RCR field descriptions (continued)

Field	Description
30 DRT	Disable receive on transmit. 0 Receive path operates independently of transmit (use for full duplex or to monitor transmit activity in half duplex mode). 1 Disable reception of frames while transmitting (normally used for half duplex mode).
31 LOOP	Internal loopback. If set, transmitted frames are looped back internal to the device and transmit output signals are not asserted. The internal bus clock substitutes for the FEC_TXCLK when LOOP is asserted. DRT must be set to 0 when setting LOOP.

46.5.10 Transmit Control Register (FEC_TCR)

The TCR configures the transmit block.

Address: 0h base + C4h offset = C4h

FEC_TCR field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 RFC_PAUSE	Receive frame control pause. This read-only status bit is asserted when a full duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This bit automatically clears when the pause duration is complete.
28 TFC_PAUSE	Transmit frame control pause. Transmits a PAUSE frame when asserted. When this bit is set, the MAC stops transmission of data frames after the current transmission is complete. At this time, GRA interrupt in the EIR is asserted. With transmission of data frames stopped, MAC transmits a MAC Control PAUSE frame. Next, the MAC clears the TFC_PAUSE bit and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC Control PAUSE frame.
29 FDEN	Full duplex enable. If set, frames transmit independent of carrier sense and collision inputs. This field must be modified only when ECR[ETHER_EN] = 0.
30 HBC	Heartbeat control. If set, the heartbeat check performs following end of transmission and the HB bit in the status register is set if the collision input does not assert within the heartbeat window. This field must be modified only when ECR[ETHER_EN] = 0.
31 GTS	Graceful transmit stop. When this bit is set, MAC stops transmission after any frame currently transmitted is complete and GRA interrupt in the EIR is asserted. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this situation, program ECR[ETHER_EN] = 0 following the GRA interrupt.

46.5.11 Physical Address Low Register (FEC_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the DA (destination address) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the 6-byte source address field when transmitting PAUSE frames.

This register is not reset and you must initialize it.

Address: 0h base + E4h offset = E4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	PADDR1																															
W

* Notes:

- u = Unaffected by reset.

FEC_PALR field descriptions

Field	Description
0–31 PADDR1	Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames.

46.5.12 Physical Address High Register and Type Field (FEC_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the DA (destination address) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the 6-byte Source Address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (8808h) for transmission of PAUSE frames. The upper 16 bits of this register are not reset and you must initialize them.

Address: 0h base + E8h offset = E8h

- * Notes:
- u = Unaffected by reset.

FEC_PAUR field descriptions

Field	Description
0–15 PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames.
16–31 TYPE	Type field in PAUSE frames. These 16 read-only bits are a constant value of 8808h.

46.5.13 Opcode/Pause Duration (FEC_OPD)

The OPD contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0001h. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field.

The lower 16 bits of this register are not reset and you must initialize them.

Address: 0h base + ECh offset = ECh

* Notes:

- x = Undefined at reset.

FEC_OPD field descriptions

Field	Description
0–15 OPCODE	Opcode field used in PAUSE frames. These read-only bits are a constant, 0001h.
16–31 PAUSE_DUR	Pause Duration field used in PAUSE frames.

46.5.14 Descriptor Individual Upper Address Register (FEC_IAUR)

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA.

This register is not reset and you must initialize it.

Address: 0h base + 118h offset = 118h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- u = Unaffected by reset.

FEC_IAUR field descriptions

Field	Description
0–31 IADDR1	The upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR1 contains hash index bit 63. Bit 0 of IADDR1 contains hash index bit 32.

46.5.15 Descriptor Individual Lower Address Register (FEC_IALR)

IALR contains the lower 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the DA field of receive frames with an individual DA.

This register is not reset and you must initialize it.

Memory map and register definition

Address: 0h base + 11Ch offset = 11Ch

FEC_GALR field descriptions

Field	Description
0–31 GADDR2	The GADDR2 register contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

46.5.18 Transmit FIFO Watermark (FEC_TFWR)

The TFWR controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement (worst case bus access latency by the transmit data DMA channel).

Address: 0h base + 144h offset = 144h

FEC_TFWR field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 TFWR	Number of bytes written to transmit FIFO before transmission of a frame begins 00 64 bytes written

Table continues on the next page...

FEC_TFWR field descriptions (continued)

Field	Description
01	64 bytes written
10	128 bytes written
11	192 bytes written

46.5.19 FIFO Receive Bound Register (FEC_FRBR)

FRBR indicates the upper address bound of the FIFO RAM. Drivers can use this value, along with the FRSR, to appropriately divide the available FIFO RAM between the transmit and receive data paths.

Address: 0h base + 14Ch offset = 14Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0

FEC_FRBR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
22–29 R_BOUND	Highest valid FIFO RAM address.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.5.20 FIFO Receive Start Register (FEC_FRSR)

FRSR indicates the starting address of the receive FIFO. FRSR marks the boundary between the transmit and receive FIFOs. The transmit FIFO uses addresses from the start of the FIFO to the location four bytes before the address programmed into the FRSR. The receive FIFO uses addresses from FRSR to FRBR inclusive.

Hardware initializes the FRSR at reset. FRSR only needs to be written to change the default value.

Address: 0h base + 150h offset = 150h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

FEC_FRSR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
22–29 R_FSTART	Address of first receive FIFO location. Acts as delimiter between receive and transmit FIFOs. For proper operation, ensure that R_FSTART is set to 48h or greater.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.5.21 Receive Descriptor Ring Start Register (FEC_ERDSR)

ERDSR points to the start of the circular receive buffer descriptor queue in external memory. This pointer must be 32-bit aligned; however, it is recommended it be made 128-bit aligned (evenly divisible by 16). You should write zeros to bits 1 and 0. Hardware ignores non-zero values in these two bit positions.

This register is undefined at reset and must be initialized prior to operation.

Address: 0h base + 180h offset = 180h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_ERDSR field descriptions

Field	Description
0–29 R_DES_START	Pointer to start of receive buffer descriptor queue.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.5.22 Transmit Buffer Descriptor Ring Start Register (FEC_ETDSR)

ETSDR provides a pointer to the start of the circular transmit buffer descriptor queue in external memory. This pointer must be 32-bit aligned; however, it is recommended it be made 128-bit aligned (evenly divisible by 16). You should write zeros to bits 1 and 0. Hardware ignores non-zero values in these two bit positions.

This register is undefined at reset and must be initialized prior to operation.

Address: 0h base + 184h offset = 184h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_ETDSR field descriptions

Field	Description
0–29 X_DES_START	Pointer to start of transmit buffer descriptor queue.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.5.23 Receive Buffer Size Register (FEC_EMRBR)

The EMRBR dictates the maximum size of all receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer. To allow one maximum size frame per buffer, EMRBR must be set to RCR[MAX_FL] or larger. To properly align the buffer, EMRBR must be evenly divisible by 16. To ensure this, bits 3-0 are forced low.

To minimize bus utilization (descriptor fetches), it is recommended that EMRBR be greater than or equal to 256 bytes.

The EMRBR is undefined at reset and must be initialized by the user.

Address: 0h base + 188h offset = 188h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_EMRBR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–27 R_BUF_SIZE	Maximum size of receive buffer size in bytes. To minimize bus utilization (descriptor fetches), set this field to 256 bytes (10h) or larger. 10h: 256 + 15 bytes (minimum size recommended) 11h: 272 + 15 bytes ... 7Fh: 2032 + 15 bytes. The FEC writes up to 2047 bytes in the receive buffer. If data larger than 2047 is received, the FEC truncates it and shows 7FFh in the receive descriptor
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.5.24 Count of frames not counted correctly (FEC_RMON_T_DROP)

See [Using the RMON and IEEE registers](#).

Address: 0h base + 200h offset = 200h

46.5.79 Using the RMON and IEEE registers

In order to use the RMON and IEEE registers to monitor FEC performance, you must prepare them using the sequence below:

1. Write zeros to the registers.
2. Enable the FEC.

Until you complete this sequence, the registers are read/write, and their reset value is undefined. After you complete this sequence, the registers become read-only, and you may read them as necessary.

46.6 Functional description

This section describes the operation of the FEC, beginning with the description of two different types of MII frames, the buffer descriptors, the hardware and software initialization sequence, then the software (Ethernet driver) interface for transmitting and receiving frames.

Following the software initialization and operation sections are sections providing a detailed description of the functions of the FEC.

46.6.1 MII data frame

Ethernet/802.3 data frames transmitted across the MII have the format specified in [Figure 46-81](#) and [Table 46-85](#).

<inter-frame> <preamble> <sfd> <data> <efd>

Figure 46-81. MII data frame format

Table 46-85. MII data frame components

Component	Description
<inter-frame>	Inter-frame period. This is an unspecified amount of time during which no data activity occurs on the MII. The de-assertion of RX_DV and TX_EN indicate the absence of data activity.
<preamble>	Preamble that begins a frame. It has the following value: 10101010 10101010 10101010 10101010 10101010 10101010 10101010 The leftmost 1 represents the LSB of the byte.
<sfd>	Start of a frame. It has the value 10101011.
<data>	Data portion of the frame. It consists of N octets which corresponds to 2N nibbles being transmitted. The order of each nibble is defined in Figure 46-82 .

Table continues on the next page...

Table 46-85. MII data frame components (continued)

Component	Description
<efd>	End-of-frame delimiter. For TXD data, it is indicated by the de-assertion of the TX_EN signal. For RXD data, it is indicated by the de-assertion of the RX_DV signal.

Figure 46-82. MII nibble/octet to octet/nibble mapping

46.6.2 MII management frame structure

A transceiver management frame being transmitted on the MII management interface uses the MDIO and MDC pins. A transaction or frame on this serial interface has the format specified in [Figure 46-83](#) and [Table 46-86](#).

<preamble> <st> <op> <phyad> <regad> <ta> <data> <idle>

Figure 46-83. MII management frame format

Table 46-86. MII management frame components

Component	Description
<preamble>	Optional preamble, consisting of a sequence of 32 continuous logic 1's.
<st>	Start of frame, consisting of a 01 pattern.
<op>	Operation code. 01 Write operation 10 Read instruction

Table continues on the next page...

Table 46-86. MII management frame components (continued)

Component	Description
<phyad>	Five-bit field that allows up to 32 PHYs to be addressed. The first address bit transmitted is the MSB of the address.
<regad>	Five-bit field that allows for 32 registers to be addressed within each PHY. The first register bit transmitted is the MSB of the address.
<ta>	Two-bit field that provides spacing between the register address field and the data field to avoid contention on the MDIO signal during a read operation.
<data>	16-bit data field. Bit 15 is the first data bit transmitted and received.
<idle>	Idle condition (MDIO is in the high-impedance state).

The MII management register set located in the PHY may consist of a basic register set and an extended register set as defined in [Table 46-87](#).

Table 46-87. MII management register set

Register address	Register name	Register set
0	Control	Basic
1	Status	
2-3	PHY identifier	Extended
4	Auto-negotiation advertisement	
5	AN link partner ability	
6	AN expansion	
7	AN next page transmit	
8-15	Reserved	
16-31	Vendor-specific	

46.6.3 Buffer descriptors

This section provides a description of the operation of the driver/DMA via the buffer descriptors. It is followed by a detailed description of the receive and transmit descriptor fields.

46.6.3.1 Driver/DMA operation with buffer descriptors

The data for the FEC frames resides in one or more memory buffers external to the FEC. Associated with each buffer is a buffer descriptor (BD), which contains a starting address (32-bit aligned pointer), data length, and status/control information (which contains the current state for the buffer). To permit maximum user flexibility, the BDs are also located in external memory and are read by the FEC DMA engine.

Software produces buffers by allocating/initializing memory and initializing buffer descriptors. Setting the RxBD[E] or TxBD[R] bit produces the buffer. Software writing to TDAR or RDAR tells the FEC that a buffer is placed in external memory for the transmit or receive data traffic, respectively. The hardware reads the BDs and consumes the buffers after they have been produced. After the data DMA is complete and the DMA engine writes the buffer descriptor status bits, hardware clears RxBD[E] or TxBD[R] to signal the buffer has been consumed. Software may poll the BDs to detect when the buffers are consumed or may rely on the buffer/frame interrupts. The driver may process these buffers, and they can return to the free list.

The ECR[ETHER_EN] bit operates as a reset to the BD/DMA logic. When ECR[ETHER_EN] is cleared, the DMA engine BD pointers are reset to point to the starting transmit and receive BDs. The buffer descriptors are not initialized by hardware during reset. At least one transmit and receive buffer descriptor must be initialized by software before ECR[ETHER_EN] is set.

The buffer descriptors operate as two separate rings. ERDSR defines the starting address for receive BDs and ETDSR defines the starting address for transmit BDs. The wrap (W) bit defines the last buffer descriptor in each ring. When W is set, the next descriptor in the ring is at the location pointed to by ERDSR and ETDSR for the receive and transmit rings, respectively. Buffer descriptor rings must start on a 32-bit boundary; however, it is recommended they be 128-bit aligned.

46.6.3.1.1 Driver/DMA operation with transmit BDs

Typically, a transmit frame is divided between multiple buffers. An example is to have an application payload in one buffer, TCP header in a second buffer, IP header in a third buffer, and Ethernet/IEEE 802.3 header in a fourth buffer. The Ethernet MAC does not prepend the Ethernet header (destination address, source address, length/type field(s)), so the driver must provide this in one of the transmit buffers. The Ethernet MAC can append the Ethernet CRC to the frame. TxBD[TC], which must be set by the driver, determines whether the MAC or driver appends the CRC.

The driver (TxBD software producer) should set up Tx BDs so a complete transmit frame is given to the hardware at once. If a transmit frame consists of three buffers, the BDs should be initialized with pointer, length, and control (W, L, TC, ABC) and then the TxBD[R] bit should be set in reverse order (third, second, then first BD) to ensure that the complete frame is ready in memory before the DMA begins. If the TxBDs are set up in order, the DMA controller could DMA the first BD before the second was made available, potentially causing a transmit FIFO underrun.

In the FEC, the driver notifies the DMA that new transmit frame(s) are available by writing to TDAR. When this register is written to (data value is not significant), the FEC RISC tells the DMA to read the next transmit BD in the ring. After started, the RISC + DMA continues to read and interpret transmit BDs in order and DMA the associated buffers until a transmit BD is encountered with the R bit cleared. At this point, the FEC polls this BD one more time. If the R bit is cleared the second time, RISC stops the transmit descriptor read process until software sets up another transmit frame and writes to TDAR.

When the DMA of each transmit buffer is complete, the DMA writes back to the BD to clear the R bit, indicating that the hardware consumer is finished with the buffer.

46.6.3.1.2 Driver/DMA operation with receive BDs

Unlike transmit, the length of the receive frame is unknown by the driver ahead of time. Therefore, the driver must set a variable to define the length of all receive buffers. In the FEC, this variable is written to the EMRBR register.

The driver (RxBD software producer) should set up some number of empty buffers for the Ethernet by initializing the address field and the E and W bits of the associated receive BDs. The hardware (receive DMA) consumes these buffers by filling them with data as frames are received and clearing the E bit and writing to the L bit (1 indicates last buffer in frame), the frame status bits (if L is set), and the length field.

If a receive frame spans multiple receive buffers, the L bit is only set for the last buffer in the frame. For non-last buffers, the length field in the receive BD is written by the DMA (at the same time the E bit is cleared) with the default receive buffer length value. For end-of-frame buffers, the receive BD is written with L set and information written to the status bits (M, BC, MC, LG, NO, CR, OV, TR). Some of the status bits are error indicators which, if set, indicate the receive frame should be discarded and not given to higher layers. The frame status/length information is written into the receive FIFO following the end of the frame (as a single 32-bit word) by the receive logic. The length field for the end of frame buffer is written with the length of the entire frame, not only the length of the last buffer.

For simplicity, the driver may assign a large enough default receive buffer length to contain an entire frame, keeping in mind that a malfunction on the network or out-of-spec implementation could result in giant frames. Frames of 2K (2048) bytes or larger are truncated by the FEC at 2047 bytes so software never sees a receive frame larger than 2047 bytes.

Similar to transmit, the FEC polls the receive descriptor ring after the driver sets up receive BDs and writes to the RDAR register. As frames are received, the FEC fills receive buffers and updates the associated BDs, then reads the next BD in the receive

descriptor ring. If the FEC reads a receive BD and finds the E bit cleared, it polls this BD once more. If RxBDE is clear a second time, FEC stops reading receive BDs until the driver writes to RDAR.

46.6.3.2 Ethernet Receive Buffer Descriptor (RxBDE)

In the RxBDE, the user initializes the E and W bits in the first longword and the pointer in the second longword. When the buffer has been DMA'd, the Ethernet controller modifies the E, L, M, BC, MC, LG, NO, CR, OV, and TR bits and writes the length of the used portion of the buffer in the first longword. The M, BC, MC, LG, NO, CR, OV, and TR bits in the first longword of the buffer descriptor are only modified by the Ethernet controller when the L bit is set.

Table 46-88. Receive Buffer Descriptor (RxBDE)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset+0	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset+2	Data Length															
Offset+4	Rx Data Buffer Pointer - A[31:16]															
Offset+6	Rx Data Buffer Pointer - A[15:0]															

Table 46-89. Receive Buffer Descriptor field descriptions

Word	Field	Description
Offset + 0	E	Empty. Written by the FEC (=0) and user (=1). 0: The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required. 1: The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 0	RO1	Receive software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
Offset + 0	W	Wrap. Written by user. 0: The next buffer descriptor is found in the consecutive location 1: The next buffer descriptor is found at the location defined in ERDSR.
Offset + 0	RO2	Receive software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
Offset + 0	L	Last in frame. Written by the FEC. 0: The buffer is not the last in a frame. 1: The buffer is the last in a frame.

Table continues on the next page...

Table 46-89. Receive Buffer Descriptor field descriptions (continued)

Word	Field	Description
Offset + 0	M	Miss. Written by the FEC. This bit is set by the FEC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use the M-bit to quickly determine whether the frame was destined to this station. This bit is valid only if the L-bit is set and the PROM bit is set. 0: The frame was received because of an address recognition hit. 1: The frame was received because of promiscuous mode.
Offset + 0	BC	Set if the DA is broadcast (FFFF_FFFF_FFFF).
Offset + 0	MC	Set if the DA is multicast and not BC.
Offset + 0	LG	Rx frame length violation. Written by the FEC. A frame length greater than RCR[MAX_FL] was recognized. This bit is valid only if the L-bit is set. The receive data is not altered in any way unless the length exceeds 2047 bytes.
Offset + 0	NO	Receive non-octet aligned frame. Written by the FEC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error. This bit is valid only if the L-bit is set. If this bit is set, the CR bit is not set.
Offset + 0	CR	Receive CRC error. Written by the FEC. This frame contains a CRC error and is an integral number of octets in length. This bit is valid only if the L-bit is set.
Offset + 0	OV	Overflow. Written by the FEC. A receive FIFO overrun occurred during frame reception. If this bit is set, the other status bits, M, LG, NO, CR, and CL lose their normal meaning and are zero. This bit is valid only if the L-bit is set.
Offset + 0	TR	Set if the receive frame is truncated (frame length > 2047 bytes). If the TR bit is set, the frame must be discarded and the other error bits must be ignored as they may be incorrect.
Offset + 2	Data Length	Data length. Written by the FEC. Data length is the number of octets written by the FEC into this BD's data buffer if L equals 0 (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the FEC once as the BD is closed.
Offset + 4	A[31:16]	RX data buffer pointer, bits [31:16] ¹
Offset + 6	A[15:0]	RX data buffer pointer, bits [15:0]

1. The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 16. The buffer must reside in memory external to the FEC. The Ethernet controller never modifies this value.

Note

When the software driver sets an E bit in one or more receive descriptors, the driver should follow with a write to RDAR.

46.6.3.3 Ethernet Transmit Buffer Descriptor (TxBD)

Data is presented to the FEC for transmission by arranging it in buffers referenced by the channel's TxBDs. The Ethernet controller confirms transmission by clearing the ready bit (TxBD[R]) when DMA of the buffer is complete. In the TxBD, the user initializes the R, W, L, and TC bits and the length (in bytes) in the first longword and the buffer pointer in the second longword.

The FEC clears the R bit when the buffer is transferred. Status bits for the buffer/frame are not included in the transmit buffer descriptors. Transmit frame status is indicated via individual interrupt bits (error conditions) and in statistic counters in the MIB block.

Table 46-90. Transmit Buffer Descriptor (TxBD)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset+0	R	TO1	W	TO2	L	TC	ABC	—	—	—	—	—	—	—	—	—
Offset+2	Data Length															
Offset+4	Tx Data Buffer Pointer - A[31:16]															
Offset+6	Tx Data Buffer Pointer - A[15:0]															

Table 46-91. Transmit Buffer Descriptor field descriptions

Word	Field	Description
Offset + 0	R	Ready. Written by the FEC and you. 0: The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The FEC clears this bit after the buffer has been transmitted or after an error condition is encountered. 1: The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this bit is set.
Offset + 0	TO1	Transmit software ownership. This field is reserved for software use. This read/write bit is not modified by hardware nor does its value affect hardware.
Offset + 0	W	Wrap. Written by user. 0: The next buffer descriptor is found in the consecutive location 1: The next buffer descriptor is found at the location defined in ETDSR.
Offset + 0	TO2	Transmit software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware nor does its value affect hardware.
Offset + 0	L	Last in frame. Written by user. 0: The buffer is not the last in the transmit frame 1: The buffer is the last in the transmit frame
Offset + 0	TC	Transmit CRC. Written by user (only valid if L is set). 0: End transmission immediately after the last data byte 1: Transmit the CRC sequence after the last data byte
Offset + 0	ABC	Append bad CRC. Written by user (only valid if L is set). 0: No effect 1: Transmit the CRC sequence inverted after the last data byte (regardless of TC value)
Offset + 2	Data Length	Data length, written by user. Data length is the number of octets the FEC should transmit from this BD's data buffer. It is never modified by the FEC.
Offset + 4	A[31:16]	Tx data buffer pointer, bits [31:16] 1
Offset + 6	A[15:0]	Tx data buffer pointer, bits [15:0]

1. The transmit buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 4. The buffer must reside in memory external to the FEC. This value is never modified by the Ethernet controller.

Note

After the software driver has set up the buffers for a frame, it should set up the corresponding BDs. The last step in setting up the BDs for a transmit frame is setting the R bit in the first BD for the frame. The driver must follow that with a write to TDAR that triggers the FEC to poll the next BD in the ring.

46.6.4 Initialization sequence

This section describes which registers are reset due to hardware reset, which registers are reset by the FEC RISC, and what locations you must initialize prior to enabling the FEC.

46.6.4.1 Hardware Controlled Initialization

In the FEC, hardware resets registers and control logic that generate interrupts. A hardware reset negates output signals and resets general configuration bits.

Other registers reset when the ECR[ETHER_EN] bit is cleared (which is accomplished by a hard reset or software to halt operation). By clearing ECR[ETHER_EN], configuration control registers such as the TCR and RCR are not reset, but the entire data path is reset.

Table 46-92. ECR[ETHER_EN] De-Assertion Effect on FEC

Register/Machine	Reset Value
XMIT block	Transmission is aborted (bad CRC appended)
RECV block	Receive activity is aborted
DMA block	All DMA activity is terminated
RDAR	Cleared
TDAR	Cleared
Descriptor Controller block	Halt operation

46.6.5 User initialization (Prior to Setting ECR[ETHER_EN])

You need to initialize portions the FEC prior to setting the ECR[ETHER_EN] bit. The exact values depend on the particular application. The sequence is not important.

The following registers require initialization:

- EIMR
- EIR (clear by writing FFFF_FFFFh)
- TFWR (optional)
- IALR / IAUR
- GAUR / GALR
- PALR / PAUR (only needed for full duplex flow control)
- OPD (only needed for full duplex flow control)
- RCR
- TCR
- MSCR (optional)
- MIB_RAM (clear)
- FRSR (optional)
- EMRBR
- ERDSR
- ETDSR
- Transmit Descriptor ring (empty)
- Receive Descriptor ring (empty)

46.6.6 Microcontroller initialization

In the FEC, the descriptor control RISC initializes some registers after ECR[ETHER_EN] is asserted. After the microcontroller initialization sequence is complete, hardware is ready for operation.

The sequence is as follows:

1. Initialize the backoff random number seed.
2. Activate receiver.
3. Activate transmitter.

4. Clear transmit FIFO.
5. Clear receive FIFO.
6. Initialize the transmit ring pointer.
7. Initialize the receive ring pointer.
8. Initialize FIFO count registers.

46.6.7 User initialization (after setting ECR[ETHER_EN])

After setting ECR[ETHER_EN], you can set up the buffer/frame descriptors and write to TDAR and RDAR. See [Buffer descriptors](#), for more details.

46.6.8 Network interface options

The FEC supports an MII and reduced MII interface for 10/100 Mbps Ethernet, as well as a 7-wire serial interface for 10 Mbps Ethernet. The RCR[MII_MODE] and RCR[RMII_MODE] bits select the interface mode. In MII mode (RCR[MII_MODE]=1 and RCR[RMII_MODE]=0), there are 18 signals defined by the IEEE 802.3 standard and supported by the EMAC. The following table shows these signals.

Table 46-93. MII mode

Signal description	EMAC pin
Transmit Clock	FEC_TXCLK
Transmit Enable	FEC_TXEN
Transmit Data	FEC_TXD[3:0]
Transmit Error	FEC_TXER
Collision	FEC_COL
Carrier Sense	FEC_CRS
Receive Clock	FEC_RXCLK
Receive Data Valid	FEC_RXDV
Receive Data	FEC_RXD[3:0]
Receive Error	FEC_RXER
Management Data Clock	FEC_MDC
Management Data Input/Output	FEC_MDIO

In RMII mode (RCR[MII_MODE]=1 and RCR[RMII_MODE]=1), the EMAC supports 8 external signals. These signals are shown in the table below.

Table 46-94. RMII mode configuration

Signal description	EMAC pin
Reference Clock	FEC_TXCLK
Transmit Enable	FEC_TXEN
Transmit Data	FEC_TXD[1:0]
Receive Data Valid	FEC_RXDV
Receive Data	FEC_RXD[1:0]
Receive Error	FEC_RXER

The 7-wire serial mode interface (RCR[MII_MODE]=1 and RCR[RMII_MODE]=0 or 1) is generally referred to as AMD mode. The following table shows the 7-wire mode connections to the external transceiver.

Table 46-95. 7-Wire mode configuration

Signal description	EMAC pin
Transmit Clock	FEC_TXCLK
Transmit Enable	FEC_TXEN
Transmit Data	FEC_TXD[0]
Collision	FEC_COL
Receive Clock	FEC_RXCLK
Receive Data Valid	FEC_RXDV
Receive Data	FEC_RXD[0]

46.6.9 FEC frame transmission

The Ethernet transmitter is designed to work with almost no intervention from software. After ECR[ETHER_EN] is set and data appears in the transmit FIFO, the Ethernet MAC can transmit onto the network. The Ethernet controller transmits bytes least significant bit (lsb) first.

When the transmit FIFO fills to the watermark (defined by TFWR), MAC transmit logic asserts FEC_TXEN and starts transmitting the (PA) sequence, the start frame delimiter (SFD), and then the frame information from the FIFO. However, the controller defers the transmission if the network is busy (FEC_CRS is asserted). Before transmitting, the controller waits for carrier sense to become inactive, then determines if carrier sense stays inactive for 60 bit times. If so, transmission begins after waiting an additional 36 bit times (96 bit times after carrier sense originally became inactive). See "Transmission errors" for more details.

If a collision occurs during transmission of the frame (half duplex mode), the Ethernet controller follows the specified backoff procedures and attempts to retransmit the frame until the retry limit is reached. The transmit FIFO stores at least the first 64 bytes of the transmit frame, so they do not have to be retrieved from system memory in case of a collision. This improves bus utilization and latency in case immediate retransmission is necessary.

When all the frame data is transmitted, FCS (frame check sequence) or 32-bit cyclic redundancy check (CRC) bytes are appended if the TC bit is set in the transmit frame control word. If the ABC bit is set in the transmit frame control word, a bad CRC is appended to the frame data regardless of the TC bit value. Following the transmission of the CRC, the Ethernet controller writes the frame status information to the MIB block. Transmit logic automatically pads short frames (if the TC bit in the transmit buffer descriptor for the end of frame buffer is set).

Settings in the EIMR determine interrupts generated to the buffer (TXB) and frame (TXF).

The transmit error interrupts are HBERR, BABT, LC, RL, and UN. If the transmit frame length exceeds MAX_FL bytes, BABT interrupt is asserted. However, the entire frame is transmitted (no truncation).

To pause transmission, set TCR[GTS] (graceful transmit stop). The FEC transmitter stops immediately if transmission is not in progress; otherwise, it continues transmission until the current frame finishes or terminates with a collision. After the transmitter has stopped, the GRA (graceful stop complete) interrupt is asserted. If TCR[GTS] is cleared, the FEC resumes transmission with the next frame.

46.6.9.1 Duplicate frame transmission

The FEC fetches transmit buffer descriptors (TxBDs) and the corresponding transmit data continuously until the transmit FIFO is full. It does not determine whether the TxBD to be fetched is already being processed internally (as a result of a wrap). As the FEC nears the end of the transmission of one frame, it begins to DMA the data for the next frame. To remain one BD ahead of the DMA, it also fetches the TxBD for the next frame. It is possible that the FEC fetches from memory a BD that has already been processed but not yet written back (it is read a second time with the R bit remains set). In this case, the data is fetched and transmitted again.

Using at least three TxBDs fixes this problem for large frames, but not for small frames. To ensure correct operation for large or small frames, one of the following must be true:

- The FEC software driver ensures that there is always at least one TxBD with the ready bit cleared.
- Every frame uses more than one TxBD and every TxBD but the last is written back immediately after the data is fetched.
- The FEC software driver ensures a minimum frame size, n . The minimum number of TxBDs is then $(\text{Tx FIFO Size} \div (n+4))$ rounded up to the nearest integer (though the result cannot be less than three). The default Tx FIFO size is 192 bytes; this size is programmable.

46.6.10 FEC frame reception

The FEC receiver works with almost no intervention from the host and can perform address recognition, CRC checking, short frame checking, and maximum frame length checking. The Ethernet controller receives serial data lsb first.

When the driver enables the FEC receiver by setting ECR[ETHER_EN], it immediately starts processing receive frames. When FEC_RXDV is asserted, the receiver first checks for a valid PA/SFD header. If the PA/SFD is valid, it is stripped and the receiver processes the frame. If a valid PA/SFD is not found, the frame is ignored.

In serial mode, the first 16 bit times of RX_D0 following assertion of FEC_RXDV are ignored. Following the first 16 bit times, the data sequence is checked for alternating 1/0s. If a 11 or 00 data sequence is detected during bit times 17 to 21, the remainder of the frame is ignored. After bit time 21, the data sequence is monitored for a valid SFD (11). If a 00 is detected, the frame is rejected. When a 11 is detected, the PA/SFD sequence is complete.

In MII mode, the receiver checks for at least one byte matching the SFD. Zero or more PA bytes may occur, but if a 00 bit sequence is detected prior to the SFD byte, the frame is ignored.

After the first 6 bytes of the frame are received, the FEC performs address recognition on the frame.

After a collision window (64 bytes) of data is received and if address recognition has not rejected the frame, the receive FIFO signals the frame is accepted and may be passed on to the DMA. If the frame is a runt (due to collision) or is rejected by address recognition, the receive FIFO is notified to reject the frame. Therefore, no collision fragments are presented to you except late collisions, which indicate serious LAN problems.

During reception, the Ethernet controller checks for various error conditions and after the entire frame is written into the FIFO, a 32-bit frame status word is written into the FIFO. This status word contains the M, BC, MC, LG, NO, CR, OV, and TR status bits, and the frame length. See "Reception errors" for more details.

Receive buffer (RXB) and frame interrupts (RFINT) may be generated if enabled by the EIMR register. A receive error interrupt is a babbling receiver error (BABR). Receive frames are not truncated if they exceed the max frame length (MAX_FL); however, the BABR interrupt occurs and the LG bit in the receive buffer descriptor (RxBD) is set. See [Ethernet Receive Buffer Descriptor \(RxBD\)](#), for more details.

When the receive frame is complete, the FEC sets the L-bit in the RxBD, writes the other frame status bits into the RxBD, and clears the E-bit. The Ethernet controller next generates a maskable interrupt (RFINT bit in EIR, maskable by RFIEN bit in EIMR), indicating that a frame is received and is in memory. The Ethernet controller then waits for a new frame.

46.6.11 Ethernet address recognition

The FEC filters the received frames based on destination address (DA) type — individual (unicast), group (multicast), or broadcast (all-ones group address). The difference between an individual address and a group address is determined by the I/G bit in the destination address field. A flowchart for address recognition on received frames appears in the figures below.

Address recognition is accomplished through the use of the receive block and microcode running on the microcontroller. The flowchart shown in [Figure 46-84](#) illustrates the address recognition decisions made by the receive block, while [Figure 46-85](#) illustrates the decisions made by the microcontroller.

If the DA is a broadcast address and broadcast reject (RCR[BC_REJ]) is cleared, then the frame is accepted unconditionally, as shown in [Figure 46-84](#). Otherwise, if the DA is not a broadcast address, then the microcontroller runs the address recognition subroutine, as shown in [Figure 46-85](#).

If the DA is a group (multicast) address and flow control is disabled, then the microcontroller performs a group hash table lookup using the 64-entry hash table programmed in GAUR and GALR. If a hash match occurs, the receiver accepts the frame.

If flow control is enabled, the microcontroller does an exact address match check between the DA and the designated PAUSE DA (01:80:C2:00:00:01). If the receive block determines the received frame is a valid PAUSE frame, the frame is rejected. The receiver detects a PAUSE frame with the DA field set to the designated PAUSE DA or the unicast physical address.

If the DA is the individual (unicast) address, the microcontroller performs an individual exact match comparison between the DA and 48-bit physical address that you program in the PALR and PAUR registers. If an exact match occurs, the frame is accepted; otherwise, the microcontroller does an individual hash table lookup using the 64-entry hash table programmed in registers, IAUR and IALR. In the case of an individual hash match, the frame is accepted. Again, the receiver accepts or rejects the frame based on PAUSE frame detection, shown in [Figure 46-84](#).

If neither a hash match (group or individual) nor an exact match (group or individual) occur, and if promiscuous mode is enabled (RCR[PROM] set), the frame is accepted and the MISS bit in the receive buffer descriptor is set; otherwise, the frame is rejected.

Similarly, if the DA is a broadcast address, broadcast reject (RCR[BC_REJ]) is asserted, and promiscuous mode is enabled, the frame is accepted and the MISS bit in the receive buffer descriptor is set; otherwise, the frame is rejected.

In general, when a frame is rejected, it is flushed from the FIFO.

**Notes:**

BC_REJ - field in RCR register (BroadCast REJect)

PROM - field in RCR register (PROMiscuous mode)

Pause Frame - valid PAUSE frame received

Figure 46-84. Ethernet address recognition—receive block decisions

**Notes:**

FCE - field in RCR register (flow control enable)

I/G - Individual/Group bit in destination address (lsb in first byte received in MAC frame)

Figure 46-85. Ethernet address recognition—microcode decisions

46.6.12 Hash algorithm

The hash table algorithm used in the group and individual hash filtering operates as follows. The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits stored in GAUR, GALR (group address hash match), or IAUR, IALR (individual address hash match). This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63. The msb of the CRC result selects GAUR (msb = 1) or GALR (msb = 0). The five least significant bits of the hash result select the bit within the selected register. If the CRC generator selects a bit set in the hash table, the frame is accepted; otherwise, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$$

Figure 46-86. CRC32 polynomial for hash computation

The following table contains example destination addresses and corresponding hash values.

Table 46-96. Destination address to 6-bit hash

48-BIT DA	6-bit hash (in hex)	Hash decimal value

46.6.13 Full duplex flow control

Full-duplex flow control allows you to transmit pause frames and to detect received pause frames. Upon detection of a pause frame, MAC data frame transmission stops for a given pause duration.

To enable PAUSE frame detection, the FEC must operate in full-duplex mode (TCR[FDEN] set) with flow control (RCR[FCE] set). The FEC detects a pause frame when the fields of the incoming frame match the pause frame specifications, as shown in the following table. In addition, the receive status associated with the frame should indicate that the frame is valid.

Table 46-97. PAUSE frame field specification

48-bit destination address	0180_C200_0001h or Physical Address
48-bit source address	Any
16-bit type	8808h
16-bit opcode	0001h
16-bit PAUSE duration	0000h — FFFFh

The receiver and microcontroller modules perform PAUSE frame detection. The microcontroller runs an address recognition subroutine to detect the specified pause frame destination address, while the receiver detects the type and opcode pause frame fields. On detection of a pause frame, TCR[GTS] is set by the FEC internally. When transmission has paused, the EIR[GRA] interrupt is asserted and the pause timer begins to increment. The pause timer uses the transmit backoff timer hardware for tracking the appropriate collision backoff time in half-duplex mode. The pause timer increments once every slot time, until OPD[PAUSE_DUR] slot times have expired. On OPD[PAUSE_DUR] expiration, TCR[GTS] is cleared allowing MAC data frame transmission to resume. The receive flow control pause status bit (TCR[RFC_PAUSE]) is set while the transmitter pauses due to reception of a pause frame.

To transmit a pause frame, the FEC must operate in full-duplex mode and you must set flow control pause (TCR[TFC_PAUSE]). After TCR[TFC_PAUSE] is set, the transmitter sets TCR[GTS] internally. When the transmission of data frames stops, the EIR[GRA] (graceful stop complete) interrupt asserts and the pause frame is transmitted. TCR[TFC_PAUSE,GTS] are then cleared internally.

You must specify the desired pause duration in the OPD register.

When the transmitter pauses due to receiver/microcontroller pause frame detection, TCR[TFC_PAUSE] may remain set and cause the transmission of a single pause frame. In this case, the EIR[GRA] interrupt is not asserted.

46.6.14 Inter-Packet Gap (IPG) time

The minimum inter-packet gap time for back-to-back transmission is 96 bit times. After completing a transmission or after the backoff algorithm completes, the transmitter waits for carrier sense to be negated before starting its 96 bit time IPG counter. Frame transmission may begin 96 bit times after carrier sense is negated if it stays negated for at least 60 bit times. If carrier sense asserts during the last 36 bit times, it is ignored and a collision occurs.

The receiver accepts back-to-back frames with a minimum spacing of at least 28 bit times. If an inter-packet gap between receive frames is less than 28 bit times, the receiver may discard the following frame.

46.6.15 Collision managing

If a collision occurs during frame transmission, the Ethernet controller continues the transmission for at least 32 bit times, transmitting a JAM pattern consisting of 32 ones. If the collision occurs during the sequence, a JAM pattern is sent after the end of the preamble sequence.

If a collision occurs within 512 bit times (one slot time), the retry process is initiated. The transmitter waits a random number of slot times. If a collision occurs after 512 bit times, then no retransmission is performed and the end of frame buffer is closed with a Late Collision (LC) error indication.

46.6.16 MII internal and external loopback

Internal and external loopback are supported by the Ethernet controller. In loopback mode, both of the FIFOs are used and the FEC actually operates in a full-duplex fashion. Internal and external loopback are configured using combinations of the RCR[LOOP, DRT] and TCR[FDEN] bits.

Set FDEN for internal and external loopback.

For internal loopback, set RCR[LOOP] and clear RCR[DRT]. FEC_TXEN and FEC_TXER do not assert during internal loopback. During internal loopback, the transmit/receive data rate is higher than in normal operation because the transmit and receive blocks use the internal bus clock instead of the clocks from the external transceiver. This causes an increase in the required system bus bandwidth for transmit

and receive data being DMA'd to/from external memory. It may be necessary to pace the frames on the transmit side and/or limit the size of the frames to prevent transmit FIFO underruns and receive FIFO overflows.

For external loopback, clear RCR[LOOP] and RCR[DRT], and configure the external transceiver for loopback.

46.6.17 RMII loopback

The FEC also supports RMII loopback. In this mode, transmit data is sent to the RMII receive logic and out the FEC_TXD[1:0] pins. To enable RMII loopback mode, set RCR[RMII_MODE, RMII_LOOP] and TCR[FDEN] and clear RCR[RMII_ECHO, LOOP].

Figure 46-87. RMII loopback mode

46.6.18 RMII echo

The Ethernet controller also supports RMII echo mode, which transmits data on FEC_TXD[1:0] as it is received on FEC_RXD[1:0]. To enable RMII echo mode, set RCR[RMII_MODE, RMII_ECHO] bits and clear RCR[RMII_LOOP, LOOP].

Figure 46-88. RMII echo mode

46.6.19 Ethernet error-managing procedure

The Ethernet controller reports frame reception and transmission error conditions using the MIB block counters, the FEC RxBDs, and the EIR register.

46.6.19.1 Transmission errors

46.6.19.1.1 Transmitter underrun

If this error occurs, the FEC sends 32 bits that ensure a CRC error and stops transmitting. All remaining buffers for that frame are then flushed and closed, and EIR[UN] is set. The FEC then continues to the next transmit buffer descriptor and begin transmitting the next frame. The UN interrupt is asserted if enabled in the EIMR register.

46.6.19.1.2 Retransmission attempts limit expired

When this error occurs, the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and EIR[RL] is set. The FEC then continues to the next transmit buffer descriptor and begins transmitting the next frame. The RL interrupt is asserted if enabled in the EIMR register.

46.6.19.1.3 Late collision

When a collision occurs after the slot time (512 bits starting at the Preamble), the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and EIR[LC] is set. The FEC then continues to the next transmit buffer descriptor and begins transmitting the next frame. The LC interrupt is asserted if enabled in the EIMR register.

46.6.19.1.4 Heartbeat

Some transceivers have a self-test feature called heartbeat or signal quality error. To signify a good self-test, the transceiver indicates a collision to the FEC within four microseconds after completion of a frame transmitted by the Ethernet controller. This indication of a collision does not imply a real collision error on the network, but is rather an indication that the transceiver continues to function properly. This is the heartbeat condition.

If TCR[HBC] is set and the heartbeat condition is not detected by the FEC after a frame transmission, a heartbeat error occurs. When this error occurs, the FEC closes the buffer, sets EIR[HB], and generates the HBERR interrupt if it is enabled.

46.6.19.2 Reception errors

46.6.19.2.1 Overrun error

If the receive block has data to put into the receive FIFO and the receive FIFO is full, FEC sets RxBD[OV]. All subsequent data in the frame is discarded and subsequent frames may also be discarded until the receive FIFO is serviced by the DMA and space is made available. At this point the receive frame/status word is written into the FIFO with the OV bit set. The driver must discard this frame.

46.6.19.2.2 Non-octet error (dribbling bits)

The Ethernet controller manages up to seven dribbling bits when the receive frame terminates past a non-octet aligned boundary. Dribbling bits are not used in the CRC calculation. If there is a CRC error, the frame non-octet aligned (NO) error is reported in the RxBD. If there is no CRC error, no error is reported.

46.6.19.2.3 CRC error

When a CRC error occurs with no dribble bits, FEC closes the buffer and sets RxBD[CR]. CRC checking cannot be disabled, but the CRC error can be ignored if checking is not required.

46.6.19.2.4 Frame length violation

When the receive frame length exceeds MAX_FL bytes the BABR interrupt is generated, and RxBD[LG] is set. The frame is not truncated unless the frame length exceeds 2047 bytes.

46.6.19.2.5 Truncation

When the receive frame length exceeds 2047 bytes, frame is truncated and RxBD[TR] is set.

Chapter 47

Peripheral Sensor Interface (PSI5)

47.1 Chip-specific PSI5 information

This chip has two instances of the PSI5 module. The two instances are located on different Peripheral Bridges.

Table 47-1. PSI5 module instances

PSI5 instance	Number of channels	Master or slave operation
PSI5_0	1	Master
PSI5_1	1	Slave

47.1.1 PSI5 GTM interface

The following table identifies the PSI5 connections with eTPU_C, which this chapter refers to as the general timer module (GTM).

Table 47-2. PSI5 GTM connections

Source		Destination		Description
Instance	Pin	Instance	Pin	
eTPU_C	Output channel 14	PSI5_0	GTM reset	eTPU_C channel 14 ¹
eTPU_C	Output channel 13	PSI5_0	GTM event	eTPU_C channel 13
eTPU_C	Output channel 14	PSI5_1	GTM reset	eTPU_C channel 14 ¹
eTPU_C	Output channel 19	PSI5_1	GTM event	eTPU_C channel 19

1. Both PSI5 instances use the same eTPU_C channel.

47.1.2 Detection of PSI5 SMC messages

On this chip, a PSI5 interrupt for received SMC messages is not mapped to an interrupt vector. To detect when each SFR receives and is ready with a new valid SMC message, poll the bits in the GISR[IS_NVSM] field.

47.2 Introduction

The PSI5 interface offers power supply and data transfer between the application and multiple sensors over a two-wire interface. Data transmission from the application to the sensor or sensors is achieved through modulation of the power supply voltage (sync pulse). Data reception from the sensor or sensors to the application is achieved through modulation of the current drawn by a sensor using Manchester encoding.

At the system level, the PSI5 interface consists of mechanisms integrated on the microcontroller and an external physical layer that provides the high-voltage supply and converts the current drawn by the sensor into a digital Manchester-encoded data stream.

47.2.1 Overview

The PSI5 is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of safety airbag systems. The technical characteristics, the low implementation overhead, as well as the attractive cost make the PSI5 also suitable for many other automotive sensor applications. The development goal of the PSI5 is a flexible, reliable communication standard for automotive sensor applications that can be used and implemented free of charge.

The main features of the PSI5 are high-speed and high-reliability data transfer at the lowest possible implementation overhead cost, offering a universal and flexible solution for multiple sensor applications. The main features of PSI5 standard are:

- Two-wire current interface
- Manchester-coded digital data transmission from sensor to ECU
- High data transmission speed of 125 Kbit/s
- High EMC robustness and low emission
- Wide range of sensor supply current
- Configurable data word length (8 to 28 bits)

- Asynchronous or synchronous operation
- Bidirectional communication

In short, PSI5 standardizes the low-level communication between peripheral sensors and electronic control units. Note that the physical layer for the IP (transceiver) is to be implemented separately outside the IP.

Figure 47-1. PSI5 digital interface block diagram

47.2.2 Features

- IPS interface for register read/write (big endian)

- Supports bidirectional full duplex operations, but with differing baud rate—low, ECU-to-sensor, fast sensor to ECU
- Manchester decoder operating at 125 Kbit/s bit rate with $\times 32$ sample clock rate
- One 64-bit sensor data receive register to which the decoded received sensor data—including header, data, timestamp, frame counter, status bits (E, EM, T, C, F) and CRC, but not including start bits—are written
- A 24-bit time stamp register with a 1 μ s resolution. When first rising edge of start bits (S0) of a message or the rising edge of the SYNC pulse is recognized, the value in the time stamp register will be written to the data receive register
- Provision of resetting the Time Stamp Counter through the reset from the GTM module
- Single 32×64 -bit RAM buffer for storing (moving) content of the data receive register once end of message is recognized
 - Related to each RAM buffer are two diagnostic registers, N and EI. Register N is used to identify the occurrence of new messages in the corresponding RAM buffer, while register EI identifies the error status of these messages. The errors that can set the EI register bits are the F (no frame), E (electrical error), EM (electrical error for SMC bits embedded in PSI5 messages), T (Timing bit error) and C (CRC error). Which of these errors actually set the EI register bits is configurable.
- DMA support for transferring RAM data (including diagnostic data) to system memory
- Support for optional serial messaging channel (SMC) and additional logic to extract SMC frames from PSI5 frames
- Operating modes supported:
 - Asynchronous mode (sensor periodically sends data, no sync pulse, one sensor per interface)
 - Synchronous mode (sync pulse generated, multiple sensor per interface)
- Sync pulse generation for synchronous modes
 - The start of each time slot (1 to 6) (see [Figure 47-128](#)) on the bus (after the end of the sync pulse) can be defined with a 1 μ s resolution

- The end of the last time slot on the bus can be defined with a 1 μ s resolution, up to a maximum sync period time of 16 ms
- Trigger logic to generate sync pulses
 - 16-bit Channel Trigger Counter (CTC) used to generate the sync pulses by comparing the values with CIPR and CTPR
 - Counter Initialize Pulse Register (CIPR) to allow configuration of initialization (offset) period
 - Channel Trigger Period (CTP) register to allow configuration of sync period. Value in CTP is the value to which the CTC is updated after each sync pulse generation
 - Possibility to have a common 1 MHz clock source
- An upstream register bit chain consisting of Preparation Register, Buffer Register, Shift register (output data) and pulse width modulation logic, is implemented. Using this, it is possible to send a data word to the sensors through use of data sync pulses: logic 1 with programmable data sync pulse width W1, logic 0 with programmable data sync pulse width W0. The data sync pulse timing can be configured to be dependent on the periodic or event driven timing SYNC pulse. Further, there is no difference between timing sync pulse and data sync pulse during transmission (ECU-to-sensor communication).

47.2.3 Modes of operation

47.2.3.1 Disable mode

Disable mode in the PSI5 reduces power consumption. This mode is entered by setting GCR[GLOBAL_DISABLE_REQ]. All the channels enter Disable mode at once when this bit is set, irrespective of the setting of PCCR[PSI5_CH_EN] and PCCR[PSI5_CH_CONFIG]. In this mode the RX, TX and common time base counters are disabled for any operation. This is the default state after module reset is released. PSI5 can exit Disable mode by clearing the GLOBAL_DISABLE_REQ bit and enabling individual PSI5 channels (setting PCCR[PSI5_CH_EN]). Note that when entering Disable mode from any other mode, the register contents are retained and are not changed. The time stamp counter AND the internal sync pulse generator are, however, reset when entering Disable mode.

There is no software reset bit in the PSI5 module. The same has to be managed outside the IP at the system level. Channels will enter "Configuration/Normal mode" based on the value of PCCR[PSI5_CH_CONFIG].

47.2.3.2 Initialization/Configuration mode

This is the configuration phase, in which, all PSI5 global, channel specific configuration/control registers can be written. The receiver and transmitter sub-blocks are disabled in this mode. The message receive registers/buffers can be accessed in this mode. This mode can be entered by clearing GCR[GLOBAL_DISABLE_REQ] and setting PCCR[PSI5_CH_CONFIG] and PCCR[PSI5_CH_EN].

47.2.3.3 Normal mode (NORMAL mode)

In Normal mode, the receiver and the transmitter blocks become active, error handling is enabled and all the PSI5 protocol functions are also enabled. In this mode, all the PSI5 global and channel-specific configuration registers are locked for writing, although these registers can still be read. Data Preparation Register, Shift Register and data output registers are writable in this mode. Apart from them, there are some register bits that can be written in this mode also. Please refer to the detailed register description. This mode can be entered clearing GCR[GLOBAL_DISABLE_REQ], clearing PCCR[PSI5_CH_CONFIG], and setting PCCR[PSI5_CH_EN].

47.2.3.3.1 PSI5 topology

The different PSI5 user operation modes define topology and parameters of the communication between ECU and sensors such as communication mode, number of data bits, error detection, cycle time, number of time slots per cycle, and bit rate.

These modes are generally denoted as

PSI5-(A / P / U / D)-dd-(P / CRC)-tttt / n(L / H)

The following figure provides a key for these notations.

Table 47-3. Normal operating states

Communication modes		Description
A	Asynchronous mode	PSI5-A describes a point-to-point connection for unidirectional, asynchronous data transmission. Each sensor is connected to the ECU by two wires. After switching on the power supply, the sensor starts transmitting data to the ECU periodically. Timing and repetition rate of the data transmission are controlled by the sensor. No Sync pulse is send from ECU side.
P	Synchronous Parallel Bus mode	The synchronous operation modes work according to the TDMA method (Time Division Multiple Access). Each sensor is connected to the ECU by two wires. The sensor data transmission is synchronized by the ECU using voltage modulation. Synchronization (sync pulses) can be optionally used for point-to-point configurations; it is mandatory for bus modes. The sensors can be arranged as parallel bus, universal bus and daisy chain topology based on sensor addressing and interchangeability of sensors.
U	Synchronous Universal Bus mode	
D	Synchronous Daisy Chain Bus mode	
Data Bits		
dd	No. of data bits	
Error Detection		
P	1 parity bit	
CRC	3-bit Cyclic Redundancy Check (CRC)	
Cycle Time		
tttt	Cycle Time in μ s	
n	Number of time slots per cycle	
Bit Rate		
L	125 Kbit/s	

47.2.3.4 Debug mode

In order to enter this mode the debugger has to be connected and it has to encounter a breakpoint. In addition, the `DEBUG_EN` bit has to be written to 1. The `DEBUG_EN` bit can be written by either the CPU or by the debugger but only in Configuration mode. Once the above conditions are satisfied the IP enters the Debug Mode. There are two debugging modes available. For simplicity these are being referred to as the “Freeze” and “Open” modes. The IP enters one of the above debugging modes, based on the configuration of a register bit `DEBUG_FREEZE_CTRL` mentioned in the Section 54.3.2.2, PSI5 Channel Control Register (`PSI5_PCCR`).

In Open mode, the core of the IP keeps on working normally and all the registers are updated from the hardware; just like they were being done in the functional mode (when the IP was out of the debug mode). Thus, even a long term entry to the Debug Mode,

won't affect the normal operation of the various registers that are to be updated by the hardware. Down side is that the IP can keep on changing the internal status bits and the registers as the time progresses.

In both the above modes, the various interface registers would be completely visible to the debugger, but debugger action would have no impact on the various status bits and counters that normally get affected by a CPU/DMA read. In this mode, the read pointers of the FIFO do not get incremented, when being read through the Pop-up registers. Thus in Debug mode, reading the DMA PSI5 Message Register (PSI5_DPMR), DMA SMC Frame Register (PSI5_DSFR) or the DMA Diagnostic Status Register (PSI5_DDSR) would keep on returning the same data. Hence the interrupts related to DMA completion operation would not get generated. Further the hardware clearing related to FAST_CLR_SMC and FAST_CLR_PSI5 bits would not have any effect and the hardware clearing would remain disabled. This is also highlighted in the following figure.

47.2.3.5 Operating modes

Figure 47-2. Operating modes

Table 47-4. State transition Table

GCR [GLOBAL_DISABLE_REQ]	PCCR		State	
	[PSI5_CH_CONFIG]	[PSI5_CH_EN]	Present	Next
1	x	x	x	All channel Disable
0	x	0	x	Specific channel Disable
0	1	1	Disable	Config
0	0	1	Config	Normal
0	x	1	Normal	Normal
0	0	1	Disable	Normal

47.3 External signal description

External signal description.

Table 47-5. PSI5 port list

Name	Function	I/O	Reset	Pullup
Signals to/from pads				
SDINn_PSI5_m ^{1, 1}	Digital sensor data input pin of PSI5 module	I	0	Active
SDOUTn_PSI5_m ¹	Digital sensor data output pin of PSI5 module (sync pulse + data)	O	0	Passive

1. “n” is the Channel Number and “m” is the Module Instance Number.

47.4 Memory map and register description

The module memory map is shown below.

Unless specifically stated, the register bits are readable in all modes, but writable only in Config mode.

Note that , an access(read/write) to any register in the unimplemented register space will result in the generation of transfer error . All word locations are byte/half word/word accessible for write. Read is always a word access. Trying to do a word operation on 16-bit registers will NOT result in the generation of any transfer error. Trying to write to

"read only" bits of implemented register space, will be ignored without the generation of any error. Trying to write to any register outside its intended mode of write(Normal/config) will be ignored without the generation of any transfer error.

For a summary of the register bit accesses in various device modes, please see [Device modes and Register bit accesses](#)

47.4.1 Global Control Register (PSI5_GCR)

The Global Control Register (PSI5_GCR)¹ provides control functions for all the PSI5 channels simultaneously.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7
Read	0							
Write								
Reset	0	0	0	0	0	0	0	
Bit	8	9	10	11	12	13	14	15
Read	0						CTC_GED	GLOBAL_DISABLE_REQ
Write								
Reset	0	0	0	0	0	0	0	

PSI5_GCR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 CTC_GED	Channel Target Counter (CTC) Global Enable/Disable. NOTE: This bit is writable in all modes.

Table continues on the next page...

PSI5_GCR field descriptions (continued)

Field	Description
	0 All the CTC counters having PCCR[CTC_GED_SEL] = 1 are reset. 1 Simultaneously starts the CTC of all the channels that have PCCR[CTC_GED_SEL] = 1.
15 GLOBAL_DISABLE_REQ	PSI5 Receive Global disable request. When set, all PSI5 channels enter Disable mode (from individual Normal or Config modes) regardless of the settings of the PCCR[PSI5_CH_CONFIG] and PCCR[PSI5_CH_EN] bits. When cleared, each PSI5 channel enters Config mode or Normal mode based on the setting of the PCCR[PSI5_CH_CONFIG] bit if PCCR[PSI5_CH_CONFIG] is set for that channel; otherwise, that particular channel continues to stay in Disable mode. The reset value is dependent on the parameter PSI5_PDIS_RST. When PSI5_PDIS_RST = 0, then the reset value is "0" (PSI5 module is enabled after reset). Note that when GLOBAL_DISABLE_REQ == 1, then all the clock enables (shown in Figure 1) from the IP go to a 0 (inactive) state. This bit is writable in all the modes. 0 PSI5 channel(s) enters Normal or Config mode, depending on the value of the PCCR[PSI5_CH_CONFIG] bit. 1 All PSI5 Channels are in Disable mode.

1. This register is not present if the specific instance is configured as a slave. Master or slave configuration of the specific PSI5 instance decides if the operating mode (DISABLE/CONFIG/NORMAL) as well as the staggering of the channels can be controlled independently. If the instance is configured as a master, then it controls its own operating mode, staggering of all the channels in that instance and the operating mode and the staggering of any associated slave instance. If the instance is configured as a slave, then its operating mode and staggering can only be controlled by another master instance. Please refer to the Device Configuration Chapter for instance specific details.

47.4.2 PSI5 Channel Control Register (PSI5_CH0_PCCR)

This section shows the PSI5 Channel Control Register.

Address: 0h base + 8h offset = 8h

PSI5_CH0_PCCR field descriptions

Field	Description
0 CTC_GED_SEL	Channel Target Counter, Global Enable/Disable Select. This bit selects whether the CTC should be enabled/disabled by CTC_GED bit (in GCR) or the CTC_ED bit. Enabling by the CTC_GED bit is used when staggering of the channels is required. NOTE: This bit is writable only in Config mode. 0 CTC enabled disabled by CTC_ED. 1 CTC enabled/disabled by CTC_GED.
1 CTC_ED	Channel Target Counter Enable/Disable. This bit is used to control the CTC locally from the channel in case the CTC_GED_SEL = 0. NOTE: This bit is writable only in Normal mode and the Config mode. 0 The CTC counters is disabled and reset. 1 The CTC counter is enabled and start counting.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 MEM_DEPTH	Can be programmed from 0 to 31 and denotes the size of the memory that should be used for storing the PSI5 messages. Area above the MEM_DEPTH is treated as being unavailable for message storage.

Table continues on the next page...

PSI5_CH0_PCCR field descriptions (continued)

Field	Description
	MEM_DEPTH also denotes the number of RAM registers available for the CPU access. Note that the same memory can be accessed sequentially (though the DMA) or randomly anytime by the CPU. 0: it indicates that only 1 location of the memory is available for storage 31: it indicates that all the 32 locations of the memory are available for storage. Notes: - Depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR, the MEM_DEPTH memory size may be accessed by CPU only (interrupts are generated) or CPU and DMA (through the dedicated DMA popup registers). - DMA_PM_DS_CONFIG = conf1 then DMA requests are disabled and only the interrupts can be used for data transfer. - DMA_PM_DS_CONFIG = conf2,conf3,conf4 then DMA requests are enabled. The interrupts should be disabled by writing a 0 in the corresponding IE bits. - For more details please refer to description of DMA_PM_DS_CONFIG in the DCRs. - The data in the memory area defined by the MEM_DEPTH parameter is always filled in a sequential fashion as in a FIFO, but can be read sequentially or randomly. There can be no slot-memory location correspondence due to the T bit errors in the manchester decoder. - The memory area above the configured MEM_DEPTH size will always be read as 0. - Irrespective of the configuration, the data can always be randomly read by the CPU from the PMRL/PMRH register. NOTE: This bit is writable only in Config mode.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 ERROR_SELECT4	The ERROR_SELECT bitfield indicates which of the C, E, EM, T, or F error conditions generate an interrupt when the EICR Interrupt Enable bit is set. The individual bits are mapped as {C,E,EM,T,F}. The corresponding error is also latched in the PSI5_EISR. Default: ERROR_SELECT = 11111: Any of C,E,EM,T,or F generate an interrupt. C error CRC Error (C) Bit 20: ERROR_SELECT[4] or C_INT_SEL NOTE: This bit is writable only in Config mode. 0 The C bit does not generate an interrupt. 1 The C bit generates an interrupt.
12 ERROR_SELECT3	Error_Select[3] or E_INT_SEL E error Electrical Error (E) NOTE: This bit is writable only in Config mode. 0 The E bit does not generate an interrupt. 1 The E bit generates an interrupt.
13 ERROR_SELECT2	Error_Select[2] or EM_INT_SEL NOTE: This bit is writable only in Config mode.

Table continues on the next page...

PSI5_CH0_PCCR field descriptions (continued)

Field	Description
	0 The EM bit does not generate an interrupt. 1 The EM bit generates an interrupt.
14 ERROR_SELECT1	Error_Select[1] or T_INT_SEL NOTE: This bit is writable only in Config mode. 0 The T bit does not generate an interrupt. 1 The T bit generates an interrupt.
15 ERROR_SELECT0	Error_Select[0] or F_INT_SEL NOTE: This bit is writable only in Config mode. 0 The F bit does not generate an interrupt. 1 The F bit generates an interrupt.
16 Reserved	This field is reserved.
17 GTM_RESET_ASYNC_EN	GTM_RESET_ASYNC_EN NOTE: This bit is writable only in Config mode. 0 Both the assertion and the deassertion of the GTM reset are treated synchronously. Inside the IP the gtm reset is synchronized on the SP_TS_CLK. 1 Assertion of the GTM reset is treated asynchronously but deassertion is synchronized on the SP_TS_CLK.(For details of SP_TS_CLK, refer to bit 23 of) PSI5 Channel Control Register (PSI5_CH0_PCCR)
18–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 DEBUG_EN	This bit allows/prevents the IP from entering the debug mode, whenever the debugger is connected and a breakpoint is encountered by the debugger: NOTE: This bit is writable only in Config mode. 0 The IP never enters the debug mode, even if the debugger is connected and a breakpoint is encountered. It keeps on working normally, as in the functional mode. 1 Whenever the debugger is connected and a breakpoint is encountered, the IP enters the debug mode. In the Debug mode, the DMA read pointers and other status registers that normally get affected by the READ operation remain unaffected.
22 DEBUG_FREEZE_CTRL	DEBUG_FREEZE_CTRL NOTE: This bit is writable only in Config mode.

Table continues on the next page...

PSI5_CH0_PCCR field descriptions (continued)

Field	Description
	0 When the IP enters the Debug mode then it goes into the “Open” mode, i.e., the core of the IP keeps on working normally. In this case, there can be a difference between the value of a particular status bit, which is there at the time Debug mode is entered and the time at which the debugger reads it, since some upcoming events might change the status. The hardware clearing, of course, remains disabled. NOTE: In the above configuration, the status of registers read through the debugger may be different when entering debug mode and when actually accessing registers at some later point of time. 1 As soon as debug mode is asserted, the state of the system registers that are affected by the hardware gets frozen to what ever it was existing at the point at which the Debug mode goes active. This can be useful for reading the state of the system at a particular point of time such that it is NOT affected by the next upcoming events. Note that Manchester decoder/ Sync Pulse Generator/ Time Stamp counters keep on working normally but the registers (data/status/timestamp) affected by these are not updated. When the IP enters the “Debug mode” then it goes into the “Freeze Mode”. Note that whenever there is a request to enter the freeze mode then the IP enters this mode, ONLY when the Manchester decoder and the Sync Pulse Generator are stopped coherently. This means that before entering the “freeze mode”, if there is any pending reception that is ongoing, then the same is completed first. Simultaneously the “sdout” line of the IP should be at a low level. Once these two conditions are satisfied, the IP enters the Debug Freeze mode. The Time Stamp counters are also halted. The fact that the freeze mode has been entered, can be checked by reading the GISR[IS_DB_FR] bit. Once the IP comes out of the freeze mode then this bit goes to 0. NOTE: In the above configuration, incoming packets could get lost while the Debug mode is active.
23 SP_TS_CLK_SEL	This bit controls which clock goes to the Sync Pulse and Time Stamp Generator Unit. NOTE: The above selection affects ONLY the clock for the Time Stamp Unit and Sync Pulse Generator. The 1 MHz clock to the rest of the logic like the Manchester decoder or the Slot Boundary Counters is still the 1 MHz from the common clock generator module. NOTE: The clock selected using this bit is called SP_TS_CLK. 0 The 1 MHz clock generated from the common clock generator module goes for clocking the Time Stamp Unit and sync pulse generator. 1 Reserved.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 FAST_CLR_SMC	This bit controls the clearing mechanism of the IS_NVSM[x], IS_CESM[x], and IS_OWSM[x] bits in the GISR. NOTE: This bit is effective only when DCR[DMA_EN_SF] = 1. When FAST_CLR_SMC = 1 then the IS_NVSM[x], IS_CESM[x], and IS_OWSM[x] bits are automatically cleared upon reading the DSFR message register, as per the slot[x] message read in from the DSFR. When reading directly from the SFR registers, this bit does not affect auto clearing. If FAST_CLR_SMC = 0 then the above bits have to be cleared by a w1c. NOTE: This bit is writable only in Config mode. 0 Fast clearing is disabled (clear when written to 1). 1 Fast clearing is enabled.
27 FAST_CLR_PSI5	This bit control the clearing mechanism of bits in NDSR(in conf2, conf3 and conf4 modes), EISR (in conf2, conf3 and conf4 modes), and OWSR(in conf2 and conf3 modes). NOTE: This bit is effective only when DMA_PM_DS_CONFIG = conf2, conf3, or conf4 else this bit has no effect and only software clearing is available. Further, though the OWSR is not directly read by

Table continues on the next page...

PSI5_CH0_PCCR field descriptions (continued)

Field	Description
	the DMA as a single register, it is cleared in specific modes (when FAST_CLR_PSI5 == 1) as can be seen below. Following are the details in the various modes of the DCR[DMA_PM_DS_CONFIG] bits: • In conf1 mode: This bit has no effect. Reading the DDSR and the DPMR returns a 0. • In conf2 mode: In this case the diagnostic bits (EISR, NDSR) are cleared ONLY when the diagnostic registers appended with the corresponding PSI5 messages are completely read using the DPMR. During the intermediate operation (when the PSI5 message has been read but the diagnostic bits are still pending), the PSI5 message read from the DPMR will not clear these bits. Both of these registers are simultaneously cleared when the corresponding DMA operation is over. However, only those bits are cleared, the corresponding messages of which form the part of the DMA request being serviced. Note that the OWSR bits are cleared upon the corresponding PSI5 message read from the DPMR. Reading the DDSR returns a 0 in this mode. • In conf3 mode: The PSI5 diagnostic register bits (EISR,NDSR) and OWSR are automatically cleared when the corresponding PSI5 message is read from the DPMR. The specific register bits of EISR,NDSR and OWSR, corresponding to each message, are cleared sequentially one by one as the corresponding message is being read by the DMA. Note that the three bits (each of EISR, NDSR, and OWSR) corresponding to a specific location are always cleared simultaneously. Reading the DDSR returns a 0. When reading from the PMRH/PMRL registers, this bit does not have any effect on fast clearing. • In conf4 mode: In this case the diagnostic bits (EISR, NDSR) are cleared as soon as these registers are read through the DDSR. These registers are cleared simultaneously in one go, as soon as the corresponding DMA request has been serviced. Only those bits of these registers are cleared, the messages of which form a part of the DMA request. Note that in this mode the reading of the PSI5 messages from the DMA is not available as the request is being used for reading the diagnostic registers. Reading the DPMR returns a 0. The PSI5 messages can be read only from the PMRH/PMRL register. Hence the OWSR has to be cleared only by w1c. • In all the above modes, when reading from the PMRH/PMRL registers, the FAST_CLR_PSI5 does not have any effect on fast clearing. • Further, In all the above cases if FAST_CLR_PSI5 = 0 then the specific diagnostic bits and the OWSR have to be cleared by w1c. NOTE: This bit is writable only in Config mode. 1 Fast Clearing Enabled 0 Fast Clearing Disables (clear when written to 1)
28 BIT_RATE	Bit Rate This bit selects the receive message bit rate (T bit) for this particular PSI5 Channel, that is, it selects the 4 MHz driven clock in the common clock generator module. NOTE: This bit is writable only in Config mode. 0 125 Kbit/s bit rate selected (4 MHz clock). 1 Reserved
29 MODE	This bit selects the operating modes. NOTE: This bit is writable only in Config mode.

Table continues on the next page...

PSI5_CH0_PCCR field descriptions (continued)

Field	Description
	0 Asynchronous operating mode (Integrated sync pulse generator module is switched off, only RX active). Note that in this mode the sync pulses from the internal sync pulse generator or the GTM are not allowed to be propagated to the output path, which always remains at logic 0. There is no T-bit error in the Asynchronous mode. 1 Synchronous operating modes (Integrated sync pulse generator module is switched on, both TX and RX subblocks active).
30 PSI5_CH_CONFIG	PSI5 Channel Config mode request. If this bit is set (and PCCR[PSI5_CH_EN] = '1') this particular psi5 channel enters Configuration mode from Disable mode. Default value is 0. User software must program all PSI5 channel parameters before clearing this bit. Once cleared, channel parameters in registers are locked for writing. The values set can not be changed until this bit is set again after entering the Disable mode NOTE: This bit can be written in all modes, but writing a 0 in the Normal mode does not change the operation mode of the device. For more details please see Figure 47-2 and Table 47-4. Do note that when going from Disable to Config mode, the programming of other bits of this register CANNOT be done in the same cycle, as the one in which this bit is being written. 1 (If PCCR[PSI5_CH_EN] = '1' and GCR[GLOBAL_DISABLE_REQ] = '0') - PSI5 Channel enters Config mode. Various configuration registers can be programmed in this mode. The only registers NOT writable in the config mode but writable in the Normal mode are the output registers PSI5_DBR and the PSI5_DSR. 0 (If PCCR[PSI5_CH_EN] = '1' and GCR[GLOBAL_DISABLE_REQ] = '0') PSI5 Channel enters Normal mode. Channel parameter registers are locked for writing. This bit can be written in all the modes but writing a "0" in the Normal mode will not change the operation mode of the device.
31 PSI5_CH_EN	PSI5 Channel Enable. If this bit is cleared this particular psi5 channel continues to stay in Disable mode even if GCR[GLOBAL_DISABLE_REQ] = 0. If set, it enters Configuration mode from Disable mode (based on PCCR[PSI5_CH_CONFIG]). Default value is 0. All state machines are disabled. This bit can be written in all modes. NOTE: When PSI5_CH_EN == 0, then the clock enable for that particular channel that goes from the IP, goes to "0" (inactive state). This also means that the only clock available to the IP in the config mode is the "ipg_clk_s". Do note that when going from Disable to Config mode, the programming of other bits of this register CANNOT be done in the same cycle, as the one in which this bit is being written. 0 PSI5 channel continues in Disable mode. 1 PSI5 channel enabled to enter Config/Normal mode.

47.4.3 DMA Control Register (PSI5_CH0_DCR)

This section defines the DMA Control Register.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	Reserved	0									0			IE_DMA_TF_SF	IE_DMA_TF_PM_DS	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_DCR field descriptions

Field	Description
0 Reserved	This field is reserved. NOTE: Only write this field with the reset value.
1–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 DMA_PM_DS_WM	0 to 31: Valid water mark levels. Value fixed by user software. Since each location has two 32-bit registers hence a total of sixty-four 32-bit words are present. The default and minimum value of dma_pm_ds_wm is '0', i.e. 1 message/Diagnostic bit of 1 location. The maximum value of dma_pm_ds_wm is 31, i.e. the actual watermark = 32 RAM locations. NOTE: - These bits are writable only in config mode. - These bits are ineffective if DMA_PM_DS_CONFIG = conf1. - These bits indicates the number of PSI5 message to be stored in FIFO / number of unread diagnostic bits in the diagnostic registers with a correspondence to the messages in the FIFO, before the corresponding DMA request is asserted. The watermark definition changes depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR as mentioned below.

Table continues on the next page...

PSI5_CH0_DCR field descriptions (continued)

Field	Description
	- When DMA_PM_DS_CONFIG = conf2 or conf3 then the watermark refers to the number of new unread PSI5 messages that are stored in the FIFO before a DMA request is asserted. - In conf2 mode of DMA_PM_DS_CONFIG, the number of words to be transferred, set in the DMA controllers TCD must be set equal to the number of words corresponding to the set water mark value + 2 words (for the two 32-bit diagnostic registers). - In conf3, the number of words to be transferred set in the DMA controllers TCD must be set equal to the number of words corresponding to the set water mark value. - When DMA_PM_DS_CONFIG = conf4 then the watermark refers to the number of new unread diagnostic bits in the diagnostic register. In this configuration the PSI5 messages can only be read by the CPU, since the DMA request would cater to reading the diagnostic bits only. - In conf4, the number of words transferred in each DMA request = 2 x 32-bit words (for the two 32-bit diagnostic registers). The water mark however refers to the number of new unread diagnostic bits pertaining to each PSI5 message in the FIFO.
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 IE_DMA_TF_SF	NOTE: This bit is writeable in Config and Normal modes. Enable for interrupt, which is generated when DMA transfer finishes for DMA SMC Frame register. 0 Interrupt is disabled. 1 Interrupt is enabled.
14 IE_DMA_TF_PM_DS	Enable for Interrupt, which is generated when DMA transfer finishes for PSI5 messages/DMA Diagnostic Status register depending on the DMA_PM_DS_CONFIG bits of the DCR. NOTE: This bit is writable only in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
15–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 IE_DMA_PM_DS_FIFO_FULL	This bit is effective only when the DMA_PM_DS_CONFIG = conf2, conf3 or conf4. It enables the FIFO FULL condition generation interrupt. For the cases which generate these FIFO FULL conditions please refer to the description of IS_DMA_PM_DS_FIFO_FULL register bit of the DSR. NOTE: This bit is writable only in Config and Normal modes.
21 IE_DMA_SFUF	Enables interrupt when there is underflow in DMA SMC Frame register when DMA is enabled. It is set when the DSFR is read without a valid DMA request, i.e. it is empty. Default value is 0. NOTE: This bit is writable only in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PSI5_CH0_DCR field descriptions (continued)

Field	Description
23 IE_DMA_PM_DS_UF	Enables interrupt when there is underflow in DMA PSI5 message register when DMA is enabled. Default value is 0. For the details as to when this underflow occurs, please refer to the details of IS_DMA_PM_DS_UF bit details of the DSR. NOTE: This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 DMA_EN_SF	Enable DMA request for SMC Frame Data NOTE: This bit is writable only in config mode. 0 DMA for SMC frame is disabled. The six dedicated 1-1 slot corresponding SMC registers can only be read by the CPU through the SFR. Reading the DSFRs returns 0. 1 DMA for SMC frame is enabled. The six dedicated slot corresponding SMC registers can be read by reading the DSFR successively. In the DMA mode the six registers are read in a round robin fashion as explained in the DSFR details. Reading directly through the SFR registers is still available.
30–31 DMA_PM_DS_CONFIG	These bits define how the PSI5 messages are stored in the MEM_DEPTH memory area and the associated diagnostic bits (EISR, NDSR) are transferred. The DPMR, DDSR, and DSFR registers should be used for DMA access and the PMRH/PMRL, NDSR, EISR, and OWSR registers should be used for CPU access. NOTE: For more details please see the description of the DCR[DMA_PM_DS_WM] bits. When DMA_PM_DS_CONFIG bits = conf2 or conf3 and if the CPU and the DMA are simultaneously used for reading the PSI5 messages, then in the course of reading the messages it is possible that there can be an overflow, though some intermediate locations, which have been read by the CPU, are empty. This will occur because the DMA access is made independent of the CPU access. The DMA logic would never know that the CPU has already read a message which was scheduled to be read by the DMA. Whenever the DMA is used for reading the PSI5 message (conf2/conf3) modes then though the CPU can read the messages in parallel through the PMRH/PMRL registers, still for the purpose of setting the Overwrite/Overflow bits only a read from the DMA through the popup registers (DPMR) would be treated as valid read. This will also be true for the SMC messages when accessed simultaneously by the CPU/DMA. NOTE: These bits are writable only in config mode. 00 conf1 The DMA request is disabled. In this mode, only the interrupts can be used for indicating that data transfer is required. 01 conf2 After transferring the "dma_pm_ds_wm" number of PSI5 messages, there will be two additional 32-bit transfers in which the NDSR and the EISR registers are sequentially transferred through the DPMR registers by using DMA. 10 conf3 "dma_pm_ds_wm" number of PSI5 messages is transferred in each DMA request. The DMA read is through the DPMR registers. 11 conf4

Table continues on the next page...

PSI5_CH0_DCR field descriptions (continued)

Field	Description
	Only the diagnostic bits are transferred through the DDSR. The DMA read is through the DDSR registers.

47.4.4 DMA Status Register (PSI5_CH0_DSR)

This section defines the DMA Status Register.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0												IS_DMA_TF_SF		IS_DMA_TF_PM_DS	0
W													w1c		w1c	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0				IS_DMA_PM_DS_FIFO_FULL	IS_DMA_SFUF	0	IS_DMA_PM_DS_UF	0							
W					w1c	w1c		w1c								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_DSR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 IS_DMA_TF_SF	This flag is set when DMA transfer finishes for DMA SMC Frame register.
14 IS_DMA_TF_PM_DS	This flag is set when DMA transfer finishes . For the various configurations of this request please refer to the descriptions of the DMA_PM_DS_CONFIG bits in the DCR. This flag is cleared by w1c.
15–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 IS_DMA_PM_DS_FIFO_FULL	Interrupt Status when there is FIFO FULL corresponding to DMA request. The FIFO FULL scenarios are detailed below with respect to the various settings of the DMA_PM_DS_CONFIG bit. conf1: FIFO FULL disabled conf2 and conf3: FIFO FULL occurs when all the memory locations become full in the PSI5 message FIFO. It indicates that without any read, any new upcoming message will now overwrite the existing messages and set the overwrite bits. This bit is cleared either by w1c or upon a PSI5 message read depending on the FAST_CLR_PSI5 bit. conf4: FIFO FULL occurs when there is a "REGISTER FULL" in the Diagnostic registers. FIFO FULL here means that the diagnostic registers contain 32 unread diagnostic bits. A new message starts changing the status of the diagnostic bits. In this configuration it is necessary to read the diagnostic bits through the DMA using the DDSR in order to prevent FIFO FULL. Of course the diagnostic registers NDSR/EISR can be read any time by the CPU, but to prevent FIFO FULL they HAVE to be read through the DDSR registers only. Also in this mode the PSI5 messages DONT contribute to the FIFO FULL. The PSI5 messages have to be read by the CPU using the PMRH/PMRL registers in order to prevent the overwrite bits from being set in the OWSR. In this mode the OWSR bits are NOT automatically cleared upon the PSI5 message read since the PSI5 message has to be read by the PMRH/PMRL register and NOT though the DPMR. The OWSR bits have to be cleared by a w1c. Reading the DPMR returns a 0 in this mode. This bit is cleared by a w1c. 0 No FIFO full. 1 FIFO full has occurred
21 IS_DMA_SFUF	SMC Frame DMA underflow: This happens when the DSFR has been read without a proper DMA request being asserted. The DSFR is empty and it is read. This bit is cleared by a w1c. 0 No underflow has occurred. 1 Underflow has occurred.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 IS_DMA_PM_DS_UF	Depending on the DMA_PM_DS_CONFIG bits following is the underflow conditions: Default value is 0. conf1: underflow disabled conf2 and conf3: Underflow happens when the software reads the PSI5 message FIFO though the DPMR, beyond the available messages (empty area). conf4: Underflow happens when the diagnostic registers are read through the DDSR without a valid DMA request and the DDSR contains no new data. The bits are cleared by a w1c.

Table continues on the next page...

PSI5_CH0_DSR field descriptions (continued)

Field	Description
0	No underflow has occurred.
1	Underflow has occurred.
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

47.4.5 General Interrupt Control Register (PSI5_CH0_GICR)

The GICR contains the bits for controlling interrupts related to:

- ECU-to-sensor communication
- the Time Stamp

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 IE_STS	Interrupt request enabled when the Sync Pulse Triggered Time Stamp value is refreshed on STSRR. NOTE: This bit is writable only in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
9 IE_DTS	Interrupt request enabled when the Data Start sequence Triggered Time Stamp value is refreshed on DTSRR. NOTE: This bit is writable only in Config and Normal modes.

Table continues on the next page...

PSI5_CH0_GICR field descriptions (continued)

Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
10 IE_DSROW	Interrupt request enabled when system tries to overwrite on Data Shift register when it is not ready to accept new data. NOTE: This bit is writable only in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
11 IE_BROW	Interrupt request enabled when system tries to overwrite on buffer register when it is not ready to accept new data. NOTE: This bit is writable only in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
12 IE_PROW	Interrupt request enabled when system tries to overwrite on Preparation register when it is not ready to accept new data. NOTE: This bit is writable only in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
13 IE_DSRR	Interrupt request enabled when Data Shift Register is ready to accept new data. NOTE: This bit is writable only in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
14 IE_BRR	Interrupt request enabled when buffer Register is ready to accept new data. NOTE: This bit is writable only in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
15 IE_PRR	Interrupt request enabled when Preparation Register ready to accept new data. NOTE: This bit is writable only in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

47.4.6 New Data Interrupt Control Register (PSI5_CH0_NDICR)

The NDICR contains the interrupt enable bits related to a new PSI5 message arrival, in the corresponding PSI5 message buffer location.

NOTE

Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

PSI5_CH0_NDICR field descriptions

Field	Description
0–31 IE_ND	Interrupt request enabled when any new message (fault-free/with fault) is received in the RAM buffer Register 'x' location [x: 0 to 31], This interrupt is generated only when corresponding RAM buffer Ready with new data. NOTE: These bits are writable only in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.

47.4.7 Overwrite Interrupt Control Register (PSI5_CH0_OWICR)

The Overwrite Interrupt Control Register (PSI5_OWICR) is related to the generation of the overwrite interrupts. The overwrite interrupt is generated when the unread PSI5 message in a particular RAM location is overwritten by another PSI5 message.

NOTE

Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH0_EICR field descriptions

Field	Description
0–31 IE_ERROR	Interrupt request enabled when any/all of the error conditions C, E, EM, T, or F is observed in a PSI5 message in the RAM buffer Register 'x' location [x: 0 to 31], This interrupt is generated only when corresponding RAM buffer Ready with new data. Which of the error condition (any of C, E, EM, T, or F) would generate the interrupt is selectable by PCCR[ERROR_SELECT] field. If all are selected then which out of C,E,EM,T,F is set can be isolated by reading corresponding received message. NOTE: These bits are writable only in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.

47.4.9 General Interrupt Status Register (PSI5_CH0_GISR)

The GISR contains the status bits related to SMC messages, ECU-to-sensor communication, and the Time Stamp.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

PSI5_CH0_GISR field descriptions

Field	Description
0 IS_DB_FR	This flag is set to “1” when the IP enters the Debug freeze mode. Please see Debug mode for details about the Debug mode. This bit is auto cleared by the hardware when the IP exits the debug freeze mode. 0 IP not in debug freeze mode. 1 IP in debug freeze mode.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 IS_CESM	These flags are set when the received SMC frame in the corresponding slot has a CRC failure (CRC recalculation on SMC). These bits are automatically cleared upon message read, when the FAST_CLR_SMC = 1 and the DMA_EN_SF = 1.
8 IS_STS	This Interrupt flag is set when the Sync Pulse Triggered Time Stamp value is refreshed on STSRR.

Table continues on the next page...

PSI5_CH0_GISR field descriptions (continued)

Field	Description
9 IS_DTS	This Interrupt flag is set when the Data Start sequence Triggered Time Stamp value is refreshed on DTSRR.
10 IS_DSROW	This flag is set when the system tries to overwrite on Data Shift register when it is not ready to accept new data.
11 IS_BROW	This flag is set when the system tries to overwrite on buffer register when it is not ready to accept new data.
12 IS_PROW	This flag is set when the system tries to overwrite on Preparation register when it is not ready to accept new data.
13 DSR_RDY	This bit acts both as a status and a control bit. Status bit Action : When "1" it indicates that the Data Shift register is ready to receive new data from the system bus side or the Data Buffer register. When "0" it indicates that there is a ongoing command transmission of the data in DSR , or the CPU has done a "w1c" to this bit leading to the new command transmission . In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_DSROW] bit gets set. A write to PSI5_DOBCR[DSR_RST] will abort the current command transmission and make the DSR_RDY as "1". Control Bit Action : When a "w1c" is done to this register bit, and PSI5_DOBCR[SW_READY] == 1 , then it indicates to the IP that the data in DSR is valid and is to be used for command shifting . This procedure is used when the data is written by the CPU to DSR directly skipping the DBR. For detailed action of this bit please refer to Data transmission . NOTE: For this field, Individual "bit setting" commands should not be used. Rather, the normal register read/write commands should be used. NOTE: In configuration mode, writes to this bit are ignored.
14 DBR_RDY	This bit acts both as a status and a control bit. Status bit Action : When "1" it indicates that the Data Buffer register is ready to receive new data from the system bus side or the Data Preparation register. When "0" it indicates that there is a ongoing shift of the data from the DPR to the DBR, or the CPU has done a "w1c" to this bit . In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_BROW] bit gets set. A write to PSI5_DOBCR[DBR_RST] will abort the current data transaction in DBR and make the DBR_RDY as "1". Control Bit Action : When a "w1c" is done to this register bit, then it indicates to the IP that the data in DBR is valid and is to be used for shifting to DSR . This procedure is used when the data is written by the CPU to DBR directly skipping the DPR. For detailed action of this bit please refer to Data transmission . NOTE: For this field, individual "bit setting" commands should not be used. Rather, the normal register read/write commands should be used. NOTE: In configuration mode, writes to this bit are ignored.
15 DPR_RDY	This bit acts both as a status and a control bit. Status bit Action : When "1" it indicates that the Data Preparation register is ready to receive new data from the system bus side . When "0" it indicates that there is a ongoing processing of the data in DPR or there is a data shift ongoing from the DPR to the DBR, or the CPU has done a "w1c" to this bit . In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_PROW] bit gets set. When PSI5_DOBCR[CMD_TYPE] == "7" then this bit remains at value "0". Control Bit Action : When a "w1c" is done to this register bit, then it indicates to the IP that the data in DPR is valid and is to be used for processing and shifting to DBR . For detailed action of this bit please refer to Data transmission .

Table continues on the next page...

PSI5_CH0_GISR field descriptions (continued)

Field	Description
	NOTE: For these register bits individual "bit setting" commands should not be used. Rather, the normal register read/write commands should be used. NOTE: In configuration mode, writes to this bit are ignored.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 IS_OWSM	Status for the SMC message overwrite bits. Each of the 6 locations correspond to the SMC message pertaining to each SFR[x] register, x = 1 to 6. These bits are automatically cleared upon message read when the FAST_CLR_SMC = 1 and the DMA_EN_SF = 1.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 IS_NVSM	These flags are set when corresponding SFR[i] receives and is ready (to read) with new valid SMC message. These bits are automatically cleared upon message read, when the FAST_CLR_SMC = 1 and the DMA_EN_SF = 1.

47.4.10 DMA PSI5 Message Register (PSI5_CH0_DPMR)

This section defines the DMA PSI5 Message Register.

Address: 0h base + 28h offset = 28h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	PSI5_RXDATA																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

PSI5_CH0_DPMR field descriptions

Field	Description
0–31 PSI5_RXDATA	PSI5_RXDATA[31:0] This popup register contain the PMRL[31:0] data followed by the PMRH[31:0] data for each of the FIFO locations, when the FIFO is read by the DMA. It would require two 32-bit IPS access to read one PSI5 Message. For each of the locations the DATA is pushed sequentially till all the data corresponding to the programmed watermark is complete after which the DMA request goes down. The depth of the FIFO is 32x64. This popup register can be used differently based on the configuration of the DMA_PM_DS_CONFIG bits in the DCR. When DMA_PM_DS_CONFIG=conf2 then it pops the PSI5 message followed by NDSR followed by EISR. When DMA_PM_DS_CONFIG= conf3, it pops only the PSI5 messages. When DMA_PM_DS_CONFIG=conf4 then it pops the NDSR followed by EISR. This register is a reflection of the location, pointed to by the DMA read pointer. For more details please refer to the PSI5 Channel Control Register (PSI5_CH0_PCCR) , DMA Control Register (PSI5_CH0_DCR) and DMA Status Register (PSI5_CH0_DSR) .

47.4.11 DMA SMC Frame Register (PSI5_CH0_DSFR)

This section shows the DMA SMC Frame Register.

Address: 0h base + 2Ch offset = 2Ch

PSI5_CH0_DSFR field descriptions

Field	Description
0–31 SMC_RXDATA	When the DMA_EN_SF = 1 then the six SFR registers are searched in a round robin fashion for the reception of the complete SMC data. The DMA request is asserted as soon as the first encountered SFR has a complete SMC frame. This request remains asserted till all the registers which have a complete data ready have transferred the data through the DMA. Each other SFR is a 32-bit register. This register is a reflection of the location, pointed to by the DMA read pointer.

47.4.12 DMA Diagnostic Status Register (PSI5_CH0_DDSDR)

This section defines the DMA Diagnostic Status Register.

NOTE

No FIFO is implemented for diagnostic registers. They are two 32-bit registers addressable by either the CPU (reading NDSR or EISR directly) or the DMA (reading the DDSR successively).

Address: 0h base + 30h offset = 30h

PSI5_CH0_DDSDR field descriptions

Field	Description
0–31 DDS	This register maps each of the individual Diagnostic registers (in the order NDSR, EISR) depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR. This register is a reflection of the location, pointed to by the DMA read pointer.

PSI5_CH0_DDSR field descriptions (continued)

Field	Description
	For more details please refer to the PSI5 Channel Control Register (PSI5_CH0_PCCR) , DMA Control Register (PSI5_CH0_DCR) and DMA Status Register (PSI5_CH0_DSR) .

47.4.13 PSI5 Message Receive Register Low (PSI5_CH0_PMRRL)

This section defines the PSI5 Message Receive Register Low.

Address: 0h base + 34h offset = 34h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	DATA_REGION															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	DATA_REGION												CRC			C
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_PMRRL field descriptions

Field	Description
0–27 DATA_REGION	These are application-specific optional bits + data payload of received message. See Reception of data frames for more details. The data is left-aligned i.e. Data Region[0]/D0 corresponds to first received bit of the PSI5 message after Start sequence detection and Data Region[n]/D'n' corresponds to successive bits up to expected number of bits (n: 8 ? n ? 28). If n < 28 remaining bit positions are filled with '0's i.e. between last received bit and CRC field.
28–30 CRC	This field represents CRC/Parity value of the data. When parity configuration is selected in the S[1-6]FCR registers, the CRC[2] bits denotes the parity.
31 C	This bit will be set if CRC/P recalculation return an Error.

47.4.14 PSI5 Message Receive Register High (PSI5_CH0_PMRRH)

This section defines the PSI5 Message Receive Register High.

NOTE

Any new PSI5 message is always stored in the PSI5 receive register (PMRRL/PMRRH). In parallel it is also stored in the RAM registers in a sequential manner like in a Ring Buffer. When a new message comes it would always overwrite the data in the PSI5 receive register. But the original message would still be available in the RAM register provided all locations in the RAM registers are not full, and an overwrite has not occurred.

Address: 0h base + 38h offset = 38h

PSI5_CH0_PMRRH field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 F	This represents that NO frame was received in the corresponding configured slot. 0 Frame was received in the corresponding configured slot. 1 No frame was received (F bit error).
2 EM	This bit indicates electrical error in the PSI5 Message at bits corresponding to Serial Messaging Channel (M0,M1), that is, at least one bit is absent during the T bit period. 0 No electrical error in M0, M1 fields. 1 Electrical error in M0, M1 fields.
3 E	This bit indicates electrical error, i.e. at least one bit is absent during the Tbit period (except M0 and M1 bits and the start bits). 0 No electrical error in fields other than M0, M1, and start fields. 1 Electrical error in fields other than M0, M1, and start fields.
4 T	This bit indicates timing error i.e. frame has started in an unconfigured slot, spread across two slots, started before the first configured slot. 0 No timing error in the corresponding slot. 1 Timing error in the corresponding slot.
5–7 SlotCounter	This value indicates the slot number in which this frame was received. More specifically, it indicates in which slot the start bits of the frame have been detected. If the start bits get detected before the start

Table continues on the next page...

PSI5_CH0_PMRRH field descriptions (continued)

Field	Description
	boundary of Slot1, then the slot counter has a value of "0". For asynchronous modes the slot counter has a fixed value of "1". The six slots are numbered as Slot1, Slot2,...Slot6.
8–31 TimeStampValue	This is 24-bit Time Stamp value appended to Received message as soon as start bits are detected. This time stamp is captured at rising edge of S0 and stored at the rising edge of S1. The specific value that is appended can be programmed by setting the TS_CAPT bit in the Slot n Frame Configuration Register (PSI5_CH0_SnFCR) . In other words these bits contain either the start bit(S0) captured time stamp or the SYNC pulse captured time stamp, dependant on TS_CAPT bit. Note that in messages where "F" bit has been set ; the value of the Time Stamp appended to the message is "0" . It is possible to reset the time stamp counter by asserting to "1" the "gtm_reset" signal from the GTM.

47.4.15 PSI5 Message Register Low i (PSI5_CH0_PMRLn)

The following figure shows the PSI5 Message Register Low i.

Address: 0h base + 3Ch offset + (8d × i), where i=0d to 31d

PSI5_CH0_PMRHn field descriptions

Field	Description
0 O	This bit carries the same information as OWSR, but appended here for each message separately. This bit is set when the current message (which is being read) has overwritten some previous unread message. Note that, if the corresponding location in the OWSR has been cleared or has been set by the SOWSR, then the same will be reflected in the message stored in the corresponding RAM location as well.
1 F	This represents that NO frame was received in corresponding configured Slot. This bit is writable in Config mode (for Test purposes). 0 Frame was received in the corresponding configured slot. 1 No frame was received (F bit error).
2 EM	This bit indicates electrical error in the PSI5 Message at bits corresponding to Serial Messaging Channel(M0, M1) i.e. at least one bit is absent during the Tbit period. This bit is writable in Config mode (for Test purposes). 0 No electrical error in M0, M1 fields. 1 Electrical error in M0, M1 fields.
3 E	This Bit Indicates Electrical Error i.e. at least one bit is absent during the Tbit period (except M0 and M1 bits and the start bits). This bit is writable in Config mode (for Test purposes). 0 No electrical error in fields other than M0, M1 and start fields. 1 Electrical error in fields other than M0, M1 and start fields.
4 T	This bit indicates timing error i.e. frame has started in an unconfigured slot or it has spread across two slots or it has started before the first configured slot. This bit is writable in Config mode (for Test purposes).

Table continues on the next page...

PSI5_CH0_PMRHn field descriptions (continued)

Field	Description
	0 No timing error in the corresponding slot. 1 Timing error in the corresponding slot.
5–7 Slot_Counter	This value indicates the slot number in which this frame was received. More specifically, it indicates in which slot the start bits of the frame have been detected. If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of "0". The slot counter is automatically incremented at each slot boundary irrespective of whether a message is received or not. For asynchronous modes the slot counter has a fixed value of "1". The six slots are numbered as Slot1, Slot2,...Slot6. This bit is writable in Config mode (for Test purposes).
8–31 TimeStampValue	This is 24-bit Time Stamp value appended to Received message as soon as start bits are detected. This time stamp is captured at rising edge of S0 and stored at the rising edge of S1. The specific value that is appended can be programmed by setting the TS_CAPT bit in the Slot n Frame Configuration Register (PSI5_CH0_SnFCR) . In other words these bits contain either the start bit (S0) captured time stamp or the SYNC pulse captured time stamp, dependant on TS_CAPT bit. Note that in messages where "F" bit has been set ; the value of the Time Stamp appended to the message is "0". It is possible to reset the time stamp counter by asserting to "1" the "gtm_reset" signal from the GTM. This bit is writable in Config mode (for Test purposes).

47.4.17 SMC Frame Register n (PSI5_CH0_SFRn)

The following figure shows the SMC Frame Register n.

NOTE

Six dedicated 32-bit SFR[x] registers for SMC are available with a 1-1 slot correspondence. These can be read by either the CPU or the DMA (when DMA_EN_SF = 1).

NOTE

No FIFO for SMC frame is available. Six 32-bit registers are available in the address space, which can be accessed by either the DMA (using the DSFR) or the CPU (using the six SFR registers), depending on the setting of the DMA_EN_SMC bit.

Address: 0h base + 13Ch offset + (4d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	IDDATA				DATA											
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_SFRn field descriptions

Field	Description
0–2 SLOT_NO	This indicates in which slot this SMC frame was received. Note that here the slot number refers to the slot in which all the re-arranged PSI5 messages (from which the M0,M1 bits have been extracted) are supposed to have occurred after the correct PSI5 message placement and Timing corrections have been performed. For SFR[1], slot_no = 1; For SFR[2], slot_no = 2; For SFR[3], slot_no = 3; For SFR[4], slot_no = 4; For SFR[5], slot_no = 5; For SFR[6], slot_no = 6; This field is writable in Config mode (for Test purposes).
3 CER	CRC Error This field is writable in Config mode (for Test purposes). 0 The present data has no CRC error. 1 The present data has a CRC error.
4 OW	Overwrite status NOTE: If the corresponding SOWSM bits in the SSESr have been set or the OWSM bits in the GISR have been cleared, then the same will be reflected in the message stored in the corresponding RAM location as well. The overwrite occurs when any unread SMC message in a particular SMC slot register gets overwritten by a new SMC message of that particular slot. Even if the SMC message has a CRC error, still if it is unread and is overwritten, the overwrite bit gets set. 0 The present data was already read when new message arrived. 1 New message has overwritten the previous unread message.
5–10 CRC	6-bit CRC for slow serial message This field is writable in Config mode (for Test purposes).
11 C	Configuration bit This bit is writable in Config mode (for Test purposes). 0 12-bit data and 8-bit message ID. 1 16-bit data and 4-bit message ID.
12–15 ID	Message ID: If C = '0' indicates ID[7:4], if C = '1' indicates ID[3:0]. This field is writable in Config mode (for Test purposes).
16–19 IDDATA	Message ID/DATA: If C = '0' indicates ID[3:0], if C = '1' indicates DATA[15:12]. This field is writable in Config mode (for Test purposes).
20–31 DATA	DATA payload This field is writable in Config mode (for Test purposes).

47.4.18 New Data Status Register (PSI5_CH0_NDSR)

The following figure shows the New Data Status Register.

Address: 0h base + 154h offset = 154h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH0_OWSR field descriptions

Field	Description
0–31 OWS	Over Write Status flags for PSI5 Messages corresponding to each PSI5 location in the RAM registers. These bits are set when any unread receive PSI5 message is overwritten by a newly arrived message). These bits can be cleared by w1c or the fast clearing. Please refer to PCCR, DCR and DSR registers for more information. Also, these bits can be set independent by writing in SOWSR.

47.4.20 Error Indication Status Register (PSI5_CH0_EISR)

The following figure shows the Error Indication Status Register.

Address: 0h base + 15Ch offset = 15Ch

PSI5_CH0_EISR field descriptions

Field	Description
0–31 ERROR	Error Status flags for PSI5 Messages corresponding to each PSI5 MB locations. These bits are set when any of the five selectable (by ERROR_SELECT) bits (C, E, EM, T or F) is set for the corresponding PSI5 Message. These bits can be cleared by w1c or the fast clearing. Please refer to PCCR, DCR and DSR registers for more information. Also, these bits can be set independently by writing in SEISR.

47.4.21 Set New Data Status Register (PSI5_CH0_SNDSR)

The following figure shows the Set New Data Status Register.

Address: 0h base + 160h offset = 160h

PSI5_CH0_SNDSR field descriptions

Field	Description
0–31 SNDS	Sets New Data Status flags for PSI5 Messages corresponding to each PSI5 MB locations. The corresponding NDS Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. NOTE: This bit is writable only in config and Normal modes.

47.4.22 Set Overwrite Status Register (PSI5_CH0_SOWSR)

The following figure shows the Set Overwrite Status Register.

Address: 0h base + 164h offset = 164h

PSI5_CH0_SOWSR field descriptions

Field	Description
0–31 SOWS	Sets overwrite status flags for PSI5 messages corresponding to each PSI5 MB locations. The corresponding OWS flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can set the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as 0. NOTE: These bits are writable only in Config and Normal modes.

47.4.23 Set Error Status Register (PSI5_CH0_SEISR)

The following figure shows the Set Error Status Register.

Address: 0h base + 168h offset = 168h

PSI5_CH0_SEISR field descriptions

Field	Description
0–31 SERROR	Sets Error Status flags for PSI5 messages corresponding to each PSI5 MB locations. The corresponding ERROR flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can set the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as 0. NOTE: These bits are writable only in Config and Normal modes.

47.4.24 Set SMC Error Status Register (PSI5_CH0_SSESR)

The following figure shows the Set SMC Error Status Register.

Address: 0h base + 16Ch offset = 16Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH0_SSESR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 SCESM	Sets IS_CESM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_CESM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. NOTE: These bits are writable only in Config and Normal modes.
8–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 SOWSM	Sets IS_OWSM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_OWSM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. NOTE: These bits are writable only in Config and Normal modes.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 SNVSM	Sets IS_NVSM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_NVSM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. NOTE: This bit is writable only in Config and Normal modes.

47.4.25 Sync Time Stamp Read Register (PSI5_CH0_STSR)

The following figure shows the Sync Time Stamp Read Register.

Address: 0h base + 170h offset = 170h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

R	DTSV															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_DTSRR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–7 SLOT_ COUNTER	3bit Slot Counter which corresponds to the slot for which the DTSRR contains the Time Stamp. The slot_counter contains the slot in which the start bits of this frame was captured (after successful detection of S1). If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of "0". The slot counter is automatically incremented at each slot boundary irrespective of whether a message is received or not. In case of asynchronous mode the slot counter has a fixed value of "1".
8–31 DTSV	Data Time Stamp Value[23:0] Whenever a valid sequence of the start bits (S0,S1) is detected then the value of the Time Stamp counter captured at the rising edge of the S0, is stored in this register at the rising edge of S1.

47.4.27 Slot n Frame Configuration Register (PSI5_CH0_SnFCR)

The following figure shows the Slot n Frame Configuration Register.

NOTE

In Asynchronous mode, the PSI5_S1FCR register has to be programmed for controlling the various parameters pertaining to the message received. The other registers PSI5_S[2-6]FCR have no effect in the asynchronous mode.

Address: 0h base + 178h offset + (4d × i), where i=0d to 5d

47.4.34 Slot *n* End Boundary Register (PSI5_CH0_SnEBR)

The following figure shows the Slot *n* Start Boundary Register (PSI5_S *n* SBR).

Slot *n* End Boundary register is a single register which can be programmed to define the "end" of the *n*th slot. The *n* can be defined in the SLOT_NO field of this register.

There are seven boundary registers for the six slots. Six of these registers (S1SBR, S2SBR, S3SBR, S4SBR, S5SBR, and S6SBR) are used to define the start of each of the six slots. The seventh register SnEBR (Slot *n* End Boundary register) defines the end of the *n*th slot. The *n* is programmed in the slot_no field of this register.

The number of slots would automatically be available from the SnEBR. The SnEBR contains the slot number of the last slot and the end boundary of the same. Each slot can separately be enabled or disabled by using the slot_en bit in the SnFCR. When the start slot boundaries are properly defined in the SnSBR (Slot *n* Start Boundary Register) register but the slot_en bit = 0 in the corresponding SnFCR (Slot *n* Frame Configuration register) register, then the corresponding slot is treated as "available" but "unconfigured." For such a slot the data/diagnostic bits all remain 0. The "T" bit will, however, get set if a message that was supposed to come in a configured slot actually arrives in an unconfigured slot. Note that the various parameters like the Data length/CRC configuration and so on are valid ONLY for the configured slots. Even when sampling a message in an unconfigured slot, these parameters would be taken from the previous/next configured slot only. It is assumed that no data would be sent in an unconfigured slot. If a data is received in this unconfigured slot it would never be treated as belonging to the unconfigured slot. As a special case if "S0" and "S1" are detected in different slots then a T-bit error is set .

NOTE

The start slot boundaries in the S *n* SBR should be correctly programmed. If this is not done, the correct operation cannot be guaranteed. Slots occurring after the slot_no value programmed in the SnEBR are treated as being unavailable (that is, the data in all the slots occurring after the SnEBR is rejected by the Manchester decoder).

Following are the examples:

- If only three slots are required between two sync pulses, program S1SBR, S2SBR, and S3SBR with the correct value of the start boundaries of the three slots and

program slot_no = 3 in the S *n* EBR and define the end boundary of the third slot in S *n* EBR. The design ignores slots 4, 5, and 6.

- For six slots, the required programming would be: program the start of each of the six slots in S1SBR, S2SBR, S3SBR, S4SBR, S5SBR, and S6SBR. Then program the end of the sixth slot in the S *n* EBR by putting slot_no = 6 and define the end boundary of the sixth slot in S *n* EBR.

Address: 0h base + 19Ch offset = 19Ch

PSI5_CH0_SnEBR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 SLOT_NO	The field indicates the Slot number{1-6} for which Slot End Boundary Time is defined. Any value other than 1-6 is defaulted to 0. A value 0 here would mean that the manchester decoder would not sample any slots. This slot number also defines the number of slots that the IP assumes to exist between 2 sync pulses.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–31 SnEBT	Slot <i>n</i> End Boundary Time. This field specifies the time in intervals of 1μs, occurring after the rising edge of timing sync pulse, at which the slot 'n' should end.

47.4.35 Data Output Block Configuration Register (PSI5_CH0_DOBCR)

The following figure shows the Data Output Block Configuration Register.

Table 47-118. CMD_TYPE details

CMD_TYPE	PSI5 Frame ¹	Effect on registers	Writeable Register lengths
"000" - 0	Short Frame(V1.3) with 31 "1s" as the start condition	Command can be written to DPR for auto calculation of stuff/start/CRC bits. Can always be overwritten in DSR/DBR registers provided DSR_RDY == 1 or DBR_RDY == 1 respectively	6 bits in DPR 15bits ² in DBR/DSR.
"001" - 1	Short Frame(V1.3) with 5 "0s" as the start condition	-do-	-do-
"010" - 2	Long Frame(V1.3) with 31 "1s" as the start condition	-do-	16bits in DPR. 29bits ² in DBR/DSR.
"011" - 3	Long Frame(V1.3) with 5 "0s" as the start condition	-do-	-do-
"100" - 4	X-Long Frame(V1.3) with 31 "1s" as the start condition	-do-	22bits in DPR. 37bits ² in DBR/DSR
"101" - 5	X-Long Frame(V1.3) with 5 "0s" as the start condition.	-do-	-do-
"110" - 6	XX-Long (V2.0) -	-do-	24 bits in DPR. 43bits ² in DBR/DSR
"111" - 7	Non Standard Length.	Command can only be written to DSR and DBR registers provided DSR_RDY == 1 or DBR_RDY == 1 respectively	Programmable from 1 to 64 bits in DBR/DSR, depending on the value of PSI5_DBOCR[DATA_LENGTH] field.

1. The start condition(31 "1s" or 5 "0s") is automatically taken care by the hardware and should NOT be written to the registers as part of the command.
2. This is also the length of the command that will be shifted out during the ECU to Sensor communication, regardless of how many "actual" bits are written to DBR/DSR.

Table 47-119. DOBCR bit configurations and the related output states

Output path states	GTM_TRIG_SEL	SP_PULSE_SEL	OP_SEL
State1 ¹	0	1	1
State2 ¹	0	0	1
State3 ¹	1	1	1
State4 ¹	1	0	1
State5 ¹	1	x	0

1. These states are shown in [Valid states for integrated sync pulse generator](#). In State5, the pulse width and period is to be controlled directly from the GTM. In this state, the PW0/1D registers have no effect on the Pulse Width Modulation, when observed on the "sdout" pin.

NOTE

Please refer to [Figure 47-147](#) for the details about the above bits. [Figure 47-147](#) is the actual implementation of [Figure](#)

47-146 such that various contentions between the switches (S1, S2, and so on) do not happen.

Address: 0h base + 1A0h offset = 1A0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	DATA_LENGTH[5:0]					DBR_RST	DSR_RST		CMD_TYPE			DEFAULT_SYNC	GTM_TRIG_SEL	SP_PULSE_SEL	OP_SEL	SW_READY
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_DOBCR field descriptions

Field	Description
0–5 DATA_LENGTH[5:0]	Can take on values from 0 to 63 corresponding to 1bit to 64bit non standard length commands. When PSI5_DOBCR[CMD_TYPE] == 7(Non Standard) , then this field controls the length of command that can be written to the DBR and the DSR registers, else the value in this field is ignored. This when DATA_LENGTH = 0, then the length of the command that can be written to DSR and the DBR is 1, when DATA_LENGTH = 1, then the length of the command that can be written to DSR and the DBR is 2 and so on, until a maximum of 64 bit length command when DATA_LENGTH = 63. Note that the length of the command that is programmed by using this field, is also equal to the length of the command that shifts out of the DSR register. In other words, it is equal to the number of bits that shift out of DSR register once the DSR_RDY goes low . After these many shifts have happened , then the value corresponding to "DEFAULT_SYNC" starts getting shifted out and DSR_RDY goes as "1".
6 DBR_RST	This is to reset and reject current content to Data Buffer Register. When this bit is written as "1" then the contents of the DBR are reset to all "0s" (if DEFAULT_SYNC == 0) or all "1s" (if DEFAULT_SYNC == 1). As soon as content is reset the DBR would be ready for new data. Reading this bit would always return a "0". Writable to 1 in one shot. This bit is writable only in the CONFIG and the Normal modes.
7 DSR_RST	This is to reset and reject current content to Data Shift Register. When this bit is written as "1" then the contents of the DSR are reset to all "0s" (if DEFAULT_SYNC == 0) or all "1s" (if DEFAULT_SYNC == 1). As soon as content is reset the DSR would be ready for new data. Reading this bit would always return a "0". Writable to 1 in one shot. This bit is writable only in the CONFIG and the Normal modes.
8–10 CMD_TYPE	These 3 bits indicate the type of command that needs to be transmitted during the ECU to sensor communication. Table 47-118 is a brief description of the same.
11 DEFAULT_SYNC	When this bit is set to "0" then the default value of DSR and DBR registers are all "0s"; when this bit is set to 1 then the default value of DBR and DSR registers are all "1s". This value is used as the value of the default sync pulses shifted at the output path when the DSR_RDY == 1.
12 GTM_TRIG_SEL	GTM event triggered/internal sync pulse generator selection as shift clock for the DSR. 0 Internal sync pulse generator shift triggered 1 GTM event shift triggered
13 SP_PULSE_SEL	Selects the source for the short pulse PWM module: 0 SP module gets the data from the DSR 1 SP module directly gets input from the GTM_event/internal sync pulse generator

Table continues on the next page...

PSI5_CH0_DOBCR field descriptions (continued)

Field	Description
14 OP_SEL	This bit selects as to which would be driving source of the "ipp_do_psi5_sdout" port. 0 The sync pulse generator select as per the Bit3 1 PWM output
15 SW_READY	When this bit is written to 1 the transfer from DBR to DSR automatically happens as soon as DSR_RDY becomes 1. When this bit is kept to 0 then the transfer from DBR to DSR will remain pending . Once the software makes this bit as "1" and DSR_RDY also goes as "1" the transfer to DSR takes place. However, note that when this bit is 0, and the DSR_RDY becomes 1, still the transfer to the DSR will NOT happen. Only when this bit is a 1 , will the transfer happen. This bit can be written in CONFIG and the Normal modes.

1. The start condition(31 "1s" or 5 "0s") is automatically taken care by the hardware and should NOT be written to the registers as part of the command.
2. This is also the length of the command that will be shifted out during the ECU to Sensor communication, regardless of how many "actual" bits are written to DBR/DSR.
3. These states are shown in [Valid states for integrated sync pulse generator](#). In State5, the pulse width and period is to be controlled directly from the GTM. In this state, the PW0/1D registers have no effect on the Pulse Width Modulation, when observed on the "sdout" pin.

47.4.36 Manchester Decoder Disable Offset (PSI5_CH0_MDDIS_OFF)

The Manchester Decoder Disable Offset register (PSI5_MDDIS_OFF) defines the time in intervals of 1 μ s, for which the Manchester decoder remains disabled after the falling edge of the sync pulse. Using this register, this time can be programmed from 0 μ s to 128 μ s. This works on the 1 μ s clock from the common clock generator module.

Address: 0h base + 1A2h offset = 1A2h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								MDDIS_OFF							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_MDDIS_OFF field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 MDDIS_OFF	These 7 bits can be used to program the time for which the Manchester Decoder remains disabled. This offset is added AFTER the falling edge of the sync pulse. Thus the total time for which the manchester decoder remains disabled = TsyncH + MDDIS_OFF where TsyncH is the high time for the sync pulse . Thus TsyncH = Pulse_Width0 or Pulse_Width1 as the case maybe, depending on whether a "0" is being pulse modulated or a "1". Note that the Manchester Decoder will ALWAYS remain disabled during the high time of the Sync Pulse. Using this register it is possible to disable the Manchester Decoder BEYOND the Sync Pulse High Time as well. Figure 47-151 shows the "MDDIS_OFF" definition.

47.4.37 Pulse Width for Data Bit Value 0 (PSI5_CH0_PW0D)

The following figure shows the Pulse Width for Data Bit 0 Register.

Address: 0h base + 1A4h offset = 1A4h

PSI5_CH0_PW0D field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 Pulse_Width0	This defines the width (in μ s) of data value '0' to be send from Data Output Register. It is the number of clock cycles(1 μ s clock) counted upto width "Pulse_Width0", as soon as trigger appears from the ISPG(Internal Sync Pulse Generator) or the GTM . Can take max value of 127. When using PSI5 version 1.3 ECU-to-sensor Communication Pulse_Width0 should be configured to 0. Figure 47-151 shows the definition of "Pulse_Width0".

47.4.38 Pulse Width for Data Bit Value 1 (PSI5_CH0_PW1D)

The following figure shows the Pulse Width for Data Bit 1 Register.

NOTE

When using the Version 1.3 format for ECU-to-sensor communication, the pulse width is NOT disabled. In this case, PW0D has to be programmed as 0. PW1D has to have the value of the length of the pulse desired when a 1 has to be transferred.

Address: 0h base + 1A6h offset = 1A6h

PSI5_CH0_PW1D field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PSI5_CH0_PW1D field descriptions (continued)

Field	Description
9–15 Pulse_Width1	This defines the width (in μ s) of data value '1' to be send from Data Output Register. It is the number of clock cycles(1 μ s clock) counted upto width "Pulse_Width1", as soon as trigger appears from the ISPG(Internal Sync Pulse Generator) or the GTM . Can take max value of 127. Figure 47-151 shows the definition of "Pulse_Width1".

47.4.39 Counter Target Pulse Register (PSI5_CH0_CTPR)

The following figure shows the Counter Target Pulse Register.

NOTE

Please see [Internal SYNC Pulse generation and coordination across PSI5 channels](#) for details about the Sync Pulse generation and coordination.

Address: 0h base + 1A8h offset = 1A8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CTPR															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_CTPR field descriptions

Field	Description
0–15 CTPR	Counter Target Pulse Register. This is the target counter value. Once the CTC (channel target counter) reaches the value of CTPR this CTC is reset. CTC is a 16 bit free running counter that starts/stops depending on the CTC_GED (in GCR) bit or the CTC_ED bit (in PCCR). It gets reset initially when its value reaches CIPR and subsequently when its value reaches CTPR. The fact that which out of CTC_GED or the CTC_ED bit enables/disables it, is dependent on the CTC_GED_SEL bit in the PCCR. When CTC_GED/CTC_ED == 0 then the CTC is reset. The minimum value of CTPR is 6. Values less than 6 will be defaulted to 0 and the CTPR counter will not start. The value in CTPR indicates the Time Period of the internally generated sync pulses. The un modulated (No PWM) internally generated sync pulses have a high time of 4-sp_ts_clk cycles i.e. the duty cycle of the un modulated internally generated sync pulses is (4/ICTPRI *100). The 4 sp_ts_clk cycles is just the nascent value of the Pulse which actually triggers the PWD counters Note that this gives one more possible state, in addition to the states shown in Valid states for integrated sync pulse generator . This additional state allows the output of the internal sync pulse generator to be made directly available at the output, without being pulse modulated. The CTPR describes ONLY the SYNC pulse period and not the sync pulse length which is governed by the PWD registers, except in State5 where in the GTM governs these parameters.

47.4.40 Counter Initialize Pulse Register (PSI5_CH0_CIPR)

The following figure shows the Counter Initialize Pulse Register.

NOTE

Due to internal Flop synchronisation there can be a jitter of +/- 1 ns between the offset times that are programmed in the CIPR of different channels and the ones actually being observed. Similarly there can be a jitter of +/- 1 ns in the programmed CTPR and the measured CTPR.

NOTE

Please see [Internal SYNC Pulse generation and coordination across PSI5 channels](#) for details about the Sync Pulse generation and coordination.

Address: 0h base + 1AAh offset = 1AAh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CIPR															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_CIPR field descriptions

Field	Description
0–15 CIPR	Counter initialize pulse register. This is the value using which the CTC gets reset, the first time after which it is enabled using CTC_GED (in GCR) or the CTC_ED bit (in PCCR). All subsequent resets are done when the CTC value reaches CTPR. The CIPR is used to set the offset time between the start of sync pulses between two different PSI5 channels, when the CTC of both of these channels are started simultaneously using CTC_GED. The offset between any two PSI5 channels would be CIPR_channel1 - CIPR_channel2 sp_ts_clk cycles. This if channel 1 has a CIPR = 0 while channel2 has CIPR = 10, then the offset would be 10 sp_ts_clk cycles.

47.4.41 Data Preparation Register Low (PSI5_CH0_DPRL)

The following figure shows the Data Preparation Register Low.

This register is CPU writable only in Normal mode and Disable mode.

This register is the lower register used for writing the standard data and the address commands and is to be used for writing standard length ECU-to-sensor commands. The CRC/stuff/start bits are automatically appended by the hardware before the command is

transferred to DBR. The commands to this register are accepted ONLY when $\text{PSI5\_GISR}[\text{DPR\_RDY}] == 1$. Whenever $\text{PSI5\_GISR}[\text{DPR\_RDY}] == 1$, then each bit of this register defaults to 0. Writing to this register when $\text{PSI5\_GISR}[\text{DPR\_RDY}] == 0$ will cause the $\text{PSI5\_GISR}[\text{IS\_PROW}]$ status bit to be set and the generation of an error interrupt, if it is enabled. Further, trying to write to this register when $\text{PSI5\_DOBCR}[\text{CMD\_TYPE}] = "7"$ results in the setting of the $\text{PSI5\_GISR}[\text{IS\_PROW}]$ bit and the resulting write is rejected.

Table 47-126. DPR details

$\text{PSI5\_DOBCR}[\text{CMD\_TYPE}]$	Standard PSI5 FRAME Types	Writeable bits in PSI5_DPRL
"0" or "1"	Short Frame(PSI5 V1.3)	6($\text{DPR}[5:0]$)

PSI5_CH0_DPRL field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 DPR	$\text{DPR}[23:0]$ are the 24-bits of the DPR register used for writing the variable length, standard ECU-to-Sensor commands, comprising of the address, data and other fields. Note that the IP is transparent to the arrangement of the address, data and other fields and it treats the bits in these fields identically for the purpose of CRC calculation and transmission. This register is writeable only when using the standard length PSI5 frames. For details about CRC calculation please refer to Data transmission . The writeable bits in this register are governed by the $\text{PSI5\_DOBCR}[\text{CMD\_TYPE}]$ bit fields as per Table 47-126 . Note that the unwriteable bits in this register field are always read as "0s". This register has to be written by the CPU.

47.4.42 Data Preparation Register High (PSI5_CH0_DPRH)

Address: 0h base + 1B0h offset = 1B0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH0_DPRH field descriptions

Field	Description
0–31 Reserved	This field is reserved. This register is always read as 0s. Writing to this register does not have any effect.

47.4.43 Data Buffer Register Low (PSI5_CH0_DBRL)

The following figure shows the Data Buffer Register Low.

This register is CPU writable only in Normal mode and Disable mode.

NOTE

When DEFAULT_SYNC == 0, then default value of this register is 00000000. When DEFAULT_SYNC == 1, then the default value of this register is FFFFFFFF. Note that the default value is different from the reset value. The reset value of the register is always "00000000". The default value is loaded once the IP enters the Normal mode.

NOTE

Further, the commands to this register are accepted ONLY when PSI5_GISR[DBR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1, then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DBR_RDY] == 0 will set the status bit PSI5_GISR[IS_BROW] and generate an error interrupt, if it is enabled.

PSI5_CH0_DBRL field descriptions

Field	Description
0–31 DBR	This register contains the Lower 32 bits(DBR[31:0]) of the max-64 bit length command (DBR[63:0]). The higher bits, DBR[63:32] are contained in the DBRH register. These fields can automatically be updated by the hardware (when the CRC/stuff/start bits are appended to the data in DPRL) or these fields can be written by the CPU(when PSI5_GISR[DBR_RDY] == 1 in the Normal mode).Hardware updation occurs when PSI5_GISR[DPR_RDY]== 0and PSI5_GISR[DBR_RDY] == 1. Depending on the PSI5_DOBCR[CMD_TYPE] value this register can have different data assignments as describe in Table 47-129 . The table (except when PSI5_DOBCR[CMD_TYPE] = "7") show the bit assignment of the DBR[31:0] when these bits are automatically updated by the hardware. When PSI5_DOBCR[CMD_TYPE] == "7"), then only the CPU can write to these registers.

47.4.44 Data Buffer Register High (PSI5_CH0_DBRH)

The following figure shows the Data Buffer Register High.

This register is CPU writable only in Normal mode and Disable mode.

NOTE

When DEFAULT_SYNC == 0 then the default value of this register is 00000000 . When DEFAULT_SYNC == 1 then the default value of this register is FFFFFFFF . Note that the default value is different from the reset value. The reset value of the register is always "00000000". The default value is loaded once the IP enters the Normal mode. Further, the

commands to this register are accepted ONLY when PSI5_GISR[DBR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DBR_RDY] == 0 will set the status bit PSI5_GISR[IS_BROW] and generate an error interrupt, if it is enabled.

PSI5_CH0_DBRH field descriptions

Field	Description
0–31 DBR	This register contains the Upper 32 bits(DBR[63:32]) of the max-64 bit length command (DBR[63:0]). The lower bits, DBR[31:0] are contained in the DBRL register. These fields can automatically be updated by the hardware (when the CRC/stuff/start bits are appended to the data in DPRL) or these fields can be written by the CPU(when PSI5_GISR[DBR_RDY] == 1 in the Normal mode).Hardware updation occurs when PSI5_GISR[DPR_RDY]== 0and PSI5_GISR[DBR_RDY] == 1. Depending on the PSI5_DBCR[CMD_TYPE] value this register can have different data assignments as describe in Table 47-131 . Note that when PSI5_DBCR[CMD_TYPE] == "7") , then only the CPU can write to these registers.

47.4.45 Data Shift Register Low (PSI5_CH0_DSRL)

The following figure shows the Data Shift Register Low.
This register is CPU writable only in Normal mode and Disable mode.

NOTE

When DEFAULT_SYNC == 0, then default value of this register is 00000000. When DEFAULT_SYNC == 1, then the default value of this register is FFFFFFFF. Note that the default value is different from the reset value. The reset value of the register is always "00000000". The default value is loaded once the IP enters the Normal mode. Further, the commands to this register are accepted ONLY when PSI5_GISR[DSR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DSR_RDY] == 0 will set the status bit GISR[IS_DSROW] and generate an error interrupt, if it is enabled. Note that for the hardware updation of DSR with DBR contents, additional condition PSI5_DOBCR[SW_READY] == 1, should also be satisfied in addition to PSI5_GISR[DSR_RDY] == 1 .

Address: 0h base + 1BCh offset = 1BCh

PSI5_CH0_DSRL field descriptions

Field	Description
0–31 DSR	This register contains the lower 32 bits, (DSR[31:0]), of the max-64 bit length command (DSR[63:0]). The higher bits, DSR[63:32], are contained in the DSRH register. These bits can be updated by the hardware or can be written by the CPU. The number of accessible bits in DSR are always equal to the number of accessible bits in DBR, which in turn depend on the value of PSI5_DOBCR[CMD_TYPE] register bits. When these bits are updated by the hardware then there is a one to one correspondence between the bit positions in this register and the bit positions in the DBRL. Thus, when updated by the hardware, then DSR[31:0] = DBR[31:0]. Hardware updation occurs when PSI5_GISR[DSR_RDY]== 1 and PSI5_GISR[DBR_RDY] == 0 and PSI5_DOBCR[SW_READY] == 1. Note that if PSI5_DOBCR[SW_READY] == 0, then the updation of the data from the DBR to DSR will NOT happen even though PSI5_GISR[DSR_RDY] == 1. These bits can be written by the CPU in the Normal mode , when PSI5_GISR[DSR_RDY] == 1'b1.

47.4.46 Data Shift Register High (PSI5_CH0_DSRH)

The following figure shows the Data Shift Register High.

This register is CPU writable only in Normal mode and Disable mode.

NOTE

When `DEFAULT_SYNC == 0` then the default value of this register is `00000000`. When `DEFAULT_SYNC == 1` then the default value of this register is `FFFFFFFF`. Further, the commands to this register are accepted ONLY when `PSI5_GISR[DSR_RDY] == 1`. Whenever `PSI5_GISR[DBR_RDY] == 1` then each bit of this register defaults to `DEFAULT_SYNC` value. Writing to this register when `PSI5_GISR[DSR_RDY] == 0` will set the status bit `GISR[IS_DSROW]` and generate an error interrupt, if it is enabled. Note that for the hardware updation of DSR with DBR contents, additional condition `PSI5_DOBCR[SW_READY] == 1`, should also be satisfied in addition to `PSI5_GISR[DSR_RDY] == 1`.

Address: `0h base + 1C0h offset = 1C0h`

PSI5_CH0_DSRH field descriptions

Field	Description
0–31 DSR	This register contains the higher 32 bits (DSR[63:32]) of the max-64 bit length command (DSR[63:0]). The lower bits, DSR[31:0], are contained in the DSRL register. These bits can be updated by the hardware or can be written by the CPU. The number of accessible bits in DSR are always equal to the number of accessible bits in DBR, which in turn depend on the value of <code>PSI5_DOBCR[CMD_TYPE]</code> register bits. When these bits are updated by the hardware then there is a one to one correspondence between the bit positions in this register and the bit positions in the DBRH. Thus when updated by the hardware, then <code>DSR[63:32] = DBR[63:32]</code>. Hardware updation occurs when <code>PSI5_GISR[DSR_RDY] == 1</code> and <code>PSI5_GISR[DBR_RDY] == 0</code> and <code>PSI5_DOBCR[SW_READY] == 1</code>. Note that if <code>PSI5_DOBCR[SW_READY] == 0</code>, then the updation of the data from the DBR to DSR will NOT happen even though <code>PSI5_GISR[DSR_RDY] == 1</code>. These bits can be written by the CPU in the Normal mode when <code>PSI5_GISR[DSR_RDY] == 1'b1</code>.

47.4.47 Device modes and Register bit accesses

1. The following bits are writable in all modes (Normal, Config, and Disable).

- GCR[GLOBAL_DISABLE_REQ]
 - PCCR[PSI5_CH_CONFIG]
 - PCCR[PSI5_CH_EN]
 - Global Counter Enable/Disable (GCR[CTC_GED]). This is to allow the Sync Pulse Generator to be enabled/disabled independently among those channels that are used for staggering, irrespective of the state of the channels NOT being used for staggering.
2. The following register is writeable only in Normal mode and is initialized to all 0s.
 - DPRL
 3. The following registers are writable ONLY in Normal mode. Initialization in Config mode depends on the value of PSI5_DOBCR[DEFAULT_SYNC] bit. When PSI5_DOBCR[DEFAULT_SYNC] == 1 in Config mode, then the below registers are initialized to all 1s in Normal mode. When PSI5_DOBCR[DEFAULT_SYNC] = 0 in Config mode, then the below registers are initialized to all 0s in Normal mode. Once in Normal mode, these registers can then be programmed for any command that needs to be sent. x
 - DBRH/DBRL
 - DSRH/DSRL
 4. The following registers are writable in Config and Normal modes only:
 - All interrupt control registers
 - All SET registers (the one shot registers which are used to set the error flags for software drivers)
 - DMA Control register
 - Channel Enable/Disable (PCCR[CTC_ED]). Using this it is possible to allow the Sync Pulse Generator to be enabled/disabled in Normal mode. The counter is reset when CTC_ED == 0
 - All w1c bits
 5. Apart from these, all other register bits can be written only in Config mode , including the Data registers(PMRH/PMRL/SFRn), that, in Normal mode, are updated by the hardware only.
 6. Debug mode: If the device is in Normal mode and the debug mode is enabled, then ONLY the registers mentioned in pts. 1, 2, 3, and 4 above can be written by the debugger. Register bits mentioned in pt. 5 above, will not be available for write through the debugger. In case the debugger has to change any register, then the device has to be brought in the Disable -> Config mode. The debugger can, however, read any register in any mode.

47.5 Functional description

The PSI5 is a communication protocol for peripheral inertial, pressure, temperature, and position sensors. These sensors are connected to the ECU by just two wires, using the same lines for power supply and data transmission. The transceiver (present externally) provides a pre-regulated voltage to the sensors and reads in the transmitted sensor data. The following figure shows a point-to-point connection for sensors 1 and 2 and bus configuration for sensors 3 and 4.

Figure 47-125. System setup (peripheral sensor connected to device)

The ECU (Electronic Control Unit) comprises PSI5 digital interface and the PSI5 transceiver (present externally).

47.5.1 Sensor-to-ECU communication

47.5.1.1 Physical layer

The PSI5 uses two wires to provide both power supply and data transmission to the sensors. The ECU provides a pre-regulated voltage to the sensors. Data transmission from the sensor to the ECU is done by current modulation on the power supply lines. Current oscillations are damped by the ECU.

47.5.1.2 Bit encoding

A "low" level ($I_{S,Low}$) is represented by the Normal (quiescent) current consumption of the sensor(s). A "high" level ($I_{S,High}$) is generated by an increased current sink of the sensor ($I_{S,Low} + \dots I_S$). The current modulation is detected within the PSI5 transceiver.

Manchester coding is used for data transmission. A logic 0 is represented by a rising slope and a logic 1 by a falling slope of the current in the middle of T bit.

Figure 47-126. Bit encoding of data from sensor

47.5.1.3 Synchronization

For synchronized operation and bus mode, a sync pulse is generated by the PSI5 receiver. The sync pulse is output from the integrated PSI5 receiver to an external PSI5 transceiver that processes these pulses to a pre-regulated voltage level on supply lines to sensors. The voltage change is detected within the sensors.

47.5.2 Data Link Layer

The PSI5 message is received as serial Manchester-coded bits. The bit stream is passed through a Manchester decoder stage that converts it to normal NRZ format bit by bit and stores it serially in the receive register (64 bits). This block clearly identifies start (00) and end of receive frame using preprogrammed frame configuration registers.

- The Manchester-coded bits can be received at the rate of 125 Kbit/s.

- The bit decoding is done using an oversampling and counting algorithm with majority voting and edge recognition. Clocks of $(125 \text{ kHz}) \times 32$ (4 MHz also referred to as 32× clock) are supplied from a common clock generator module. This clock is used for oversampling of the receive bit and thereby decoding it as normal 1 or 0 (NRZ).
- The Manchester decoder is masked (switched off) for the duration when the sync pulse is transmitted. In addition to this, it can be configured to be off for an additional time, after the falling edge of the sync pulse. The duration of this time is configurable in the MDDIS_OFF register.
- It uses a 2003 voter to recognize the encoded half bits.
- There is a 3005 majority voting glitch filter at the data input of the Manchester decoder.

47.5.2.1 Reception of data frames

The extended PSI5 (Power Train Applications) receive data frame consists of p bits containing:

- Two start bits (S1 and S2) {S1=0, S2=0}
- One parity bit (P) with even parity (or 3 CRC bits C0, C1, and C2).
- A data region (D0.....D[k – 1]) with $k = 8$ to 28 bits with 1-bit granularity.
- The total length of a PSI5 frame is $p = k + 3$ data bits (in case of frames with parity bit) or $p = k + 5$ data bits (in case of frames with CRC).
- Data bits are received LSB first. The parity or CRC check bits cover the bits of the entire data region.

The length of the data region can vary between $k = 8$ to 28 bits (with 1-bit granularity). The data region can be split into the following fields and regions:

- The bits D0 and D1 can optionally represent Serial Messaging Channel M0, M1.
 - This Serial Messaging Channel (SMC) is used to receive initialization data during fast startup phase or slow acknowledgement/response messages (to command transmitted from ECU requesting data or diagnostic information from the sensor).

Note, that the maximum length of the entire data region is 28 bits. Thus the signal payload region and the optional data fields cannot concurrently be used at their maximum length in some cases.

As the PSI5 module is targeted for powertrain applications, the data frame format differs from standard PSI5 frames for safety applications specified in version 1.3 of the PSI5 specifications. More specifically for supporting the version 2.0 powertrain substandard. The Powertrain data frame format and optional Serial Messaging Channel (SMC) frame format are shown in the following figure.

Figure 47-127. Receive data frame format

47.5.2.2 Data Frame Configuration Control

Figure 47-128. Data frame configuration and sampling

At the receive path, as many as six frame slots (reception windows) can be programmed with a start time of consecutive slots (slot1 to slot6) and end time or last slot which can be configured through the Slot n Start/End Configuration Registers (Slot 1 Start Boundary Register (PSI5_CH0_S1SBR)-Slot 6 Start Boundary Register (PSI5_CH0_S6SBR) and Slot n End Boundary Register (PSI5_CH0_SnEBR)) there are seven registers for six slots. The slot time value is with respect to timing sync pulse.

The following range is always maintained for T_{sync} (during programming of the GCR and CTPR registers) when timing (sync) pulses are generated through the Sync Pulse Generator.

$$T_{sync} < 16\text{ms}$$

For the maximum defined six frame slots, six frame configuration registers (S1FCR, S2FCR, S3FCR, S4FCR, S5FCR, and S6FCR) are also available. In these registers it is possible to configure the payload region of the expected frames, in addition to other channel-specific parameters.

47.5.2.3 Data frame handling

The following figure shows the detection of the start bits and the various parameters for the same.

Figure 47-129. Start Bit Detection

The following figure shows how the bits are differentiated into a “1” or a “0” based on the various margins and sample points.

Start Sequence Measured: $T_p = 32$ and $TDcH = 20$

Calculations:

$TDcL = T_p - TDcH = 12$, $\Delta Dc = TDcH - T_p/2 = 4$; $TMarginL = TDcL/2 = 6$; $TMarginH = TDcH/2 = 10$

If $DATA\_BIT(N) = 0$, $TWI = TDcH + TMarginL = 26$; signal sampled at $TWI-3$, -2 and -1

- If signal low, expect rising edge between $TWL0$ and $TWR0$ then $DATA\_BIT(N+1) = 0$.

$TWL0 = TDcH + TMarginL$ and $TWR0 = T_p + TMarginH$

- If signal high, expect falling edge between $TWL0$ and $TWR0$ then $DATA\_BIT(N+1) = 1$.

$TWL0 = TDcH + TMarginL$ and $TWR0 = T_p + \Delta Dc + TMarginL$

If $DATA\_BIT(N) = 1$, $TWI = TDcL + TMarginH = 22$; signal sampled at $TWI-3$, -2 and -1

- If signal low, expect rising edge between $TWL1$ and $TWR1$ then $DATA\_BIT(N+1) = 0$.

$TWL1 = TDcL + TMarginH$ and $TWR1 = T_p - \Delta Dc + TMarginH$

- If signal high, expect falling edge between $TWL1$ and $TWR1$ then $DATA\_BIT(N+1) = 1$.

$TWL1 = TDcL + TMarginH$ and $TWR1 = T_p + TMarginL$

IDLE state can be reached in two ways:

- Idle can be detected after zero (last data bit). In this the edge is searched in the same window as for data zero i.e. $TWL0 = 26$ to $TWR0 = 42$
- Idle is detected after one (last data bit). In this the edge is searched in the same window as for data one i.e. $TWL0 = 22$ to $TWR0 = 38$

Figure 47-130. Bit Extraction

47.5.2.3.1 Start of frame recognition

47.5.2.3.2 Data state

In the data state, the Manchester decoder samples the number of data bits corresponding to the configured length of the data payload region and 3-bit CRC or 1-bit parity.

47.5.2.3.3 Message diagnostic checks

During the data state, electrical correctness of each bit in regard of Manchester encoding is checked. If an incorrect bit is detected, a 0 is written into the data payload region. Following completion of reception, correctness of the entire message is checked with the CRC and timing of the message reception.

- CRC is recalculated for the data and compared with received CRC bits. The CRC comparison result is stored as a status bit, denoted as the C field in the receive register and the RAM register. Irrespective of the value of the “C” bit the, the frame is always stored in the RAM register and is never discarded.
- If at least one bit is electrically faulty (apart from M0M1), then the bit field E is set to 1 and stored as status bit in the receive register and the RAM register.
- The EM bit is set to 1 if any of M0 or M1 bits are electrically faulty. Note that the E and the EM bits can be set only when a valid start sequence has been detected.
- Set status bit field T in the receive register to 1 if the frame received is in the wrong slot (boundary violations). This bit is NOT set for asynchronous modes.
- Set status bit F if no frame is received in defined frame slot. This bit is NOT set for asynchronous modes.
- The incoming frames after the sync pulse are to be numbered from 1 to 6 (max). This is done by a 3-bit slot counter, which is incremented automatically after the end of each slot irrespective of whether a valid message is received or not. This 3-bit value is stored in the receive register and the RAM registers as the "slot_counter" field.

47.5.2.3.4 T-bit handling

The following paragraphs describe how the IP handles error cases that generate T bit errors. A number of examples are shown, including the error free case, which is used to explain the reception process.

47.5.2.3.4.1 Error free case

Figure 47-131. Error free case

In this case, all messages are received in the correct slots.

- As soon as the Manchester decoder block is enabled (after the SYNC pulse has finished and any configured disable offset has expired, pink region) the IP checks for the first configured message and starts monitoring the output of the PSI5 transceiver.
- The IP identifies a correct start of message sequence (S0, S1) == '00', and captures the slot counter when the first rising edge of the start sequence is detected. This first rising edge detected is the mid-point transition of the Manchester encoded S0 bit of the message start sequence.
- The expected number of bits configured in the message is received and decoded. Any error in the Manchester encoded bits of the message E bit is set - unless the error is in one of the first two bits and SMC message is configured, in which case the EM bit is set.
- After the final bit is received, a check is made that the message CRC or parity is correct. If the CRC or parity check is not correct, C bit is set for the message.
- Once the CRC checks have been made, the received message — along with the status bits, slot counter in which the start sequence was received, the timestamp of the message, the message data and CRC or parity is saved to the channel message FIFO.

- As soon as the received message has been stored, the idle state of the bus is verified and monitoring of the transceiver output restarts to check for the next configured message.
- If the serial message channel (SMC) is configured, the first two data bits are extracted from a sequence of 7 PSI5 messages as long as no electrical error is detected in those bits (EM error). If the correct start sequence for the SMC message is detected on M1 (6 logical 1s and a logical 0) in those 7 messages, M0 and M1 from the following 11 messages are also extracted and saved in the SMC buffer allocated to the slot in which the PSI5 message is received (in total, 18 PSI5 messages are needed to build one SMC message). When the SMC has been received, the CRC is checked and the status of the check is saved in the SMC buffer. If an EM error occurs after a start sequence has been detected and before the end of the message is reached, M0 and M1 are both saved as 0 and the rest of the message is received, at which point the CRC is checked as normal.

47.5.2.3.4.2 Message Too Early

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	1	Yes	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

Figure 47-132. Message Too Early

In this scenario, MSG2 reception starts early, before slot 2 boundary is crossed, and so the slot counter is captured as “1” and because the message starts in the wrong slot, the T bit is set. If no other errors are detected during reception, the assumption is that the

correct MSG2 has been received but not entirely in it's correct slot. The status of the message will include the T bit set and slot counter will be 1, so software can interpret that MSG2 was too early.

The SMC message is received correctly.

47.5.2.3.4.3 Message Too Late

Figure 47-133. Message Too Late

In this scenario, MSG1 reception starts later than expected and ends after slot 2 boundary is crossed. The slot counter is captured as “1” and because the message ends in the wrong slot, the T bit is set. If no other errors are detected during reception, the assumption is that the correct MSG1 has been received but not entirely in it's correct slot. The status of the message will include the T bit set and slot counter will be “1”, so software can interpret that MSG1 was late.

The SMC message is received correctly.

47.5.2.3.4.4 Message Missing

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	Yes	No	No	2	0/0
MSG4	4	No	No	No	No	4	M0/M1

Figure 47-134. Message Missing

In this scenario, MSG2 is missing.

At the end of slot 2, the IP writes message buffer location 2 (MSG2 location) with slot counter 2 and the F bit set. The data and timestamp regions are filled with 0s.

The IP waits until the start of the next configured slot (slot 4) to update the SMC buffer 2 with “00”. If slot 4 was not configured, the SMC for the missing MSG2 would be updated at the end of the final slot.

47.5.2.3.4.5 Message Too Much Late (in unconfigured slot)

Figure 47-135. Message Much Too Late (in unconfigured slot)

In this scenario, MSG2 reception doesn't start in its own slot, and the F bit is set for message buffer location 2 (MSG2a).

Because slot 3 is not configured, the IP continues to wait for MSG2 in slot 3 and does not update the SMC message buffer 2. The IP recognizes the MSG2 start condition in the normal way and updates PSI5 message buffer 3 (MSG2b), capturing slot 3 as the start slot counter and setting T bit, so that the software can recognize that MSG2 has come in slot 3.

When MSG2 has been received, SMC message buffer 2 is updated at the end of slot 3. MSG4 is received normally.

NOTE

Any scenario where an expected message arrives in an unconfigured slot, leads to an issue when DMA access is used to read the PSI5 message buffer. This is because instead of the expected three entries in the PSI5 message buffer, there will be four, and assuming the DMA watermark is set for the expected three messages, the DMA request will be activated before MSG4 has been received.

In order to overcome this, if DMA access is required, no slots can be left unconfigured and the DMA watermark must be set to the number of slots in the SYNC period. In that way, the DMA will always be synchronised, but depending on how the 'empty' slot is configured, when a message is too late as described here, the result can be that the late message and its associated SMC content is lost.

47.5.2.3.4.6 Message Much Too Late (in unconfigured slot)

Figure 47-136. Message Much Too Late (in unconfigured slot)

In this scenario, MSG1 is received much too late, in the second of two unconfigured slots.

When MSG1 does not arrive in slot 1, MSG1a is saved in the message buffer with F bit set. The IP waits throughout the two unconfigured slots and is received in slot 3 with slot counter 3. Because MSG1b is received completely in slot 3 it is saved in the message buffer with T bit set.

MSG4 is received normally.

47.5.2.3.4.7 Message Too Late (in last slot)

Figure 47-137. Message Much Too Late (in last slot)

In this scenario, the last message is received late.

MSG1 and MSG2 are received error free.

MSG4 is late with the start sequence identified in the correct slot 4, with slot counter 4 captured. The end of the message occurs after the end of the final slot, but before the Manchester decoder is disabled by the SYNC pulse on the bus. The message is received correctly with the T bit set.

47.5.2.3.4.8 Message Too Late (in last slot)

Figure 47-138. Message Much Too Late (in last slot)

In this scenario, the last message is received late in the last slot.

MSG1 and MSG2 are received error free.

MSG4 is late with the start sequence identified in the correct slot 4, with slot counter 4 captured. The end of the message occurs after the Manchester decoder is disabled by the SYNC pulse on the bus, so the last part of the message cannot be received correctly. Nevertheless, the message reception is completed and the message is stored in the message buffer with the T bit set and 0 written in the buffer for all bits received while the Manchester decoder is disabled. This leads to E and C bit errors.

In an extreme case, it could also lead to EM bit errors, in which case the SMC buffer will also be written with (0,0) otherwise, the correct bits are written to the SMC buffer.

47.5.2.3.4.9 Message Too Early (in first slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	0	Yes	No	No	No	1	M0/M1
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

Figure 47-139. Message Much Too Early (in first slot)

In this scenario, the first message is received early.

As soon as the Manchester decoder disable phase has ended, the IP verifies the idle condition on the signal line and then looks for the first message start sequence. MSG1 start sequence is received before the start of slot 1 with slot counter 0 captured. MSG1 is then received normally and saved with slot counter 0 and T bit set.

SMC bits M0/M1 are saved to SMC buffer 1.

MSG2 and MSG4 are received normally.

NOTE

This scenario can be avoided if the start of slot 1 is configured to coincide with the end of the Manchester decoder disable phase.

47.5.2.3.4.10 Message Too Early (in first slot and overlaps Manchester Decoder disable)

Figure 47-140. Message Too Early (in first slot)

In this scenario, the first message is received early and overlaps with the Manchester decoder disable phase.

As soon as the Manchester decoder disable phase has ended, the IP starts looking for “idle condition” on the signal line by monitoring it for 42 counts of the sample clock. If the signal line is found to be initially high or if a valid transition occurs in the time frame of 42 samples of the sample clock, the Manchester decoder stops decoding until the end of slot 1. Decoding will restart at the beginning of slot 2.

MSG1 is assumed to be lost and the “F” bit is set for that message with the Slot Counter as “1”. If MSG1 SMC is configured then SMC is saved with “00” appended for the M0/M1 bits.

47.5.2.3.4.11 Message Too Late (overlaps next message)

Figure 47-141. Message Too Late (overlaps next message)

In this scenario, MSG1 is received too late and overlaps with MSG2.

MSG1 start is recognized in slot 1. The last bits of MSG1 are disrupted by the start of MSG2 leading to likely E and C bit errors.

At the end of MSG1, idle time is found to be violated by either the signal line being high as soon as NO_DETECT_STATE is entered or FIRST_TRANSITION_DETECT occurs within 42 counts of the idle detect sample clock. The Manchester decoder stops decoding until the end of slot 2. Decoding is restarted at the start of slot3. MSG2 is not received and MSG2 location in the memory will be saved with the F-bit set. The SMC buffer 2 will be updated with 00.

MSG3 and MSG4 are received correctly in their own slots.

47.5.2.3.5 Data Frame Storage

Once the data frame is received and all required status fields updated (for example, Time stamp, C, E, EM, T, F and Frame Counter), this 64-bit value in the data receive register is moved to the RAM Register (PMB).

- This RAM buffer is a 32 (depth) × 64 (frame size) register array with DMA transfer capability (both single or burst).
- Also, the individual RAM locations can be accessed directly by the microcontroller core any time.
- Care needs to be taken that receive data is assigned to the sensor and frame slot unambiguously.

47.5.2.3.6 Message diagnostics

Apart from the regular status bits (mentioned above), a few more diagnostic checks are done and stored as status bits along with each data frame location in RAM. These are:

- Diagnosis registers are associated with each sensor data RAM buffer to indicate
 - RAM buffer has been filled with data.
 - RAM buffer has been overwritten before data previously stored was read.
 - Data written to buffer includes an error bit (E, EM, C, T, or F, configurable).
- The diagnosis registers are able to be read with a single DMA access.
- After successfully completing a read access, these registers are reset by hardware. This is done by mapping these diagnosis bits byte-wise so that one byte access clears a single bit without affecting other bits.

Figure 47-142. Diagnosis Information attached to every frame

Note

See [Implementation of EI Diagnostic Register](#) for more detail.

47.5.2.3.7 SMC message extraction

The optional messaging channel M0, M1 (shown in [Figure 47-127](#)) is used by sensors to send an SMC frame along with the normal PSI5 frame. It takes 18 PSI5 frames to send one SMC frame.

The extraction of SMC bits is done for each slot separately and stored separately into the SMC frame receive buffers. The size of the SMC frame receive buffers is 6 (no of slots) × 32 (depth of SMC frame, as defined below)

The extraction logic works as follows:

- Search for SMC start sequence 111111 followed by 0 on M1 and keep storing last 6 bits {CRC} on M0.
- If the start sequence is detected it continues with further extraction and storage of M1 and M0.
 - Store the extracted frame on the corresponding slot buffer.

- Move the SMC frame to corresponding SFR[i] register period. Once complete, the SMC frame is extracted and generates an interrupt, so that it can be read by the CPU.
- If the start sequence is not detected, it continues with the search.

The SMC frame is extracted in hardware and stored separately as memory-mapped registers. The size of the SMC frame receive buffers is 6 (no of slots) $\times$ 32 (depth of SMC frame).

47.5.2.4 Message Read Logic

PSI5 supports two kinds of read access to received sensor data.

- Read access through memory-mapped RAM registers. These registers can be read by the CPU any time or, specifically, when the concerned interrupts are raised. Applicable for both the SMC and the PSI5 messages.
- Read access through DMA request. Here the DMA sequencer treats the memory-mapped registers as a block and reads them sequentially. Note that even if the DMA is used, the CPU can read the RAM registers any time by addressing them. This is applicable for both the SMC and the PSI5 messages. When reading the PSI5 messages, it is possible to read only the PSI5 messages or PSI5 + diagnostic registers.

Figure 47-143. PSi5 and SMC Message Read Logic Block

47.5.2.5 CRC Recalculation

Error detection is realized by a single bit even parity (recommended for 10 or fewer bits) or a 3-bit CRC (recommended for long data words). The transmission error detection is selectable (by frame configuration register) as:

- 1-bit even parity
- 3-bit CRC

The generator polynomial of the CRC is $g(x)=1+x+x^3$ with a binary CRC initialization value of 111. The transmitter extends the data bits by three 0s (as MSBs). This augmented data word is fed (LSB first) into the shift registers of the CRC check. Start bits are ignored in this check. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the buffer registers contain the CRC checksum. These three check bits are transmitted in reverse order (MSB first: C2, C1, C0).

Figure 47-144. CRC calculation scheme

Table 47-134. CRC Calculation (at transmitter side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	0	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	1	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	1	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	1

Table 47-135. Transmitted and Received Sensor Data

Transmitted Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0
Received Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0

Table 47-136. CRC Re-Calculation (At Receiver Side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	1	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	0	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	0	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	0

Syndrome = 000 → Transmission successful

The correct transmission is checked by the PSI5 receiver by comparing the syndrome (content of the shift register after reception of both data bits and CRC bits) with the zero vector. For error free reception, all shift registers have to be zero.

47.5.3 ECU-to-sensor communication

Whereas the sensor-to-ECU communication is realized by current modulation, voltage modulation on the supply lines is used to transmit commands to the sensors. A predefined start sequence allows the sensors to recognize that a command is being transmitted during all synchronous operation modes.

47.5.3.1 Physical Layer

A logical 1/0 is represented by data sync pulse of variable length, a logical 1 by the sync pulse of width W1(programmable from 0 to 127 μ s) and logical '0' by sync pulse with W0{programmable from 0 to 127 μ s}.

47.5.3.2 Data Link Layer

47.5.3.3 Bit coding

The bit period is the cycle time as specified for the operation mode, for example, 500 μ s in the PSI5-P10P-500/3L mode. (For details about this topology, please refer [Section PSI5 topology](#)) The lower limit depends on the filter characteristics of the hardware circuitry used for the sync signal detection (subsequent sync signals might vary the internal $V_{ss, base}$ reference).

47.5.3.4 Data transmission

The IP supports the standard and the Non-Standard ECU to Sensor communication Formats . In the Non-Standard mode of communication it can be used to send any frame size programmable from 1-64 bits. In the Standard Formats it supports both the V1.3 and the V2.0 of the PSI5 ECU to Sensor Communication as briefed below in [Figure 47-145](#) and the text that follows it.

Figure 47-145. Standard Frame Fomats Supported

- **Short(V1.3)** : It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- "010", S, "A0, A1, A2", S, "F0, F1, F2", S, "C2, C1, C0" where "010" is the start sequence "S" is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes and "C2-C0" is the CRC. Please refer [Figure 47-145](#) for the frame structure.
 - The CRC polynomial used is $x^3 + x^2 + 1$ with a binary initialisation value of "111(C2:C0)".
 - The transmitter extends the data bits by three zeros (as MSBs).
 - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0..F2,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
 - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[5],000) with DPR[0] being fed first in the CRC calculator.
- **Long(V1.3 - 4bit Data Nibble)** : It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- "010", S, "A0, A1, A2", S, "F0, F1, F2", S, "X0, X1, X2", S, "X3, X4, X5, S, "D0, D1, D2", S,"D3, C2, C1", S, "C0" where "010" is the start sequence "S" is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes, "X0-X5" is the Range Address, "D0-D3" is the data and "C2-C0" is the CRC. Please refer [Figure 47-145](#) for the frame structure.
 - The CRC polynomial used is $x^3 + x^2 + 1$ with a binary initialisation value of "111(C2:C0)".
 - The transmitter extends the data bits by three zeros (as MSBs).
 - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0..F2,X0..X5,D0...D3,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved .
 - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[15],000) with DPR[0] being fed first in the CRC calculator.
- **Long(V1.3 - 8bit Data Word)** : It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - "010", S, "A0, A1, A2", S, "F0, F1, F2", S, "X0, X1, D0", S, "D1, D2, D3, S, "D4, D4, D6", S,"D7, C2, C1", S, "C0" where "010" is the start sequence "S" is the stuff

bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes, "X0-X1" is the Range Address, "D0-D7" is the data and "C2-C0" is the CRC .Please refer [Figure 47-145](#) for the frame structure.

- The CRC polynomial used is $x^3 + x^2 + 1$ with a binary initialisation value of "111(C2:C0)".
 - The transmitter extends the data bits by three zeros (as MSBs).
 - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0..F2,X0..X1,D0...D7,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved .
 - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[15],000) with DPR[0] being fed first in the CRC calculator.
- **X-Long(V1.3)** : It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - "010", S, "A0, A1, A2", S, "F0, F1, F2", S, "X0, X1, X2", S, "X3, X4, X5", S, "X6, X7, D0", S, "D1, D2, D3", S, "D4, D5, D6", S, "D7, C2, C1", S, "C0" where "010" is the start sequence "S" is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes,"X0-X5" is the Range Address , "D0-D3" is the data and "C2-C0" is the CRC . Please refer [Figure 47-145](#) for the frame structure.
- The CRC polynomial used is $x^3 + x^2 + 1$ with a binary initialisation value of "111(C2:C0)".
 - The transmitter extends the data bits by three zeros (as MSBs).
 - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0..F2,X0...X7,D0...D7,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved .
 - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[21],000) with DPR[0] being fed first in the CRC calculator.
- **XX-Long(V2.0)** : It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C5 comes Last) Data Stream - "011111110", "A0, A1, A2", "C", "D0, D1", S, "D2, D3, D4" D5, D6, D7, S, "D8, D9, D10, D11, D12, D13", S, "D14, D15, D16, D17, D18, D19", S, "C0, C1, C2, C3, C4, C5"

where "01111110" is the start sequence, "S" is the stuff bit(0), A0-A2 is the sensor address, "C" is the configuration bit, "D0-D19" is the data and "C0-C5" is the CRC. Please refer [Figure 47-145](#) for the frame structure.

- The CRC polynomial used is $x^6 + x^4 + x^3 + 1$ with a binary CRC initialization value 010101(C5:C0) .
- The transmitter extends the data bits by six zeros (as MSBs).
- The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,D0..D19,"000000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved .
- When mapping this sequence to the DPR register bits for calculating the CRC ; then it becomes (DPR[0],DPR[1]....DPR[23],000000) with DPR[0] being fed first in the CRC calculator.

47.5.3.4.1 Transmission Data Framing

The output data transmission block is constructed of seven sub-blocks:

- Data preparation register
- Buffer register
- Data shift register
- Periodic Sync Pulse Trigger Generator
- "GTM driven" sync pulse trigger input (GTM external to PSI5)
- Pulse length modulation block
- OR gate

47.5.3.4.2 Data Preparation Register (64-bit register, DPRH + DPRL, DPRH is fixed at 0)

Upto 24 bits of this register can be written by the CPU. These register bits contain the ECU to sensor command that needs to be transmitted after being appended with the CRC, start bits and stuff bits. The hardware automatically calculates the CRC and adds the start and the stuff bits, before transferring the command to DBR.

- Having written the data to the DPR, the DPR_RDY bit has be cleared with a w1c. This indicates to the internal logic that the data in the DPR is valid and is to be processed.
- If DPR_RDY = 0 and a new command is written to the DPR then the command is rejected and GISR[IS_PROW] is set.
- If the CRC or parity bit calculation is finished, then the data is shifted to the Buffer register with the start bits and the sync bits appended as well. This transfer is done to the Buffer register only if the Buffer register is ready for new data, which is indicated by GISR[DBR_RDY] == 1.
- As mentioned above, once this tranfer is done, the DPR_RDY becomes 1 and a new command can be written to it.

47.5.3.4.3 Data Buffer Register (64-bit register)

- This register has two subregisters DBRH (higher register) and DBRL (lower register). Both of them are collectively referred to as DBR. DBR is of length 64 bits DBR[63:0]
- The bits accessible for functionality are dependent on the value of PSI5_DOBCR[CMD_TYPE]. For the writeable bits corresponding to different setting of the PSI5_DOBCR[CMD_TYPE] field please refer bit description in CMD_TYPE[2:0]
- When DPR_RDY == 0 and DBR_RDY goes to 1 then internal logic automatically transfers the data from the DPR (with CRC + stuff bits + sync bits) to the DBR. DBR_RDY goes low and DPR_RDY goes 1.
- If DBR_RDY == 1 AND DPR_RDY == 1, then the data to be transmitted to sensors can be written to this register directly via system bus skipping preparation register in case application includes the start and sync bits and calculates the CRC/Parity itself. If the CPU writes to the DBR when DBR_RDY == 1 but DPR_RDY == 0 and PSI5_DOBCR[CMD_TYPE] != 7, then the results can be unpredictable since the DPR has a pending data that needs to be transferred to DBR.

- If the CPU is writing to the DBR as mentioned above, then the DBR_RDY bit has to be cleared by a w1c. This indicates to the internal logic that the data in the DBR is valid and is to be used for the shift operation.
- If while DBR_RDY == 0, and a new command is directly written to the DBR then the command is rejected and GISR[IS_BROW] bit is set.
- If while DBR_RDY == 0 a new command HAS to be written in the DBR then DOBCR[DBR_RST] has to be written to 1. Writing a 1 to DBR_RST will reject the current command in the DBR and generate DBR_RDY = 1.
- If the Data Shift Register signals that it is ready for new data (PSI5_GISR[DSR_RDY] == 1), the data of the Buffer register is shifted into the data shift register provided PSI5_DOBCR[SW_READY] is 1.
- If PSI5_DOBCR[SW_READY] == 0 then the data from the DBR is NOT transferred to the DSR automatically even if the DSR_RDY goes as 1. In such a case the IP waits for the software to make the PSI5_DOBCR[SW_READY] bit as 1; only then does it transfer the contents to the DSR.

47.5.3.4.4 Data Shift Register (64-bit register)

- This register has two subregisters DSRH (higher register) and DSRL (lower register). Both of them are collectively referred to as DSR. DSR is of length 64 bits DSR[63:0]. This register has a 1-1 correspondence with the bits in the DBR register when this register is updated automatically by the hardware.
- The bits accessible for functionality are dependent on the value of PSI5_DOBCR[CMD_TYPE]. For the writeable bits corresponding to different setting of the PSI5_DOBCR[CMD_TYPE] field please refer bit description in CMD_TYPE[2:0].
- When DBR_RDY == 0 and DSR_RDY goes to 1 then internal logic automatically transfers the data from the DBR to the DSR provided PSI5_DOBCR[SW_READY] == 1'b1, else this transfer remains pending till PSI5_DOBCR[SW_READY] is '0'. Once the transfer is complete, DSR_RDY goes low and DBR_RDY goes 1. DSR contents that would finally get transferred, can be read at this stage, i.e., when DBR_RDY becomes "1".
- Making PSI5_DOBCR[SW_READY] now as '0' will not interrupt the ongoing transfer in the DSR.

- If `DPR_RDY == 1 AND DBR_RDY == 1 AND DSR_RDY == 1`, then the data to be transmitted to sensors can be written to this register directly via system bus skipping Buffer register. If the CPU writes to the DSR when `DSR_RDY == 1` but `DBR_RDY == 0` then the results can be unpredictable since the DBR has a pending data that needs to be transferred to DSR.
- When `PSI5_DOBCCR[CMD_TYPE] == 7` and If `DBR_RDY == 1 AND DSR_RDY == 1`, then the data to be transmitted to sensors can be written to this register directly via system bus skipping Buffer register. If the CPU writes to the DSR when `DSR_RDY == 1` but `DBR_RDY == 0` then the results can be unpredictable since the DBR has a pending data that needs to be transferred to DSR.
- If the CPU is writing to the DSR as mentioned above then the `DSR_RDY` bit has to be cleared by a `wlc`. This indicates to the internal logic that the data in the DSR is valid and is to be used for the shift operation.
- If while `DSR_RDY == 0`, and a new command is directly written to the DSR then the command is rejected and `GISR[IS_DSROW]` is set.
- If while `DSR_RDY == 0` a new command HAS to be written in the DSR then `DOBCCR[DSR_RST]` has to be written to 1. Writing a 1 to `DSR_RST` will reject the current command in the DSR and generate `DSR_RDY = 1`.
- This register is clocked by the ISPG pulses or the GTM pulses, as described in [Sync Pulse Trigger Generation](#).
- Once the shift operation is complete in the DSR then `DSR_RDY` becomes 1.

47.5.3.4.5 Sync Pulse Trigger Generation

The sync pulse trigger can be used to generate the timing pulses or the data pulses.

The sync pulse can be generated based on triggers from two different sources:

- **ISPG (Internal Sync Pulse Generator):** Composed of CTPR, CIPR and Channel Target Counter (per channel). The internal sync pulse generator is clocked by the internal 1 MHz clock. The Channel Target Counter operates with a 1 μ s resolution (when using the 1 MHz clock). The ISPG is implemented to allow generation of internal periodic trigger. Please Refer [Figure 47-151](#) for the ISPG structure and [Figure 47-150](#) for the CTPR and CIPR explanation. The ISPG uses the Channel Target Counters (CTCs) for generating the sync pulse. The CTCs can be triggered globally (simultaneous for all channels) or locally (individual to each channel). The `CTC_GED` bit in the Global Control Register (GCR) ensures that all the CTCs start/stop simultaneously. The individual target values when the trigger pulse is generated are set in the Counter Target Pulse Register (CTPR) and the Channel Initial Pulse

Register (CIPR). These registers are present for each channel. When staggering the channels, the CTC_GED bit should be used for providing a simultaneous trigger to the staggered channels. It is also possible for a subset of channels to work on the above arrangement while the remaining channels independently generate trigger pulses for which start/stop is controlled locally to the channels.

- For each channel, it is possible to configure the trigger period by software using sync pulse generator control/configuration register and setting compare values in Counter Target Pulse Register(s). The Counter Initial Pulse Register (CIPR) can be used to provide the initial offset between various channels.
- It is possible to deactivate each channel separately for the purpose of Sync Pulse generation.
- The periodic pulses can be used to synchronize sensor-to-ECU communication (synchronization timing pulses) [State 1 of [Valid states for integrated sync pulse generator](#)] or can be used as data pulse during ECU-to-sensor communication (through the DOBCR) [State 2 of [Valid states for integrated sync pulse generator](#)].
- When programming the CTPR, the Tsync period should be programmed ≥ 6 SP_TS_CLK cycles (For details of SP_TS_CLK, refer to Bit 23 of Section 54.3.2.2, PSI5 Channel Control Register (PSI5_PCCR))
- **GTM event controlled:** Generation of sync Trigger/Pulse can be done based on events (e.g., crank angle or software) through **general timer module (GTM)** output to the PSI5 interface.
 - Here the sync trigger pulses come from an external GTM module.
 - The sync pulse programming (period, etc.) is done inside GTM.
 - In [Figure 47-146](#), if switches S2 and S21 are closed and S22 and S23 are open, the GTM trigger is used for data pulse generation (data pulses for ECU-to-sensor communication). [State 4 of [Valid states for integrated sync pulse generator](#)]

- In [Figure 47-146](#), if switches S2 and S22 are closed and S21 and S23 are open, the GTM trigger is used for timing pulse generation (synchronization pulse for sensor-to-ECU communication). [State 3 of [Valid states for integrated sync pulse generator](#)]
- In [Figure 47-146](#), if switches S2 and S23 are closed and S21 and S22 are open, the GTM trigger is passed directly to data sync port without pulse length modulation. In this case the sync pulse length is defined by the GTM pulse length. [State 5 of [Valid states for integrated sync pulse generator](#)]
- **Programming and control :** For achieving the various states of ISPG control or the GTM control, the switches S1, S2, S11, S12, S21, S22, and S23, shown in [Figure 47-146](#) can be set (closed) or cleared (open) by writing to the three equivalent bits (GTM_TRIG_SEL, SPULSE_SEL and OP_SEL) belonging to the DOBCR, as shown in [Figure 47-147](#). The programming of various states mentioned above, with reference to the [Valid states for integrated sync pulse generator](#) can be seen in [Table 47-4](#) and also shown in [Figure 47-153](#). The sending of the ECU to sensor commands, can be controlled by PSI5_GISR[DPR_RDY, DBR_RDY, DSR_RDY] bits and the PSI5_DOBCR register bits.

47.5.3.4.5.1 Timing Pulses

Timing pulses can also be produced without pulse width modulation also . These timing pulses can be generated through two sources:

- Periodic sync pulse from ISPG . In this case the synchro pulse from the internal sync pulse generator can be made available without any modulation. Referring [Figure 47-147](#), in synchronous mode , if DOBCR[GTM_TRIG_SEL] == 0 and DOBCR[OP_SEL] == 0 then the internal sync pulse generator output can be made available without any modulation . The high time of this pulse is fixed at 4 μ s.
- Referring [Figure 47-147](#), in synchronous mode , if DOBCR[GTM_TRIG_SEL] == 1 and DOBCR[OP_SEL] == 0 , then the GTM trigger can be used for timing pulse generation without any Pulse Width Modulation.

47.5.3.4.5.2 Data pulse generation

Data pulses are produced through Pulse Length modulation block based on triggers from one of the two selectable sources **ISPG** or the **GTM**, during ECU-to-sensor communication. The selection between the above two sync sources can be done by software programming Pulse length control/configuration register.

- A logical '1' in Data Output Register LSB is coded as data sync pulse of width W1 {up to 127 μ s}.
- A logical '0' in Data Output Register LSB is coded as data sync pulse of width W0 {up to 127 μ s}.
- The two widths are programmable in Pulse Length Control/Config Register.
- The Data Shift Register is shifted Right by everytime as bit is transmitted.

Figure 47-146 shows the data transmission block.

Figure 47-147. ECU-to-sensor communication registers (implementation of the Data Transmission Block figure)

The above figure details the implementation of Figure 47-146 and shows how the various bits mentioned in Section 54.3.2.30, Data Output Block Configuration Register (PSI5_DOBCR) control the behavior of the Output Command path. The above figure also shows the various clock sources to the Internal Sync Pulse Generator and the Time Stamp counter.

47.5.3.5 Response to ECU-to-sensor frames

The response to an ECU-to-sensor frame can be optionally transmitted in two ways:

- Out-of range values of data frame (as fast response coded as normal PSI5 payload region)
- Serial messaging channel (verification of the response frames must be handled by the software)

47.5.4 Tx/Rx scenario

The diagram below shows the communication scenario in synchronous modes. For asynchronous mode, sync pulses are not generated and sensor transmits data asynchronously.

Figure 47-148. Synchronous mode communication scenarios

47.5.5 Interrupt handling

Configurable interrupts based on events (for example, reception of valid message), errors, DMA transfers, and so on are implemented. The following types of events can generate an interrupt:

- Reception of a new PSI5 message
- Reception of a new SMC message
- Unread SMC message overwritten in the SMC buffer area (PSI5_SFR)
- Unread PSI5 message overwritten in the PSI5 buffer area (PSI5_PMRH, PSI5_PMRL)
- Dedicated interrupts for selectable errors, mentioned below:
 - Bit C is set
 - Bit E and/or EM is set
 - Bit T is set
 - No PSI5 frame was received in a defined frame slot (Bit F is set)
- ECU-to-sensor communication-related interrupts
 - The application tries to load new data into the data preparation register before the register has signaled that it is ready for new data. (Note that the new command will be ignored in this case.)
 - The application loads new data into the data buffer register before the register has signaled that it is ready for new data. (Note that the new command will be ignored in this case.)
 - The application loads new data into the data shift register before the register has signaled that it is ready for new data. (Note that the new command will be ignored in this case.)
- DMA related interrupts (transfer finished/FIFO_FULL/underflow)

Various interrupt signals that represent the above events are:

- PSI5 new message arrival interrupt (**Status flags in PSI5_NDSR**) This is asserted when any of the programmed storage PSI5 locations (max 32) receive a new PSI5 message (error/error free). This interrupt also indicates that the PSI5 receive register (PMRRL/PMRRH) has been updated with a new PSI5 message.

- SMC message, ECU-to-sensor communication, and Time Stamp related interrupts (**All Status flags in PSI5_GISR**) : This is asserted during following events:
 - When a new SMC message is received in its corresponding slot OR
 - When there is a CRC error in any SMC message OR
 - When an unread message in some corresponding SMC location (in PSI5_SFR) gets overwritten by a new SMC message OR
 - When DPR is ready for receiving a new data OR
 - When DBR is ready for receiving a new data OR
 - When DSR is ready for receiving a new data OR
 - When there is an attempt to write to DPR while it is NOT ready OR
 - When there is an attempt to write to DBR while it is NOT ready OR
 - When there is an attempt to write to DSR while it is NOT ready OR
 - When data time stamp register is updated with new time stamp value OR
 - When the sync time stamp read register is updated with a new time stamp.
- PSI5 Message Overwrite Interrupt (**Status Flags in PSI5_OWSR**) : This is asserted when any of the programmed storage locations in the memory (max 32) have an unread PSI5 message that is overwritten by a new upcoming PSI5 message. Corresponds to OWSR.
- PSI5 Error interrupt (**Status Flags in PSI5_EISR**) : This is asserted when any of the programmed storage locations in the memory (max32) have an error in the PSI5 message. It is used only for PSI5 messages.
- DMA Interrupt (**Status Flags in PSI5_DSR**) :
 - When the DMA transfer corresponding to conf2, conf3 or conf4 finishes OR
 - When the DMA transfer corresponding to SMC message gets over OR
 - When there is an FIFO_FULL/Underflow in the PSI5 RAM register area OR
 - When there is an underflow in the SMC message area.

47.5.5.1 Error conditions

- C: CRC/parity error on received data, evaluated after recalculating CRC on received data and comparing with received CRC or recalculating parity on received data and comparing with received parity.
- E: Electrical error during any Tbit period (excluding Messaging field M0M1) during frame reception (not applicable during Idle state); that is, if at least one bit is absent during its Tbit period.
- EM: Electrical error on M0M1 field.
- T: Timing error during frame reception violates the slot boundary. Here, all the corner cases and conditions are taken care of (for example, the isolation of correct slot to correct message if the message is too early or too late with respect to its expected position, the crossing of the slot boundary when one frame overlaps the other, and so on).
- F: No frame received during a particular slot time in case of sync mode.

47.5.6 DMA support

NOTE

DMA master ID replication mode is not allowed together with PSI5.

- The PSI5 module generates separate DMA transfer requests for PSI5 message/diagnostic status and SMC messages.
- A single DMA request is used for PSI5 messages and diagnostic data. The request is triggered based on the selected DMA configuration (either PSI5 message or Diagnostic data or both). After choosing the configuration, data is available on respective DMA pop-up registers.
- DMA requests for PSI5 messages and diagnostic registers are based on the watermark level of message buffers (to be treated as FIFO for the DMA). PSI5 message buffer FIFOs get data from the PSI5 receiver in the order they are received.

- DMA requests for SMC messages are based on successful storage of each SMC frame to the message buffers. The SMC message buffers get data from SMC extraction logic in fixed round-robin arbitration sequence.
- Please see [Single DMA request for PSI5/diagnostic message buffers](#) for PSI5 DMA handling and [Single DMA request for SMC received messages](#) for SMC DMA handling

47.5.6.1 Single DMA request for PSI5/diagnostic message buffers

A common DMA request (per PSI5 block) is generated for PSI5 message/diagnostic buffers. The depth (up to 32 in present context) of the message buffer is programmable via the MEM_DEPTH filled in the PCCR. The width of each location of the PSI5 message buffer is 64 bits. When reading PSI5 message through the DMA, the 32-bit DPMR is sequenced with the data from the PSI5 message buffer. When reading the diagnostic registers through the DMA, the 32-bit DDSR is sequenced as NDSR followed by EISR. The DMA operation will happen as follows:

- Based on the DMA configuration chosen, one of the three DMA transfer sequence is initiated:
 - PSI5 buffer followed by diagnostic data sequenced to DPMR
 - PSI5 data sequenced to DPMR
 - Diagnostic buffer data sequenced to DDSR
- The DMA request is asserted when the number of messages stored in the buffer crosses the configured watermark number of messages.
- DMA request is deasserted once the "watermark" number of messages have been read.
- If the number of unread messages is still greater than the watermark programmed, then the DMA request is reasserted.
- The received message data is read from a common memory-mapped 32-bit DMA PSI5 message register (DPMR). Thus, a single PSI5 message (64 bits wide) will require two IPS read operations. The diagnostic data is read either through the DPMR or through the DDSR (single 32-bit register) by the DMA controller via the IPS interface.
- It is assumed that the DMA Controller's Transfer Control Descriptor (TCD) would be set to transfer bytes equal to the messages indicated by watermark level, as described in DMA_PM_DS_WM[4:0] in [DMA Control Register \(PSI5_DCR\)](#). It is assumed

that when responding to a DMA request, the DMA controller will read faster than the rate at which messages are received and stored in the buffer/FIFO which will cause the DMA request to deassert.

- The next received message will be updated on the common memory map register once the previous message is read by the DMA (by the DMA sequencer).
- The store signal from the synchronization logic will push the message into the memory-mapped RAM registers and in parallel also into the PSI5 receive register. [Figure 47-143](#) shows the format in which the messages will be stored in any message buffer (RAM registers) and finally when being read from DMA access register.
- For more details about DMA programming, please refer to [PSI5 Channel Control Register \(PSI5_PCCR\)](#), [DMA Control Register \(PSI5_DCR\)](#), [DMA Status Register \(PSI5_DSR\)](#), [DMA PSI5 Message Register \(PSI5_DPMR\)](#) and [DMA Diagnostic Status Register \(PSI5_DDSR\)](#).

47.5.6.2 Single DMA request for SMC received messages

A separate DMA request (each channel) is generated for the SMC message buffer. Each SMC received messages would be stored in the internal registers and read out by DMA controller via a common memory-mapped DMA SMC Frame Register (DSFR) (single 32-bit register for each message buffer). The data flow will happen as follows:

- A request is asserted when the system buffer successfully receives one complete SMC message, and remains asserted until all complete messages have been read. Data is read from the DMA PSI5 Message Register in the memory map.
- It is the job of an internal sequencing logic to provide the next complete received message. The internal sequencer works in a round-robin fashion checking for the slot-specific registers for each SMC message. Thus the sequence will be slot1--slot2-- slot3-- slot4--slot5--slot6--slot1 and so on. In whichever slot it encounters the first complete SMC message the DMA request would be asserted and the sequencer will wait for this data to be read before moving on to the next slot in its loop. If a particular slot message remains unread and a new SMC message for the same slot comes in then the previous message would be overwritten and the OW bit would be set.

- The DMA controller should be programmed to read only one message in one DMA transfer. Otherwise, if it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur. User software should ensure there is no overflow.
- For more details about DMA programming please refer "PCCR-PSI5 Channel Control Register" on page 267, "DCR-DMA Control Register" on page 272, "DSR-DMA Status Register" on page 276 and "DSFR-DMA SMC Frame Register" on page 284

47.5.7 Message read through interrupt generation

There is a separate interrupt request for received messages for each PSI5 channel. Each PSI5 channel can be configured individually to generate an interrupt on reception of messages. An interrupt is asserted when the corresponding PSI5 channel has received a complete message (PSI5 or SMC). Please see [Interrupt handling](#) for more details about interrupts. The interrupt routine should be coded in such a way to take the least amount of overhead (in CPU cycles) while entering the routine and start reading the available messages. The routine should be capable of accessing the corresponding PSI5 channel which is enabled to give out messages via interrupts through the IPS Interface. In response to these interrupts, the CPU is expected to read interrupt status register for individual PSI5 Channel (depending on which interrupt was asserted) and store it in system memory.

47.6 Initialization information

47.6.1 Initialization

47.6.1.1 Sensor startup and initialization

After each power-on or under-voltage reset, the sensor performs an internal initialization which is divided into three phases:

- Initialization Phase1: No data transmission.

- Initialization Phase 2: Transmission of type code and serial number of sensor.
- Initialization Phase 3: Transmission of "Sensor Ready" or "Sensor Defect" or other sensor specific data.

As this PSI5 implementation is targeted towards powertrain devices/sensors the standard initialization phase is modified and tuned for those applications. The comparison of the original scheme and enhanced schemes are shown in the figure below. The following figure also describes that the initialization content is the same as defined in V1.3, and the only modification is that it is transmitted using the SMC channel when a fast startup is required. "Fast Initialization Phase" below means that the sending of first sensor data is fast, but the sending of sensor initialization data will actually be much slower.

Figure 47-149. Fast initialization phase

47.7 Design Assumptions and Limitations

47.7.1 Assumptions

- Slot Configuration Register would always be programmed with valid number of bits for frame configuration.
- There will be no Timing error bits (T) in async mode. Only CRC Error (C) and Electrical Error (E) bits would be appended to message. There is no time out condition for the Manchester decoder in case of Async mode. 'NFR' bit is not set in Async mode.

47.7.2 Limitations

As this is a PSI5 receiver, designed primarily to only receive the PSI5/SMC data and store as it is into the RAM buffer. So, it would not be responsible neither to recognize the content of the received messages nor do any decision making based on the content. Similarly, for Command it would not recognize the content of command and would transmit as it is writing into corresponding DSR and reception of PSI5 messages would not in any way depend on the content of command as far as PSI receiver is concerned. Its the responsibility of SW to sequence the issue of commands across the PSI5 channels and thereby recognize the content of received message and infer it.

47.8 Miscellaneous descriptions

47.8.1 Internal SYNC Pulse generation and coordination across PSI5 channels

Each PSI5 channel has the Channel Target Pulse Registers (CTPR) and Channel Initialize Pulse Register (CIPR). The CTPR defines the period of the internal sync pulse generation and the CIPR defines the initial offset time with respect to the sync pulse trigger. The sync pulse trigger can be generated from either the PSI5_GCR[CTC_GED] global bit or the PSI5_PCCR[CTC_ED] channel specific bit.

When staggering of the channels is required then the PSI5_GCR[CTC_GED] global bit is used as a common trigger for all the PSI5 channels in which PSI5_PCCR[CTC_GED_SEL] bit is set to 1. Setting this bit to 1 triggers the internal sync pulse generators of all the PSI5 channels and the trigger of each channel is then automatically staggered with respect to the other channel, depending on the value of the CIPR.

When the specific PSI5 channel is not to be kept as a part of staggered channels, then the channel-specific PSI5_PCCR[CTC_GED_SEL] bit has to be kept as 0. The channel in this case, has to be triggered locally by writing a 1 to the PSI5_PCCR[CTC_ED] of that specific channel. This triggers the internal Sync Pulse Generator of that specific channel without affecting other channels.

Following is the procedure for starting the internal Sync Pulse Generators:

- If in Normal mode, then stop and reset all Channel Trigger Counters (CTCs) by setting the global PSI5_GCR[CTC_GED] bit to 0 or the channel specific PSI5_PCCR[CTC_ED] to 0.
- Enter Config mode.
- In Config mode, load all CTCs with the initialization value (offset) from CIPR.
- In Config mode, load all Counter Target Pulse Registers (CTPR) with the needed sync pulse period.
- Enter Normal mode.
- Send global start trigger (using PSI5_GCR[CTC_GED] bit) to all CTCs for synchronized start for the staggered channels OR send a local start trigger (by using the PSI5_PCCR[CTC_ED]) for channels not staggered.
- If the Compare Unit detects that the value in the CTC is equal to the value in CTPR, the CTC is automatically reset by hardware and restarts with 0.
- In Normal mode, if required, the CTC can be stopped and reset by writing a "0" to the PSI5_GCR[CTC_GED] or the PSI5_PCCR[CTC_ED] as the case may be.
- A sync pulse trigger is created. (See below.)

For the details about the operation of the below interface, please see Section 54.3.2.34, Counter Target Pulse Register (PSI5_CTPR), Section 54.3.2.35, Counter Initialize Pulse Register (PSI5_CIPR) and [Sync Pulse Trigger Generation](#).

Figure 47-150. CIPR and CTC

Figure 47-151 shows the various parameters (CIPR/CTPR, and so on) and the associated jitter, across different channels when these channels are staggered. (The figure also shows some other parameters, such as the modulated pulse width parameters and the Manchester decoder disable parameters.)

Figure 47-151. Sync Pulse Generation Parameters and Jitters

Figure 47-151 shows the various jitters.

Note 1: All channels with CTC_GD selected will be enabled at the same time, enabling staggering of the ispg_out signals.

Note 2: This structure is replicated in each channel, with CTC_GED being a common signal to all channels.

Chapter 48

SENT Receiver (SRX)

48.1 Chip-specific SRX information

This chip has two instances of the SRX module.

Table 48-1. SRX module instances

Instance	Input/receive channels	FIFO depth
SRX_0	6	16
SRX_1	6	16

48.2 Introduction

The Single Edge Nibble Transmission (SENT) Receiver (SRX) module is a multi-channel receiver for receiving serial data frames which are being transmitted by a sensor implementing the SENT encoding scheme and present them to the CPU for further processing.

This module is based on the SAE J2716 information report titled "SENT - Single Edge Nibble Transmission for Automotive Applications" and released on January 27, 2010 (<http://www.sae.org>), Apr2007 and Feb2008. As per this standard, the SENT protocol is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/Ds and PWM and as a simpler low-cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

The SENT encoding scheme is a unidirectional communications scheme from the sensor / transmitting device to the controller /receiving device which does not include a coordination signal from the controller/receiving device. The sensor signal is transmitted as a series of pulses with data encoded as falling to falling edge periods.

48.2.1 Features

The SENT receiver module has the following features:

- The number of SENT channels supported are device-specific. See the device configuration details.
- Unified message read logic to transfer all messages received to system memory via interrupts or DMA
 - Programmable option per channel to support reading of messages via DMA or Interrupt
 - Internal round robin arbitration sequencer to loop across channels to read messages from each channel leaving CPU/DMA transparent to this process
 - A FIFO for storing the received Fast Messages from all channels that are to be read out via DMA. FIFO depth is device-specific. See the device configuration section for details.
 - All received messages are stored excluding the synchronization pulse (for Fast messages) and identifiers (for Slow Serial Messages)
 - Separate buffers for storing Fast and Slow Serial Messages
 - Separate DMA and Interrupts generated for Fast and Slow Serial Messages
- Supports compensation for variation in SENT Tx Clock up to $\pm 25\%$ and adjusts its measurement for drift in the Transmitter and Receiver clocks per channel
 - Calibration pulse correction factor per channel is available for use by software
- Implements for each channel all receiver diagnostics as specified by the SAE Specifications
- Internal 4-bit CRC calculator that can be configured to compute CRC in both Legacy and Recommended method (as given in SAE SENT Specification) for both Fast and Short Serial Message per channel
- Internal 6-bit CRC calculator for Enhanced Serial Messages per channel

- Supports all bit rates by having per channel configurable Rx clock periods from 3 μ s to 90 μ s
- Support for configurable number of data nibbles per channel
- Option to disable individual channel via programmable control bit
- Time stamping on start of each valid message (i.e. without errors) across all channels. This time stamp is appended to each message for synchronization of messages and for application to understand how much time has elapsed between successive sensor readings
- Support for pause pulse per channel. This can be enabled by programming a bit in the control register for that channel
- Input Programmable Filter on each channel to filter any glitches on input. This filter duration is programmable by the user software.
- 32-bit register interface for programming the module's registers and reading the received messages
- Works on two clocks, one for accurate receive operations (high frequency receiver clock or protocol clock) and other for message read logic (system bus clock) and the module can work irrespective of the frequency relationship between the two clocks. See [Clocks and resets](#) for more details on the clocks.

48.2.2 Modes of operation

Modes of operation.

48.2.2.1 Debug mode

In debug mode, message reception will be halted (without waiting for the current message being received to be completed) and all existing status and messages will be retained. DBG_FRZ bit is required to be set for this mode. On debug exit, a calibration length error (CAL_LEN_ERR) can be reported and the channels will start receiving messages from a valid calibration pulse.

48.2.2.2 Low power modes

SENT Receiver behavior is affected by chip-specific low power modes (for example, STOP or WAIT modes). These low power modes should either gate-off both the system bus clock and the protocol clocks or reduce their frequencies, depending on the application.

On exiting from these low power modes, calibration length error (CAL_LEN_ERR) can get set in channel status registers as the SENT sensor (transmitter) could be in the middle of a message transmission at that point. Thus, software should clear all error status bits after exiting the low power modes.

Modes where both system bus clock and protocol clock are gated: In this case, both message reception and interrupt / DMA request generation will halt. The internal receiver channels will freeze (since clock is not there) and will not receive any messages. Messages which are completely received before entering the low power mode can be read after the low power mode exit.

Modes where frequency of system bus clock is changed: For reduced power consumption the system bus clock can be reduced but not below a minimum value (See [System bus clock requirements](#)) to avoid overflow of received messages. Protocol clock should not go below the minimum value (See [High frequency receiver clock \(protocol clock\) requirements](#)) for accurate receive operations.

Note

Gating of clocks in the low power mode is chip-specific, see the chapter that refers how the modules behave in low power modes.

NOTE

If the SOC requests entry to debug or stop mode, the message being received currently is discarded and the SOC enters debug/stop mode immediately. This does not affect the messages received completely prior to entering debug mode and will still be present on the message buffer and registers until they are read out.

NOTE

The message read registers [Channel 'n' Fast Message Data Read Register (n = 0 to (CH-1)) (CHn_FMSG_DATA), Channel 'n' Fast Message CRC Read Register (n = 0 to (CH-1)) (CHn_FMSG_CRC), Channel 'n' Fast Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn_FMSG_TS), Channel 'n' Serial Message Read Register (Bit 3) (n = 0 to (CH-1))

(CHn_SMSG_BIT3), Channel 'n' Serial Message Read Register (Bit 2) (n = 0 to (CH-1)) (CHn_SMSG_BIT2), Channel 'n' Serial Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn_SMSG_TS), DMA Fast Message Data Read Register (DMA_FMSG_DATA), DMA Fast Message CRC Read Register (DMA_FMSG_CRC), DMA Fast Message Time Stamp Read Register (DMA_FMSG_TS), DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3), DMA Slow Serial Message Bit2 Read Register (DMA_SMSG_BIT2) and DMA Slow Serial Message Time Stamp Read Register (DMA_SMSG_TS)] will appear to lose their contents in the following conditions:

- The very first message is being received but not yet completely received and the MCU enters debug or freeze mode, the current message reception will get discarded and message read registers (as mentioned above) will read zeros
- Auto clear functionality is enabled (GBL_CTRL[FAST_CLR] = 1). In this case, when first message is read, it will get clear the message read registers (due to auto clear functionality being enabled). On reading again, the message read registers (as mentioned above) might read zeros.

If the MCU requests entry to debug or stop mode, the message being received currently by SENT Receiver is discarded and the MCU enters debug/stop mode immediately. This does not affect the messages received completely, prior to entering debug mode and these messages will still be present on the message buffer and registers until they are read out. Thus allow one message to be received completely and do not enable "Auto Clear" (GBL_CTRL[FAST_CLR] = 0), to allow messages to be read in debug or stop mode.

48.2.3 Block diagram

Figure 48-1. SENT Receiver block diagram

48.2.4 Design overview

The SENT Receiver Module is a unified receiver module comprising of a number of receiver channels and a unified DMA and Register Space for accessing the messages from each channel. [Figure 48-1](#) shows the top level block diagram for the SENT Receiver module.

Each channel of the SENT Receiver is composed of a Clock Generation and Adjustment block to generate the receiver clock and adjust it for frequency variation in the transmitter clock. This block also detects the synchronization/calibration pulse which is present in every SENT message.

The SENT Receiver State Machine controls the sequencing of decoding the messages and combining the information as nibbles. In parallel a diagnostic block is running that monitors the incoming messages for any errors and also verifies the CRC of the received messages. The fast and serial message extractors collate the message nibbles and add the channel number and time stamp information to the messages. A free running time stamp counter is used to add the time stamp value to each message received. The value of this counter is input to each channel and the channel logic appends the time stamp to each message. These messages are then formatted to be stored in the DMA FIFOs (for channels which are selected to be connected to the DMA) or in corresponding message read buffer. Only the messages that pass the diagnostics checks are forwarded to be stored in the FIFOs or buffers.

The SENT Receiver provides two mechanisms for reading the received messages, which are via DMA transfers and via Interrupts. Based on the control bit settings in the control registers, a DMA request or Interrupt is asserted to signal the DMA controller or CPU that messages are available to be read.

The free running time stamp counter, register block and DMA interface are common for all channels configured. The register space contains all the necessary registers for all channels. The register space is 32-bit aligned and accessible via 8-/16-/32-bit accesses. The registers for all un-configured channels are marked as reserved.

48.2.4.1 Functional overview

After reset, the SENT module comes up in the disabled state. All channel enable bits and the global enable bit are set to 0 and the user software must program the SENT module parameters correctly before enabling it. The user software must correctly configure all parameters to avoid any underflow or overflow in the message FIFOs or buffers.

Once enabled, the Receiver Clock Generation and Adjustment block detects the synchronization pulse. Until then, the state machine blocks all subsequent operations of the receiver. Once the synchronization pulse is detected, the receiver clock tick period is compensated for variation in transmitter clock tick period and the state machine then waits for the reception of data nibbles. The adjusted receiver clock is used to sample the data nibbles from the incoming serial message. The state machine waits until the status and communication nibble and configured number of data nibbles are received. The state machine then waits for the pause pulse (if configured to receive a pause pulse). The fast and serial message extractor block provides the state machine with the information on how many nibbles have been received. All diagnostics checks are computed in parallel. Once all required data nibbles are received, the CRC is checked, time stamp and channel number is added to the message. The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer along with the message. This final message is stored in the DMA FIFO or message buffer as described in the subsequent sections. Any error detected during the receive process causes the status bits in the corresponding channel's status register to be set.

The above process repeats across each enabled channel in parallel and keeps pushing error free messages into the FIFOs or buffers on high frequency receiver clock. The module's message read logic synchronizes all these messages on the bus clock and pops out these messages on any DMA or CPU read access. Any DMA underflow errors are stored in the global status register while the overflow errors are stored in the corresponding channel's status register. In case of an overflow in Fast Messages, the newer messages received will overwrite the previous message.

For detailed description on the complete functionality of each block, see [Functional description](#).

48.3 External signal description

This section lists all inputs to the SENT Receiver block.

48.3.1 SENT_RX [(CH-1):0]

These pins serve as the serial data input for each of the SENT Receiver channel. There is one bit per channel supported by the device. The SENT sensor input pads on the device using this module should have pull-up enabled to ensure a 1'b1 is seen at the module input when SENT sensor is not driving any data.

Note

The value of CH is device-specific. See the device configuration details.

48.4 Memory map and register definition

This section provides a detailed description of all registers accessible in the SENT Receiver block.

The following table gives an overview on all SENT Receiver registers. The memory map comprises of 32-bit aligned registers which can be accessed via 8-bit, 16-bit, or 32-bit accesses. Write access to reserved locations will generate transfer error. Read access to reserved locations will also generate transfer error and the read data bus will show all 0s. The Memory Map and complete module is in Big Endian Format.

The module will not check for correctness of programmed values in Register Space and software must ensure that correct values are being written.

NOTE

Register Address = Base Address + Address Offset, where the Base Address is defined at the MCU level and the Address Offset is defined at the module level. The number of registers are device specific. See the device configuration section for details.

NOTE

The value of the CH is device-specific. See the device configuration section for details.

SRX_GBL_CTRL field descriptions

Field	Description
0–7 TSPRSC	Time Stamp Prescaler Value. Value in number of clock cycles of high frequency receiver clock set in order to obtain a clock frequency for the time stamp counter block. 0 to 255 - Time Stamp Clock = (High Frequency Clock)/(Value + 1). Value set by user software should be such that the clock period is at least 1 μ s. If the high frequency clock input is 75 MHz, then the value set in this field would be 0x4A (or 74) to obtain a 1 μ s clock. Note: Since the time stamp clock is common for all channels, the timestamp clock frequency must be at least twice the fastest receiver channel in the application. This is to ensure that the time stamp clock is fast enough to show change in timestamp from message to message.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 FIFOWM	DMA Read FIFO Water Mark Level. Indicates the number of Fast Messages to be stored in FIFO before a DMA request is asserted. Default = 1 message. 0 Invalid Value. Should not be used 1 to 31 Valid water mark levels. Value fixed by user software. NOTE: The number of bytes to be transferred set in the DMA Controller's TCD must be set equal to the number of bytes corresponding to the set water mark value.

Table continues on the next page...

SRX_GBL_CTRL field descriptions (continued)

Field	Description
16 NIB_LEN_VAR_LIMIT	Decides the allowable jitter/clock drift limit for nibble length measurement. NOTE: This bit should be set to 1 for proper functioning of Sent Rx. 0 Allows a jitter/clock drift of approx upto 12.5% of transmitter clock tick period. This actual allowed jitter/drift value is dependent on the transmitter clock tick period and HF receiver clock period. 1 Allows a jitter/clock drift as per SAE spec (50%).
17–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 FMFOIE	Fast Message FIFO Overflow Interrupt Enable: Enables interrupt assertion when Fast Message is received on a channel which has DMA enabled after FIFO is full. Default value is 0. 0 Interrupt is disabled 1 Interrupt is enabled
22 FMDUIE	Fast Message DMA Underflow Interrupt Enable: Enables interrupt assertion when there is an underflow condition on Fast Message DMA registers. Default value is 0. 0 Interrupt is disabled 1 Interrupt is enabled
23 SMDUIE	Slow Serial Message DMA Underflow Interrupt Enable: Enables interrupt assertion when there is an underflow condition on Slow Message DMA registers. Default value is 0. 0 Interrupt is disabled 1 Interrupt is enabled
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 FIFO_EN	FIFO enable bit. Enables FIFO when DMA is enabled. When this bit is low, data is read from module as explained in DMA request for Fast Message reading when FIFO is disabled and when the bit is high, data is read from module as explained in DMA request for Fast Message reading via FIFO . Default value is 0. 0 FIFO is disabled 1 FIFO is enabled
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 FAST_CLR	Fast Clearing Enable bit. Enables clearing of ready status (for both fast and slow) bit automatically when corresponding message is read. Default value is 1. See Fast Message Ready Status Register (SRX_FMSG_RDY) and Slow Serial Message Ready Status Register (SRX_SMSG_RDY) for details on the ready status bits. 0 Fast Clearing is disabled. Bits will be cleared by writing 1 1 Fast Clearing is enabled
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 DBG_FRZ	Debug Freeze. This bit will enable the debug mode support. SENT Module will freeze in debug mode if this bit is set. Default is 0. 0 No effect in debug mode 1 Freeze in debug mode

Table continues on the next page...

SRX_GBL_CTRL field descriptions (continued)

Field	Description
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 SENT_EN	SENT Receiver Global Enable. This bit enables or disables the complete receiver module irrespective of the setting of individual channel enable bits. User software must program all channel parameters before setting this bit. Default is 0. 0 Entire module is disabled 1 Module is enabled

48.4.2 Channel Enable Register (SRX_CHNL_EN)

This register is used to enable individual SENT Receiver channels in the module. The user software must ensure all channel parameters and control settings have been programmed before writing to this bit. In case these parameters are changed while the channel is enabled, normal operation is not guaranteed.

NOTE

Reads of bits beyond those for the supported number of channels should be ignored, and these bits must be written to 0.

Address: 0h base + 4h offset = 4h

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 EN_CH	Enable bits for channels 5 to 0 . All channels are disabled after reset. User software must program all channel parameters before setting this bit. Once set, other channel parameters in registers should not be changed until this bit is cleared. Only Interrupt Enable and Status bits can be written to. 0 Channel is disabled 1 Channel is enabled. Channel parameter registers are locked for writing

48.4.3 Global Status Register (SRX_GBL_STATUS)

This register provides the status of various conditions in the module that are common across all channels.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0					FMFO	FMDU	SMDU	0							
W						w1c	w1c	w1c								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SRX_GBL_STATUS field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 FMFO	Fast Message FIFO Overflow: Interrupt status bit which indicates that Fast Message is received on any channel which has DMA enabled after FIFO is full. Default value is 0. This bit is valid only when fifo is enabled 0 No Overflow 1 Overflow occurred
22 FMDU	Fast Message DMA Underflow: Interrupt Status bit that indicates when there is an underflow in Fast Message buffers or FIFO in any channel which has DMA enabled. If FIFO is enabled, it is set when FIFO is empty and software still reads Fast Message DMA registers. And if FIFO is not enabled, it is set when there is no message in the DMA buffers for read and the software still reads the Fast Message DMA register. Default value is 0. 0 No underflow 1 Underflow occurred
23 SMDU	Slow Serial Message DMA Underflow: Interrupt Status bit that indicates when there is an Underflow in Slow Serial Message DMA buffers on channel which has DMA enabled. The bit is set when there is no

Table continues on the next page...

SRX_GBL_STATUS field descriptions (continued)

Field	Description
	message in the DMA buffers for read and the software still reads the Slow Serial Message registers. Default value is 0. 0 No underflow 1 Underflow occurred
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.4 Fast Message Ready Status Register (SRX_FMSG_RDY)

The bits of this register are asserted when a Fast Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (via [Fast Message DMA Control Register \(SRX_FDMA_CTRL\)](#)), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (via [Fast Message Ready Interrupt Control Register \(SRX_FRDY_IE\)](#)) and the channel is enabled, the message ready status bit in this register will be asserted on Fast Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Proper flow cannot be guaranteed if neither is selected.

These bits can be configured to be cleared via "Write 1 to Clear" or "Fast Clearing Mechanism". The configuration is done by writing to the FAST_CLR bit in the [Global Control Register \(SRX_GBL_CTRL\)](#) .

NOTE

Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																									F_RDY

SRX_FMSG_RDY field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 F_RDY	Fast Message Data Ready Status bits for channels 5 to 0 . Each bit indicates that a Fast Message is ready to be read by CPU from that specific channel. This bit is asserted only when DMA is NOT enabled for that

Table continues on the next page...

SRX_FMSG_RDY field descriptions (continued)

Field	Description
	channel (from the DMA Control Register) and an error free message is received, irrespective of the value of corresponding enable bit in Message Ready Interrupt Control Register. Reading the message from the corresponding memory-mapped Fast Message Read Registers would automatically clear this bit (Fast Clearing Mechanism).
	NOTE: These bits are either "write 1 to clear" (w1c) or self-clearing depending on the value of the FAST_CLR BIT in the Global Control Register (GBL_CTRL).
	The clearing mechanism is selected by user by programming the FAST_CLR bit in the Global Control register. See Section Global Control Register (SRX_GBL_CTRL) for details on FAST_CLR bit.
	NOTE: When using the fast clearing option, these bits will not clear till the complete message is read out which requires the CPU to read all 3 fast message registers via 32-bit read accesses. For 8/16-bit accesses fast clearing mechanism should not be used as it is not supported.
	NOTE: When the fast clearing option is not configured, the bits will be cleared only if 1 is written to those bits.
	0 No Fast Message is available to be read out via Interrupt
	1 Fast Message is available to be read out via Interrupt

48.4.5 Slow Serial Message Ready Status Register (SRX_SMSG_RDY)

The bits of this register are asserted when a Slow Serial Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (via [Fast Message DMA Control Register \(SRX_FDMA_CTRL\)](#) and [Slow Serial Message DMA Control Register \(SRX_SDMA_CTRL\)](#)), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (via [Fast Message Ready Interrupt Control Register \(SRX_FRDY_IE\)](#) and [Slow Serial Message Ready Interrupt Enable Register \(SRX_SRDY_IE\)](#)) and the channel is enabled, the message ready status bit in this register will be asserted on Slow Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Erroneous flow can happen if neither is selected.

These bits can be configured to be cleared via "Write 1 to Clear" or "Fast Clearing Mechanism". The configuration is done by writing to the FAST_CLR bit in the [Global Control Register \(SRX_GBL_CTRL\)](#).

NOTE

Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRX_DMA_FMSG_CRC field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 CRC4b	4-bit CRC value of the message.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.13 DMA Fast Message Time Stamp Read Register (SRX_DMA_FMSG_TS)

The resolution of the time stamp is set by programming the Time Stamp Prescaler Value in the [Global Control Register \(SRX_GBL_CTRL\)](#) register. DMA Source Size must be set to 32 bits when reading this register (DMA_FMSG_TS) via DMA. When FIFO is enabled, fast messages are read out from FIFO through the DMA Fast Message Data Read register only. Reading this register will generate an access error.

Address: 0h base + 48h offset = 48h

SRX_DMA_FMSG_TS field descriptions

Field	Description
0–31 TS	Time Stamp for received message. Indicates the relative time when the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) was detected

48.4.14 DMA Slow Serial Message Bit3 Read Register (SRX_DMA_SMSG_BIT3)

The above register (DMA_SMSG_BIT3) is common for all types of slow serial messages. Bit C defines the type of enhanced packet and bit TYPE defines whether it is short serial or enhanced serial message. Since this register is used to read both Short and Enhanced Serial Messages, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE Specification as shown in [Table 48-83](#), [Table 48-84](#) and [Table 48-85](#). [Table 48-83](#) and [Table 48-84](#) shows the enhanced serial messages format to be used when reading this register for these two types of messages. [Table 48-85](#) shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

NOTE

If the TYPE bit in the register reads '0', then remainder bits (for CFG, ID and DATA) will be redundant and read zeros. The short serial message will be located in DMA_SMSG_BIT2 register fields. If TYPE bit is '1', then the message in register is

Enhanced Serial Message and using CFG bit, software can decode the ID and DATA fields.

Address: 0h base + 50h offset = 50h

SRX_DMA_MSG_BIT3 field descriptions

Field	Description
0–3 CHNUM	Channel Number. Indicates the channel number of the received message being read by DMA. Valid values are 0 to 5 .
4 TYPE	Serial Message Type. Indicates the type of Serial Message received 0 Short Serial Message 1 Enhanced Serial Message
5–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 CFG	Configuration bit 'C'. Indicates the type of Enhanced Serial message 0 Enhanced Serial Message with 8-bit ID field 1 Enhanced Serial Message with 4-bit ID field
22–25 ID7_4_ID3_0	ID Field. Value depends on setting of 'C' bit. If 'C' bit is 0, this field is ID[7:4] and if the 'C' bit is 1, this field is ID[3:0]
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–30 ID3_0_DATA15_12	ID or Data Field. Value depends on setting of 'C' bit. If 'C' bit is 0, this field is ID[3:0] and if the 'C' bit is 1, this field is Data[15:12]
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.15 DMA Slow Serial Message Bit2 Read Register (SRX_DMA_SMSG_BIT2)

This register (DMA_SMSG_BIT2) is common for all types of slow serial messages. Hence, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE Specification as shown in [Table 48-83](#), [Table 48-84](#) and [Table 48-85](#). [Table 48-83](#), and [Table 48-84](#) shows the enhanced serial messages format to be used when reading this register for these two types of messages. [Table 48-85](#) shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

Address: 0h base + 54h offset = 54h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRX_DMA_SMSG_BIT2 field descriptions

Field	Description
0–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 SMCRC	6-bit CRC value of the message. When TYPE bit in DMA Slow Serial Message Bit3 Read Register (SRX_DMA_SMSG_BIT3) is set to 0, this CRC is of 4-bits for Short Serial Messages and when TYPE bit is set to 1, this CRC is of 6-bits for Enhanced Serial Messages.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 DATA[11:0]	12-bit Data Value

48.4.16 DMA Slow Serial Message Time Stamp Read Register (SRX_DMA_SMSG_TS)

The resolution of the time stamp is set by programming the Time Stamp Prescaler Value in the [Global Control Register \(SRX_GBL_CTRL\)](#) register.

DMA Source Size must be set to 32 bits when reading this register (DMA_SMSG_TS) via DMA.

Memory map and register definition

Address: 0h base + 58h offset = 58h

SRX_DMA_SMSG_TS field descriptions

Field	Description
0–31 TS	Time Stamp for the received message. Indicates the relative time of detection of the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) of the last Fast Message that completed the Serial Message. Time Stamp for Slow Serial Messages is not latched when the Slow Serial Message starts but when the Slow Serial Message is completely received.

48.4.17 Channel 'n' Clock Control Register (n = 0 to (CH-1))
(SRX_CHn_CLK_CTRL)

NOTE

The value of the CH is device-specific. See the device configuration section for details.

The SENT Receiver module generates the Receiver Sensor Clock (or simply Receiver Clock) internally to sample the incoming filtered sensor data. The user software must program the prescaler value (for Receiver Clock) to match the ideal Sensor Tx Clock period. The generated Receiver Clock is compensated for variations and clock drift that might occur in the Sensor Tx Clock. See [Adjustment for variation in sensor \(Tx\) clock](#) for more details.

This register configures the generation and subsequent compensation logic of the Receiver Clock. User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the [Channel Enable Register \(SRX_CHNL_EN\)](#).

Address: 0h base + 60h offset + (16d × i), where i=0d to 5d

SRX_CHn_CLK_CTRL field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–15 CM_PRSC	Compensated Prescaler Value. This is the compensated prescaler value calculated by Clock Compensation logic and this value is used to compensate for sensor Tx clock variation. This value is indicated as a read only field for use by user software, if needed. This is a 15-bit value. '= Rx Prescaler Value' No variation, hence no compensation or Compensation is disabled '< Rx Prescaler Value' Tx Clock is SLOWER than the programmed receive clock '> Rx Prescaler Value' Tx Clock is FASTER than the programmed receive clock Thus, the new Receiver Clock Tick Period can be computed by software as Compensated Prescaler Value x High Frequency Receiver Clock Period Note: The value provided in this field is ceil value of actual tick period as measured by the Receiver.
16 COMP_EN	Compensation Enable. To enable compensation logic to adjust the receiver clock against variation in Tx clock on this channel. User must set the Prescaler Value before enabling this bit. 0 Compensation is disabled 1 Compensation is enabled
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–31 PRSC	Rx Prescaler Value. This factor is required to generate required Receiver Clock tick from the High Frequency Receiver Clock. This value can only be written when Channel Enable bit is Zero. Hence this value must be programmed before enabling the channel. If required receiver clock tick period (Trx_clk) is not divisible by the high frequency receiver clock (protocol clock) period (Thf_clk), the required prescaler value will have a fractional part which cannot be programmed. In this case then user is advised to program the prescaler value to the lower integer value. 0 Prescaler is bypassed. Should not be used. Non-Zero Value Enables Prescaler The required value is computed by software as follows: $\text{Prescaler\_value} = \text{floor}\left(\frac{T_{\text{rx\_clk}}}{T_{\text{hf\_clk}}}\right)$ (both clock periods taken in μs). Please see High frequency receiver clock (protocol clock) requirements before setting this value.

Table continues on the next page...

SRX_CHn_CLK_CTRL field descriptions (continued)

Field	Description
	e.g. if the required receiver clock tick period is 43 μ s and the High Frequency Receiver clock is selected to be 62.5 MHz (or 0.016 μ s) then, Prescaler Value = $43/0.016 = 2687.5$. Hence user must program 2687 in this register.

**48.4.18 Channel 'n' Status Register (n=0 to (CH-1))
(SRX_CHn_STATUS)**

This registers stores information about certain events and error conditions that occur in the channel during the message reception process. The assertion of these bit is not linked to any message but it is a general alert to the CPU that a particular condition (error or normal event) happened in the recent past. Messages are automatically discarded when an error is detected.

User software can clear these bit at any time by writing 1 to them. This register can be updated at any time irrespective of the setting in the [Channel Enable Register \(SRX_CHNL_EN\)](#) bit for the corresponding channel.

NOTE

The value of the CH is device-specific. See the device configuration section for details.

Address: 0h base + 64h offset + (16d $\times$ i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SRX_CHn_STATUS field descriptions

Field	Description
0 BUS_IDLE	Bus Idle Status. This bit indicates that the sensor interface has been idle for more than the period defined by the programmed Bus Idle Count value(in Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CHn_CONFIG)). CPU should write 1 to this clear this bit once it is read. 0 Bus is not idle 1 Channel has been idle for more than the allowed value
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 CAL_RESYNC	Successive Calibration Check (Option 2 of SAE SENT Spec) Resynchronized. This bit indicates that Successive Calibration Check (Option 2 of SAE Spec) has failed three times and has resynchronized to assume 3rd message to be correct and will be received. The successive calibration check error will also be asserted during re-synchronization (to indicate the 3rd error being detected). 0 No interrupt 1 Interrupt Status condition has occurred
5 CAL_20_25	Calibration Variation 20 - 25% Interrupt Status. This bit indicates that the calibration pulse received on this channel has variation in between $\pm 20\%$ to $\pm 25\%$ from 56 ticks. 0 No Interrupt 1 Interrupt Status condition has occurred
6 MSG_OFLW	Slow Serial Message Overflow Status. This bit indicates overflow occurred on this channel. Overflow will cause state machine to halt stopping reception of new messages. 0 No Interrupt 1 Interrupt Status condition has occurred
7 FMSG_OFLW	Fast Message Overflow Status. This bit indicates overflow occurred on this channel. Overflow happens when effective data read rate by CPU is slower than data receive rate on channel. On overflow, new incoming messages will overwrite the previous messages (that are not read out) stored in the receiver buffers. However, any message that is currently being read out by DMA or CPU will not get over-written. 0 No Interrupt 1 Interrupt Status condition has occurred

Table continues on the next page...

SRX_CHn_STATUS field descriptions (continued)

Field	Description
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 PP_DIAG_ERR	This diagnostic checks status bit indicates that the ratio of calibration pulse length to overall message length (with pause pulse) is more than $\pm 1.5625\%$ between two messages. This check is valid only for messages with pause pulse. This bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
10 CAL_LEN_ERR	This diagnostic checks status bit indicates that Calibration pulse is more than 56 ticks $\pm 25\%$. This bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
11 CAL_DIAG_ERR	Successive Calibration pulses differ by $\pm 1.56\%$. SAE spec defines it be 1.5625% but the accuracy of this check depends on the frequency of protocol clock (See High frequency receiver clock (protocol clock) requirements). This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
12 NIB_VAL_ERR	Any nibble data value <0 or >15 . This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
13 SMSG_CRC_ERR	Checksum error in Slow Serial Message. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
14 FMSG_CRC_ERR	Checksum error in Fast Message. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
15 NUM_EDGES_ERR	Not the expected number of negative edges between calibration pulse. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel. This bit will not set in case of "Option 2" for successive calibration pulse check is selected. This error will only set when "Option 1" for successive calibration check is selected (SUCC_CAL_CHK). This bit is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.19 Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CHn_CONFIG)

This register (CHn_CONFIG) provides the configurability for interrupt assertion for various events and error as explained in [Channel 'n' Status Register \(n=0 to \(CH-1\)\) \(SRX_CHn_STATUS\)](#) and control bits for selection of various receive options that might be required by the user software. This register also configures the width of noise glitches (on the sensor input) to be filtered out by the input programmable filter.

User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the [Channel Enable Register \(SRX_CHNL_EN\)](#).

NOTE

The value of the CH is device-specific. See the device configuration section for details.

Address: 0h base + 68h offset + (16d × i), where i=0d to 5d

0010	127*4 Receiver Clock Tick Counts										
0100	127*8 Receiver Clock Tick Counts										
1000	127*16 Receiver Clock Tick Counts										

Table continues on the next page...

SRX_CHn_CONFIG field descriptions (continued)

Field	Description
4 IE_CAL_ RESYNC	Successive Calibration Check Resynchronized Interrupt Enable: This bit enables interrupt assertion when Successive Calibration diagnosis has failed three times in case of "Option 2" being selected for Successive Calibration Check Method and the check resynchronizes the take the third message to be correct. 0 Interrupt is disabled 1 Interrupt is enabled
5 IE_CAL_20_25	Calibration Variation 20 - 25% Interrupt Enable. This bit enables interrupt assertion when corresponding status bit is set. 0 Interrupt is disabled 1 Interrupt is enabled
6 IE_SMSG_OFLW	Slow Serial Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Slow Serial Messages in corresponding channel 0 Interrupt is disabled 1 Interrupt is enabled
7 IE_FMSG_OFLW	Fast Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Fast Messages in corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
8 FCRC_CHK_ OFF	Fast Message CRC Check Off: This bit can be used to switch off CRC check in Fast Message 0 Check is enabled 1 Check is disabled/off
9 IE_PP_DIAG_ ERR	Ratio of calibration pulse length to message length varies by more than $\pm 1.5625\%$ between two frames. Valid for messages with pause pulse. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
10 IE_CAL_LEN_ ERR	Calibration pulse is wider than 56 ticks $\pm 25\%$. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
11 IE_CAL_DIAG_ ERR	Successive Calibration pulses differ by more than $\pm 1.56\%$. SAE spec defines it be 1.5625% but the accuracy of this check depends on the protocol clock. For instance for 62.5 MHz, this check will fail for 1.56% and passes for 1.55%. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
12 IE_NIB_VAL_ ERR	Any nibble data value <0 or >15 . This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled

Table continues on the next page...

SRX_CHn_CONFIG field descriptions (continued)

Field	Description
13 IE_SMSG_CRC_ERR	Checksum error in Slow Serial Message. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
14 IE_FMSG_CRC_ERR	Checksum error in Fast Message. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
15 IE_NUM_EDGES_ERR	Not the expected number of negative edges between calibration pulse. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
16 DCHNG_INT	Enable for Interrupt on Reception of Fast Message with Changed Data: This bit is used to enable storing and generating corresponding DMA or Message Ready Interrupt Request for Fast Message only when any of the data nibbles after different from previously received Fast Message on that channel. If a new Fast Message is received that has same values for all data nibbles as that of previous message then the current message will be discarded and will not be stored in the buffer, or FIFO, and neither Fast Message Ready Interrupt nor DMA request will be generated. 0 All Fast Messages will be received even if data nibbles are same 1 Only Fast Messages with differing values of data nibbles will be received
17 CAL_RNG	Valid Calibration Pulse Range Selection: This bit is used to control whether 20% variation or 25% variation in Calibration Pulse will be tolerated when detecting a Calibration Pulse 0 20% variation is acceptable 1 25% variation is acceptable
18 PP_CHKSEL	Pause Pulse Diagnostic Check Selection: This bit controls which diagnostic checks to run when messages are enabled to be received with pause pulses. 0 Both Successive Calibration Pulse Check and Pause Pulse Diagnostic are run 1 Only Pause Pulse Diagnostic is run. Successive Calibration Pulse Check is disabled.
19 FCRC_TYPE	Fast Message CRC Type. This indicates the type of CRC method to be used for CRC Diagnostic Check on the received fast messages 0 Recommended implementation (additional 0 data nibble XORed with the rest of the nibbles) 1 Legacy implementation (no additional 0 data nibble is XORed)
20 FCRC_SC_EN	Fast Message CRC Status and Communication Nibble Enable. This bit enables the inclusion of Status and Communication Nibble when CRC is calculated for Fast Messages. 0 Status and Communication Nibble not included in CRC calculation 1 Status and Communication Nibble is included in CRC calculation
21 SCRC_TYPE	Slow Serial Message CRC Type. This indicates the type of CRC method to be used for CRC Diagnostic Check on the received slow serial messages. 0 Recommended implementation (additional 0 data nibble XORed with the rest of the nibbles) 1 Legacy implementation (no additional 0 data nibble XORed)
22 PAUSE_EN	Pause Pulse Enable. Enables the channel receiver to detect a pause pulse.

Table continues on the next page...

SRX_CHn_CONFIG field descriptions (continued)

Field	Description
	0 Detection of Pause Pulse is disabled 1 Detection of Pause Pulse enabled
23 SUCC_CAL_CHK	Successive Calibration Pulse Check Method. This bit indicates the method to be used for performing the successive calibration pulse check. Default value is 1. 0 Option 2 i.e. Low Latency Option as per SAE Specification 1 Option 1 i.e. Preferred but High Latency Option as per SAE Specification
24–31 FIL_CNT	Input Filter Sample Count. This indicates twice the number of Protocol Clock (of High Frequency Receiver Clock) cycles required for channel input from device's pad to remain stable before it is sampled as 0 or 1. This field defines the width of glitches to be filtered out by the input programmable filter on that channel. Only one bit should be set in this field and the output of filter will be offset by twice the same number of clocks plus additional 3 clocks due to synchronization. Default value is '4'. 0 No filtering. Input from device's pad is only synchronized 1 Non-Zero Filtering is enabled

48.4.20 Channel 'n' Fast Message Data Read Register (n=0 to (CH-1)) (SRX_CHn_FMSG_DATA)

Address offset: 0x0160 + 0x18 x n

This is register CHn_FMSG_DATA. The contents of this register are same as [DMA Fast Message Data Read Register \(SRX_DMA_FMSG_DATA\)](#) .

NOTE

The value of the CH is device-specific. See the device configuration section for details.

Address: 0h base + 160h offset + (24d × i), where i=0d to 5d

0–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 SMCRC	6-bit CRC value of the message. When TYPE bit in DMA Slow Serial Message Bit3 Read Register (SRX_DMA_SMSG_BIT3) is set to 0, this CRC is of 4-bits for Short Serial Messages and when TYPE bit is set to 1, this CRC is of 6-bits for Enhanced Serial Messages.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 DATA[11:0]	12-bit Data Value

48.4.25

Channel 'n' Serial Message Time Stamp Read Register (n=0 to (CH-1)) (SRX_CHn_SMSG_TS)

Address offset: 0x0174 + 0x18 x n

This is register CHn_SMSG_TS. The contents of this register are same as [DMA Slow Serial Message Time Stamp Read Register \(SRX_DMA_SMSG_TS\)](#).

Address: 0h base + 174h offset + (24d × i), where i=0d to 5d

SRX_CHn_SMSG_TS field descriptions

Field	Description
0–31 TS	Time Stamp for the received message. Indicates the relative time of detection of the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) of the last Fast Message that completed the Serial Message. Time Stamp for Slow Serial Messages is not latched when the Slow Serial Message starts but when the Slow Serial Message is completely received.

48.5

Functional description

This section describes the function of the SRX.

48.5.1

Initialization sequence

All the channels are required to be configured before enabling them by writing into corresponding channel enable bit in the [Channel Enable Register \(SRX_CHNL_EN\)](#). There are some registers which must be configured and some which are to be changed if reset value is not as required for that channel. After enabling the channel, no configuration should be changed and if required to be changed, the user needs to first disable the channel and then reconfigure the channel parameters. The following must to be configured before enabling the corresponding channel:

- Time Stamp Prescaler Value in [Global Control Register \(SRX_GBL_CTRL\)](#) to generate the time stamping clock

- Rx Prescaler Value in [Channel 'n' Clock Control Register \(n = 0 to \(CH-1\)\) \(SRX_CHn_CLK_CTRL\)](#) to generate the channel's receiver clock
- Compensation enable in [Channel 'n' Clock Control Register \(n = 0 to \(CH-1\)\) \(SRX_CHn_CLK_CTRL\)](#)
- Channel Configuration settings in the [Channel 'n' Configuration Register \(n=0 to \(CH-1\)\) \(SRX_CHn_CONFIG\)](#)
- Number of Data Nibbles in Channel in the [Data Control Register 1 \(SRX_DATA_CTRL1\)](#)
- Control bits that control whether messages received in channel are to read by interrupt or DMA in [Fast Message DMA Control Register \(SRX_FDMA_CTRL\)](#), [Slow Serial Message DMA Control Register \(SRX_SDMA_CTRL\)](#), [Fast Message Ready Interrupt Control Register \(SRX_FRDY_IE\)](#) and [Slow Serial Message DMA Control Register \(SRX_SDMA_CTRL\)](#)

48.5.2 DMA read logic

The SENT Receiver module generates separate DMA requests for all Fast Messages and Slow Serial Messages received. The DMA requests are common for all channels. Each packet stored in the channels' buffers are appended with a time stamp taken from a free running time keeping counter and the channel number on which it was received. Details on this time stamp counter can be found in [Time stamp logic](#).

48.5.2.1 DMA request for Fast Message reading via FIFO

A single DMA request is generated for all Fast Messages received on any channel. There is a DMA read FIFO to store the incoming messages from all the channels and allow them to be read via DMA. The DMA operation will happen as follows:

- DMA request will be asserted when number of messages stored in FIFO crosses the configured watermark level (in [Global Control Register \(GBL_CTRL\)](#)).
- DMA request will be de-asserted when number of messages stored goes below watermark level. It is assumed that DMA Controller's TCD would be set to transfer bytes equal to the messages indicated by watermark level so as to empty the FIFO.
- It is assumed that when responding to a DMA request, the DMA controller will read at a rate faster than the rate at which messages are getting received and stored in FIFO.

- The complete received message can be read by three consecutive read accesses to DMA Fast Message Data Read Register. The message will be read out in following sequence:
 - Fast Message data as described by DMA Fast Message Data Read Register (DMA_FMSG_DATA)
 - CRC for the Fast Message as described by DMA Fast Message CRC Read Register (DMA_FMSG_CRC)
 - Time stamp value for the Fast Message as described by DMA Fast Message Time Stamp Read Register (DMA_FMSG_TS)
- The channel number is prefixed in each valid message (no error) to allow software to identify messages pertaining to a channel
- [Table 48-82](#) shows the format in which the messages will be stored in any memory-mapped message buffer and when being read out from FIFO.
- Since multiple messages can be received at the same time, there is a [Fixed round robin sequencing logic](#), which will scan all active channels configured for DMA and store their message into the FIFO one by one. Channel configured for DMA but do not have ready messages will be automatically skipped till their turn comes again in the round robin sequence.
- Messages received can be stored in a different order to which they are actually received. The time stamp will indicate the order of reception of messages in a particular channel. However, the time stamp cannot be used to determine the order across channels.

This figure below shows the data for the three 32-bit accesses to be made by DMA to get one complete message with time stamp.

Table 48-82. Format of storing of Fast Messages in FIFO

CH NUM [3:0]	Status and Comm [3:0]	Data 1 [3:0]	Data 2 [3:0]	Data 3 [3:0]	Data 4 [3:0]	Data 5 [3:0]	Data 6 [3:0]
			CRC [3:0]				
TIME STAMP [31:0]							

Figure 48-81. Fast Message DMA Read Logic using FIFO

48.5.2.1.1 Fixed round robin sequencing logic

Figure 48-81 shows a scenario where 8 channels (0-7) with all channels are enabled for DMA reading except channel 2. DMA request will be asserted when FIFO has received packets more than watermark level set. Figure 48-81 shows channels 6 and 4 have not received the complete message. The following points describe the complete round robin sequencing scheme.

- The round robin sequencing logic which stores the messages in the FIFO by looping through each channels' Fast Message register and checking for the availability of the message.
- As shown in Figure 48-81, the arbitration logic will check for messages in sequence 0 -> 1 -> 3 -> 5 -> 7 and back to channel 0 and keep looping. Channel 2 is skipped as it's not enabled to be read via DMA) and channel 4 and 6 are skipped as message is not received completely at the instance the sequencing logic checked their buffers. This sequence continues in this fashion.
- The sequence in which messages are stored in FIFO is not deterministic and depends on the sequence they are detected after the noise filtering by the input filter of the channel.
- The DMA controller responds to the DMA request by reading from the DMA Fast Message Read register. When a DMA read happens, a message is read from the FIFO and split into three 32-bit values and provided to DMA in the order as described in previous section. The three 32-bit values together form one complete Fast Message.
- Once all three 32-bit access are completed, the next data from the FIFO is popped.

Figure 48-81 also shows how the received data (light gray colored boxes) from a channel is stored in FIFO along with the time stamp and channel number appended (both white colored).

48.5.2.2 DMA request for Fast Message reading when FIFO is disabled

In this mode no FIFO will be used as it is disabled via the FIFO Enable bit in the Global Control Register (GBL_CTRL). Fast Messages received are stored in a single system bus clock domain buffer to be read out by the DMA Controller via the DMA Fast Message Read register set. Note the DMA Controller must read all 3 DMA Read Registers to obtain the complete message, unlike the case when FIFO is enabled and message is read out from the DMA Fast Message Data Read register only. The data flow will happen as follows:

- A DMA request will be asserted when any of the DMA enabled channels has successfully received one complete Fast Message. The request is kept asserted till all messages (across DMA enabled channels) have been read out.
- DMA Controller should read the complete message by accessing each register of the DMA Fast Message Read register set, the registers being:
 - [DMA Fast Message Data Read Register \(SRX_DMA_FMSG_DATA\)](#)
 - [DMA Fast Message CRC Read Register \(SRX_DMA_FMSG_CRC\)](#)
 - [DMA Fast Message Time Stamp Read Register \(SRX_DMA_FMSG_TS\)](#)
- A fixed round robin sequencing runs, as shown in [Figure 48-82](#), and this logic checks for messages in sequence 0→1→3→5→7 and back to channel 0 and so on. Channel 2 is skipped as it is not DMA enabled) and channel 4 and 6 are skipped as message is not received completely. This sequence continues like this.
- The sequence in which messages are read through DMA interface is not deterministic and depends on the sequence in which they are completely received.
- When the sequencing logic detects a message ready to be read, it will update the DMA Fast Message Read register set for DMA read and move to the next channel when this message is read out completely (i.e., 3 read accesses to the above mentioned registers)
- The DMA controller should be programmed to read only one message in one DMA transfer (i.e. 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur
- User software should ensure there is no overflow in channels. In case overflow occurs, the message in the channel buffer will get overwritten by the newly received message. However, when a DMA read is in progress, the buffers will not be overwritten if overflow occurs to maintain data integrity.
- The Round Robin sequencing logic loops through each DMA enabled channel and halts at any channel having data till it is read out by the DMA Controller.

Figure 48-82. Fast Message DMA read logic (when FIFO is disabled)

48.5.2.3 DMA request for Slow Serial Message reading

A separate DMA request (different from DMA request for Fast Message) is generated for all slow serial messages received on all channels. The data flow will happen as follows:

- Request will be asserted when any of the DMA enabled channels has successfully received one complete serial message (short or enhanced) and kept asserted till all messages have been read from their respective memory-mapped registers

- Similar to DMA read for Fast Messages, data for slow serial messages will be read from DMA Slow Serial Message Read register set in memory map, the register set comprising of:
 - [DMA Slow Serial Message Bit3 Read Register \(SRX_DMA_SMSG_BIT3\)](#)
 - [DMA Slow Serial Message Bit2 Read Register \(SRX_DMA_SMSG_BIT2\)](#)
 - [DMA Slow Serial Message Time Stamp Read Register \(SRX_DMA_SMSG_TS\)](#)
- A fixed round robin sequencing logic will be running and it will update the DMA Slow Serial Message Read register set for DMA read and move to the next channel when this message is read out completely (i.e., 3 DMA read accesses to the above mentioned registers)
- The channel number and time stamp will also be appended for every message
- A message type bit (TYPE) will also be appended to distinguish between short and enhanced serial messages
- The DMA controller should be programmed to read only one message in one DMA transfer (i.e. 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur
- Since serial messages receive rate is very slow, user software should ensure there is no overflow
- The fixed round robin sequence logic for DMA read is the same as that used for Fast Messages (see [DMA request for Fast Message reading when FIFO is disabled](#))

[Figure 48-83](#) shows the sequencing of channels for serial messages to be read when DMA read is done on DMA Slow Serial Message Read register set.

Note: The arrows in the figure indicate next DMA transfer. One DMA Read Register set (3 registers) will be read in

Figure 48-83. Slow Serial Message DMA read logic

The formats in which the 3 types of Serial Messages will be stored in the buffers are shown in figures below.

Table 48-83. Enhanced Serial Message with 8-bit ID field

31		1	16				15		0		0					
CH NUM [3:0]		P							0	C	ID [7:4]		0	ID [3:0]		0
				CRC [5:0]						Data Field [11:0]						
TIME STAMP [31:0]																

Table 48-84. Enhanced Serial Message with 4-bit ID field

31		1	16				15		1		0			
CH NUM [3:0]		P							0	C	ID [3:0]	0	Data Field [15:12]	0
			CRC [5:0]						Data Field [11:0]					
TIME STAMP [31:0]														

Table 48-83 and Table 48-84 shows the enhanced serial messages. Bit C (shown in figure) or CFG (as shown in DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3) description) defines the type of enhanced packet and bit P (shown in figure) or bit TYPE (shown in DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3) description) defines whether it is short serial or enhanced serial message. CRC, ID and Data fields are stored in format as received and shown in SAE specification with just one exception that CRC is shifted to align with 16-bit boundary.

Table 48-85 shows the short serial message. Field locations have been placed in such a way to allow a common register to read all the slow serial messages and also match the bit positions in actual message defined by SAE Specification.

Table 48-85. Short serial message

31	0	16	15	0
CH NUM [3:0]	P			
		CRC [3:0]	ID [3:0]	Data Field [7:0]
TIME STAMP [31:0]				

Again, three 32-bit accesses to be made by DMA to get one complete message with time stamp.

48.5.3 Message reading via interrupts

There is one interrupt request per channel for a Fast message received and one for a serial message received. Each channel is individually configurable to enable or disable interrupt on reception of Fast or Slow Serial messages separately. In case of interrupt request of Fast Message, an interrupt will be asserted when any of the channels has received a complete Fast Message without errors and that channel is not configured for DMA Reads. The interrupt routine should be coded in such a way to take the least amount of overhead (in CPU cycles) while entering the routine and start reading the available messages. The routine should be capable of accessing all channels that are enabled to give out messages via interrupts through the Register Interface.

In response to these interrupts, the CPU is expected to read interrupt status register for fast or Slow Messages (depending on which interrupt was asserted) and store it in system memory. Using this status register value, the interrupt routine can decide from which channels the message is to be read. For instance if bit corresponding to channel 0 is set then routine should read from the address location corresponding to Channel 0 Fast Message Read registers and move onto the next asserted bit. The interrupt routine should scan through all the bits of this stored interrupt status register value and read corresponding channel's fast or Slow Message registers. In this manner all available messages can be read. After scanning through all the bits of status register stored in system memory, routine can read again the message ready interrupt status register to find out if any other channel has received in the mean time. This will save another interrupt routine time mainly from stacking/unstacking delay.

It is assumed that the interrupt controller will be able to respond fast enough to avoid any overflow as only one message per channel will be stored and the system bus clock frequency is sufficient to avoid this.

48.5.3.1 Suggested software interrupt service routine steps

These are suggested step to have an interrupt routine that can read all messages quickly and avoid any underflow/overflow. Actual implementations can vary.

When separate Fast Message and Slow Serial Message Interrupts are used:

The Fast Message Interrupt should have higher priority than Slow Serial Message Interrupt. The suggested ISR steps for a Fast Message Interrupts can be

- Read the Fast Message Ready Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register set (3 registers). Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Fast Message Status Registers again to ensure no new message has arrived during the ISR.
- If there are no bits set, exit the ISR, else repeat this process.

The ISR steps for Slow Serial Message Interrupt can be same as for Fast Message ISR.

When common Fast Message and Slow Serial Message Interrupts are used:

The suggested ISR steps can be

- Read the Fast Message Status Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register. Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Slow Serial Message Status Register into a new variable

- Shift out bits starting from MSB from this new variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Slow Serial Message Read Register. Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, software can again check both Fast and Slow Serial Message Ready register to ready any message that might have been received while the routine was being serviced, or can choose to exit the routine.

48.5.4 Overflow behavior

This section describes the overflow behavior.

48.5.4.1 Fast messages buffers/FIFO

Overflow in Fast Message buffers or FIFO can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full. When FIFO is used, overflow is indicated when the FIFO gets full and another fast message is to be stored.

When an overflow event occurs, the newly received message overwrite the previously stored message and the overflow status bit is set. However, if overflow asserts while CPU/DMA is reading that channel (i.e. all 3 read registers have not yet been read), then that message is not overwritten. While messages are being overwritten, the slow message reception is not hampered.

48.5.4.2 Slow message buffers

Overflow in Slow Message buffers can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full.

When an overflow event occurs, further reception of slow messages is halted until the buffers are read out by CPU or DMA. Since it is less likely that CPU or DMA do not read the read registers for 32 or 36 fast message length duration, an overflow in slow messages would not be as frequent as in fast messages.

48.5.5 Adjustment for variation in sensor (Tx) clock

The clock used by the Channel Receiver (referred to as Receiver Clock, or Rx_CLK) to sample the message nibbles is generated from a High Frequency Receiver Clock or Protocol Clock. This high frequency receiver clock is divided using a prescaler counter which generates a tick when it rollovers on reaching a count equal to the Prescaler Value programmed in the channel's clock control register. The receive clock is generated separately for each channel. By varying this Prescaler Factor, we can control the period of the receive clock and make it close to the Transmitter clock used by the sensor for the particular channel.

After reset and once channel is enabled, the compensated prescaler value is set to Zero and the user software programs the Prescaler Value to obtain the desired receiver clock frequency for the particular channel. Thus, the receiver starts working by assuming that the transmitter is sending messages on the frequency that is programmed in its channel clock control register. The channel's input after filtering is continuously measured by the Prescaler Counter. The compensation logic checks each pulse length and determines the calibration pulse from them. When a calibration pulse is detected, the compensated prescaler value is computed and stored in the Channel's Clock Control Register ([Channel 'n' Clock Control Register \(n = 0 to \(CH-1\)\) \(SRX_CHn_CLK_CTRL\)](#)). Software can use this value to determine the variation in Tx Clock.

Note

A pause pulse may incidentally be detected as a synchronization/calibration pulse during start up after reset. The correction value would be computed on the pause pulse too but since the next synchronization pulse would follow, the logic would again detect the falling edge on the synchronization pulse and the correction value would now be correctly computed on the correct synchronization pulse.

The Clock Compensation or Correction happens for every messages that is received and the compensated prescaler value remains constant for that message.

48.5.5.1 Adjustment for nibble length variation

Section 6.2 of SAE Specifications specifies the maximum allowable limits for clock drift and jitter for the transmitter and receiver separately. This can cause the length of nibbles to vary and can cause incorrect sampling of data nibbles. This variation is adjusted by the SENT Receiver when nibbles are being sampled.

48.5.6 Input programmable filter

The Input Programmable Filter ensures that only valid input pin transitions are received by the SENT Receiver module. The input programmable filter is an 8-bit programmable up counter that increments on the high frequency receiver clock. The sensor input signal from device's pad is synchronized by high frequency receiver clock. When a state change occurs in the sensor input signal, the 8-bit counter resets and starts counting up on the high frequency receiver clock. As long as the new state is stable on the pin, the counter remains incrementing. If a counter overflow occurs, the new pin value (i.e. sensor input) is validated and latched in the filtered output flop (also running on high frequency receiver clock). If the opposite edge appears on the sensor input before validation (i.e. overflow), the counter is reset and the input is not passed onto the filtered output. At the next pin transition, the counter starts counting again. Any pulse that is shorter than a full range of the masked counter is regarded as a glitch and it is not passed on to the filter output. The number of samples (or the match value of the up counter) is programmable by the user in the channel's configuration register [Channel 'n' Configuration Register \(n=0 to \(CH-1\)\) \(SRX_CHn_CONFIG\)](#). When zero is programmed into the registers, it bypasses the filter and the synchronized input is output as the filtered output. A non-zero value delays the filtered output by the number of clocks proportional to the programmed value in the Channel Configuration Register ([Channel 'n' Configuration Register \(n=0 to \(CH-1\)\) \(SRX_CHn_CONFIG\)](#)). A timing diagram of the input filter when FIL_CNT is 4, is shown in the following figure.

Figure 48-84. Input programmable filter timing diagram

48.5.7 Receiver diagnostics

Most of the receiver diagnostics are controlled by the Fast Message State Machine. The following checks are conducted by the receiver in each channel

- Calibration pulse length < 56 clock ticks – 25% or > 56 clock ticks + 25%

- Not the expected number of falling edges between calibration pulses. (Message length is pre-defined by each sensor device and programmed by user for each channel)
- Checksum error. Two 4-bit CRC checks and one 6-bit CRC check according to the message type. User has a programmable option to select the method of CRC to use i.e. Legacy or Recommended.
- Any nibble data values measured as < 0 or > 15
- Successive calibration pulses differ by $> +1.5625\%$ (1/64) or $< -1.5625\%$. The accuracy of this check will depend on the frequency of the protocol clock used.
- For messages with pause pulse, an additional diagnostic is done; however, this diagnostic will not fail any message (to reduce latency in message reception) but the failure of this diagnostic will be indicated in the channel's status register.

On detection of any of the above errors, the receiver rejects the current packet until a new calibration pulse is detected. Occurrence of an error is flagged in the respective channel's status register ([Channel 'n' Status Register \(n=0 to \(CH-1\)\) \(SRX_CHn_STATUS\)](#)). If error interrupt is enabled, an error interrupt will be generated. There is a single error interrupt generated for all errors, so the CPU must read the status register to find out which error occurred. Once error condition is flagged, subsequent errors (except NUM_EDGES_ERR) are automatically masked out until a valid calibration pulse is detected, after which all checks are automatically enabled. This is done to avoid multiple assertions of the interrupt to CPU in case the channel become unstable and send wrong data continuously.

48.5.7.1 Calibration pulse length check

The calibration pulse length check happens in conjunction with Clock Compensation Logic since current calibration pulse is detected in this block. The Clock Compensation Logic detects a calibration pulse of length between 42 and 70 tick counts. This check will assert the CAL_LEN_ERR status bit on failure.

48.5.7.2 Successive calibration pulse check

The successive calibration pulse check checks if successive calibration pulses differ by $> +1.5625\%$ (1/64) or $< -1.5625\%$. The accuracy of this check will depend on the frequency of the protocol clock used. Specifically, the higher the frequency, the closer the check will be to 1.5625%. So if protocol clock is T_{HF_CLK} and channel tick period is

T_{TX_CLK} then the check will be of $1.5625\% \pm \{100 \times (4 \times T_{HF\_CLK}) / (42 \times T_{TX\_CLK})\}$. So it won't allow variance in clock of a channel by $1.5625\% - \{100 \times (4 \times T_{HF\_CLK}) / (42 \times T_{TX\_CLK})\}$. This check will assert the CAL_DIAG_ERR status bit on failure.

When Option 2 of successive calibration pulse check is enabled, the CAL_RESYNC bit will be asserted on every third successive error detected by this check.

48.5.7.3 Not the expected number of edges check

The number of negative edges between two successive calibration pulses is counted and compared with expected number of edges in case of preferred option of successive calibration pulse check. The expected number of nibbles is the sum of following:

- Status and Communication nibble (1 No.)
- Data nibbles (Programmable as per user software)
- CRC nibble (1 No.)
- Pause Pulse, if configured (1 No.)

This check ("Not the expected number of edges check") will assert the NUM_EDGES_ERR status bit on failure. The check does not run when Option 2 (low latency) of successive calibration pulse check is enabled. This check is not masked after any other error is detected so it could be redundant if it is flagged along with CAL_DIAG_ERR and CAL_LEN_ERR. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

48.5.7.4 Nibble value check

As part of this check, the lengths of the following nibbles are checked to remain in between 0 and 15 nibble values(11.5 ticks to 27.5 ticks):

- Status and Communication nibble
- all Data nibbles
- CRC nibble

The nibble value check will assert the NIB_VAL_ERR status bit on failure. This error can be flagged along with NUM_EDGES_ERR in which case the former can be ignored as the number of pulses in the message is incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. In case, errors are accumulated, the above cannot be deduced.

48.5.7.5 CRC check

The CRC check will compute both 4-bit and 6-bit CRC as requested by State Machine control logic. Two 4-bit CRCs and one 6-bit CRC are supported to compute the CRC on Fast/Slow Serial Message (4-bit CRC) and Enhanced Serial Message (6-bit CRC) respectively. The SENT Receiver Module allows the user to calculate the 4-bit CRC using either the legacy CRC implementation method or the new recommended CRC implementation via a control bit in the channel's corresponding control register. Please refer to SAE SENT Specification for details on CRC algorithm.

Asserting the CHn_CONFIG_REG[11] bit, causes the Status and Communication nibble to be included in the 4-bit CRC calculation for Fast Serial Messages. De-asserting this bit enables normal operation as described above.

This check will assert the FMSG_CRC_ERR or SMSG_CRC_ERR status bit on failure, depending on whether the check is run for Fast Message or Slow Message.

The FMSG_CRC_ERR can be flagged along with the NUM_EDGES_ERR, in which case the CRC error can be ignored as the number of pulses in the message was incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

48.5.7.6 Pause pulse diagnostic

The pause pulse diagnostic checks whether the ratio of calibration pulse length to full message length (including pause pulse) varies from one message to another by less than 1.5625% (as per spec). In order to have reduced latency of operation, message reception is not gated due to this check and no messages are discarded. However, when this check fails, a status bit is asserted to let the software know of this condition. The successive calibration pulse check can be configured to operate along with this check. This configurability is added to avoid conflicting results from the two checks.

There can be some inaccuracy in measuring pause pulse length as SAE specification specifies maximum clock drift/jitter up to maximum nibble length only and the frequency of high frequency receiver clock (protocol clock) used, allows clock compensation logic

to ensure accuracy up to maximum nibble length. Hence there could be some inaccuracy in this check when sampling pause pulses that are larger than the maximum nibble pulse length.

This check will assert the PP_DIAG_ERR status bit on failure. This check does not run when reception of pause pulse is disabled.

When the Single Edge Nibble Transmission (SENT) Receiver (SRX) is configured to receive a pause pulse (Channel 'n' Configuration Register - CHn_CONFIG[PAUSE_EN] = 1) and the length of the pause pulse from the sensor is in range of the valid calibration pulse length, the NUM_EDGES error can get asserted spuriously (Channel 'n' Status Register - CHn_STATUS(NUM_EDGES_ERR) = 1) when there is any diagnostic error (other than number of expected edges error) or overflow in the incoming messages from the sensor.

Software can distinguish a spurious NUM_EDGES_ERR error from a real one by monitoring other error bits. The following tables will help distinguish between a false and real assertion of NUM_EDGES_ERR error and other errors. Software should handle the first error detected as per application needs and other bits can be evaluated based on these tables. Table 1 contains information due to erratum behavior and Table 2 below contains clarification of normal NUM_EDGES_ERR behavior.

Table 48-86. Behavior of NUM_EDGES_ERR

First Error Detected	Other error bits asserted	Cause for extra error bits getting asserted	Action
NIB_VAL_ERR	NUM_EDGES_ERR asserted twice	Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are seen as back to back calibration pulses and no edges in between.	Ignore both NUM_EDGES_ERR error

Table continues on the next page...

**Table 48-86. Behavior of NUM_EDGES_ERR
(continued)**

FMSG_CRC_ERR	NUM_EDGES_ERR asserted twice	Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are seen as back to back calibration pulses and no edges in between.	Ignore both NUM_EDGES_ERR errors
CAL_LEN_ERR	NUM_EDGES_ERR asserted once	Since the calibration pulse is not detected as a valid calibration pulse, the internal edges counter does not detect the end of one message and start of bad message (which has CAL_LEN_ERR); hence the NUM_EDGES_ERR gets asserted.	Ignore NUM_EDGES_ERR error

Table 48-87. Expected behavior, clarification of NUM_EDGES_ERR cases

First Error Detected	Other error bits asserted	Cause for extra error bits getting asserted	Action
NUM_EDGES_ERR (when edges are less than expected)	NIB_VAL_ERR is asserted	When the actual number of edges in the message are less than expected, then a pause pulse gets detected as a nibble since the state machine expects nibbles when actually there is a pause pulse present. This generates NIB_VAL_ERR.	Ignore the NIB_VAL_ERR
NUM_EDGES_ERR (when edges are more than expected)	NIB_VAL_ERR and PP_DIAG_ERR are asserted	When the actual number of edges in a message are more than expected, then after receiving the programmed number of data nibbles, the state machine expects a pause pulse. However, the pause pulse comes later and gets detected as a nibble and hence NIB_VAL_ERR is asserted. Since the message length is not correct, PP_DIAG_ERR is also asserted.	Ignore NIB_VAL_ERR and PP_DIAG_ERR

48.5.8 Time stamp logic

A single counter maintains the time stamp for all channels which can be used by the software to determine the relative time of arrival of the messages for each channel. The time stamp counter is a 32-bit counter.

The clock for this counter is derived from the high frequency receiver clock using a Time Stamp Prescaler Counter that divides the high frequency receiver clock to generate the clock of required resolution. The user must program the time stamp prescaler value (in [Global Control Register \(SRX_GBL_CTRL\)](#)) in order to generate the time stamp clock. The period of the time stamp clock must be less than that of the fastest receiver channel being used, or it can be set at some fixed value determined by application, such as 1 μ s. For example, if the high frequency receiver clock is 60 MHz, the required prescaler value is 59 to generate a time stamp clock of 1 μ s resolution.

Note

The rollover of time stamp values should be determined in user software, by comparing the time stamp values in previous and current messages that are read out. User software should adjust the time stamp values in these messages accordingly, after reading them.

The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer. However, if the current message is found to be in error, the message buffer is discarded. Thus, the time stamp will be available to user software for only those messages which do not have any error.

The time stamp for a serial message is sampled at the end of the message i.e. when the serial message is completely received and when the message is found to have no errors. the time stamp is stored in the message read buffer to be read by the user software. Again, for messages with error the message and time stamp are discarded.

48.5.8.1 Limitation

Since the same counter is used for all channels, it may happen that more than 1 message is received within the same time stamp across different channels. Hence the software would not be able to determine the sequence of arrival of messages which have the same time stamp value.

48.5.9 Bus Idle Diagnostic

This diagnostic checks the connected sensors for inactivity. SENT module can indicate if the idle period on a particular channel has crossed the period defined by the programmed value in Bus Idle Count (in [Channel 'n' Configuration Register \(n=0 to \(CH-1\)\) \(SRX_CH_n_CONFIG\)](#)). Status bit (bus_idle in [Channel 'n' Status Register \(n=0 to \(CH-1\)\) \(SRX_CH_n_STATUS\)](#)) will be set when idle period crosses the allowed value. CPU should write 1 to this clear this bit once it is read.

48.6 Clocks and resets

The SENT Receiver works on two clocks. First is the System Bus Clock that is used to program the registers and read messages via DMA or Interrupt from the module's Register Interface. Second is the High Frequency Receiver Clock or Protocol Clock that is used for accurate message receiving operations. There is a single asynchronous reset which is the system asynchronous reset and one internal reset for each of the channel logic.

48.6.1 Clocking strategy

The following figure shows the clock domain in which each module is functioning.

Figure 48-85. SENT Receiver module clock domains

48.6.2 System bus clock requirements

Since all the received messages are read on the System Bus Clock it is necessary that both the interrupt service routine and the DMA controller must be able to access all channels with messages ready to be read within a time to prevent overflow in any channel. The minimum time available to the CPU or DMA is the case when the smallest Fast Message is received back to back on all channels while working on the smallest receive clock tick period.

Now, the smallest Fast Message size with valid checksum as per SAE Specifications is 154 ticks. At 3 μ s receive clock tick with a -20% variation in the transmitter clock tick, the effective receiver clock tick is 2.4 μ s (after compensation). This gives us the time in which the minimum size Fast Message is received in any channel as $154 \times 2.4 = 369.6$

μs. Now since messages are arriving in parallel, 369.6 μs is the time available for CPU or DMA to access all channels to prevent an overflow in the channel that received the very first message.

Thus, if assume that ' N_{CHNL} ' channels are being used and all channels have messages ready to be read together from either DMA or CPU then the time available to read a message in one channel will be $369.6/N_{\text{CHNL}}$ μs or $\sim 370/N_{\text{CHNL}}$ μs. Since the CPU or the DMA needs to make three 32-bit accesses in order to read a complete message and taking the time required for one 32-bit read access as ' T_{RD} ' (assuming it to be same for DMA and CPU); we can determine the minimum frequency for the System Bus Clock as:

For CPU,

$$3 \times T_{\text{RD}} + T_{\text{ISR}} + T_{\text{WAKUP}} < 370 / N_{\text{CHNL}}$$

where T_{ISR} is the overhead in initiating an ISR and T_{WAKUP} is the time to wakeup from low power mode

For DMA,

$$3 \times T_{\text{RD}} + T_{\text{WAKUP}} < 370 / N_{\text{CHNL}}$$

Replacing $T_{\text{RD}} = N_{\text{RD}} \times T_{\text{SYS\_CLK}}$ and $T_{\text{ISR}} = N_{\text{ISR}} \times T_{\text{SYS\_CLK}}$, where N_{RD} is the number of System Bus Clock cycles in one 32-bit read access, N_{ISR} is the number of System Bus Clock Cycles in initiating an interrupt service routine and $T_{\text{SYS\_CLK}}$ is the period of the same clock, we get

For CPU,

$$(3 \times N_{\text{RD}} + N_{\text{ISR}}) \times T_{\text{SYS\_CLK}} + T_{\text{WAKUP}} < 370 / N_{\text{CHNL}}$$

(all units is μs)

For DMA,

$$3 \times N_{\text{RD}} \times T_{\text{SYS\_CLK}} + T_{\text{WAKUP}} < 370 / N_{\text{CHNL}}$$

(all units is μs)

48.6.3 High frequency receiver clock (protocol clock) requirements

For accurate receive operations, the protocol is required to satisfy a minimum frequency defined as per formula: Guard Band > $2.5 \times T_{\text{HF\_CLK}}$

where T_{HF_CLK} is the High Frequency Receiver Clock or Protocol Clock in ns and Guard Band is guard band in ns as specified in SAE specification, at particular transmitter uTick.

Note

T_{HF_CLK} in the above equation should be chosen based on the fastest sensor clock (with minimum guard band as specified in SAE spec) among all channels in the device.

Chapter 49

Enhanced Serial Communication Interface (eSCI)

49.1 Chip-specific eSCI information

This chip has six instances of the eSCI module. Some feature details vary among the instances.

The following table summarizes the feature differences. The table does not list feature details that the instances share.

Table 49-1. eSCI instance feature differences

Instance	DMA support
eSCI_A and eSCI_B	Yes
eSCI_C, eSCI_D, eSCI_E, and eSCI_F	No: descriptions of eSCI DMA functionality do not apply to these instances

NOTE

For eSCI_D, the single wire feature does not apply for TX/RX via PCSA3 because this pad works only as an output.

49.1.1 eSCI clocking

For information about eSCI clock sources and the eSCI's module clock (MCLK), see the [Clock generation](#) diagram, the [Peripheral clocks](#) diagram, and other details in the Clocking chapter.

49.1.2 eSCI registers: core access in supervisor mode

On this chip, all core accesses to eSCI registers occur in supervisor mode.

49.2 Introduction

The eSCI block is an enhanced SCI block with a LIN master interface layer and DMA support. The LIN master layer complies with the specifications LIN 1.3, LIN 2.0, LIN 2.1, and SAE J2602/1.

49.2.1 Bibliography

- LIN Specification Package Revision 1.3; December 12, 2002
- LIN Specification Package Revision 2.0; September 23, 2003
- LIN Network for Vehicle Applications, SAE J2602/1, September 1, 2005
- LIN Specification Package Revision 2.1; November 24, 2006

49.2.2 Acronyms and Abbreviations

The following table contains acronyms and abbreviations used in this document.

Table 49-2. Acronyms and Abbreviations

Term	Description
eSCI	Enhanced SCI block with LIN support and DMA support
SCI	Serial Communications Interface
LIN	Local Interconnect Network - A protocol for low-cost automobile networks
LIN PE	LIN Protocol Engine, Finite State Machine to control logic of the LIN hardware.
MCLK	Module Clock, defined in Module Clock
TCLK	Transmitter Clock, defined in Transmitter Clock
RCLK	Receiver Clock, defined in Receiver Clock
RSC	Receiver Sample Counter, defined in Receiver Clock

49.2.3 Glossary

Table 49-3. Glossary

Term	Definition
Logic level one	The voltage that corresponds to Boolean true (1) state.

Table continues on the next page...

Table 49-3. Glossary (continued)

Term	Definition
Logic level zero	The voltage that corresponds to Boolean false (0) state.
Set	To set a bit or bits means to establish logic level one on the bit or bits.
Clear	To clear a bit or bits means to establish logic level zero on the bit or bits.
Asserted	A signal that is asserted is in its active state. An active low signal changes from logic level one to logic level zero when asserted, and an active high signal changes from logic level zero to logic level one.
Preamble	The term preamble describes an idle character which is <i>transmitted</i> by the eSCI module.
Bit time	Duration of a single bit in a transmitted byte field or character, equivalent to the duration of one transmitter clock cycle defined in Transmitter Clock
frame	Entity that consists of the start bit followed by payload bits followed by one or more stop bits
LIN byte field	Special instance of a frame
SCI frame	Special instance of a frame
LIN frame	Sequence of break character followed by LIN byte fields
LIN TX frame	A LIN frame with the frame header, data byte fields, and checksum field transmitted by the eSCI module
LIN RX frame	A LIN frame with the header field transmitted by the eSCI module and the data byte fields and checksum field received by the eSCI module
module is idle	Module is idle, described in Module Idle Condition

49.2.4 Overview

The eSCI block allows asynchronous serial communications with peripheral devices and other CPUs. It includes special support to interface to LIN slave devices.

Figure 49-1. eSCI Block Diagram

49.2.5 Features

The eSCI block includes these distinctive features:

- Full-duplex operation
- Standard mark/space non-return-to-zero (NRZ) format
- 13-bit baud rate selection
- Programmable frame, payload, and character format
- Support of 2 stop bits in receiver path
- Hardware parity generation and checking
 - Programmable even or odd parity
- Programmable polarity of RXD pin
- Separately enabled transmitter and receiver
- Two receiver wake-up methods:

- Idle line wake up
- Address mark wake up
- Interrupt-driven operation with eight flags:
 - Transmitter empty
 - Transmission complete
 - Receiver full
 - Idle receiver input
 - Receiver overrun
 - Noise error
 - Framing error
 - Parity error
- Receiver framing error detection
- 1/16 bit-time noise detection
- 2 channel DMA interface
- LIN support
 - LIN Master Node functionality (master and slave task)
 - Compatible with LIN slaves from revisions 1.x and 2.0 of the LIN standard
 - Detection of Bit Errors, Physical Bus Errors and Checksum Errors
 - All status bit can generate maskable interrupts
 - Application layer CRC support
 - Programmable CRC polynomial
 - Detection and generation of wake-up characters
 - Programmable wake-up delimiter time
 - Programmable slave timeout
 - Can be configured to include header bits in checksum
 - LIN DMA interface

49.2.6 Modes of Operation

The eSCI module has two functional operational modes, SCI and LIN mode. The availability of register bits and fields depends on the selected operational mode.

49.2.6.1 Module Idle Condition

Doze mode, Disable mode and Stop mode can only be entered when the module is idle. The module is idle if

- all five active status bits DACT, WACT, LACT, TACT, and RACT in the Interrupt Flag and Status Register 1 (eSCI_IFSR1) are 0, and
- no interrupt request is pending, i.e either the interrupt flag or its related interrupt enable is 0.

To ensure that the module goes idle, the application should clear all interrupt enable bits before triggering the mode change.

49.2.6.2 SCI Mode

The SCI mode is the default functional operational mode and is described in [SCI Mode](#).

49.2.6.3 LIN Mode

The LIN mode is the second functional operational mode and is described in [LIN Mode](#).

49.2.6.4 Disabled Mode

In the Disabled mode the eSCI module indicates to the clocking system, that all module clocks can be turned off.

The eSCI module is in the Disabled Mode, if the MDIS bit in the Control Register 2 (eSCI_CR2) is set and the module is idle.

49.3 External Signal Description

The eSCI module is connected to a total of two external pins.

49.3.1 Detailed Signal Descriptions

49.3.1.1 eSCI Transmit Pin (TXD)

This pin serves as transmit data output and as the receive data input of eSCI.

49.3.1.2 eSCI Receive Pin (RXD)

This pin serves as receive data input of the eSCI.

49.4 Memory Map and Register Definition

Writes to a reserved register location do not have any effect and reads of these locations return a zero.

NOTE

All R/W registers are writable only in supervisor mode of the core performing the write.

eSCI memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Baud Rate Register (eSCI_BRR)	16	R/W	0004h	49.4.1/2682
2	Control Register 1 (eSCI_CR1)	16	R/W	0000h	49.4.2/2683
4	Control Register 2 (eSCI_CR2)	16	R/W	2000h	49.4.3/2685
6	SCI Data Register (eSCI_SDR)	16	R/W	0000h	49.4.4/2687
8	Interrupt Flag and Status Register 1 (eSCI_IFSR1)	16	w1c	8000h	49.4.5/2689

C	LIN Control Register 1 (eSCI_LCR1)	16	R/W	0000h	49.4.7/2692
E	LIN Control Register 2 (eSCI_LCR2)	16	R/W	0000h	49.4.8/2694

Table continues on the next page...

eSCI memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
10	LIN Transmit Register (eSCI_LTR)	8	R/W	00h	49.4.9/2694
14	LIN Receive Register (eSCI_LRR)	8	R	00h	49.4.10/2696
18	LIN CRC Polynomial Register (eSCI_LPR)	16	R/W	C599h	49.4.11/2697
1A	Control Register 3 (eSCI_CR3)	16	R/W	0000h	49.4.12/2697

49.4.1 Baud Rate Register (eSCI_BRR)

This register provides the control value for the serial baud rate. The baud rate and clock generation is specified in [Baud Rate and Clock Generation](#).

A byte write access to only the upper byte of this register (eSCI_BRR[0:7]) will not change the content of the register, instead, the written byte is stored internally into a shadow register. A subsequent byte write access to only the lower byte of this register (eSCI_BRR[8:15]) updates the lower byte and copies the content of the shadow register into the upper byte.

A byte write access to only the lower byte of this register (eSCI_BRR[8:15]) without a preceding byte write access to only the upper byte copies a value of all zero into the upper byte.

A 16-bit write access to this register updates both the lower and upper byte immediately and is the recommended write access type for this register.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0			SBR												
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

eSCI_BRR field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–15 SBR	Serial Baud Rate. This field provides the baud rate control value SBR.

49.4.2 Control Register 1 (eSCI_CR1)

This register provides bits to configure the functionality of the module, provides the interrupt enable bits for the interrupt flags provided in [Interrupt Flag and Status Register 1 \(eSCI_IFSR1\)](#) and provides the control bits for the transmitter and receiver.

Table 49-7. Receive Source Mode Selection

LOOPS	RSRC	Receiver Input Mode
0	0	Dual Wire Mode
0	1	Reserved
1	0	Loop Mode
1	1	Single Wire Mode

Address: 0h base + 2h offset = 2h

Bit	0	1	2	3	4	5	6	7
Read	LOOPS	Reserved	RSRC	M	WAKE	0	PE	PT
Write								
Reset	0	0	0	0	0	0	0	0

Read	TIE	TCIE	RIE	ILIE	TE	RE	RWU	SBK
Write								
Reset	0	0	0	0	0	0	0	0

eSCI_CR1 field descriptions

Field	Description
0 LOOPS	Loop Mode Select. This control bit together with the RSRC control bit defines the receiver source mode. The mode coding is defined in Table 49-7 and the modes are described in Receiver Input Mode Selection .
1 Reserved	This field is reserved. Application must not write 1 to this bit.
2 RSRC	Receiver Source Control. This control bit together with the LOOPS control bit defines the receiver source mode. The mode coding is defined in Table 49-7 and the modes are described in Receiver Input Mode Selection .
3 M	Frame Format Mode. This control bit together with the M2 bit of the Control Register 3 (eSCI_CR3) controls the frame format used. The supported frame formats and the related settings are defined in Frame Formats .
4 WAKE	Receiver Wake-up Condition. This control bit defines the wake-up condition for the receiver. The receiver wake-up is described in Multiprocessor Communication . 0 Idle line wake-up. 1 Address mark wake-up
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 PE	Parity Enable. This control bit enables the parity bit generation and checking. The location of the parity bits is shown in Frame Formats .

Table continues on the next page...

eSCI_CR1 field descriptions (continued)

Field	Description
	0 Parity bit generation and checking disabled. 1 Parity bit generation and checking enabled.
7 PT	Parity Type. This control bit defines whether even or odd parity has to be used. 0 Even parity (even number of ones in character clears the parity bit). 1 Odd parity (odd number of ones in character clears the parity bit).
8 TIE	Transmitter Interrupt Enable. This bit controls the eSCI_IFSR1[TRDE] interrupt request generation. 0 TDRE interrupt request generation disabled. 1 TDRE interrupt request generation enabled.
9 TCIE	Transmission Complete Interrupt Enable. This bit controls the eSCI_IFSR1[TC] interrupt request generation. 0 TC interrupt request generation disabled. 1 TC interrupt request generation enabled.
10 RIE	Receiver Full Interrupt Enable. This bit controls the eSCI_IFSR1[RDRF] interrupt request generation. 0 RDRF interrupt request generation disabled. 1 RDRF interrupt request generation enabled.
11 ILIE	Idle Line Interrupt Enable. This bit controls the eSCI_IFSR1[IDLE] interrupt request generation. 0 IDLE interrupt request generation disabled. 1 IDLE interrupt request generation enabled.
12 TE	Transmitter Enable. This control bit enables and disables the transmitter. The control features of the transmitter are described in Transmitter States and Transitions . 0 Transmitter disabled. 1 Transmitter enabled.
13 RE	Receiver Enable. This control bit enables and disables the receiver. The control features of the receiver are described in Receiver States and Transitions . 0 Receiver disabled. 1 Receiver enabled.
14 RWU	Receiver Wake-Up Mode. This bit controls and indicates the receiver wake-up mode, which is described in Multiprocessor Communication . NOTE: This bit should be set in SCI mode only. 0 Normal receiver operation. 1 Receiver is in wake-up mode.
15 SBK	Send Break Character. This bit controls the transmission of break characters, which is described in Break Character Transmission . NOTE: This bit should be set in SCI mode only. 0 No break characters will be transmitted. 1 Break characters will be transmitted.

49.4.3 Control Register 2 (eSCI_CR2)

This register provides bits to configure the functionality of the module, and interrupt enable bits for the interrupt flags provided in [Interrupt Flag and Status Register 1 \(eSCI_IFSR1\)](#) and control bits for the transmitter and receiver.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7
Read								
Write								
Reset	0	0	1	0	0	0	0	0
Bit	8	9	10	11	12	13	14	15
Read								
Write								
Reset	0	0	0	0	0	0	0	0

eSCI_CR2 field descriptions

Field	Description
0 MDIS	Module Disabled Mode. This bit controls the Module Mode of Operation, which is described in Modes of Operation . 0 Module is not in Disabled Mode. 1 Module is in Disabled Mode, if module is idle.
1 FBR	Fast Bit Error Detection. This bit controls the Bit Error Detection mode. NOTE: This bit is used in LIN mode only. 0 Standard Bit error detection performed as described in Standard Bit Error Detection . 1 Fast Bit error detection performed as described in Fast Bit Error Detection .
2 BSTP	DMA Stop on Bit Error or Physical Bus Error. This bit controls the transmit DMA requests generation in case of bit errors or physical bus errors. Bit errors are indicated by the BERR flag in the Interrupt Flag and Status Register 1 (eSCI_IFSR1) and physical bus errors are indicated by the PBERR flag in the Interrupt Flag and Status Register 2 (eSCI_IFSR2) . NOTE: This bit is used in LIN mode only. 0 Transmit DMA requests generated regardless of bit errors or physical bus errors. 1 Transmit DMA requests are not generated if eSCI_IFSR1[BERR] flag or eSCI_IFSR2[PBERR] flags are set.
3 BERRIE	Bit Error Interrupt Enable. This bit controls the BERR interrupt request generation. 0 BERR interrupt request generation disabled. 1 BERR interrupt request generation enabled.
4 RXDMA	Receive DMA Control. This bit enables the receive DMA feature. When this bit is cleared, a pending receive DMA request is deasserted.

Table continues on the next page...

eSCI_CR2 field descriptions (continued)

Field	Description
	0 Receive DMA disabled. 1 Receive DMA enabled.
5 TXDMA	Transmit DMA Control. This bit enables the transmit DMA feature. When this bit is cleared, a pending transmit DMA request is deasserted. 0 Transmit DMA disabled. 1 Transmit DMA enabled.
6 BRCL	Break Character Length. This bit is used to define the length of the break character to be transmitted. The settings are specified in Break Character Formats .
7 TXDIR	TXD pin output driver control. This bit has no effect. In this device, TXDIR does not control the output driver of the TXD pin in Single Wire Mode. The function is controlled by the relevant Pad Control Register in the System Integration Unit.
8 BESM	Fast Bit Error Detection Sample Mode. This bit defines the sample point for the Fast Bit Error Detection Mode. NOTE: This bit is used in LIN mode only. 0 Sample point is RS9. 1 Sample point is RS13.
9 BESTP	Bit Error Transmit Stop. This control bit defines the behavior of the eSCI Transmit Pin TXD while the bit error flag eSCI_IFSR1[BERR] is 1. NOTE: This bit is used in LIN mode only. 0 Application Data Values driven onto TXD pin. 1 Recessive Data Value 1 driven onto TXD pin.
10 RXPOL	RXD Pin polarity. This bit controls the polarity of the RXD pin. See Inverted Data Frame Formats . 0 Normal Polarity. 1 Inverted Polarity.
11 PMSK	Parity Bit Masking. This bit defines whether the received parity bit is presented in the related bit position in the SCI Data Register (eSCI_SDR) . 0 The received parity bit is presented in the bit position related to the parity bit. 1 The value 0 is presented in the bit position related to the parity bit.
12 ORIE	Overrun Interrupt Enable. This bit controls the eSCI_IFSR1[OR] interrupt request generation. 0 OR interrupt request generation disabled. 1 OR interrupt request generation enabled.
13 NFIE	Noise Interrupt Enable. This bit controls the eSCI_IFSR1[NF] interrupt request generation. 0 NF interrupt request generation disabled. 1 NF interrupt request generation enabled.
14 FEIE	Frame Error Interrupt Enable. This bit controls the eSCI_IFSR1[FE] interrupt request generation. 0 FE interrupt request generation disabled. 1 FE interrupt request generation enabled.
15 PFIE	Parity Error Interrupt Enable. This bit controls the eSCI_IFSR1[PF] interrupt request generation.

Table continues on the next page...

eSCI_CR2 field descriptions (continued)

Field	Description
0	PF interrupt request generation disabled.
1	PF interrupt request generation enabled.

49.4.4 SCI Data Register (eSCI_SDR)

In SCI mode this register is used to provide transmit data and retrieve received data. In LIN mode any write access to this register is ignored. In case of read accesses to this register during data transmission/reception this register provides a part of the transmitted/received data.

If the application writes to the lower byte of this register (eSCI_SDR[8:15]), the internal commit flag iCMT, which is not visible to the application, is set to indicate that the register has been updated and ready to transmit new data.

If the application reads from the lower byte of this register (eSCI_SDR[8:15]), a signal is send to the internal receiver unit to indicate that the register was read and is ready to receive new data. The read access will not change the content of any register.

Address: 0h base + 6h offset = 6h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	RN		ERR	0												
Write		TN														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eSCI_SDR field descriptions

Field	Description
0 RN	Received Most Significant Bit. The semantic of this bit depends on the frame format selected by eSCI_CR3[M2], eSCI_CR1[M], and eSCI_CR1[PE]. [M2=0,M=1,PE=0]: value of received data bit 8 or address bit. [M2=0,M=1,PE=1]: value of received parity bit if eSCI_CR2[PMSK]=0, 0 otherwise. [M2=1,M=0,PE=1]: value of received parity bit if eSCI_CR2[PMSK]=0, 0 otherwise . [M2=1,M=1,PE=1]: value of received parity bit if eSCI_CR2[PMSK]=0, 0 otherwise . It is 0 for all other frame formats.
1 TN	Transmit Most Significant Bit. The semantic of this bit depends on the frame format selected by eSCI_CR3[M2], eSCI_CR1[M], and eSCI_CR1[PE]. [M2=0,M=1,PE=0]: value to be transmitted as data bit 8 or address bit. It is not used for all other frame formats.

Table continues on the next page...

eSCI_SDR field descriptions (continued)

Field	Description
2 ERR	Receive Error Bit. This bit indicates the occurrence of the errors selected by the Control Register 3 (eSCI_CR3) during the reception of the frame presented in SCI Data Register (eSCI_SDR). In case of an overrun error for subsequent frames this bit is set too. 0 None of the selected errors occurred. 1 At least one of the selected errors occurred.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 RDTD	The contents of this field vary by bit and by semantic as follows. Most-significant 4 bits (RDTD[11:8]): Received Data. The semantic of this field depends on the frame format selected by eSCI_CR3[M2] and eSCI_CR1[M]. [M2=1,M=1]: value of the received data bits 11:8. (Rx=BITx) . It is all 0 for all other frame formats . Fifthmost-significant bit (RDTD[7]): When read, this is Received Bit 7. The semantic of this bit depends on the format selected by eSCI_CR3[M2], eSCI_CR1[M], and eSCI_CR1[PE]. [M2=0,M=0,PE=0]: value of received BIT7 or ADDR BIT. [M2=0;M=0,PE=1]: value of received PARITY BIT if eSCI_CR2[PMSK]=0, 0 otherwise. For all other frame formats it is the value of received BIT7. When written, this is Transmit Bit 7.The semantic of this bit depends on the format selected by eSCI_CR3[M2], eSCI_CR1[M], and eSCI_CR1[PE]. [M2=0,M=0,PE=0]: value of transmit BIT7 or ADDR BIT. [M2=0;M=0,PE=1]: not used. PARITY BIT is generated internally before transmission. For all other frame formats it is the value of transmit BIT7. Remaining bits (RDTD[6:0]): When read, these are Received bits 6 to 0. Value of received BITx is shown in bit Rx. When written, these are Transmit bits 6 to 0. Value of bit Tx is transmitted in BITx.

49.4.5 Interrupt Flag and Status Register 1 (eSCI_IFSR1)

This register provides interrupt flags that indicate the occurrence of module events. The related interrupt enable bits are located in [Control Register 1 \(eSCI_CR1\)](#) and [Control Register 2 \(eSCI_CR2\)](#).

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7
Read	TDRE	TC	RDRF	IDLE	OR	NF	FE	PF
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	1	0	0	0	0	0	0	0
Bit	8	9	10	11	12	13	14	15
Read	0		DACT	BERR	WACT	LACT	TACT	RACT
Write				w1c				
Reset	0	0	0	0	0	0	0	0

eSCI_IFSR1 field descriptions

Field	Description
0 TDRE	Transmit Data Register Empty Interrupt Flag. This interrupt flag is set when the content of the SCI Data Register (eSCI_SDR) was transferred into internal shift register. NOTE: This flag is set in SCI mode only.
1 TC	Transmit Complete Interrupt Flag. This interrupt flag is set when a frame, break or idle character transmission has been completed and no data were written into SCI Data Register (eSCI_SDR) after the last setting of the TDRE flag and the SBK bit in Control Register 1 (eSCI_CR1) is 0. NOTE: This flag is set in SCI mode only. In case of no data available for transmission, it is also set if the preamble was transmitted after the enabling of the transmitter.
2 RDRF	Receive Data Register Full Interrupt Flag. This interrupt flag is set when the payload data of a received frame was transferred into the SCI Data Register (eSCI_SDR) and the receive DMA is disabled. NOTE: This flag is set in SCI mode only.
3 IDLE	Idle Line Interrupt Flag. This interrupt flag is set when an idle character was detected and the receiver is not in the wake-up state. NOTE: This flag is set in SCI mode only.
4 OR	Overrun Interrupt Flag. This interrupt flag is set when an overrun was detected as described in Receiver Overrun . NOTE: This flag is set in SCI mode only.
5 NF	Noise Interrupt Flag. This interrupt flag is set when the receiver has detected noise during the reception of a frame, as described in Bit Sampling .
6 FE	Framing Error Interrupt Flag. This interrupt flag is set when the payload data of a received frame was transferred into the SCI Data Register (eSCI_SDR) or LIN Receive Register (eSCI_LRR) and the receiver has detected a framing error during the reception of that frame, as described in Stop Bit Verification .

Table continues on the next page...

eSCI_IFSR1 field descriptions (continued)

Field	Description
7 PF	Parity Error Interrupt Flag. This interrupt flag is set when the payload data of a received frame was transferred into the SCI Data Register (eSCI_SDR) and the receiver has detected a parity error for the character, as described in Reception Error Reporting . NOTE: This flag is set in SCI mode only.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 DACT	DMA Active. The status bit is set when a transmit or receive DMA request is pending . 0 No DMA request pending. 1 DMA request pending.
11 BERR	Bit Error Interrupt Flag. This flag is set when a bit error was detected as described in Standard Bit Error Detection . Note: This flag is set in LIN mode only.
12 WACT	LIN Wake-Up Active. The status bit is set as long as the LIN wakeup engine receives a LIN wake-up signal . 0 No LIN wakeup signal reception in progress . 1 LIN wakeup signal reception in progress .
13 LACT	LIN Active. This status bit is set as long as the LIN protocol engine is about to transmit or receive LIN frames . 0 No LIN frame transmission or reception in progress . 1 LIN frame transmission or reception in progress .
14 TACT	Transmitter Active. This status bit is set as long as the transmission of a frame or special character is ongoing . 0 No transmission in progress . 1 Transmission in progress .
15 RACT	Receiver Active. This status bit is set as long as the receive is active. The set and clear conditions for the SCI mode are described in Receiver States and Transitions . The set and clear conditions for the LIN mode are described in LIN byte field reception . 0 No reception in progress . 1 Reception in progress .

49.4.6 Interrupt Flag and Status Register 2 (eSCI_IFSR2)

This register provides interrupt flags that indicate the occurrence of LIN related events. The related interrupt enable bits are located in [LIN Control Register 1 \(eSCI_LCR1\)](#) and [LIN Control Register 2 \(eSCI_LCR2\)](#). All interrupt flags in this register will be set in LIN mode only .

Address: 0h base + Ah offset = Ah

Bit	0	1	2	3	4	5	6	7
Read	RXRDY	TXRDY	LWAKE	STO	PBERR	CERR	CKERR	FRC
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	1	0	0	0	0	0	0
Bit	8	9	10	11	12	13	14	15
Read	0						UREQ	OVFL
Write							w1c	w1c
Reset	0	0	0	0	0	0	0	0

eSCI_IFSR2 field descriptions

Field	Description
0 RXRDY	Receive Data Ready Interrupt Flag. This interrupt flag is set when the payload data of a received frame was transferred into the LIN Receive Register (eSCI_LRR) and the receive DMA is disabled. NOTE: This bit should be cleared only after reading the data from the LIN Receive Register (eSCI_LRR)
1 TXRDY	Transmit Data Ready Interrupt Flag. This interrupt flag is set when a) the content of the LIN Transmit Register (eSCI_LTR) was processed by the LIN PE to generate frame header or frame transmit data, or b) when the module has transmitted a LIN wakeup signal frame.
2 LWAKE	LIN Wake-up Received Interrupt Flag. This interrupt flag is set when a LIN Wake-up character was received, as described in LIN Wake Up .
3 STO	Slave Timeout Interrupt Flag. This interrupt flag is set when a Slave-Not-Responding-Error is detected. A detailed description is given in Slave-Not-Responding-Error Detection .
4 PBERR	Physical Bus Error Interrupt Flag. This interrupt flag is set when the receiver input remains unchanged for at least 31 RCLK clock cycles after the start of a byte transmission, as described in LIN Error Reporting .
5 CERR	CRC Error Interrupt Flag. This interrupt flag is set when an incorrect CRC pattern was detected for a received LIN frame.
6 CKERR	Checksum Error Interrupt Flag. This interrupt flag is set when a checksum error was detected for a received LIN frame.
7 FRC	Frame Complete Interrupt Flag. This interrupt flag is set when a LIN TX frame has been completely transmitted or a LIN RX frame has been completely received.
8–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

eSCI_IFSR2 field descriptions (continued)

Field	Description
14 UREQ	Unrequested Data Received Interrupt Flag. This interrupt flag is set when unrequested activity has been detected on the LIN bus, as described in LIN Error Reporting .
15 OVFL	Overflow Interrupt Flag. This interrupt flag is set when an overflow as described in Overflow Detection was detected.

49.4.7 LIN Control Register 1 (eSCI_LCR1)

This register provides control bits to control and configure the LIN hardware. This register provides the interrupt enable bits for the interrupt flags in [Interrupt Flag and Status Register 2 \(eSCI_IFSR2\)](#).

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	LRES	0	WUD		0		PRTY	LIN	RXIE	TXIE	WUIE	STIE	PBIE	CIE	CKIE	FCIE
Write		WU														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eSCI_LCR1 field descriptions

Field	Description
0 LRES	LIN Protocol Engine Stop and Reset. This bit is used to stop and reset the LIN protocol engine as described in LIN Protocol Engine Stop and Reset . 0 LIN protocol engine is operational. 1 LIN protocol engine is reset and stopped.
1 WU	LIN Bus Wake-Up Trigger. This bit is used to trigger the generation of a wake-up signal frame on the LIN bus, as described in LIN Wake Up . 0 Write has no effect. 1 Write triggers the generation of a wake-up signal.
2–3 WUD	LIN Bus Wake-Up Delimiter Time. This field determines how long the LIN protocol engine waits after the end of the transmitted wake-up signal, before starting the next LIN frame transmission. 00 3 bit times. 01 7 bit times. 10 31 bit times. 11 63 bit times.
4–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 PRTY	Parity Generation Control. This bit controls the generation of the two parity bits in the LIN header.

Table continues on the next page...

eSCI_LCR1 field descriptions (continued)

Field	Description
	0 Parity bits generation disabled. 1 Parity bits generation enabled.
7 LIN	LIN Mode Control. This bit controls whether the device is in SCI or LIN Mode. 0 SCI Mode. 1 LIN Mode.
8 RXIE	Receive Data Ready Interrupt Enable. This bit controls the eSCI_IFSR2[RXRDY] interrupt request generation. 0 RXRDY interrupt request generation disabled. 1 RXRDY interrupt request generation enabled.
9 TXIE	Transmit Data Ready Interrupt Enable. This bit controls the eSCI_IFSR2[TXRDY] interrupt request generation. 0 TXRDY interrupt request generation disabled. 1 TXRDY interrupt request generation enabled.
10 WUIE	LIN Wake-up Received Interrupt Enable. This bit controls the eSCI_IFSR2[LWAKE] interrupt request generation. 0 LWAKE interrupt request generation disabled. 1 LWAKE interrupt request generation enabled.
11 STIE	Slave Timeout Flag Interrupt Enable. This bit controls the eSCI_IFSR2[STO] interrupt request generation. 0 STO interrupt request generation disabled. 1 STO interrupt request generation enabled.
12 PBIE	Physical Bus Error Interrupt Enable. This bit controls the eSCI_IFSR2[PBERR] interrupt request generation. 0 PBERR interrupt request generation disabled. 1 PBERR interrupt request generation enabled.
13 CIE	CRC Error Interrupt Enable. This bit controls the eSCI_IFSR2[CERR] interrupt request generation. 0 CERR interrupt request generation disabled. 1 CERR interrupt request generation enabled.
14 CKIE	Checksum Error Interrupt Enable. This bit controls the eSCI_IFSR2[CKERR] interrupt request generation. 0 CKERR interrupt request generation disabled. 1 CKERR interrupt request generation enabled.
15 FCIE	Frame Complete Interrupt Enable. This bit controls the eSCI_IFSR2[FRC] interrupt request generation. 0 FRC interrupt request generation disabled. 1 FRC interrupt request generation enabled.

49.4.8 LIN Control Register 2 (eSCI_LCR2)

This register provides the interrupt enable bits for the interrupt flags in [Interrupt Flag and Status Register 2 \(eSCI_IFSR2\)](#).

Address: 0h base + Eh offset = Eh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0						UQIE	OFIE	0							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eSCI_LCR2 field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 UQIE	Unrequested Data Received Interrupt Enable. This bit controls the eSCI_IFSR2[UREQ] interrupt request generation. 0 UREQ interrupt request generation disabled. 1 UREQ interrupt request generation enabled.
7 OFIE	Overflow Interrupt Enable. This bit controls the eSCI_IFSR2[OVFL] interrupt request generation. 0 OVFL interrupt request generation disabled. 1 OVFL interrupt request generation enabled.
8–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

49.4.9 LIN Transmit Register (eSCI_LTR)

This register is used by the application to initiate the LIN frame header generation for both LIN TX frames and LIN RX frames. If a LIN TX frame is generated, this register is used to provide the payload data for the LIN TX frame.

If the LIN PE is in the idle state (eSCI_LCR1[LRES] = 1) or performs a wakeup, each write access to this register is ignored.

In case of a read access, the register provides the last data written into this register in the DATA field.

If the application initiates a LIN TX frame transfer, i.e the TD bit is set to 1, the content and usage shown in [Figure 49-11](#) applies. The initiation and transmit of a TX frame is described in [LIN TX Frame generation](#).

**Figure 49-11. LIN Transmit Register (eSCI_LTR) - LIN TX frame generation**

If the application initiates an LIN RX frame, i.e the TD bit is set to 0, the content and usage shown in [Figure 49-12](#) applies. The initiation and transmit of a RX frame is described in [LIN RX frame generation](#).

**Figure 49-12. LIN Transmit Register (eSCI_LTR) - LIN RX frame generation**

Each successful write access to this register increments the internal write access counter and enables the writing to the next field. The write access counter is reset if

- the LIN PE is in the idle state (eSCI_LCR1[LRES] = 1)
- a LIN TX frame was completely transmitted (eSCI_IFSR1[FRC] was set to 1)
- a LIN RX frame was completely received (eSCI_IFSR1[FRC] was set to 1)

Table 49-15. Structure of the LTR[DATA] when written to

Field	Description
P	Identifier Parity. This field provides the identifier parity which is used to create the protected identifier if the automatic identifier parity generation is disabled, i.e the PRTY bit in LIN Control Register 1 (eSCI_LCR1) is 0.
ID	Identifier. This field is used for the identifier field in the protected identifier.
LEN	Frame Length. This field defines the number of data bytes to be transmitted or received.
CSM	Checksum Model. This bit controls the checksum calculation model used. 0: Classic Checksum Model (LIN 1.3). 1: Enhanced Checksum Model (LIN 2.0).
CSE	Checksum Enable. This bit control the generation and checking of the checksum byte. 0: No generation and checking of checksum byte. 1: Generation and checking of checksum byte.

Table continues on the next page...

Table 49-15. Structure of the LTR[DATA] when written to (continued)

Field	Description
CRC	CRC Enable. This bit controls the generation of checking standard or enhanced LIN frames, which are described in LIN frame formats . 0: Standard LIN frame generation and checking. 1: Enhanced LIN frame generation and checking.
TD	Transfer Direction. This bit controls the transfer direction of the data, CRC, and checksum byte fields. 0: Data, CRC, and Checksum byte fields received, described in LIN RX frame generation . 1: Data, CRC, and Checksum byte fields transmitted, described in LIN TX Frame generation .
TO	Timeout Value. The content of the field depends on the transfer direction. RX frame: Defines the time available for a complete RX frame transfer, as described in the note in Fast Bit Error Detection . TX frame: Must be set to 0.
D	Transmit Data . Data bits for transmission.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7
Read	DATA							
Write								
Reset	0	0	0	0	0	0	0	0

eSCI_LTR field descriptions

Field	Description
0-7 DATA	When read: The value written in the most recent successful write access When written: See the description in this section

49.4.10 LIN Receive Register (eSCI_LRR)

This register provides the data bytes of received in case of an LIN RX frame was initiated.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7
Read	D							
Write								
Reset	0	0	0	0	0	0	0	0

eSCI_LRR field descriptions

Field	Description
0–7 D	Receive Data . This field provides the data bytes of received LIN RX frames.

49.4.11 LIN CRC Polynomial Register (eSCI_LPR)

This register provides the CRC polynom for generation and processing of CRC-enhanced LIN frames.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	P															
Write																
Reset	1	1	0	0	0	1	0	1	1	0	0	1	1	0	0	1

eSCI_LPR field descriptions

Field	Description
0–15 P	Polynomial bit $x^{P[n]}$. Used to define the LIN polynomial. Reset value results in $x^{15} + x^{14} + x^{10} + x^8 + x^7 + x^4 + x^3 + 1$, which is the polynomial used for the CAN protocol.

49.4.12 Control Register 3 (eSCI_CR3)

This register is used to control the frame formats and the generation of the ERR bit in the [SCI Data Register \(eSCI_SDR\)](#).

Address: 0h base + 1Ah offset = 1Ah

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0				ERO	ERFE	ERPE	M2	0							
Write					E											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eSCI_CR3 field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

eSCI_CR3 field descriptions (continued)

Field	Description
4 EROE	ERR flag overrun enable. 0 eSCI_SDR[ERR] flag not affected by overrun detection. 1 eSCI_SDR[ERR] flag is set on overrun detection during frame reception.
5 ERFE	ERR flag frame error enable. 0 eSCI_SDR[ERR] flag not affected by frame error detection. 1 eSCI_SDR[ERR] flag is set on frame error detection for the data provided in eSCI_SDR.
6 ERPE	ERR flag parity error enable. 0 eSCI_SDR[ERR] flag not affected by parity error detection. 1 eSCI_SDR[ERR] flag is set on parity error detection for the data provided in eSCI_SDR.
7 M2	Frame Format Mode 2. This control bit together with the M bit of the Control Register 1 (eSCI_CR1) controls the frame format used. The supported frame formats and the related settings are defined in Frame Formats .
8–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

49.5 Functional Description

This section provides a complete functional description of the eSCI block, detailing the operation of the design from the end user perspective in a number of subsections.

49.5.1 Module Control

The operational mode of the module is controlled by the MDIS bit in the Control Register 2 (eSCI_CR2). The module can transmit and receives data when it is enabled, i.e MDIS=0.

49.5.2 Frame Formats

The eSCI module uses the standard NRZ mark/space data format. The eSCI supports three basic frame types, which are the data frames, break characters, and idle characters.

49.5.2.1 Data Frame Formats

Each data frame contains a character that is surrounded by a start bit, an optional parity or address bit, and one or two stop bits. The supported data frame formats for transmission and reception are specified in [Table 49-19](#). The supported data frame formats for reception only are specified in [Table 49-20](#).

Table 49-19. Supported Data Frame Formats for RX and TX

Control				Frame Content				
eSCI_CR3	eSCI_CR1			Start Bits	Payload Bits			Stop Bits
M2	M	PE	WAKE		Character Bits	Address Bits ¹	Parity Bits	
LIN byte fields (Figure 49-16)								
0	0	0	0	1	8	0	0	1
SCI Frames (8 payload bits)(Figure 49-17)								
0	0	0	0	1	8	0	0	1
0	0	0	1	1	7	1	0	1
0	0	1	0	1	7	0	1	1
SCI Frames (9 payload bits) (Figure 49-18)								
0	1	0	0	1	9	0	0	1
0	1	0	1	1	8	1	0	1
0	1	1	0	1	8	0	1	1

1. The address bit identifies the frame as an address character. See [Multiprocessor Communication](#).

Table 49-20. Supported Data Frame Formats for RX only

Control				Frame Content				
eSCI_CR3	eSCI_CR1			Start Bits	Payload Bits			Stop Bits
M2	M	PE	WAKE		Character Bits	Address Bits	Parity Bits	
SCI Frames (2 stop bits) (see Figure 49-19)								
1	0	1	0	1	8	0	1	2
1	1	1	0	1	12	0	1	2

The structure of the LIN byte fields in normal polarity is shown in [Figure 49-16](#).

Figure 49-16. LIN Byte Field Format

The structures of the supported SCI frame formats with 8 payload bits are shown in [Figure 49-17](#).

Figure 49-17. SCI Frame Formats (8 payload bits)

The structures of the supported SCI frame formats with 9 payload bits are shown in [Figure 49-18](#).

Figure 49-18. SCI Frame Formats (9 payload bits)

The structures of the supported SCI frame formats with 2 stop bits in normal polarity are shown in [Figure 49-19](#). This frame format is supported for reception only.

Figure 49-19. SCI Frame Formats (2 stop bits)

49.5.2.1.1 Inverted Data Frame Formats

The structures of the supported data frame formats in inverted polarity are shown in the following figure. These frame types are supported for reception only. The polarity of the RXD pin is controlled by the RXPOL bit in the Control Register 2 (eSCI_CR2).

Figure 49-20. Inverted SCI Frame Formats

49.5.2.2 Break Character Formats

The supported break character formats are specified in [Table 49-21](#).

Table 49-21. Supported Break Character Formats

Control ¹			Break Character Content		
eSCI_CR3	eSCI_CR1	eSCI_CR2	Start Bit	Character Bits	Delemit Bits
M2	M	BRCL			
LIN Break Symbol (see Figure 49-21)					
0	0	0	1	9	1
0	0	1	1	12	1
SCI Break Character (see Figure 49-22)					
0	0	0	1	9	0
0	0	1	1	12	0
0	1	0	1	10	0
0	1	1	1	13	0

1. All codings which are not listed are reserved and must not be used.

The structure and content of the LIN break symbols is shown in [Figure 49-21](#).

**Figure 49-21. LIN Break Symbol Format**

The structure and content of the SCI break characters is shown in [Figure 49-22](#).

**Figure 49-22. SCI Break Character Formats**

49.5.2.3 Idle Character Formats

An idle character is a sequence of bits with the value 1. The supported idle character formats are specified in [Table 49-22](#). The preamble has the same structure and content as an idle character.

Table 49-22. Supported Idle Character Formats

Control		Idle Character Length
eSCI_CR3[M2]	eSCI_CR1[M]	
Idle Characters (see Figure 49-23)		
0	0	10
0	1	11
1	0	12
1	1	16

The structure and content of the idle characters is shown in [Figure 49-23](#).

Figure 49-23. Idle Character Formats

49.5.3 Baud Rate and Clock Generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and the transmitter. The value written to the SBR field in the Baud Rate Register (eSCI_BRR) determines the module clock divisor. The baud rate clock is synchronized with the bus clock and drives the receiver. The baud rate clock divided by 16 drives the transmitter. The receiver has an acquisition rate of 16 samples per bit time.

The baud rate generator is enabled when the TE bit or RE bit in the Control Register 1 (eSCI_CR1) is set to 1 for the first time. The baud rate generator is disabled when SBR = 0.

Baud rate generation is subject to one source of error:

- Integer division of the module clock may not give the exact required target baud rate.

The following table lists some examples of achieving target baud rates with a module clock frequency of MCLK = 10.2 MHz.

Table 49-23. Baud Rates Error Example (MCLK = 10.2 MHz)

eSCI_BRR[SBR]	RCLK (Hz)	TCLK (Hz)	Target Baud Rate	Error (%)
17	600,000.0	37,500.0	38,400	2.3
33	309,090.9	19,318.2	19,200	.62
66	154,545.5	9659.1	9600	.62
133	76,691.7	4793.2	4800	.14
266	38,345.9	2396.6	2400	.14
531	19,209.0	1200.6	1200	.11
1062	9604.5	600.3	600	.05
2125	4800.0	300.0	300	.00
4250	2400.0	150.0	150	.00
5795	1760.1	110.0	110	.00

49.5.3.1 Module Clock

For the frequency of module clock MCLK and the system bus clock, see the chip-specific eSCI information. MCLK has the same phase as the system bus clock.

49.5.3.2 Transmitter Clock

The transmitter clock TCLK is used to drive the data to the serial bus via the TXD pin. It is derived from the system bus clock by the baud rate generator. The baud rate generator is controlled by the value of the SBR field in the Baud Rate Register (eSCI_BRR). The frequency of the transmitter clock is determined by the following equation and defines the length of the transmitted bits, which is denoted as the *bit time*.

$$f_{\text{TCLK}} = \frac{f_{\text{MCLK}}}{16 \cdot \text{SBR}}$$

49.5.3.3 Receiver Clock

The receiver clock RCLK is used to sample the data received on the RXD or TXD pin. It is derived from the system bus clock by the baud rate generator. The baud rate generator is controlled by the value of the SBR field in the Baud Rate Register (eSCI_BRR). The frequency of the receiver sample clock is determined by the following equation.

$$f_{\text{RT}} = \frac{f_{\text{MCLK}}}{\text{SBR}}$$

The frequency of the receiver clock is 16 times the frequency of the transmitter clock, thus each bit is sampled with 16 samples. Each of the 16 samples of a bit has a sample number assigned, which is defined by the receiver sample counter RSC. The n-th sample is denoted by RS_n. The receiver sample counter RSC is updated with each rising edge of the receiver clock RCLK.

49.5.4 Baud Rate Tolerance

A transmitting device may be operating at a baud rate below or above the receiver baud rate. Accumulated bit time misalignment can cause one of the three stop bit data samples RS₈, RS₉, and RS₁₀ to fall outside the actual stop bit. A noise error will occur if the stop bit sample RS₈, RS₉, and RS₁₀ samples are not all the same logical value 1. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the RS₈, RS₉, and RS₁₀ stop bit samples are a logic zero.

49.5.4.1 Faster Receiver Tolerance

In this case the receiver has a higher baud rate than the transmitter, thus the stop bit sampling starts already in the last transmitted payload bit. To ensure the correct, noise and framing error free reception of the stop bit, the samples RS₈, RS₉, and RS₁₀ must be located in the transmitted stop bit as shown in the following figure.

Figure 49-24. Faster Receiver

The maximum tolerance that ensures error free reception can be calculated with the assumption that RS₇ is sampled during the last transmitted payload bit and RS₈ is sampled in the stop bit.

For an frame with n payload bits the transmitter starts the transmission of the stop bit

$$t_{XSTOP} = (n + 1) \cdot 16 \cdot RT_{TR}$$

after the start of the transmission of the start bit.

For an frame with n payload bits the receiver samples the RS8 sample of the stop bit

$$rx_{STOP} = (n + 1) \cdot 16 \cdot RT_{RE} + 7 \cdot RT_{RE}$$

after the successful qualification of the start bit.

To ensure error free reception of the stop bit, the transmitter must start the transmission of the stop bit before the receiver samples RSC8.

$$tx_{STOP} < rx_{STOP}$$

The maximum percent difference between the receiver baud rate and the transmitter baud rate is:

$$\Delta \text{baudrate} \leq \left(\frac{rx_{STOP} - tx_{STOP}}{rx_{STOP}} \right) \times 100$$

The maximum percent differences for the supported frames is given in the following table.

Table 49-24. Faster Receiver Maximum Tolerance

payload bits	max baudrate difference	tx _{STOP}	rx _{STOP}
8	4.63%	144	151
9	4.19%	160	167
13	3.03%	224	231

49.5.4.2 Slower Receiver Tolerance

In this case the receiver has a slower baud rate than the transmitter, thus the stop bit sampling is still running while the next start bit is already transmitted. To ensure the correct, noise and framing error free reception of the stop bit, the samples RS8, RS9, and RS10 must be located in the transmitted stop bit as shown in the following figure.

Figure 49-25. Slower Receiver

Functional Description

The maximum tolerance that ensures error free reception can be calculated with the assumption that RS11 is sampled in the transmitted start bit and RS10 is sampled in the last stop bit.

For a frame with n payload bits and s stop bits, the transmitter starts the transmission of the next start bit

$$t_{xSTART} = (n + s + 1) \cdot 16 \cdot RT_{TR}$$

after the start of the transmission of the previous start bit.

For a frame with n payload bits and s stop bits, the receiver samples the RS10 sample of the last stop bit

$$r_{xSTOP} = (n + s) \cdot 16 \cdot RT_{RE} + 9 \cdot RT_{RE}$$

after the successful qualification of the start bit.

To ensure error free reception of the last stop bit, the transmitter must start the transmission of the start bit after the receiver samples RS10.

$$r_{xSTOP} < t_{xSTART}$$

The maximum percent difference between the receiver baud rate and the transmitter baud rate is:

$$\Delta \text{baudrate} \leq \left(\frac{t_{xSTART} - r_{xSTOP}}{t_{xSTART}} \right) \times 100$$

The maximum percent differences for the supported frames is given in the following table.

Table 49-25. Slower Receiver Maximum Tolerance

payload bits	stop bits	max baudrate difference	r_{xSTOP}	t_{xSTART}
8	1	4.37%	153	160
9	1	3.97%	169	176
9	2	3.57%	185	196
13	2	2.73%	249	256

49.5.5 SCI Mode

49.5.5.1 SCI Mode Configuration

The application must configure the following bits and fields in order to achieve correct SCI operation.

- enable *SCI* Mode
 - LIN Control Register 1 (eSCI_LCR1)[LIN]:= 0
- select *baud rate*
 - Baud Rate Register (eSCI_BRR)[SBR]
- select *receiver input* mode
 - Control Register 1 (eSCI_CR1)[LOOPS]
 - Control Register 1 (eSCI_CR1)[RSRC]
- select *frame format*
 - Control Register 1 (eSCI_CR1)[M]
 - Control Register 1 (eSCI_CR1)[PE]
 - Control Register 1 (eSCI_CR1)[WAKE]
 - Control Register 3 (eSCI_CR3)[M2]
- select *parity type*
 - Control Register 1 (eSCI_CR1)[PT]

49.5.5.2 Transmitter

The transmitter supports the transmission of all frame types defined in [Table 49-19](#), of all break characters defined in [Table 49-21](#), and of all idle characters defined in [Table 49-22](#).

49.5.5.2.1 Transmitter States and Transitions

The transmitter has four basic states which are shown and described in [Table 49-26](#). The state transitions that can be triggered by the application commands are shown in [Table 49-27](#). The state transitions that can be triggered by the module are shown [Table 49-28](#). The state diagram of the transmitter is shown in [Figure 49-26](#).

Figure 49-26. Transmitter State Diagram

The current state of the transmitter can be determined by the TE control bit in the Control Register 1 (eSCI_CR1) and the TACT status bit in Interrupt Flag and Status Register 1 (eSCI_IFSR1).

Table 49-26. Transmitter States

State	Indication		Description
	eSCI_CR1[TE]	eSCI_IFSR1[TACT]	
Idle	0	0	Transmitter is <i>disabled</i> and <i>no</i> transmission is running
Ready	1	0	Transmitter is <i>enabled</i> and <i>no</i> transmission is running
Run	1	1	Transmitter is <i>enabled</i> and transmission is running
Stop	0	1	Transmitter is <i>disabled</i> and transmission is running

The application triggers a transition described in [Table 49-27](#) when it issues a command by writing to the TE bit in the Control Register 1 (eSCI_CR1). The transition is triggered only if the conditions are fulfilled. As a result of the transition the state of the transmitter is changed as shown in [Figure 49-26](#) and the action given in [Table 49-27](#) is executed.

Table 49-27. Transmitter Application Transitions

Transition	Command	Precondition	Action	Description
EN	eSCI_CR1[TE]:=1	eSCI_CR1[TE]=0	iPRE:=1	Transmitter is <i>enabled</i> by application command.
DIS	eSCI_CR1[TE]:=0	eSCI_CR1[TE]=1		Transmitter is <i>disabled</i> by application command

The module transition shown in [Table 49-28](#) are triggered when the described condition or event occurs. The send break bit SBK in the Control Register 1 (eSCI_CR1) is checked for the start condition. The internal commit bit iCMT, the transmitter active bit TACT in the Interrupt Flag and Status Register 1 (eSCI_IFSR1), the TDRE, and the TC flag in the Interrupt Flag and Status Register 1 (eSCI_IFSR1) are changed as a action result of the transition.

Table 49-28. Transmitter Module Transitions

Transition	Condition	Action	Description
start	(State=Ready) and (SBK=1 or iPRE=1 or iCMT=1)	TACT:=1	Start of transmission of data frame or special character when data are available or character transmission request is pending.
done	State=Run and last stop bit transmitted	TACT:=0 TC:= (SBK=0 & iPRE=0 & iCMT=0)	Finished transmission of data frame or special character and transmitter still enabled. Transmission is complete if no transmit request is pending.
halt	State=Stop and last stop bit transmitted	TACT:=0 TC:=1 iCMT:=0	Finished transmission of data frame or special character and transmitter was disabled.

49.5.5.2.2 Frame and Character Transmission

The transmitter starts the transmission of a data frame or special character when the condition for the *start* transition as described in [Table 49-28](#) is fulfilled. There are three source for data or character transmission. The priority among these source are specified in the following table. All three sources can be available at one point in time.

Table 49-29. Transmit Source Priority

Priority	Indication	Transmission Source
(highest) 0	iPRE=1	Preamble.
1	eSCI_CR1[SBK]=1	Break character.
(lowest) 2	iCMT=1	SCI Data Register (eSCI_SDR) frame.

49.5.5.2.3 CPU Controlled SCI Data Frame Transmission

The transmission of a data frame is started when the transmitter is in its Ready state and only the commit bit iCMT is set.

As the first step, the content of the SCI Data Register (eSCI_SDR) is transferred into the internal transmitter shift register. When this transfer is finished, the internal commit bit iCMT is cleared and the transmit data register empty flag TDRE in the Interrupt Flag and Status Register 1 (eSCI_IFSR1) is set. If the transmit interrupt enable bit TIE in the Control Register 1 (eSCI_CR1) is also set, the TDRE flag generates a transmitter interrupt request.

The transmitter shift register then shifts a frame out through the TXD output signal, which is prefaced with a start bit and appended with the parity bit, if configured, and the configured number of stop bits.

When the last stop bit has been transmitted and the application has not disabled the transmitter, the transmitter returns to the Ready state via the *done* transition. If no frame or character transmit request is pending, the transfer complete flag TC in the Interrupt Flag and Status Register 1 (eSCI_IFSR1) is set.

If the application has disabled the transmitter while the frame is transmitted and stop bit has been transmitted, the transmitter goes into the Idle state via the *halt* transition. The transfer complete flag TC in the Interrupt Flag and Status Register 1 (eSCI_IFSR1) is set and the internal commit bit iCMT is cleared.

49.5.5.2.4 DMA Controlled SCI Data Frame Transmission

In this mode, the eSCI module handles the generation of Data Frames internally.

When new data is required for transmission, the module generates the transmit DMA request and the DMA controller delivers the required data via write accesses to SCI Data Register (eSCI_SDR). The write access to the low byte of SCI Data Register (eSCI_SDR) triggers the transmission of the data. The write access to the high byte of SCI Data Register (eSCI_SDR) triggers no internal operation.

The application requests the eSCI module to enter this mode by setting the TXDMA bit in the Control Register 2 (eSCI_CR2). From this point in time, the module starts the generation of DMA requests and frame transmission. Before entering this mode, the application should perform the following actions:

1. Configure the module for SCI mode.
2. Enable the transmitter by setting TE in Control Register 1 (eSCI_CR1) to 1.
3. Setup the DMA controller channel and provide frame data in system memory

A block diagram which presents an overview of the DMA Controlled Date Frame Transmission is shown in the following figure.

Figure 49-27. DMA Controlled SCI Data Frame generation

49.5.5.2.5 Parity Generation

The eSCI module generates the parity bit in transmitted data frame when the parity enable bit PE in the Control Register 1 (eSCI_CR1) is set. The parity type bit PT in the Control Register 1 (eSCI_CR1) defines whether the odd or even parity is generated.

49.5.5.2.6 Preamble Transmission

The transmission of a preamble is started when the transmitter is in Ready state, the internal iPRE bit, which is not visible to the application, is set, and the SBK in the Control Register 1 (eSCI_CR1) is clear.

After the transmission of the stop bit and if the application has not disabled the transmitter, the transmitter returns to the Ready state via the *done* transition. If no frame or character transmit request is pending, the transfer complete flag TC in the Interrupt Flag and Status Register 1 (eSCI_IFSR1) is set.

If the application has disabled the transmitter while the preamble is transmitted and if the stop bit has been transmitted, the transmitter goes into the Idle state via the *halt* transition. The transfer complete flag TC in the Interrupt Flag and Status Register 1 (eSCI_IFSR1) is set and the internal commit bit iCMT is cleared.

49.5.5.2.7 Break Character Transmission

The transmission of a break character is started when the transmitter is in Ready state and the send break character bit SBK in the Control Register 1 (eSCI_CR1) is set. After the transmission of the break character and if the application has not disabled the transmitter,

the transmitter returns to the Ready state via the *done* transition and restarts the transmission. As long as SBK bit remains set, the transmitter continues to send break characters.

When the application has cleared the SBK bit or has disabled the transmitter, the transmitter continues to transmit the current break character and after it has finished the transmission of this break character it transmits a stop bit. The stop bit at the end of a break character sequence guarantees the recognition of the start bit of the next data frame.

After the transmission of the stop bit and if the application has not disabled the transmitter, the transmitter returns to the Ready state via the *done* transition. If no frame or character transmit request is pending, the transfer complete flag TC in the Interrupt Flag and Status Register 1 (eSCI_IFSR1) is set.

If the application has disabled the transmitter while the break character is transmitted and if the stop bit has been transmitted, the transmitter goes into the Idle state via the *halt* transition. The transfer complete flag TC in the Interrupt Flag and Status Register 1 (eSCI_IFSR1) is set and the internal commit bit iCMT is cleared.

49.5.5.3 Receiver

The receiver supports the reception of all data frame types defined in [Table 49-19](#) and [Table 49-20](#), of all break character defined in [Table 49-21](#), and of all idle characters defined in [Table 49-22](#).

49.5.5.3.1 Receiver States and Transitions

The receiver has four basic states which are shown and described in [Table 49-30](#). The state transitions that can triggered by the application commands are shown in [Table 49-31](#). The state transitions that can triggered by the module are shown in [Table 49-32](#). The state diagram of the transmitter is shown in the following figure.

Figure 49-28. Receiver State Diagram

The current state of the receiver can be determined by the RE and RWU bit in the Control Register 1 (eSCI_CR1) and the RACT status bit in Interrupt Flag and Status Register 1 (eSCI_IFSR1).

Table 49-30. Receiver States

State	Indication			Description
	RE	RACT	RWU	
Idle	0	0	0	Receiver is <i>disabled</i> and <i>no</i> reception is running
Ready	1	0	0	Receiver is <i>enabled</i> and <i>no</i> reception is running
Run	1	1	0	Receiver is <i>enabled</i> and reception is running
Wake-up	1	-	1	Receiver is in wake-up mode

The application triggers a transition described in [Table 49-31](#) when it issues a command by writing to the RE bit in the Control Register 1 (eSCI_CR1). The transition is triggered only if the conditions are fulfilled. As a result of the transition, the state of the receiver is changed as shown in the preceeding figure and the action given in [Table 49-31](#) is executed.

Table 49-31. Receiver Application Transition

Transition	Command	Condition	Action	Description
EN	RE:=1	RE=0		Receiver is <i>enabled</i> by application command.
DIS	RE:=0	RE=1		Receiver is <i>disabled</i> by application command
SLP	RWU:=1	RE=1		Receiver is set into wake-up mode

The module transitions shown in [Table 49-32](#) are triggered when the described event occurs.

Table 49-32. Receiver Module Transition

Transition	Condition	Action	Description
start	(State=Ready,Run) and (start bit qualified)	RACT:=1	Start of reception of data frame or break character.
done	(State=Run) and (start bit not verified or idle character received)	RACT:=0	Start Bit not Verified or Idle Character received.
wake0	(State=Wake-up) and (idle character received)	RWU:=0	Wake-up Idle Character received.

Table continues on the next page...

Table 49-32. Receiver Module Transition (continued)

Transition	Condition	Action	Description
wake1	(State=Wake-up) and (address frame received)	RWU:=0	Wake-up address frame received.

49.5.5.3.2 Receiver Input Mode Selection

This section describes the three receiver input modes supported by the eSCI module. The modes are selected by the LOOPS and RSRC control bits in the Control Register 1 (eSCI_CR1).

49.5.5.3.3 Dual Wire Mode

In Dual Wire Mode, the eSCI uses the TXD pin for transmitting and the RXD pin for data receiving.

Figure 49-29. Dual Wire Mode

49.5.5.3.4 Single Wire Mode

In Single Wire Mode, the RXD pin is disconnected from the eSCI module and the TXD pin is used for both receiving and transmitting.

Figure 49-30. Single Wire Mode

In this device, the TXDIR bit (eSCI_CR2[TXDIR]) does not determine whether the TXD pin is going to be used as an input or an output. The relevant pad control register in the System Integration Unit must be programmed for input or output.

49.5.5.3.5 Loop Mode

In Loop Mode, the input of the receiver is driven by the output of the transmitter. The RXD pin is disconnected from the eSCI module.

Figure 49-31. Loop Mode

49.5.5.3.6 Frame and Character Reception

The receiver is started when it is in Ready or Wake-up state and on the selected receiver input (see [Receiver Input Mode Selection](#)) an active signal is sampled. The receiver enters the Run or Wake-up state. The received bits are recovered by the bit sampling described in [Bit Sampling](#). During the reception, the received bits are shifted into the internal shift register.

49.5.5.3.7 Break Character Detection

The receiver does not provide any means to detect the reception of a break character. Instead, break characters are processed as data frames. Due to the received 0 at the stop bit location, the reception of a break character causes at least a framing error. The error reporting is performed as described in [Reception Error Reporting](#).

49.5.5.3.8 Idle Character Detection

The Idle character detection starts after the reception of the last stop bit.

49.5.5.3.9 CPU Controlled SCI Data Frame Reception

This section describes the reception process when the receiver is in the Run state.

When the required number of frame bits have been received, the payload bits of the received frame are transferred into SCI Data Register (eSCI_SDR) if the RDRF flag is 0. The receive data register full flag RDRF in Interrupt Flag and Status Register 1 (eSCI_IFSR1) is set. If the receive interrupt enable bit RIE in the Control Register 1 (eSCI_CR1) is set, the RDRF interrupt request is generated.

If an idle character has been detected, the IDLE flag in the Interrupt Flag and Status Register 1 (eSCI_IFSR1) is set. If the idle line interrupt enable bit ILIE in the Control Register 1 (eSCI_CR1) is set, the IDLE interrupt request is generated.

If any of the receiver errors described in [Reception Error Reporting](#) have occurred, that corresponding flags will be set.

If the application is disabled the receiver, by clearing the receiver enable bit RE in the Interrupt Flag and Status Register 1 (eSCI_IFSR1), the current frame is discarded and no flags will be updated.

49.5.5.3.10 DMA Controlled SCI Data Frames Reception

In this mode, the eSCI module controls the reception of SCI Data frames automatically and utilizes the connected DMA channels. A block diagram which presents an overview of the DMA Controlled SCI Data Frame reception is shown in the following figure. The RX DMA channel is used to transfer the received frame data into the memory.

When new data is received, the module generates the receive DMA request and the DMA controller retrieves the provided data from the SCI Data Register (eSCI_SDR). The read access from the low byte of the SCI Data Register (eSCI_SDR) signals the end of the DMA cycle for the current data and triggers the reception of new data. The read access from the SCI Data Register (eSCI_SDR) triggers no internal action.

The application requests the eSCI module to enter this mode by setting the RXDMA bit in the Control Register 2 (eSCI_CR2). From this point in time, the module start the generation of DMA requests and frame transmission and reception. Before entering this mode, the application should perform the following actions:

1. Configure the module for SCI mode.
2. Enable the receiver by setting RE in Control Register 1 (eSCI_CR1) to 1.
3. Setup the DMA controller channel.

Figure 49-32. DMA Controlled SCI Data Frame Reception

49.5.5.3.11 Receiver Overrun

When the eSCI module has received a frame and attempts to transfer the payload data of the received frame into the SCI Data Register (eSCI_SDR) but neither the application nor the DMA controller hasSCI Data Register (eSCI_SDR) since its last update, the overrun flag OR in the Interrupt Flag and Status Register 1 (eSCI_IFSR1) is set. The data contained in SCI Data Register (eSCI_SDR) are not changed and the received data are lost.

49.5.5.3.12 Wake-up Frame Reception

This section describes the reception process when the receiver is in the Wake-up state.

When the required number of frame bits have been received, the payload bits of the received frame are transferred into SCI Data Register (eSCI_SDR) if the RDRF flag is 0.

If the *address-mark* wake-up mode is selected and the received frame has the address bit set, the receive data register full flag RDRF in Interrupt Flag and Status Register 1 (eSCI_IFSR1) is set. If the receive interrupt enable bit RIE in the Control Register 1 (eSCI_CR1) is set, the RDRF interrupt request is generated. The RWU bit is cleared, and the receiver enters the Run state via the wake1 transition.

If the *idle line* wake-up mode is selected and the receiver has detected an idle character, The RWU bit is cleared, and the receiver enters the Ready state via the wake0 transition.

If any of the receiver errors described in [Reception Error Reporting](#) have occurred, the corresponding flags will be set.

49.5.5.3.13 Bit Sampling

The receiver samples the selected receiver input (see [Receiver Input Mode Selection](#)) with the receiver clock RCLK. The bit sampling for start bit detection is shown in [Figure 49-33](#), the bit sampling for data and stop bit reception is shown in [Figure 49-34](#). The samples indicated by dashed arrows are not used by the receiver. The received data bits are transferred into the internal shift register after the data strobing. If noise or framing errors are detected, this is flagged as described in [Reception Error Reporting](#).

49.5.5.3.14 Bit Synchronization

To adjust for baud rate mismatch, a synchronization of the cyclic receive sample counter RSC is performed during start bit reception as described in [Start Bit Sampling](#).

49.5.5.3.15 Start Bit Sampling

Figure 49-33. Start Bit Sampling and Strobing

The sampling of the start bit consists of three phases, the start bit qualification, the start bit verification, and the start bit noise detection.

49.5.5.3.15.1 Start Bit Qualification

To adjust for baud rate mismatch, the cyclic receive sample counter RSC is re-synchronized after a successful start bit qualification.

A start bit is successfully qualified if

- the start qualification is active, and
- a low sample is read, and
- the low sample was preceded by three consecutive high samples.

The start bit qualification becomes active

- after module reset, or
- after receiver disable and subsequent enable, or
- after the 7-th sample if the start bit verification failed, or
- after the 10-th sample of last stop bit of the preceding frame (example shown in [Figure 49-33](#)).

The start bit qualification becomes inactive

- after successful start bit qualification.

49.5.5.3.15.2 Start Bit Verification

After the successful start bit qualification the receiver starts to verify the start bit by a two out of three samples majority voting.

A start bit is verified if at least two out of the three sample RSC3, RSC5, and RSC7 are sampled low. Noise is detected when exactly one out of the three samples is high. In this case, the noise flag eSCI_IFSR1[NF] is set. The result of the start bit verification is summarized in [Table 49-33](#).

Table 49-33. Start Bit Verification Result

[RSC3, RSC5, RSC7]	Start Bit Verified	Verification Noise Detected
000	Yes	No
001	Yes	Yes
010	Yes	Yes
100	Yes	Yes
011	No	No
101	No	No
110	No	No
111	No	No

If the start bit verification was *not successful*, the receiver activates the start bit qualification. If the start bit verification was *successful*, the receiver continues sampling to perform data noise detection on the samples at RSC8, RSC9, and RSC10. The result of the start bit data noise detection is summarized in [Table 49-34](#). If noise is detected, the noise flag eSCI_IFSR1[NF] is set.

Table 49-34. Start Bit Noise Detection

[RSC8, RSC9, RSC10]	Noise Detected
000	No
001	Yes
010	Yes
100	Yes
011	Yes
101	Yes
110	Yes
111	Yes

49.5.5.3.16 Data Bit Sampling

**Figure 49-34. Data and Stop Bit Sampling and Strobing**

To determine the value of a data bit and to detect noise, a two out of three majority voting is performed on the samples RSC8, RSC9, and RSC10. The following table summarizes the results of the data bit sample. The receiver detects the number of data bit according to the selected frame format. If noise is detected, the noise flag eSCI_IFSR1[NF] is set.

Table 49-35. Data Bit Sampling

[RSC8, RSC9, RSC10]	Data Bit Value	Noise Detected
000	0	No
001	0	Yes
010	0	Yes
100	0	Yes
011	1	Yes
101	1	Yes
110	1	Yes
111	1	No

49.5.5.3.17 Stop Bit Verification

The reception of a valid stop bit is verified if at least two out of the sample RSC8, RSC9, and RSC10 are sampled high. If this is not the case, a framing error is detected. Noise is detected if not all of the samples are of the same value. In this case, the noise flag eSCI_IFSR1[NF] is set. The result of the stop bit verification is summarized in the following table.

Table 49-36. Stop Bit Verification

[RSC8, RSC9, RSC10]	Stop Bit Verified	Framing Error Detected	Noise Detected
000	No	Yes	No
001	No	Yes	Yes
010	No	Yes	Yes
100	No	Yes	Yes
011	Yes	No	Yes
101	Yes	No	Yes
110	Yes	No	Yes
111	Yes	No	No

49.5.5.3.18 Parity Checking

The eSCI module calculates the parity of a received character and checks it versus the received parity bit in the received data frame when the parity enable bit PE in the Control Register 1 (eSCI_CR1) is set. The parity type bit PT in the Control Register 1 (eSCI_CR1) defines whether to check for odd or even parity generation. If a parity error is detected, it is reported as described in [Reception Error Reporting](#).

49.5.5.4 Reception Error Reporting

The receiver can detect four error types: parity errors, framing errors, noise errors, and the overrun error.

The receiver reports the errors detected during frame reception at the end of the reception of the last stop bit of a frame. For error reporting the receiver utilizes the OR, NF, FE, and PF flags in the Interrupt Flag and Status Register 1 (eSCI_IFSR1).

If the receiver has detected an overrun as described in [Receiver Overrun](#), only the OR flag is set. All other error flags are not updated.

If the receiver has detected noise as described in [Bit Sampling](#), the NF flag is set.

If the receiver has *not* detected an overrun and has detected a framing error as described in [Bit Sampling](#), the FE flag is set.

If the receiver has *not* detected an overrun and has detected a parity error as described in [Parity Checking](#), the PF flag is set.

49.5.5.5 Multiprocessor Communication

The multiprocessor communication allows one processor to send blocks of frames to other processors on the same serial link. To avoid the received data interrupt for frames not intended for the processor, the eSCI receiver can be put into the Wake-up state. If the receiver is in the Wake-up state, the eSCI will still load the received data into the SCI Data Register (eSCI_SDR), but will not set the RDRF flag and consequently not request the RDRF interrupt.

The receiver leaves the Wake-up state and clears the RWU bit in the Control Register 1 (eSCI_CR1) when the wake-up pattern configured by WAKE bit in Control Register 1 (eSCI_CR1) is received. The eSCI module supports two types of wake-up patterns, the idle-line wakeup pattern and the address-mark wake-up pattern.

49.5.5.5.1 Idle-Line Wake Up

The idle-line wake-up mode is selected when the WAKE bit in Control Register 1 (eSCI_CR1) is 0. In this mode, the receiver leaves the wake-up state when an idle character is detected as described in [Idle Character Detection](#). The next received frame is the address frame that contains address information which can be evaluated by the application. If the application decides not to receive the frame block, it can set the RWU bit in the Control Register 1 (eSCI_CR1) and return the receiver to the wake-up state.

Figure 49-35. Idle-Line Wake Up

49.5.5.5.2 Address-Mark Wake Up

The address-mark wake-up mode is selected when the WAKE bit in Control Register 1 (eSCI_CR1) is 1. If the WAKE bit is set, the address bit is added to the frame format. In this mode, the receiver leaves the wake-up state when a data frame with the address bit value of 1 was received. This frame is the address frame and contains address

information which can be evaluated by the application. If the application decides not to receive the frame block, it can set the RWU bit in the Control Register 1 (eSCI_CR1) and return the receiver to the wake-up state. All data frames that belong to the frame block must have the address bit cleared.

Figure 49-36. Address-Mark Wake Up

49.5.6 LIN Mode

The eSCI provides support for the LIN protocol. It can be used to automate most tasks of a LIN master. In conjunction with the DMA interface it is possible to transmit entire LIN frames and sequences of LIN frames as well as to receive data from LIN slaves without application intervention. There is no special support for LIN slave mode.

49.5.6.1 LIN Mode Configuration

The application must configure the following bits and fields in order to achieve correct LIN operation. The configuration of bits and fields not mentioned in this section depend on the connected LIN slaves and the current application.

- enable *LIN* Mode
 - LIN Control Register 1 (eSCI_LCR1)[LIN]:= 1
- select *RXD* pin as receiver input
 - Control Register 1 (eSCI_CR1)[LOOPS]:= 0
 - Control Register 1 (eSCI_CR1)[RSRC]:= 0
- select *LIN byte fields* as used frame format
 - Control Register 1 (eSCI_CR1)[M]:= 0
 - Control Register 1 (eSCI_CR1)[PE]:= 0
 - Control Register 1 (eSCI_CR1)[WAKE]:= 0
 - Control Register 3 (eSCI_CR3)[M2]:= 0

- select *break character length* of 13 bit as required by LIN 2.0
 - Control Register 2 (eSCI_CR2)[BRCL]:= 1
- select transmission stop on *bit error* detection
 - Control Register 2 (eSCI_CR2)[BESTP]:= 1
- select transmission DMA stop on *bit error* detection
 - Control Register 2 (eSCI_CR2)[BSTP]:= 1
- enable both *transmitter* and *receiver*
 - Control Register 1 (eSCI_CR1)[TE]:= 1
 - Control Register 1 (eSCI_CR1)[RE]:= 1

49.5.6.2 LIN frame formats

The term LIN frame refers to a sequence of LIN byte fields preceded by a break character, both are described in [Frame Formats](#). The eSCI module allows to generate LIN frames for LIN slaves of LIN standards 1.3 and 2.0.

49.5.6.2.1 LIN byte field reception

The reception of a LIN byte field starts with the successful start bit qualification and is finished with the reception of the 16-th sample of the stop bit when no start bit qualification pattern has been detected. If a start bit qualification pattern has been detected at or after the 10-th sample of the stop bit, the reception ends at this sample. An ongoing reception is indicated by the RACT status bit in Interrupt Flag and Status Register 1 (eSCI_IFSR1).

The RACT flag is set if all of the following conditions are fulfilled:

1. the receiver is enabled (eSCI_CR1[RE] = 1), and
2. the LIN task is not in reset (eSCI_LCR1[LRES] = 0), and
3. the start bit qualification pattern has been received (see [Start Bit Sampling](#)).

The RACT flag is cleared if at least one of the following conditions is fulfilled,

1. the receiver is disabled (eSCI_CR1[RE] = 0), or
2. the LIN task is in reset (eSCI_LCR1[LRES] = 1), or

3. the start bit verification fails at sample 7 according to [Table 49-33](#), or
4. the 16-th sample of the stop bit has been received and no start bit qualification pattern has been detected at or after the 10-th sample.

49.5.6.2.2 Standard LIN frames

A standard LIN frame, shown in the following figure consists of a break character, a sync field, an ID field, zero or more data fields, and a checksum field. The data fields and the checksum field are generated by the LIN master for TX LIN frames and generated by the LIN slave for RX LIN frames. The header fields will always be generated by the LIN master.

Figure 49-37. Standard LIN frame format

49.5.6.2.3 CRC Enhanced LIN frames

The CRC Enhanced LIN frames shown in the following figure contain two additional CRC byte fields. These fields are located between the last data field and the Checksum field. The value of the CRC is calculated on the same byte fields as the Checksum is calculated on. The polynom used for the CRC calculation is defined by LIN CRC Polynomial Register (eSCI_LPR). The eSCI module generates the CRC fields for TX frames and checks the CRC fields for RX frames if the CRC bit in the LIN Transmit Register (eSCI_LTR) was written with a value of 1.

Figure 49-38. CRC Enhanced LIN frame format

The CRC Enhanced LIN frames are not part of the LIN standard.

49.5.6.3 LIN TX Frame generation

The eSCI module supports two modes of LIN TX Frame generation, the CPU controlled mode and the DMA controlled mode. In the CPU controlled mode, the application provides the required frame configuration and frame data by subsequent CPU write accesses to the LIN Transmit Register (eSCI_LTR). In the DMA controlled mode, the DMA controller provides the required frame configuration and frame data in response to DMA requests generated by the eSCI module.

49.5.6.3.1 CPU Controlled LIN TX Frame generation

In this mode, the application initiates the generation of an LIN TX Frame and provides the data to be transmitted by a sequence of subsequent CPU write accesses to the LIN Transmit Register (eSCI_LTR). When the eSCI module has processed the data written into LIN Transmit Register (eSCI_LTR), the TXRDY interrupt flag in the Interrupt Flag and Status Register 2 (eSCI_IFSR2) will be set.

The application should clear the TXRDY interrupt flag *before* writing data into the LIN Transmit Register (eSCI_LTR) because the eSCI module will set the TXRDY one clock cycle after the write access.

The first data written to the LIN Transmit Register (eSCI_LTR) provides the Identifier and Identifier Parity fields. The second data written defines the number of data bytes to be transmitted. The third data written defines the CRC and checksum generation. The TD bit has to set to 1 in order to invoke the LIN TX frame generation. The value of the TO field is ignored by the eSCI module for LIN TX frames.

After the third data was written the generation of a LIN TX frame is started. Firstly, a break field is transmitted, then the synch field and the protected identifier field.

All subsequent write accesses to the LIN Transmit Register (eSCI_LTR) provide data bytes to be transmitted via the LIN bus. A data byte field will be transmitted as soon as data are available. After the last data byte, defined by the value written to the LEN field, was send out, the configured CRC and checksum fields will be send out.

After the transmission of the checksum field of the LIN TX frame, the write access counter for the LIN Transmit Register (eSCI_LTR) is reset and the FRC interrupt flag in the Interrupt Flag and Status Register 2 (eSCI_IFSR2) is set.

49.5.6.3.2 DMA Controlled LIN TX Frame generation

In this mode, the eSCI module controls the generation of an LIN TX Frame. When new data is required for transmission, the eSCI module generates the transmit DMA request and the DMA controller delivers the required data. The application requests the eSCI module to enter this mode by setting the TXDMA bit in the Control Register 2 (eSCI_CR2). From this point in time, the module starts the generation of DMA requests and initiates the frame transmission. Before entering this mode, the application should perform the following actions:

1. Configure the module for LIN mode.
2. Enable the transmitter by setting TE in Control Register 1 (eSCI_CR1) to 1.
3. Setup the DMA controller channel and provide frame data in system memory.

A block diagram which presents an overview of the DMA Controlled LIN TX Frame is shown in the following figure. The content of the fields in the memory is the same as described in LIN Transmit Register (eSCI_LTR) - LIN TX frame generation.

Figure 49-39. DMA Controlled LIN TX Frame generation

49.5.6.4 LIN RX frame generation

The eSCI module supports two modes of LIN RX Frame generation and reception, the CPU controlled mode and the DMA controlled mode. In the CPU controlled mode, the application provides the required data by subsequent CPU write accesses to the LIN Transmit Register (eSCI_LTR) and retrieves the received data by subsequent CPU read accesses to the LIN Receive Register (eSCI_LRR). In the DMA controlled mode, the DMA controller provides the required frame configuration data in response to DMA requests generated by the eSCI module and transfers the received frame data to the memory in response to DMA requests generated by the eSCI module.

49.5.6.4.1 CPU Controlled LIN RX Frames generation

In this mode, the application initiates the generation of a LIN RX Frame by a sequence of subsequent CPU write accesses to the LIN Transmit Register (eSCI_LTR). When the eSCI module has processed the data written into LIN Transmit Register (eSCI_LTR), the TXRDY interrupt flag in the Interrupt Flag and Status Register 2 (eSCI_IFSR2) will be set.

The application should clear the TXRDY interrupt flag *before* writing data into the LIN Transmit Register (eSCI_LTR) because the eSCI module will set the TXRDY one clock cycle after the write access.

The first data written to the LIN Transmit Register (eSCI_LTR) provides the Identifier and Identifier Parity fields. The second data written defines the number of data bytes requested from the LIN slave. The third data written defines the CRC and checksum generation. The TD bit has to set to 0 to invoke the RX frame generation. The TO field defines the upper part of the timeout value. The fourth byte written defines the lower part of the timeout value.

After the fourth byte was written the generation of a LIN RX frame is started. Firstly, a break field is transmitted, then the synch field and the protected identifier field. After the transmission of the protected identifier, the eSCI module starts to receive the frame data transmitted by the LIN slave. When the module has received a complete byte field, the received data are transferred into the LIN Receive Register (eSCI_LRR) and the receive data ready flag RXRDY in the Interrupt Flag and Status Register 2 (eSCI_IFSR2) is set.

The application can retrieve the received data by subsequent read access from LIN Receive Register (eSCI_LRR) after checking the RXRDY flag. The application should clear the RXRDY flag immediately after reading the LIN Receive Register (eSCI_LRR).

After the reception of the configured number of data from the slave, the module starts the reception of the configured CRC and Checksum byte fields. These data are not transferred into the LIN Receive Register (eSCI_LRR). The CRC and Checksum checking is performed internally. In case of errors, they will be reported as described in [LIN Error Reporting](#).

After the reception of the checksum field of the LIN RX frame, the FRC interrupt flag in the Interrupt Flag and Status Register 2 (eSCI_IFSR2) is set.

49.5.6.4.2 DMA Controlled LIN RX Frames generation

In this mode, the eSCI module controls the generation of LIN RX frame header and the reception of the frame data automatically and utilizes the two connected DMA channels. A block diagram which presents an overview of the DMA Controlled LIN RX Frame generation and reception is shown in [Figure 49-40](#). The content of the header fields in the memory is the same as described in LIN Transmit Register (eSCI_LTR) - LIN RX frame generation. The TX DMA channel is used to fetch the LIN RX frame header and control information. The RX DMA channel is used to transfer the received frame data into the memory.

When new data is required for transmission, the module generates the transmit DMA request and the DMA controller delivers the required data. When new data is received, the module generates the receive DMA request and the DMA controller retrieves the provided data.

The application requests the eSCI module to enter this mode by setting the RXDMA bit in the Control Register 2 (eSCI_CR2). From this point in time, the module starts the generation of DMA requests and frame transmission and reception. Before entering this mode, the application should perform the following actions:

1. Configure the module for LIN mode.
2. Enable transmitter and receiver by setting TE and RE in Control Register 1 (eSCI_CR1) to 1.
3. Setup the two DMA controller channels and provide frame header data in system memory.

Figure 49-40. DMA Controlled LIN RX Frame generation and reception

49.5.6.5 LIN Error Reporting

This section describes error checking and the signaling of detected errors in LIN mode.

49.5.6.5.1 Physical Bus Error Detection

If the receiver input is sampled 0 for at least 31 sample clock cycles after the start of the transmission of a LIN frame, the physical bus error flag PBERR in the Interrupt Flag and Status Register 2 (eSCI_IFSR2) will be set.

49.5.6.5.2 Unrequested Activity Detection

If an unrequested byte is received (i.e. a byte which is not part of an RX frame) which is not recognized as a wake-up or break character, the bit error flag BERR in the Interrupt Flag and Status Register 1 (eSCI_IFSR1) is set. In addition the RXRDY flag will also be set, the LINRX register must be read before normal operations can proceed.

49.5.6.5.3 Standard Bit Error Detection

The standard bit error detection is enabled when the fast bit error detection control bit FBR in the Control Register 2 (eSCI_CR2) is 0. The standard bit error detection is performed after each LIN byte field transmission.

During the transmission of the LIN frame header and LIN frame data, the receiver is running and receives the signal values on the serial bus. After the complete transmission and the related reception of a LIN byte field, the eSCI compares the data that was transmitted and the data that has been received. If they do not match, the bit error interrupt flag BERR in the Interrupt Flag and Status Register 1 (eSCI_IFSR1) is set.

49.5.6.5.4 Fast Bit Error Detection

Fast Bit Error Detection has been designed to allow flagging of LIN bit errors while they occur, rather than flagging them after a byte transmission has completed (see [Figure 49-41](#)).

Figure 49-41. Fast Bit Error Detection on a LIN Bus

If fast bit error detection bit FBR in the Control Register 2 (eSCI_CR2) is set, the eSCI will compare the transmitted and the received data stream while the transmitter is active (not idle). Once a mismatch between the transmitted data and the received data is detected, the bit error flag BERR will be set.

To adjust to different bus loads the sample point at which the incoming bit is compared to the one which was transmitted can be selected with the BESM bit in the Control Register 2 (eSCI_CR2). If eSCI_CR2[BESM] = 1, the comparison will be performed with sample RS13, otherwise with RS9 (see [Figure 49-42](#)) (also see [Bit Sampling](#)).

Figure 49-42. Timing Diagram Fast Bit Error Detection

Note

To calculate the exact position of the sample point with regard to the RX pin, the delays through the pads and the two Bus Clock cycle delay through the input synchronizer also needs to be taken into account.

49.5.6.5.5 Slave-Not-Responding-Error Detection

The Slave-Not-Responding-Error is defined in [LIN Specification Package Revision 1.3; December 12, 2002](#); 6 ERROR AND EXCEPTION HANDLING. The LIN specification requires that a NO_RESPONSE_ERROR has to be detected if a message frame is not fully completed within the maximum length $T_{\text{FRAME\_MAX}}$ by any slave task upon transmission of the SYNCH and IDENTIFIER fields. The maximum frame length $T_{\text{FRAME\_MAX}}$ is defined in [LIN Specification Package Revision 1.3; December 12, 2002](#); 3.3 LENGTH OF MESSAGE FRAME AND BUS SLEEP DETECT, as

$$T_{\text{FRAME\_MAX}} = (10 \cdot N_{\text{DATA}} + 45) \cdot 1.4$$

where N_{DATA} is the number of data byte fields of the message frame.

The STO interrupt flag in the Interrupt Flag and Status Register 2 (eSCI_IFSR2) will be set, if an LIN RX frame was not fully received in the amount of time specified in the timeout value field TO in the LIN Transmit Register (eSCI_LTR). The time period starts with the falling edge of the transmitted LIN break character and is specified in units of transmit bits.

To achieve LIN compliant Slave-Not-Responding-Error detection, the timeout value TO in the LIN Transmit Register (eSCI_LTR) field has to be set to $T_{\text{FRAME\_MAX}}$ when a LIN RX frame is initiated.

49.5.6.5.6 Checksum Error Detection

If the checksum enable bit CSE in the LIN Transmit Register (eSCI_LTR) was set, the checksum checking is performed based on the received checksum byte. The checksum mode is selected by the CSM bit in the LIN Transmit Register (eSCI_LTR). If the value received in the checksum bytes did not match the calculated checksum, the checksum error flag CKERR in the Interrupt Flag and Status Register 2 (eSCI_IFSR2) will be set.

49.5.6.5.7 CRC Error Detection

The CRC checking is performed on the two received CRC bytes CRC1 and CRC2 if the CRC Enhanced LIN frame format was selected by the CRC bit in the LIN Transmit Register (eSCI_LTR). If the value received in the two CRC bytes did not match the calculated CRC pattern, the CRC error flag CERR in the Interrupt Flag and Status Register 2 (eSCI_IFSR2) will be set.

49.5.6.5.8 Overflow Detection

When the receiver has received the next byte field, which should be transferred into the LIN Receive Register (eSCI_LRR), but neither the application nor the RX DMA channel have read data from this register since the last update, the received data overflow flag OVFL in the Interrupt Flag and Status Register 2 (eSCI_IFSR2) will be set. In this case the content of the LIN Receive Register (eSCI_LRR) is not changed. The data received most recently are lost.

49.5.6.6 LIN Wake Up

The section describes the LIN Wake Up behavior of the eSCI module.

49.5.6.6.1 LIN Wake-Up Request Generation

The eSCI module can cause the LIN bus to exit the sleep mode by sending a wake-up signal frame, which consists of a wake-up signal 0x80 (consisting of 8 dominant bits followed by 1 recessive bit), followed by the wake-up delimiter period as defined by the WUD field in the LIN Control Register 1 (eSCI_LCR1), followed by Idle time which is n bits, where $n \geq 0$. This Idle time depends on the time until next frame is started by the software.

Figure 49-43. LIN Wake-Up Signal Frame

The application triggers the transmission of a wake-up signal frame by writing 1 to the LIN bus wake-up trigger WU in the LIN Control Register 1 (eSCI_LCR1).

The LIN Specification 2.0 requires the generation of LIN wake-up signals as dominant pulses longer than 250 μ s and shorter than 5 ms. To achieve this, the eSCI module has to be programmed to a baud rate between 32 kBaud and 1.6 kBaud. With each of these baud rate settings, the wake-up signal is transmitted as a dominant pulse longer than 250 μ s and shorter than 5 ms.

49.5.6.6.2 LIN Wake-Up Request Detection

The eSCI module detects a LIN wake-up requests when

1. one of the characters 0x00, 0x80, or 0xC0 has been received,
2. followed by zero or more low bits,
3. followed by at least one high bit, and
4. no LIN frame transmission or reception is started or running during the reception above

If a LIN wake-up request has been detected, the LIN wake-up flag LWAKE in the Interrupt Flag and Status Register 2 (eSCI_IFSR2) will be set after the reception of the first high bit.

The LIN Specification 2.0 requires the detection of LIN wake-up requests as dominant pulses longer than 150 μ s. To achieve this, the eSCI module has to be programmed to the maximum baud rate that is not greater than 43.77 kBaud. With this baud rate setting, any dominant pulse longer than 150 μ s is decoded as at least 7 dominant bits (one start and 6 data bits) and consequently as one of the characters 0xC0, 0x80, or 0x00.

49.5.6.7 LIN Protocol Engine Stop and Reset

The LIN protocol engine is stopped and reset when the application sets the LRES control bit in the LIN Control Register 1 (eSCI_LCR1) to 1. In this case, the LIN protocol engine will stop immediately. No new transmissions or receptions are initiated, the LIN serial

bus is driven with the recessive value 1. Additionally to the stop and reset of the LIN protocol engine the receiver and transmitter modules are stopped and reset as well, and the receive and transmit DMA requests are deasserted.

In order to start the LIN Protocol Engine with idle transmitter and receiver processes, the LRES bit should be asserted until all of the status bits DACT, WACT, LACT, TACT, and RACT in the Interrupt Flag and Status Register 1 (eSCI_IFSR1) are cleared. These status bits are cleared within one bit time after assertion of the LRES bit.

49.5.7 Interrupts

This section describes the interrupt sources and interrupt request generation.

49.5.7.1 Interrupt Flags and Enables

All interrupt sources, interrupt flags, and interrupt enable bits are listed in the following table. This table indicates the operational modes, where the interrupt flags can be set by the eSCI module.

Table 49-37. eSCI Interrupt Flags and Interrupt Enable Bits

Interrupt Source	Operational Mode	Interrupt Flag	Interrupt Enable Bit
Transmitter	SCI	eSCI_IFSR1[TDRE]	eSCI_CR1[TIE]
Transmitter	SCI, LIN	eSCI_IFSR1[TC]	eSCI_CR1[TCIE]
Receiver	SCI	eSCI_IFSR1[RDRF]	eSCI_CR1[RIE]
Receiver	SCI	eSCI_IFSR1[IDLE]	eSCI_CR1[ILIE]
Receiver	SCI	eSCI_IFSR1[OR]	eSCI_CR2[ORIE]
Receiver	SCI, LIN	eSCI_IFSR1[NF]	eSCI_CR2[NFIE]
Receiver	SCI, LIN	eSCI_IFSR1[FE]	eSCI_CR2[FEIE]
Receiver	SCI	eSCI_IFSR1[PF]	eSCI_CR2[PFIE]
Receiver	LIN	eSCI_IFSR1[BERR]	eSCI_CR2[BERRIE]
Receiver	LIN	eSCI_IFSR2[RXRDY]	eSCI_LCR1[RXIE]
Transmitter	LIN	eSCI_IFSR2[TXRDY]	eSCI_LCR1[TXIE]
Receiver	LIN	eSCI_IFSR2[LWAKE]	eSCI_LCR1[WUIE]
Receiver	LIN	eSCI_IFSR2[STO]	eSCI_LCR1[STIE]
Receiver	LIN	eSCI_IFSR2[PBERR]	eSCI_LCR1[PBIE]
Receiver	LIN	eSCI_IFSR2[CEERR]	eSCI_LCR1[CIE]
Receiver	LIN	eSCI_IFSR2[CKERR]	eSCI_LCR1[CKIE]
Receiver	LIN	eSCI_IFSR2[FRC]	eSCI_LCR1[FCIE]
Receiver	LIN	eSCI_IFSR2[UREQ]	eSCI_LCR2[URIE]
Transmitter, Receiver	LIN	eSCI_IFSR2[OVFL]	eSCI_LCR2[OFIE]

49.5.7.2 Interrupt Request Generation

The eSCI module provides one hardware interrupt request signal to the systems interrupt controller. This interrupt request signal is asserted if and only if at least one of the interrupt flags and the corresponding interrupt enables are set to 1. Otherwise the interrupt line is deasserted.

49.6 Application Information

49.6.1 SCI Data Frames Separated by Preamble

To separate SCI data frame with preambles with minimum idle line time, use this sequence between messages:

1. write to SCI Data Register (eSCI_SDR)
 - this sets the internal iCMT bit which requests the data transmission
2. wait until TDRE in Interrupt Flag and Status Register 1 (eSCI_IFSR1) is set
 - this indicates the start of transmission; the iCMT bit was cleared
3. clear and subsequently set the TE bit in Control Register 1 (eSCI_CR1)
 - this sets the internal iPRE bit which requests the preamble transmission
4. write to SCI Data Register (eSCI_SDR)
 - this sets the internal iCMT bit which requests the data transmission

The priority scheme of the transmitter which is described in [Table 49-29](#) ensures that the preamble is transmitted before the data frame.

Chapter 50

Resets

50.1 Overview

This device supports the following system reset sources:

- Power-on reset (at power up)
- External reset (from RESET pin)
- Fault Collection and Control Unit (FCCU) reset
- FCCU Output Supervision Unit (FOSU) reset
- Dual core reset
- JTAG reset
- Self Test Control Unit (STCU) reset
- Software system reset
- Life cycle manipulation reset

A reset event caused by any of the above sources will trigger a reset cycle with the assertion of internal reset signals as well as the assertion of the RSTOUT pin. Software may set the SIU_SRCR[SER] bit to 1 to assert the RSTOUT pin without causing an internal reset cycle. This action is referred to as a software external reset. After the reset cycle completes, software may learn the source of the last reset cycle by looking at the Reset Status Register (SIU_RSR) in the SIU. The SIU_RSR register is updated for all reset sources except JTAG and life cycle manipulation reset.

Power-on reset is the most comprehensive form of reset. It affects all modules without exception. Other sources of reset do not affect special hardware that needs to be active during the reset cycle, like for example the state machine of the reset controller. Some modules are affected by all reset sources, but are released from reset state before other modules during the execution of the reset cycle. This reset releasing sequence allows device configuration data to be read from flash memory and applied to the system before the completion of the reset cycle and prior the cores starting code execution.

When the reset cycle completes, the RSTOUT pin is negated. In parallel, the CSE security engine starts execution of the secure boot, and Core 0 starts execution. Core 1 and the associated checker core are kept in reset state until software running on Core 0 configures its reset vector and enables it to start code execution. Reset vectors and core resets are configured by the SIU_RSTVEC0 and SIU_RSTVEC1 registers.

The reset cycle can be extended by the assertion of the RESET pin. This is useful to allow JTAG communication to be established during the reset cycle, so that debugging configuration may be done before the cores start executing.

50.2 Reset sequence

The following figure illustrates the reset flow.

Figure 50-1. Internal reset flow diagram

When power-up is the source of the reset cycle, the following sequence of events takes place:

1. A power-on reset (POR) signal resets everything while power supplies are ramping up.
2. When supply rails are within acceptable (yet still untrimmed) voltage ranges, the POR signal is negated, the RSTOUT pin is asserted, and an internal reset signal is asserted to all modules.

NOTE

Some components are exceptions to this internal reset assertion. They include the reset controller, flash memory, and DCF clients (ERROR function and Reset escalation), all of which are affected only by POR.

3. The reset controller waits for 4 clock cycles so that the reset signal can propagate through the registers, then it negates the reset signals going to the STCU, FCCU and PASS, because these modules need to be active during the reset cycle.
4. The reset controller waits until the flash memory finishes its initialization, then negates the reset signal going to the SSCM module.
5. The SSCM reads device configuration and trimming data from DCF records stored in flash memory and applies the configuration data to the system. Refer to the DCF chapter for more information.
6. When the SSCM is done, the reset controller waits until the RESET pin is negated and then starts a timer that counts for a pre-determined number of clock cycles, which depends on the reset source (see [RSTOUT](#)).
7. If reset escalation is enabled, the reset cycle proceeds with reset escalation evaluation. A reset escalation counter is incremented at the end of every non-POR reset cycle. If the counter exceeds the number programmed in the RET field of SIU_RCR, then the device is locked permanently into a reset state which can only be undone by a power-up cycle. To avoid reaching the reset escalation threshold, software must reset the escalation counter by servicing the SIU_RCR register (write something to the RET field; writing zero disables the reset escalation process).
8. If the device was not locked at reset state by the reset escalation process, the STCU may take control of clocks and resets of the device to execute self-test diagnostics. Self-test is executed during the reset cycle when the following conditions are satisfied:
 - The reset cycle was initiated from power-up or RESET pin or FOSU reset
 - STCU execution is enabled by DCF configuration
 - JCOMP pin is not asserted and debug mode is not engaged

After the self-test is finished, the STCU records the test results and then triggers a new internal reset cycle via an STCU reset request. This new reset cycle will not trigger a self-test execution.

9. If the STCU did not execute, then the reset cycle reaches its normal termination flow, the SIU_RSR register is updated, the RSTOUT pin is negated, and the internal reset signals are negated.

Reset cycles initiated by sources other than power-up, RESET pin, or FOSU do not affect all modules. For a reset cycle initiated by the STCU, the STCU itself is not reset, so that diagnostic results from the previous reset cycle are preserved.¹ Other sources of internal reset will not reset the STCU, FCCU, FOSU and PASS modules (they have information that needs to be preserved through the reset cycle).

50.3 Reset pins

50.3.1 RESET

The RESET pin is an active low input. The RESET pin must be asserted by an external device during power-up or whenever an external reset is required.

The RESET pin has hysteresis, and the hysteresis is always enabled.

The reset controller provides a glitch detector connected to the RESET pin. If the reset controller detects that the RESET pin is asserted for more than two peripheral clock cycles, the event is latched. After the latch is set, if the RESET pin is negated before 10 clock cycles is reached, the reset controller sets the RGF bit without affecting any of the other bits in the reset status register (SIU_RSR). The latch is cleared when the RGF bit is set or a valid reset is recognized. The RGF bit remains set until cleared by a software or the RESET signal asserts for 10 clock cycles.

50.3.2 RSTOUT

The RSTOUT pin is an active low output that uses a push/pull configuration. The RSTOUT pin is driven low by the MCU for all internal and external reset sources.

The time interval between RESET pin negation and RSTOUT pin negation is deterministic, but it depends on the reset source, as shown in the following table. The actual time interval is the value in [Table 50-1](#) plus 4 clock cycles.

The RSTOUT pin can also be asserted by a write to the SER bit of the System Reset Control Register (SIU_SRCR); however, an internal reset cycle is not initiated under this circumstance. The duration of RSTOUT assertion caused by setting the SER bit depends on whether the clock source is the IRC or not, as given in the following table.

1. The FCCU needs to be reset after a self-test run, because FCCU logic is part of the LBIST tests.

Table 50-1. Clock Cycles for Different Reset Sources

Source ¹	Description	Number of clock cycles
PORS	Power-on reset	2400
ERS	External reset (RESET pin)	2410
FOSURS	FOSU reset	2430
FCCURS	FCCU reset	2460
CPURS	Simultaneous core 0 and core 1 reset	2490
STCURS	STCU reset	2500
SSRS	Software system reset	2510
SERF ²	Software external reset	2520 (IRC) / 17200 (other)

1. Bits of the SIU_RSR register.

2. RSTOUT duration depends on the clock source: if IRC, duration is 2520; for all others, duration is 17200.

50.4 Reset sources

50.4.1 Power-on reset

The internal power-on reset signal is asserted when voltage and temperature monitors indicate that the device temperature and/or power supply voltages have reached values outside normal operating ranges. Control and configuration registers for temperature and voltage monitors are located within the Power Management Control (PMC) digital interface module.

POR is the highest priority reset and if POR is detected while any other reset is being processed, after reset cycle completion SRS will have just the PORS set.

50.4.1.1 Voltage monitors

The following out-of-range voltage events can trigger a power-up reset cycle:

- POR: below absolute minimum value required for starting device wake-up process
- Low voltage Detection (LVD): below minimum power supply voltage specification
- High Voltage Detection (HVD): above maximum power supply voltage specification

A power-up reset cycle is triggered unconditionally when supply voltages fall below POR thresholds. LVD and HVD events can also trigger a power-up cycle if enabled in the PMC module. LVD/HVD events are also routed from the PMC to the FCCU to be handled there.

LVD/HVD events which are enabled to trigger reset will cause a POR reset cycle. When the reset cycle finishes, the PORS flag is set in the SIU_RSR register. If LVD/HVD are routed to the FCCU, and the FCCU is enabled to generate reset from these sources, then an FCCU reset cycle is triggered. When the FCCU reset cycle finishes, the FCCURS bit is set in the SIU_RSR register. The FCCU reset cycle will not reset the FCCU itself, therefore information about the LVD/HVD events can still be recovered from the FCCU registers.

See the the PMC chapter and the device data sheet for information on monitored voltages and threshold values.

50.4.1.2 Temperature monitors

The following table identifies the temperatures for which out-of-range temperature events can trigger a power-up reset cycle:

Table 50-2. Temperature events configurable to cause POR

Temperature	Temperature Sensor name	PMC name	Out-of-range event
-40°C	Low temperature	Temperature 0	Temperature is below this threshold
150°C	High temperature 1	Temperature 2	Temperature is above this threshold
165°C	High temperature 2	n/a	No event: This device does not support 165°C monitoring.

These events trigger a power-up cycle if enabled in the PMC module. Alternatively, the PMC can be configured to route the temperature events to the FCCU to be handled there.

Temperature events that are enabled to trigger a reset cause a POR cycle. When the reset cycle finishes, the PORS flag is set in the SIU_RSR register. If the temperature events are routed to the FCCU, and the FCCU is enabled to generate reset from these sources, then an FCCU reset cycle is triggered. When the FCCU reset cycle finishes, the FCCURS bit is set in the SIU_RSR register. The FCCU reset cycle will not reset the FCCU itself, so information about the LVD/HVD events can still be recovered from the FCCU registers.

See the detailed descriptions of the Temperature Sensor and PMC modules as well as the device Data Sheet for information about monitored temperatures and threshold values.

50.4.2 External reset

Assertion of the RESET pin triggers an internal reset cycle. The reset cycle will be sustained as long as RESET is kept asserted. When RESET is negated, the reset controller initiates a timer that counts for a predetermined number of clock cycles, as shown in [Table 50-1](#), before resuming the reset cycle.

If the RESET pin was the source reset, or if it was asserted during the last reset cycle, then the ERS bit is asserted in the SIU_RSR register.

If POR is the current reset source being processed, then a RESET pin is detected, after reset cycle completion SRS will have PORS and ERS set.

If the Reset pin is the current reset source being processed, then if any other reset is detected (except POR), after reset cycle completion SRS will have just ERS set and PORS will keep its previous value.

50.4.3 FCCU reset

The Fault Collection and Control Unit collects failure events coming from different sub-systems within the device. One of the possible reactions to a failure event is the triggering of an internal reset cycle.

Failure sources include:

- All failure indication signals from modules within the MCU
- Logic and signals monitored by the FCCU itself
- Software-initiated failure indications
- External failure input.

Available failure reactions are:

- Assertion of an interrupt (maskable or nonmaskable)
- Resetting the MCU
- Changing the state of the failure indication pins, ERRORn
- No reaction

The FCCU itself is not affected by an FCCU reset. The FCCU is reset when the reset source is one of the following:

- Power-up
- RESET pin
- FOSU reset
- STCU reset

When the reset cycle that was initiated by the FCCU finishes, the FCCURS bit is asserted in the SIU_RSR register. Since the FCCU itself is not reset when the reset source is an FCCU reset, information about the failure that caused reset is still available in the FCCU module to be read by software.

Refer to the FCCU chapter for information on failure sources that can generate a reset cycle.

50.4.4 FOSU reset

As the FCCU is a central component in reacting to errors, it is itself supervised. This supervision is provided by the FCCU Output Supervision Unit (FOSU). The FOSU receives failure indications at the same time as the FCCU. Unless the respective failure is switched off, the FOSU will observe the outputs of the FCCU (IRQ, RESET, error pins). If the FCCU does not react within a predefined timing window, the FOSU assumes the FCCU has failed and causes a reset cycle.

A FOSU reset cycle resets the FCCU and the FOSU itself. The FOSU is reset when the reset source is one of the following:

- Power-up
- RESET pin
- FOSU reset
- STCU reset

When the FOSU reset cycle finishes, the FOSURS bit is asserted in the SIU_RSR register.

50.4.5 Dual core reset

Core 0 and Core 1 Reset Vector Registers described in the SIU chapter allow software executing on either core to place the other core in reset by setting the RST bit in the appropriate Reset Vector Register. Any attempt to reset both cores by setting both RST bits will result in an immediate internal reset.

When the reset cycle that was initiated by this reset source finishes, the CPURS bit is asserted in the SIU_RSR register.

50.4.6 JTAG reset

An internal reset cycle is initiated when JTAG is enabled and either the EXTEST, CLAMP, or HIGHZ instructions are executed by the JTAG controller. Since these instructions affect the state of the package pins, the state of the RSTOUT pin is determined by the JTAG instruction itself. The reset status bits in the SIU_RSR are not affected by this reset source.

50.4.7 Software system reset

A software system reset occurs when software asserts the SSR bit in the System Reset Control Register (SIU_SRCR), triggering an internal reset cycle and the assertion of the RSTOUT pin. Once the reset cycle begins, the SSR bit is automatically cleared. When the reset cycle finishes, the SSRS bit is set in the SIU_RSR register.

50.4.8 Software external reset

A write of one to the SER bit in the SIU_SRCR causes the external RSTOUT pin to be asserted for a predetermined number of clock cycles (refer to [RSTOUT](#)). The SER bit automatically clears after the clock counting expires. A software external reset does not cause an internal reset cycle. Only the RSTOUT pin is affected. The SERF bit in the SIU_RSR is set, but no other status bits are affected. The SERF bit in the SIU_RSR is not automatically cleared after the RSTOUT clock cycles expire, and remains set until cleared by software or another reset besides the software external reset occurs.

During a software external reset, the e200z7 cores will continue to execute instructions, timers that are enabled will continue to operate, and interrupt requests will continue to be processed. It is the responsibility of the application to ensure devices connected to RSTOUT are not accessed during a software external reset, and to determine how to manage MCU resources when using the software external reset.

50.4.9 STCU reset

When the reset cycle is triggered by a power-up event or by the assertion of the RESET pin or a FOSU reset, and if enabled by DCF configuration, the Self-Test Control Unit executes a series of hardware self tests based on shifting pseudo-random data into the device registers and then comparing the resulting signature with a golden reference stored in flash memory. It also triggers the execution of self-test hardware within the embedded

memories. By the end of the self-test runs, the device is left with random data in its registers; therefore, the STCU sends a signal to the reset controller to trigger a new reset cycle.

The STCU itself is not affected by STCU reset cycle; therefore, test results are preserved to be read by software after the reset cycle finishes. The FCCU is also one of the structures included in the STCU tests; therefore, it also needs to be reset after the execution of STCU diagnostics.

When the reset cycle that was initiated by this reset source finishes, the STCURS bit is asserted in the SIU_RSR register.

50.4.10 Life cycle manipulation reset

When SSCM loads information from UTest memory corresponding to the life cycle slots and that information includes invalid programmed values, a life cycle manipulation reset occurs. See [SSCM security reset and LC state](#) for further details.

50.5 Reset configuration

During reset, the SSCM reads various configuration and trimming data from flash memory and applies them to the device before the reset cycle finishes. See the DCF chapter for a complete list of DCF records. Following is a list of main functions configured by DCF records and information in other locations in UTest flash memory:

- Pull up/down of external I/O pins
- Boot mode (internal, serial, EBI, auto-baud)
- Crystal oscillator trimming and configuration
- RC oscillator trimming
- Trimming for voltage regulators and power supply monitors
- ADC trimming
- Temperature sensor trimming
- Flash access control bits and passwords
- Security, life cycle, and censorship
- STCU configuration

50.5.1 Weak pull up/down configuration

Initial pull up/down configuration of external I/O pins is available in the Miscellaneous DCF record, which is read by the SSCM from UTEST flash memory during reset and applied to the pad drivers.

As an alternative to the DCF record method, a legacy mode is available that uses the WKPCFG pin to do the same configuration. For all resets except a software external reset, the WKPCFG pin is applied at the assertion of the internal reset signal and latched upon negation of reset. Legacy mode is used when the legacy bit is asserted in the Miscellaneous DCF record.

Either coming from the DCF record or from the WKPCFG pin, the pull configuration is stored in the WKPCFG bit in the Reset Status Register.

50.5.2 Boot configuration

Configuration data required by the boot code is available in the Miscellaneous DCF record, which is read by the SSCM from UTEST flash memory during the reset cycle. As an alternative to the DCF record method, a legacy mode is available in which the boot configuration data is latched from package pins at the end of the reset cycle. Either coming from the DCF record or from package pins, the boot configuration data is placed in the Reset Status Register (SIU_RSR) to be read by the boot code.

The boot configuration data in SIU_RSR is also affected by the security life cycle of the component. If the life cycle has reached the “in field” state, then boot mode is forced to be internal only. See the table below and also refer to the SIU_RSR description in the SIU chapter.

Table 50-3. Boot configuration data

Mode (LEG bit in Misc DCF record)	SIU_RSR fields	
	BOOTCFG ¹	ABR
Normal (LEG=0)	Loaded from bits 14–15 of Misc DCF	Loaded from bit 13 of Misc DCF
Legacy (LEG=1)	Latched from BOOTCFG[0:1] pins	Latched from EVTO pin ²

1. BOOTCFG is forced to 0b00 (internal boot) if life cycle is “in-field.”

2. Latching from EVTO works as follows. If no debug tool is attached to the device and EVTO is held at low logic level during reset, the ABR bit reset state is logic one. Otherwise it is zero.

50.6 Boot sequence

When the reset cycle finishes, the following sequence of events takes place:

1. In parallel, immediately after reset is negated, the Cryptographic Services Engine (CSE) starts running its secure boot code, and core 0 starts executing boot code from address 0xFFFF_FFFC.
2. Core 1 is held in reset state until software writes a boot vector in SIU_RSTVEC1 and then negates SIU_HLT1[CORE1] or SIU_RSTVEC1[RST1]. When either of these bits is negated, core 1 starts executing code at the address specified by the boot vector.
3. Execution of the checker core is controlled by the LOCKSTEP_EN bit of the Miscellaneous DCF Client. If disabled, the checker core is kept in reset state after the end of the reset cycle even if core 1 starts executing code. When the checker core is disabled, RCCU error checking is also disabled. Enabling or disabling checker core execution requires a reset cycle to take effect.

Chapter 51

System Boot

51.1 Overview

The Boot Assist Module (BAM) is a 4-KB block of read-only memory, containing the boot program code for the MCU. The BAM program supports the following boot modes:

- Boot from internal flash memory
- Serial boot via SCI or CAN interface with optional baud-rate detection (available if the device life cycle is not “in-field”)
- Boot from a memory connected to the MCU development bus (EBI)¹ with multiplexed or separate address and data lines (available if the device life cycle is not “in-field”)

On the MPC5777C device, only Core0 is enabled out of reset; therefore, the BAM program is executed by Core0 after the reset cycle finishes. Depending on the boot mode, the program initializes the appropriate minimum MCU resources to start user application code. Note that the BAM is pure software; therefore, all registers and resources accessed and modified by the BAM can also be accessed by customer software.

51.2 Features

- Initial MMU setup with minimum address translation for all internal MCU resources
- MMU configuration to boot user application, compiled as Classic PowerPC Book E code or as NXP VLE code
- Passes control to user application code in the internal flash memory or external memory device
- Automatic switch to serial boot mode if internal or external flash is blank or invalid
- Serial boot by loading user program via CAN bus or eSCI to the internal SRAM
 - Not available at “in-field” device life cycle

1. EBI not available on all packages.

- Only public password protection is used
- Optional automatic detection of the host SCI or CAN speed
- Boot from an external memory device, connected to the EBI
 - Not available at “in-field” device life cycle
 - Option to boot from 16-bit memory device with separate data and address lines
 - Option to boot from 32/16-bit memory device with multiplexed data and address lines
- Controls MCU core Watchdog Timer and/or the Software Watchdog Timer (SWT)

51.3 Modes of operation

51.3.1 Normal boot

Core 0 is released from reset immediately at the end of the reset cycle and it begins execution of the BAM code from the reset vector contained in the SIU_RSTVEC0 register.

51.3.2 Parallel secure boot

The Cryptographic Service Engine (CSE) and Core0 are released from reset at the same time. Core0 starts executing the BAM code in parallel with CSE execution. The BAM code is ignorant of the result of the secure boot code execution; it always continues with its own code execution.

51.3.3 Debug mode

The BAM program is not executed when the MCU exits reset in OnCE debug mode. Before accessing the MCU resources, use the development tool to initialize the MCU.

51.3.4 Internal boot mode

BAM looks for customer code at predefined locations in flash memory, then starts execution of that code from flash.

51.3.5 Serial boot mode

BAM loads customer code into internal SRAM using the eSCI or CAN serial interface, then executes that program. The program can then control:

- Downloading of data, and
- Erasing and programming of the internal or external flash memory

51.3.6 Development bus boot mode

This boot mode is intended for packaged versions of the device that have the development bus pinned out. The development bus (EBI) boot mode can be used for application code development.

51.4 Memory Map

The BAM occupies 16 KB of memory space, 0xFFFF_C000 to 0xFFFF_FFFF. The actual code size of the BAM program is less than 4 KB and starts at 0xFFFF_F000, repeating itself every 4 KB in the BAM address space. The CPU starts the BAM program execution at its reset vector from address 0xFFFF_FFFC.

The BAM exits to user code at 0xFFFF_FFF8. The last instruction the BAM executes is a BLR. The link register is pre-loaded with the user application start address. The value of the start address depends on the boot mode:

- Booting from internal or external flash memory—32-bit word following a valid RCHW holds the start address value
- Serial boot—set according to the serial boot protocol

The following table shows the BAM address map.

Table 51-1. BAM memory map

Address	Description
0xFFFF_C000 – 0xFFFF_EFFF	BAM program mirrored
0xFFFF_F000 – 0xFFFF_FFFF	BAM program
0xFFFF_FFFC	MCU reset vector
0xFFFF_FFF8	BAM last executed instruction

51.5 Functional Description

51.5.1 BAM program flow chart

The following figure shows the BAM program flow.

Figure 51-1. BAM program flow chart

51.5.2 BAM program operation

When Core0 is released from reset state, it fetches the boot vector corresponding to the BAM code from the SIU_RSTVEC0 register. The first thing the BAM program does is to configure the MMU to allow access to all MCU internal resources, according to [Table 51-2](#). This MMU setup remains untouched through internal flash boot mode.

Table 51-2. MMU configuration for internal flash boot

TLB entry	Region	Logical base address	Physical base address	Size	Attributes
0	Peripheral Bridge B and BAM	0xFFE0_0000	0xFFE0_0000	2 MB	Guarded
					Big endian
					Global PID
					Cache Inhibit
1	Internal flash	0x0000_0000	0x0000_0000	16 MB	Not guarded
					Big endian
					Global PID
2	EBI	0x2000_0000	0x0000_0000	16 MB	Not guarded
					Big endian
					Global PID
3	Internal SRAM	0x4000_0000	0x4000_0000	512 KB	Not guarded
					Big endian
					Global PID
					Cache Inhibit
4	Peripheral Bridge A	0xC3E0_0000	0xC3E0_0000	2 MB	Guarded
					Big endian
					Global PID
					Cache Inhibit

The MMU regions are mapped with logical addresses the same as physical addresses except for the External Bus Interface (EBI). The logical EBI address space is mapped to physical address space of the internal flash memory. This allows code, written to run from external memory, to execute from internal flash memory.

After the MMU configuration, the BAM uses information from the read-only SIU_RSR[BOOTCFG] field to decide what type of boot that it must do, according to [Table 51-3](#).

Table 51-3. BOOTCFG field description

BOOTCFG[0:1]	Description
00	Internal boot from flash memory
01	Serial boot from eSCI or FlexCAN

Table continues on the next page...

Table 51-3. BOOTCFG field description (continued)

BOOTCFG[0:1]	Description
10	Non-muxed EBI boot (16-bit data, non-muxed address bus)
11	Muxed EBI boot mode (16-bit data, muxed address bus)

The BOOTCFG field is the only place that the BAM will look to determine what type of boot it should attempt. The value of the BOOTCFG field is loaded into the SIU_RSR by internal hardware during reset, from one of the following possible sources:²

1. BOOTCFG pins
2. BOOTCFG field of the Miscellaneous DCF record
3. Fixed value 00 (Internal Boot)

Which of these sources is used depends on the life cycle and the legacy mode settings of the device.

Table 51-4 describes the source selection of the BOOTCFG field depending on the above settings.

Table 51-4. BOOTCFG source selection

Life cycle	Legacy mode?	BOOTCFG source
Different than In Field	Yes	BOOTCFG pins
	No	BOOTCFG field of Miscellaneous DCF record
In Field	X ¹	Fixed to 00 (Internal Boot)

1. "X" means that the value of this entry has no effect on the determination of the BOOTCFG source.

For all cases presented where serial boot mode is available, a 64-bit public password is required. The password is 0xFEED_FACE_CAFE_BEEF. After a match is detected, the BAM code goes on executing the serial boot flow. Otherwise, it stays on a loop until a reset is issued due to the watchdog settings.

The internal and EBI boot modes require no password, but it is still possible to have the flash memory inaccessible due to protection settings on the PASS module. Therefore, access to flash should be granted by not blocking the flash memory regions used by the BAM.

2. The BOOTCFG field is the only place that the BAM will look to determine what type of boot it should attempt. Other device settings affect the boot mode, but they are all factored in by the internal hardware when it loads BOOTCFG into the SIU_RSR register.

51.5.3 Reset Configuration Half Word (RCHW)

The Reset Configuration Half Word defines boot options and must be programmed to predefined locations in the internal flash or at the beginning of the external flash device. The 32-bit word after the RCHW must be programmed with the user application's starting address. The BAM passes control to the user application at this starting address.

Table 51-6 provides possible RCHW locations in the internal flash. When booting from the external flash device, the RCHW must reside in the first 16-bit half word of the flash memory.

BOOT_BLOCK_ADDRESS

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
				SWT	WTE	PS0	VLE	0	1	0	1	1	0	1	0
								Boot Identifier = 0x5A							

Table 51-5. RCHW field descriptions

Field	Description
0–3	Reserved. These bit values are ignored when the halfword is read. Program to 0 for future compatibility.
4 SWT	Software watchdog timer enable. This bit determines if the software watchdog timer is enabled after passing control to the user application code. 0 Disable software watchdog timer 1 Enable software watchdog timer after reset. The time-out period is 392400 cycles of the Internal RC Oscillator.
5 WTE	MCU core watchdog timer enable. This bit determines if the core software watchdog timer is enabled after passing control to the user application code. 0 Disable core software watchdog timer 1 Enable core watchdog timer after reset. The timeout period is 2.5×2^{18} cycles of the CPU clock. ¹
6 PS0	Port size. Defines the width of the data bus connected to the memory on D_CS0. After system reset, the BAM changes D_CS0 to a 16-bit port to fetch the RCHW from either 16- or 32-bit external memories. Then the BAM reconfigures the EBI as a 16- or 32-bit port, depending on this bit. 0 32-bit D_CS0 port size 1 16-bit D_CS0 port size NOTE: Used in development bus boot modes only (that is, 496- and 516-pin packages). Do not clear this bit if the device only has a 16-bit data bus.
7 VLE	VLE Code Indicator. This bit configures the MMU entries 1–3 coded as Classic Book E instructions or as NXP VLE instructions. 0 User code executes as classic Book E code 1 User code executes as NXP VLE code
8–15 BOOTID[0:7]	Boot identifier. This field serves two functions: - Indicates which block in flash memory contains the boot program - Indicates if the flash memory is programmed (BOOTID = 0x5A) or invalid

1. Upon exiting reset, the CPU clock is connected to the Internal RC Oscillator at 16 MHz.

51.5.3.1 Application Start Address Register

Application Start Address Register, shown below, is the 32-bit word after the RCHW in the application code memory device (internal or external flash memory). The BAM uses the value from this location as a start address of the user application to pass control to.

BOOT_BLOCK_ADDRESS + 0x0000_0004

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
A0	A1	A2	A3	A4	A5	A6	A7	A8	A9	A10	A11	A12	A13	A14	A15

16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
A16	A17	A18	A19	A20	A21	A22	A23	A24	A25	A26	A27	A28	A29	A30	A31

51.5.4 Internal boot mode

Upon reset exit, when the BAM program starts running, the system clock is by default sourced by the Internal RC Oscillator (IRC). If internal boot mode was configured in the SIU_RSR[BOOTCFG] field, the BAM program executes the following tasks:

1. Configures a machine check exception handler, since it will be accessing flash memory locations that may be corrupted and cause a bus error
2. Searches for a valid RCHW in predefined locations, as shown in the following table.

NOTE

In the search for a valid RCHW, the location with priority 0 has highest priority and the location with priority 4 has lowest priority.

Table 51-6. Possible RCHW locations in internal flash memory

Priority	Address
0	0x0080_0000
1	0x0002_0000
2	0x0003_0000
3	0x0000_0000
4	0x0001_0000

3. If a valid RCHW is not found, the BAM program checks for the life cycle state of the device (SSCM_LCSTAT[LC]). For any life cycle other than In Field, the BAM program switches to the serial boot mode. Otherwise, the search for the RCHW will continue until SWT requests a reset.
4. If the BAM program finds a valid RCHW:

- `BOOT_BLOCK_ADDRESS` is the address (from [Table 51-6](#)) of the valid RCHW
- The BAM program fetches the application start address from `BOOT_BLOCK_ADDRESS + 0x4`
- The BAM branches to this start address (shown in [Application Start Address Register](#))
- The MMU TLB entries 1,2,3 are programmed with VLE attribute if the `RCHW[VLE] = 1`
- The watchdog timers are programmed as shown in the table below

Table 51-7. Watchdog timeout settings

Core WD		SWT	
Clock source	Condition	Clock source	Condition
IRC 16 MHz	Enabled if <code>RCHW[WTE] = 1</code> Timeout = 2.5×2^{18} cycles	IRC 16 MHz	Enabled if <code>RCHW[SWT] = 1</code> Timeout = 392400 cycles

51.5.5 Serial boot mode

When serial boot mode is detected, either because of the `BOOTCFG` configuration or because a valid RCHW word was not found in any of the expected locations in flash memory, the BAM program does the following:

1. Initializes the FlexCAN_A RAM to avoid ECC errors
2. Uses message buffers in FlexCAN_A for program stack and variables
3. Polls the `SIU_RSR[XOSC]` bit until it indicates that the oscillator has locked
4. Switches the clock source to the crystal oscillator by setting `SIU_SYSDIV[SYSCLKSEL] = 0x1`
5. Disables the core watchdog timer and sets the SWT timeout period to 2.5×2^{27} cycles
6. Waits for the host to send a 64-bit password by either the CAN or SCI
7. Receives start address, size of download code in bytes, and VLE bit
8. Receives the application code data
9. Disables the SWT and enables the core watchdog timer with a timeout period of 2.5×2^{28} CPU clock cycles
10. Branches to the loaded code at the start address

The MMU setup depends on how the BAM entered serial boot mode. If it attempted to boot from the development bus but switched to serial boot because it could not find a valid RCHW in Flash, the MMU is set up as for that mode (see [Table 51-13](#)). Otherwise, the MMU setup matches [Table 51-2](#).

Serial boot mode can run in two modes, depending on the state of the SIU_RSR[ABR] bit:

- Standard serial boot mode—fixed baud rates derived from the MCU system frequency. EVTO pin is kept high during reset.
- Baud Rate Detection serial boot mode—allows communication with adaptable speed, based on measured baud rate of the host transmission. EVTO pin has to be driven low for this mode.

In enhanced mode, the SIU_RSR[ABR] bit is loaded from the ABR bit of the Miscellaneous DCF record. In legacy mode, the latching of the EVTO pin status in the SIU_RSR register is done following ways:

- If no debug tool is attached, then the state of EVTO pin is latched upon negation of system reset
- If a debug tool, using EVTO pin, is attached, the state of EVTO pin is latched upon enabling the Nexus module

The EVTO pin is pulled up by an internal pull-up. Actively driven low EVTO pin selects the Baud Rate Detection mode.

When Fixed Baud Rate mode is selected, the BAM program configures the RXD_A pin to be the input of the eSCI_A module, CNRX_A pin as an input and CNTX_A as an output of the CAN_A module. When Baud Rate Detection Mode is selected, the BAM program configures RXD_A and CNRX_A pins as GPI inputs for polling their state by the CPU.

The SCI and CAN controller pin configuration summaries are shown in [Table 51-8](#).

Table 51-8. CAN/eSCI pin configuration for CAN/eSCI fixed baud rate boot modes

Pins	Reset Function	Initial Serial Boot Mode		Serial Boot Mode after a valid CAN message received		Serial Boot Mode after a valid eSCI message received	
		Function	Pad Configuration	Function	Pad Configuration	Function	Pad Configuration
CNTX_A	GPIO	CNTX_A	Push/Pull output, with medium slew rate	CNTX_A	Push/Pull output, with medium slew rate	GPIO	—
CNRX_A	GPIO	CNRX_A	Input with pullup and hysteresis	CNRX_A	Input with pullup and hysteresis	GPIO	—
TXD_A	GPIO	GPIO	—	GPIO	—	TXD_A	Push/Pull output, with medium slew rate
RXD_A	GPIO	RXD_A	Input with pullup and hysteresis	GPIO	—	RXD_A	Input with pullup and hysteresis

The BAM configures the communication modules for reception with fixed baud rates as shown in [Table 51-9](#) and then waits for data reception. The watchdog timers are configured as shown in [Table 51-10](#).

Table 51-9. Serial boot fixed baud rates

Crystal frequency (MHz)	Peripheral clock frequency (MHz)	Desired SCI baud rate (baud)	Actual SCI baud rate (baud)	CAN baud rate ¹ (baud)
f_{xtal}	$f_{per} = 0.5 \times f_{xtal}$	—	$f_{per} \div 416$ ²	$f_{per} \div 40$ ³
8	4	9600	9615	100K
12	6	14400	14423	150K
16	8	19200	19230	200K
20	10	24000	24038	250K
40	20	48000	48076	500K

1. The CAN engine is clocked by the system clock.
2. The transmitter clock frequency, which is denoted by the bit time, is determined by the equation $f_{CLK} = f_{sys} \div (16 \times SBR) = SCI_{BaudRate}$ where SBR is a constant defined on BAM code to provide the correct baud rate.
3. The Baud Rate Division Factor is defined as $BRF = (PRES DIV + 1) \times \text{Number of Time Quanta}$, where the number of time quanta is dependent on the SYN_REG, Time Segment 1, and Time Segment 2 constants. See [Figure 51-2](#).

Table 51-10. Watchdog timeout settings for serial boot

Core WD		SWT	
Clock source	Condition	Clock source	Condition
XOSC $\div$ 2 4–20 MHz	Disabled during boot Enabled after boot Timeout = 2.5×2^{28} cycles	IRC 16 MHz	Enabled during boot Disabled after boot Timeout = 2.5×2^{27} cycles

If a message containing 8 bytes with ID 0x11 is received by the CAN controller first, the BAM program:

- Transitions to serial CAN boot mode
- Disables the eSCI
- Configures RXD_A to its reset state
- Transitions to the CAN serial download protocol routine

If a byte from eSCI is received first, the BAM program:

- Transitions to the Serial SCI Boot sub-mode
- Disables CAN_A module
- Configures CAN_A's pins to their reset state
- Transitions to the SCI serial download protocol routine

51.5.5.1 CAN controller configuration in fixed baud rate mode

The CAN controller is configured to operate at a baud rate equal to system frequency divided by 40, using the standard 11-bit identifier format detailed in the CAN 2.0A specification. See [Table 51-9](#) for examples of baud rates. Only one message buffer 0 is used for all communications.

The bit timing is configured as shown in the following figure.

Note: 1 Time quanta = 4 System clock periods

Figure 51-2. CAN bit timing

The BAM program ignores CAN errors and all received messages are assumed to be good. Received messages are transmitted back. The host processor must compare the MCU transmissions with the sent data and restart the process if an error is detected.

51.5.5.2 SCI controller configuration in fixed baud rate mode

The eSCI is configured for 1 start bit, 8 data bits, no parity, 1 stop bit and operates at a baud rate equal to system clock divided by 416. See [Table 51-9](#) for examples of baud rates.

The BAM program ignores the eSCI errors. All data received is assumed to be good and is sent back through the TXD pin. The host processor must compare the MCU transmitted data with the sent data and restart the process if an error is detected.

51.5.5.3 Serial boot mode download protocol

The download protocol follows four steps:

1. Host sends 64-bit password.
2. Host sends start address, size of download code in bytes, and VLE bit.
3. Host sends the application code data.

4. The MCU switches to the loaded code at the start address.

The communication is done in half-duplex manner; any transmission from host is followed by the MCU transmission. The host computer should not send data until it receives echo from the MCU. All multi-byte data structures must be sent most-significant byte (MSB) first.

When the CAN is used for serial download, the data is packed into standard CAN messages in the following manner:

- A message with 0x11 ID and 8-byte length to send the password. The MCU transmits back the same data, but with ID of 0x1.
- A message with 0x12 ID and 8-byte length to send the start address, length, and the VLE mode bit. The MCU transmits back the same data, but with ID of 0x2.
- Messages with 0x13 ID are used to send the downloaded data. The MCU transmits back the same data with ID of 0x3.

When the SCI is used for serial download, the data must be sent on a byte-by-byte basis. The MCU transmits back the received bytes.

NOTE

Since the MCU starts up with the system clock derived from the Internal RC Oscillator (IRC), it does not wait for the crystal oscillator to stabilize before finishing the reset sequence and negating the $\overline{\text{RTSTOUT}}$ pin. The BAM program starts executing with the IRC clock, but it needs to switch to the crystal oscillator (XOSC) clock in case of serial boot. Before switching to the XOSC clock, the BAM program waits for the SIU_RSR[XOSC] bit to be asserted, which is an indication that the crystal oscillator has settled. As a consequence, the external device that will upload the serial code needs to wait enough time after $\overline{\text{RSTOUT}}$ negates to allow the crystal oscillator to stabilize. The exact time depends on the crystal used, but is typically less than 10 ms. On the other hand, the code must be uploaded before the SWT timeout expires. The SWT timeout is 21 seconds.

51.5.5.4 Download protocol execution

The BAM program executes the serial boot according to the following steps:

1. Download 64-bit password.
 - The received 8-byte password is checked for validity. For a password to be valid, none of its four 16-bit half words must equal 0x0000 or 0xFFFF.
 - The password is compared to the fixed value of 0xFEED_FACE_CAFE_BEEF.

- If the password check fails, the MCU stops responding. Assert RESET to force the MCU out of this state.
 - If the password check passes, the BAM transitions to the next step in the protocol.
2. Download start address, size of download, and VLE bit.

The BAM considers the next 8 bytes to contain a 32-bit start address, the VLE mode bit, and a 31-bit code length, as shown below.

- START_ADDRESS defines where the received data is stored and where the MCU branches after the download is finished. The two least significant bits of the start address are ignored by the BAM program, thus the loaded code should be 32-bit word aligned.
 - CODE_LENGTH defines how many data bytes to be loaded.
 - VLE instructs the MCU to program MMU entries 1–3 with VLE attribute. If it is 1, the downloaded code must be compiled to VLE instructions, if it is 0 the code contains classic Power Book E architecture instructions.
3. Download data.

Each byte of data received is stored in the MCU memory, starting at the START_ADDRESS specified in the previous step. The data increments through memory until the number of bytes stored matches CODE_LENGTH specified in the previous step.

The BAM program buffers incoming data, collecting up to 8 bytes. The buffered data is written to the RAM with 64-bit writes to prevent ECC errors, which may happen if the MCU RAM is protected by 64-bit ECC code.

Once the buffered data is written to the RAM, the BAM program refreshes the SWT.

NOTE

Only system RAM supports 64-bit writes; therefore, attempting to download data to other RAM apart from system RAM causes errors.

If the start address of the downloaded data is not on an 8-byte boundary, the BAM writes 0x0 to the memory locations from the proceeding 8-byte boundary to the start address (maximum 4 bytes). The BAM also writes 0x0 to all memory locations from the last byte of data downloaded to the following 8 byte boundary (maximum 7 bytes). An additional 8 zero bytes are written to prevent possible ECC errors that may be caused by the CPU pre-fetching.

4. Switch to the loaded code.

The BAM program waits for the last echo message transmission to complete, then the active communication controller is disabled. Its pins revert to GPIO inputs.

To provide compatibility with older devices, the BAM:

- Writes the core's time base registers (TBU and TBL) with 0x0
- Enables the core watchdog to cause a reset after a timeout period of 2.5×2^{28} CPU clock cycles
- Disables software watchdog (SWT)

The BAM code passes control to the loaded code at START_ADDRESS, which was received in step 2 of the protocol.

NOTE

The loaded code must periodically refresh the core watchdog timer or change the timeout period to a value that does not cause resets during normal operation.

51.5.5.5 Baud rate detection procedure

When SIU_RSR[ABR] is set, the BAM program enters into Baud Rate Detection mode.

The following additional steps are taken:

1. The baud rate detection routine is copied to the beginning of the system RAM from the BAM ROM to improve baud rate detection accuracy.
2. The CPU branches to the RAM.
3. The MCU configures the CNRX_A and RXD_A pins as general purpose inputs.
4. The MCU polls these GPIs until one of them goes low.

- If the CNRX_A pin transitions first, the BAM program starts CAN baud rate detection routine, ignoring RXD_A. After detecting the CAN baud rate, the BAM program transitions to the CAN download protocol routine described above.
- If the RXD_A pin transitions first, the SCI baud rate detection and download protocol routines are called, ignoring any further CAN pins activity.

The host, executing the serial boot, should send a test frame so that the MCU can detect the host communication speed. When booting through the SCI, the host should send a zero byte as the test frame. When booting through the CAN, the host should send zero ID, zero length message as the test frame.

51.5.5.5.1 SCI baud rate detection

The host must send a zero byte to allow the MCU to detect the serial link baud rate. The host transmits one start bit, eight zero data bits, and one stop bit (the MCU does not echo it).

The MCU polls the RXD_A pin for high-to-low transition and starts the e200 core Time Base counter (TB). Then the MCU polls for low-to-high transition on the pin and when it happens, the MCU turns off the TB counter. The TB content is used to calculate incoming signal baud-rate. The SCI baud rate is equal to the TB content divided by 288. (Measured over 9 bits with 16 system clocks per bit and the core frequency is two times higher than system frequency).

51.5.5.6 CAN baud rate detection

The host transmits a zero length message with zero 11 bit ID and MCU measures time over 40 bits, polling CNRX_A pin for high and low, according to the sent data. The MCU does not acknowledge this message.

The CAN baud rate depends on the number of quantas per bit and serial clock frequency, which is defined by a prescaler. The CAN baud rate detection routine selects these parameters to maximize number of quantas per bit and achieve minimum difference between measured value and duration of the 40 CAN bits, to be programmed with selected pair of the parameters.

The CAN controller can be programmed with 8 to 25 number of quantas per bit. The bit timing parameters, which can be selected by the baud rate detection routine, are shown in the table below.

Table 51-11. Lookup table for CAN bit timing

Time quanta per bit	Time segment 1		Time Segment 2	RJW
	PROPSEG	PSEG1	PSEG2	
8	1	3	3	2
9	2	3	3	2
10	3	3	3	2
11	4	3	3	2
12	3	4	4	2
13	4	4	4	3
14	5	4	4	3
15	6	4	4	4
16	7	4	4	3
17	8	4	4	3
18	7	5	5	4
19	8	5	5	4
20	7	6	6	4
21	8	6	6	4
22	7	6	6	4
23	8	6	6	4
24	7	7	7	4
25	8	7	7	4

Maximum and minimum speeds of the serial communication modules are defined by the MCU system frequency and shown in the table below.

Table 51-12. Maximum and minimum detectable baud rates (crystal oscillator as reference clock source)

F_{xtal} (MHz)	$F_{sys} = 0.5 \times F_{xtal}$ (MHz)	Max baud rate for CAN ¹ (bps)	Min CAN baud rate ($F_{sys}/25/256$) (bps)	Max baud rate for SCI ($F_{sys}/160$) (bps)	Min baud rate for SCI ($F_{sys}/160/2^{13}$) (bps)
8	4	1M	625	25K	3.0
12	6		937.5	37.5K	4.6
16	8		1250	50K	6.1
20	10		1562.5	62.5K	7.6
40	20		3125	125K	15.2

1. Limited by 1 Mbps by CAN standard.

51.5.6 Booting from the development bus

If the MCU boots in one of the Development Bus boot modes, the BAM program:

- Reprograms the MMU entries for EBI and internal flash (see [Table 51-13](#))
- Sets up the EBI and development bus pins
- Tries to read RCHW from logical address 0x2000_0000

If the valid RCHW is read from that address, the BAM program:

- Reads the user application code start address from 0x2000_0004 address
- Parses RCHW
- Sets up watchdogs
- Updates EBI, SRAM, and internal flash MMU entries (1–3), according to RCHW[VLE]
- Passes control to the user code

If no valid RCHW was read, BAM switches to serial boot mode.

Table 51-13. MMU configuration for development bus boot modes

TBL entry	Region	Logical base address	Physical base address	Size	Attributes
1	Internal flash	0x0000_0000	0x2000_0000	16 MB	Not guarded
					Big endian
					Global PID
2	EBI	0x2000_0000	0x2000_0000	16 MB	Not guarded
					Big endian
					Global PID

51.5.6.1 EBI configuration for separate address and data development bus boot mode

The BAM program sets up EBI related registers as shown in the table below.

Table 51-14. Development bus/EBI register settings for separate address data lines mode

Register	Function	Value	Comments
EBI_CAL_BR0	—	0x2000_0803	Sets the base address to 0x2000_0000, 16-bit wide bus, burst Inhibit
EBI_CAL_OR0	—	0xFF80_00F0	Set 15 wait states, 8MB

Table continues on the next page...

Table 51-14. Development bus/EBI register settings for separate address data lines mode (continued)

Register	Function	Value	Comments
SIU_PCR259–SIU_PCR293	D_ADD[12:30], D_ADD_DAT[0:15]	0x0440	Set pads to 20pf drive strength
SIU_PCR305–SIU_PCR307	D_ADD[9:11]		
SIU_PCR256	D_CS0	0x443	Set pads to 20pf drive strength and pull-up enable
SIU_PCR295	D_WE0		
SIU_PCR297	D_OE		
SIU_PCR298	D_TS		

RCHW[PS0] must be programmed to 1, since the development bus does not support 32-bit port size in that sub-mode.

51.5.6.2 EBI configuration for multiplexed address and data development bus boot mode

The BAM program sets up EBI related registers as shown in the table below.

Table 51-15. Development bus/EBI register settings multiplexed mode

Register	Function	Value	Comments
The following registers are programmed when RCHW[PS0] = 1			
EBI_MCR	—	0x0000_0806	AD multiplexed mode, small port size use D16–31
EBI_CAL_BR0	—	0x2000_0883	Sets the base address to 0x2000_0000,16-bit wide bus, AD multiplexed mode, burst Inhibit
EBI_CAL_OR0	—	0xFF80_00F0	Set 15 wait states, 8 MB
SIU_PCR259–SIU_PCR262	D_ADD[12:15],	0x440	Set pads to 20 pf drive strength
SIU_PCR305–SIU_PCR307	D_ADD[9:11]		
SIU_PCR263–SIU_PCR277	D_ADD_DAT[16:30]	0x840	Set pads to 20 pf drive strength
SIU_PCR257	D_ADD_DAT[31]		
SIU_PCR278–SIU_PCR293	D_ADD_DAT[0:15]	0x440	Set pads to 20 pf drive strength
SIU_PCR256	D_CS0	0x443	Set pads to 20 pf drive strength and pullup enable
SIU_PCR295	D_WE0		
SIU_PCR297	D_OE		
SIU_PCR298	D_TS		
SIU_PCR299	D_ALE		
The following register is reprogrammed when RCHW[PS0] = 0			
EBI_CAL_BR0	—	0x2000_0083	Sets the base address to 0x2000_0000,32-bit wide bus, AD multiplexed mode, burst Inhibit

If the boot memory device is 32 bits wide, the RCHW must be programmed in two first half-words of the memory because when the MCU tries to read RCHW, the EBI is configured to use data lines 16–31 for 16-bit port accesses.

Chapter 52

System Status and Configuration Module (SSCM)

52.1 Chip-specific SSCM information

This chip has one instance of the SSCM. The SSCM is part of the reset and boot subsystem.

52.1.1 SSCM and UTEST flash memory

The SSCM loads data stored in multiple locations of the UTEST portion of flash memory.

52.1.1.1 Life Cycle (LC) slots

To determine the chip's Life Cycle status, the SSCM reads and interprets the LC slots according to the [Life Cycle](#) information. The SSCM_LCSTAT[LC] field presents the results of the determination. The following table shows the LC slots' locations in UTEST flash memory.

Table 52-1. Life Cycle slots in UTEST flash memory

Start address	End address	Bytes	Description
0040_0200h	0040_020Fh	16	Life Cycle slot 0 - MCU Production
0040_0210h	0040_021Fh	16	Life Cycle slot 1 - Customer Delivery
0040_0220h	0040_022Fh	16	Life Cycle slot 2 - OEM Production
0040_0230h	0040_023Fh	16	Life Cycle slot 3 - In Field
0040_0240h	0040_024Fh	16	Life Cycle slot 4 - Failure Analysis

52.1.1.2 System configuration data in DCF records and UTEST_OFFSET location

Some DCF records in UTEST flash memory store data for system configuration. The SSCM scans these DCF records to provide information about the current state and configuration of the system.

On this chip, the UTEST_OFFSET location at which the SSCM looks for DCF records is 0040_0300h.

The following table summarizes these records. See the DCF Records chapter for additional details.

Table 52-2. DCF records in UTEST flash memory scanned by SSCM

Address	Purpose
0040_0300h	STCU2 configuration
	PASS configuration
	Tamper Detect configuration
	Miscellaneous configurations, such as boot mode

52.1.1.3 Sources of errors flagged by SSCM_STATUS[CER]

When set to 1, the CER field in the SSCM System Status (SSCM_STATUS) register indicates that the SSCM has detected a configuration error during reset while loading initial system configuration.

On this chip, this field is set to 1 in these cases:

- When the process of loading any STCU2 DCF record encounters one of the conditions that generates a transfer error listed in the STCU2's IPS bus interface description
- When a DCF record that has the parity attribute is loaded without parity alignment

For a list of DCF clients and the corresponding DCF records on this chip, see Table 5-6.

52.1.2 SSCM security reset and LC state

The SSCM provides a security mechanism to prevent device manipulation while loading the configuration data from dedicated slots in UTEST flash memory.

The SSCM ensures that the Life Cycle slots are correctly programmed and that at least one LC slot is valid. The Life Cycle state can only progress forward. Any attempt to move the LC state backward causes a security reset. This reset occurs in the cases where "System Reset" is the result of the scenarios in [Table 52-14](#).

52.1.3 SSCM_ERROR[PAE] and abort responses to illegal accesses

The SSCM_ERROR register's PAE field controls the abort responses to some illegal accesses to off-platform peripherals.

NOTE

This field has no effect on on-platform peripherals or on peripheral slots that are not allocated.

PAE, when set to 1, generates a transfer error in either of these cases of illegal accesses:

- The CPU tries to access any non-existing peripheral.
- The global module enable memory space is accessed.

Regardless of the PAE field, these cases always generate a transfer error:

- An access is attempted to a halted off-platform module.
- An accessed off-platform peripheral reports a transfer error.

52.2 Introduction

52.2.1 Overview

The System Status and Configuration Module (SSCM) is pictured in the figure below.

Figure 52-1. SSCM block diagram

52.2.2 Glossary

The table below shows a glossary of terms used through out the text.

Table 52-3. Glossary

Term	Definition
0011b	Binary numbers
0Fh	Hexadecimal numbers
Pin	External physical connection.
Signal	Electronic construct whose state or change in state conveys information.
X	In certain contexts, such as a signal encoding, this indicates a don't care. For example, if a field is binary coded X001b, the state of the first bit is a don't care.
y	y is used for a place holder of 1 hex digit for unknown values.

52.2.3 Features

The SSCM includes these distinct features:

- System Configuration and Status

- Device Mode and System Status
- Decodes the Device Life Cycle
- Peripheral abort enable/disable

52.2.4 Modes of operation

The SSCM operates identically in all system modes.

52.3 External signal description

The SSCM has no external pins.

52.4 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the SSCM.

The table below shows the memory map for the SSCM. Note that all addresses are offsets; the absolute address may be calculated by adding the specified offset to the base address of the SSCM.

NOTE

All registers are accessible via 8-bit, 16-bit or 32-bit reads and/or writes. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries. As an example, the STATUS register is accessible by a 16-bit read or write, SSCM Base + 02h, but performing a 16-bit access to SSCM Base + 0003h is illegal (that is, you should not make any transfer that is not aligned to burst size boundary).

NOTE

SSCM does not generate transfer errors in all memory holes.

NOTE

Reserved IPS register access is prohibited.

SSCM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SSCM System Status (SSCM_STATUS)	16	R	See section	52.4.1/2776
6	SSCM Error Configuration Register (SSCM_ERROR)	16	R/W	0000h	52.4.2/2778
34	Life Cycle Status Register (SSCM_LCSTAT)	32	R	See section	52.4.3/2779

52.4.1 SSCM System Status (SSCM_STATUS)

The System Status register reflects the current state of the system.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7
Read	0	CER	MER	NXEN1	NXEN	1	Reserved	0
Write		w1c	w1c					
Reset	0	0	0	*	*	1	*	0
Bit	8	9	10	11	12	13	14	15
Read	Reserved			1	0	0	0	
Write								
Reset	*	*	*	1	0	0	0	0

* Notes:

- Reserved field: Each bit of this field can reset to 0 or 1.
- Reserved field: This field can reset to 0 or 1.
- NXEN field: Reset value depends on the device status after leaving reset.
- NXEN1 field: Reset value depends on the device status after leaving reset..

SSCM_STATUS field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 CER	Configuration Error This field indicates that the SSCM has detected a configuration error during reset while loading initial device configuration. See the chip-specific SSCM information for details about sources of the error. If a non-permanent error is detected, this bit can be cleared by writing a 1. 0 No configuration problem detected by the SSCM 1 Device configuration is not correct
2 MER	Memory Configuration Error This field indicates that the SSCM has received notification of a memory configuration error. This error may have been detected during the reset sequence.

Table continues on the next page...

SSCM_STATUS field descriptions (continued)

Field	Description
	If a detected error is not permanent, this field can be cleared by writing 1 to it. 0 No memory configuration problem detected by the SSCM 1 Device memory configuration is not correct
3 NXEN1	Processor 1 Nexus enable status 0 Processor 1 Nexus disabled. 1 Processor 1 Nexus enabled
4 NXEN	Processor 0 Nexus enable status 0 Processor 0 Nexus disabled. 1 Processor 0 Nexus enabled
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
6 Reserved	This field is reserved. This field is for internal use. Users should ignore read values and should not attempt to write the field.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–10 Reserved	This field is reserved. This field is for internal use. Users should ignore read values and should not attempt to write the field.
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

52.4.2 SSCM Error Configuration Register (SSCM_ERROR)

The Error Configuration register is a read-write register that controls the error handling of the system.

Address: 0h base + 6h offset = 6h

Bit	0	1	2	3	4	5	6	7
Read	0							
Write								
Reset	0	0	0	0	0	0	0	0
Bit	8	9	10	11	12	13	14	15
Read	0						PAE	Reserved
Write								
Reset	0	0	0	0	0	0	0	0

SSCM_ERROR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 PAE	Peripheral Bus Abort Enable. This bit enables bus aborts on: - any access to a peripheral slot that is not used on the device. - This feature is intended to aid in debugging when developing application code. - illegal accesses to off-platform peripherals. - On platform peripherals cannot be controlled by SSCM peripheral abort. 0 Illegal accesses to non-existing peripherals do not produce a Prefetch or Data Abort exception 1 Illegal accesses to non-existing peripherals produce a Prefetch or Data Abort exception
15 Reserved	This field is reserved.

52.4.3 Life Cycle Status Register (SSCM_LCSTAT)

Address: 0h base + 34h offset = 34h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0						Reserved		0						LC	
W																
Reset	0	0	0	0	0	0	*	*	0	0	0	0	0	*	*	*

* Notes:

- LC field: Reset value is the Life Cycle of the device, and is unaffected by reset.
- Reserved field: Reset Value is '11' for a valid secured part.

SSCM_LCSTAT field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 Reserved	This field is reserved.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 LC	Life Cycle Determined by the SSCM by reading the LC slots. The encoding is: 000 Failure Analysis 001 Reserved 010 OEM Production 011 Customer Delivery 100 Reserved 101 Reserved 110 MCU Production 111 In Field

52.5 Functional description

The primary purpose of the SSCM is to provide information about the current state and configuration of the system that may be useful for configuring application software and for debug of the system.

52.5.1 DCF mechanism

The DCF mechanism has been developed to handle settings of device parameters via OTP flash memory.

Starting at location UTEST_OFFSET the user can store a series of DCF records - the device will process these records during the system reset sequence before the CPU leaves reset. The first record needs to be a start record followed by an application-specific number of data records as required, and finally a stop record.

Each record is 64 bits in length. [Table 52-8](#) shows the DCF start record. The start record must be placed at UTEST_OFFSET to indicate to the device that the following data records should be processed.

Table 52-8. DCF start record

0:31
05AA 55AFh
0:31
0000 0000h

The data records are structured similar to a CPU write instruction - 15 bits of client select, 15 bits of address, 32 bits of payload data plus a STOP bit - See [Table 52-9](#). In a data record the STOP bit must always be programmed to 0. Some clients support a parity bit.

Table 52-9. Format of a DCF data record

0:31			
WDATA[31:0]			
0:14	15:29	30	31
CS[14:0]	ADDR[16:2]	PRTY	STOP

The stop record indicates that processing should stop. The general format of the stop record is shown in [Table 52-10](#). Only the STOP bit needs to be 1 in order to form a stop record – All other bits are ignored. An unprogrammed location in UTEST flash will be interpreted as a stop record.

Table 52-10. DCF stop record

0:30	31
rsvd	1

Table continues on the next page...

Table 52-10. DCF stop record (continued)

0:31
rsvd

If n data records are to be stored in UTEST, the data structure must be as shown in [Table 52-11](#).

Table 52-11. Series of DCF records in UTEST

ADDR offset	DATA			
00h	05AA 55AFh			
04h	0000 0000h			STOP=0
08h	WDATA[31:0]			
0Ch	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
10h	WDATA[31:0]			
14h	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
...	...			
$8n - 1 + 0h$	reserved			
$8n - 1 + 4h$	reserved			1
$8n + 0h$				
$8n + 4h$				

There must never be an unprogrammed record in the data structure, as that would be interpreted as a stop record, so subsequent records would be ignored. This allows programming the records in several sessions, each time appending new records at the end of the list, as shown in [Figure 52-5](#).

**Figure 52-5. Appending DCF records**

In this case, a record may overwrite a client's value which was already set by a previous record. However whether such an operation is allowed depends on the rules given for the client - some clients are write-once, only allow setting bits but not clearing, and so on.

The parity bit (PRTY) is required for some DCF records. The parity scheme used is even parity, so the number of 1s in the WDATA and PRTY fields needs to be even. (For example, if the WDATA field has the value 0000_0001h then the PRTY field needs to be set to 1, so that the total number of 1s is even.)

NOTE

When programming DCF records, ensure that programming is not interrupted and can complete without error.

52.5.2 Life Cycle

The SSCM will determine the Life Cycle (LC) of the device by reading the LC slots from the UTEST flash memory. The read operation is done during the reset phase with normal timings and it is protected by operating monitors. In addition, a set of sanity checks executed over the LC read data guarantee the integrity of the final LC value.

At the end of the reset phase, the LC can have one of the following values:

- MCU Production
- Customer Delivery
- OEM Production
- In Field
- Failure Analysis

Life cycle can only be moved in the direction shown below:

Figure 52-6. Life cycle sequence

The LC is written into 5 slots, 128 bits each, at fixed locations in the UTEST flash memory block. Each LC slot is read in one single atomic operation and it is organized into two fields:

- the valid field
- the invalid field

Depending on the possible combination of the data programmed into these fields, each LC slot can have one of the possible 4 statuses as seen in [Table 52-12](#).

Table 52-12. LC slot status

LC slots		LC slot value
Valid field (64 bits)	Invalid field (64 bits)	
Erased	Erased	Erased
Marked	Erased	Active
Marked	Marked	Inactive
Any other values		Illegal

"Marked" in this case means that the value has been programmed with the bit pattern 55AA_50AF_55AA_50AFh. "Erased" is detected by the bit pattern FFFF_FFFF_FFFF_FFFFh. [Table 52-13](#) shows how the slots are arranged in memory.

Table 52-13. LC slots in memory

Offset	LC slot word
00h	Valid[31:0]
04h	Valid[63:32]
08h	Invalid[31:0]
0Ch	Invalid[63:32]

The Life Cycle is determined as shown in [Table 52-14](#)

NOTE

"Erased" means the slot returns all 1s.

Table 52-14. LC slots

LC slot 0 MCU Production	LC slot 1 Customer Delivery	LC slot 2 OEM Production	LC slot 3 In Field	LC slot 4 Failure Analysis	Resulting life cycle
Active	Erased	Erased	Erased	Erased	MCU Production
Inactive	Active	Erased	Erased	Erased	Customer Delivery
Inactive	Inactive	Active	Erased	Erased	OEM Production
Inactive	Inactive	Inactive	Active	Erased	In Field
Inactive	Inactive	Inactive	Inactive	Active	Failure Analysis
Erased	Erased	Erased	Erased	Erased	System Reset
Illegal ¹	Illegal	Illegal	Illegal	Erased	In Field

1. Any value programmed other than shown in table above for Erased, Active, and Inactive would be treated as illegal.

NOTE

When programming Life Cycle, ensure that programming is not interrupted and can complete without error.

NOTE

Any other combination of values will result in a system reset.

NOTE

No one should program “ILLEGAL” even if able to do that.
Device behavior is not guaranteed for these combinations.

52.6 Initialization and application information

52.6.1 Reset

The reset state of each individual bit appears in the detailed register descriptions.

52.7 Additional safety measures

52.7.1 Spurious reset protection

The SSCM implements protection against spurious module resets (for example, resets which only effect the SSCM, but not other modules) by gating the state machines status with the expected status of the system reset controller logic. If a spurious reset occurs, the SSCM will not interfere with the flash memory bus or overwrite configuration registers. However, internal SSCM status will be lost.

Chapter 53

Power Management

53.1 Overview

The MPC5777C microcontroller includes a robust power management infrastructure that enables applications to select among various operational modes and to monitor internal voltages for high- and low-voltage conditions. The monitoring capability is also used to ensure supply voltages and internal voltages are within the required ranges before the microcontroller can leave RESET.

The power management infrastructure consists of a Power Management Unit (PMU), which itself consists of a digital portion and an analog portion of a Power Management Controller (PMC).

Figure 53-1. Power management overview

For details about any module, see the chapter dedicated to the module.

53.2 Functional description

The analog portion of the PMC provides a linear voltage regulator (LDO) and a switching mode regulator (SMPS) to generate the internal digital core supply and monitors various internal regulating points and supply voltages of the chip for functional safety purposes. The analog portion of the PMC includes an additional regulator for the flash memory block to provide the necessary 3.3 V source to the flash memory module.

The digital portion of the PMC contains the registers and digital logic to generate a power-on reset (POR) in response to particular voltage detection (VD) events and to execute a self test of the analog block. The PMC digital logic also contains the controls for PMC analog outputs to be sensed with the ADC module. In addition, the PMC digital logic contains the enable signals and other register controls for the Temperature Sensor modules.

The PMC connects to the Fault Collection and Control Unit (FCCU) and the flash memory controller. The on-chip ADCs receive signals from the PMC for diagnostic purposes.

53.3 Power modes

MPC5777C does not support ultra-low power modes that require power gating or separate power domains. The core logic implements stop and low frequency power saving modes, which may result in core current steps. To avoid undershoots or overshoots that trigger LVD or HVD events, ramp frequency changes smoothly.

53.4 External supply

The chip provides a bypass option that allows the core supply and flash memory supply to be supplied from an external source.

53.5 Power management supply description

See the product Data Sheet for supply descriptions.

53.6 Voltage monitoring

The PMC senses functional reset and supply voltages continuously to keep the chip in a safe operating range. When the voltage exceeds or falls below the limits defined by recommended electrical operating conditions, the PMC triggers a reset or, alternatively, an interrupt. See the PMC_REE and PMC_LVD_HVD_INTR_ENB registers' descriptions for more information.

Chapter 54

Power Management Controller (PMC)

54.1 Introduction

The Power Management Controller (PMC) consists of two blocks: an analog power management block and a digital controller for the analog block.

The PMC digital controller contains the registers and digital logic to generate a POR in response to voltage-threshold events detected by the analog block. The PMC digital logic also contains:

- the controls for PMC analog outputs to be sensed with the ADC module.
- the enable signals and other registers for the Temperature Sensors.

NOTE

Temperature Sensor 0 and Temperature Sensor 1 each monitor two temperatures: temperature 0 refers to -40°C , and temperature 2 refers to 150°C . Register field notation such as TEMP1_0 designates Temperature Sensor 1's monitoring of temperature 0, or -40°C .

54.1.1 Features

The PMC module provides:

- 16 MHz clock frequency
- 32-bit IPS bus interface
- Memory-mapped configuration, control, and status registers
- Built-in self test for LVD and HVD during non-functional User mode

- Automatic loading of factory-defined trim/control information during POR for HVDs, LVDs, regulators, and voltage bandgap (via the DCF interface)
- Automatic loading of factory-defined trim configuration and control information to the analog PMC block
- Configuration and monitoring of the two Temperature Sensors
- Interrupt or POR generation for HVDs and LVDs (based on the configuration)
 - Option to generate interrupt, POR, or no action in response to:
 - LVD_CORE_COLD
 - HVD_CORE
 - HVD_HV
 - HVD_FLASH
 - Automatic POR generation (except during PMC self test) in response to:
 - POR098_c
 - LVD_CORE_HOT
 - POR_HV
 - LVD_HV
 - LVD_FLASH
 - LVD_IO
- Interrupt or POR generation for Temperature Sensors (based on the configuration)
- Fault injection to the FCCU for LVDs, HVDs, Temperature Sensors, and self test via IPS interface
- Precision LVD (low-voltage detection) and HVD (high-voltage detection)
- Bandgap voltage reference for:
 - LVDs and HVDs
 - ADC voltage reference channel
- FCCU: Software-triggered fault injection for LVDs, HVDs, Temperature Sensors, and LVD self test
- Self test logic for the LVDs and HVDs

54.2 Memory Map and Registers

Attempts to access 32-bit spaces starting at offset D4h result in a transfer error.

For *undocumented* 32-bit spaces at offsets lower than D4h:

- The reset value of the 32-bit space at offset B0h is 0000_0080h.
- The reset value of every other 32-bit space is 0000_0000h.
- Reads of and writes to these locations do not generate a transfer error, but the locations are reserved. Any writes to these locations must write the reset value.

54.2.1 Temperature Sensor Interrupt Enable Register (PMC_TS_IER)

This configuration register contains a set of Interrupt Enable bits, each of which corresponds to a bit in the Temperature Event Status Register (ESR_TD). These bits indicate whether an interrupt occurs when the temperature event occurs. A 0 indicates that no interrupt is to be sent, and a 1 indicates that an interrupt is to occur when the detected temperature event occurs. Enable these bits by writing 1 to the TS_EN field of this register. After TS_EN is 1, this register's Interrupt Enable bits can be read or written at any time.

Address: 0h base + 88h offset = 88h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	TS_EN	0														
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PMC_TS_IER field descriptions

Field	Description
0 TS_EN	Temperature Sensor interrupts Enable 0 Temperature sensor interrupts are not enabled. 1 Enable temperature sensor interrupts.
1–25 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
26 Reserved	Reserved This field is reserved.
27 TS1_2IE	Temperature Sensor 1 input 2 Interrupt Enable This bit determines whether an interrupt is seen by the system when the temperature rises above its corresponding threshold (flag 2).

Table continues on the next page...

PMC_TS_IER field descriptions (continued)

Field	Description
	0 No interrupt. 1 Interrupt occurs.
28 TS1_0IE	Temperature Sensor 1 input 0 Interrupt Enable This bit determines whether an interrupt is seen by the system when the temperature falls below its corresponding threshold. 0 No interrupt. 1 Interrupt occurs.
29 Reserved	Reserved This field is reserved.
30 TS0_2IE	Temperature Sensor 0 input 2 Interrupt Enable This bit determines whether an interrupt is seen by the system when the temperature rises above its corresponding threshold (flag 2). 0 No interrupt. 1 Interrupt occurs.
31 TS0_0IE	Temperature Sensor 0 input 0 Interrupt Enable This bit determines whether an interrupt is seen by the system when the temperature falls below its corresponding threshold. 0 No interrupt. 1 Interrupt occurs.

54.2.2 Temperature Event Status Register (PMC_ESR_TD)

This register indicates the state of the two Temperature Sensor modules' signals. When a temperature event occurs, the corresponding flag bit sets to 1. To clear a flag bit to 0, write 1 to it.

Address: 0h base + 8Ch offset = 8Ch

PMC_ESR_TD field descriptions

Field	Description
0–25 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
26 Reserved	Reserved This field is reserved.
27 TEMP1_2	Temperature Sensor 1 event flag 2 This bit is associated with the temperature for the high temperature sensor 2 point (150°C). It sets to 1 when the temperature exceeds its corresponding threshold, and it clears to 0 when 1 is written to this bit location. When this bit is 1: If the TS_IER[TS1_2IE] bit is also 1, an interrupt is sent to the CPU.

Table continues on the next page...

PMC_ESR_TD field descriptions (continued)

Field	Description
	- If REE_TD[TEMP1_2] is also 1, a system reset is generated, which clears TS_IER[TS1_2IE] and negates the interrupt request. - If REE_TD[TEMP1_2] is 1 <i>and</i> RES_TD[TEMP1_2] is 0, a POR is generated. NOTE: If this flag is cleared to 0 while the over-temperature condition still exists, the flag will not automatically reassert to 1 until after the device falls below the corresponding over-temperature threshold. 0 Currently no occurrence. 1 Temperature occurrence detected.
28 TEMP1_0	Temperature Sensor 1 event flag 0 This bit is associated with the temperature for the cold temperature sensor 0 point (–40°C). It sets to 1 when the temperature falls below its threshold, and it clears to 0 when 1 is written to this bit location. When this bit is 1: - If the TS_IER[TS1_0IE] bit is also 1, an interrupt is sent to the CPU. - If REE_TD[TEMP1_0] is also 1, a system reset is generated, which clears TS_IER[TS1_0IE] and negates the interrupt request. - If REE_TD[TEMP1_0] is 1 <i>and</i> RES_TD[TEMP1_0] is 0, a POR is generated. NOTE: If this flag is cleared to 0 while the under-temperature condition still exists, the flag will not automatically reassert to 1 until after the device rises above the under-temperature threshold. 0 Currently no occurrence. 1 Temperature occurrence detected.
29 Reserved	Reserved This field is reserved.
30 TEMP0_2	Temperature Sensor 0 event flag 2 This bit is associated with the temperature for the high temperature sensor 2 point (150°C). It sets to 1 when the temperature exceeds its corresponding threshold, and it clears to 0 when 1 is written to this bit location. When this bit is 1: - If the TS_IER[TS0_2IE] bit is also 1, an interrupt is sent to the CPU. - If REE_TD[TEMP0_2] is also 1, a system reset is generated, which clears TS_IER[TS0_2IE] and negates the interrupt request. - If REE_TD[TEMP0_2] is 1 <i>and</i> RES_TD[TEMP0_2] is 0, a POR is generated. NOTE: If this flag is cleared to 0 while the over-temperature condition still exists, the flag will not automatically reassert to 1 until after the device falls below the corresponding over-temperature threshold. 0 Currently no occurrence. 1 Temperature occurrence detected.
31 TEMP0_0	Temperature Sensor 0 event flag 0 This bit is associated with the temperature for the cold temperature sensor 0 point (–40°C). It sets to 1 when the temperature falls below its threshold, and it clears to 0 when 1 is written to this bit location. When this bit is 1: If the TS_IER[TS0_0IE] bit is also 1, an interrupt is sent to the CPU.

Table continues on the next page...

PMC_ESR_TD field descriptions (continued)

Field	Description
	- If REE_TD[TEMPO_0] is also 1, a system reset is generated, which clears TS_IER[TS0_0IE] and negates the interrupt request. - If REE_TD[TEMPO_0] is 1 <i>and</i> RES_TD[TEMPO_0] is 0, a POR is generated. NOTE: If this flag is cleared to 0 while the under-temperature condition still exists, the flag will not automatically reassert to 1 until after the device rises above the under-temperature threshold. 0 Currently no occurrence. 1 Temperature occurrence detected.

54.2.3 Temperature Reset Event Enable register (PMC_REE_TD)

This register controls whether the temperature detect signal event causes a reset. If the desired flag bit is enabled, the temperature detect event can cause a reset to be generated when the selected temperature passes the trigger event.

NOTE

These bits can be loaded from a DCF record in the UTEST portion of the flash memory. When they are loaded from a DCF record, they cannot be changed by a register write.

Address: 0h base + 90h offset = 90h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

54.2.6 Temperature Sensor Fault Injection Register (PMC_TS_FIR)

This FCCU Fault Injection register enables user software to artificially generate FCCU faults corresponding to TEMP SENS. Writing 1 to one of these bits generates a single cycle pulsed fault to the FCCU block. The bit clears to 0 automatically in the next cycle.

Address: 0h base + A4h offset = A4h

PMC_TS_FIR field descriptions

Field	Description
0–30 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
31 TSNS_FAULT	Temperature Sensor Fault injection. A write to this bit sends a FCCU fault (single cycle) for TEMP SENSOR. 0 No fault is sent. 1 Single cycle fault injected.

54.2.7 Voltage Detect User Mode Test Register (PMC_SELF_TEST_UM_VD_REG)

This register is used for testing LVDs and HVDs during user mode.

NOTE

A PMC self test of any or all LVDs and HVDs can be interrupted by these reset sources and thereby become corrupted:

- Writing 1 to SIU_SRCR[SSR]
- JTAG reset
- FCCU reset

Due to this corruption, the PMC or FCCU might report incorrectly that a PMC self test of any or all LVDs and HVDs failed.

If software detects one of these reset sources when exiting reset and the PMC or FCCU reports a failed PMC self test of any or all LVDs and HVDs, execute the PMC self test again to confirm the failure.

Field	Description
31 LVD_CORE_ COLD	LVD Core Cold Enable/Disable This bit enable/disable the generation of Interrupt due to an event on this supply. 0 Interrupt is disabled. 1 Interrupt is Enabled.

54.2.10 LVD/HVD Event Status Register
(PMC_LVD_HVD_EVENT_STATUS)

This status register contains the latched status of the voltage detect events. These bits indicate the state of the voltage detect events, including whether a voltage level event has occurred at any time in the past but has not been cleared (via writing 1). These bits are read-only, and they are cleared by writing 1 to the corresponding ESR register bit.

31 LVD_CORE_COLD	LVD Core Cold Status Flag 0 No occurrence has happened. 1 An occurrence has happened.

54.2.11 ADC Channel Select Register (PMC_ADC_CS)

This register contains the SRAM Brownout control and the analog channel mux of the analog PMC module.

Address: 0h base + C4h offset = C4h

PMC_ADC_CS field descriptions

Field	Description																																														
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.																																														
22 STND_BY_ RAM_BO_CLR	Standby RAM Brownout Clear A write to this bit generates a 1-clock-wide pulse. It is a self-clearing pulse.																																														
23 STND_BY_ RAM_BR_ DETCT	Standby RAM Brownout Detect This bit is the detection status flag for the Standby RAM Brownout Detection circuit. When Standby RAM logic detects a brownout event, this bit is set to 1. To clear this flag, two separate write accesses are required: first write 1 to STND_BY_RAM_BO_CLR, and then write 1 to STND_BY_RAM_BR_DETCT. 0 Currently no occurrence. 1 Standby RAM Brownout occurrence detected.																																														
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.																																														
26–31 ADC_CS	Analog-to-Digital Converter Channel Select. These bits are used to control the analog PMC's test mux going to the ADC. This is to probe the internal node voltages of the PMC for testing, calibration and characterization purposes by one of the ADCs of the SoC. Encoding values not listed are reserved. <table border="1"> <thead> <tr> <th>ADC_CS[5:0]</th><th>Function</th></tr> </thead> <tbody> <tr><td>000000</td><td>ADC channel off</td></tr> <tr><td>011110</td><td>Reserved</td></tr> <tr><td>011101</td><td>Reserved</td></tr> <tr><td>011100</td><td>POR098_c sense</td></tr> <tr><td>011011</td><td>POR098_c reference</td></tr> <tr><td>011010</td><td>Reserved</td></tr> <tr><td>011001</td><td>Reserved</td></tr> <tr><td>011000</td><td>Reserved</td></tr> <tr><td>010111</td><td>Reserved</td></tr> <tr><td>010110</td><td>LVD_CORE_COLD sense</td></tr> <tr><td>010101</td><td>LVD_CORE_COLD reference</td></tr> <tr><td>010100</td><td>LVD_CORE_HOT sense</td></tr> <tr><td>010011</td><td>LVD_CORE_HOT reference</td></tr> <tr><td>010010</td><td>HVD_CORE sense</td></tr> <tr><td>010001</td><td>HVD_CORE reference</td></tr> <tr><td>010000</td><td>POR_HV divider tap</td></tr> <tr><td>001111</td><td>POR_HV reference (PMC band gap 1200 mV)</td></tr> <tr><td>001110</td><td>Reserved</td></tr> <tr><td>001101</td><td>Reserved</td></tr> <tr><td>001100</td><td>LVD_HV divider tap</td></tr> <tr><td>001011</td><td>LVD_HV reference (PMC band gap 1200 mV)</td></tr> <tr><td>001010</td><td>HVD_HV divider tap</td></tr> </tbody> </table>	ADC_CS[5:0]	Function	000000	ADC channel off	011110	Reserved	011101	Reserved	011100	POR098_c sense	011011	POR098_c reference	011010	Reserved	011001	Reserved	011000	Reserved	010111	Reserved	010110	LVD_CORE_COLD sense	010101	LVD_CORE_COLD reference	010100	LVD_CORE_HOT sense	010011	LVD_CORE_HOT reference	010010	HVD_CORE sense	010001	HVD_CORE reference	010000	POR_HV divider tap	001111	POR_HV reference (PMC band gap 1200 mV)	001110	Reserved	001101	Reserved	001100	LVD_HV divider tap	001011	LVD_HV reference (PMC band gap 1200 mV)	001010	HVD_HV divider tap

54.2.12 Reset Event Enable Register (PMC_REE)

This Reset Event Enable Register controls whether or not the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a POR to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash memory during the boot sequence. If the bits loaded from flash memory are programmed to be enabled (set), these bits cannot be disabled (cleared).

NOTE

This register is cleared on POR or a reset due to RESET pin assertion or FOSU failure indication.

CAUTION

Except when they occur during a PMC self test, the following VD events *always* result in a POR. The result of these VD events cannot be programmed:

- POR098_c
- LVD_CORE_HOT
- POR_HV
- LVD_HV
- LVD_FLASH
- LVD_IO

Address: 0h base + D0h offset = D0h

	When writing to this field, always write the reset value.
31 LVD_CORE_ COLD	Reset Enable/Disable Control This particular bit enable or disable the generation of reset due to an event on this supply. 0 Reset is disabled, no reset will be generated even if there is event occurred on this supply. 1 Reset is enabled. A reset will be generated if an event is detected on this supply.

54.3 Functional description

54.3.1 Analog PMC interface

The digital block uses the analog PMC interface to configure factory-defined trim values for the regulators and LVDs that are in the analog block.

54.3.2 Temperature Sensor interface logic

The digital PMC block provides control and configuration information, including module enables, to the two Temperature Sensors.

54.3.3 POR phase gates

The interface with the SIU module is used during the power-on sequence and startup. It provides various phase gates, thereby enabling the SIU to properly complete the reset sequence.

It also provides reset sources based on LVD and HVD events and their enable/disable control through the REE register.

The temperature sensor provides another reset source, based on the under/over temperature events and their control through the REE_TD and RES_TD registers.

54.3.4 Flash memory interface to DCF

During power up, trim values for the regulators, LVDs, and HVDs are read from flash memory by the SSCM and then provided to the digital PMC via the DCF interface.

The reset event enable (REE) configurations that are stored in flash memory are also provided to the PMC via the DCF interface. These REE configurations are used, by default, to configure which programmable voltage detection (VD) events generate a POR.

54.3.5 FCCU interface

The digital block generates various fault indications to the FCCU block:

- Separate, corresponding, active-high fault indications are generated whenever an LVD or HVD defect is detected in the analog block.
- A fault indication is generated when a self test task results in a failure.
- A fault condition is generated whenever over-temperature or under-temperature events occur in the temperature sensor.

The figure below show the exact logic for the generation fault indications to FCCU block.

Figure 54-13. Fault generation to FCCU

See [FCCU Fault Injection Register \(PMC_FIR\)](#) for details.

54.3.6 LVD/HVD self test mechanism

The PMC implements an LVD/HVD self test mechanism for use in satisfying safety goals. The digital block assists and controls the analog block during execution of the self test.

Currently, three self test modes are supported by the analog block. Select the mode using the SELF_TEST_UM_VD_REG[ST_MODE] field.

The self test status and result are provided in the SELF_TEST_UM_VD_REG register's ST_DONE and ST_RESULT fields, respectively.

NOTE

Self tests must execute with the FM_PER_CLK frequency at 8 MHz.

54.3.6.1 Default mode

The self test always occurs during startup (power on). The self test starts after the SSCM has completed reads from the flash memory. A counter is provided that starts from zero and increments by one after a factory-defined time gap. The counter value is the source for the self test output signal, which is provided to the analog block.

Meanwhile, the LVD/HVD indication from the analog block is latched in the SELF_TEST_UM_VD_REG register. At the end of the self test, after all of the LVDs/HVDs have been tested, the SELF_TEST_UM_VD_REG[ST_DONE] status bit is set to 1 and all bits in the SELF_TEST_UM_VD_REG register are read to see if the value of each is 1.

- If one or more bits is not set to 1, a fault indication to the FCCU block is generated, and the SELF_TEST_UM_VD_REG[ST_RESULT] field is set to 0.
- If each of the register bits is set to 1, the test is considered passed, the SELF_TEST_UM_VD_REG[ST_RESULT] bit is set to 1, and no fault indications are provided to the FCCU.

NOTE

The total run time of the self test is 300 μ s (factory-defined default).

54.3.6.2 Software-triggered self test

This mode is entered by software by writing 01b to the SELF_TEST_UM_VD_REG[ST_MODE] field. The complete self test, as is performed in default mode, is executed. The difference is that the self test in this mode is initiated by the host while the self test in default mode is started automatically during power on.

54.3.6.3 Single voltage detect test

This mode is entered by software writing 10b to the SELF_TEST_UM_VD_REG[ST_MODE] field. The test completes after the prescribed time gap has elapsed (factory-defined default is 20 μ s). The PASS/FAIL result is then updated based on whether or not the corresponding VD output trips.

NOTE

During execution of the VD self test, all of the LVD and HVD outputs—including PORs, which are also under self test—are masked. Therefore, they have no effect on POR generation or any reset and/or fault generation.

Chapter 55

JTAG Controller (JTAGC)

55.1 Chip-specific JTAGC information

This chip has one instance of the JTAGC module.

55.1.1 JTAG ID

The JTAG ID depends on the version of the chip.

Table 55-1. JTAG ID by chip version

Maskset	JTAG ID
1N45H	0837_701Dh
2N45H	0837_701Dh
3N45H	1837_701Dh

For details, see [Device identification register](#).

55.2 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

55.2.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. Refer to the chip-specific configuration information as well as [Register description](#) for more information about the JTAGC registers.

Figure 55-1. JTAG (IEEE 1149.1) block diagram

55.2.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
 - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to [Table 55-5](#) for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register

- Bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

55.2.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

55.2.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

55.2.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in [JTAGC block instructions](#).

55.2.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

55.3 External signal description

The JTAGC consists of a set of signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 55-2. JTAG signal properties

Name	I/O	Function	Reset State
TCK	Input	Test Clock	Weak pulldown
TDI	Input	Test Data In	Weak pullup
TDO	Output	Test Data Out	High Z ¹
TMS	Input	Test Mode Select	Weak pullup
JCOMP	Input	JTAG Compliancy	Weak pulldown

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

55.3.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

55.3.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

55.3.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in [TAP controller state machine](#).

55.3.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

55.3.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

55.4 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

55.4.1 Instruction register

The JTAGC block uses a 5-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in

the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 00001b , making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	4	3	2	1	0
R	0	0	0	0	1
W	Instruction Code				
Reset:	0	0	0	0	1

Figure 55-2. Instruction register

55.4.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

55.4.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Part Revision Number				Design Center						Part Identification Number					
W																
Reset	PRN				DC						PIN					
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Part Identification Number				Manufacturer Identity Code											1
W																
Reset	PIN (contd.)				MIC											1

The following table describes the device identification register functions.

Table 55-3. Device identification register field descriptions

Field	Description
PRN	Part Revision Number. Contains the revision number of the part. Value is 0x0 for masksets 1N45H and 2N45H, 0x1 for maskset 3N45H.
DC	Design Center. Indicates the design center. Value is 0x20.
PIN	Part Identification Number. Contains the part number of the device. 0x377.
MIC	Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x00E.
IDCODE ID	IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

55.4.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

1. The reset value of JTAG_PASSWORD is 256 'b0.

The following table describes the JTAG_PASSWORD register functions.

Table 55-4. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

55.4.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in [Boundary scan](#). The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

55.5 Functional description

This section explains the JTAGC functional description.

55.5.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

55.5.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to [ACCESS_AUX_x instructions](#).

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

Figure 55-3. Shifting data through a register

55.5.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 55-4. IEEE 1149.1-2001 TAP controller finite state machine

55.5.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

55.5.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

55.5.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 55-5. General 5-bit JTAG instructions

Instruction	Code[4:0]	Instruction Summary
IDCODE	00001	Selects device identification register for shift
SAMPLE/PRELOAD	00010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	00011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	00100	Selects boundary scan register and applies preloaded values to output pins. NOTE: Execution of this instruction asserts functional reset.
Factory debug reserved	00101	Intended for factory debug only
Factory debug reserved	00110	Intended for factory debug only
ENABLE_JTAG_PASSWORD	00111	Selects JTAG_PASSWORD register
HIGHZ	01001	Selects bypass register and three-states all output pins. NOTE: Execution of this instruction asserts functional reset.
Factory debug reserved	01010	Intended for factory debug only
CLAMP	01100	Selects bypass register and applies preloaded values to output pins. NOTE: Execution of this instruction asserts functional reset.

Table continues on the next page...

Table 55-5. General 5-bit JTAG instructions (continued)

Instruction	Code[4:0]	Instruction Summary
Factory debug reserved	01110	Intended for factory debug only
Factory debug reserved	01111	Intended for factory debug only
BYPASS	11111	Selects bypass register for data operations
Reserved ¹	All other opcodes	Decoded to select bypass register

1. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

The ACCESS_AUX instructions are described in the chip configuration debug information.

55.5.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

55.5.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

55.5.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

55.5.4.4 EXTEST External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

55.5.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

55.5.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

55.5.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a

single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

55.5.4.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

55.5.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

55.5.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

55.6 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller
2. Load the appropriate instruction for the test or action to be performed

56.3 Introduction

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities. IEEE 1149.7 defines enhanced test and debug capabilities which are backwards compatible with IEEE P1149.1. This standard is also known as "Compact JTAG" or "CJTAG".

The module implements the following parts of the IEEE 1149.7 standard:

- IEEE 1149.1 compliant behavior while allowing multiple on-chip TAP controllers
- Ability to assert test reset
- Improved system scan performance with one-bit IR and DR chip bypass paths

- Physical connection of a Debug and Test System (external tool) to a running system without corrupting its operation
- Operation with both 4-pin and 2-pin scan topologies

56.3.1 Types of operation

The 1149.7 standard provides a scalable and flexible solution to meet the needs of varied component and system complexities. There are three types of operation:

- **Compliant**
 - Compliant with the IEEE 1149.1 standard
 - Four-pin operation using the "Standard Protocol" — IEEE 1149.1 signaling where TCK, TMS, TDI and TDO signals transfer control/data information
 - More than one TAPC may be associated with the TAP (once made visible by private instructions)
- **Extended**
 - Compatible with the IEEE 1149.1 standard
 - Four-pin operation using the "Standard Protocol" — IEEE 1149.1 signaling where TCK, TMS, TDI(C) and TDO(C) signals transfer control/data information
 - Additional test/debug functions
- **Advanced**
 - Two-pin operation using the "Advanced Protocol" — signaling where TCK(C) and TMS(C) signals transfer control/data information
 - The TMS(C) signal is operated in a bidirectional manner with the TMS, TDI and TDO TAP information serialized and transferred via this signal

56.3.2 Deployment by class

The TAP.7 capabilities are deployed using five capability classes (T0–T4), each matching the needs of certain scan topologies and mixes of 1149.1 TAPs and 1149.7 TAPs. The classes provide the following capability:

- **Compliant Operation** – provides behavior compliant with the IEEE 1149.1-2001 standard:
 - **Class T0** – 1149.1 compliance when multiple TAPs are used on the same chip.
- **Extended Operation** – extends the capabilities of the IEEE 1149.1-2001 standard:
 - **Class T1** – T0 + Test access port power management, functional reset, and test reset.
 - **Class T2** – T1 + Chip bypass (1-bit) for IR/DR Scans + hot-connection with no errors..
 - **Class T3** – T2 + Star operation (TAPs are paralleled) with series equivalent scans for test.
- **Advanced Operation** – adds capabilities addressing test and debug needs in complex environments:
 - **Class T4** – T3 + Scan with two pins with the Advanced Protocol. A number of protocol optimizations maximize scan performance. TDI(C)/TDO(C) pins are optional and may have programmable function when implemented.

56.3.3 1149.7 TAP signals

The TAP signals for the T0–T4 TAP.7 classes are listed in the following table. Signal names that end in “C” are associated with expanded functionality (beyond the functionality provided by the IEEE 1149.1 standard).

The table uses the following notation:

- M = Mandatory signal
- MC = Mandatory signal with expanded functionality
- O = Optional signal
- OC = Optional signal with expanded functionality

The CJTAG module provides T4 capability and implements the following pins:

- TCKC
- TDIC
- TDOC
- TMSC
- nTRST

Table 56-2. TAP.7 signal list

Signal name	Description	Class				
		T4	T3	T2	T1	T0
TCK/TCKC	Test clock	MC	M	M	M	M
TMS/TMSC	Test mode select	MC	M	M	M	M
TDI/TDIC	Test data input	OC	MC	M	M	M
TDO/TDOC	Test data output	OC	MC	M	M	M
nTRST	Test reset	O	O	O	O	O
Mandatory signal count (minimum)		2	4	4	4	4

56.3.4 TAP.7 architecture

The TAP.7 hardware architecture is shown in the following figure. It is described with the hardware layers listed below:

- **STL – System Test Logic** – Logic with 1149.1 compliant behavior and underlying TAP hierarchy (T0 capabilities). Provides an IEEE 1149.1 interface for the T0 TAP. 7. This logic is outside the CJTAG module.
- **RSU – Reset and Selection Unit** – A hardware layer that is placed between the APU, EPU, or STL and the TAP.7 signals (Added as an option to support the use of the Control Protocol) Provides reset and TAP.7 Controller selection services.
- **EPU – Extended Protocol Unit** – A hardware layer that is placed between the STL and the TAP.7 signals. (Added for T1, T2, and T3 capabilities). Provides an IEEE 1149.1 interface for the T1–T3 TAP.7s.
- **APU – Advanced Protocol Unit** – A hardware layer that is placed between the STL/ EPU and the TAP.7 signals (added for T4 capabilities). Provides a T4 TAP.7 interface that is either narrow or wide, with the wide version providing an IEEE 1149.1 interface.

The CJTAG module supports T4 functionality that includes STL, RSU, EPU, and APU hardware layers.

Figure 56-1. TAP.7 Controller Architecture

56.3.5 Protocols

The TAP.7 architecture utilizes the three protocols shown in the following figure.

Figure 56-2. TAP.7 Behaviors

The Standard Protocol transfers data with the TMS(C) signal value being sampled with a TCK(C) edge. The Advanced and Control Protocols use both data transferred with the TMS(C) signal value being sampled with a TCK(C) signal edge and escape sequences. The Standard Protocol may be used to switch to the use of the Advanced Protocol and

vice versa. The Control Protocol can also be used to switch between the use of the Standard and the Advanced Protocol. The mandatory and optional deployment of these protocols with the TAP.7 classes is shown in the following table.

Table 56-3. Class/protocol relationship

Class	Protocol		
	Standard	Control	Advanced
T0 – T2	Mandatory	Optional	N/A
T3	Mandatory	Mandatory	N/A
T4	Mandatory	Mandatory	Mandatory

The CJTAG module implements T4 functionality and supports the Standard, Advanced, and Control Protocols.

56.3.5.1 Standard Protocol

The Standard Protocol is the signaling defined by the IEEE 1149.1 standard. This protocol is also used to implement TAP.7 commands using only the TCK(C) and TMS(C) signals in a manner that does not require either TAP.7 controller instruction or data registers. The TAP.7 controller does not add bits to the scan paths of underlying technology. The Standard Protocol can be used to manage the TAP.7 controller functionality independent of the function associated with the availability of the TDI and TDO signals. The Standard Protocol supports STL data transfers only when these signals are present and provide the 1149.1 functionality defined by the IEEE 1149.1 standard.

56.3.5.2 Advanced Protocol

The Advanced Protocol supports both STL data transfers and management of the TAP.7 controller functionality with both the 2-signal (narrow) and 4-signal (wide) configurations. The Advanced Protocol serializes the TMS, TDI, and TDO information used with the Standard Protocol using only the TCK(C) and TMS(C) signals. A number of additional scan formats provide bit sequences optimized for specific use cases. Each of these additional scan formats affects the TMSC signaling sequences.

56.3.5.3 Control Protocol

The Control Protocol uses Escape sequences to reset the TAP.7 controller, place a TAP.7 controller offline or online, and indicate End of Transmission (EOT) with the Advanced Protocol. The characteristics of this protocol provide Hot-Connect-Protection by requiring a preamble of alternating ones and zeroes preceding a selection escape when a TAP controller is started up offline.

56.4 Operating models

The following figure illustrates a simplified view of the CJTAG operating model.

Figure 56-3. CJTAG operating model

56.5 CJTAG implementation summary

The CJTAG module is a T4 TAP.7 controller that implements the following functions.

56.5.1 T0 functions

- IDCODE. - implemented in chip level TAPC (JTAGC module)
- 1149.1 Compliance at start-up
- Isolating / Excluding of embedded TAPs – implemented in chip level TAPC (JTAGC module)
- Operation with other technologies and scan topologies
- Multiple embedded TAPs

56.5.2 T1 functions

- EPU Command processing
- EPU Class-Specific Registers
- Asserting a test reset to the STL (TRESET Register)

56.5.3 T2 functions

- “Super Bypass” function – JScan0, JScan1, JScan2 scan formats. Allows the STL to be coupled or decoupled.

56.5.4 T3 functions

- Generation of a TAP.7 controller reset with a Reset Escape Sequence
- JScan3 Scan Format

56.5.5 T4 functions

- TMSC sampling on rising edge or falling edge of TCKC
- MScan (For test and debug)
- OScan 0-7
- TDIC and TDOC / Alternate pin function multiplexing (wide 4 only)

56.6 Ancillary services

56.6.1 Overview

Ancillary services are pertinent to any TAP.7 controller implemented with an RSU, such as the CJTAG module.

Ancillary services include:

- Resets
- Start-up options

- Escape sequences
- TAPC state machine

56.6.2 Resets

The TAP.7 controller reset function expands the reset function provided by the IEEE 1149.1 standard to provide additional reset types. It supports six reset types, Type-0 – Type-5, listed below. It can be implemented with as few as two reset types (Type-2 and Type-4), or as many as six reset types (all types) of reset inputs: This is determined by the class and options implemented.

The CJTAG module utilizes Type-0, Type-2, Type-3, Type-4, and Type-5 resets.

- **Type-0** – Reset of the TAP.7 by power management logic (power-on reset)
- **Type-1** – Chip level generated Test Reset. (equivalent to Type-2)
- **Type-2** – Externally generated Test Reset (nTRST/nTRST_PD pin)
- **Type-3** – TAP.7 controller generated reset
- **Type-4** – *Test-Logic-Reset* state
- **Type-5** – TAP.7 Controller TReset Register reset of the CLTAPC.

Figure 56-4. Conceptual view of the EPU reset logic and state machines

56.6.2.1 Type 5 reset

A Type-5 reset affects only the STL via the nSYS_TRST pin. It is asserted when the TRESET Register value is a logic 1. This register is set to its inactive state by reset Types 0-4.

56.6.2.2 Type 4 reset

A Type-4 reset is created by the *Test-Logic-Reset* state. It does not affect the TAP.7 TAPC state machine state as this state is the source of this reset, nor does it cause the assertion of the nSYS_TRST signal. It does however affect the coupling and decoupling of the STL. The Type-4 reset initializes the TAP.7 registers and most controller state machines. It affects but does not initialize the control state machine managing TAP.7 controller selection. It also establishes the default operating conditions.

56.6.2.3 Type 3 reset

A Type-3 reset is created by reset requests generated by the TAP.7 controller. A Type-3 reset performs the functions associated with a Type-4 reset and creates the *Test-Logic-Reset* state.

A Type-3 reset is generated in response to reset requests generated by EPU and APU logic

- A reset escape sequence
- Reset protocol sequences (delay packet directive, check packet directive)

A Type-3 reset request is generated with a reset escape sequence. This function is similar to but not the same as the reset function generated by a test reset pin. The Advanced Protocol includes certain bit patterns that initiate Type-3 resets. These bit patterns assist in the initialization of the TAP.7 controller when the TCKC signal is sourced by the TS and the external tool/TS connection is broken. The external tool may also generate these sequences, if desired, while the external tool/TS connection remains intact. These reset requests cause a Type-3 reset that is one clock wide.

With this being the case, consideration may be given to integrating the CJTAG module without the use of the Test Reset signal (nTRST/nTRST_PD pin).

56.6.2.4 Type 2 reset

A Type-2 reset is created by chip level logic to initialize the TAP.7 controller when TAP.7 power control is not implemented. It is unimplemented otherwise. It performs all of the functions of the Type-3 reset in addition to initializing the escape sequence detection logic.

56.6.2.5 Type 1 reset

A Type-1 reset is created with either the nTRST or nTRST_PD pin. It is not created when neither of these pins is implemented. It performs all of the functions of the Type-2 reset. It initiates TAP.7 controller power down provided the TAP.7 power control mode permits power down.

56.6.2.6 Type 0 reset

A Type-0 reset is implemented when TAP.7 controller power down is implemented. It performs all of the functions of a Type-1 reset and also initializes the TAP.7 power control logic.

56.6.2.7 Reset State Machine

The Reset State Machine assists in the translation of the reset inputs to the reset outputs. It handles Type-3 reset controller reset requests. The state machine state assures Type-0, Type-1, and Type-2 resets are forwarded to the STL without modifying their duration.

This state machine allows a Type-3 reset only when its state is “T3 Reset” (two TCK(C) falling edges have occurred in the absence of a Type-0, Type-1, and Type-2 reset).

Figure 56-5. Reset state machine

Table 56-4. Reset state descriptions

Reset state		Description
ARA	Async. Reset Asserted	An async. reset has occurred or is occurring
ARC	Async. Reset Completed	An async. reset has occurred and has been released
No Reset	No Reset	No Reset
T3 Reset	Type-3 Reset	A Type-3 reset request has been processed.

Type-0, Type-1, and Type-2 resets are fully asynchronous. These resets are passed directly to nSYS_TRST without modification. The Type-3, Type-4, and Type-5 resets are fully synchronous.

The effects of the TAP.7 controller reset types are shown in the following table.

Table 56-5. Reset effects

Reset	CLTAPC	Pin-Hi-Z	State Machines other than CSM	Control State Machine (CSM)	TAPC SM State	Escape Sequence Detection	Power Control State
Type-5	Yes	–	–	–	–	–	–
Type-4	–	Yes	Yes	–	–	–	–
Type-3	Yes	Yes	Yes	Yes	Yes	–	–
Type-2	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-1	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-0	Yes	Yes	Yes	Yes	Yes	Yes	Yes

56.6.3 Start-up Options

56.6.3.1 Overview

The TAP.7 start-up options are shown in the following table. The only startup option currently supported by the CJTAG module is 1149.1 Compliant.

Table 56-6. Start-up Options

Start-up Option	Description
1149.1 Compliant	TAP.1 signal functionality, the CLTAPC is coupled
1149.1 Compatible	TAP.7 signal functionality, the CLTAPC is decoupled

Table continues on the next page...

Table 56-6. Start-up Options (continued)

Start-up Option	Description
1149.1 Protocol Compatible	No, or alternate TDIC/TDOC signal functionality, the CLTAPC is decoupled.
Offline-at-Start-up (Dormant)	The TAP.7 controller is offline and awaits synchronization to external tool operation so as to be placed online, the CLTAPC is decoupled after its state is moved to <i>Run-Test/Idle</i>

56.6.3.2 1149.1 Compliant start-up

Start-up behavior with the 1149.1 Compliant behavior start-up option:

- 1149.1-specific behavior / Standard protocol
- The TAPC finite state machine operated in lock step with the CLTAPC finite state machine.
- The TDIC and TDOC pins are present and provide the TDI and TDO function.
- The CLTAPC is coupled at start-up.

With this start-up option, the TAP.7 controller may be programmed and the scan topology may be interrogated. If the scan topology is known to be the Series Scan Topology at power-up, the TAP.7 can be operated as though it is a TAP.1.

Table 56-7. Reset values for TAP.7 startup options

Start-up Option	Type-0 – Type-3 Reset?	Default TAP.7 and TAP.7 controller characteristics				
		TAP.7 Controller online	CLTAPC Coupled	SGC Reg. == 1	SCNFMT	Initial TMSC pin bias
1149.1 Compliant	x	Yes	Yes	Yes	JScan0	PU

56.6.4 RSU operation

The RSU uses TCKC and TMSC with the control protocol for configuration control.

56.6.4.1 General Operation

From a very high level, the RSU enables the remainder of the TAP.7 functionality when the TAP.7 controller is Online and disables the remainder of the TAP.7 functionality otherwise. The RSU either consumes or discards the TMS(C) information while the TAP.7 controller is Offline. The relationship of the escape sequence detection, technology selection logic, and the underlying technology is shown in the following figure.

Figure 56-6. Conceptual view of technology selection mechanism

56.6.4.2 Common Signaling Across Technologies

With the TAP.7 architecture, the signaling conventions chosen for technology selection is multiple data transitions of the TMS(C) signal while the TCK(C) signal is a logic 1. The common signaling space is available when the external tool sources the TCK(C) signal as it is capable of creating these signaling conventions. It is unavailable when the TS sources the TCK(C) signal as the external tool cannot stop the TCKC signal at a logic 1 to create these signaling conventions.

56.6.4.3 Escape Sequence Detection

TAP.7 TAPC interprets the count of the number of TMS(C) edges while TCK(C) is a logic 1 as one of four escape sequences. Each escape sequence has a different function and TMSC edge count. These escape sequences, their edge counts, and their functions are described below:

- **Custom** (2 or 3 edges) – Ends scan and transport transfers with a TAP.7 controller, may be used for other purposes with another technology.
- **Reset** (> 7 edges) – Resets all technologies (generates a Type-3 TAP.7 TAPC reset)

The external tool creates an escape sequence by generating one or more TMS(C) edge pairs while the TCK(C) signal is a logic 1 value. Even and odd TMS(C) edge counts beginning with two are given the same meaning.

An escape sequence:

- Can be detected only when a Type-0, Type-1 or Type-2 reset is **not** asserted.
- Begins and ends while the TCK(C) is a logic 1.
- Uses TMS(C) as a clock while the TCK(C) is a logic 1.
- Overlays additional control information onto the normal information that is transferred with the TCK(C) and the TMS(C) without changing the normal information.
- Must be detected when TCK(C) is a logic 1 regardless of the TCK(C) and TMS(C) drive histories.

56.6.4.3.1 Custom escape sequence

An online technology can use the custom escape sequence in any manner it chooses. It is used as the End of Transmission (EOT) of certain data types (formats OScan4-7) with T4 and above TAP.7s.

56.6.4.3.2 Reset escape sequences

A reset event initializes all technologies sharing the TCK(C) and TMS(C) connectivity. A reset escape sequence resets the technology. It is recommended that this reset occur with the falling edge of TCKC. With a TAP.7 controller a reset escape sequence generates a Type-3 reset beginning with the falling edge of TCK(C) following the asynchronous detection of the event.

56.6.5 TAPC State Machine

T1 and above TAP.7s require knowledge of the TAPC state machine state. With T2 and above TAPs this knowledge must be developed independently of the CLTAPC. This is generally accomplished by implementing a TAPC state machine within the EPU. This TAPC state machine provides the function of the state machine within a standard 1149.1 TAPC. It is recommended that this state machine is implemented to change state on the falling edge of TCK(C) as this has numerous advantages to a TAP.7 controller. The EPU does not contain 1149.1 Instruction or Data Registers. The APU controls the state changes of this TAPC state machine with T4 and above TAP.7s.

Figure 56-7. Falling edge TAP controller state machine

56.7 EPU (Extended Protocol Unit) Operation

56.7.1 EPU Operation

The EPU adds functionality to the BYPASS and IDCODE instructions.

56.7.1.1 Zero-bit DR-Scans (ZBS)

A zero-bit DR-Scan (ZBS) is a TAPC-state sequence that begins with the *Select-DR-Scan* state and ends with an exit from the *Update-DR* state without an intervening *Shift-DR* state. The external tool controls the EPU using ZBSs.

The use of ZBSs can begin immediately following the *Test-Logic-Reset* state since this state initializes the Instruction Registers of TAPs with either the *BYPASS* or *IDCODE* instructions.

56.7.1.2 Utilizing ZBSs for TAP.7 Controller Functionality

Beginning with a ZBS count of zero, the ZBS count is incremented with each consecutive occurrence of a ZBS without encountering a *Shift-DR* state. This count cannot be incremented past seven. *Run-Test/Idle* is the only state that may occur between consecutive occurrences of ZBSs without terminating the count of consecutive ZBSs.

56.7.1.3 Locking the ZBS Count

When a DR-Scan containing a *Shift-DR* state occurs, and the ZBS count is greater than zero, the ZBS count is not incremented when the *Update-DR* state is reached. It is instead locked at its current value. ZBSs occurring after locking the ZBS count do not affect the locked ZBS count. Locking the ZBS count is the equivalent of storing the count for subsequent use.

56.7.1.4 Control levels

Locking the ZBS count activates a control level that is equal to the locked ZBS count (1-7) when ZBSs are being used for TAP.7 functionality and merely locks the ZBS count otherwise.

1. ZBSs may be used by the STL or another function
2. TAP.7 command generation
3. Reserved control level
4. Accesses to optional TAP.7 scan paths
5. Accesses to optional TAP.7 scan paths

6. Force offline operation (optional)
7. External tool uses

Control level one may be used by the STL since there is no TAP.7 controller functionality associated with this control level.

Control level two enables DR-Scans to create TAP.7 commands. A portfolio of these commands supports the deployment of TAP.7 controllers in the Series or Star Scan Topologies. These commands manage TAP.7 controller registers and perform other functions.

Control level three is reserved for use with a subsequent specification revision.

Control levels four and five provide access to custom (private) scan paths when access to these paths is permitted by a TAP.7 register bit used for this purpose. The EPU provides a 1-bit scan path otherwise. No other EPU functionality is associated with these control levels. The CJTAG module does not support the use of this control level.

Control level six may be optionally used to force offline operation with a TAP.7 controller that supports this capability. The EPU provides a 1-bit scan path for this control level. The CJTAG module does not support the use of this control level.

Control level seven is reserved for external tool use. With this control level, external tool capabilities may be managed using the same infrastructure used to manage TAP.7 controller capability. The EPU provides a 1-bit scan path for this control levels.

56.7.1.5 Exiting a Control Level

A control level is exited when one of the following occurs:

- The *Select-IR-Scan* TAP.7 controller state
- The *Test-Logic-Reset* state
- Certain TAP.7 controller commands (Exit Control Level – ECL register bit)
- An event that synchronizes the operation of TAP.7 controllers

56.7.1.6 Zeroing the ZBS Count

Events causing an exit from a control level also zero the ZBS count. Scan Selection Directives (SSDs) associated with T3 and above TAP.7s zero the ZBS count when the control level has not been locked.

56.7.1.7 Utilizing ZBSs within the STL

After the *Test-Logic-Reset* state, ZBSs are used for basic EPU control. ZBSs that are intended for TAP.7 use are henceforth called "**TAP.7 ZBSs**". ZBSs that are intended for other uses are henceforth called "**Other ZBSs**". Two TAP.7 registers enable the STL's use of ZBSs. Storing these registers causes a control level exit, zeroes the ZBS count, and enables the use of Other ZBSs. Storing the Suspend Register (**SUSPEND**) suspends the use of control levels. Storing the ZBS Inhibit Register (**ZBSINH**) inhibits ZBS detection.

When either of these methods is used, the *Test-Logic-Reset* state enables the use of TAP.7 ZBSs in addition to initializing the TAP.7 controller.

The operation of the TAP.7 controller changes with the use of these two paths.

When the System Path is used:

- A count of eight consecutive ZBSs is used to create a logic 0 SUSPEND Register value.
- The CLTAPC supplies the TAP.7 scan path and controls the drive of TDO(C), provided it is not bypasses.
- The EPU supplies the TAP.7 scan path (a one bit bypass) when the CLTAPC is bypassed.
- Functions supporting Boundary Scan in a Star Scan Topology are enabled.

When the EPU Path is used:

- When the control level has not been locked, the TDO(C) signal remains high-impedance.
- The command control level may be created
- When commands are used, the TDO(C) signal remains high-impedance except during *Shift-DR* states within CR-Scans, and remains high impedance at other times.
- Auxiliary scan paths may be accessed with control levels four and five.

56.7.2 EPU Registers

56.7.2.1 Global

A global register is a register whose value is stored at the same time and with the same value as registers with the same name in all TAP.7 TAPCs sharing an external tool connection. They are stored using TAP.7 TAPC commands dedicated for this purpose. These commands store a single global register. Global registers manage TAP.7 TAPC functions that affect the synchronized operation of a TAP.7 TAPC. An example of a global register is the Scan Format (SCN_FMT) Register used to define the TAPC signal protocol.

A second means of storing all global registers is available. The selection of the TAP.7 TAPC with the technology selection function stores either the Scan Format register value (short form) or all global registers (long form). Storing all global registers provides a simple means to synchronize the values of all global registers when Technology Selection causes a non-operating TAP.7 TAPC to become operational while other TAPCs are operational.

56.7.2.2 Local

Local registers manage TAP.7 TAPC functions that do not affect the synchronized operation of TAP.7 TAPCs. Local registers are conditionally stored using TAP.7 controller commands dedicated for this purpose. These commands provide for changing the value of these registers one at a time with a unique value in a Series Scan Topology based on the TAPC's position on the scan chain. Local registers are stored with a unique value in a Star Scan Topology based on a TAPC address assigned to the TAPC.

Registers programmed with commands are described in this section. The CJTAG module implements all mandatory T4 registers as well as the optional APFC, TRESET, and RDBACK0 registers. There are 16 mandatory and 10 optional registers that can be grouped in classes as shown in Read-only – Configuration and register read back..

- **Control** – TAP.7 controller behaviors and characteristics.
- **Options** – Control of optional functions.
- **Select** – Controls the selection of a TAP.7 for Scan and execution of conditional commands.
- **Read-only** – Configuration and register read back.

Table 56-8. TAP.7 controller register list (managed with commands)

Register type	Global/local	Width	Register mnemonic	Name
Control	Global	1	ECL	Exit Control Level
		1	SUSPEND	Suspend
		1	ZBSINH	ZBS Detect Inhibit
		5	SCNFMT	Scan Format
		1	SSDE	SSD Enable
		2	DLYC	Delay control
		2	RDYC	Ready Control
Options	Local	1	TRESET	Test Reset
		2	APFC	Aux. Pin Func. Cntl.
Select	Local	1	CGM	Cond. Group Member
		1	SGC	Scan Group Candidate
		1	SEDGE	Sampling Edge
Read-only	Local	32	RDBACK0	Read-back 0
		32	RDBACK1	Read-back 1
		32	CNFG0	Configuration Register 0

M = Mandatory register

O = Optional register

56.7.2.3 Register Descriptions

56.7.2.3.1 Exit Control Level (ECL)

Storing this register zeroes the ZBS count and unlocks the control level.

This register is set using the STMC command. It remains logic 1 only momentarily before immediately returning to logic 0.

This register is cleared by a global register load.

56.7.2.3.2 Suspend (SUSPEND)

Setting this register suspends the use of control levels. When this register is a logic 1, the "System Path" (STL) is used.

1 – Suspend use of control levels. Enables "System Path."

0 – Enable use of control levels.

SUSPEND is set with the STMC command.

This register is cleared when 8 consecutive ZBSs are detected without the locking of the ZBS count.

This register is cleared by a global register load.

56.7.2.3.3 ZBS Inhibit (ZBSINH)

Storing to ZBSINH inhibits ZBS detection.

1 – Inhibit ZBS detection.

0 – Enable ZBS detection.

ZBSINH is set with the STMC command.

This register is cleared by a global register load.

56.7.2.3.4 Scan Format (SCNFMT[4:0])

Set using Store Scan Format (STFMT) command.

Read using Scan String (SCNS) command.

Table 56-9. Scan Format Register Values

TAPC.7 Class	SCNFMT	Description
T2–T4	00000	JScan0: • 1149.1 Compliant Operation. • Requests the coupling of the CLTAPC when the Run-Test/Idle state is reached.
	00001	JScan1: • 1149.1 Compatible Operation • Requests the decoupling of the CLTAPC when the Run-Test/Idle state is reached.
	00010	JScan2: • 1149.1 Compatible Operation. • Requests the coupling or decoupling of the CLTAPC when the Run-Test/Idle state is reached based on the value of the CACT register

Table continues on the next page...

Table 56-9. Scan Format Register Values (continued)

TAPC.7 Class	SCNFMT	Description
T3–T4	00011	JScan3: • Non-compatible 1149.1 Operation • Allows the detection of a T2 TAP.7 controller that is deployed in a Star-4 topology. • Enables TDOC signal behavior that prevents drive conflicts in a Star-4 Scan Topology. • Enables the use of SSDs
T4	01000	OScan0 • Data rate dependent components • Single TAP.7 communication • Debug and Test applications
	01001	OScan1 • TAP.1 components • Single/Multi-TAP.7 communication • Debug and Test applications
	01010	OScan2 • TAP.1 components • No TDI or TDO in non-shift states • Debug applications
	01011	OScan3 • TAP.1 components • No TDI in non-shift states • No TDO in any state

Table continues on the next page...

Table 56-9. Scan Format Register Values (continued)

TAPC.7 Class	SCNFMT	Description
T4	01100	OScan4 - Data rate dependent components - Single TAP.7 communication - Debug and Test applications
	01101	OScan5 - TAP.1 components - Single/Multi-TAP.7 communication - Debug and Test applications
	01110	OScan6 - TAP.1 components - No TDI or TDO in non-shift states - Debug applications
	01111	OScan7 - TAP.1 components - No TDI in non-shift states - No TDO in any state
	10000	MScan - Data rate dependent components - Multi TAP.7 communication - Directed CID assignment - Virtually any IP with compliant or non-compliant 1149.1 behavior
	10001 – 11111	Reserved

The use of a Scan Format value other than 00000b – 10000 shall not change the value of the SCNFMT Register.

56.7.2.3.5 Scan Selection Directive Enable (SSDE)

This register specifies whether the Scan Selection State may be managed using the scan selection directives.

0 – Scan selection directives are not enabled.

1 – Scan selection directives are enabled.

This register is set using the STMC command.

This register is read using SCNS (Scan String), RDBACK0.

56.7.2.3.6 Delay Control (DLYC[1:0])

The Delay Control register provides a means for the external tool to delay the completion of an SP. This delay is essentially an external tool stall. This delay may be zero, one, two, or n TCKC periods. This delay is especially useful when the TCKC is sourced by the TS and a Standard-to-Advanced Protocol adapter is added to an external tool supporting only the Standard Protocol. It allows an external tool design additional time to receive TDO, advance the external tool TAPC state, receive TMS and TDI information, and begin generation of a new SP payload. The DLYC register should be programmed before the use of the Advanced Protocol begins after the use of the Standard Protocol.

Set using the STMC command.

Read using SCNS, RDBACK0

Bits 18-17 of the "Global Register."

56.7.2.3.7 Ready Control (RDYC[1:0])

The Ready Control register defines behavior exhibited in the SP payload output bit frames when the STL stall opportunities (RDY bits) are included as control information. This register defines the number of additional bits inserted in these bit frames. These bits provide more time for a high-performance external tool to ascertain whether the TAP.7 controller is ready to complete the SP payload. The use of these bits makes a high-performance external tool design easier as input and output buffer delays play less of a role in limiting the TAP.7 controller performance. The RDYC register should be programmed before the use of the Advanced Protocol begins.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the Global register state.

56.7.2.3.8 Test Reset (TRESET)

Asserts a test reset to the STL.

0 – The nSYS_TRST and SYS_TMS signals presented to the STL is not influenced by this bit.

1 – The nSYS_TRST presented to the STL is asserted and the SYS_TMS signal is a logic 1.

Set using the STC1 command.

The effects of the TRESET Register may be modified by a private TAP.7 controller register. When this private register is unimplemented or has a value of zero, the TRESET register causes the maximum initialization of the STL with nSYS_TRST and the SYS_TMS logic 1 value. Otherwise, the value of the private register may modify the function of the TRESET Register bit.

When the TRESET Register is a logic 1, the STL scan path appears broken as the state of CLTAPC remains *Test-Logic-Reset* while the EPUTAPC state progression continues. When the operation of the EPUTAPC and CLTAPC controllers is coupled, as with a T1 TAP.7, the state of these two TAPCs may be resynchronized to the *Run-Test/Idle* state by:

- An STC1 Command that sets the TRESET Register value to a logic 0.
- A stay in the Run-Test/Idle state of two or more SYS_TCK periods immediately following the Update-DR state of this command

A failure to follow the guidelines is considered a programming error and will result in erroneous system operation. The EPUTAPC and CLTAPC states will not be synchronized as they progress through the state diagram.

56.7.2.3.9 Auxiliary Pin Function Control (APFC[1:0])

This register enables TDI and TDO alternate functions when 2-pin TAP.7 operation is selected.

0x – TDI and TDO have JTAG function.

1x – TDI and TDO have alternate function.

Set using STC2 command.

Read using SCNS, RDBACK0.

56.7.2.3.10 Conditional Group Member (CGM)

Used by STC1, STC2, STTESTM, and EXC3 – EXC0 commands as the “condition” for updating registers.

Set and cleared using MCM and SCNB commands.

Read using SCNS, RDBACK0.

56.7.2.3.11 Scan Group Candidate (SGC)

This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used.

- **0** – Decoupling action.
- **1** – Coupling action.

Set and cleared using STMC, MSC, and SCNB commands.

Read using SCNS, RDBACK0.

56.7.2.3.12 Sampling Edge (SEDGE)

The Sampling Edge register defines the TCKC edge used to sample the TMSC input.

- **0** – Sample TMSC on the TCKC falling edge.
- **1** – Sample TMSC on the TCKC rising edge.

Set and cleared using STC1 command.

Read using SCNS, RDBACK0

56.7.2.3.13 Read Back 0 (RDBACK0)

Non-transport related register information.

Read using SCNS command.

Unimplemented registers shall read back as "0".

Table 56-10. RDBACK register format

Bit	Width	Register Mnemonic	Name

	32	CNFG0	Configuration Register 0				

NC = No Change

DF = Default Scan Format

DM = Default Power Control Mode

DCA = Default Coupling Action

DT = Default Topology

DP = Default Pin Function

56.7.3 EPU Commands

There are two command types:

- Two Part Commands
- Three Part Commands

Any number of two-part and three part commands may be issued in any combination before the command control level is exited. If the command control level is exited before a two- or three-part command is completed, the command is aborted and becomes a NOP.

56.7.3.1 Two Part Commands

TAP.7 controller commands are 10-bit values. The 10-bit commands are created by two consecutive DR-Scans when the control level is locked at the command control level (two). The first DR-Scan provides a five-bit command opcode. The second DR-Scan provides a five-bit operand. These two scans are called the command part one (CP1) and command part two (CP2), respectively. A command created entirely with these two scans is called a two-part command.

56.7.3.2 Three Part Commands

Some commands are used to send and/or receive data values other than values embedded in the command's operand. These commands are called three-part commands. With these commands, CP1 and CP2 are followed by an additional DR-Scan to transport a data value to or from an EPU scan path. When used for this purpose, the DR-Scan is called a Control Register Scan (CR-Scan). The CR-Scan is a minimum of zero bits in length with there being no maximum length. The CR-Scan path is described in SECTION.

56.7.3.3 Command Sequence

The two 5-bit values concatenated to create the 10-bit command represent the number of Shift-DR states between the *Capture-DR* and *Update-DR* states of CP1 and CP2. The count within CP1 creates the MSBs of the command while the count within CP2 creates the LSBs of the command. The command is decoded when the *Update-DR* state of the second DR-Scan is reached. A determination as to whether the command is a two- or three-part command is made at this point. The command format is shown in the following figure.

Figure 56-8. DR_Scan sequence used for command creation

The 10-bit command created by CP1 and CP2 determines the command's function and whether the command is a two- or three-part command. If the command is a two part command, the function specified by the command is performed when command part 2 completes. If the command is a three-part command, the DR-Scan following CP2 performs a TAP.7 controller function designated by the 10-bit controller command. This DR-Scan is called a **Control-Register Scan** (CR-Scan) and can be any length. A CR-Scan has many of the attributes of the DR-Scan as it moves data between the external tool and TAP.7 controller and accesses various EPU scan paths. There are many two part commands, but only three three-part commands, each having a special purpose.

56.7.3.4 Commands

There are 11 mandatory and 5 optional commands that can be grouped in classes as shown in the following list:

- Store – The operand is stored in a register or causes an action.
- Select – Controls participation of Scan and conditional command execution.
- Scan – Inputs and outputs with a CR-Scan.
- Enumerate – Controller ID allocation and de-allocation.
- Private – Commands available for chip-specific definition.

The definition of the commands with their operands is shown in the following table.

Table 56-13. – TAP.7 controller command list

Command class	Opcode count	Mnemonic	Name	TAP.7 class			
				1	2	3	4
Store	0x00	STMC	Store Miscellaneous Control	M	M	M	M
	0x01	STC1	Store Conditional 1-bit	M	M	M	M
	0x02	STC2	Store Conditional 2-bit	M	M	M	M
	0x03	STFMT	Store Format	-	M	M	M
	0x04	STDCST	Store Data Channel State	-	-	-	-
Select	0x06	MCM	Make Cond. Group Member	M	M	M	M
	0x07	MSC	Make Scan Group Candidate	-	M	M	M
Scan	0x08	SCNB	Scan Bit	M	M	M	M
	0x09	SCNS	Scan String	M	M	M	M
Enumerate ¹	0x0A	CIDA	Allocate Controller ID	-	-	M	M
	0x0B	CIDD	De-allocate Controller ID	-	-	M	M
Reserved	0x0C–0x1F	Reserved	Reserved	-	-	-	-

1. Enumerate commands are not currently supported by the CJTAG module.

56.7.3.4.1 Store Commands

Store commands are two-part commands that are available in both Star and Series Scan Topologies. The Store Miscellaneous Control (STMC) Command performs control functions that affect all TAP.7 controllers sharing an external tool connection. It stores values in one-bit and two-bit registers.

The Store Conditional 1 bit (STC1) and Store Conditional 2 bit (STC2) Commands store one-bit and two-bit values in registers, respectively. These commands operate two ways:

1. Unconditionally storing registers in all TAP.7 controllers or
2. Storing registers in only the TAP.7 controllers that have a logic 1 Conditional Group Member (CGM) Register value.

The Store Format (STFMT) Command unconditionally stores a five-bit Scan Format value.

The Store Data Channel State (STDCST) Command stores a five-bit value identifying the states supporting transport.

56.7.3.4.2 Select Commands

Select commands are two-part commands that are available in both Star and Series Scan Topologies. Their primary use is to select TAP.7 controllers of interest in a Star Scan Topology. These commands define the TAP.7 controller(s) participating in scans and the TAP.7 controllers that conditionally execute STC1 and STC2 Commands.

The Make Conditional Group Member (MCM) Command specifies which TAP.7 controllers execute store conditional commands as it manages the Command and Path Enable (CAPE) Register. This register also affects the execution of private commands and is utilized in EPU scan path selection.

The Make Scan Group Candidate (MSC) command manages the SGC register. This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used. Select commands execute only when the CIDI Register is a logic 0, indicating the TAP.7 controller's CID is valid, and are treated as no operations otherwise.

56.7.3.4.3 Scan Commands

Scan commands are three-part commands that are available in both Star and Series Scan Topologies. The CR-Scan portion of Scan Bit (SCNB) and Scan String (SCNS) Commands is used to set and test bits (SCNB) or transfer strings of bits (SCNS). The commands may be used to access both public and private registers.

56.7.3.5 Command Definitions

56.7.3.5.1 Store Commands

56.7.3.5.1.1 Store Miscellaneous Control Command (STMC)**Table 56-14. Store Miscellaneous Control**

STMC		Store Miscellaneous Control				
Opcode	Operand	bbb		x	y	Description
00000	bbb x y	000	StateCtl	0	0	NOP
				0	1	ExitCmdLev(ECL)
				1	0	Exit/Suspend (SUSPEND) = 1
				1	1	ZBS Inhibit (ZBSINH) = 1
		001	ScanCtl	0	-	SGC = y
				1	-	CGM = y
		010	RdyCtl	-	-	RDYC = xy
		011	DlyCtl	-	-	DLYC = xy
		100	ScnFunc	0	-	SSDE = y
				1	0	Star-4 Topology Test
				1	1	Reserved
		101	Reserved	-	-	Reserved
		110				
		111				

56.7.3.5.1.2 Store Conditional 1-bit (STC1)**Table 56-15. Store Conditional 1 bit (STC1)**

STC1		Store Conditional 1 bit			
Opcode	Operand	c	bbb	CAPE	Description
00001	c bbb v	0	000	-	SREDGE = v
			001	-	Reserved
			010	-	TRESET = v
			011 – 111	-	Reserved
		1	—	0	No change
			000	1	SREDGE = v
			001	1	Reserved
			010	1	TRESET = v
			011 – 111	1	Reserved

56.7.3.5.1.3 Store Conditional 2-bit (STC2)**Table 56-16. Store Conditional 2 bit (STC2)**

56.7.3.5.2 Select Commands

This section describes the select commands with their operands.

56.7.3.5.2.1 Make Conditional Group Member (MCM)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the CGM bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The CGM Register is also stored with the STMC and SCNB commands.

Table 56-18. Make Conditional Group Member (MCM)

MCM		Conditional Group Member	
Opcode	Operand	m	Description
00110	m iiii	0	CGM bit of the non-targeted controller is cleared
		1	CGM bit of the targeted controller is set. CGM bit of a non-targeted controller is unaffected.

56.7.3.5.2.2 Make Scan Group Candidate (MSC)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the SGC bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The SGC Register is also stored with the STMC and SCNB commands.

Table 56-19. Make Scan Group Candidate (MSC)

MSC		Make Scan Group Candidate	
Opcode	Operand	m	Description
00111	m iiii	0	SGC bit of the non-targeted controller is cleared
		1	SGC bit of the targeted controller is set. SGC bit of a non-targeted controller is unaffected.

56.7.3.5.3 Scan Commands

56.7.3.5.3.1 Scan Bit (SCNB)

This is a 3-part command. The operand chooses the bit to be read or written by the CR-Scan.

Table 56-20. Scan Bit (SCNB)

SCNB			Scan Bit		
Opcode	Operand	CR-Scan	yyyyy	Description	R/W
01000	yyyyy	-	0	Scan Group Candidate (SGC)	Write only
		-	1	Conditional Group Member (CGM)	Write only
		-	2	CNFG[0]	Read only
		-	3	CNFG[1] (not implemented)	Read only
		-	4	CNFG[2] (not implemented)	Read only
		-	5	CNFG[3] (not implemented)	Read only
		-	6	Functional reset requested (FRESETR) (not implemented)	Read only
		-	7	Series topology detect	Write only
		-	15 – 8	Reserved	Read only

56.7.3.5.3.2 Scan String (SCNS)

This is a 3-part command. The operand chooses the string to be read or written by the CR-Scan.

Table 56-21. Scan String (SCNS)

SCNS			Scan String		
Opcode	Operand	CR-Scan	yyyyy	Description	R/W
01001	yyyyy	-	0	RDBACK[0] Register [31:0]	Read only
		-	1	RDBACK[1] Register [31:0] (not implemented)	Read only
		-	2	CNFG[0] Register [31:0]	Read only
		-	3	CNFG[1] Register [31:0] (not implemented)	Read only
		-	4	CNFG[2] Register [31:0] (not implemented)	Read only
		-	5	CNFG[3] Register [31:0] (not implemented)	Read only
		-	6 - 7	Reserved (read logic 0)	Read only
		-	31 - 8	Private – available for customization	

56.7.4 EPU operating states

The TAP.7 controller and STL share the use of ZBSs. The EPU has three operating states as shown in the following figure:

Figure 56-9. EPU operating states

The values of the SUSPEND and ZBSINH Registers determine the type of operation as shown in the following table. The Test-Logic-Reset state sets the SUSPEND and ZBSINH Register values to a logic 0.

Table 56-22. ZBS use state characteristics with both TAP.7 and other ZBS use

ZBSINH	SUSPEND	EPU operating State	ZBS use by:	Until
0	0	RUNNING	EPU	Command allocates to STL
0	1	SUSPENDED	STL	ZBS sequence allocates to EPU
1	0	STOPPED	STL	Test-Logic-Reset state allocates to EPU
1	1	Not possible		

56.7.5 System and EPU Paths

The System path is utilized when the external tool requires access to system (STL) resources. This path is used when either the SUSPEND Register is a logic 1 or the ZBS count is less than or equal to one. The EPU path is used otherwise.

The EPU scan path is constructed from five types of EPU scan paths:

- **Bypass** – A 1-bit scan path
- **Bit** – Supports set and test bit operations (a 1-bit shift register)
- **String** – Support 32-bit reads or 32-bit writes
- **Enumerate** – A 36-bit scan path that transports a TAPC address with T3 and above TAP.7s
- **Auxiliary** – An n-bit scan path that transports 1 – n bits using a conventional IEEE 1149.1 style DR-Scan path using Control Levels 4 and 5.

56.8 APU (Advanced Protocol Unit) Operation

56.8.1 Overview

The Advanced Protocol Unit (APU) is placed between the EPU and the RSU to create the T4 TAP.7 controller. The APU delivers advanced capabilities with a number of operating modes (new scan formats) that utilize the Standard Protocol and the Advanced Protocol in both the narrow and wide T4 TAP.7 versions.

The APU enables scan transfers with two signals by serializing the information related to a TAPC state machine state. It provides a number of serialization formats to balance scan flexibility and scan performance. It multiplexes the use of the TMSK signal for T4 TAP.7 controller functions. The serialization is bypassed to provide T3 TAP.7 capability.

With a wide TAP.7, the chip architect may choose to implement the TDIC and TDOC signal functions as fixed functionality (the T3 TDIC and TDOC functions) or as programmable between the T3 TDIC and TDOC signal functions and an alternate function using a TAP.7 controller register. In this case, the default signal function may be either of the programmable choices. Programmable TDIC and TDOC functionality provides a means to fully utilize these signals in any scan topology as the T3 TAP.7 functionality is fully supported.

The entire EPU infrastructure (i.e., ZBS detection, control-level management, and command generation) is utilized when either the Standard Protocol or the Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state machine state progression. The EPU is unaware of the APU's existence. All T4 features are managed outside of the EPU.

The TAP.7 serialization schemes are specified with scan formats that complement the JScan 0-3 Scan Formats inherited from the T3 TAP.7. The scan formats are called advanced scan formats as they support two-signal operation.

Two groups of scan formats (MScan and OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. The OScan Scan Format is broken into two groups with the same function, one group has better performance but may only be used with an external tool sourced TCKC. The external tool chooses a scan format that matches the constraints imposed by the application, chip components, and possibly the external tool itself.

The MScan and OScan formats address Test and Debug use cases. The mandatory MScan and OScan0-1 formats emphasize flexibility over performance. The remaining optional Oscan2-7 formats emphasize performance over flexibility by not transmitting unneeded information such as TDI and TDO in non-shift TAPC state machine states.

The optional capabilities added with T4 and above TAP.7s change the bit sequences seen at the TAP.7 signals. A TAP.7 controller comprehends only the bit sequences generated by the use of the features it supports. It is never exposed to bit sequences it does not comprehend. A check for supporting an enabled feature is made before the feature is used (alters the bit sequences). When a T4 TAP.7 controller detects the use of an unsupported scan format, it halts its operation and places itself in a state where its operation may be resumed. This state is henceforth called "offline". A TAP.7 controller that is not offline is henceforth called "online". While offline the TAP.7 controller awaits the detection of a

special signaling sequence called the Online Activation Protocol. This protocol sequence places an offline TAP.7 controller online and synchronizes the operation of all online TAP.7s.

The Advanced Protocol Unit supports the stall of a transfer by both the external tool and STL at any TAPC state.

The APU provides the following functions:

- Bypass (for operation with the Standard Protocol)
- Scan control (for SP use)
- Configuration Control (for CP use)

The Scan Control, Configuration Control, and Transport Control functions are idled when the Standard Protocol is used as the Bypass Function connects the TCKC and TMSC pins to the EPU.

Figure 56-10. Conceptual block diagram of the APU functions

The APU's internal interface includes a connection to EPU registers, the EPU's TAP interface, connections to chip-level data channels (when they are implemented), and reset signaling with the EPU. The APU's TAP interface provides mutually exclusive use of the TMSC pin for:

- Bypass Function
- Scan Control Function
- Configuration Control Function

When the Standard Protocol is used, the APU's Bypass function connects the EPU directly to the TAP.7 pins. When the TDIC and TDOC pin functions are not available (narrow TAP.7 or TDIC and TDOC pin functions are an alternate function), the APU sources a logic 1 to the EPU inputs associated with these pins.

When the Advanced Protocol is used, the APU multiplexes the use of the TMSC pin between the other APU functions. Scan Control acts as a serial to parallel converter, translating the parallel information at the EPU's TAP interface into bidirectional serial transfers. Since the Scan Control is literally a protocol adaptor, the entire EPU infrastructure (ZBS detection, control-level management, and command generation) is utilized when either the Standard or Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state progression.

56.8.2 Operation

The conceptual view of the APU operation is shown in the following figure.

Figure 56-11. Conceptual view of APU operation

The APU operating states managing the use of the TAP pins and the ancillary (RSU) services use of the TMS pin.

APU operating states:

- **BPA** – ByPass Active
- **CPA** – Change Packet Active
- **SPA** – Scan Packet Active

56.8.2.1 BPA

The *BPA* state allocates the use of the TMS pin to the Standard Protocol. This state is entered two ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up online.
- From the CPA state when a TAP.7 controller register write specifies the use of the Standard Protocol.

56.8.2.2 CPA

The *CPA* state allocates the use of the TMSC pin to a CP. This state is entered in one of three ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up offline.
- A value specifying the use of the Advanced Protocol is written to the SCNFMT Register when using the Standard Protocol.
- A TAP.7 controller register write occurs when using the Advanced Protocol.

56.8.2.3 SPA

The *SPA* state allocates the use of the TMSC pin to an SP. This state is entered when the SCNFMT Register specifies the use of the Advance Protocol when a CP ends.

56.8.3 Escape sequences

Escape-sequence detection provides services to the Reset Logic, Scan, Configuration Control, and Transport Control functions as outlined below:

- **Scan and Transport Control** – End of Transfer (EOT) escape sequence detected.
- **Configuration Control** – Synchronize Advanced Protocol (SAP) escape sequence.
- **Reset Logic** – Reset (RES) escape sequence detected.

An EOT escape sequence is used to increase the efficiency of OScan Scan formats.

An SAP escape sequence is used to place TAP.7 controllers online.

A RES escape sequence asynchronously causes generation of a Type-3 Reset. Following a RES escape sequence, the drive of the TMSC pin is inhibited so it is not driven when TCKC becomes a logic 0 immediately following the RES escape sequence.

56.8.4 Signal behaviors

The TCKC signal:

- The test clock

The TMS signal:

- An input when the Standard Protocol is used
- Bi-directional when the Advanced Protocol is used

The TDI and TDO signals:

- Deleted with a narrow TAP.7
- One of two functions with a wide TAP.7
 - Fixed – as the TAP.7 TDIC and TDOC pin functions, or
 - Programmable – as the TAP.7 TDIC and TDOC signal functions or alternate functions with a TAP.7 controller reset establishing the default signal function.

56.8.5 APU Functions

56.8.5.1 Bypass Active (BPA) Function

When the Standard Protocol is used, the APU connects the EPU inputs and outputs directly to the TAP.7 pins. If the TDIC and TDOC pin functions are not present (e.g., a narrow TAP.7 or the TDIC and TDOC pins have an alternate function assigned to them), the APU provides a logic 1 to the EPU for unsupported pin functions and ignores the EPU's TDO output data.

56.8.5.2 Scan Packet Active (SPA) Function

The Scan Control function is encapsulated within the Scan Packet Active (SPA) state. With the Standard Protocol, the external tool and TAP.7 exchange the scan information associated with a single TAPC state machine state in one TCK period using the TMS(C), TDI(C), and TDO(C) pins. With the Advanced Protocol all or part of this information is exchanged serially within a Scan Packet (SP) as shown in . There is a one to one correspondence between SPs and TAPC state machine state changes, except when the SPA state precedes the CPA state. In this case the SP preceding a CP does not advance the TAPC state machine state.

Figure 56-12. Scan Packet Sequence

A comparison of the parallel transfer of TAP information with the Standard Protocol and the serialization and de-serialization of the TAP information using the TCKC and TMSC pins with the Advanced Protocol is shown in FIGURE. The IEEE 1149.1 signals between the EPU and STL are prefixed with SYS_.

The APU manages the serialization and de-serialization of the scan information. The APU converts the TDI and TMS information within a Scan Packet (SP) into the TMS and TDI information presented to the EPU. It converts the combination of the EPU TDO and EPU TDO_OE signals into the TDO information in the same SP. If the EPU indicates that the TDO pin drive is not enabled, logic 1 TDO data is created, otherwise the TDO data is the supplied by either the EPU or STL.

Information within a Scan Packet is first passed from the external tool to the TAP.7 followed by information passed from the TAP.7 to the external tool. In this example the scan format specifies the exchange of the TMS, TDI, and TDO TAPC information. Each TAPC state machine state takes three TCKC periods. Other scan formats specify the exchange of different mixes of information. Control information is added with the most flexible scan formats. Some scan formats send less information and consequently take fewer TCKC periods.

Figure 56-13. Serialization and De-serialization of Scan Packet Information

In order to produce comparable TAPC state machine state rates with a TAP.1 and TAP.7 controller:

- Full-cycle timing between the external tool and TAP.7 allows operation at higher TCKC frequencies.
- The number of bits transferred to advance a TAPC state machine is minimized. (reaching as few as one for some scan formats.)

The TAP.7 controller provides both full-cycle bit timing (falling TCKC edge to falling TCKC edge) and half-cycle bit timing (falling TCKC edge to rising TCKC edge), with a TAP.7 register used to define the type of timing used. Half-cycle timing is used as the default following a TAP.7 controller reset. The TCKC frequency is reduced to accommodate half-cycle timing.

With full-cycle timing, the TMSC input and output data are both output with and sampled with the falling edge of the TCKC. This means that the entire TCKC period may be spent transferring a bit from the external tool to the TAP.7 or vice-versa. The TCKC frequency can therefore be maximized when full-cycle timing is used. With half-cycle timing, the APU samples the TMSC input data with the rising edge of the TCKC and outputs TMSC data with the falling edge of TCKC.

Minimizing the number of bits transferred per TAPC state machine state is affected by a number of factors. The information that must be transferred per TAPC state machine state varies for different test and debug applications. Also, with some test and debug

applications, all TAPC state machine states do not require that the same amount of information be transferred. This is especially true with debug applications where specialized use of the TAP is more likely.

56.8.5.3 Control Process Active (CPA) Function

While using the Advanced Protocol, all TAP.7 configuration changes occur within the CPA state. All online and offline transitions also occur while in the CPA state. When entering the CPA state from the BPA or SPA state, the CPA state checks for the use of supported features affecting the Advanced Protocol. The CPA state is exited when the enabled features affecting the Advanced Protocol are supported.

Figure 56-14. CPA State Entry from BPA State with Continued Online Operation

An SP preceding a CP does not advance the TAPC state machine state. This SP performs housekeeping functions that assure the contents of the SP preceding this SP have been fully utilized. This has significance when the SP contains control information that allows the STL to stall the completion of a SP.

Figure 56-15. CPA State Entry from the SPA State with Continued Online Operation

When an unsupported feature is enabled, the TAP.7 controller is placed offline. This suspends the TAP.7 controller's operation at a point where its operation may later be synchronized to the remainder of the system. The APU stops advancing the EPU's and CLTAPC's TAPC state machine state while offline. It also suspends Data Channels activity while offline. The detection of the appropriate Online Activation Protocol while

the TAP.7 controller is offline places the TAP.7 controller online and causes an exit from the CPA state to the SPA state. An offline to online transition initiates the use of a predefined set of mandatory features in all online TAP.7 controllers to assure they operate synchronously.

Figure 56-16. CPA State Entry from the BPA State with Offline Operation

Figure 56-17. CPA State Entry from the SPA State with Offline Operation

A TAP.7 controller reset places the TAP.7 controller offline when the offline at start-up option is used. From this point the TAP.7 controller awaits being placed online.

56.8.6 Configuration Change Packets (CP)

A Change Packet (CP) is composed of three element types:

- **Preamble** – A 1-bit value that is a don't care. This bit facilitates a Standard to Advanced Protocol change with some external tool implementations.

- **Body** – Two or more bits representing one or more CP directives
 - **00** – CP_END
 - **01** – CP_NOP (extends the body by 1-bit)
 - **10** – CP_NOP (extends the body by 1-bit)
 - **11** – CP_RES (Generate a Type-3 TAP.7 controller reset coincident with the post amble bit.
- **Post amble** – A 1-bit value that is a don't care. This bit facilitates and Advanced to Standard Protocol change with some external tool implementations.

A minimum-length CP has a Preamble, a 2-bit Body, and a Post amble. This can be as simple as four logic zero values.

56.8.7 Scan Packet

A Scan Packet defines the period of TMS pin activity where control information exchanged by the external tool and TAP.7 controller affects the TAPC state, except when the SP precedes a Change Packet. The external tool should view the Scan Packet as:

- Exchanging only the necessary TAPC information (TMS, TDI, and TDO or some subset thereof)
- Causing an advance of the TAP.7 TAPC state when it is not followed by a Change Packet.
- Causing an advance of the STL TAPC state when it is not followed by a Change Packet and when the STL is coupled.

With this perspective, the external tool views Scan Packets as running a virtual TAPC state machine at the TAP.7 pins. The effects of each Scan Packet take effect when the Scan Packet completes. The real TAP.7 and STL controller state machine states may change state before or after the virtual state machine.

56.8.8 SP Format

A SP serially exchanges the TDI, TMS, and TDO or a subset thereof, between the external tool and TAP.7 controller. Control information may be added to this exchange. A SP has three parts:

- **Payload** – Data + Control information (all scan formats), the payload content is varied to trade-off performance and flexibility. RDY bit(s) within the payload are included with some scan formats to provide the STL a means to stall progression of the TAPC state.
- **Delay** – Control information (optional) providing separation of adjacent payloads in time. Delay elements support simple external tool implementations where a delay element is used to stall progression of the TAPC state while it develops a new SP following the completion of the prior payload.

The header elements, delay elements, and control information within the payload element is consumed by the TAP.7 controller. This and other control information within the SP payload is not visible to the EPU and STL TAPCs.

56.8.8.1 Payload Element Content

56.8.8.1.1 Input and Output Bit Frames

An input bit frame is sourced by the external tool and an output bit frame is sourced by the TAP.7 controller. The payload may contain an input bit frame, an output bit frame, or both. When an input bit frame arrives at the TAP.7 controller, the TDI and TMS information within it is presented in parallel to the TAP.1 controllers within the EPU and STL. The output bit frame begins when the input frame is completed. The payload is completed when the EPU and STL are ready to utilize this information and the TDO data needed to complete the output bit frame is available. This process is repeated for each SP.

With input bit frames, MScan and OScan scan formats have no control bits input bit frames.

With output bit frames:

- TDO information passed to the external tool is a logic 1 when the EPU indicates the TDO pin would be high impedance.
- RDY bits provide TAP.7 stall opportunities with MScan and some OScan formats.
- PC0 and PC1 bits are added to MScan scan formats to allow Wire-ANDed output.

56.8.8.1.2 Varying the content of input and output bit frames

The various scan formats (MScan, OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. These scan formats vary the content of SPs to balance flexibility and performance for different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. The MScan and OScan scan formats determine the factors affecting the payload content as shown in the following table.

Table 56-23. Factors determining the SP payload content

Scan format	Payload content determined by the:	
	TAPC state	Header
MScan	–	–
OScan	Yes	–

56.8.8.2 Delay Element Content

A delay element can be zero, one, two, or n bits in length. One and two bit delay elements are fixed length with neither the external tool or TAP.7 controller driving the TMSC pin. The TMSC pin is kept at the last value driven by either the external tool or TS. With an n-bit delay elements, the external tool drives the TMSC pin for the first n-1 bits and may drive the TMSC pin the nth bit. With an n-bit delay element the string of delay element bits is a series of directives virtually the same as those used by a CP (DLY_NOP, DLY_END, and DLY_RES).

56.8.8.3 Scan Formats

56.8.8.3.1 Overview

Scan formats utilizing the Advanced Protocol address different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. In one extreme two types of control information, the first allowing the stall of the completion of the Scan Packet, and the second supporting the Wire-AND of TAP.7 controller output are added to the TMS, TDI, and TDO information within the Scan Packet. In the other extreme, the external tool may minimize the information transferred for each TAPC state using its understanding of the application and transfer only the data of interest. In some cases the transfer of only one bit of information per TAPC is

required. There are a number of scan formats that operate between these two extremes. The external tool chooses a scan format that best matches the performance/functionality needs of the application.

The scan formats added to specify the use of the Advance Protocol are listed below:

- **MScan** – Maximum flexibility.
- **OScan0-7** – Optimized for test and debug applications.

These scan formats provide seven different functions. Five factors have influenced the definition of these scan formats:

- Supporting the capabilities of the IEEE1149.x and IEEE 1532 Standards.
- Providing the STL and external tool an opportunity to stall the TAPC state progression.
- Providing a minimum pin count and scalable functionality.
- Maximizing the efficiency of scan operations utilized for applications debug operations.
- Providing a rich set of capability for high end applications debug.

The performance and flexibility of MScan and OScan scan formats are shown in [Table 56-24](#) and [Table 56-26](#). The performance and flexibility of these scan formats are given subjective/approximate ratings in these tables. These ratings range from least to best. Use cases for these scan formats are also included in these tables.

56.8.8.3.2 MScan scan formats

The MScan scan format provides a universal scan function. It is the most flexible but lowest-performance scan format. The Scan Packets used by these scan formats are packed with data and control information and is the same for all TAPC states. This scan format accommodates the deployment of IEEE 1149.1 IP with non-compliant behavior within the STL. The STL is allowed to stall the TAPC state progression (to pace the arrival of Scan Packets with its ability to process them), and uses Wire-ANDed Output.

Table 56-24. MScan scan format use case summary

Scan format	Supporting	Performance	Flexibility	TCKC source
MScan	STL Stalls	Least	Best	External tool or TS
	Test			
	Non-compliant behavior STL IP			
	Multi-chip debug communication			
	Controller ID Allocation			

Table 56-25. MScan Scan Packet content

	Non-shift TAP controller states							Shift TAP controller states					
MScan	nTDI	TMS	PC0	RDY	PC1	TDO		nTDI	TMS	PC0	RDY	PC1	TDO

**Figure 56-18. MScan Transaction**

56.8.8.3.3 OScan Scan Formats

The OScan scan formats provide optimization choices where no knowledge of the data content of the scan exchange is needed. The Scan Packet content of these scan formats is modulated by a combination of the scan format and the TAPC state for some OScan scan formats. For instance, TDI data and TDO data is not exchanged for non-shift TAPC states and included in shift TAPC states in certain OScan formats. The modulation of Scan Packet content with TAPC state varies by scan format.

Figure 56-19. OScan Scan Packet content/TAPC state relationships

OScan scan formats replicate four functions in two forms:

- **OScan0 – OScan3:** Providing the best performance for a test clock source by the target system.
- **OScan 4 – OScan7:** Providing the best performance for a test clock sourced by the external tool.

The OScan4 – OScan7 scan formats are more efficient, as EOT escape sequences are used to identify an exit from the Shift-xR TAPC state. A Scan Packet associated with the Shift-xR TAPC state does not include a TMS bit. Instead, and EOT escape sequence overlaid on an nTDI bit causes an exit from shift TAPC state with no exit from this state occurring otherwise. A look at the 32-bit DR-Scan shows the impact of this optimization. A total of 96 bits are required when each Scan Packet associated with a Shift TAPC state when TMS is included in these Scan Packets while a total of 64 bits are required when TMS is not included in these Scan Packets. Assuming the EOT escape adds the equivalent of three bit periods, the number of TCK periods for this transfer is 67/96 or roughly 70% of the total without this optimization.

These scan formats may only be used with an external tool sourced TCKC as EOTs are utilized to improve its performance. The OScan0 – OScan3 Scan Formats always have a TMS bit included in the Scan Packet. The OScan scan format use case summary is shown in the following table.

Table 56-26. OScan scan format use case summary

Scan Format	Supporting	Performance	Flexibility	TCKC Source
OScan0	Stalls	↓	Best	External tool
OScan1	Test		↑	
OScan2	Debug Performance			
OScan3	Debug Downloads (input only)	Best	↑	External tool or TS
OScan4	Stalls	↓		
OScan5	Test			
OScan6	Debug Performance			
OScan7	Debug Downloads (input only)	Best		

Certain OScan optimizations are applied in a hierarchical manner.

- **Optimization I:** OScan1/OScan5 – RDY bit(s) and their trailing ONE bits are deleted from all Scan Packets.
- **Optimization II:** OScan2/OScan6 – Optimization I + nTDI and TDO bits are deleted from Scan Packets associated with non-shift TAPC states.
- **Optimization III:** OScan3/OScan7 – Optimization II + TDO bits are deleted from Scan Packets.
- **Optimization IV:** OScan4 – OScan7 – TMS bits are deleted from Scan Packets associated with shift TAPC states.

Table 56-27. OScan Scan Format "Payload"

Scan Format	Non-shift TAP controller states					Shift TAP controller states			
OScan0	nTDI	TMS	RDY	TDO		nTDI	TMS	RDY	TDO
OScan1	nTDI	TMS	–	TDO		nTDI	TMS	–	TDO
OScan2	–	TMS	–	–		nTDI	TMS	–	TDO
OScan3	–	TMS	–	–		nTDI	TMS	–	–
OScan4	nTDI	TMS	RDY	TDO		nTDI	–	RDY	TDO
OScan5	nTDI	TMS	–	TDO		nTDI	–	–	TDO
OScan6	–	TMS	–	–	Note 1	nTDI	TMS	–	TDO
					Note 2	nTDI	–	–	TDO
OScan7	–	TMS	–	–		nTDI	–	–	–

Note 2: Following Shift-xR Scan Packet

56.9 Functional Description

This section combines the information given in the Ancillary Services, EPU Operation, and APU Operation sections into a single reference for performing common TAP.7 tasks.

56.9.1 Switching from Standard Protocol to Advanced Protocol

Upon exit of Type-0 to Type-4 reset, the CJTAG begins operation in Standard Protocol 4-pin mode. The following steps are required to move from Standard Protocol 4-pin mode to Advanced Protocol (either 4-pin or 2-pin) mode.

The first step required to move to the Advanced Protocol is to change the CJTAG control level to control level 2 via zero-bit scans (ZBS), as described in [Control levels](#).

After the control level is set to control level 2, TAP.7 commands can be executed as described in [EPU Commands](#). Execution of the Store Scan Format (STFMT) to set the scan format to any OSCAN0-7 or MSCAN format begins the switch from the Standard Protocol to the Advanced Protocol.

Once the STFMT command is executed selecting an Advanced Protocol scan format, the CJTAG transitions to the intermediate Control Protocol mode. The Control Protocol uses TMS inputs to control Configuration Change Packets as described in [Control Process Active \(CPA\) Function](#) and [Configuration Change Packets \(CP\)](#). Loading a change packet body value of 00 (CP_END) results in the switch to the Advanced Protocol.

If Advanced Protocol 2-pin operation is desired, the APFC register should be written to a value of 10 or 11 prior to the execution of the STFMT command that selects an advanced scan format. The APFC register is written via the Store Conditional 2-bit (STC2) command described in [Store Conditional 2-bit \(STC2\)](#).

Chapter 57

JTAG Data Communication (JDC)

57.1 Introduction

The JTAG Data Communication (JDC) module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory mapped register space and an external tool that accesses the JTAG port.

57.2 Overview

The JDC module consists of IPS accessible registers, JTAG accessible registers, and associated logic to coordinate movement of data from one register domain to another.

The JDC implements the following IPS data registers, occupying separate memory space:

- 32-bit memory mapped register that can be read or written via IPS (JOUT_IPS), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 32-bit memory mapped register that can only be read via IPS (JIN_IPS), and whose contents are loaded from a JTAG register (JIN).

In addition to the data registers themselves, logic is implemented to indicate when new data has been shifted in via the JTAG port and is ready to be read from the JIN_IPS register, and when new data has been written to the JOUT_IPS register and is ready to be read via the JTAG port. The state of these flags is captured into a status register (MSR), and also provided to a JTAG register (JOUT) for tool visibility.

There is a single bus interface to port register data out to the JTAGC, and a single bus interface to port data in from the JTAGC. The architecture is shown in the following figure.

Figure 57-1. JDC block diagram

57.3 Memory mapped registers

Four 32-bit registers are implemented. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.

JDC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (JDC_MCR)	32	R/W	0000_0000h	57.3.1/2899
4	Module Status Register (JDC_MSR)	32	R/W	0000_0000h	57.3.2/2900
8	JTAG Output Data Register (JDC_JOUT_IPS)	32	R/W	0000_0000h	57.3.3/2901
C	JTAG Input Data Register (JDC_JIN_IPS)	32	R	0000_0000h	57.3.4/2902

57.3.1 Module Configuration Register (JDC_MCR)

The MCR is used to enable the interrupt outputs of the JDC. This register is reset by system functional reset.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	Reserved															JIN_IEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	Reserved															JOUT_IEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

JDC_MCR field descriptions

Field	Description
0–14 Reserved	This field is reserved.
15 JIN_IEN	JIN Interrupt Enable. 0 Setting of MSR[JIN_INT] bit does not assert the JIN interrupt 1 Setting of MSR[JIN_INT] bit asserts the JIN interrupt
16–30 Reserved	This field is reserved.
31 JOUT_IEN	JOUT Interrupt Enable. 0 Setting of MSR[JOUT_INT] bit does not assert the JOUT interrupt 1 Setting of MSR[JOUT_INT] bit asserts the JOUT interrupt

57.3.2 Module Status Register (JDC_MSR)

The MSR holds the JTAG register status and interrupt bits. This register is reset by system functional reset.

Address: 0h base + 4h offset = 4h

JDC_MSR field descriptions

Field	Description
0–12 Reserved	This field is reserved.
13 JIN_RDY	JIN Ready (read only). 0 Cleared upon software read of JIN_IPS contents via IPS 1 Set when new data is written to the JIN_IPS register
14 Reserved	This field is reserved.
15 JIN_INT	JIN Interrupt.

Table continues on the next page...

JDC_MSR field descriptions (continued)

Field	Description
	0 Cleared by writing logic 1 1 Set when new data is written to the JIN_IPS register
16–28 Reserved	This field is reserved.
29 JOUT_RDY	JOUT Ready (read only). 0 Cleared upon tool read of JOUT register via JTAG port 1 Set when new data is written to the JOUT_IPS register
30 Reserved	This field is reserved.
31 JOUT_INT	JOUT Interrupt. 0 Cleared by writing logic 1 1 Set when JOUT_RDY bit is cleared by tool reading JOUT register

57.3.3 JTAG Output Data Register (JDC_JOUT_IPS)

The JOUT_IPS register holds data written via IPS. The JOUT_IPS contents are ported out and captured into the JOUT register to be read via the JTAG port. This register is reset by system functional reset.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

JDC_JOUT_IPS field descriptions

Field	Description
0–31 Data	JOUT_IPS data.

57.3.4 JTAG Input Data Register (JDC_JIN_IPS)

Data written to the JTAG input data register (JIN) via the JTAG port is held in the JIN_IPS register, where it can be read via IPS. This register is reset by system functional reset.

Address: 0h base + Ch offset = Ch

JDC_JIN_IPS field descriptions

Field	Description
0–31 Data	JIN_IPS data.

57.4 Non-Memory mapped register definition

The JDC also implements two JTAG accessible registers that are not memory mapped. One JTAG register is used to shift in data to be placed in the JIN_IPS register. The other JTAG register captures data from the JOUT_IPS register and ready status from the MSR to be shifted out via the JTAG port.

57.4.1 JTAG output data register (JOUT)

The JOUT register captures data from the JOUT_IPS register upon execution of the JOUT_READ JTAG instruction. It also holds the JIN_RDY and JOUT_RDY status bits. This register is reset by system power-on reset and JTAG reset. The following figure shows the format of the JOUT register.

1. The reset value of the JOUT register is 34'b0.

The JOUT register is described in the following table.

Table 57-6. JOUT JTAG register field descriptions

Field	Description
JOUT_IPS Data	Data value from JOUT_IPS register
JIN_RDY	State of JIN_RDY bit from MSR
JOUT_RDY	State of JOUT_RDY bit from MSR

57.4.2 JTAG input data register (JIN)

Data is written to the JIN register via JTAG during execution of the JIN_WRITE JTAG instruction. The JIN data is later captured in the JIN_IPS register to be read via IPS. This register is reset by system power-on reset and JTAG reset. The following figure shows the format of the JIN register.

1. The reset value of the JIN register is 32'b0.

The JIN register is described in the following table.

Table 57-7. JIN JTAG register field descriptions

Field	Description
JIN Data	Contains data to be captured in JIN_IPS register upon exit of Update-DR state when executing WRITE_JIN JTAG instruction.

57.5 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data into a memory mapped register that can be accessed via IPS. It also provides the ability to capture data written to a memory mapped register into a JTAG shift register for output via the JTAG port. An overview of the module functionality is described below.

- A software write to the JOUT_IPS register sets the JOUT_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port. The state of the JOUT_RDY bit is reflected in the MSR and also ported out to the JOUT register. A JTAG read of the JOUT register via execution of the JOUT_READ

instruction with a JOUT_RDY bit whose value is logic 1 indicates the register contains new data. The JOUT_RDY flag bit is cleared upon exit of the Capture-DR JTAG state during execution of the JOUT_READ instruction. Clearing the JOUT_RDY bit indicates to software that a new data value can be written to the JOUT_IPS register.

- A JTAG write to the JIN register via execution of the JIN_READ JTAG instruction updates the contents of the JIN_IPS register upon exit of the Update-DR state. An update of the JIN_IPS register sets the JIN_RDY flag bit, indicating new data is available to be read via IPS. The state of the JIN_RDY bit is reflected in the MSR register and also ported out to the JOUT register. The JIN_RDY flag bit is cleared upon software read of the JIN_IPS register. A JTAG read of the JOUT register with a JIN_RDY value of logic 0 indicates new data can be written to the JIN register.

57.5.1 JTAG register access

Refer to the JTAGC documentation for information on how to access the JTAG registers.

57.5.1.1 JDC block instructions

The JDC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 57-8. JTAG instructions

Instruction	Code[4:0]	Instruction Summary
Reserved	00001	Factory debug reserved
JOUT_READ	00010	Selects JOUT data register. Data from JOUT_IPS is captured into JOUT data register upon entry to Capture-DR state while JOUT_READ is active.
JIN_WRITE	01110	Selects JIN data register. Data from JIN is captured into JIN_IPS upon exit of Update-DR state while JIN_WRITE is active.
BYPASS	11111	Selects bypass register for data operations
Reserved	All other opcodes	Decoded to select bypass register

Chapter 58

Nexus Development Interface (NDI)

58.1 Overview

The NDI integrates seven individual Nexus modules that provide the chip's development support interface.

All seven Nexus modules are connected to the Nexus Port Controller (NPC). The following table lists the modules.

Table 58-1. Nexus modules of NDI

Nexus modules	For detailed information, see
Two Nexus e200z7 core interfaces (NZ7C3): one each for Core0 and Core1	<i>e200z759n3 Core Reference Manual</i> (document number e200z759n3CRM)
Two Nexus eTPU development interfaces (NDEDI and NSEDI)	Nexus eTPU Development Interface (NDEDI)
Two Nexus crossbar eDMA interfaces (NXDM): one each for eDMA_A and eDMA_B One Nexus crossbar SIPI interface (NXSI)	Nexus eDMA Interface (NXDM) and Nexus SIPI Interface (NXSI)

The chip has no debug capability for the CSE module. CSE is not traceable.

NOTE

In each core, simultaneous access to debug control registers by software and Nexus hardware is not possible. When debug registers are allocated to Nexus hardware, they cannot be accessed by software.

58.2 Nexus clients for TAP access

After the NDI is out of the reset state: To grant the NDI ownership of the TAP, a specific instruction must be loaded in the JTAG Controller (JTAGC) module. Each Nexus client has its own JTAGC instruction opcode for ownership of the TAP, granting that client read/write access to the TAP's registers. The following table shows the JTAGC instruction opcode for each Nexus client. After the JTAGC opcode for a client has been loaded, the client is enabled by loading its NEXUS-ENABLE instruction.

Table 58-2. JTAG client select instructions

JTAGC instruction	Opcode	Description
ACCESS_AUX_NPC	10000	Enables access to the NPC TAP controller
ACCESS_AUX_ONCE	10001	Enables access to the primary OnCE TAP controller (Core0)
ACCESS_AUX_eTPU	10010	Enables access to the eTPU Nexus TAP controller (ETPU A/B)
ACCESS_AUX_NXDM	10011	Enables access to the eDMA Nexus TAP controller (eDMA_A)
Reserved	10100	Not used
ACCESS_AUX_SIPI	10101	Enables access to the SIPI Nexus TAP controller
ACCESS_AUX_eTPU_Secondary	10110	Enables access to secondary ETPU Nexus TAP controller (ETPU C)
ACCESS_AUX_NXDM_B	10111	Enables access to the second eDMA Nexus TAP controller (eDMA_B)
Reserved	11000	Not used
ACCESS_AUX_ONCE_1	11001	Enables access to the secondary OnCE TAP controller (Core1)
ACCESS_AUX_PAR	11010	Enables parallel access to both OnCE TAP controllers (Core0 and Core1)
ACCESS_AUX_MULTI	11100	Enables serial access to both OnCE TAP controllers (Core0 followed by Core1)
ACCESS_AUX_JDC	11101	Enables access to the JDC TAP controller
Reserved	11110	Not used
BYPASS	11111	Selects bypass register for data operations

58.3 Debug break and cross-triggering

This chip supports central break control among the cores and debug modules such as eTPU, eDMA, and Watchdog, allowing synchronous restart control for all cores when exiting debug mode.

Figure 58-1. Debug break and cross-triggering logic

58.3.1 Break control

Multiple modules on the chip, including the Nexus trace blocks, have debug features that allow them to request device-wide breaks to enter debug mode. All debug mode entry requests are combined (logically ORed) together, and the result produces the debug requests to the cores and peripherals.

The cross-triggering logic generates these debug request signals:

- Debug Request signal (active high) for all non-core peripherals
- External Debug Request (active high) for requesting an external debug event to cores

58.3.2 Cross-triggering control

Cross-triggering provides the ability to select whether modules enter debug mode upon receiving halt request signals from Nexus modules. In response to debug mode entry, some modules can be programmed to halt operation or to continue normal operation. This cross-triggering feature is implemented through debug control bits in the modules. The cores and peripherals can be programmed selectively with their respective control bits.

58.3.3 Synchronous restart control

The cross-triggering logic implements a feature that enables all debug peripherals—cores and peripherals that are put in the debug state—to restart synchronously, as follows:

1. The debugging tool sequentially scans the CPUSCR for each core to restore the proper processor state.
2. The debugging tool scans into the main chip TAP controller the instruction whose execution selects all core TAP controllers in parallel.
3. To enable any combination of cores to exit debug mode synchronously: The debugging tool simultaneously scans into each core's TAP instruction register (OCMD) the 10-bit sequence 180h, which sets both the GO and EX fields to 1 and clears RS[0:6] field to 0.
4. If a core exits debug mode, it sets a flag OnCE go+exit command.
5. When the OR of the core OnCE go+exit command signals is asserted, all other selected non-cores and peripherals in debug synchronously exit debug mode.

58.4 Nexus eDMA Interface (NXDM) and Nexus SIPI Interface (NXSI)

The e200z7 eDMA Nexus module (NXDM) and SIPI module (NXSI) comply with the Class 3 defined data trace feature of the IEEE-ISTO 5001-2003 standard.

58.4.1 Introduction

The NXDM can be programmed to trace data accesses for the eDMA module on the system bus. The NXSI can be programmed to trace data accesses for the SIPI module on the system bus. This eDMA module and SIPI module as well as the Nexus module are components of the e200z7 platform. All output messages and register accesses are compliant with the protocol defined in the IEEE-ISTO 5001 standard.

NOTE

The auxiliary port and its signals, such as MCKO, MSEO[1:0], MDO[15:0] and others, are referenced. The device NPC module arbitrates the access of the single auxiliary port. The functions of the NXDM and SIPI modules are described without the interaction of the NPC, as if Nexus has a dedicated auxiliary port, to simplify the description.

58.4.1.1 Block Diagrams

Figure 58-2 shows a block diagram of the NXDM. The block diagram of the NXSI is the same.

Figure 58-2. NXDM and NXSI Block Diagram

58.4.1.2 Features

Features include the following:

- Data trace via data write messaging (DWM) and data read messaging (DRM). This provides the capability for the development tool to trace reads and/or writes through the eDMA and SIPI modules to (selected) internal memory resources.
- Watchpoint messaging via the auxiliary pins.
- Watchpoint trigger enable of data trace messaging (DTM).

- Registers for data trace, watchpoint generation, and watchpoint trigger.
- All features controllable and configurable via the JTAG port.
- Power management.
 - Low power design
 - Dynamic power management of FIFOs and control logic

58.4.2 External Signal Description

The NXDM and NXSI modules use the same pins and pin protocol as the JTAG Controller and NPC modules.

58.4.2.1 Rules for Output Messages

The NXDM and NXSI modules observe the same rules for output messages as the NPC.

58.4.2.2 Auxiliary Port Arbitration

The NXDM and NXSI modules arbitrate for the shared Nexus port. This arbitration is handled by the NPC based on prioritized requests from the NXDM, NXSI, and the other Nexus clients sharing the port.

58.4.3 NXDM and NXSI Programmers Model

This section describes the programmers model. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. See the JTAGC module details for more information about Nexus register access.

58.4.3.1 NXDM and NXSI Nexus Register Map

Table 58-3. NXDM and NXSI Register Map

The data trace end address registers define the end addresses for each trace channel.

Access: R/W

**Figure 58-8. Data Trace Start Address Registers (DTEA1, DTEA2)**

Table 58-8 illustrates the range that is selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 58-8. Data Trace Address Range Options

Programmed Values	Range Control Bit Value	Range Selected
DTSA < or = DTEA	0	DTSA → ← DTEA
DTSA < or = DTEA	1	← DTSA DTEA →
DTSA > DTEA	-	Invalid range, no trace

NOTE

DTSA must be less than (or equal to) DTEA to guarantee correct data write/read traces. When the range control bit is 0 (internal range), accesses to DTSA and DTEA addresses are traced. When the range control bit is 1 (external range), accesses to DTSA and DTEA are not traced.

58.4.3.2.7 Breakpoint / Watchpoint Control Register 1 (BWC1)

Breakpoint/watchpoint control register 1 controls attributes for generation of NXDM and NXSI watchpoint number 1.

Access: R/W

**Figure 58-9. Break / Watchpoint Control Register 1 (BWC1)**

Table 58-9. BWC1 Field Description

Field	Description
31-30 BWE1	Breakpoint/watchpoint #1 enable 00 Internal Nexus watchpoint #1 disabled 01-10 Invalid value 11 Internal Nexus watchpoint #1 enabled
29-28 BRW1	Breakpoint/watchpoint #1 read/write select 00 Watchpoint #1 hit on read accesses 01 Watchpoint #1 hit on write accesses 10 Watchpoint #1 on read or write accesses 11 Invalid value
27-18	Reserved, read as 0.
17-16 BWR1	Breakpoint/watchpoint #1 register compare 00 No register compare (same as BWC1[31:30] = 2'b00) 01 Invalid value 10 Compare with BWA1 value 11 Invalid value
15 BWT1	Breakpoint/watchpoint #1 type 0 Invalid value 1 Watchpoint #1 on data accesses
14-0	Reserved, read as 0.

58.4.3.2.8 Breakpoint / Watchpoint Control Register 2 (BWC2)

Breakpoint/watchpoint control register2 controls attributes for generation of NXDM and NXSI watchpoint number 2.

**Figure 58-10. Break / Watchpoint Control Register 2 (BWC2)**

Table 58-10. BWC1 Field Description

Field	Description

29-28 BRW2	Breakpoint/watchpoint #1 read/write select 00 Watchpoint #2 hit on read accesses 01 Watchpoint #2 hit on write accesses 10 Watchpoint #2 on read or write accesses 11 Invalid value
27-18	Reserved, read as 0.
17-16 BWR2	Breakpoint/watchpoint #2 register compare 00 No register compare (same as BWC1[31:30] = 2'b00) 01 Invalid value 10 Compare with BWA2 value 11 Invalid value
15 BWT2	Breakpoint/watchpoint #2 type 0 Invalid value 1 Watchpoint #2 on data accesses
14-0	Reserved, read as 0.

58.4.3.2.9 Breakpoint/Watchpoint Address Registers 1 and 2 (BWA1 and BWA2)

The breakpoint/watchpoint address registers are compared with bus addresses to generate internal watchpoints.

**Figure 58-11. Breakpoint / Watchpoint Address Registers (BWA1, BWA2)**

58.4.3.2.10 Unimplemented Registers

Unimplemented registers are those with client select and index value combinations other than the ones listed in [Table 58-3](#). For unimplemented registers, the NXDM and NXSI modules drive TDO to zero during the "SHIFT-DR" state. The modules also transmit an error message with the invalid access opcode encoding.

58.4.3.2.11 Programming Considerations ($\overline{\text{RESET}}$)

If Nexus3 register configuration is to occur during system reset (as opposed to debug mode), all NXDM configuration should be completed between the negation of JCOMP and system reset de-assertion, after the JTAG DID register has been read by the tool.

58.4.3.2.12 IEEE 1149.1 (JTAG) Test Access Port

The NXDM and NXSI modules use the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. See the JTAGC module details for more information about the JTAG interface.

The NXDM and NXSI modules implement a 4-bit instruction register (IR). The valid instructions and method for register access are outlined in the JTAGC module details.

58.4.3.2.12.1 NXDM and NXSI JTAG DID Register

This JTAG DID register that is included in the NXDM and NXSI modules provides key development attributes to the development tool concerning the NXDM and NXSI blocks. The register is accessed through the standard JTAG IR/DR paths. Refer to the PMC chapter.

Figure 58-12. NXDM and NXSI JTAG DID Register

Table 58-11. NXDM and NXSI JTAG DID Field Descriptions

Field	Description
31-28 PRN ¹	Embedded part revision number (0x0)
27-22 DC	Freescale design center ID number (0x1F)

Table continues on the next page...

Table 58-11. NXDM and NXSI JTAG DID Field Descriptions (continued)

Field	Description
21-12 PIN	NXDM and NXSI module part identification number, defines the features set. (0x60)
11-1 MIC	Manufacturer identity code 0x00E Freescale
0	Fixed per JTAG 1149.1 1 Always set

1. The revision number is initially 0 and could change in the future.

58.4.3.2.12.2 Enabling the NXDM and NXSI TAP Controllers

Assertion of a power-on-reset signal or assertion of the JCOMP pin resets all TAP controllers on the device. Upon exit from the test-logic-reset state, the IR value is loaded with the JTAG DID. When the NXDM or NXSI TAP is accessed, this information helps the development tool obtain information about the Nexus module it is accessing, such as version, sequence, feature set, and so forth.

58.4.3.2.12.3 NXDM and NXSI Register Access via JTAG

Access to Nexus register resources is enabled by loading a single instruction (NEXUS_ACCESS) into the JTAG Instruction Register (IR). This IR is part of the IEEE 1149.1 TAP controller within the NXDM and NXSI modules.

After the JTAG NEXUS_ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in [Table 58-3](#).

Reading/writing of a Nexus register then requires two (2) passes through the data-scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the Nexus register to be accessed by providing an index (refer to [Table 58-3](#)), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG data register (DR). [Figure 58-13](#) shows the format of this register.
2. The second pass through the DR then shifts the data in or out of the JTAG port, lsb first.
 - a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the capture-DR state.
 - b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the update-DR state.

**Figure 58-13. JTAG DR for NEXUS Register Access****Table 58-12. DR Read/Write Encoding**

Nexus Register Index	Description
Read/Write (R/W)	0 Read 1 Write

58.4.4 Functional Description

58.4.4.1 Enabling NXDM and NXSI Operation

The NXDM (and NXSI) module is enabled by loading a single instruction (ACCESS_AUX_TAP_DMA or ACCESS_AUX_TAP_NXSI) into the JTAG instruction register (IR), and then loading the corresponding OnCE OCMD register with the NEXUS_ACCESS instruction. After it is enabled, the module is ready to accept control input via the JTAG pins.

The Nexus module is disabled when the JTAG state machine reaches the test-logic-reset state. This state can be reached by the assertion of the JCOMP pin or by cycling through the state machine using the TMS pin. The Nexus module is also disabled if a power-on reset (POR) event occurs.

If the NXDM (and NXSI) module is disabled, no trace output is provided, and the module disables (drive inactive) auxiliary port output pins (MDO[15:0], MSEO[1:0], MCKO). Nexus registers are not be available for reads or writes.

58.4.4.2 TCODEs Supported by NXDM and NXSI

The NXDM and NXSI pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages. The NXDM and NXSI blocks currently support the public TCODEs seen in [Table 58-13](#).

Table 58-13. Public TCODEs Supported

Message Name	Packet Size Bits		Packet Name	Packet Type	Packet Description
	Min	Max			
Data Trace - Data Write Message	6	6	TCODE	Fixed	TCODE number = 5
	4	4	SRC	Fixed	Source processor identifier (multiple Nexus configuration)
	3	3	DSZ	Fixed	Data size (refer to Table 58-15)
	1	32	U-ADDR	Variable	Unique portion of the data write value
	1	64	DATA	Variable	Data write value
Data Trace - Data Read Message	6	6	TCODE	Fixed	TCODE number = 6
	4	4	SRC	Fixed	Source processor identifier (multiple Nexus configuration)
	3	3	DSZ	Fixed	Data size (refer to Table 58-15)
	1	32	U-ADDR	Variable	Unique portion of the data read value
	1	64	DATA	Variable	Data read value
Error Message	6	6	TCODE	Fixed	TCODE number = 8
	4	4	SRC	Fixed	Source processor identifier (multiple Nexus configuration)
	5	5	ECODE	Fixed	Error code (refer to Table 58-14)
Data Trace - Data Write Message w/ Sync	6	6	TCODE	Fixed	TCODE number = 13 (0xD)
	4	4	SRC	Fixed	Source processor identifier (multiple Nexus configuration)
	3	3	DSZ	Fixed	Data size (refer to Table 58-15)
	1	32	F-ADDR	Variable	Full access address (leading zero (0) truncated)
	1	64	DATA	Variable	Data write value
Data Trace - Data Read Message w/ Sync	6	6	TCODE	Fixed	TCODE number = 14 (0xE)
	4	4	SRC	Fixed	Source processor identifier (multiple Nexus configuration)
	3	3	DSZ	Fixed	Data size (refer to Table 58-15)
	1	32	F-ADDR	Variable	Full access address (leading zero (0) truncated)
	1	64	DATA	Variable	Data read value

Table continues on the next page...

Table 58-13. Public TCODEs Supported (continued)

Message Name	Packet Size Bits		Packet Name	Packet Type	Packet Description
	Min	Max			
Watchpoint Message	6	6	TCODE	Fixed	TCODE number = 15 (0xF)
	4	4	SRC	Fixed	Source processor identifier (multiple Nexus configuration)
	4	4	WPHIT	Fixed	Number indicating watchpoint sources

Table 58-14. Error Code (ECODE) Encoding (TCODE = 8)

Error Code (ECODE)	Description
00000	Invalid value
00001	Invalid value
00010	Data Trace overrun
00011	Invalid value
00100	Invalid value
00101	Invalid access opcode (Nexus Register unimplemented)
00110	Watchpoint overrun
00111	Invalid value
01000	Data Trace and Watchpoint overrun
01001-11111	Invalid value

Table 58-15. Data Trace Size (DSZ) Encodings (TCODE = 5, 6, 13, 14)

DTM Size Encoding	Transfer Size
000	Byte
001	Halfword (two bytes)
010	Word (four bytes)
011	Doubleword (eight bytes)
100-111	Invalid value

58.4.4.2.1 Data Trace

This section deals with the data trace mechanism supported by the NXDM and NXSI modules. Data trace is implemented via data write messaging (DWM) and data read messaging (DRM).

58.4.4.2.2 Data Trace Messaging (DTM)

XDM and NXSI data trace messaging is accomplished by snooping the NXDM and NXSI data bus, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NXDM (and NXSI) module traces all data access that meet the selected range and attributes.

NOTE

Data trace is ONLY performed on DMA or SIPI accesses to the system bus.

58.4.4.2.3 DTM Message Formats

The NXDM (and NXSI) block supports five types of DTM Messages - data write, data read, data write synchronization, data read synchronization and error messages.

58.4.4.2.3.1 Data Write and Data Read Messages

The data write and data read messages contain the data write/read value and the address of the write/read access, relative to the previous data trace message. Data write message and data read message information is messaged out in the following format:

Figure 58-14. Data Write/Read Message Format

58.4.4.2.3.2 DTM Overflow Error Messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards incoming messages until it has completely emptied the queue. After it is emptied, an error message is queued. The error encoding indicates which types of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message incorporates the data trace only error encoding (00010). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message incorporates error encoding (01000).

Error information is messaged out in the following format:

Figure 58-15. Error Message Format

58.4.4.2.3.3 Data Trace Synchronization Messages

A data trace write/read w/ sync. message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (refer to [Table 58-16](#)):

- Initial data trace message upon exit from system reset or whenever data trace is enabled is a synchronization message.
- Upon returning from a low power state, the first data trace message is a synchronization message.
- Upon returning from debug mode, the first data trace message is a synchronization message.
- After occurrence of queue overrun (can be caused by any trace message), the first data trace message is a synchronization message.
- After the periodic data trace counter has expired indicating 255 without-sync data trace messages have occurred since the last with-sync message occurred.
- Upon assertion of the Event In ($\overline{\text{EVTI}}$) pin, the first data trace message is a synchronization message if the eic bits of the dc register have enabled this feature.
- Upon data trace write/read after the previous dtm message was lost due to an attempted access to a secure memory location.
- Upon data trace write/read after the previous dtm message was lost due to a collision entering the fifo between the dtm message and any of the following: error message, or watchpoint message.

Data trace synchronization messages provide the full address (without leading zeros) and insure that development tools fully synchronize with data trace regularly.

Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read w/ sync. messages is as follows:

Nexus eDMA Interface (NXDM) and Nexus SIPI Interface (NXSI)

Max length = 109 bits; Min length = 15 bits

Figure 58-16. Data Write/Read w/ Sync Message Format

Exception conditions that result in data trace synchronization are summarized in [Table 58-16.](#)"

Table 58-16. Data Trace Exception Summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (JCOMP), queue pointers, counters, state machines, and registers within the NXDM and NXSI module are reset. If data trace is enabled, the first data trace message is a data write/read w/ sync. message.
Data Trace Enabled	The first data trace message (after data trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a low power mode or debug mode the next data trace message is converted to a data write/read w/ sync. message.
Queue Overrun	An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. After it is emptied, an error message is queued. The error encoding indicates the types of messages that attempted to be queued while the FIFO was being emptied. The next DTM message in the queue is a data write/read w/ sync. message.
Periodic Data Trace Synchronization	A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read w/ sync. message is queued. The periodic data trace message counter then resets.
Event In	If the nexus module is enabled, an EVTI assertion initiates a data trace write/read w/ sync. message upon the next data write/read (if data trace is enabled and the eic bits of the dc register have enabled this feature).
Attempted Access to Secure Memory	Any attempted read or write to secure memory locations temporarily disable data trace & cause the corresponding DTM to be lost. A subsequent read/write queues a data trace read/write with sync. message.
Collision Priority	All messages have the following priority: Error → WPM → DTM. A DTM message which attempts to enter the queue at the same time as an error message, or watchpoint message is lost. A subsequent read/write queues a data trace read/write with sync. message.

58.4.4.2.4 DTM Operation

58.4.4.2.4.1 Enabling Data Trace Messaging

Data trace messaging can be enabled in one of two ways.

- Setting the DC1[TM] field to enable data trace
- Using the WT[DTS] field to enable data trace on watchpoint hits

58.4.4.2.4.2 DTM Queueing

NXDM and NXSI implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

NOTE

If multiple trace messages must be queued at the same time, watchpoint messages have the highest priority (WPM → DTM).

58.4.4.2.4.3 Relative Addressing

The relative address feature is compliant with IEEE-ISTO Nexus 5001-2003 and is designed to reduce the number of bits transmitted for addresses of data trace messages. Relative addressing is the same as described for the NZ7C3.

58.4.4.2.4.4 Data Trace Windowing

Data write/read messages are enabled via the RWT1(2) field in the data trace control register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA registers and by the RC1(2) field in the DTC. All eDMA or SIPI initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

58.4.4.2.4.5 System Bus Cycle Special Cases

Table 58-17. System Bus Cycle Special Cases

Special Case	Action
System bus cycle aborted (DABORT asserted)	Cycle ignored
System bus cycle with data error	Data Trace Message discarded
System bus cycle completed without error	Cycle captured and transmitted
System bus cycle is an instruction fetch	Cycle ignored

58.4.4.2.5 Data Trace Timing Diagrams (Eight MDO configuration)

Data trace timing for the NXDM and NXSI is the same as for the NZ7C3.

58.4.4.3 Watchpoint Support

The NXDM and NXSI module provides watchpoint messaging via the auxiliary pins, as defined by IEEE-ISTO 5001-2003.

Watchpoint messages can be generated using the NXDM and NXSI defined internal watchpoints.

58.4.4.3.1 Watchpoint Messaging

Enabling watchpoint messaging is accomplished by setting the watchpoint messaging enable bit, DC1[WEN]. Using the BWC1 and BWC2 registers, two independently controlled internal watchpoints can be initialized. When a DMA or SIPI access address matches on BWA1 or BWA2, a watchpoint message is transmitted.

The Nexus module provides watchpoint messaging using the TCODE. When either of the two possible watchpoint sources asserts, a message is sent to the queue to be messaged out. This message indicates the watchpoint number.

Figure 58-17. Watchpoint Message Format

Table 58-18. Watchpoint Source Description

Watchpoint Source (4 bits)	Watchpoint Description
XXX1	Invalid value
XX1X	Invalid value
X1XX	Internal Watchpoint #1 (BWA1 match)
1XXX	Internal Watchpoint #2 (BWA2 match)

58.4.4.3.2 Watchpoint Error Message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. After it is emptied, an error message is queued. The error encoding indicates which types of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message incorporates the watchpoint only error encoding (00110). If a data trace message also attempts to enter the queue while it is being emptied, the error message incorporates error encoding (01000).

Error information is messaged out in the following format (refer to [Figure 58-18](#)).

Figure 58-18. Error Message Format

Chapter 59

Nexus Port Controller (NPC)

59.1 Chip-specific NPC information

The NPC connects to several other Nexus modules that compose the chip's Nexus Development Interface (NDI).

For more information, see the chip-level details about debug and development support.

59.1.1 DID register reset value

The reset value of the [Nexus Device ID \(DID\) Register](#) depends on the chip version.

The PRN, PIN, and DC parameters define the chip-specific values of correspondingly named fields in the DID register. The following table provides their values.

Table 59-1. Reset values of PRN, DC, and PIN fields of DID register

DID field	Device-specific value
PRN	0h for masksets 1N45H and 2N45H 1h for maskset 3N45H
DC	20h
PIN	377h

59.1.2 NPC MDO pins

The number of available Message Data Out (MDO) pins varies by NPC mode of operation. The following table shows the number of MDO pins available in full-port mode and reduced-port mode.

Table 59-2. MDO pins available by NPC mode of operation

Mode	Number of available MDO pins
Full-port mode	16
Reduced-port mode	12

59.2 Introduction

The following figure is a block diagram of the Nexus Port Controller (NPC) block.

Figure 59-1. Nexus Port Controller Block Diagram

59.2.1 Overview

On a system-on-a-chip device, there are often multiple blocks that require development support. Each of these blocks implements a development interface based on the IEEE-ISTO 5001-2001 standard. The blocks share input and output ports that interface with the development tool. The NPC controls the usage of the input and output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

59.2.2 Features

The NPC block performs the following functions:

- Controls arbitration for ownership of the Nexus Output Port
- Nexus Device Identification Register and Messaging
- Generates MCKO enable and frequency division control signals
- Generates a Nexus DDR mode status indication output signal
- Controls sharing of $\overline{\text{EVTO}}$
- Generates an MCKO clock gating control signal to enable gating of MCKO when the auxiliary output port is idle
- Control of the device-wide debug mode
- Generates asynchronous reset signal for Nexus blocks based on JCOMP input, censorship status, and power-on reset status
- Selectable mode for transmission of processor status information on MDO Auxiliary Output Port pins
- System clock status indication via MDO[0] following power-on reset
- Provides Nexus support for censorship mode

59.2.3 Modes of operation

The NPC block uses the JCOMP input, the censorship status signal and an internal power-on reset indication as its primary reset signals. Upon exit of reset, the mode of operation is determined by the Port Configuration Register (PCR) settings.

59.2.3.1 Reset

The NPC block is asynchronously placed in reset when either power-on reset is asserted, JCOMP is not set for Nexus access, the device enters censored mode, or the TAP controller state machine is in the Test-Logic-Reset state. Holding TMS high for 5 consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Following negation of power-on reset, the NPC remains in reset until the system clock achieves lock. The NPC is unaffected by other sources of reset. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state
- The output port pins are negated
- The TDI, TMS, and TCK TAP inputs are ignored (when in power-on reset, censored mode or JCOMP not set for NPC operation only)
- Registers default back to their reset values

59.2.3.2 Disabled-Port Mode

In disabled-port mode, output pin port enable signals are negated, thereby disabling message transmission. Any debug feature that generates messages can not be used. The primary features available are class 1 features and read/write access to the registers. Class 1 features include the ability to trigger a breakpoint event indication through EVTO.

59.2.3.3 Full-Port Mode

Full-port mode (FPM) is entered by asserting the MCKO_EN and FPM bits in the PCR. In All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific.

59.2.3.4 Reduced-Port Mode

Reduced-port mode (RPM) is entered by asserting the MCKO_EN bit and negating the FPM bit in the PCR. All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific.

59.2.3.5 Censored Mode

In censored mode, it should not be possible to read the contents of internal Flash externally. The NPC and all other Nexus blocks are held in reset when in censored mode , preventing Nexus read/write to memory mapped resources and the transmission of Nexus trace messages.

59.2.3.6 Nexus Double Data Rate Mode

Nexus double data rate (DDR) mode is enabled by asserting the DDR_EN bit in the PCR. DDR mode is only supported for MCKO_DIV settings of sys_clk/2, sys_clk/4 and sys_clk/8. In double data rate mode, message data is updated between each edge (both rising and falling) of MCKO, effectively doubling the message throughput of single data rate mode.

59.3 External signal description

59.3.1 Overview

The NPC pin interface provides for the transmission of messages from Nexus blocks to the external development tools and for access to Nexus client registers. The NPC pin definition is outlined in the following table. Pull information for the JTAG signals can be found in the JTAG chapter.

Table 59-3. NPC Signal Properties

Name	Port	Function	Reset State
EVTO_B	Nexus	Event Out pin	0b1
JCOMP	JTAG	JTAG Compliancy and TAP Sharing Control	—
MDO	Auxiliary	Message Data Out pins	0 ¹
MSEO	Auxiliary	Message Start/End Out pins	0b11
TCK	JTAG	Test Clock Input	—
TDI	JTAG	Test Data Input	—
TDO	JTAG	Test Data Output	High Z ²
TMS	JTAG	Test Mode Select Input	—

1. Following a power-on reset, MDO[0] remains asserted until power-on reset is exited and the system clock achieves lock.
2. TDO output buffer enable is negated when the NPC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented on TDO at the SoC level.

59.3.2 Detailed signal descriptions

This section describes each of the signals listed in [Table 59-3](#) in more detail. Note that the JTAG test clock (TCK) input from the pin is not a direct input to the NPC. The NPC requires two separate input clocks for TCK clocked logic, one for posedge (rising edge TCK) logic and one for negedge (falling edge TCK) logic. Both clocks are derived from the pin TCK, and generated external to the NPC.

59.3.2.1 EVTO_B — Event Out

Event Out ($\overline{\text{EVTO}}$) is an output pin that is asserted upon breakpoint occurrence to provide breakpoint status indication. The $\overline{\text{EVTO}}$ output of the NPC is generated based on the values of the individual $\overline{\text{EVTO}}$ signals from all Nexus blocks that implement the signal.

59.3.2.2 JCOMP — JTAG Compliancy

The JCOMP signal provides the ability to share the TAP. The NPC TAP controller remains in reset until it is enabled using the JCOMP signal.

59.3.2.3 MDO — Message Data Out

Message Data Out (MDO) are output pins used for uploading OTM, BTM, DTM, and other messages to the development tool. The development tool should sample MDO on the rising edge of MCKO. The width of the MDO bus used is determined by reset configuration.

59.3.2.4 MSEO_B — Message Start/End Out

Message Start/End Out ($\overline{\text{MSEO}}$) is an output pin that indicates when a message on the MDO pins has started, when a variable length packet has ended, or when the message has ended. The development tool should sample $\overline{\text{MSEO}}$ on the rising edge of MCKO.

59.3.2.5 TCK — Test Clock Input

Test Clock Input (TCK) pin is used to synchronize the test logic and control register access through the JTAG port.

59.3.2.6 TDI — Test Data Input

Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK.

59.3.2.7 TDO — Nexus Test Data Output

Test Data Output (TDO) pin transmits serial output for instructions and data. TDO is three-stateable and is actively driven in the SHIFT-IR and SHIFT-DR controller states. TDO is updated on the falling edge of TCK and sampled by the development tool on the rising edge of TCK.

59.3.2.8 TMS — Test Mode Select

Test Mode Select Input (TMS) pin is used to sequence the IEEE 1149.1-2001 TAP controller state machine. TMS is sampled on the rising edge of TCK.

59.4 Register definition

This section provides a detailed description of the NPC registers accessible to the end user. Individual bit-level descriptions and reset states of the registers are included.

The following table shows the NPC registers by index values. The registers are not memory-mapped and can only be accessed via the TAP. The NPC block does not implement the client select control register because the value does not matter when accessing the registers.

Note that the bypass and instruction registers have no index values. These registers are not accessed in the same manner as Nexus client registers. Refer to the individual register descriptions for more detail.

Table 59-4. NPC registers

Index	Register
0	Device ID Register (DID)
127	Port Configuration Register (PCR)

59.4.1 Register descriptions

This section consists of NPC register descriptions.

59.4.1.1 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS instruction or any unimplemented instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

59.4.1.2 Instruction register

The NPC block uses a 4-bit instruction register as shown in the following table. The instruction register is accessed via the SELECT_IR_SCAN path of the tap controller state machine, and allows instructions to be loaded into the block to enable the NPC for register access (NEXUS_ENABLE) or select the bypass register as the shift path from TDI to TDO (BYPASS or unimplemented instructions).

Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in synchronous loading of the BYPASS instruction. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the BYPASS instruction. During the Capture-IR TAP controller state, the instruction register is loaded with the value of the previously executed instruction, making this value the register’s read value when the TAP controller is sequenced into the Shift-IR state.

	3	2	1	0
R	Previous Instruction Opcode			
W	Instruction Opcode			
Reset:	BYPASS Instruction Opcode (0xF)			

59.4.1.3 Nexus Device ID (DID) Register

The device identification register, shown in the following figure, allows the part revision number, design center, part identification number, and manufacturer identity code of the part to be determined through the output port.

Table 59-7. DID field descriptions

Bit	Name	Description
31:28	PRN	Part Revision Number These bits contain the revision number of the part
27:22	DC	Design Center These bits indicate the device design center
21:12	PIN	Part Identification Number These bits contain the part number of the device
11:1	MIC	Manufacturer Identity Code These bits contain the reduced Joint Electron Device Engineering Council (JEDEC) ID for NXP, 0xE.
0	Bit [0]	IDCODE Register ID Bit [0] identifies this register as the device identification register and not the bypass register

59.4.1.4 Port Configuration Register (PCR)

Register index: 127																
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	FPM	MCK O_G T	MCK O_E N	MCKO_DIV			Reserved	DDR_EN	Reserved	0	0	0	Reserved		0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved	0	0	0	0	0	Reserved	Reserved	0	0	0	0	0	0	0	PSTA T_EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The PCR, shown in the figure above, is used to select the NPC mode of operation, enable MCKO and select the MCKO frequency, and enable or disable MCKO gating. This register should be configured as soon as the NPC is enabled.

NOTE

The mode or clock division must not be modified after MCKO has been enabled. Changing the mode or clock division while MCKO is enabled can produce unpredictable results.

Table 59-9. PCR field descriptions

Bit	Name	Description
31	FPM	Full Port Mode The value of the FPM bit determines if the auxiliary output port uses the full MDO port or a reduced MDO port to transmit messages. 0 A subset of MDO pins are used to transmit messages 1 All MDO pins are used to transmit messages
30	MCKO_GT	MCKO Clock Gating Control This bit is used to enable or disable MCKO clock gating. If clock gating is enabled, the MCKO clock is gated when the NPC is in enabled mode but not actively transmitting messages on the auxiliary output port. When clock gating is disabled, MCKO is allowed to run even if no auxiliary output port messages are being transmitted. 0 MCKO gating is disabled 1 MCKO gating is enabled
29	MCKO_EN	MCKO Enable This bit enables the MCKO clock to run. When enabled, the frequency of MCKO is determined by the MCKO_DIV field. 0 MCKO clock is driven to zero 1 MCKO clock is enabled

Table continues on the next page...

Table 59-9. PCR field descriptions (continued)

Bit	Name	Description
28:26	MCKO_DIV	MCKO Division Factor The value of this signal determines the frequency of MCKO relative to the system clock frequency when MCKO_EN is asserted. Table 59-10 shows the meaning of MCKO_DIV Values. In this table, SYS_CLK represents the system clock frequency.
25	Reserved	
24	DDR_EN	Double Data Rate Mode Enable This bit enables Nexus double data rate (DDR) mode. In DDR mode, message data is updated between each edge of MCKO, effectively doubling message throughput. NOTE: DDR mode should not be used with Aurora mode 0 DDR mode disabled 1 DDR mode enabled
23	Reserved	
19:18	Reserved	
15	Reserved	
9	Reserved	
8	Reserved	
0	PSTAT_EN	Processor Status Mode Enable¹ This bit enables processor status (PSTAT) mode. In PSTAT mode, all auxiliary output port MDO pins are used to transmit processor status information, and Nexus messaging is unavailable. 0 PSTAT disabled 1 PSTAT mode enabled

1. PSTAT Mode is intended for factory processor debug only. The PSTAT_EN bit should be written to disable PSTAT mode if Nexus messaging is desired. No Nexus messages are transmitted under any circumstances when PSTAT mode is enabled.

Table 59-10. MCKO_DIV Values

MCKO_DIV[2:0]	MCKO Frequency
0	Reserved
1	SYS_CLK/2
2	Reserved
3	SYS_CLK/4
4	Reserved
5	Reserved
6	Reserved
7	SYS_CLK/8

59.5 Functional Description

59.5.1 NPC reset configuration

The NPC is placed in disabled mode upon exit of reset. If message transmission via the output port is desired, a write to the PCR is then required to enable the NPC and select the mode of operation. Asserting MCKO_EN places the NPC in enabled mode and enables MCKO. The frequency of MCKO is selected by writing the MCKO_DIV field. Asserting or negating the FPM bit selects full-port or reduced-port mode, respectively.

The following table describes the NPC reset configuration options.

Table 59-11. NPC reset configuration options

Power On Reset status asserted?	JCOMP asserted high	MCKO_EN bit of the Port Configuration Register	FPM bit of the Port Configuration Register	Configuration
yes	x	X	X	Reset
no	no	X	X	Reset
no	yes	0	X	Disabled
no	yes	1	1	Full-Port Mode
no	yes	1	0	Reduced-Port Mode

59.5.2 Auxiliary Output Port

The auxiliary output port is shared by each of the Nexus modules on the device. The NPC communicates with each of the Nexus modules and arbitrates for access to the port.

59.5.2.1 Output Message Protocol

The protocol for transmitting messages via the auxiliary port is accomplished with the $\overline{\text{MSEO}}$ functions. The $\overline{\text{MSEO}}$ pins are used to signal the end of variable-length packets and the end of messages. They are not required to indicate the end of fixed-length packets. MDO and $\overline{\text{MSEO}}$ are sampled on the rising edge of MCKO.

The following figure illustrates the state diagram for $\overline{\text{MSEO}}$ transfers. All transitions not included in the figure are reserved, and must not be used.

Figure 59-2. MSEO Transfers (for 2-bit MSEO)

59.5.2.2 Output Messages

In addition to sending out messages generated in other Nexus blocks, the NPC can also output the device ID message contained in the device ID register on the MDO pins. The device ID message can also be sent out serially through TDO.

[Figure 59-3](#) describes the device ID output message that the NPC can transmit on the auxiliary port. The TCODE is the first packet transmitted.

Message Name	Min. Packet Size (bits)	Max Packet Size (bits)	Packet Type	Packet Name	Packet Description
Device ID Message	6	6	fixed	TCODE	Value = 1
	32	32	fixed	ID	DID register contents

Figure 59-3. NPC output messages

59.5.2.3 Rules of Message

- A variable-sized field within a message must end on a port boundary. (Port boundaries depend on the number of MDO pins active with the current reset configuration.)
- A variable-sized field may start within a port boundary only when following a fixed-length field.
- Super-fields must end on a port boundary.
- When a variable-length field is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest order bit so that it can end on a port boundary.
- Multiple fixed-length packets may start and/or end on a single clock.
- When any packet follows a variable-length packet, it must start on a port boundary.
- The field containing the TCODE number is always transferred out first, followed by subsequent fields of information.
- Within a field, the lowest significant bits are shifted out first. The following figure shows the transmission sequence of a message that is made up of a TCODE followed by two fields.

Figure 59-4. Transmission Sequence of Messages

59.5.3 IEEE 1149.1-2001 (JTAG) TAP

The NPC block uses the IEEE 1149.1-2001 test access port (TAP) for accessing registers. Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers as well. TAP signals include TCK, TDI, TMS, and TDO. There may also be other blocks on the MCU that use the TAP and implement a TAP controller.

Refer to the IEEE 1149.1-2001 specification for further detail on electrical and pin protocol compliance requirements.

The NPC implements a Nexus controller state machine that transitions based on the state of the IEEE 1149.1-2001 state machine shown in [Figure 59-6](#). The Nexus controller state machine is defined by the IEEE-ISTO 5001-2001 standard. It is shown in [Figure 59-7](#).

The instructions implemented by the NPC TAP controller are listed in the following table. The value of the NEXUS-ENABLE instruction is 0b0000. Each unimplemented instruction acts like the BYPASS instruction. The size of the NPC instruction register is 4 bits.

Table 59-12. Implemented Instructions

Instruction Name	Private/Public	Opcode	Description
NEXUS-ENABLE	public	0x0	Activate Nexus controller state machine to read and write NPC registers.
BYPASS	private	0xF	NPC BYPASS instruction. Also the value loaded into the NPC IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

Figure 59-5. Shifting Data Into Register

59.5.3.1 Enabling the NPC TAP controller

Assertion of the power-on reset signal or entry into censored mode or setting JCOMP to a value other than the NPC enable encoding resets the NPC TAP controller. When not in power-on reset or censored mode, the NPC TAP controller is enabled by driving JCOMP with the NPC enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

NOTE: The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 59-6. IEEE 1149.1-2001 TAP Controller State Machine

59.5.3.2 Retrieving device IDCODE

The Nexus TAP controller does not implement the IDCODE instruction. However, the device identification message can be output by the NPC through the output port or shifted out serially by accessing the Nexus Device ID register through the TAP.

Transmission of the device identification message on the auxiliary output port MDO pins occurs immediately after a write to the PCR, if the NPC is enabled for auxiliary port mode. Transmission of the device identification message serially via the TAP is achieved by performing a read of the register contents as described in [Selecting a Nexus Client Register](#).

59.5.3.3 Loading NEXUS-ENABLE Instruction

Access to the NPC registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in [Figure 59-7](#), transitions to the REG_SELECT state. The Nexus controller has three states: idle, register select, and data access. [Table 59-13](#) illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Figure 59-7. NEXUS Controller State Machine

Table 59-13. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction

Table continues on the next page...

**Table 59-13. Loading NEXUS-ENABLE instruction
(continued)**

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS_ENABLE instruction.
3 TCKS				
8	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
9	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
10	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

59.5.3.4 Selecting a Nexus Client Register

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows development tool access to all Nexus registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus Controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in the following table. The read/write control bit is set to 1 for writes and 0 for reads.

MSB	LSB
7-bit register index	R/W

Figure 59-8. IEEE 1149.1 Controller Command Input

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state. When reading a register, the register value is loaded into the JTAG shifter during the CAPTURE-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

The following table illustrates a sequence which writes a 32-bit value to a register.

Table 59-14. Write to a 32-Bit Nexus Client Register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 6 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

59.5.4 Nexus JTAG Port Sharing

Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers. When Nexus has ownership of the TAP, only the block whose NEXUS-ENABLE instruction is loaded has control of the TAP. This allows the interface to all of these individual TAP controllers to appear to be a single port from outside the device. If no register is selected as the shift path for a Nexus block, that block acts like a single-bit shift register, or bypass register.

59.5.5 MCKO Control

MCKO is an output clock to the development tools used for the timing of $\overline{\text{MSEO}}$ and MDO pin functions. MCKO is derived from the system clock and its frequency is determined by the value of the MCKO_DIV field in the PCR. Possible operating frequencies include system clock, one-half system clock, one-quarter system clock, and one-eighth system clock speed.

The NPC also generates an MCKO clock gating control output signal. This output can be used by the MCKO generation logic to gate the transmission of MCKO when the auxiliary port is enabled but not transmitting messages. The setting of the MCKO_GT bit inside the PCR determines whether or not MCKO gating control is active. The MCKO_GT bit resets to a logic 0. In this state gating of MCKO is disabled. To enable gating of MCKO, the MCKO_GT bit in the PCR is written to a logic 1.

59.5.6 $\overline{\text{EVTO}}$ Sharing

The NPC block controls sharing of the $\overline{\text{EVTO}}$ output between all Nexus clients that produce an $\overline{\text{EVTO}}$ signal. The NPC assumes incoming $\overline{\text{EVTO}}$ signals will be asserted for one system clock period. After receiving a single clock period of asserted $\overline{\text{EVTO}}$ from any Nexus client, the NPC latches the result, and drives $\overline{\text{EVTO}}$ for one MCKO period on the following clock. When there is no active MCKO, such as in disabled mode, the NPC drives $\overline{\text{EVTO}}$ for two system clock periods. $\overline{\text{EVTO}}$ sharing is active as long as the NPC is not in reset.

59.5.7 Nexus Reset Control

The JCOMP input that is used as the primary reset signal for the NPC is also used by the NPC to generate a single-bit reset signal for other Nexus blocks. If JCOMP is negated, an internal reset is asserted, indicating that all Nexus modules should be held in reset. Internal Nexus reset is also asserted when the device is in censored mode.

59.5.8 System Clock Locked Indication

Following a power-on reset, MDO[0] can be monitored to provide the lock status of the system clock. MDO[0] is driven to a logic 1 until the system clock achieves lock after exiting power-on reset. Once the system clock is locked, MDO[0] is negated and tools may begin Nexus configuration. Loss of lock conditions that occur subsequent to the exit of power-on reset and the initial lock of the system clock do not cause a Nexus reset, and therefore do not result in MDO[0] driven high.

59.6 Initialization/Application Information

59.6.1 Accessing NPC tool-mapped registers

To initialize the TAP for Nexus register accesses, the following sequence is required:

1. Enable the Nexus TAP controller
2. Load the TAP controller with the NEXUS-ENABLE instruction

To write control data to NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and set the write bit to select the register with a pass through the SELECT-DR-SCAN path in the TAP controller state machine.
2. Write the register value with a second pass through the SELECT-DR-SCAN path. Note that the prior value of this register is shifted out during the write.

To read status and control data from NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and clear the write bit to select register with a pass through SELECT-DR-SCAN path in the TAP controller state machine.
2. Read the register value with a second pass through the SELECT-DR-SCAN path. Data shifted in is ignored.

See the IEEE-ISTO 5001-2001 standard for more detail.

Chapter 60

Nexus eTPU Development Interface (NDEDI)

60.1 Chip-specific NDEDI information

This chip contains two Nexus eTPU Development Interface modules.

- A dual NDEDI covers eTPU_A and eTPU_B. The NDEDI's ENGINE1 corresponds to eTPU_A and ENGINE2 corresponds to eTPU_B.
- A single Nexus eTPU Development Interface (NSEDI) covers eTPU_C. The single interface has the same features as the NDEDI but is for a single eTPU engine.

Each interface also includes a coherent dual-parameter controller (CDC) for coherent access to eTPU parameters. In each interface, the eTPU modules and CDC unit appear as separate Nexus clients.

60.1.1 NDEDI/NSEDI device-specific parameters

The following table provides the chip-specific parameter values of the NDEDI module and NSEDI module. Each parameter has a placeholder "variable" name that appears in the detailed NDEDI description.

Table 60-1. Device-specific parameters

Parameter	Variable name	Description	NDEDI value	NSEDI value
Full-Port Mode MDO pins	N	Number of MDO pins used for message transmission in full-port mode: This value is the same for all Nexus blocks sharing the port.	16d	16d
Reduced-Port Mode MDO pins	J	Number of MDO pins used for message transmission in reduced-port mode: This value is the same for all Nexus blocks sharing the port.	12d	12d
SRC Packet size	K	Number of bits used for the SRC packet in messages	4d	4d

Table continues on the next page...

Table 60-1. Device-specific parameters (continued)

Parameter	Variable name	Description	NDEDI value	NSEDI value
HIST Packet size	H	Number of bits used for the HIST packet in messages	26d	26d
Queue size	Q_SIZE	Depth of the event queue used to store events before transmission	32d	32d
Stall Threshold	STALL_THRESHOLD	Number of spots within the queue used as a threshold to delay the processor	7d	7d
ENGINE1 SRC value	ENGINE1_SRC	SRC packet value for messages generated by ENGINE1	2h	Ah
ENGINE2 SRC value	ENGINE2_SRC	SRC packet value for messages generated by ENGINE2	3h	—
CDC SRC value	CDC_SRC	SRC packet value for messages generated by the CDC	4h	Ch
Manufacturer ID	DID_MIC	Manufacturer code used in the DID register	Eh	Eh
Design Center ID	DID_DC	Design center code used in the DID register	20h	20h
Part Revision Number	DID_PRN	Part revision number used in the DID register	4h	4h
Part Identification Number	DID_PIN	Part identification number used in the DID register	224h	124h

60.2 Introduction

The Nexus ETPU Development Interface (NDEDI) provides real-time development capabilities for the ETPU system including two engines and the coherent dual-parameter controller (CDC) in compliance with the IEEE-ISTO 5001-2002 standard. The NDEDI interfaces to the ETPU via dedicated trace busses. The main development features supported are breakpoint/watchpoint configuration, debug mode register access, enter debug mode at reset negation or during normal execution, single stepping of instructions, branch trace, data trace, ownership trace, and watchpoint trace. Combined, these features make the interface for each engine compliant with Class 3 of the IEEE-ISTO 5001-2002 standard.

Both engines have their own Nexus register sets that allows trace to be set up independently for each of them. The only exception to this is the data trace address range registers that are shared. All the registers are accessed via the JTAG port. Output messages between the engines and other sources are differentiated by the value of the SRC packet in the output messages.

The NDEDI block is combined with similar blocks for other intelligent peripherals, a read/write access block, and a Nexus Port Controller block to provide the complete IEEE-ISTO 5001-2002 interface for a system-on-a-chip design. The JTAG port and Nexus auxiliary port pins are shared by all of the Nexus based blocks on the chip.

60.3 Features

The NDEDI block is compliant with the IEEE-ISTO 5001-2002 standard, and implements the following features:

- Full duplex pin interface for medium and high visibility throughput
 - Pin interface shared among all Nexus-based development interfaces on the device
 - One of two modes selected during reset: full-port mode (FPM) and reduced-port mode (RPM)
- Auxiliary Output Port
 - 1 MCKO (Message Clock Out) pin
 - MDO (Message Data Out) port (port size is SoC specific)
 - 2 $\overline{\text{MSEO}}$ (Message Start/End Out) pins
 - 1 $\overline{\text{EVTO}}$ (Event Out) pin
- Auxiliary Input Port
 - 1 $\overline{\text{EVTI}}$ (Event In) pin
- IEEE 1149.1 (JTAG) Test Access Port (TAP)
 - Support for optional Multi-JTAG TAP Linking Module (TLM)
 - 4 pins (TDI, TDO, TMS, and TCK)
 - Reset input $\overline{\text{TRST}}$ driven by either the Nexus Port Controller or an external pin
- ETPU Development Support
 - IEEE-ISTO 5001-2002 standard class 3 compliant for both engines
 - Read/Write registers in debug mode
 - Ability to enter debug mode at reset negation or during normal execution

- Ability to single step an instruction and re-enter debug mode
- Breakpoint and Watchpoint Configuration
- Execute external microcode instructions in debug mode providing indirect read/write accesses to ETPU registers
- Read the microprogram counter in debug mode
- Change the microprogram counter by executing external microcode instructions in debug mode
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This allows the development tool to trace reads and writes to selected shared parameter RAM (SPRAM) address ranges
 - Four data trace windows with programmable address ranges and access attributes are provided. Data trace windowing reduces the requirement on the auxiliary port bandwidth by constraining the number of trace locations. The four trace window address ranges are shared among the dual engines and the ETPU Coherent Dual-Parameter Controller (CDC)
- Ownership Trace via Ownership Trace Messaging (OTM). OTM provides visibility of which channel is being serviced. An ownership trace message is transmitted to indicate when a new channel service request is scheduled, allowing the development tools to trace task flow. A special OTM is sent when the engine enters in idle, meaning that all requests were serviced and no new requests are yet scheduled
- Program Trace via Branch Trace Messaging (BTM). BTM displays program flow discontinuities (start, jump, return, etc....), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced
 - Public messages are used for jump, and return instructions
 - Private messages are used to indicate special ETPU cases not covered by public messages. These messages include the writes to the channel register, the start of a channel service and the trace enabling after a watchpoint hit
 - Branch/Predicate History is kept on direct branches (taken and not taken) and predicated instructions (executed or not executed) to minimize the number of messages transmitted
- Watchpoint Messaging (WPM) via the auxiliary port. WPM provides visibility of the occurrence of the ETPUs' watchpoints

- Event Queue Interface. The Event Queue array is located external to the NDEDI block to separate hard and soft IP. The depth of the Event Queue is specified in the SoC Guide
- Read/Write Access functions are provided on the device level by a block separate from the NDEDI block

60.4 Modes of operation

60.4.1 Reset

The NDEDI block is placed in reset when Nexus is reset, or the TAP controller state machine is in the Test-Logic-Reset state. Holding TMS high for 5 consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Nexus reset results in asynchronous entry into the reset state. The NDEDI is unaffected by other sources of reset. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state
- The auxiliary output port pins are negated
- The auxiliary output port enable outputs are negated
- The TDI, TMS, and TCK TAP inputs are ignored
- Registers default back to their reset values

Note that the NDEDI is not reset by the system reset signal. The system reset signal is used though to make ETPU entering in debug mode from reset condition and to synchronize Program Trace and Data Trace messages.

60.4.2 Disabled-port mode

In disabled-port mode, auxiliary output pin port enable signals are negated, thereby disabling message transmission. Thus, the NDEDI class 3 features are not available in this mode. The primary features available are class 1 features and read/write access to the registers.

60.4.3 Full-port mode

Full-port mode (FPM) is determined by the chip Nexus configuration. See the chip-specific NPC information. In full-port mode, the block is enabled and the FPM port enable is asserted indicating that all available MDO pins are to be used for message transmission. All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific. Refer to the SoC guide for this information.

60.4.4 Reduced-port mode

Reduced-port mode (RPM) is determined by the chip Nexus configuration. See the chip-specific NPC information. In reduced-port mode, the block is enabled and the RPM port enable is asserted indicating that only a subset of the MDO pins are to be used for message transmission. All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific. Refer to the SoC guide for this information.

60.4.5 Stop mode

The NDEDI supports the IPI Green-Line Interface stop mode mechanism. When a request is made to enter stop mode, the NDEDI block waits for the ETPU to acknowledge the stop condition so no trace information is lost. The NDEDI then completes transmitting all pending messages, emptying the Event Queue. Finally, NDEDI transmits a debug status message to indicate it is entering stop mode, and if Program Trace is enabled it will send a correlation message. Refer to [Functional description](#) for further information about the messages. After this is completed, the request to enter stop mode is acknowledged. No breakpoint requests are sent to the engines while they are in stop mode. After the acknowledgement, the system clock input may be shut off by the clock driver on the device. While the clocks are shut off, the development tool must not access NDEDI registers via the JTAG test access port.

60.5 External signal description

The following section describes the External Signal description.

60.5.1 Overview

The NDEDI pin provides interface for the transmission of messages and for accessing Nexus registers. The NDEDI pin definition is outlined in the following table.

Table 60-2. NDEDI signal properties

Name	Port	Function	Reset State	Pull ¹
EVTI	Auxiliary	Event In pin	—	Up
EVTO	Auxiliary	Event Out pin	1	—
MCKO	Auxiliary	Message Clock Out pin (from NPC)	—	—
MDO[J-1:0] or MDO[N-1:0]	Auxiliary	Message Data Out pins	0	—
MSEO[1:0]	Auxiliary	Message Start/End Out pins	0b11	—
TCK	TAP	Test Clock Input	—	—
TDI	TAP	Test Data Input	—	Up
TDO	TAP	Test Data Output	0	—
TMS	TAP	Test Mode Select Input	—	Up
TRST	TAP	Test Reset Input	—	Up

1. The pull is not implemented in this block. Refer to the SoC guide for more details.

60.5.2 Detailed signal descriptions

This section describes each of the signals listed in the preceding table in more detail.

60.5.2.1 $\overline{\text{EVTI}}$ - Event In

Event In ($\overline{\text{EVTI}}$) is used to initiate program and data trace synchronization messages or to generate a breakpoint. $\overline{\text{EVTI}}$ is edge-sensitive for synchronization and breakpoint generation.

60.5.2.2 $\overline{\text{EVTO}}$ - Event Out

Event Out ($\overline{\text{EVTO}}$) is an output pin to development tools comprising exact timing for a single watchpoint or breakpoint occurrence. $\overline{\text{EVTO}}$ is asserted for 1 MCKO clock¹.

1. NDEDI asserts The EVTO indication for 1 system clock.

60.5.2.3 MCKO - Message Clock Out

Message Clock Out (MCKO) is an output clock to the development tools used for the timing of MDO and $\overline{\text{MSEO}}$ pin functions. The frequency of MCKO is determined by the NPC block. Refer to the NPC BG for more information.

The MCKO signal is generated external to the NDEDI block but is included in this document for functional clarity. An input is provided to this block to keep logic synchronized to MCKO.

60.5.2.4 MDO - Message Data Out

Message Data Out (MDO) are output pins used for uploading messages to the development tool. The development tool must sample MDO on the rising edge of MCKO. The width of the MDO bus is determined by the Nexus full port mode configuration. See the chip-specific NPC information for further information.

60.5.2.5 MSEO[1:0] - Message Start/End Out

Message Start/End Out ($\overline{\text{MSEO}}$) is an output pin that indicates when a message on the MDO pins has started, when a variable length packet has ended, or when the message has ended. The development tool must latch $\overline{\text{MSEO}}$ on the rising edge of MCKO.

60.5.2.6 TCK - Test Clock Input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the JTAG port.

60.5.2.7 TDI - Test Data Input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

60.5.2.8 TDO - Test Data Output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is actively driven in the 'SHIFT-IR' and 'SHIFT-DR' states of the JTAG state machine. TDO changes on the falling edge of TCK and is sampled on the rising edge of TCK.

60.5.2.9 TMS - Test Mode Select

Test Mode Select (TMS) is an input pin used to sequence the JTAG state machine. TMS is sampled on the rising edge of TCK.

60.5.2.10 $\overline{\text{TRST}}$ - Test Reset Input

The Test Reset Input is used to asynchronously reset the NDEDI block and initialize the JTAG controller. This signal can be generated in the Nexus Port Controller or driven by an external pin. Refer to the SoC Guide for more information.

60.6 Register definition

This section provides a detailed description of all NDEDI registers accessible to the development tool. Individual bit-level descriptions and reset states of each register are included.

The following table shows the NDEDI registers by client select and index values. These registers are not memory-mapped and can only be accessed via the TAP.

Table 60-3. NDEDI Registers

CS	Index	Register
Client-Independent Registers		
X	0	Device Identity (DID)
X	1	Client Select Control (CSC)
ENGINE1 Control/Status Registers		
ENGINE1_SRC	2	ENGINE1 Development Control (NDEDI_ENGINE1_DC)
ENGINE1_SRC	4	ENGINE1 Development Status (NDEDI_ENGINE1_DS)
ENGINE1_SRC	11	ENGINE1 Watchpoint Trigger (NDEDI_ENGINE1_WT)
ENGINE1_SRC	13	ENGINE1 Data Trace Control (NDEDI_ENGINE1_DTC)
ENGINE1_SRC	22	ENGINE1 Breakpoint/Watchpoint Control 1 (NDEDI_ENGINE1_BWC1)
ENGINE1_SRC	23	ENGINE1 Breakpoint/Watchpoint Control 2 (NDEDI_ENGINE1_BWC2)

Table continues on the next page...

Table 60-3. NDEDI Registers (continued)

CS	Index	Register
ENGINE1_SRC	24	ENGINE1 Breakpoint/Watchpoint Control 3 (NDEDI_ENGINE1_BWC3)
ENGINE1_SRC	30	ENGINE1 Breakpoint/Watchpoint Address 1 (NDEDI_ENGINE1_BWA1)
ENGINE1_SRC	31	ENGINE1 Breakpoint/Watchpoint Address 2 (NDEDI_ENGINE1_BWA2)
ENGINE1_SRC	38	ENGINE1 Breakpoint/Watchpoint Data 1 (NDEDI_ENGINE1_BWD1)
ENGINE1_SRC	39	ENGINE1 Breakpoint/Watchpoint Data 2 (NDEDI_ENGINE1_BWD2)
ENGINE1_SRC	64	ENGINE1 Program Trace Channel Enable (NDEDI_ENGINE1_PTCE)
ENGINE1_SRC	69	ENGINE1 Microinstruction Debug Register (NDEDI_ENGINE1_INST)
ENGINE1_SRC	70	ENGINE1 Microinstruction Program Counter (NDEDI_ENGINE1_MPC)
ENGINE1_SRC	71	ENGINE1 Channel Flag Status Register(NDEDI_ENGINE2_CSFR)
ENGINE2 Control/Status Registers		
ENGINE2_SRC	2	ENGINE2 Development Control (NDEDI_ENGINE2_DC)
ENGINE2_SRC	4	ENGINE2 Development Status (NDEDI_ENGINE2_DS)
ENGINE2_SRC	11	ENGINE2 Watchpoint Trigger (NDEDI_ENGINE2_WT)
ENGINE2_SRC	13	ENGINE2 Data Trace Control (NDEDI_ENGINE2_DTC)
ENGINE2_SRC	22	ENGINE2 Breakpoint/Watchpoint Control 1 (NDEDI_ENGINE2_BWC1)
ENGINE2_SRC	23	ENGINE2 Breakpoint/Watchpoint Control 2 (NDEDI_ENGINE2_BWC2)
ENGINE2_SRC	24	ENGINE2 Breakpoint/Watchpoint Control 3 (NDEDI_ENGINE2_BWC3)
ENGINE2_SRC	30	ENGINE2 Breakpoint/Watchpoint Address 1 (NDEDI_ENGINE2_BWA1)
ENGINE2_SRC	31	ENGINE2 Breakpoint/Watchpoint Address 2 (NDEDI_ENGINE2_BWA2)
ENGINE2_SRC	38	ENGINE2 Breakpoint/Watchpoint Data 1 (NDEDI_ENGINE2_BWD1)
ENGINE2_SRC	39	ENGINE2 Breakpoint/Watchpoint Data 2 (NDEDI_ENGINE2_BWD2)
ENGINE2_SRC	64	ENGINE2 Program Trace Channel Enable (NDEDI_ENGINE2_PTCE)
ENGINE2_SRC	69	ENGINE2 Microinstruction Debug Register (NDEDI_ENGINE2_INST)
ENGINE2_SRC	70	ENGINE2 Microinstruction Program Counter (NDEDI_ENGINE2_MPC)
ENGINE2_SRC	71	ENGINE2 Channel Flag Status Register(NDEDI_ENGINE2_CSFR)

CDC_SRC	13	CDC Data Trace Control (NDEDI_CDC_DTC)
ENGINE1/ENGINE2/CDC Shared Control/Status Registers		
ENGINE1_SRC or ENGINE2_SRC or CDC_SRC	65	NDEDI Data Trace Address Range 0 (NDEDI_DTAR0)
ENGINE1_SRC or ENGINE2_SRC or CDC_SRC	66	NDEDI Data Trace Address Range 1 (NDEDI_DTAR1)
ENGINE1_SRC or ENGINE2_SRC or CDC_SRC	67	NDEDI Data Trace Address Range 2 (NDEDI_DTAR2)
ENGINE1_SRC or ENGINE2_SRC or CDC_SRC	68	NDEDI Data Trace Address Range 3 (NDEDI_DTAR3)

60.6.1 Register descriptions

This section consists of NDEDI register descriptions. The ENGINE1 and ENGINE2 registers are shown in the preceding table. To simplify the document, the description of registers with the same content is only given once instead of being repeated for each ENGINE. This is denoted in the text as ENGINE_x where ENGINE_x can be replaced by either ENGINE1 or ENGINE2.

60.6.1.1 Device Identity Register (DID)

The DID register contains the unique identification information.

Client Select: X

Register index: 0

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Part Revision Number				Design Center						Part Identification Number

																1

Figure 60-1. Device Identity Register (DID)

Table 60-4. DID field descriptions

Field	Description
PRN	Part Revision Number Bits[31:28] contain the revision number of the part.
DC	Design Center Bits [27:22] indicate the Freescale Design Center.
PIN	Part Indication Number Bits[21:12] contain the part number of the device.
MIC	Manufacturer Identity Code Bits [11:1] contain the reduced Joint Electron Device Engineering Council (JEDEC) ID for Freescale.
Bit[0]	IDCODE Register ID Bit [0] identifies this register as the device identification register and not the bypass register.

60.6.1.2 Client Select Control Register (CSC)

Client Select: X

Register index: 1

Register definition

Figure 60-2. Client Select Control Register (CSC)

Table 60-5. CSC field decription

Field	Description
CS	Client Select The value of the CS field determines which client is accessed. The number of bits implemented for the CS field (K) is MCU dependent, and is the same number of bits as the size of the SRC field transmitted with messages. Refer to the SoC Guide for the size on a particular MCU. The value written to the CSC register to access a client register is the same value as the SRC field a client uses in its messages. For example, to access an NDEDI ENGINE1 register, the CSC register is written with a value of ENGINE1_SRC.

60.6.1.3 ENGINE_x Development Control Register (NDEDI_ENGINE_x_DC)

The NDEDI_ENGINE_x_DC register controls various trace and debug features as described below.

When a field is set to a reserved value the behavior defaults to the reset values behavior.

Client Select: ENGINE_x_SRC

Register index: 2

Figure 60-3. ENGINE_x Development Control Register (NDEDI_ENGINE_x_DC)

Table 60-6. NDEDI_ENGINEx_DC field descriptions

Field	Description
CHW	ENGINEx CHAN Register Write Trace The CHW bit enables the tracing of writes to the CHAN register in the ENGINEx execution unit. CHAN register write tracing requires the channel being serviced to have program trace enabled. 0 = Tracing not enabled for ENGINEx CHAN writes. 1 = Tracing enabled for ENGINEx CHAN writes
PINS	Stop Pins in Debug Mode The PINS bit controls whether the ENGINEx pins are sampled when the ENGINEx enters debug mode. When PINS is set, the pins are not sampled during debug mode or when executing a forced instruction from the microinstruction register. The pins are sampled during single steps. 0 = Sample pins in the halted state 1 = Stop sampling pins in the halted state
CLKS	Stop TCR Clocks The CLKS bit controls whether the TCR clocks from ENGINEx stop running when the ENGINEx enters debug mode. When CLKS is set, TCR is not updated during debug mode or when executing a forced instruction from the microinstruction register. TCR is updated during single steps. 0 = Do not stop TCRs during debug mode 1 = Stop TCRs during debug mode
CBT	Client Breakpoint Timing The CBT bit controls the timing of an ENGINEx halt due to an external breakpoint source or due to a breakpoint at the twin engine. For this bit to matter, CBI or HTWIN must be set to 1. 0 = Halt at the end of the current microcycle 1 = Halt at the completion of the current instruction thread
HTWIN	HTWIN — Halt on Twin Engine Breakpoint Along with CBT, the HTWIN bit controls the action taken on breakpoints occurrences at the twin engine. If the Twin Engine that is causing a breakpoint exit debug state, the ENGINEx shall resume its operation. If the HTWIN bit is cleared while the ENGINEx is in debug state due to a Twin Engine Breakpoint, the ENGINEx shall resume its operation. This bit must not be cleared when the engine is neither halted nor stopped. 0 = Do not halt for breakpoints in the twin Engine 1 = Halt for twin Engine's breakpoint
EBC	EVT$\overline{O}$ Breakpoint Controller The EBC bit controls the generation of EVT$\overline{O}$ due to any of the following breakpoint types: Exit of System Reset, DBR assertion, SW, TWIN Engine, EVTI, MISC Error, Illegal Instruction, Single Step or External. 0 = Breakpoint status indication is not output on EVT$\overline{O}$ 1 = Breakpoint status indication is output on EVT$\overline{O}$

Table continues on the next page...

Table 60-6. NDEDI_ENGINEx_DC field descriptions (continued)

Field	Description
CBR	Clear Breakpoint Request Writing this bit to one clears breakpoint requests caused by the following conditions: • Exit of system reset • Internal breakpoint (due to: instruction address match, accesses to the SPRAM, channel service and writes to the CHAN register) • Single Step breakpoint • EVTI assertion • Halt instruction at the engine • MISC miscompare • Illegal instruction at the engine. Asserting this bit causes it to clear one clock later. This means that the development tool can never read this bit with a value other than zero. The ETPU must always execute the first instruction after exiting a breakpoint condition, in such a way that it does not halt twice at the same position. The breakpoints caused by external/system debug request or twin engine are not cleared by the assertion of this bit. This bit must not be asserted when the engine is not halted. 0 = No action 1 = Clear breakpoint requests
CBI	Client Breakpoint Input Along with CBT, the CBI bit controls the action taken on breakpoints from external sources. The breakpoint condition caused by the external source is only cleared if CBI equals 0 or if the external breakpoint is negated. This bit must not be cleared when the engine is neither halted nor stopped. 0 = Do not halt for other clients' breakpoints 1 = Halt for other clients' breakpoints

Table continues on the next page...

Table 60-6. NDEDI_ENGINEx_DC field descriptions (continued)

Field	Description
DBE	Debug Enable DBE enables debug mode. When DBE is asserted, the occurrence of any of the following events will cause the processor to enter debug mode: • DBR assertion • Twin Engine breakpoint • External breakpoint • Exit of system reset • Internal breakpoint (due to: instruction address match, accesses to the SPRAM, channel service and writes to the CHAN register) • Single Step breakpoint • EVTI assertion • Halt instruction at the engine • MISC miscompare • Illegal instruction at the engine. No breakpoints will occur if DBE is not asserted. If this bit is negated while in debug mode a request to resume the processor operation will be sent to the engine. This bit must not be cleared when the engine is either halted nor stopped. This bit is necessary to use features such as single stepping and breakpoints, but does not affect neither watchpoint, program trace nor data trace operations. 0 = Debug mode disabled 1 = Debug mode enabled
DBR	Debug Request Mechanism to allow development tool to request processor to enter debug mode. When written, and DBE equals 1 this bit forces the ENGINEx to enter debug mode. The engine will not exit debug mode while this bit is asserted and DBE equals 1. 0 = Exit debug mode if there are no pending breakpoint sources 1 = Request debug mode

Table continues on the next page...

Table 60-6. NDEDI_ENGINEx_DC field descriptions (continued)

Field	Description
OVC	OVC — Overrun Control The NDEDI can be programmed to stall the ENGINEx operation avoiding errors related to that engine due to full Event Queue. The ENGINEx can't be stalled neither in the middle of an atomic sequence of accesses to the SPRAM nor in the middle of the Time Slot Transition(TST). Please refer to the ETPU BG for further information. The overrun control field controls how the NDEDI reacts when the Queue is about to get full. If programmed to delay the processor, the NDEDI asserts the request to delay the processor when the Event Queue has only STALL_THRESHOLD available positions, and negates the delay request as soon as there are STALL_THRESHOLD + 1 available positions. The request to delay the processor does not affect neither the other engine nor the CDC operations. Therefore, in some extreme cases an overrun message may be generated even with OVC configured to delay the processor. If an error event happens, the processor will be delayed until the Event Queue is enabled for storing snapshots again, which will happen as the Event Queue gets empty. If the OVC field is changed to 0b011 while the Event Queue has less than STALL_THRESHOLD available positions the NDEDI will automatically assert the stall request. If the OVC field is changed to a value other than 0b011 while the ENGINEx is in STALL state, the NDEDI will automatically negate the stall request. A breakpoint request prevails over the request to delay the processor. Thus, if a breakpoint request happens at the same time of a stall request, the ETPU will enter in HALT state instead of STALL state. OVC values: 000b = Generate overrun message 001b–010b = Reserved 011b = Stall Processor to prevent overruns for ENGINEx 100b–111b = Reserved
EIC	ENGINEx $\overline{\text{EVTI}}$ Control The $\overline{\text{EVTI}}$ control (EIC) field can be configured for synchronization or breakpoint generation. The $\overline{\text{EVTI}}$ signal is edge sensitive. ENGINEx_EIC values: 00b = $\overline{\text{EVTI}}$ assertion causes the next ENGINEx program and data trace message to be a synchronization message (the next CDC data trace messages are synchronized if the next message from either Engines are synchronized). 01b = $\overline{\text{EVTI}}$ assertion causes ENGINEx breakpoint generation 10b = No operation 11b = Reserved
TM	Trace Mode The TM field enables BTM, DTM, and OTM for ENGINEx. One or all types of trace may be enabled at a single time by writing to the TM field. Note: Data and Program Trace can also be enabled through watchpoint triggers. The two enable sources are ORed together to form the true trace enable. TM values: 000b = No trace enabled 1xxb = BTM enabled x1xb = DTM enabled xx1b = OTM enabled

60.6.1.4 ENGINE_x Development Status Register (NDEDI_ENGINE_x_DS)

The NDEDI_ENGINE_x_DS register shows the status of various conditions that impact development support. All status bits are dynamic and do not require clearing. If the Class 3 is enabled, any time the value of any bit in this register changes, a Debug Status Event is queued, and then will generate a Debug Status Message. If the Event Queue is not enabled to store snapshots while a DS event should be queued, then an error event is queued as soon as the Event Queue is enabled for storing snapshots.

DS register dynamically tracks the debug condition status even when several of them are simultaneously asserted. For instance, if EVTI and external debug are asserted at the same time, ETPU will enter in debug mode and NDEDI will assert the bits EBP(EVTI) and CBP. Then, if CBR is asserted the EBP bit will be cleared but the CBP bit will continue to be active since the external debug request is still on.

In some extreme cases NDEDI may not signalize more than one breakpoints condition at the same address. Please refer to [Multiple breakpoint conditions at the same address](#) for more details about this limitation.

Figure 60-4. ENGINE_x Development Status Register (NDEDI_ENGINE_x_DS)

Table 60-7. NDEDI_ENGINE_x_DS field descriptions

Field	Description
HAT	Halted with Active Thread The HAT bit indicates if the engine was halted during the execution of a thread or while it was IDLE. 0 = The ETPU engine is halted with no thread currently active 1 = The ETPU engine is halted in the middle of a thread execution

Table continues on the next page...

Table 60-7. NDEDI_ENGINEx_DS field descriptions (continued)

Field	Description
IIBP	Illegal Instruction Breakpoint Status The IIBP bit indicates if there is a breakpoint due to an illegal instruction execution causing the halt condition 0 = Breakpoint source is not an illegal instruction execution 1 = Breakpoint source is an illegal instruction execution
CBP	Client Breakpoint Status The CBP bit indicates if there is a breakpoint from an external client causing the halt condition 0 = Breakpoint source is not an external client 1 = Breakpoint source is an external client
TBP	Twin Breakpoint Status The TBP bit indicates if there is a breakpoint from the twin ETPU engine causing the halt condition 0 = Breakpoint source is not the twin ETPU engine 1 = Breakpoint source is the twin ETPU engine
EBP	EVTI Breakpoint Status The EBP bit indicates if there is a breakpoint caused by EVTI assertion 0 = Breakpoint source is not EVTI assertion 1 = Breakpoint source is EVTI assertion
BP	Internal Breakpoint Status The BP field shows which hardware breakpoints¹ have occurred causing the ENGINEx to enter debug mode . BP values: 0b0000000 = No Breakpoint Condition Occurred 0b1xxxxxx = ETPU Breakpoint 1 (based on BWC1 register) 0bx1xxxxx = ETPU Breakpoint 2 (based on BWC2 register) 0bxx1xxxx = Channel Register Write Breakpoint 0bxxx1xxx = Host Service Request Breakpoint 0bxxxx1xx = Link Register Breakpoint 0bxxxxx1x = MRL Breakpoint 0bxxxxxx1 = TDL Breakpoint
DBS	Debug Status The DBS bit indicates if ENGINEx is in debug mode. The fields HAT, IIBP, CBP, TBP, EBP, BP, HWB, SWB and SSS are only meaningful if the processor is indicated as halted. 0 = Processor not halted. 1 = Processor halted in debug mode

Table continues on the next page...

Table 60-7. NDEDI_ENGINEx_DS field descriptions (continued)

Field	Description
STP	Stop Status Indicates if the ENGINEx is in stop mode . Besides the IPI Green line stop mode mechanism, the ETPU engines may independently be programmed for STOP mode by asserting the MDIS bit of the ECR register. Thus, the STP field indicates if the engine is in stop mode no matter if due to the IPI Green line stop mode assertion or due to the MDIS field. Please refer to the ETPU BG for further information about the stop mode mechanisms. 0 = Processor not stopped 1 = Processor stopped in low power mode
HWE	Hardware Error Status Indicates if the ENGINEx has encountered a HW error . The only hardware error defined for the ENGINE is a MISC miscompare.Please refer to the ETPU BG for further information about MISC. 0 = No HW error 1 = Non-recoverable HW error occurred
HWB	Hardware Breakpoint Status Indicates if one of the hardware breakpoints described at the BP field has occurred . 0 = No hardware breakpoint occurred 1 = Hardware breakpoint occurred
SWB	Software Breakpoint Status Indicates if a software breakpoint has occurred. A software breakpoint occurs with the execution of the HALT instruction. For further information, please refer to the ETPU BG. 0 = No software breakpoint occurred 1 = Software breakpoint occurred
SSS	Single Step Status Indicates if the processor is halted for debug mode due to single step occurrence . 0 = Processor not halted due to single step 1 = Processor halted in debug mode due to single step

1. A hardware breakpoint is a breakpoint configured by BWC1, BWC2 or BWC3.

60.6.1.5 ENGINEx Watchpoint Trigger Register (NDEDI_ENGINEx_WT)

The NDEDI_ENGINEx_WT register allows traces to be enabled and/or disabled on the occurrence of a watchpoint.If the same watchpoint is programed to enable and disable a trace, the occurrence of the watchpoint toggles the current value of the trace flags If one watchpoint occurs to enable trace and a different watchpoint occurs to disable trace at the same time the current value of the trace flags will also be toggled.Trace enable flags from triggers (PTEF and DTEF) are ORed with the appropriate bit in the TM field of the DC register and sent to the trace blocks.

Field	Description
RC3	Range Control 3 Controls which addresses match data trace window 3 . 0 = Trace address inside (inclusive) of data trace window 3 1 = Trace addresses outside (exclusive) of data trace window 3

60.6.1.7 ENGINEx Breakpoint/Watchpoint Control 1/2 Register (NDEDI_ENGINEx_BWC1/2)

The ENGINEx Breakpoint/Watchpoint Control 1 Register is used to configure ENGINEx breakpoint/watchpoint 1 along with the NDEDI_ENGINEx_BWA1 and NDEDI_ENGINEx_BWD1 registers.

The ENGINEx Breakpoint/Watchpoint Control 2 Register is used to configure ENGINEx breakpoint/watchpoint 2 along with the NDEDI_ENGINEx_BWA2 and NDEDI_ENGINEx_BWD2 registers.

These registers are responsible for configuring the hardware breakpoints/watchpoints 1 and 2. And every field of this register is related to these breakpoints only. When a field is set to a reserved value the behavior defaults to the reset values behavior.

The register can be configured for breakpoint/watchpoint based on data write values, instruction address and data read or write addresses.

When a hardware breakpoint occurs the program execution is halted before the instruction is executed. This means that data access breakpoints occur before the SPRAM access actually takes place.

The data accesses that occur within the Time Slot Transition (TST) do not generate a hardware breakpoint. Thus, it is not expected that the ETPU system signalize these transactions to the NDEDI interface.

Register index: 23

Figure 60-8. ENGINE_x Breakpoint/Watchpoint Control 2 Register (NDEDI_ENGINE_x_BWC2)

Table 60-10. NDEDI_ENGINEx_BWC1/2 field descriptions

Field	Description
BWE	Breakpoint/Watchpoint Enable The BWE field is used to enable the ENGINEx hardware breakpoint or watchpoint. BWE values: 0b00 = Disabled 0b01 = Breakpoint Enabled 0b10 = Reserved 0b11 = Watchpoint Enabled Changing BWE from 'Breakpoint Enabled'(BWE=0b01) to 'Watchpoint Enabled'(BWE=0b11) and vice-versa must only be done while ETPU is either halted or stopped. To set BWE as either 'Breakpoint Enabled'(BWE=0b01) or 'Watchpoint Enabled'(BWE=0b11) while ETPU is neither halted nor stopped the user must previously set BWE as 'Disabled' (BWE=0b00). All other fields of this register must only be changed when BWE=0b00 (disabled) when the engine is not stopped or halted, in 3 steps: (a) write BWE=0b00; (b) change other fields; (c) write BWE with a valid non-zero value, keeping the other fields unchanged.
BRW	Breakpoint/Watchpoint Read/Write Select The BRW field selects if read and/or write accesses cause a hardware breakpoint/watchpoint. BRW values: 0b00 = Match on read SPRAM access 0b01 = Match on write SPRAM access 0b10 = Match on any SPRAM accesses 0b11 = Reserved
BME	Breakpoint/Watchpoint Data Mask Enable The BME field selects which data bytes are used for hardware breakpoint/watchpoint generation. BME values: 0b0000 = All bytes of data compared 0b1xxx = Most significant byte of data masked out ... 0bxxx1 = Least significant byte of data masked out
BSU	Breakpoint/Watchpoint Data Size Unit The BSU is a read-only field to indicate the data size unit used by the NDEDI block. This field always reads as 0b00 to indicate the data size unit is 1 byte.

Table continues on the next page...

Table 60-10. NDEDI_ENGINEx_BWC1/2 field descriptions (continued)

Field	Description
BWO	Breakpoint/Watchpoint Operand The BWO selects if address and/or data matching is done and if matching is done on data fetches or instruction fetches. BWO values: 0b00x = Breakpoint/Watchpoint Disabled 0bx10 = Reserved 0b011 = Compare data of a SPRAM write access with BWD 0b100 = Compare instruction Address with BWA 0b101 = Compare Address of a SPRAM write/read access with BWA 0b111 = Compare Data and Address of a SPRAM write access with BWD and BWA respectively
EOC	$\overline{\text{EVTO}}$ Control The EOC bit controls the action of the $\overline{\text{EVTO}}$ output at the occurrence of a hardware breakpoint or watchpoint. 0 = Breakpoint/Watchpoint status indication is not output on $\overline{\text{EVTO}}$ 1 = Breakpoint/Watchpoint status indication is output on $\overline{\text{EVTO}}$
SCMSK	Serviced Channel Mask Value The SCMSK field is used to mask what bits of the SCMV field are compared to the serviced channel. When a bit in the SCMSK field is 0, that bit is not compared for masking purposes. serviced channel match = (SCMV&SCMSK) == (Serviced Channel & SCMSK);
SCMV	Serviced Channel Match Value The SCMV field value is compared against the ENGINEx serviced channel when generating the breakpoints and watchpoints.

60.6.1.8 ENGINEx Breakpoint/Watchpoint Address 1/2 Register (NDEDI_ENGINEx_BWA1/2)

The ENGINEx Breakpoint/Watchpoint Address 1 Register is used to configure ENGINEx hardware breakpoint/watchpoint 1 along with the NDEDI_ENGINEx_BWC1 and NDEDI_ENGINEx_BWD1 registers. It is used for data access and instruction fetches breakpoints.

The ENGINEx Breakpoint/Watchpoint Address 2 Register is used to configure ENGINEx hardware breakpoint/watchpoint 2 along with the NDEDI_ENGINEx_BWC2 and NDEDI_ENGINEx_BWD2 registers. It is used for data access and instruction fetches breakpoints.

Table 60-11. NDEDI_ENGINE_x_BWA1/2 field descriptions

Field	Description
BWAM	Breakpoint/Watchpoint Address Mask The BWAM field is used to select which address bits are compared for breakpoint and watchpoint generation. $\text{address match} = (\text{BWA} \& \text{BWAM}) == (\text{Address} \& \text{BWAM});$
BWA	Breakpoint/Watchpoint Address The BWA field is used to compare address operands (address of instruction or data). The BWA field represent a word addressable address. The most significant two bits are ignored for address of data comparisons because the SPRAM address space is only 14 bits.

60.6.1.9 ENGINE_x Breakpoint/Watchpoint Data 1/2 Register (NDEDI_ENGINE_x_BWD1/2)

The ENGINE_x Breakpoint/Watchpoint Data 1 Register is used to configure the ENGINE_x hardware breakpoint/watchpoint 1 along with the NDEDI_ENGINE_x_BWC1 and NDEDI_ENGINE_x_BWA1 registers. It is used for data access breakpoints only.

The ENGINE_x Breakpoint/Watchpoint Data 2 Register is used to configure the ENGINE_x hardware breakpoint/watchpoint 2 along with the NDEDI_ENGINE_x_BWC2 and NDEDI_ENGINE_x_BWA2 registers. It is used for data access breakpoints only.

Table 60-12. NDEDI_ENGINEx_BWD1/2 field descriptions

Field	Description
BWD	Breakpoint/Watchpoint Data The BWD field is used to compare data operands whether in a SPRAM write access. Depending on the size of the access, only certain bits of BWD are compared against the data written to the SPRAM. Table 60-13 shows which bits of BWD are compared against the data written to the SPRAM.

Table 60-13. Bits compared against BWD

Operation size	Bits compared
8-bits	8 most significant bits of BWD
24-bits	24 least significant bits of BWD
32-bits	All bits from BWD

60.6.1.10 ENGINEx Program Trace Channel Enable Register (NDEDI_ENGINEx_PTCE)

The NDEDI_ENGINEx_PTCE register enables program tracing for each of the 32 ENGINEx channels. There is one enable bit per channel. And the bit corresponding to the serviced channel is the only bit tested for enabling program trace. For these bits to have any effect, program trace must also be enabled in the TM field of the DC register or via a watchpoint trigger.

Client Select: ENGINEx_SRC

Register index: 64

60.6.1.11 ENGINEx Breakpoint/Watchpoint Control 3 Register (NDEDI_ENGINEx_BWC3)

The ENGINEx Breakpoint/Watchpoint Control 3 Register is used to configure miscellaneous ENGINEx hardware breakpoint/watchpoint sources. This is a vendor-defined register with different fields than BWC1 and BWC2.

When a field is set to a reserved value the behavior defaults to the reset values behavior.

Client Select: ENGINEx_SRC

Register index: 24

**Figure 60-14. ENGINEx Breakpoint/Watchpoint Control 3 Register (NDEDI_ENGINEx_BWC3)****Table 60-15. NDEDI_ENGINEx_BWC3 field descriptions**

Field	Description
SCMV	Serviced Channel Match Value The SCMV field value is compared against the serviced channel register when generating a breakpoint due to a write in the CHAN register or due to the start of a service.
SCMSK	Serviced Channel Mask Value The CMSK field is used to mask what bits of the SCMV field are compared to the serviced channel register when generating a breakpoint due to a write in the CHAN register or due to the start of a service. When a bit in the SCMSK field is 0, that bit is not compared for masking purposes.

Table continues on the next page...

Table 60-15. NDEDI_ENGINEx_BWC3 field descriptions (continued)

Field	Description
BCRW	Break on Channel Register Write The BCRW field configures the action when there is a write to the CHAN register and there is a serviced channel match (as described bellow). The breakpoint causes execution to halt before the CHAN register is written. serviced channel match = (SCMV&SCMSK) == (Serviced Channel & SCMSK); BCRW values: 0b00x = Disabled 0b01x = Breakpoint Enabled 0b10x = Reserved 0b11x = Watchpoint Enabled 0bxx0 = Breakpoint/Watchpoint status indication not output on $\overline{\text{EVTO}}$ 0bxx1 = Breakpoint/Watchpoint status indication output on $\overline{\text{EVTO}}$
BHSR	Break on Host Service Request The BHSR field configures the action when there is a serviced channel match (as described bellow) and the host service request is asserted at the beginning of the channel service. The breakpoint causes execution to halt after the time slot transition (TST) completes but before the first instruction of the thread is executed. serviced channel match = (SCMV&SCMSK) == (Serviced Channel & SCMSK); BHSR values: 0b00x = Disabled 0b01x = Breakpoint Enabled 0b10x = Reserved 0b11x = Watchpoint Enabled 0bxx0 = Breakpoint/Watchpoint status indication not output on $\overline{\text{EVTO}}$ 0bxx1 = Breakpoint/Watchpoint status indication output on $\overline{\text{EVTO}}$
BLINK	Break on Link Service Request The BLINK field configures the action when there is a serviced channel match (as described bellow) and the link service register is asserted at the beginning of the channel service. The breakpoint causes execution to halt after the time slot transition (TST) completes but before the first instruction of the thread is executed. serviced channel match = (SCMV&SCMSK) == (Serviced Channel & SCMSK); BLINK values: 0b00x = Disabled 0b01x = Breakpoint Enabled 0b10x = Reserved 0b11x = Watchpoint Enabled 0bxx0 = Breakpoint/Watchpoint status indication not output on $\overline{\text{EVTO}}$ 0bxx1 = Breakpoint/Watchpoint status indication output on $\overline{\text{EVTO}}$

Table continues on the next page...

Table 60-15. NDEDI_ENGINEx_BWC3 field descriptions (continued)

Field	Description
BMRL	Break on Match Recognition Request The BMRL field configures the action when there is a serviced channel match (as described bellow) and either MRL1 or MRL2 is asserted at the beginning of the channel service. The breakpoint causes execution to halt after the time slot transition (TST) completes but before the first instruction of the thread is executed. serviced channel match = (SCMV&SCMSK) == (Serviced Channel & SCMSK); BMRL values: 0b00x = Disabled 0b01x = Breakpoint Enabled 0b10x = Reserved 1 0b11x = Watchpoint Enabled 0bxx0 = Breakpoint/Watchpoint status indication not output on $\overline{\text{EVTO}}$ 0bxx1 = Breakpoint/Watchpoint status indication output on $\overline{\text{EVTO}}$
BTDL	Break on Transition Detect Request The BTDL field configures the action when there is a serviced channel match (as described bellow) and the TDL1 or TDL2 is asserted at the beginning of the channel service. The breakpoint causes execution to halt after the time slot transition (TST) completes but before the first instruction of the thread is executed. serviced channel match = (SCMV&SCMSK) == (Serviced Channel & SCMSK); BTDL values: 0b00x = Disabled 0b01x = Breakpoint Enabled 0b10x = Reserved 0b11x = Watchpoint Enabled 0bxx0 = Breakpoint/Watchpoint status indication not output on $\overline{\text{EVTO}}$ 0bxx1 = Breakpoint/Watchpoint status indication output on $\overline{\text{EVTO}}$

60.6.1.12 ENGINEx Microinstruction Debug Register (NDEDI_ENGINEx_INST)

The NDEDI_ENGINEx_INST register is used for forcing a microinstruction on the microinstruction register. This register must only be accessed while the ENGINEx is halted. Writes to this register are ignored if accessed while the ENGINEx is not halted.

Client Select: ENGINEx_SRC

Register index: 69

Figure 60-15. ENGINE_x Microinstruction Debug Register (NDEDI_ENGINE_x_INST)

Writes to the register in debug mode force the execution of an arbitrary instruction. This is used to retrieve information about internal status, set internal flag values among other things during debug mode. Some fields of this microinstruction may be ignored, for instance an END instruction will be ignored. For further information about the arbitrary instruction refer to the ETPU BG Section 4.10.2.7.

Reads from the register returns 0.

60.6.1.14 ENGINEx Channel Flag Status Register (NDEDI_ENGINEx_CFSR)

The NDEDI_ENGINEx_CFSR register provides read-only access to the flags of the channel being serviced by ENGINEx. Reads to this register when ENGINEx is out of halt mode return zero., Transition Detection and Match Recognition flags are available in two versions: One reflecting the Branch Condition Selection (BCC), TDL1/2 and MRL1/2, and an ‘internal’ version, ITDL1/2 and IMR1/2, reflecting the flag value within the channel logic.

Table 60-19. NDEDI_CDC_DTC field description (continued)

Field	Description
RWT2	CDC Read/Write Trace 2 Control RWT2 controls whether data trace messages are generated for CDC accesses inside ETPU data trace window 2 (see Data Trace Address Range 2 Register (NDEDI_DTAR2)), and if so, whether reads, writes, or both generate the data trace messages. RWT2 values: 0b00 = No CDC data trace messages generated for ETPU window 2 0b01 = Enable CDC data read trace for ETPU window 2 0b10 = Enable CDC data write trace for ETPU window 2 0b11 = Enable CDC data read and write trace for ETPU window 2
RWT3	CDC Read/Write Trace 3 Control RWT3 controls whether data trace messages are generated for CDC accesses inside ETPU data trace window 3 (see Data Trace Address Range 3 Register (NDEDI_DTAR3)), and if so, whether reads, writes, or both generate the data trace messages. RWT3 value: 0b00 = No CDC data trace messages generated for ETPU window 3 0b01 = Enable CDC data read trace for ETPU window 3 0b10 = Enable CDC data write trace for ETPU window 3 0b11 = Enable CDC data read and write trace for ETPU window 3
RC0	Range Control 0 Controls which addresses match data trace window 0 . 0 = Trace address inside (inclusive) of data trace window 0 1 = Trace addresses outside (exclusive) of data trace window 0
RC1	Range Control 1 Controls which addresses match data trace window 1 . 0 = Trace address inside (inclusive) of data trace window 1 1 = Trace addresses outside (exclusive) of data trace window 1
RC2	Range Control 2 Controls which addresses match data trace window 2 . 0 = Trace address inside (inclusive) of data trace window 2 1 = Trace addresses outside (exclusive) of data trace window 2
RC3	Range Control 3 Controls which addresses match data trace window 3 . 0 = Trace address inside (inclusive) of data trace window 3 1 = Trace addresses outside (exclusive) of data trace window 3

60.6.1.16 Data Trace Address Range 0 Register (NDEDI_DTAR0)

The NDEDI_DTAR0 register defines a data trace address range. The address range is shared by the two ENGINES and the CDC. All three of these clients can independently enable the range for reads and/or writes. If the start address value is greater than the end address value, all accesses are considered to have the address value outside to the data trace window 0.²

Notice that the combination of the start and end addresses for data trace into one register does not follow the standard's recommended method of having separate registers for start and end addresses.

Client Select: ENGINE1_SRC or ENGINE2_SRC or CDC_SRC

Register index: 65

Figure 60-19. Data Trace Address Range 0 Register (NDEDI_DTAR0)

Table 60-20. NDEDI_DTAR0 field descriptions

Field	Description
DTSA0	Data Trace Start Address 0 The DTSA0 field is the start address for ETPU data trace window 0.
DTEA0	Data Trace End Address 0 The DTEA0 field is the end address for ETPU data trace window 0.

2. If RC0 equals 1 for a determined source all accesses from that source will have the address value acknowledged.

60.6.1.17 Data Trace Address Range 1 Register (NDEDI_DTAR1)

The NDEDI_DTAR1 register defines a data trace address range. The address range is shared by the two ENGINES and the CDC. All three of these clients can independently enable the range for reads and/or writes. If the start address value is greater than the end address value, all accesses are considered to have the address value outside to the data trace window 1.³

Notice that the combination of the start and end addresses for data trace into one register does not follow the standard's recommended method of having separate registers for start and end addresses.

Client Select: ENGINE1_SRC or ENGINE2_SRC or CDC_SRC

Register index: 66

Figure 60-20. Data Trace Address Range 1 Register (NDEDI_DTAR1)

Table 60-21. NDEDI_DTAR1 field descriptions

Field	Description
DTSA1	Data Trace Start Address 1 The DTSA1 field is the start address for ETPU data trace window 1.
DTEA1	Data Trace End Address 1 The DTEA1 field is the end address for ETPU data trace window 1.

3. If RC1 equals 1 for a determined source all accesses from that source will have the address value acknowledged.

60.6.1.18 Data Trace Address Range 2 Register (NDEDI_DTAR2)

The NDEDI_DTAR2 register defines a data trace address range. The address range is shared by the two ENGINES and the CDC. All three of these clients can independently enable the range for reads and/or writes. If the start address value is greater than the end address value, all accesses are considered to have the address value outside to the data trace window 2.⁴

Notice that the combination of the start and end addresses for data trace into one register does not follow the standard's recommended method of having separate registers for start and end addresses.

Client Select: ENGINE1_SRC or ENGINE2_SRC or CDC_SRC

Register index: 67

Figure 60-21. Data Trace Address Range 2 Register (NDEDI_DTAR2)

Table 60-22. NDEDI_DTAR2 field descriptions

Field	Description
DTSA2	Data Trace Start Address 2 The DTSA2 field is the start address for ETPU data trace window 2.
DTEA2	Data Trace End Address 2 The DTEA2 field is the end address for ETPU data trace window 2.

4. If RC2 equals 1 for a determined source all accesses from that source will have the address value acknowledged.

60.6.1.19 Data Trace Address Range 3 Register (NDEDI_DTAR3)

The NDEDI_DTAR3 register defines a data trace address range. The address range is shared by the two ENGINES and the CDC. All three of these clients can independently enable the range for reads and/or writes. If the start address value is greater than the end address value, all accesses are considered to have the address value outside to the data trace window 3.⁵

Notice that the combination of the start and end addresses for data trace into one register does not follow the standard's recommended method of having separate registers for start and end addresses.

Client Select: ENGINE1_SRC or ENGINE2_SRC or CDC_SRC

Register index: 68

Figure 60-22. Data Trace Address Range 3 Register (NDEDI_DTAR3)

Table 60-23. NDEDI_DTAR3 field descriptions

Field	Description
DTSA3	ETPU Data Trace Start Address 3 The DTSA3 field is the start address for ETPU data trace window 3.
DTEA3	ETPU Data Trace End Address 3 The DTEA3 field is the end address for ETPU data trace window 3.

60.6.2 Unimplemented Registers

Unimplemented registers are those with client select and index value combinations other than those listed in Table 60-3 . NDEDI will treat unimplemented registers like the JTAG BYPASS instruction.

5. If RC3 equals 1 for a determined source all accesses from that source will have the address value acknowledged.

60.7 Functional description

This section describes the functional description.

60.7.1 NDEDI reset configuration

This section describes the reset configuration of NDEDI.

60.7.1.1 Enabling NDEDI Class 1 operation

The NDEDI Class 1 features are always enabled after exiting the JTAG Test-Logic-Reset state. But they are disabled while the JTAG is in this state. Thus, allowing low power mode for a production part. The registers are always reset while in the JTAG Test-Logic-Reset state.

60.7.1.2 Enabling NDEDI Class 3 operation

When NDEDI input `nex_mcko_en` is asserted the NDEDI Classes 1 and 3 are enabled after exiting the JTAG Test-Logic-Reset state, otherwise the NDEDI Class 3 features will be disabled, entering in the Disable-Port Mode, thus no trace output will be provided, and auxiliary port output pins will be disabled (driven inactive or used for an alternate function if sharing pins).⁶

60.7.2 Auxiliary output port

This section describes the Auxiliary output ports.

60.7.2.1 Output Message Protocol

The protocol for transmitting messages via the auxiliary port is accomplished with the $\overline{\text{MSEO}}$ functions. MDO and $\overline{\text{MSEO}}$ must be sampled by the development tool on the rising edge of MCKO .

6. Class 1 features are still available in Disable-Port Mode.

The following figure illustrates the state diagram for $\overline{\text{MSEO}}$ transfers. All transitions not included in the figure are reserved, and are never generated by the NDEDI block.

Figure 60-23. $\overline{\text{MSEO}}$ Transfers

60.7.2.2 Output messages

The following table describes the messages that the NDEDI can transmit on the auxiliary port.

Table 60-24. NDEDI messages

Message Name	Min. Packet Size (bits)	Max Packet Size (bits)	Packet Type	Packet Name	Packet Description
Debug Status Message	6	6	fixed	TCODE	Value = 0
	K	K	fixed	SRC	Client that is the source of the message
	32	32	fixed	STATUS	Value of the Development Status register
Ownership Trace Message	6	6	fixed	TCODE	Value = 2
	K	K	fixed	SRC	Client that is the source of the message
	16	16	fixed	PROCESS	Process ID. This value depends on the ETPU state at the beginning of a service
Data Trace, Data Write Message	6	6	fixed	TCODE	Value = 5
	K	K	fixed	SRC	Client that is the source of the message
	2	2	fixed	SIZE	Size of data access (8, 24, or 32 bits)
	1	14	variable	U-ADDR	Unique portion of the data write address. Most significant bits that have 0 values may be truncated
	1	32	variable	DATA	Data value written
Data Trace, Data Read Message	6	6	fixed	TCODE	Value = 6
	K	K	fixed	SRC	Client that is the source of the message
	2	2	fixed	SIZE	Size of data access (8, 24, or 32 bits)
	1	14	variable	U-ADDR	Unique portion of the data read address. Most significant bits that have 0 values may be truncated
	1	32	variable	DATA	Data value read
Error Message	6	6	fixed	TCODE	Value = 8
	K	K	fixed	SRC	Client that is the source of the message
	5	5	fixed	ECODE	Error Code
Data Trace, Data Write with Sync Message	6	6	fixed	TCODE	Value = 13
	K	K	fixed	SRC	Client that is the source of the message
	2	2	fixed	SIZE	Size of data access (8, 24, or 32 bits)
	1	14	variable	F-ADDR	Full address of the memory location written. Most significant bits that have 0 values may be truncated
	1	32	variable	DATA	Data value written
Data Trace, Data Read with Sync Message	6	6	fixed	TCODE	Value = 14
	K	K	fixed	SRC	Client that is the source of the message
	2	2	fixed	SIZE	Size of data access (8, 24, or 32 bits)
	1	14	variable	F-ADDR	Full address of the memory location read. Most significant bits that have 0 values may be truncated
	1	32	variable	DATA	Data value read
Watchpoint Hit Message	6	6	fixed	TCODE	Value = 15
	K	K	fixed	SRC	Client that is the source of the message
	7	7	fixed	WPHIT	Number indicating watchpoint source

Table continues on the next page...

Table 60-24. NDEDI messages (continued)

Message Name	Min. Packet Size (bits)	Max Packet Size (bits)	Packet Type	Packet Name	Packet Description
Resource Full Message	6	6	fixed	TCODE	Value = 27
	K	K	fixed	SRC	Client that is the source of the message
	4	4	fixed	RCODE	Resource Code. Refer to Table 60-26
	1	H	variable	HIST	Branch/Predicate Instruction History. This packet is terminated by a stop bit set to 1 after the last history bit. This allows the tool to determine which bits are part of the history packet and which are padded zeros
Program Trace, Indirect Branch with History Message	6	6	fixed	TCODE	Value = 28
	K	K	fixed	SRC	Client that is the source of the message
	1	8	variable	I-CNT	Number of instruction units executed since the last taken branch, not taken direct branch, or predicated instruction
	1	14	variable	U-ADDR	Unique portion of the branch target address for an indirect branch. Most significant bits that have 0 values may be truncated
	1	H	variable	HIST	Branch/Predicate Instruction History. This packet is terminated by a stop bit set to 1 after the last history bit. This allows the tool to determine which bits are part of the history packet and which are padded zeros
Program Trace, Indirect Branch with History Sync Message	6	6	fixed	TCODE	Value = 29
	K	K	fixed	SRC	Client that is the source of the message
	1	8	variable	I-CNT	Number of instruction units executed since the last taken branch, not taken direct branch, or predicated instruction
	1	14	variable	F-ADDR	Full branch target address for an indirect branch. Most significant bits that have 0 values may be truncated
	1	H	variable	HIST	Branch/Predicate Instruction History. This packet is terminated by a stop bit set to 1 after the last history bit. This allows the tool to determine which bits are part of the history packet and which are padded zeros
Program Trace Correlation Message	6	6	fixed	TCODE	Value = 33
	K	K	fixed	SRC	Client that is the source of the message
	4	4	fixed	EV-CODE	Event Code
	1	8	variable	I-CNT	Number of instruction units executed since the last taken branch, not taken direct branch, or predicated instruction
	1	H	variable	HIST	Branch/Predicate Instruction History. This packet is terminated by a stop bit set to 1 after the last history bit. This allows the tool to determine which bits are part of the history packet and which are padded zeros

Table continues on the next page...

Table 60-24. NDEDI messages (continued)

Message Name	Min. Packet Size (bits)	Max Packet Size (bits)	Packet Type	Packet Name	Packet Description
Program Trace, Channel Start Service Message	6	6	fixed	TCODE	Value = 58 (Vendor-Defined Message)
	K	K	fixed	SRC	Client that is the source of the message
	5	5	fixed	S-CHAN	Number of the channel being serviced
	1	8	variable	I-CNT	Number of instruction units executed since the last taken branch, not taken direct branch, or predicated instruction
	1	14	variable	F-ADDR	Full address of the first instruction. Most significant bits that have 0 values may be truncated.
	1	H	variable	HIST	Branch/Predicate Instruction History. This packet is terminated by a stop bit set to 1 after the last history bit. This allows the tool to determine which bits are part of the history packet and which are padded zeros
Program Trace, Channel Trace Enable Message	6	6	fixed	TCODE	Value = 59 (Vendor-Defined Message)
	K	K	fixed	SRC	Client that is the source of the message
	5	5	fixed	S-CHAN	Number of the channel being serviced
	1	14	variable	F-ADDR	Full address of the first instruction after the program trace is enabled by a watchpoint. Or, the full address of the first instruction after the Event Queue gets empty after a Queue Overrun. Most significant bits that have 0 values may be truncated
	0	5	variable	CHAN	Channel Register Value. Only sent if different from S-CHAN value
Channel Register Write Message	6	6	fixed	TCODE	Value = 60 (Vendor-Defined Message)
	K	K	fixed	SRC	Client that is the source of the message
	1	5	variable	CHAN	Value written to the channel register

The following table describes the Error Code encodings for the error messages generated by the NDEDI block.

Table 60-25. Error Codes Encodings(ECODE)

Error Code	Description
0b00000	Ownership trace overrun
0b00001	Program trace overrun
0b00010	Data trace overrun
0b00110	Watchpoint Overrun
0b00111	Program and/or Data and/or Ownership Trace Overrun
0b01000	Program Trace and/or Data Trace and/or Ownership Trace and/or Watchpoint Overrun
0b11000	Debug Status Overrun

Table continues on the next page...

Table 60-25. Error Codes Encodings(ECODE) (continued)

Error Code	Description
0b11001	Debug Status Overrun and/or Program and/or Data and/or Ownership Trace Overrun
0b11010	Debug Status and/or Program Trace and/or Data Trace and/or Ownership Trace and/or Watchpoint Overrun

The following table describes the Resource Code encodings for the resource full messages.

Table 60-26. Resource Codes Encodings

Resource Code	Resource	DATA Packet Count	DATA Packet Value
0b0000	Program Trace, Sequential Counter	1	Branch/Predicate Instruction History. This packet is terminated by a stop bit set to 1 after the last history bit. The value that causes the counter to fill is always the same and can be determined without sending the value
0b0001	Program Trace, Branch/Predicate History	1	Branch/Predicate Instruction History. This packet is terminated by a stop bit set to 1 after the last history bit

Message formatting is performed by the message formatter block. Raw messages read from the message queues are independent of the number of MDO pins implemented.

The following table shows the various message formats and the location of variable length packets. Notice that for variable-length packets, the transmitted size of the packet is determined from the range of the least significant bit to the most significant non-zero-valued bit (i.e. most significant 0 value bits are not transmitted).

Table 60-27. Message Packet Sizes

Message	TCODE	Packet #1	Packet #2	Packet #3	Packet #4	Packet #5	Packet #6	Min. Size ¹ (bits)	Max Size ² (bits)
Debug Status Message	0	Fixed = K	Fixed =32	NA	NA	NA	NA	38+K	38+K
Ownership Trace Message	2	Fixed = K	Fixed =16	NA	NA	NA	NA	22+K	22+K

Program Trace, Channel Trace Enable Message	59	Fixed = K	Fixed=5	Variable Min = 1 Max = 14	Variable Min = 0 Max = 5	NA	NA	12+K	30+K

Table continues on the next page...

Table 60-27. Message Packet Sizes (continued)

Message	TCODE	Packet #1	Packet #2	Packet #3	Packet #4	Packet #5	Packet #6	Min. Size ¹ (bits)	Max Size ² (bits)
Channel Register Write Message	60	Fixed = K	Variable Min = 1 Max = 5	NA	NA	NA	NA	7+K	11+K

1. Minimum information size. The actual number of bits transmitted depends on the number of MDO pins.
2. Maximum information size. The actual number of bits transmitted depends on the number of MDO pins.
3. Packet is fixed and NDEDI always transmits 2 bits, but other sources sharing the auxiliary port may have a different packet size{ndedi_msg_checker, ndedi_dt_rnd}. Packet size can always be determined by the value of the SRC packet.
{Statement}

The double edges in the preceding table indicate the starts and ends of messages. The shaded edges in the preceding figure indicate the end of a variable length packet which is not also the end of the message. Packets without shaded areas between them are grouped into super packets and are transmitted together without end-of-packet indications between them.

60.7.2.2.1 Rules of messaging

- A variable-length packet within a message must end on a port boundary (Port boundaries depend on the number of MDO pins active with the current reset configuration)
- A variable-length packet may start within a port boundary only when following a fixed-length packet.
- Superblocks must end on a port boundary
- When a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest order bit so that it can end on a port boundary
- Multiple fixed-length packets may start and/or end on the same clock
- When any packet follows a variable-length packet, it must start on a port boundary
- The packet containing the TCODE number is always transferred out first, followed by subsequent packets of information
- Within a packet, the least significant bits are shifted out first. The following figure shows the transmission sequence of a message that is made up of a TCODE followed by two packets

Figure 60-24. Transmission Sequence of Messages

60.7.2.2.2 Examples

The following are examples of branch trace and data trace messages.

The following figure illustrates how the indirect branch with history public message is transmitted. *Notice that the example uses a 4-bit MDO port*. For this example, 4 bits are shifted out in the I-CNT packet, 5 bits are shifted out in the HIST packet, and 11 bits are shifted out for the UADDR packet. Notice also that T0, S0, H0, I0, and A0 are the least significant bits where:

Tx= TCODE packet bits (Fixed)

Sx= SRC packet bits (Fixed)

Hx = HIST packet bits (Variable)

Ix= I-CNT packet bits (Variable)

Ax= UADDR packet bits (Variable)

Clock	MDO[3:0]				MSEO[1:0]	State
	3	2	1	0		
0	X	X	X	X	X	End Message or Idle
1	T3	T2	T1	T0	00	Start Message
2	S1	S0	T5	T4	00	Normal Transfer
3	I2	I1	I0	S2	00	Normal Transfer
4	0	0	0	I3	01	End Packet
5	A3	A2	A1	A0	00	Normal Transfer
6	A7	A6	A5	A4	00	Normal Transfer
7	0	A10	A9	A8	01	End Packet
8	H3	H2	H1	H0	00	Normal Transfer
9	0	0	0	H4=1	11	End Message

Figure 60-25. Indirect Branch with History Message (4 MDO pins)

The following figure shows the same message being sent using 8 MDO pins

Clock	MDO[7:0]								$\overline{\text{MSEO}}[1:0]$	State
	7	6	5	4	3	2	1	0		
0	X	X	X	X	X	X	X	X	X	End Message or Idle
1	S1	S0	T5	T4	T3	T2	T1	T0	00	Start Message
2	0	0	0	I3	I2	I1	I0	S2	01	End Packet
4	A7	A6	A5	A4	A3	A2	A1	A0	00	Normal Transfer
5	0	0	0	0	0	A10	A9	A8	01	End Packet
3	0	0	0	H4=1	H3	H2	H1	H0	11	End Message

Figure 60-26. Indirect Branch with History Message (8 pins)

The following figure illustrates how a data write with sync message is transmitted. *Notice that the example uses a 16-bit MDO port*. For this example, 7 bits are sent for the F-ADDR packet, and 5 bits are sent for the DATA packet. Notice also that T0, S0, A0, and D0 are the least significant bits where:

Tx= TCODE packet bits (Fixed)

Sx= SRC packet bits (Fixed)

Zx = SIZE packet bits (Fixed)

Dx= DATA packet bits (Variable)

Ax= F-ADDR packet bits (Variable)

Clock	MDO[15:0]																$\overline{\text{MSEO}}[1:0]$	State

3	0	0	0	0	0	0	0	0	0	0	0	D4	D3	D2	D1	D0	11	End Message

Figure 60-27. Data Write with Sync Message (16 pins)

60.7.2.2.3 Temporal Ordering of Transmitted Messages

All Messages are sent out in the sequence their related event actually occurred. The ETPU interface with the NDEDI provides the ETPU signals to be monitored and captured. At the occurrence of any event that would cause a message, a snapshot of all information needed by the Message Formatter to generate a message is queued. Doing so, several events from either Engines or CDC can be queued at the same time.

Whenever the auxiliary port is idle, the Event Queue is read and the appropriate messages are formatted. Then, NDEDI sends a request for the auxiliary port, and as soon as the auxiliary port is granted the message is sent. If more than one messages are to be sent, the Message Formatter respects the following priority: Messages related to Error, Debug Status, Watchpoints, Program Trace and Data Trace. A request for the auxiliary port is sent for every messages within the snapshot.

NDEDI maintain temporal ordering of messages relative to ENGINE1, ENGINE2 and CDC, but not relative to messages generated by other clients sharing the auxiliary port.

The Time Slot Transition (TST) is considered to be an active state, and since data are accessed at the SPRAM, it is possible that Data Trace Events are recognized within TST.

⁷ For further information about TST, please refer to the ETPU BG.

60.7.3 IEEE 1149.1 (JTAG) Input Port

The NDEDI block uses the IEEE 1149.1 TAP for accessing registers. This port is shared among all TAP controllers on the MCU. This sharing is controlled by the value in the instruction register and client select control register.

The NDEDI implements a Nexus controller state machine that transitions based on the state of the IEEE 1149.1 state machine shown in [Figure 60-29](#) . The Nexus controller state machine, shown in [Figure 60-30](#), is defined by the IEEE-ISTO 5001-2002 standard.

The instructions implemented by the NDEDI TAP controller are listed in the following table. If any other instruction is received it will be treated as a BYPASS.

7. Due to ETPU operation, speculative accesses may also happen within TST and will be traced.

Table 60-28. Implemented Instructions

Instruction Name	Priv ate/ Pub lic	Opcode	Description
NEXUS-ENABLE	publi c	4'b0000	Activate Nexus controller state machine to read and write NDEDI registers
BYPASS	publi c	4'b1111	Implements a single shift register stage providing a minimum serial length between TDI and TDO

Data is shifted between TDI and TDO starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

Figure 60-28. Shifting Data Into Register

60.7.3.1 Enabling the NDEDI TAP Controller

Assertion of the $\overline{\text{TRST}}$ input resets all TAP controllers on the MCU. The controllers are loaded with the BYPASS instruction upon exit of the 'TEST-LOGIC-RESET' JTAG controller state. Loading the NEXUS-ENABLE instruction grants access to Nexus debug. NDEDI acts as BYPASS by loading any other instruction. The TDO bit is driven with the value of the instruction register while in 'SHIFT_IR' state.

Figure 60-29. IEEE 1149.1 16-State Finite State Machine

60.7.3.2 Loading NEXUS-ENABLE Instruction

Access to the NDEDI registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. The current instruction value is loaded into the IEEE 1149.1 shifter in the 'CAPTURE_IR' state. The instruction is shifted in via the 'SELECT-IR-SCAN' path and loaded in the 'UPDATE-IR' state. At this point, the Nexus controller state machine, shown in the following figure, transitions to the 'REG_SELECT' state. The following table illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Figure 60-30. Nexus Controller State Machine

Table 60-29. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1 controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1 shifter is ready. Shift in all but the last bit of the NEXUS_ENABLE instruction
4 TCKs				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	NEXUS-ENABLE ready to be read

60.7.3.3 Selecting an IEEE 1149.1 Register

When the NEXUS-ENABLE instruction is loaded in the NDEDI TAP controller instruction register, the input port allows development tool access to all NDEDI registers. Each register has a 7-bit address index. Some clients have registers with the same index as registers in other clients. Therefore, to access the registers of a particular client, the Client Select Control register must be set for that client.

All register access is performed via the 'SELECT-DR-SCAN' path. The Nexus state machine defaults to the register select state when enabled. Accessing a register requires two passes through the 'SELECT-DR-SCAN' path: one pass to select the register and the second pass to read/write the register.

The first pass through the 'SELECT-DR-SCAN' path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in the following figure. The read/write control bit is set to 1 for writes and 0 for reads. The current value of the Controller Command Input is captured into the IEEE 1149.1 shifter during the 'CAPTURE-DR' state while the Nexus controller state machine is in the 'REG_SELECT' state.

Figure 60-31. IEEE 1149.1 Controller Command Input

The second pass through the 'SELECT-DR-SCAN' path is used to read or write the register data by shifting in the data (LSB first) during the 'SHIFT-DR' state. When reading a register, the current register value is loaded into the IEEE 1149.1 shifter during the 'CAPTURE-DR' state. When writing a register, the value is loaded from the IEEE 1149.1 shifter to the register during the 'UPDATE-DR' state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

The following table illustrates a sequence which writes a 32-bit value to a register

Table 60-30. Writing to a Register

Clock	TM S	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1 controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through 'SELECT-DR-SCAN' path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input

Table continues on the next page...

Table 60-30. Writing to a Register (continued)

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 6 bits of register index shifted in
7 TCKs				
12	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
13	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
14	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through 'SELECT-DR-SCAN' path
15	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
16	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
48	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI
49	1	UPDATE-DR	DATA_ACCESS	Value written to register
50	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to 'SELECT-DR-SCAN' to write another register

60.7.4 Microcode Development Support

The NDEDI contains a number of hardware hooks that aid in the development of microcode for the ETPUs. This features described in this section make the ETPUs compliant with Nexus Class 1 features.

The main features provided are the abilities to:

- Read and write ETPU internal registers in debug mode
- Read and write SPRAM in debug mode
- Enter a debug mode at reset negation
- Enter a debug mode during normal execution
- Single step instructions and re-enter debug mode
- Stop program execution on instruction/data breakpoints or channel service breakpoints and enter debug mode
- Set breakpoints or watchpoints

- Execute external microcode instruction in debug mode
- Read/write the microprogram counter register value in debug mode

Refer to [Initialization/Application Information](#) on how the following functions provide the features listed above.

60.7.5 Debug Status

The NDEDI module provides the Debug Status via the auxiliary port, as defined by the IEEE-ISTO 5001-2002 standard.

60.7.5.1 Messaging

The NDEDI block provides debug status messaging using IEEE-ISTO 5001-2002 standard-defined public messages. When the development status register changes, a debug status change event is sent to the Event Queue. If the debug status change condition occurs while the Event Queue is not enabled for storing snapshots, a debug status overrun message is generated.

The debug status message has the format shown in the following figure.

Figure 60-32. Debug Status Message Format

The DS packet correspond to the ENGINE_x DS register value described in [Figure 60-4](#).

60.7.5.2 Error Messages

A debug status overrun error event is queued if a debug status event occurs while the Event Queue is not enabled for storing snapshots. The error event is stored as soon as the Event Queue is enabled which happens when the queue gets empty.

The error message has the format shown in the following figure.

Figure 60-33. Debug Status Error Message Format

60.7.5.3 Synchronization

Upon the exit of debug mode, the next program and data trace messages are synchronization messages. The exit of debug mode by one of the Engines causes data and program synchronization for that Engine only.

60.7.5.4 Timing Diagrams

Note that all of the following timing diagrams assume a 3-bit SRC size and a 16-bit MDO port. The state variable is not a signal, but instead is derived from $\overline{\text{MSEO}}$. It is included for clarity. Refer to [Figure 60-23](#) for $\overline{\text{MSEO}}$ state diagram.

The following abbreviations are used for the state variable in the diagrams:

- ID = Idle
- SM = Start Message
- NT = Normal Transfer
- EP = End Packet
- EM = End Message

Figure 60-34. Debug Status Message

Figure 60-35. Debug Status Overrun Error Message

60.7.6 Ownership Trace

Ownership trace provides a macroscopic view of the ETPU program flow. This is done by generating an ownership trace event at the start of each channel service and whenever an engine becomes idle.

Each engine within the ETPU system generates ownership traces independently, and the events are queued in the order in which they occur.

60.7.6.1 Messaging

Ownership trace information is transmitted via the auxiliary port using an ownership trace message (OTM).

Ownership trace information is transmitted in the format shown in the following figure.

Figure 60-36. Ownership Trace Message Format

Notice that the channel number and entry points number in the preceding figure are concatenated to form the variable length PROCESS packet defined by the IEEE-ISTO 5001-2002 standard.

60.7.6.2 OTM Flow

A channel generates an ownership trace message when service starts if ownership trace is enabled for the ETPU via the development control register. If ownership trace is enabled and an engine becomes idle, NDEDI will transmit a special OTM with the PROCESS packet set to 0.

60.7.6.3 Timing Diagram

The following figure shows an example of an ownership message being transmitted on the auxiliary port. The diagram assumes a 3-bit SRC size and a 16-bit MDO port. The state variable is not a signal but instead, it is derived from $\overline{\text{MSEO}}$. It is included for clarity. Refer to [Figure 60-23](#) for $\overline{\text{MSEO}}$ state diagram.

The following abbreviations are used for the state variable in the diagrams:

- ID = Idle
- SM = Start Message
- NT = Normal Transfer
- EP = End Packet
- EM = End Message

Figure 60-37. Ownership Trace Message

60.7.7 Program Trace

This section details the program trace mechanism supported by the NDEDI for the dual Engine system. Program trace is implemented via a combination of Branch Trace Messaging (BTM) and Ownership Trace Messaging (OTM) as per the IEEE-ISTO 5001-2002 standard definition.

60.7.7.1 Branch Trace Messaging

Branch trace messaging facilitates program trace by providing the following types of information:

- Messages for the start of channel services, each containing the full address of the first instruction to execute and history and sequential count information left over from the previously traced channel service. This message is always synchronizing
- Messages to indicate that the Program Trace was enabled in the middle of a thread or after the Queue is enabled for storing snapshots and it was previously disabled due to queue overrun. It includes the address of the enable point, the value of the serviced channel and the CHAN reg value only if it differs from the serviced channel value
- Messages to indicate that the internal history buffer has filled and been reset. The current value of the history buffer is included in each of these messages
- Messages to indicate that the internal sequential instruction counter has overflow and been reset. The current value of the history buffer is included in each of these messages
- Messages for taken indirect branches, each including a branch/predicate instruction⁸ history packet, sequential instruction count, and the unique portion of the branch target address. Indirect branch messages that are generated with pending synchronization event include the full branch target address (instead of the unique portion of the address)
- Messages to indicate the entry into debug mode, the entry into low power mode, or the end of channel service with no new service pending
- Messages for writes to the CHAN register, indicating the value assigned to the register

The address packet of a program trace address excludes the 2 least significant bits of the byte address because they are zero for all instruction addresses.

60.7.7.2 Branch Trace Message Formats

There are seven types of messages used by the ETPU for branch tracing. These types are shown in the following table.

8. Predicate Instructions depend on the AS/CE field within ETPU instructions.

Table 60-31. ETPU BTM Messages

Message	Synchronizing	Public/Private
Resource Full Message	No	Public
Indirect Branch with History Message	No	Public
Indirect Branch with History Synchronization Message	Yes	Public
Program Trace Correlation Message	No	Public
Channel Start Service Message	Yes	Private
Channel Trace Enable Message	Yes	Private
Channel Register Write Message	No	Private

The occurrence of any of the following conditions requires subsequent synchronization:

- Exit of system reset
- Exit of low power mode
- Exit of debug mode
- Write to the Development Control Register or the Program Trace Channel Enable Register⁹
- 255 branch trace messages of the same are queued without synchronization
- Assertion of the Event In ($\overline{\text{EVTI}}$) pin, depending on how the development control register is configured
- A watchpoint occurrence¹⁰
- A queue overrun

The message that follows any of these synchronizing events will be a synchronizing message if it is not a Resource Full Message or a Channel Register Write Message which have no synchronizing information. If the ETPU reaches the idle the next program trace message will be a Channel Start Service Message or a Channel Trace Enable Message, that are synchronizing.

60.7.7.2.1 Resource Full Messages

The resource full message is generated when the branch/predicate history buffer is full or the sequential instruction counter overflows.

9. Only the Source that have the register written will generate a synchronization message.

10. A Watchpoint occurrence for one Engine generates synchronization message for that Engine only.

For messages caused by the branch/predicate history buffer filling, the current value of that buffer is transmitted as part of the resource full message. This information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch history for a message. The HIST value is reset by this message, and the I-CNT value is reset as a result of a bit being added to the history buffer.

For messages caused by sequential instruction counter overflow, the HIST packet is also transmitted. This occurrence indicates that exactly 256 sequential instructions have been executed without a history bit being recorded or a message (other than CHAN_WRITE) being generated. The HIST and I-CNT values are reset by this message.

The resource full message has the format shown in the following figure.

Figure 60-38. Resource Full Message Format

60.7.7.2.2 Indirect Branch with History Messages

The indirect branch with history message is generated on a taken indirect branch with no synchronization event pending. The program trace indirect branch with history message has the format shown in the following figure.

Figure 60-39. Indirect Branch with History Message Format

60.7.7.2.3 Indirect Branch with History Synchronization Messages

The indirect branch with history synchronization message is generated on a taken indirect branch with a synchronization event pending.

The program trace indirect branch with history synchronization message has the format shown in the following figure.

Figure 60-40. Indirect Branch with History Synchronization Message Format

60.7.7.2.4 Program Trace Correlation Message

The program trace correlation message is generated at the end of an ETPU channel service if there is no new service, if there is a new service which channel is not enabled for tracing, if program trace is disabled in the middle of a thread being traced, upon entry into debug mode, or upon entry into low power mode.

The message contains the history and sequential instruction count information generated during the previous traced service since the last message generation.

The correlation message also contains an event code that indicates the event responsible for the generation of the message. Event code encodings are shown in the following table.

Table 60-32. Event Code Encodings

EV-CODE	Description
0b0000	Entry into Debug Mode
0b0001	Entry into Low Power Mode
0b0010	Program Trace disabled in the middle of a thread
0b1110	End Channel Service (no new service)
all others	Reserved

The program trace correlation message has the format shown in the following figure.

Figure 60-41. Program Trace Correlation Message Format

60.7.7.2.5 Channel Start Service Message

The channel start service message is generated at the start of an ETPU channel service. The message contains the history and sequential instruction count information generated during the previous traced service since the last message generation. The message also contains the address of the first instruction of the current service.

The program trace channel start service message has the format shown in the following figure.

Figure 60-42. Channel Start Service Synchronization Message Format

60.7.7.2.6 Channel Trace Enable Message

If the program trace is enabled in the middle of a thread or after the Queue is enabled for storing snapshots and it was previously disabled due to queue overrun, the Channel Trace Enable Message is sent indicating to the development tool the number of the channel being serviced and the address of the current instruction.¹¹ If the CHAN register value differs from the serviced channel, the CHAN field is sent at the end of the message indicating the current CHAN register value.¹²

The program trace channel trace enable message has the format shown in the following figure.

Figure 60-43. Channel Trace Enable Synchronization Message Format

60.7.7.2.7 Channel Register Write Messages

The channel register write message is generated when the CHAN register is written to by the microcode. This message is not necessary to reconstruct program flow and generation is enabled/disabled by the CHW bit in the ENGINE_x development control register. Program trace must be enabled for this message to be generated.

The channel register write message has the format shown in the following figure

-
11. The message does not contains the history and sequential instruction count information since the trace of this channel was disabled until there.
 12. Usually the CHAN register equals the serviced channel.

Figure 60-44. Channel Register Write Message Format

60.7.7.3 Branch Trace Messaging Operation

Figure 60-45 and Figure 60-46 show the basic flow used to generate branch trace messages for the ETPUs. The following acronyms are used in the figures:

- CHAN - CHAN register in ETPU execution unit
- S-CHAN - Channel being serviced
- HIST - Nexus shift register whose value is transmitted in the HIST packet of many BTMs
- I-CNT - Nexus sequential instruction counter whose value is transmitted in the HIST packet of many BTMs
- CWE - Channel Write Event
- IHE - Indirect Branch with History Event
- IHS - Indirect Branch with History Synchronization Event
- CSE - Channel Start Service Event
- CTE - Channel Trace Enable Event
- RFE - Resource Full Event
- PCE - Program Trace Correlation Event

Figure 60-45. Branch Trace Message Generation (Part 1)

Figure 60-46. Branch Trace Message Generation (Part 2)

60.7.7.3.1 Relative Addressing

The relative address feature is compliant with the IEEE-ISTO 5001-2002 standard recommendations and is designed to reduce the number of bits transmitted for addresses of program trace messages.

The address transmitted for a determined source is relative to the address of the previous branch trace message sent for that source. It is generated by XORing the new address with the previous address, and then using only the results up to the most significant '1' in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address. The following figure shows how a relative address is generated and how it can be used to recreate the original address.

Engine 1: Current Address (A1) = 0x65DC,
 Engine 2: Current Address (B1) = 0x7238

Next Message Relative to Engine 1: Address (A2) = 0x1AF8

Address Generation:

A1 = 110 0101 1101 11 00
 A2 = 001 1010 1111 10 00
 A1 ^ A2 = 111 1111 0010 01 00

Address Message (M1) = 111 1111 0010 01

Address Recreation:

A1 ^ M1 = A2
 A1 = 110 0101 1101 11 00
 ME1 = 111 1111 0010 01
 A1 ^ ME1 = 001 1010 1111 10 00 = A2

Next Message Relative to Engine 2: Address (B2) = 0x54C8

Address Generation for Engine 2

B1 = 111 0010 0011 10 00
 B2 = 101 0100 1100 10 00
 B1 ^ B2 = 010 0110 1111 00 00

Address Message (ME2) = 10 0110 1111 00

Address Recreation:

B1 ^ M1 = B2
 B1 = 111 0010 0011 10 00
 ME2 = 010 0110 1111 00
 B1 ^ ME2 = 101 0100 1100 10 00 = B2

Figure 60-47. Relative Address Generation and Recreation

60.7.7.3.2 Enabling Program Trace

Program trace for the ETPU is enabled on a channel-by-channel basis. This selective enabling allows the tool more control over how much information gets transmitted.

For program trace information to be generated for a channel, the appropriate bit in the program trace channel enable register must be set and program trace must be enabled via the TM field in the DC register or via a watchpoint trigger.

Any combination of channels can be enabled for trace at the same time by configuring the program trace channel enable register. See [ENGINEx Program Trace Channel Enable Register \(NDEDI_ENGINEx_PTCE\)](#) for more details.

Note that since the registers may be changed in the middle of a thread, program trace may be enabled or disabled in the middle of a thread.

If program trace for a determined channel is enabled in the middle of a service routine, a Channel Trace Enable Message is sent to the development tool indicating the number of the channel being serviced and the address of the current instruction. Otherwise, normal program trace begins only on the following service for that channel.

If program trace for a determined channel is disabled in the middle of a service routine, a Program Correlation Message is sent to the development tool indicating that the trace is disabled and informing the HIST and I-CNT values.

60.7.7.3.3 Branch/Predicate Instruction History

The HIST packet provides a history of direct branch and predicated instruction execution used for reconstructing the program flow. This packet is implemented as a left-shifting shift register. The register is always pre-loaded with a value of 1. This bit acts as a stop bit so the tool can determine which bit is the end of the history information. The pre-loaded 1 bit itself is not part of the history information but is transmitted with the packet.

A value of 1 is shifted into the HIST packet on a taken direct branch (conditional or unconditional) and on a predicate instruction whose predicate condition was evaluated as true. A value of 0 is shifted into the HIST packet on a not taken direct branch and on a predicate instruction whose predicate condition was evaluated as false.

A direct branch is a branch whose target address is hard-coded into the microcode instruction at compile time. An indirect branch is a branch whose target address depends on run time conditions. The indirect branches in the ETPU are return from subroutine, dispatch jump, and dispatch call.

For the ETPU, predicated instructions are those that execute ALU operations conditionally based on the value of the C, Z, or N flags. This conditional execution is controlled by the value of the AS/CE packet in the ETPU microcode instruction formats A3, B4, B5, and B6.

60.7.7.3.4 Sequential Instruction Count

The I-CNT packet, present in many of the program trace messages, represents the number of ETPU microcode instructions executed since the start of channel service, last taken direct branch, last not-taken direct branch, last taken indirect branch, or last predicated instruction.¹³ In other words, I-CNT is reset whenever it is transmitted within a message or a bit is recorded to HIST.

When a sequential instruction is executed and the current I-CNT value is 255, a resource full message is transmitted to tell the tool that the I-CNT has reached a value of 256. The current HIST packet is transmitted as part of this message and reset inside the NDEDI. The HIST and I-CNT information in the resource full message are combined with information from subsequent messages to provide the development tool a full picture of the program flow.

If additional HIST bits are recorded between a resource full message for the I-CNT and the next program trace message, the I-CNT overflow can be ignored by the tool. In this case, the HIST packet transmitted by any resource full messages and the next program trace are concatenated to provide the full HIST information.

Multiple I-CNT resource full messages can be received between other program trace messages. In these cases, the HIST packets are concatenated, and the I-CNT values are added only when no HIST bits were recorded between the resource full messages.

60.7.7.3.5 Interleaved ENGINE1 and ENGINE2 messages

Both ENGINE1 and ENGINE2 can be enabled for program trace at the same time. Each Engine microcode instruction takes two system clocks to execute. The dual Engine system alternates instruction completion between ENGINE1 and ENGINE2, thus one module never completes an instruction in the same clock as the other.

The NDEDI block formats and queues ENGINE1 and ENGINE2 messages in the order they are generated. There is no way for the development tool to infer any other temporal information from the ETPU messages.

60.7.7.4 Timing Diagrams

Note that all of the following timing diagrams assume a 3-bit SRC size and either a 4-bit MDO port or a 16-bit MDO port. The state variable is not a signal, but instead is derived from MSEO. It is included for clarity. Refer to [Figure 60-23](#) for MSEO state diagram.

The following abbreviations are used for the state variable in the diagrams:

13. ETPU does not have a conditional indirect branch. Thus, there is no not-taken indirect branch.

- ID = Idle
- SM = Start Message
- NT = Normal Transfer
- EP = End Packet
- EM = End Message

Figure 60-48. Resource Full Message, I-CNT Overflow

Figure 60-55. Channel Trace Enable Message with different values for CHAN and S-CHAN

Figure 60-56. Channel Register Write Message

60.7.8 Data Trace

Dual Engines perform loads and stores to the Shared Parameter RAM (SPRAM). The NDEDI block gathers information about these accesses on a dedicated bus. The NDEDI block traces all SPRAM accesses that meet the selected address range and attributes. This includes accesses from either Engines as well as Coherent Dual-Parameter Controller (CDC) accesses. SPRAM accesses can have data sizes of 8, 24, and 32 bits. The NDEDI block supports all three data sizes.

Whenever performing 8-bits accesses, the ETPU accesses the 8 most significant bits of the word addressed, while the 24-bits accesses are accomplished by accessing the 24 least significant bits. Thus, since the ETPU system uses the Big Endian convention and since the ETPU data addresses are byte-relative the two least significant bits of the transmitted address follows the convention shown in the following table.

Table 60-33. Two least significant bits for Data Trace Addresses

Value	Access
0b00	ETPU 8-bit or 32-bit accesses
0b01	ETPU 24-bit accesses
0b1x	Are not meaningful for ETPU

60.7.8.1 Data Trace Message Formats

There are four types of Data Trace Messages (DTMs):

- Data Write Message
- Data Read Message
- Data Write with Synchronization Message
- Data Read with Synchronization Message

All of the data trace messages contain a SIZE packet. The following table shows the decoding for this packet.

Table 60-34. Data Trace SIZE Packet Decodings

SIZE Packet	Access Size
0b00	Not Meaningful
0b01	24 bits
0b10	8 bits
0b11	32 bits

60.7.8.1.1 Data Write Message

The data write message contains the data write value and the address of the target location relative to the address of the previous data trace message from the same source.

The data write message has the format shown in the following figure.

Figure 60-57. Data Write Message Format

60.7.8.1.2 Data Read Message

The data read message contains the data read value and the address of the target location relative to the address of the previous data trace message from the same source.

The data read message has the format shown in the following figure.

**Figure 60-58. Data Read Message Format**

60.7.8.1.3 Data Trace Synchronization Messages

The occurrence of any of the following conditions requires the following data trace message to be synchronizing:

- Exit of system reset
- Exit of low power mode
- Exit of debug mode
- Write to the development control register or data trace control register¹⁴
- Write to any of the ETPU data trace address range registers
- Exit of NDEDI reset
- 255 data trace messages of the same source are queued without synchronization
- Assertion of the Event In ($\overline{\text{EVTI}}$) pin, depending on how the development control register is configured
- A watchpoint occurrence¹⁵
- A queue overrun

Data trace synchronization messages provide the full addresses (without leading zeros) and ensure that the development tools fully synchronize with data trace regularly. Each synchronization message provides a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted.

There are two types of data trace synchronization messages: data write synchronization and data read synchronization.

60.7.8.1.3.1 Data Write Synchronization Message

The data write synchronization message has the format shown in the following figure.

14. Only the Source that have the register written will generate a synchronization message.

15. A Watchpoint occurrence for one Engine generates synchronization message for that Engine only.

**Figure 60-59. Data Write Synchronization Message Format****60.7.8.1.3.2 Data Read Synchronization Message**

The data read synchronization message has the format shown in the following figure.

**Figure 60-60. Data Read Synchronization Message Format****60.7.8.2 Data Trace Operation**

Data tracing is performed by snooping a dedicated ETPU/Nexus interface for SPRAM read and write cycles. Data trace functions are enabled by setting the appropriate fields in the following registers:

- ENGINE1 Development Control (NDEDI_ENGINE1_DC) Register
- ENGINE2 Development Control (NDEDI_ENGINE2_DC) Register
- ENGINE1 Data Trace Control (NDEDI_ENGINE1_DTC) Register
- ENGINE2 Data Trace Control (NDEDI_ENGINE2_DTC) Register
- CDC Data Trace Control (NDEDI_CDC_DTC) Register
- ETPU Data Trace Address Range 0 (NDEDI_ETPU_DTAR0) Register
- ETPU Data Trace Address Range 1 (NDEDI_ETPU_DTAR1) Register
- ETPU Data Trace Address Range 2 (NDEDI_ETPU_DTAR2) Register
- ETPU Data Trace Address Range 3 (NDEDI_ETPU_DTAR3) Register

For details on register configuration, refer to [Register descriptions](#).

The dual Engines and CDC data tracing share the same Data Trace Address Range Registers. This enables usage of more address ranges for one client when the others are not being traced, or monitoring a certain range regardless of which client accesses the range.

The ETPU provides information to the NDEDI block when the access is actually being performed. The NDEDI does not have to track a bus protocol or check for error conditions on the accesses, since SPRAM does not generate errors. Any access signaled by the ETPU/NDEDI interface completes without error. Data trace flow is depicted in the following figure.

Figure 60-61. ETPU/CDC Data Trace Flow Diagram

60.7.8.2.1 Data Trace Windowing

Data trace windowing is provided so the development tool can decrease the auxiliary port usage by limiting the accesses that are traced.

Data trace windowing is achieved via the address range defined by the DTSA and the DTEA fields of the DTAR registers. These registers are shared by ENGINE1, ENGINE2, and the CDC. SPRAM accesses will be traced if their address fall in any of these ranges and the specific range is enabled in the data trace control register of the source making the access. Data read and/or data write trace may be enabled via the Read/Write Trace Control fields in the data trace control registers.

Data trace ranges are 32-bit aligned. This alignment is done by making the two least significant bits of the DTSA and DTEA fields read only. Since the two least significant bits of DTSA and DTEA are read only and default to different values, DTSA can never equal DTEA. The following figure shows the relationship between the DTSA and DTEA fields.

Programmed Value	Ranged Selected
DTSA<DTEA	DTSA → ← DTEA
DTSA>DTEA	All addresses are out of Range ¹
DTSA==DTEA	Impossible ²

Figure 60-62. Data Trace Address Range Options

60.7.8.2.2 Relative Addressing

The relative address feature is compliant with the IEEE-ISTO 5001-2002 standard recommendations and is designed to reduce the number of bits transmitted for addresses of data read and data write messages.

The address transmitted for a determined source is relative to the address of the previous data trace message sent for that source. It is generated by XORing the new address with the previous address and then using only the results up to the most significant '1' in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address. The following figure shows how a relative address is generated and how it can be used to recreate the original address.

Previous Address (A1) = 0xC10, New Address (A2) = 0xF64

Address Generation:

A1 = 1100 0001 0000
 A2 = 1111 0110 0100
 A1 ^ A2 = 0011 0111 0100

Address Message (M1) = 11 0111 0100

Address Recreation:

A1 ^ M1 = A2
 A1 = 1100 0001 0000
 M1 = 0011 0111 0100
 A1 ^ M1 = 1111 0110 0100 = A2

Figure 60-63. Relative Address Generation and Recreation1

60.7.8.3 Timing Diagrams

Note that all of the following timing diagrams assume a 3-bit SRC size and either a 4-bit MDO port or a 16-bit MDO port. The state variable is not a signal, but instead is derived from $\overline{\text{MSEO}}$. It is included for clarity. Refer to [Figure 60-23](#) for $\overline{\text{MSEO}}$ state diagram.

The following abbreviations are used for the state variable in the diagrams:

- ID = Idle
- SM = Start Message
- NT = Normal Transfer
- EP = End Packet
- EM = End Message

Figure 60-64. Data Write Message

Figure 60-65. Data Read Message

Figure 60-66. Data Write with Synchronization Message

Figure 60-67. Data Read with Synchronization Message

60.7.9 Watchpoint Trace

The NDEDI module provides ETPU watchpoint messaging via the auxiliary port, as defined by the IEEE-ISTO 5001-2002 standard.

60.7.9.1 Messaging

The NDEDI block provides watchpoint messaging using IEEE-ISTO 5001-2002 standard-defined public messages. When a watchpoint occurs, a watchpoint event is sent to the Event Queue. If the watchpoint condition occurs while the Event Queue is not enabled for storing snapshots, a watchpoint overrun message is generated.

The watchpoint message has the format shown in the following figure.

Figure 60-68. Watchpoint Hit Message Format

The values for the WPHIT packet are described in [Table 60-35](#) . Notice that WPHIT is never 0 because the message is only generated when a watchpoint has occurred.

Table 60-35. WPHIT Values

Value	Meaning
0b1xxxxxx	ETPU Watchpoint 1 (based on BWC1 register)
0bx1xxxxx	ETPU Watchpoint 2 (based on BWC2 register)
0bxx1xxxx	Channel Register Write Watchpoint
0bxxx1xxx	Host Service Request Watchpoint
0bxxxx1xx	Link Register Watchpoint
0bxxxxx1x	MRL Watchpoint
0bxxxxxx1	TDL Watchpoint

60.7.9.2 Error Messages

A watchpoint overrun error event is queued if an watchpoint event occurs and the Event Queue is not enabled for storing snapshots. This event is queued as soon as the Event Queue gets empty.

The error message has the format shown in the following figure.

Figure 60-69. Watchpoint Overrun Error Message Format

60.7.9.3 Synchronization

Upon the occurrence of a watchpoint, the next program and data trace messages are synchronization messages. A watchpoint in one of the Engines causes data and program synchronization for that Engine only.

60.7.9.4 Timing Diagrams

Note that all of the following timing diagrams assume a 3-bit SRC size and a 16-bit MDO port. The state variable is not a signal, but instead is derived from $\overline{\text{MSEO}}$. It is included for clarity. Refer to [Figure 60-23](#) for $\overline{\text{MSEO}}$ state diagram.

The following abbreviations are used for the state variable in the diagrams:

- ID = Idle
- SM = Start Message
- NT = Normal Transfer
- EP = End Packet
- EM = End Message

Figure 60-70. Watchpoint Message

Figure 60-71. Watchpoint Overrun Error Message

60.7.10 ETPU Message Queue

The NDEDI implements an external Q_SIZE location Queue that is shared by data trace, ownership trace, program trace, watchpoint, error and debug status events.

One single microcycle may generate a combination of data trace, ownership trace, program trace, watchpoint, error and debug status events. The data trace events related to one engine have different timing though, being generated at the system clock subsequent to the other events. Thus, since the ENGINE1 and ENGINE2 alternate instructions, a snapshot may contain data trace information regarding to one engine and other events information related to the other engine.

With the occurrence of one or more events at one specific cycle, a snapshot of the signals, that can give information about all events, is queued in only one location of the Queue. The information of the source which have generated the events is also queued at the same position, so the Message Formatter can reconstruct the messages of the occurred events. [Figure 60-72](#) shows the Event Queue Block Diagram.

The Queue operation is transparent to the user.

The Event Queue is read whenever there is at least one position of the FIFO occupied and there are no concurrent writes to the Queue. Thus, the appropriate message is formatted and a request to send the message is sent to the Nexus Port Controller (NPC). The request will be assigned a level based on the number of used positions in the Queue as shown in the following table.

Table 60-36. MDO Request Level

Level	Used positions (q) as a fraction of the Queue size
0	$q = 0$
1	$1 \leq q < 0.5$
2	$0.5 \leq q < 0.75$
3	$0.75 \leq q^1$

1. The MDO request will also be 3 whenever the Queue is disabled for storing new snapshots due to an overrun.

According to the request priority of the NDEDI and the other Nexus Blocks within the chip, the NPC will grant the Auxiliary port to the NDEDI, and as soon as the auxiliary port is granted, the NDEDI will send the message. If there are other pending messages in the same snapshot, a new request is sent and a new grant is expected from the NPC. The next snapshot is only read when there are no pending messages to be sent in the current snapshot and there are no concurrent write accesses to the Queue.

If more than one message event are to be sent, the Message Formatter sends first the Messages related to Debug Status, then the Messages related to Watchpoints, then the messages related to Program Trace and latest the Data Trace Messages.

If the Q_SIZE position of the Queue is full and an event occurs, the Event Queue is disabled for storing any information. The MDO request level will be 3 until the last snapshot is sent. When the Queue gets empty, an Error event is queued containing information of all lost events. At this point, snapshots may be queued again.¹⁶

NDEDI keep temporal ordering of messages relative to ENGINE1, ENGINE2 and CDC, but not relative to messages generated by other clients sharing the auxiliary port.

Figure 60-72. Event Queue

60.7.10.1 Queue Control

The queue is able to perform a single read or write operation per system clock. Thus, since there are no buffers to neither traces nor watchpoint events, the Message Formatter can only read the Event Queue if no events happen at the same time.

60.7.10.2 Error Messages

A trace or watchpoint overrun error occurs when an event cannot be queued. The error code (ECODE) within the error message indicates what type of trace overrun has occurred and that messages might have been lost for any or all of these events. [Table 60-25](#) shows the error code encodings for the various overrun error conditions.

16. If ENGINE_x is in stall condition, and an error happens, the ENGINE_x operation will only be resumed after the Queue is empty.

When information is lost, the Event Queue is disabled and no events are queued until the Event Queue gets empty. After the Event Queue gets empty an error message is queued indicating which information was lost for each source. At this point the Queue is enabled for storing snapshots again.

If multiple sources lose information at the same time multiple error messages are sent. In this case, the message related to the Engine 1 will be sent first, then the message related to the Engine 2 and finally the Error message related to the CDC.

The error message has the format shown in the following figure.

Figure 60-73. Error Message Format

60.7.10.3 Timing Diagrams

Note that the following timing diagram assumes a 3-bit SRC size and a 16-bit MDO port. The state variable is not a signal, but instead is derived from $\overline{\text{MSEO}}$. It is included for clarity. Refer to [Figure 60-23](#) for $\overline{\text{MSEO}}$ state diagram.

The following abbreviations are the values for the state variable in the diagram:

- ID = Idle
- SM = Start Message
- NT = Normal Transfer
- EP = End Packet
- EM = End Message

Figure 60-74. Error Messages (Program/Data/Ownership Trace Overrun)

Notice that three overrun messages are transmitted in the preceding figure. The first is an overrun indication for ENGINE1, the second is an overrun indication for ENGINE2, and the third is an overrun indication for the CDC.

60.8 Initialization/Application Information

The following section describes the Initialization/Application Information process.

60.8.1 Accessing NDEDI tool-mapped registers

To initialize the JTAG port for register accesses, the following sequence is required:

1. Enable the Nexus TAP controller
2. Retrieve Device ID if needed
3. Load the Nexus TAP controller with the NEXUS-ENABLE instruction

To write control data to NDEDI tool-mapped registers, the following sequence is required:

1. Write to the client select control register, if needed
2. Write the 7-bit register index and set the write bit to select register with a pass through the SELECT-DR-SCAN path in the JTAG state machine
3. Write the register value with a pass through the SELECT-DR-SCAN path. Notice that the prior value of this register is shifted out during the write

To read status and control data from NDEDI tool-mapped registers, the following sequence is required:

1. Write to the client select control register if needed
2. Write the 7-bit register index and clear write bit to select register with a pass through SELECT-DR-SCAN path
3. Read the register value with a pass through the SELECT-DR-SCAN path. Data shifted in is ignored

See [IEEE 1149.1 \(JTAG\) Input Port](#) for more detail.

60.8.2 Program Trace Reconstruction

This section details the program trace reconstruction mechanism supported by Nexus3 for the NDEDI. Program trace is implemented via Branch Trace Messaging (BTM) as per the Class 3 IEEE-ISTO 5001-2002 standard.

60.8.2.1 Branch Trace Messages

Branch Trace Messaging allows program trace by providing the following types of information:

- Messaging for start of program trace
 - Channel Start Message (CSM)
 - Channel Trace Enable Message (CTM)
- Branches with run-time target address (indirect branches)
 - Indirect Branch with History Message (IHM)
 - Indirect Branch with History and Synchronization Message (IHS)
- Discontinuity Information:
 - History including information of predicated instruction execution and information of all branches taken or not taken with compile-time target address. (direct branches)
 - Information of the amount of sequential instructions executed since the last branch. (ICNT)
 - Channel Start Message (CSM)
 - Indirect Branch with History and Synchronization Message (IHS)
 - Resource Full Message (RFM)
 - Program Correlation Message (PCM)
- Information of Program Trace End
 - Channel Start Message (CSM)
 - Program Correlation Message (PCM)
- Program trace overrun

- An Error Message will be issued if program trace information is lost due to FIFO overrun. The following error codes indicates program trace error: ECODE = 0b00001, 0b00111, 0b01000, 0b11001 and 0b11010

60.8.2.2 Assembly Code

The assembly code is necessary for gathering information about the direct branches location, target addresses for direct branches, predicated instructions location and "non-flush" indication.

The following eTPU instruction formats¹⁷ can generate direct branches:

E1, E2, E3 and E4

The following eTPU instruction formats can be predicated:

A3, B4, B5 and B6 but only if AS/CE differs 0, 1 and 7.

The following eTPU instruction formats can be indirect branches:

A1 with RTN = 1, D1, D2, D3 and D4

The Branch instructions have the capability of executing one instruction before changing the flow to the target address. The instruction being executed before the change of flow is hereafter called "non flushed" instruction.

The following eTPU instruction formats can lead to "non flushed" instructions:

D1, D2, D3, D4, E1, E2, E3 and E4 if FLS = 1

The other formats will lead to sequential instructions.

60.8.2.3 Branch Indication

The branch indication within the eTPU/NDEDI system happens at the instruction execution instead of the branch target execution. Thus it is important to notice that the "non flushed" instruction will be stored in the subsequent HIST/ICNT information. It is also important to notice that a CTM message is not issued if program trace is enabled in a "non flushed" instruction. In this case a CTM will be issued in the subsequent instruction.

17. Please refer to the ETPU Block Guide for further information about the instructions format.

60.8.2.4 Code Reconstruction

The CSM and CTM messages indicate the starting program trace address. Thus, these messages must be used as a starting point in order to synchronize the reconstruction program with the Assembly code.

From the starting point, the program flow can be completely reconstructed unless an Error message is issued. If an Error message is issued, watchpoints must be used to enable/disable program trace reducing the number of program trace messages.

60.8.2.5 Program Reconstruction Examples

Follows a code example where the reconstruction can be performed with the generated messages.

The program reconstruction will be performed by using the following two components:

- A copy of the program. Ideally this would be a listing file from the assembler;
- The program trace messages sent to the development tool;

60.8.2.5.1 Example 1

Follows the Example Code file:

```
234 FFFFFFFF format:F1.
235 010F64D1 format:A2 t2abd:"RAR", imm:578.
236 F7E846FF format:E4 j/c:"jump",bcc:"false",fls:"no_flush",bcf:"true",
    baf:567.
237 8AD4A218 format:B1 shf:"ror",cin:"no_carry",binv:"inv",t2abd:"P[31:24]",
    rw:"write",t4abs:"TRR",t4bbs:"BS=0,1st_2nd",src:">>1",p/d:"P",
    ccs:"flag_size",end:"yes",aid:24.
```

Follows the messages generated for a certain run example:

1. CSM (s=0x3) [S-CHAN=0x1e] [I-CNT=0x0000] [faddr=0x0234] [HIST=0x00000001];
2. PCM (s=0x3) [event=0x0] [I-CNT=0x01] [HIST=0x00000001];
3. CTM (s=0x3) [S-CHAN=0x001e] [faddr=0x0235] [CHAN=0x00000000];
4. PCM (s=0x3) [event=0x0] [I-CNT=0x00] [HIST=0x00000002];
5. CTM (s=0x3) [S-CHAN=0x001e] [faddr=0x0237] [CHAN=0x00000000];
6. CSM (s=0x3) [S-CHAN=0x11] [I-CNT=0x0001] [faddr=0x0443] [HIST=0x00000001];

Reconstruction:

The reconstruction starts with CSM pointing to the 0x0234 address. Note that ICNT = 0x0 and HIST = 0x1 indicating that there was no previous thread being executed.

PCM with event = 0x0 indicates that eTPU entered in debug mode. ICNT = 0x01 and HIST = 0x1 means that there were no direct branches and only one sequential instruction. Thus, instruction at address 0x0234 was executed and then eTPU entered in debug mode.

The third message is CTM which indicates that Program Trace was enabled again (eTPU exited debug mode) at address 0x0235. Then, another PCM with event = 0x0 was issued indicating entry in debug mode. From the code it is possible to inquire that instruction at address 0x0235 is a sequential instruction and the instruction at address 0x0236 is a conditional jump with "no flush".

HIST = 0b10 indicates that the first branch after address 0x0235 was reached but not taken. ICNT = 0x0 indicates that no sequential instruction after the last branch was executed, thus, it is possible to conclude that the code entered in debug mode just after executing the instruction at address 0x0236.

The fifth message is CTM which indicates a new Program Trace enable at address 0x0237.

The next message refers to CSM, and it indicates that a new thread is starting at address 0x0443. HIST=0b1 and ICNT=0b1 refers to the old thread and states that one sequential instruction (at address 0x0237) was executed before starting the new thread. This is the expected behavior since the address 0x0237 contains a "end=yes" command.

60.8.2.5.2 Example 2

Follows the Example Code file:

```
336 CB5CE283 3083 format:D1 mrle:"match_off",psc:"high",fls:"flush",rw:"write",
    pscs:"opac2",flc:"flags=P[25:24]",circ:"nop",
    r/d:"dispatch_call",p/d:"P",rsiz:"24",aid:131,
    end:"no".
...
41B 00AF6531 3962 format:A2 t2abd:"RAR", imm:1065.
41C F32083BF 3965 format:E4 j/c:"jump",bcc:"LSR",fls:"no_flush",bcf:"false",
    baf:1053.
41D 11092F98 3968 format:A1 t2d:"DIOB",rtn:"nop",IMM:9608768.
41E 004F7757 3971 format:B3 shf:"<<1",cin:"use_carry",binv:"inv",t4bbs:"SR",rw:"read",
    t4abs:"AS[23:0]=0",t2abd:"MACH",src:">>1",p/d:"DIOB",
    ccs:"no_flags",zro:"clear",end:"yes",
    stc:"no_inc/dec".
```

Follows the messages generated for a certain run example:

1. CSM (s=0x3) [S-CHAN=0x0f] [I-CNT=0x0001] [faddr=0x0336]
[HIST=0x0000000a];

2. IHM (s=0x3) [I-CNT=0x00] [uaddr=0x072d] [HIST=0x00000001];
3. CSM (s=0x3) [S-CHAN=0x14] [I-CNT=0x0003] [faddr=0x0345]
[HIST=0x00000003];

Reconstruction:

The first CSM indicates that the thread will be started at the address 0x0336. The next message is an IHM with I-CNT = 0x0 and HIST = 0x1 indicating that no instructions were executed until the indirect branch. The message indicates u-addr = 0x072d, thus the target address of this instruction is 0x041b (0x0336 XOR 0x072d). Note that since the instruction at 0x0336 is a flush instruction, then the instruction at 0x0337 is not supposed to be executed.

The next message refers to CSM, and it indicates that a new thread is starting at address 0x0345. Since HIST = 0x3, either the next branch (after address 0x041b) was taken or the next predicated instruction (after address 0x041b) was executed. From address 0x041b the next branch instruction is located at 0x041c address, thus all instructions were executed until this address.

The instruction within the address 0x041c refers to a branch with no_flush instruction to address 0x041d.

Since I-CNT = 0x3, it is expected that 3 sequential instructions are executed after the branch instruction.

The instruction within 0x041d will be executed since it is a non-flushed instruction, then it will be executed again since 0x041d is the target for the branch instruction executed before, and finally the instruction within the address 0x041e is executed. Note that the instruction within 0x041e contains a "end=yes" command which will finish the current thread.

60.8.3 Microcode Development Support

The following sections describe the steps required to perform various class 1 features with the NDEDI block.

60.8.3.1 Read and Write SPRAM In Debug Mode

Reading and writing to the SPRAM is done through Nexus read/write access hardware external to the NDEDI block. Refer to the MCUs SoC Guide for details. SPRAM reads and writes are done the same in debug mode as they are in run mode.

60.8.3.2 Read and Write ETPU Internal Registers in Debug Mode

1. Select an area of the SPRAM to be used for dumping the register values
2. Read the current value of those SPRAM locations and store them
3. Write to the SPRAM as needed for writing internal ETPU registers
4. Execute external microcode that reads values from the SPRAM location and writes the values to registers or reads registers and writes the values to the SPRAM. See [Execute Forced Microcode Instruction in Debug Mode](#) for more details
5. Read the SPRAM as needed to retrieve register read values
6. Write the SPRAM back to the original values

60.8.3.3 Enter Debug Mode at the Negation of Reset

If the DBE field of the ETPU's Development Control register is asserted, NDEDI ETPU will enter debug mode as soon as the system reset is negated. Configure other bits as appropriate.

60.8.3.4 Enter Debug Mode During Normal Execution

To enter debug mode during normal execution, write the ETPU's Development Control register to set the DBE and DBR bits. Configure other bits as appropriate.

60.8.3.5 Stop Program Execution on a Breakpoint

There are four possibilities to stop the program execution on a Breakpoint:

1. Program execution halts at the end of the current microcycle when a synchronous breakpoint condition is reached. A synchronous breakpoint condition occurs due to the following breakpoints:
 - Breakpoint due to DBR assertion
 - Twin Engine breakpoint¹⁸

18. Depending on CBT value

- External breakpoint¹⁹
 - Breakpoint due to exit of system reset
 - breakpoint due to start of a channel service
 - Single Step breakpoint
 - breakpoint due to EVTI assertion
 - breakpoint due to MISC miscompare
2. Program execution stops at the beginning of the current microcycle when an asynchronous breakpoint condition is reached. An asynchronous condition occurs due to the following breakpoints:
 - breakpoint due to SPRAM access
 - breakpoint due to Illegal instruction
 - breakpoint due to CHAN register write
 3. Program execution stops at the end of the current thread if a twin breakpoint or an external source requests to enter in debug mode and the NDEDI is programmed to enter in debug mode only at the end of the current thread
 4. Whenever fetching an instruction, if the microprogram counter matches the BWA related to one of the breakpoint conditions programmed for breaking into an instruction fetch, the instruction is tagged indicating that it must not be executed. The microengine halts just before the execution of this instruction if it was supposed to be executed²⁰.

See [Set Breakpoint or Watchpoints](#) and [Register descriptions](#) for details on configuring breakpoints.

60.8.3.5.1 Multiple breakpoint conditions at the same address

The ETPU block must always execute the first instruction after exiting debug mode.

Assume that an engine is halted due to a synchronous breakpoint at a given address. As soon as the engine exits debug mode, the instruction at the given address will be executed anyway, even if other breakpoint conditions are matched, for instance tagged instructions or asynchronous breakpoints.

19. Depending on CBT value

20. Instructions flushed after a JUMP are not considered to be executed

Although the DS register doesn't signalize the other breakpoint conditions, the development tool can infer from the NDEDI registers and pre-loaded code if the engine is halted in one of these conditions.

60.8.3.6 Single Step Instructions and Re-Enter Debug Mode

To single step an instruction from shared code memory in debug mode, write to the Engine's Development Control register so the CBR bit is asserted, the DBR bit is cleared and the SS bit is asserted. Single stepping causes the Engine to exit debug mode for a microcycle where the TCRs, decrementors, and microprogram counter can update. Program Trace messages are generated within Single Step operation.

60.8.3.7 Set Breakpoint or Watchpoints

There are two main ETPU breakpoint/watchpoint sources that are independent of each other but have identical configuration registers. Each can be configured as either a breakpoint or watchpoint that detects reads and/or writes, compares data and/or address. Each can be configured to occur only on certain Channel services.

In addition, there is a breakpoint/watchpoint that can be configured to occur when the CHAN register is written to a certain value.

There are also four channel service breakpoint/watchpoints that can be configured to occur when a specific channel is serviced for one of the following reasons: host service request, link request, match detect, and transition detect.

Breakpoints cause the Engine to halt. Watchpoints cause a watchpoint hit message. All breakpoint/watchpoint sources can be configured to assert EVTO on an breakpoint/watchpoint occurrence.

Refer to [Register descriptions](#) for detailed descriptions of breakpoint/watchpoint registers.

60.8.3.8 Execute Forced Microcode Instruction in Debug Mode

To execute a forced instruction in debug mode, write the instruction into the Microinstruction debug register. This mechanism does not cause the Engine to exit debug mode so the microprogram counter is not updated (unless a branch instruction is executed) and the TCRs and decrementors are not updated if the CLKS bit is asserted in the Development Control Register. Executing instructions in this manner is useful for reading and writing internal Engine registers.

Chapter 61

Development Trigger Semaphore (DTS)

61.1 Introduction

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways this module can be used, including as a component of an external real-time data acquisition system.

Note

When used as a component of a triggered data acquisition system, Nexus read/write access is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2012 Nexus standards, which use the Nexus Auxiliary port.

61.2 Overview

The Development Trigger Semaphore (DTS) module consists of registers and a small amount of combinational logic to generate an output signal—DTS Trigger Output (DTO). The registers are as follows:

- **DTS_SEMAPHORE** register—Any bit in this 32-bit register, when set to a value of logic '1', causes the DTS module output signal to be asserted if the corresponding **DTS_EN** bit is set in the **DTS_ENABLE** register. This enables an external tool to detect up to 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access.

- **DTS_SEMAPHORE_B** register—Any bit in this 32-bit register, when set to a value of logic '1', causes the DTS module output signal to be asserted if the corresponding **DTS_EN_B** bit is set in the **DTS_ENABLE** register. This enables an external tool to detect an additional 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access.
- **DTS_STARTUP** register—This register provides a mechanism for the external tool to notify software running on the CPU that the tool is connected and can provide information about either the type of tool or options that can be used by the software.
- **DTS_ENABLE** register—This register provides an enable/disable capability for the DTS feature.

The architecture is shown in the following figure.

Figure 61-1. DTS block diagram

The DTS Trigger Output (DTO) signal is connected to one of the EVTO inputs of the Nexus Port Controller (NPC). The other EVTO inputs are connected to the other Nexus modules in the device. DTO is asserted when any bit in a semaphore register is set and the DTS function of that register is enabled.

Note

When the DTS module is enabled ($\text{DTS\_ENABLE}[\text{DTS\_EN}] = 0b1$ or $\text{DTS\_ENABLE}[\text{DTS\_EN\_B}] = 0b1$), all other Nexus EVTO functions associated should be disabled by the tool and

EVTO becomes the DTO. Unlike the EVTO function that only asserts for one clock, the DTO function remains asserted until the tool reads the semaphore register that is the source of the assertion, clearing the register's contents.

The following figure shows an example of the chain of events that begins with setting of a bit in the DTS_SEMAPHORE register and the clearing of the register caused by a Nexus read.

Figure 61-2. DTO event sequence example

61.3 DTS device connections

The following figure shows the DTS device connections. The DTS module connects to the Peripheral Bridge (PBRIDGE) for access to the registers. The PBRIDGE is connected to the device modules through a slave port of the Crossbar bus interface (XBAR).

Figure 61-3. DTS device connections

The registers have limited access as described in [DTS register access](#). Access is based on the XBAR Master ID of the accessing module. Writing to the semaphore registers is limited to the cores and the eDMA module and is restricted to only setting bits. Only an access via a Nexus Read/Write Access from an external tool can clear bits in the semaphore registers (semaphore register bits are cleared automatically when read). Similarly, the DTS_ENABLE and DTS_STARTUP registers can only be written via a Nexus Read/Write Access.

Note

Nexus Read/Write Accesses use the core load/store bus to perform accesses, but Nexus accesses have a different Master ID than normal core load/stores.

61.3.1 DTS register access

A summary of accesses to all DTS registers by bus masters is provided in the following table. Only proper 32-bit accesses are valid. The effects of write accesses that are not 32 bits are not defined.

Table 61-1. DTS register access effects

Register	32-bit read				32-bit write			
	RWA ¹	Core	eDMA	Other crossbar masters	RWA ¹	Core	eDMA	Other crossbar masters
DTS_ENABLE	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_STARTUP	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_SEMAPHORE	Data and Clear ²	Data	Data	Data	No effect	Bit OR	Bit OR	No effect
DTS_SEMAPHORE_B	Data and Clear ²	Data	Data	Data	No effect	Bit OR	Bit OR	No effect

1. Nexus Read/Write access via an external tool

2. A read of the semaphore registers by Nexus Read/Write Access module is destructive and clears all bits in the register

Access to DTS module registers is controlled based on the XBAR Master ID of the accessing module.

Note

The XBAR Master ID should not be confused with the Master Port number of the XBAR. See the Crossbar Switch (XBAR) chapter for details.

Tools must access the DTS registers through the Nexus Read/Write Access mechanism of a core. External tool accesses through either core appear as if the access is via the core and therefore do not have the same level of access as a Nexus Read/Write Access.

61.4 Memory mapped registers

Only certain types of accesses are allowed to the DTS registers. See the description for each register to determine the accesses that are allowed.

DTS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Output Enable Register (DTS_ENABLE)	32	R/W	0000_0000h	61.4.1/3057
4	Startup Register (DTS_STARTUP)	32	R/W	0000_0000h	61.4.2/3058
8	Semaphore Register (DTS_SEMAPHORE)	32	R/W	FFFF_FFFFh	61.4.3/3059
C	Semaphore Extension (DTS_SEMAPHORE_B)	32	R/W	FFFF_FFFFh	61.4.4/3060

61.4.1 Output Enable Register (DTS_ENABLE)

The DTS_ENABLE register controls the DTS Trigger Output ($\overline{D\overline{T}O}$) and whether $\overline{D\overline{T}O}$ is active on the $\overline{E\overline{V}T\overline{O}}$ output pin of the device. The DTS_ENABLE register can be read by the core, but can only be written by a Nexus Read Write Access (RWA).

NOTE

Access to the DTS_SEMAPHORE, DTS_SEMAPHORE_B, and DTS_STARTUP registers are unaffected by the state of this register.

Address: 0h base + 0h offset = 0h

DTS_ENABLE field descriptions

Field	Description
0–29 Reserved	This field is reserved.
30 DTS_EN_B	DTS Enable B. Controls whether the $\overline{D}\overline{T}\overline{O}$ signal is routed to the $\overline{E}\overline{V}\overline{T}\overline{O}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{R}\overline{E}\overline{S}\overline{E}\overline{T}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE_B register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE_B register asserts the DTS trigger output signal ($\overline{D}\overline{T}\overline{O}$).
31 DTS_EN	DTS Enable. Controls whether the $\overline{D}\overline{T}\overline{O}$ signal is routed to the $\overline{E}\overline{V}\overline{T}\overline{O}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{R}\overline{E}\overline{S}\overline{E}\overline{T}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE register asserts the DTS trigger output signal ($\overline{D}\overline{T}\overline{O}$).

61.4.2 Startup Register (DTS_STARTUP)

The DTS_STARTUP register is used for tool detection and startup information exchange between external data acquisition tool and the embedded controller. DTS_STARTUP register can be read by the core, the eDMA module and Nexus but can only be updated by a Nexus Read Write Access (RWA).

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DTS_STARTUP field descriptions

Field	Description
0–31 AD	Application Dependent register bits. The bits have no defined meaning to the microcontroller. They are used to by an external tool to pass information (for example, application options and status) to application

DTS_STARTUP field descriptions (continued)

Field	Description
	software running on target microcontroller at startup time. Use a Nexus RWA 32-bit write access to update the contents of this register. A device reset (either from the $\overline{\text{RESET}}$ pin or an internally generated reset) clears all bits in the register. A Nexus reset does not change the contents of the register.

61.4.3 Semaphore Register (DTS_SEMAPHORE)

The DTS_SEMAPHORE register is used by software to assert the $\overline{\text{DTO}}$ signal on the device $\overline{\text{EVTO}}$ pin. A one in any bit of this register causes the $\overline{\text{DTO}}$ signal on the $\overline{\text{EVTO}}$ pin to be driven low. The intended use of this register is for the $\overline{\text{DTO}}$ signal to notify tools that data is available. Individual bits are used to identify the specific data.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DTS_SEMAPHORE field descriptions

Field	Description
0–31 ST	Semaphore Trigger. When a core or eDMA writes a logical '1' to a bit, the bit is set. A write of '0' by the core or DMA does not change the state of the bit. - All register bits are set to '1' by a device reset. - A Nexus reset does not change the state of this register. - The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA. - For the core or DMA, only 32-bit write or read accesses are valid. - A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

61.4.4 Semaphore Extension (DTS_SEMAPHORE_B)

The DTS_SEMAPHORE_B register is used by software to assert the $\overline{DTO}$ signal on the device $\overline{EVTO}$ pin. A one in any bit of this register causes the $\overline{DTO}$ signal on the $\overline{EVTO}$ pin to be driven low. The intended use of this register is for the $\overline{DTO}$ signal to notify tools that data is available. Individual bits are used to identify the specific data.

Address: 0h base + Ch offset = Ch

DTS_SEMAPHORE_B field descriptions

Field	Description
0–31 ST_B	Semaphore Trigger Extension. When a core or eDMA writes a logical '1' to a bit, the bit is set. A write of '0' by the core or DMA does not change the state of the bit. • All register bits are set to '1' by a device reset. • A Nexus reset does not change the state of this register. • The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA. • For the core or DMA, only 32-bit write or read accesses are valid. • A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

61.5 Example application

The calibration process of a new engine requires real-time access to calibration tables and the ability to update the tables in real-time The DTS module enables this capability by enabling software to assert a signal to an external device pin to notify an external tool that data is available. The tool can then retrieve the data.

In this type of application the DTS_SEMAPHORE register and DTS Trigger Output (DTO) signal provide a mechanism to notify the calibration tool that the calibration variable or variables (or sets of measurements), up to 32, have been updated with new values and are available for the tool to access.

Note

It is the user's responsibility to ensure that the tool has time to retrieve the data prior to that particular trigger being set a second time. It is also permissible to have multiple triggers active at the same time or for a second trigger to be set before a previous trigger has been serviced, as long as it is not the same trigger (unless it is acceptable to the tool to not receive every data set).

The following table shows an example DTS startup sequence for an external real-time data acquisition system. The startup and synchronization sequence can be as simple or as complicated as the need requires. However, a typical startup sequence is as follows:

1. The DTS_STARTUP register is cleared by a power on reset or any CPU reset.
2. The tool writes a non-zero value to the DTS_STARTUP register.
3. The CPU (user application software) then reads the value of the DTS_STARTUP register. Based on this value, different initialization options can be selected. The bits can be used for any application specific definitions.
4. Since the DTS_SEMAPHORE register is cleared when the tool reads the current value. The tool should perform all necessary initialization before reading this register. The application software can then check that the DTS_SEMAPHORE register was cleared by the tool, to determine that it is safe to start using it for its intended raster trigger semaphore function.
5. An optional hand shake from the CPU can be used to inform the tool that the user software has detected that the tool is attached and the CPU has performed the proper initialization for the tool by writing a predefined value to the DTS_SEMAPHORE register (the example shown in the figure above uses 0xAAAA_AAAA—all A's was used since it is unrealistic that 16 channels could be enabled very quickly after start up after a reset).

Figure 61-8. DTS startup sequence example

Chapter 62

Fault Collection and Control Unit (FCCU)

62.1 Chip-specific FCCU information

The FCCU on this chip supports 46 non-critical faults (NCFs).

62.1.1 FCCU register default values

The following table documents FCCU register default values that are specific to this chip. For the default values of all other FCCU registers, see [Register descriptions](#).

Table 62-1. FCCU register default values

Register	Default value
FCCU_CFG	0000_0000h ¹
FCCU_NCF_CFG0	FFFF_FFFFh
FCCU_NCF_CFG1	0000_FFFFh
FCCU_NCFS_CFG0	2200_2000h
FCCU_NCFS_CFG1	0000_0000h
FCCU_NCFS_CFG2	0000_0000h
FCCU_NCF_E0	0000_5040h
FCCU_NCF_E1	0000_0000h
FCCU_NCF_TOE0	0000_0000h
FCCU_NCF_TOE1	0000_0000h
FCCU_NCF_TO	0000_FFFFh
FCCU_CFG_TO	0000_0006h

1. FCCU_CFG resets to 0000_0000h after the chip resets the FCCU. After a Configuration-state timeout, the value of FCCU_CFG is 0000_0008h. For details, including the value of FCCU_CFG after an OP31 operation, see [FCCU_CFG register event bit values by source \(N and C\)](#).

62.1.2 FOSU_COUNT value

The FCCU Output Supervision Unit (FOSU) has a timer whose duration is the value FOSU_COUNT. On this chip, the value is 8000 IRCOSC clock cycles.

62.1.3 FCCU fault inputs

The following table identifies the various fault input signals to the FCCU, how they can be tested, and the default reaction to each input after the FCCU itself is reset.

Table 62-2. FCCU non-critical fault (NCF) mapping

NCF	Fault	Fault description	Error reaction path check ¹	Default reaction after reset
0	TEMP_ERROR	Event indication from temperature sensor. The fault is cleared by clearing the status in PMC_ESR_TD, followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST + TSNS_FAULT bit of Temperature Sensor Fault Injection Register (PMC_TS_FIR)	No reaction
1	LVD_ERROR	Voltage out of range indication from LVDs. The fault is cleared by clearing the status in PMC_LVD_HVD_EVENT_STATUS, followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LVD assertion test by tap point manipulation + LVD_FAULT bit of FCCU Fault Injection Register (PMC_FIR)	No reaction
2	HVD_ERROR	Voltage out of range indication from HVDs. The fault is cleared by clearing the status in PMC_LVD_HVD_EVENT_STATUS, followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	HVD assertion test by tap point manipulation + HVD_FAULT bit of FCCU Fault Injection Register (PMC_FIR)	No reaction
3	DPMC_SELF_TEST	Digital PMC initialization error during self test. The fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm]. The status gets cleared if the fault is not persistent.	LBIST+ STEST_FAULT bit of FCCU Fault Injection Register (PMC_FIR)	No reaction
4	MEMORY_DCF_SAFETY_ERR	Indication of fault during timing/repair configuration initialization by SSCM of different memories. Faults can be caused by parity or triple-redundant errors in loaded configuration data. The status is cleared by clearing SSCM_STATUS[CERS], followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm]. The status gets cleared if the fault is not persistent. Additionally, this error will cause a MBIST failure. This channel bit is cleared in case of reset.	LBIST	No reaction

Table continues on the next page...

Table 62-2. FCCU non-critical fault (NCF) mapping (continued)

NCF	Fault	Fault description	Error reaction path check ¹	Default reaction after reset
5	SSCM_XFER_ERR	SSCM transfer or parity error during DCF loading (trimming, STCU, and UTEST Miscellaneous ²). This fault is also asserted when there is a flash memory ECC double bit detection during flash memory reset reads or coherency checks done on the flash memory test row reads. The fault is cleared by clearing SSCM_STATUS[CER], followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm]. This channel bit is cleared in case of reset.	Not testable (but wrong configuration can trigger other detection)	No reaction
6	STCU_UF	STCU unrecoverable error during self-test. Fault is cleared by clearing STCU2_ERR_STAT[UFSF] followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	SW check of BIST MISR or Feedback loop via FCCU Fake bit	Reset
7	STCU_RF	STCU recoverable error during self-test. Fault is cleared by clearing STCU2_ERR_STAT[RFSF] followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	SW check of BIST MISR or Feedback loop via FCCU Fake bit	No reaction
8	STCU_LMBIST_USR_ERR	Activation of LBIST or MBIST control during application mode. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm]. The status will clear if the fault is not persistent.	Feedback loop via FCCU Fake bit.	No reaction
9	SPURIOUS_DEBUG_SSCM_ACTIVATION	JTAG, NPC, or Debug functionality moved out of reset or SSCM activation during application mode. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST + Feedback loop via FCCU Fake bit	No reaction
10	RCCU_0	Safety cores out of sync during lockstep. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST + Feedback loop via FCCU Fake bit connected to additional RCCU input	No reaction
11	RCCU_1	Safety cores out of sync during lockstep. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST + Feedback loop via FCCU Fake bit connected to additional RCCU input	No reaction
12	WDRS_DBRC0	Core 0 Watchdog Timer reset status (TSR[WRS]) and Core 0 Debug Reset Control (DBCR0[RST]). The fault is cleared by clearing FCCU_NCF_Sn[NCFSm] after the status has been cleared in TSR[WRS].	LBIST + SW test by not triggering WD during startup	Reset
13	WDRS_DBRC1	Core 1 Watchdog Timer reset status (TSR[WRS]) and Core 1 Debug Reset Control (DBCR0[RST]). The fault is cleared by clearing FCCU_NCF_Sn[NCFSm] after the status has been cleared in TSR[WRS].	LBIST + SW test by not triggering WD during startup	No reaction
14	SWTRS0	Software Watchdog A reset. The fault is cleared by clearing FCCU_NCF_Sn[NCFSm] after the status has been cleared inside SWT_A.	LBIST + SW test by not triggering SWT during startup	Reset
15	SWTRS1	Software Watchdog B reset. The fault is cleared by clearing FCCU_NCF_Sn[NCFSm] after the status has been cleared inside SWT_B.	LBIST + SW test by not triggering SWT during startup	No reaction
16	SWTINT0	Software Watchdog A interrupt request. The fault is cleared by clearing FCCU_NCF_Sn[NCFSm] after the status has been cleared inside SWT_A.	LBIST + SW test by not triggering SWT during startup	No reaction

Table continues on the next page...

Table 62-2. FCCU non-critical fault (NCF) mapping (continued)

NCF	Fault	Fault description	Error reaction path check ¹	Default reaction after reset
17	FLASH_INIT ³	Flash memory initiation error. This fault is intended for debug purposes only because, if such an error occurs, no code will run from flash memory. It is expected that this fault is read through development tools.	LBIST	No reaction
18	SSCM_INIT	SSCM initiation error. DCFs might not have loaded properly.	LBIST	No reaction
19	PER_CE	Indication of correctable errors in eTPU, M_CAN, and FlexCAN RAM Controllers. The fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm]. For proper eTPU SCM and SDM monitoring, eTPU_MESR_MECR[MECIE] must be set to 1.	Error injection in eTPU, FlexCAN, M_CAN + LBIST + Feedback loop via FCCU Fake bit	No reaction
20	PER_UCE	Indication of uncorrectable errors in eTPU, M_CAN, and FlexCAN RAM Controllers. The fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm]. The eTPU combines uncorrectable errors and other sources in a single exception signal. The exact exception source must be determined with the help of the eTPU Global Exception.	Error injection in eTPU, FlexCAN, M_CAN + LBIST + Feedback loop via FCCU Fake bit	No reaction
21	FLS_CE	Indication of correctable errors in flash memory. The fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST	No reaction
22	FLS_UCE	Indication of uncorrectable errors in flash memory. The fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST	No reaction
23	PLL_0	PLL0 loss of lock. For this fault source to be asserted, the Loss of Lock Interrupt must be enabled by writing 1 to PLLDIG_PLL0CR[LOLIE]. Fault is cleared by clearing PLLDIG_PLL0SR[LOLF], followed by clearing FCCU_NCF_Sn[NCFSm]. NOTE: Always configure this fault to generate a reset instead of an interrupt.	LBIST + Forced loss by PLL reconfiguration	No reaction
24	PLL_1	PLL1 loss of lock. For this fault source to be asserted, the Loss of Lock Interrupt must be enabled by writing 1 to PLLDIG_PLL1CR[LOLIE]. Fault is cleared by clearing PLLDIG_PLL1SR[LOLF], followed by clearing FCCU_NCF_Sn[NCFSm]. NOTE: When PLL1 is used as a system clock: Configure this fault to generate a reset instead of an interrupt.	LBIST + Forced loss by PLL reconfiguration	No reaction
25	CMU_0_OSC	Loss of XOSC clock. The fault is cleared by clearing CMU_ISR[OLRI] of CMU_0, followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm]. NOTE: When XOSC is used as a system clock: Configure this fault to generate a reset instead of an interrupt.	LBIST	No reaction
26	CMU_0_PLL	Exception from monitor CMU_0 (PLL0). The fault is cleared by clearing CMU_ISR[FHHI], CMU_ISR[FLLI], or both of CMU_0, followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST + Test by misconfiguration	No reaction

Table continues on the next page...

Table 62-2. FCCU non-critical fault (NCF) mapping (continued)

NCF	Fault	Fault description	Error reaction path check ¹	Default reaction after reset
27	CMU_COMP	Exception from monitors CMU_1, CMU_2, and CMU_3. The fault is cleared by clearing CMU_ISR[FHHI], CMU_ISR[FLLI], or both of CMU_n, followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST + Test by misconfiguration	No reaction
28	CMU_OTHER	Exception from monitors CMU_4 to CMU_8. The fault is cleared by clearing CMU_ISR[FHHI], CMU_ISR[FLLI], or both of CMU_n, followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST + Test by misconfiguration	No reaction
29	EDC_ECC_FLASH	Indication of a hardware fault in the ECC of the flash memory resulting in corrupted ECC detection/correction. Fault is cleared by a dummy read of the flash memory followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST	No reaction
30	EDC_ECC_FLASH_C	Indication of hardware fault in the Flash Memory Controller resulting in corrupted ECC detection/correction. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST	No reaction
31	ENC_ERR_FLASH	Indication of hardware fault resulting in corrupted flash memory access. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST	No reaction
32	ADDR_FDBK_ERROR_FLASH_C	Indication of an addressing error in the Flash Memory Controller resulting in corrupted flash memory access. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST	No reaction
33	XBAR Transaction Monitor	Indication by the Crossbar Integrity Checker (XBIC) of a corrupted transaction in the crossbar. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST + proper configuration of XBIC Error Injection Register (XBIC_EIR)	No reaction
34	ADDR_FDBK_ERROR_PRAM + RAM_LWB_ERROR ⁴	Indication of an addressing error in system RAM or a write error in the RAM Controller resulting in corrupted RAM access. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST	No reaction
35	SSCM_PASS_ERROR	An ECC error occurred while SSCM or PASS was fetching data from flash memory.	LBIST	No reaction
36	EDC_ERROR_PRAM	Indication of a fault in the RMW logic of the system RAM resulting in an incorrect RMW access and a potentially corrupted RAM word. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST	No reaction
37	DFT1	Test circuitry Group 1 activation. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST	No reaction
38	DFT2	Test circuitry Group 2 activation. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST	No reaction
39	DFT3	Test circuitry Group 3 activation. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST	No reaction
40	DFT4	Test circuitry Group 4 activation. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST	No reaction

Table continues on the next page...

Table 62-2. FCCU non-critical fault (NCF) mapping (continued)

NCF	Fault	Fault description	Error reaction path check ¹	Default reaction after reset
41	Safety Core Machine Check Exception	Safety Core exception indication. The fault is cleared by clearing the status in MCSR register of the Safety core followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST + willfully cause an exception (for example, access a non-existing address)	No reaction
42	Lockstep mode	Indication of disabled Checker Core or RCCUs. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	LBIST	No reaction
43	ERROR_IN_ERR	Error input pin (external to the MCU) signaling an error condition. The fault is cleared by clearing the fault driving the pin followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	External activation of EIN. External entity must pull the error input low.	No reaction
44	Unused	—	—	—
45	ERM_CE	ERM module detected single ECC error. The fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	EIM + LBIST + Feedback loop via FCCU Fake bit	No reaction
46	ERM_UCE	ERM module detected multiple ECC error. The fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].	EIM + LBIST + Feedback loop via FCCU Fake bit	No reaction

1. All channels can use feedback loop via FCCU Fake bit.
2. TDM does not have parity error during DCF loading. For UTEST Miscellaneous, only the DCF clients for PMC Digital have parity detection.
3. This fault occurs after any flash memory programming. To avoid unexpected behavior, configure the reaction to this fault carefully if flash memory programming is executed.
4. Fault 34 might be asserted during MBIST and LBIST execution. Before running MBISTs, configure this channel to result in no reset reaction. If this channel becomes asserted during MBIST testing, simply clear the fault and take no further action.

62.1.4 Error signal flow diagram

* This condition must be satisfied only when FCCU is configured for Bistable fault-output mode (FCCU_CFG[FOM]).

Figure 62-1. Error signal flow

62.1.5 Restriction on configuring RESET and NMI reactions on same FCCU channel

Do not configure an FCCU channel to have both a RESET reaction (using the FCCU_NCFS_CFG n register) and an NMI reaction (using the FCCU_NMI_EN n register) at the same time. If the FCCU channel is serviced and the chip resets, the NMI interrupt address is undefined and halts the chip.

62.1.6 FCCU_CFG register event bit values by source (N and C)

For each bit in the [Configuration \(FCCU_CFG\)](#) register, this table specifies the values of N and C for this chip. For information on how to interpret and use these values, see [FCCU_CFG register bit value sources \(N and C\) by event](#).

62.2 Introduction

The Fault Collection and Control Unit (FCCU) offers a hardware channel to collect faults and to place the device into a safe state when a failure in the device is detected. No CPU intervention is requested for collection and control operation.

The FCCU offers a systematic approach to fault collection and control. The distinctive features of the module are:

- Redundant collection of hardware checker (for example, RCCU) results
- Redundant collection of fault information from safety relevant modules on the device
- Collection of test results
- Configurable fault control
- Configurable internal reactions for each NCF:
 - No reaction
 - IRQ
 - Functional reset
 - NMI
- External reactions via configurable output pins
- Watchdog timer for the reconfiguration phase
- Lockable configuration
- Nonvolatile memory interface (NVMCFG signals) for configuration loading
- One of the fault-output (EOUT) signals is high to indicate operational (OK) state (in bi-stable operation mode). The above is not true in case the error out protocol is configured to be a toggling protocol, for example, dual rail and time switching.

- After power on, the EOUT signals have high impedance.¹ They show operational state only after configuration by software.
- In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_{min} , even if SW tries to release it before (for the case of error pin configured in Bi-stable mode only).
- The overall fault detection, processing and indication time is less than 10 ms.
- The actual maximum time is 5 CLKSAFE cycles.

The FCCU circuitry is checked at the start-up by the self-checking procedure. The FCCU is operative with the default configuration immediately after the completion of the self-checking procedure. Internal (functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable. The default configuration can be modified only in the CONFIG state. FCCU is designed to function when CLKSYS is faster than the CLKSAFE clocks.

62.2.1 Acronyms and abbreviations

Term	Description
CF	Critical fault
CPU	Central processing unit
EOUT	Error out
FOSU	FCCU output supervision unit
FSM	Finite state machine
INTC	Interrupt controller
intf	Interface
IRQ	Interrupt request
NCF	Noncritical fault
NMI	Nonmaskable interrupt
NVM	Nonvolatile memory
RCC	Redundancy control checkers
RCCU	Redundancy control checker unit
SoC	System-on-chip
STCU	Self-test control unit
SW	Software

1. Actual value depends on device specific setting at pad level.

62.3 Main features

- Management of noncritical faults
- HW or SW fault recovery management
- Fault detection and collection
- Fault injection (fake faults)
- External reaction (fault state): EOUT signaling. Error indication via the pin(s) is controlled by the FCCU.
- Internal chip reactions (alarm state): interrupt request
- Internal chip reactions (fault state):
 - functional reset
 - NMI
- Bi-Stable, Dual-Rail and Time Switching output protocols on EOUT
- Internal (to the FCCU) watchdog timer for the reconfiguration phase
- Configuration lock
- Nonvolatile memory interface (NVMCFG signals) for configuration loading

62.4 Block diagram

The following figure is a top-level diagram of the FCCU module.

Figure 62-2. FCCU block diagram

This table describes the FCCU submodules.

Table 62-3. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers
HNSHK blocks (master and slave blocks)	Includes the FSM's ability to support the handshake between the REG interface and the FSM unit due to the usage of 2 asynchronous clocks (IPS system clock and RC oscillator clock)
FSM unit	Implements the main functions of the FCCU. The FSM also includes the: • Watchdog timer (WDG) • Alarm timer (ALRT)
FAULT intf	Implements the interface for the fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

62.5 Signal description

62.5.1 Signals

This table describes the signals on the boundary of FCCU.

Signal	Direction	Function	Active level	Clock
Clock and reset				
CLKSYS	Input	System Clock—Supplies the primary clock.	Rising edge	—
CLKSAFE0	Input	Safe Clock 0—Supplies one of two 16 MHz clocks for use by various redundant submodules. This clock and CLKSAFE1 are often referred to as the same clock (CLKSAFE).	Rising edge	—
CLKSAFE1	Input	Safe Clock 1—Supplies one of two 16 MHz clocks for use by various redundant submodules. This clock and CLKSAFE0 are often referred to as the same clock (CLKSAFE).	Rising edge	—
EOUT interface				
EIN[1:0]	Input	Error Input—Provide the mechanism for FCCU to capture the states that off-chip logic drives on the associated EOUT[1:0] signals. (On the chip, the EOUT signals are connected to their corresponding EIN signals.) FCCU captures the states in the EIN1 and EIN0 fields.	—	Asynchronous
EOUT[1:0]	Output	Error Output—Indicate FCCU's condition (Faulty, Nonfaulty, or Configuration) to off-chip logic.	Programmable	CLKSAFE0, CLKSAFE1
FOSU interface				

Table continues on the next page...

Signal description

Signal	Direction	Function	Active level	Clock
FIF	Output	FCCU In Fault—Indicates to the FOSU module, if present, that FCCU is recognizing a fault. FCCU asserts and then deasserts this signal in two cases: <i>Case 1</i> When the EOUT signals are programmed to be always low (FCCU_SET_CLEAR), FCCU asserts this signal until the EOUT signals are programmed not to be always low. <i>Case 2</i> When the EOUT signals are programmed not to be always low (FCCU_SET_CLEAR), FCCU asserts this signal when all of the following are true: - FCCU enters Fault state as the result of a fault. - If the fault is a noncritical fault, and the EOUT signals are in a fault-output mode (FOM) other than Bistable, the associated EOUTENx field is set to enabled. FCCU deasserts this signal when FCCU leaves Fault state.	High	CLKSAFE0, CLKSAFE1
Interrupt interface				
NMIOUT	Output	Nonmaskable Interrupt Output—Sends a nonmaskable interrupt request to the processor core or cores when FCCU enters Fault state as the result of a noncritical fault for which NMI is enabled as the reaction (FCCU_NMI_ENa[NMIENx]).	Low	CLKSYS
NVM interface				
NVMCFG[21:0]	Input	Nonvolatile Memory Configuration—Provide the values of certain bits in the Configuration (FCCU_CFG) register when certain events occur. See Configuration (FCCU_CFG). Some or all of these signals may be driven by bits in a data record in nonvolatile (flash) memory or may be tied high (1) or low (0). See FCCU_CFG register bit value sources (N and C) by event.	Static value	—

Table continues on the next page...

Signal	Direction	Function	Active level	Clock
SSCMDONE	Input	SSCM Done—After an FCCU reset, indicates that the SSCM module is now driving any NVMCFG signals that are associated with a data record stored in nonvolatile (flash) memory.	High	CLKSYS

62.6 Put FCCU in Configuration or Normal state

62.6.1 Introduction

You put FCCU in Configuration state to change its configuration. You put FCCU in Normal state to save changes to the configuration.

62.6.2 About changing states

When changing states, keep the following in mind:

- To put FCCU in Configuration state, FCCU must be in Normal state.
- After FCCU is reset, the configuration is temporarily locked. You must temporarily unlock the configuration before you can put FCCU in Configuration state.
- When FCCU is in Configuration state, FCCU doesn't actually save the changes you make to the configuration. To save changes to the configuration, you must manually put FCCU in Normal state. If FCCU automatically leaves Configuration state and enters Normal state because the configuration-timer interval (**TO**) expires (called a Configuration-state timeout), FCCU changes the value of the [Configuration \(FCCU_CFG\)](#) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration-state timeout value, see [FCCU_CFG register bit value sources \(N and C\) by event](#). For a list of configuration registers, see [Configuration registers](#).

62.6.3 Put FCCU in Configuration state

1. Temporarily unlock the configuration (see [Temporarily unlock the configuration](#)).
2. To determine FCCU's state, run the OP3 operation (see [Run an operation](#)).
3. Check the operation status (**OPS**).
 - If the operation status is Successful, go to step 4.
 - If the operation status is Aborted, go to step 2.

4. Check the FCCU status ([STATUS](#)).
 - If the FCCU status is Configuration, FCCU is in Configuration state. Stop.
 - If the FCCU status is Normal, go to step [5](#).
 - If the FCCU status is Alarm or Fault, go to step [7](#).
5. To put FCCU in Configuration state, run the OP1 operation (see [Run an operation](#)).
6. Check the operation status ([OPS](#)).
 - If the operation status is Successful, FCCU is in Configuration state. Stop.
 - If the operation status is Aborted, the configuration is probably permanently locked. Go to step [9](#).
7. Recover all faults.
8. Go to step [2](#).
9. Reset FCCU.

62.6.4 Put FCCU in Normal state

1. To determine FCCU's state, run the OP3 operation (see [Run an operation](#)).
2. Check the operation status ([OPS](#)).
 - If the operation status is Successful, go to step [3](#).
 - If the operation status is Aborted, go to step [1](#).
3. Check the FCCU status ([STATUS](#)).
 - If the FCCU status is Normal, FCCU is in Normal state. Go to step [8](#).
 - If the FCCU status is Configuration, go to step [4](#).
 - If the FCCU status is Alarm or Fault, go to step [6](#).
4. To put FCCU in Normal state, run the OP2 operation (see [Run an operation](#)).
5. Check the operation status ([OPS](#)).
 - If the operation status is Successful, FCCU is in Normal state. Go to step [8](#).
 - If the operation status is Aborted, go to step [4](#).
6. Recover all faults.
7. Go to step [1](#).
8. If you want to prevent changes to the configuration, lock it:
 - To require a key to unlock the configuration, temporarily lock the configuration (see [Temporarily lock the configuration](#)).
 - To require a reset of FCCU to unlock the configuration, permanently lock the configuration (see [Permanently lock the configuration](#)).

62.7 Run operations

62.7.1 Introduction

You run operations to perform actions such as putting FCCU in Configuration state or reading a timer. For a complete list of operations you can run, see [OPR](#).

62.7.2 About running operations

When running operations, keep the following in mind:

- FCCU ignores any operations initiated while the operation status is In Progress.
- Certain operations must be unlocked before you can initiate them. After you initiate them, they are again locked.

62.7.3 Run an operation

1. Check the operation status ([OPS](#)).
2. If the operation status is In Progress, go to step 1.
3. If the operation must be unlocked before you can initiate it, unlock the operation ([CTRLK](#)) using a 32-bit write.

NOTE

The [Control Key \(FCCU_CTRLK\)](#) register used in this step and the [Control \(FCCU_CTRL\)](#) register used in the next step must be written with consecutive instructions. Do not use read-modify-write instructions, such as bit-field instructions, to modify these registers.

4. Initiate the operation ([OPR](#)) using a 32-bit write.
5. Check the operation status ([OPS](#)).
6. If the operation status is In Progress, go to step 5.

The operation status is now Idle (OP15 only), Aborted, or Successful.

62.8 Lock and unlock the configuration

62.8.1 Introduction

After you configure FCCU, you can lock its configuration to prevent accidental changes.

62.8.2 About locking the configuration

When locking the configuration, keep the following in mind:

- If you attempt to lock the configuration while FCCU is in Configuration state, FCCU doesn't actually lock the configuration until FCCU leaves Configuration state—that is, either you put FCCU in Normal state, or FCCU puts FCCU in Normal state because the configuration-timer interval ([TO](#)) expires.
- After you permanently lock the configuration, you must reset FCCU before you can put FCCU in Configuration state.

62.8.3 Temporarily lock the configuration

1. From Supervisor mode, write a lock value to [TRANSKEY](#).
2. Put FCCU in Normal state if it's in Configuration state (see [Put FCCU in Normal state](#)).

62.8.4 Temporarily unlock the configuration

- From Supervisor mode, write the unlock value to [TRANSKEY](#).

62.8.5 Permanently lock the configuration

1. From Supervisor mode, write the lock value to [PERMNTKEY](#).
2. Put FCCU in Normal state if it's in Configuration state (see [Put FCCU in Normal state](#)).

The configuration is permanently locked until FCCU is reset.

62.9 Functional description

62.9.1 Definitions

In general, the following definitions are applicable for the fault management:

- **HW recoverable fault:** the fault indication is an edge-triggered and level-sensitive signal that remains asserted until the fault cause is deasserted. That is, if logical 0 on the fault signal indicates fault, then the status flags are valid as long as the fault line stays at 0. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched external to the FCCU in the module where the fault occurred. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- **SW recoverable fault:** the fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the fault is recoverable by itself when the fault condition gets corrected.

62.9.2 FSM description

FCCU functionality is depicted by the finite state machine (FSM) state diagram.

Basically four states are identified with the following meaning:

- **Configuration:** Used only to modify the configuration of FCCU from its default. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, noncritical fault masking) can be accessed in write mode only in Configuration state.

Configuration state is accessible only in Normal state and if the configuration is not locked. The permanent configuration lock can be disabled by a reset which also resets the FCCU. The transient lock register is unlocked by writing BCh into it. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (that is, other than BCh). Key to lock FCCU permanently is FFh, written in the FCCU_PERMNT_LOCK register.

After the release of reset the state of the transient lock will be locked. The state of the permanent lock will be unlocked.

The locking feature only restricts the FSM movement into Configuration state. Once the user enters Configuration state and then tries to lock the configuration, the locking of configuration will be effective after FCCU moves to Normal state, it will not be effective in the current Configuration state.

The Configuration to Normal state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request to mode change to Normal appears at the same time, watchdog timeout has the priority and hence the Configuration registers (those that are writable only in Configuration state) are reset to their default values. The movement to Normal is made.

The incoming faults, occurring during the configuration phase (Configuration state) are latched in order to process them when FCCU is moved into Normal state, according to the new configuration.

All pending faults that occur during Configuration state result in both of the following:

- Highest-priority state transition
- Interrupt generation (NMI or alarm IRQ)

If the state transition occurs, it gives the reset reaction corresponding to the worst case based on all the faults (pending or nonpending faults) that occurred during Configuration state.

- Normal: This is FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following state transitions occur on one of the following events:
 - unmasked noncritical faults with the timeout disabled → FCCU moves to Fault state
 - unmasked noncritical faults with the timeout enabled → FCCU moves to Alarm state
 - masked noncritical faults → FCCU stays in Normal state
- Alarm: FCCU moves into Alarm state when an unmasked noncritical fault occurs and the timeout is enabled. The transition to Alarm state goes along with an interrupt alarm, if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to Fault state. The timeout is reinitialized if FCCU enters Normal state. The timeout restarts following the recovery from Fault state.
- Fault: FCCU moves into Fault state when one of the following condition occurs:
 - timeout related to a noncritical fault when FCCU is in Alarm state
 - unmasked noncritical faults with the timeout disabled

The transition from Normal/Alarm to Fault state goes along with the generation of:

- NMI interrupt (optional)
- EOUT signaling (optional)
- SW option: functional reset
- Non Maskable Interrupt (NMI) is routed only to the Safety Core

After moving to Fault state, if there is either a previous pending fault or a new fault for which NMI is enabled, NMI generation takes place.

Multiple faults can occur at the same time. Consider the case where there is a fault for which Alarm state is enabled and IRQ is programmed along with a fault for which Alarm state is disabled. In that case, the FSM moves to Fault state, but with the generation of alarm IRQ for the fault which has IRQ enabled.

Figure 62-3. FCCU state diagram

62.9.3 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (noncritical) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a noncritical fault (unmasked and with time-out disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the noncritical faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will remain in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the noncritical faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will move to the ALARM state (if any noncritical fault is still pending and the time-out is not elapsed).

In general, no fault nesting is supported except for the noncritical faults that cause an ALARM to FAULT state transition. In this case the NCF timer is stopped until the FAULT state is recovered. If FCCU is in ALARM state and another fault comes, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

62.9.4 STCU interface

The STCU interface includes:

- A set of signals resulting from the self-checking procedure connected externally at the FCCU.

The STCU fault signals are processed by the FCCU when the SoC is re-booted following the self-testing procedure. The STCU includes a status register that stores the self-testing results (flags).

- a mask that inhibits the EOUT dummy signaling until the STCU self-checking procedure has been completed.

During the self-testing procedure, depending on the STCU results, three cases are applicable:

1. STCU completes the self-testing procedure successfully. The SoC reboots and the FCCU is responsible for fault collection and indication.
2. STCU completes the self-testing procedure with low severity failures. The FCCU records the fault condition but does not, by default, trigger a reset cycle.
3. STCU completes the self-testing procedure with serious failures. The FCCU triggers a reset cycle in response to this fault input from the STCU. Because the fault condition survives reset, new reset cycles are subsequently triggered until the reset escalation feature takes control, freezing the chip in the reset state until a POR.

**Figure 62-4. STCU-FCCU (case 1)****Figure 62-5. STCU-FCCU (case 2)****Figure 62-6. STCU-FCCU (case 3)**

62.9.5 Nonvolatile memory interface

FCCU includes a nonvolatile memory interface (NVMCFG signals) that provides the values of certain bits in the [Configuration \(FCCU_CFG\)](#) register when certain events occur. See [Configuration \(FCCU_CFG\)](#). Whether any of these signals are actually connected to nonvolatile (flash) memory is chip-specific. Some or all of these signals may be driven by bits in a data record in nonvolatile (flash) memory or may be tied high (1) or low (0). See [FCCU_CFG register bit value sources \(N and C\) by event](#).

The timing diagram related to the NVM interface is given in [Figure 62-7](#).

Figure 62-7. NVM interface

62.9.6 EOUT interface

62.9.6.1 Introduction

You use the EOUT[1:0] signals to indicate FCCU's condition to off-chip logic. For information on the availability and names of these FCCU signals on the boundary of this chip, see the chip-specific FCCU information.

62.9.6.2 The FCCU conditions

There are three FCCU conditions:

Condition	Description
Faulty	The fault-output (EOUT) timer is running (see How the fault-output (EOUT) timer works).
Nonfaulty	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in Alarm or Normal state.
Configuration	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in Configuration state.

62.9.6.3 How the fault-output (EOUT) timer works

FCCU starts the fault-output (EOUT) timer when all of the following are true:

- The fault-output (EOUT) signals are not programmed to be always low ([FCCU_SET_CLEAR](#)).
- The fault-output (EOUT) timer isn't already running.
- FCCU enters Fault state as the result of a fault.

When the fault-output (EOUT) timer is already running and a new fault occurs:

- When FCCU is in Configuration state: FCCU doesn't restart the fault-output (EOUT) timer.
- When FCCU is in Normal state or Alarm state:
 - And Alarm state is enabled for the fault (noncritical): FCCU enters (or remains in) Alarm state but doesn't restart the fault-output (EOUT) timer.
 - And Alarm state is disabled for the fault (noncritical): FCCU enters Fault state and restarts the fault-output (EOUT) timer.
- When FCCU is in Fault state: FCCU restarts the fault-output (EOUT) timer.

FCCU stops and reinitializes the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bistable fault-output mode ([FOM](#)), T_min has expired.
- All faults that caused FCCU to enter or remain in Fault state since FCCU started the fault-output (EOUT) timer have been cleared, causing FCCU to return to Normal state.

62.9.6.4 Prepare the EOUT signals to indicate FCCU's condition

Make sure all of the following are true:

- The EOUT signals are active ([FCCU_SET_AFTER_RESET](#)).
- The EOUT signals are controlled by FCCU's finite state machine ([FCCU_SET_CLEAR](#)).

62.9.6.5 More about the EOUT interface

Different fault-output modes (protocols) for the fault-output (EOUT) interface are supported (FCCU_CFG[FOM]):

- Dual-Rail
- Time-Switching
- Bistable
- Test

You can further configure the fault-output modes using the following attributes:

Attribute	Field	Setting used in the example diagrams and tables that follow
Switching mode	FCCU_CFG[SM]	Slow
Polarity selection	FCCU_CFG[PS]	For the faulty indication, EOUT1 is high, and EOUT0 is low.

The EOUT frequency is generated by dividing the CLKSAFE frequency by a fixed factor of 2^{18} .

With a CLKSAFE frequency of 16 MHz, this drives a signal of 61 Hz on EOUT.

The external monitor of the EOUT protocol should oversample the EOUT signals in order to synchronize periodically the external clock (used by the monitor) and CLKSAFE (which detects the edge transition of the EOUT protocol) in Dual-Rail or Time-Switching fault-output mode.

In case of a failure event or on software request for EOUT indication, the signal(s) are set to the faulty state for a minimum time T_{min} , even if software tries to release it before. If software configures the error pins to OK(1), and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and the error signals indicate NOK, such as an incoming fault is not masked when software has set the error signal to high. During the T_{min} by a non-software fault, the FCCU FSM moves independently of this

signal state (low), and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in, and it is not possible to set the signals to OK by software moving FCCU to Configuration state, as long as this timer is running. No software intervention is needed to bring the signal from the low state.

Software can bring the pin back to OK state by clearing the faults and waiting for the T_min interval to expire, after which the FCCU automatically enters Normal state and the error signal indicates OK.

In case another failure event happens within T_min after a first one, the T_min counter is restarted.

NOTE

The transition from Fault to Configuration state is not possible but is shown to display the behavior in all four states—reset, normal, error, and configuration.

NOTE

FCCU remains in Normal state when a fault is disabled; therefore, NA (not applicable) appears in the following table.

NOTE

The following table is valid only when the EOUT signals are active ([FCCU_SET_AFTER_RESET](#)).

Table 62-4. FCCU error pin behavior on state transitions

Fault signaling state	Transition from Normal to Fault state			Normal+Configuration states			Transition from Normal to Alarm state		
	with Fault disabled enabled						with Fault disabled enabled		
	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad
Disabled	NA OK	NA 1	NA OK	OK	1	OK	NA OK	NA 1	NA OK
Enabled	NA NOK	NA 1	NA NOK	OK	1	OK	NA OK	NA 1	NA OK

NOTE

The first time FCCU is in Configuration state, the EOUT pads are in a high-impedance state; thereafter, their states reflect the programmed EOUT protocol.

62.9.6.6 Dual-rail protocol

Dual-rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, dual-rail encoded circuits use two wires to carry each bit. The encoding scheme is given in [Table 62-5](#) and the related timing diagram is given in [Figure 62-8](#) and [Figure 62-9](#).

Table 62-5. Dual-rail encoding

Logical state	Dual-rail encoding (output pins EOUT[1:0])	Note
non-faulty	10	toggling
non-faulty	01	
faulty	00	toggling
faulty	11	
reset	Hi impedance ¹	no toggling
configuration	same as NORMAL	toggling

1. Final value depends on the SoC setting at pad level.

As long as FCCU is in NORMAL or ALARM state, output will show "non-faulty" signal. Output pins EOUT[0:1] will toggle between 01 and 10 with a given frequency of 61 Hz.

In the RESET phase the output pins are set as "high impedance".

Note

[Figure 62-8](#) and [Figure 62-9](#) are formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

Figure 62-8. Dual-rail protocol (slow switching mode)

Figure 62-9. Dual-rail protocol (fast switching mode)

62.9.6.7 Time-switching protocol

The encoding scheme is given in [Table 62-6](#) and the related timing diagram is given in [Figure 62-10](#).

Table 62-6. Time-switching encoding

Logical state	Time-switching encoding (output pins EOUT[1:0])	Note
non-faulty	10	toggling
non-faulty	01	
faulty	10	no toggling
reset	high-Z ¹	no toggling
configuration	same as NORMAL	toggling

1. Final value depends on device specific settings at pad level.

As long as FCCU is in NORMAL or ALARM state, outputs will show "non-faulty" signal. Output pins #0, #1 will toggle between 01 and 10 with frequency of 61 Hz.

In the FAULT state, the output pin EOUT[0] is set as low.

In Time Switching mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".²

Note

[Figure 62-10](#) is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

2. Actual value depends on device specific settings at pad level.

Functional description

Figure 62-10. Time-switching protocol

62.9.6.8 Bi-stable protocol

The encoding scheme is given in [Table 62-7](#) and the related timing diagram is given in [Figure 62-11](#).

Table 62-7. Bi-stable encoding

Logical state	Bi-stable encoding (output pins EOUT[1:0])	Note
non-faulty	01	no toggling
faulty	10	no toggling
reset	high-Z ¹	no toggling
configuration	same as NORMAL	no toggling

1. Final value depends on device specific settings at pad level.

In the FAULT state, the faulty logical state is indicated. In NORMAL or ALARM state, "no-faulty" state is indicated. In Bi-stable mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".³

Note

[Figure 62-11](#) is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

3. Actual value depends on device specific settings at pad level.

Figure 62-11. Bi-stable protocol

62.9.7 Error signal flow

See the chip-specific FCCU information for the diagram of the signal flow.

62.10 Register descriptions

The FCCU registers are listed in the table below. Any address offset not explicitly mentioned in this table is reserved.

The FCCU supports word (32-bit), half-word (16-bit), and byte (8-bit) read and write accesses.

Follow these register-access guidelines:

- Don't read from or write to any addresses that are not shown in the following table. Doing so may result in a transfer error.
- Don't write to any of the configuration registers unless FCCU is in Configuration state. Doing so results in a transfer error.
- Don't write to FCCU_TRANS_LOCK or FCCU_PERMNT_LOCK unless your code runs in Supervisor mode. Doing so results in a transfer error.

All the registers accessible in write mode only in CONFIG state are referred as configuration registers. These configuration registers return to the default value after configuration watchdog timer expires. These are the registers protected by FCCU_TRANS_LOCK and FCCU_PERMNT_LOCK registers. The configuration register setting has effect only when the FCCU state exits from the CONFIG state.

Register descriptions

For each possible NCF failure source, a different reaction—including no reaction—is configurable through the use of NMI, IRQ, and reset selection registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by functional resets.

FCCU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
0	Control (FCCU_CTRL)	32	R/W	0000_00C0h	62.10.1/3096

62.10.1 Control (FCCU_CTRL)

Initiates and indicates the status of operations, indicates that FCCU successfully loaded configuration data from the NVMCFG signals, controls glitch-filter settings, and enables Debug mode.

Address: 0h base + 0h offset = 0h

FCCU_CTRL field descriptions

Field	Description
0 FILTER_ BYPASS	Filter bypass 0 glitch filter not bypassed 1 glitch filter bypassed
1-2 FILTER_WIDTH	Filter width 00 filters glitches up to 50 μs 01 filters glitches up to 75 μs 10 filters glitches up to 100 μs 11 filters glitches up to 100 μs

Table continues on the next page...

FCCU_CTRL field descriptions (continued)

Field	Description
3–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 DEBUG	Debug Mode Enable Specifies whether Debug mode is enabled. If so, FCCU enters Debug mode when the Debug signal is asserted. When FCCU enters Debug mode, it halts operation and remains in the state it was in before it entered Debug mode. NOTE: FOSU doesn't halt when FCCU enters Debug mode. Therefore, FOSU can still cause a reset if a fault occurs while FCCU is in Debug mode. 0 Disabled 1 Enabled
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–25 OPS	Operation status. This bit can be read and cleared (via OP15 operation) by the software. 00 Idle 01 In progress 10 Aborted 11 Successful
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 OPR	Operation Run Initiates operations that perform actions such as putting FCCU in Configuration state or reading a timer. For information on how to run operations, see Run operations. FCCU ignores any write to this field while the operation status (OPS) is In Progress. After completion of an operation, FCCU sets this field to OP0. The following events result in an operation status (OPS) of Aborted: - Writing to a Noncritical Fault Status (FCCU_NCF_Sn) register (which automatically initiates the OP12 operation) without first successfully unlocking the register (NCFK) - Initiating an OP1 operation when FCCU is not in Normal state or the configuration is locked - Initiating an OP1, OP2, or OP31 operation without first unlocking the operation (CTRLK) 00000 OP0—No operation 00001 OP1—Applies only when the configuration is unlocked, when FCCU is in Normal state, and immediately after you unlock the operation (CTRLK). Put FCCU in Configuration state. 00010 OP2—Applies only immediately after you unlock the operation (CTRLK). Put FCCU in Normal state. 00011 OP3—Capture FCCU's state and the states of the EOUT signals in the Status (FCCU_STAT) register. 00100 OP4—Read the FCCU frozen status flags (NA Freeze Status (FCCU_N2AF_STATUS)). 00101 OP5—Read the FCCU frozen status flags (AF Freeze Status (FCCU_A2FF_STATUS)). 00110 OP6—Read the FCCU frozen status flags (NF Freeze Status (FCCU_N2FF_STATUS)). 00111 OP7—Read the FCCU frozen status flags (FA Freeze Status (FCCU_F2A_STATUS)). 01000 Reserved 01001 Reserved

Table continues on the next page...

FCCU_CTRL field descriptions (continued)

Field	Description
	01010 OP10—Read the Noncritical Fault Status (FCCU_NCF_Sn) register.
	01011 Reserved
	01100 OP12—Do not initiate this operation; it is automatically initiated by FCCU. A Noncritical Fault Status (FCCU_NCF_Sn) register status clear operation is in progress.
	01101 OP13—Clear the freeze status registers (see the freeze registers).
	01110 OP14—Do not initiate this operation; it is automatically initiated by FCCU. A Configuration-state timeout is in progress. For more information, see Configuration registers .
	01111 OP15—Set the operation status (OPS) to Idle.
	10000 Reserved
	10001 OP17—Read the Alarm-state timer (XTMR).
	10010 Reserved
	10011 OP19—Read the Configuration-state timer (XTMR).
	10100 Reserved
	10101–11110 Forbidden. Writing any of these values returns an operation status (OPS) of Aborted with no side effect.
	11111 OP31—Applies only immediately after you unlock the operation (CTRLK). Load configuration data from the NVMCFG signals to certain fields in the Configuration (FCCU_CFG) register, but without resetting FCCU (for testing and debugging). See FCCU_CFG register bit value sources (N and C) by event . The operation status (OPS) for this operation is always Successful.

62.10.2 Control Key (FCCU_CTRLK)

Writable only with a 32-bit write. Unlocks locked operations so you can initiate them (OPR). For information on how to unlock locked operations before you initiate them, see [Run an operation](#).

NOTE

Reading from this register always returns the value 0000_0000h.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_CTRLK field descriptions

Field	Description
0–31 CTRLK	Locked-Operation Control Key

FCCU_CTRLK field descriptions (continued)

Field	Description
	Unlocks locked operations so you can initiate them (OPR). For information on how to unlock locked operations before you initiate them, see Run an operation. NOTE: You must initiate an operation in the instruction that immediately follows the instruction that unlocks it; otherwise, the operation is again locked. 9137_56AFh: Unlock OP1. 825A_132Bh: Unlock OP2. 29AF_8752h: Unlock OP31. Any other value: Do nothing.

62.10.3 Configuration (FCCU_CFG)

Writable only when FCCU is in Configuration state. Specifies the global configuration for FCCU.

The values of the bits in this register are affected by writes as well as any of the following events:

- The chip resets FCCU.
- FCCU automatically leaves Configuration state and enters Normal state because the configuration-timer interval ([TO](#)) expires. This is called a Configuration-state timeout.
- You run an OP31 operation.

For information on the sources of bit values for these events, see [FCCU_CFG register bit value sources \(N and C\) by event](#).

NOTE

If you specify a new value for any of the fields in this register that affect the EOUT signals while the fault-output (EOUT) timer is running (FCCU is indicating a fault on the EOUT signals), FCCU doesn't use the new settings you specified until after the fault-output (EOUT) timer expires (FCCU stops indicating a fault on the EOUT signals).

Register descriptions

Address: 0h base + 8h offset = 8h

- * Notes:
- For information on this register's reset value, see [FCCU_CFG register bit value sources \(N and C\) by event](#). x = Undefined at reset.

FCCU_CFG field descriptions

Field	Description
0–6 Reserved	This field is reserved.

Table continues on the next page...

FCCU_CFG field descriptions (continued)

Field	Description
7 FCCU_SET_AFTER_RESET	Fault-Output (EOUT) Activate For fault-output (EOUT) signaling, controls whether the EOUT signals are active. 0 Inactive (the EOUT signals are in a high-impedance state) 1 Active (the EOUT signals indicate FCCU's condition)
8–9 FCCU_SET_CLEAR	Fault-Output (EOUT) Control Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Controls whether the fault-output (EOUT) signals are controlled by FCCU's finite state machine (FSM). 00 Controlled by the FSM 01 Always low 10 Controlled by the FSM 11 High until a fault occurs on a channel, regardless of whether that fault is disabled; thereafter, controlled by the FSM. Note: FCCU ignores an attempt to write this value if the fault-output (EOUT) timer is already running.
10–11 Reserved	This field is reserved.
12–15 Reserved	This field is reserved. Always write the reset value to this field.
16 FOPE	Fault-Output (EOUT) Prescaler Extension For fault-output (EOUT) signaling, specifies the most significant bit of the derived prescaler that controls the signaling frequency. For more information, see the description of the FOP field.
17–18 Reserved	This field is reserved. Always write the reset value to this field.
19 Reserved	This field is reserved. Always write the reset value to this field.
20 Reserved	This field is reserved. Always write the reset value to this field.
21 SM	Fault-Output (EOUT) Switching Mode For fault-output (EOUT) signaling, controls how quickly the signals switch between faulty and nonfaulty indication. Applies only to Dual-Rail and Time-Switching fault-output modes. 0 Slow: No EOUT frequency violation during the FCCU state transition (Normal to Fault or vice versa, and Configuration to Normal). The indication transition occurs after a maximum delay equal to the duration of the semiperiod of the EOUT frequency. 1 Fast: The indication transition (Normal to Fault or vice versa, and Configuration to Normal) occurs immediately. A pulse with the minimum duration corresponding to the CLKSAFE period can occur in this mode. It implies a frequency violation of the EOUT protocol.
22 PS	Fault-Output (EOUT) Polarity Selection For fault-output (EOUT) signaling, controls the polarity of the signals for fault-output-mode indications that hold the signals low or high (versus toggling them or placing them in a high-impedance state). Applies only to Time-Switching fault-output mode (for faulty and configuration indications) and Bistable fault-output mode (for all indications). 0 For the faulty indication, EOUT1 is high, and EOUT0 is low. 1 For the faulty indication, EOUT1 is low, and EOUT0 is high.

Table continues on the next page...

FCCU_CFG field descriptions (continued)

Field	Description
23–25 FOM	Fault-Output (EOUT) Mode For fault-output (EOUT) signaling, controls the protocol of the signaling. NOTE: In the test modes, a simple double-stage resynchronization stage is used to resynchronize the EOUT input/outputs with CLKSAFE. 000 Dual-Rail (default state) [EOUT[1:0]= outputs] 001 Time-Switching [EOUT[1:0]= output to be used] 010 Bistable 011 Reserved 100 Reserved 101 Test 0 (controlled by the FCCU_EINOUT register; EOUT1 is an output; EOUT0 is an input) 110 Test 1 (controlled by the FCCU_EINOUT register; EOUT1 and EOUT0 are both outputs) 111 Test 2 (controlled by the FCCU_EINOUT register; EOUT1 is an input; EOUT0 is an output)
26–31 FOP	Fault-Output (EOUT) Prescaler For fault-output (EOUT) signaling, specifies the least significant bits of the derived prescaler that controls the signaling frequency. The derived prescaler is the concatenation of FOPE and FOP and is represented by {FOPE, FOP}. The following equation defines the signaling frequency in terms of the CLKSAFE frequency ($\text{CLKSAFE}_{\text{freq}}$) and the derived prescaler: $\text{EOUT}_{\text{freq}} = \text{CLKSAFE}_{\text{freq}} / (((\text{FOPE, FOP}) + 1) \times 2 \times 2048)$ The following example values and meanings are for the derived (7-bit) prescaler, not FOP alone. The meanings show the derived prescaler followed by the corresponding value by which the input clock frequency is then divided. 0000000: 0; divide by 2×2048 (4096) 0000001: 1; divide by 4×2048 (8192) 0000010: 2; divide by 6×2048 (12,288) ... 0001000: 8; divide by 18×2048 (36,864) ... 1111101: 125; divide by 252×2048 (516,096) 1111110: 126; divide by 254×2048 (520,192) 1111111: 127; divide by 256×2048 (524,288) NOTE: Writing to FCCU_CFG sets FOP to 0.

62.10.4 Noncritical Fault Configuration (FCCU_NCF_CFGn)

Contains the configuration of noncritical faults in terms of fault-recovery management. The configuration depends on the type of signaling of a fault event. Hardware-recoverable faults should be configured only if a previous latching stage captures and holds the physical fault; otherwise, the fault can be lost. All other faults should be configured as software faults.

NOTE

These registers are writable only when FCCU is in Configuration state.

Noncritical Fault Configuration (FCCU_NCF_CFGn) register (value of n)	Offset	NCFCx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit
0	1Ch	31	0

* Notes:

- The reset value is chip-specific. See the chip-specific FCCU information.x = Undefined at reset.

FCCU_NCF_CFGn field descriptions

Field	Description
0–31 NCFCx	Noncritical Fault Configuration. Defines the fault recovery mode. Hardware-recoverable faults are self-recovered (status flag clearing and related) if the root cause (input fault) has been removed. Software-recoverable faults are recovered (status flag clearing) by software clearing of the related status flag. For the mapping of the NCFCx fields among registers, see the earlier table in this register description. 0 Hardware-recoverable fault 1 Software-recoverable fault

62.10.5 Noncritical Fault State Configuration (FCCU_NCFS_CFGn)

The FCCU_NCFS_CFGx registers contain the configuration of each noncritical fault in terms of fault reaction (functional reset request pulse) when it is the root cause for the FAULT state transition.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

Table 62-16 shows FCCU configuration register channels.

Table 62-16. FCCU NCFS configuration register channels

Address offset	Register name	Channel range (x)
4Ch	FCCU_NCFS_CFG0	NCFSCx[15:0]

FCCU_NCFS_CFGn field descriptions

Field	Description
0–31 NCFSCx	Noncritical fault state configuration See Table 62-16 for register offset to channel number relationship. 00 No reset reaction 01 Reset request pulse (FAULT state reaction) 10 Reset request pulse (FAULT state reaction) 11 No reset reaction

62.10.6 Noncritical Fault Status (FCCU_NCF_Sn)

The FCCU_NCF_Sx register contains the latched fault indication collected from the noncritical fault sources. Faults are latched also in the CONFIG state and independently from the enabling or reactions programmed for the NCF.

No reactions are executed until the FCCU moves in the NORMAL state.

FCCU reacts and moves from the NORMAL state into the ALARM state only if the respective enable bit for a fault is set in the FCCU_NCF_Ex register and the respective enable bit for the timeout is set in the FCCU_TOEx register.

FCCU reacts and moves from the NORMAL or ALARM state into the FAULT state if the respective enable bit for a fault is set in the FCCU_NCF_Ex register and the respective enable bit for the timeout is disabled in the FCCU_TOEx register.

FCCU reacts and moves from the ALARM state into the FAULT state if the timeout (FCCU_TO register) is elapsed before recovering from the fault.

The timeout is stopped only when the FCCU returns in the NORMAL state.

The FCCU_NCF_Sx register is encoded respectively into the N2FF_STATUS or A2FF_STATUS register to freeze the entry condition in the FAULT state. The status bits of the FCCU_NCF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the proper key into the FCCU_NCFK register.
2. Clear the status (flag) bit NCFSx => the opcode OP12 is automatically set into the FCCU_CTRL.OPR field.
3. Wait for the completion of the operation (FCCU_CTRL.OPS field).
4. Read the FCCU_NCF_Sx register in order to verify the effective deletion and in case of failure to repeat the sequence.

As result of the above sequence, in addition the FAULT interface provides support to clear the external fake FAULT root .

NOTE

There should not be any other operation in between the above steps.

The FCCU moves from the FAULT or ALARM state into the NORMAL state if all the source faults that caused the transition into the FAULT state have been removed (HW recoverable fault) or cleared via SW (SW recoverable fault). In case of nested faults that are not all recovered, the FCCU will remain in the FAULT or ALARM state.

The SW application executes the FCCU_NCF_Sx read operation by the following sequence:

1. Set the OP10 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_NCF_Sx register.

In case of re-configuration of the FCCU (CONFIG state), before to return in NORMAL state the pending status bits into the FCCU_NCF_Sx must be cleared in order to avoid a false transition in ALARM/FAULT state.

The following faults are ignored:

- to write a wrong key into the FCCU_NCFK register
- to attempt to clear a HW recoverable fault

Noncritical Fault Status (FCCU_NCF_Sn) register (value of n)	Offset	NCFSx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit

FCCU_NCF_Sn field descriptions

Field	Description
0–31 NCFSx	Noncritical fault status. The status bits related to the noncritical fault configured as HW recoverable faults are read-only and the flag is self cleared when the fault source is removed. For the mapping of the NCFSx fields among registers, see the earlier table in this register description. 0 No "noncritical" fault latched 1 "Noncritical" fault latched

62.10.7 Noncritical Fault Key (FCCU_NCFK)

The FCCU_NCFK register implements the key access to clear the status flags of the FCCU_NCF_Sx register.

The status bits of the FCCU_NCF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the key into the FCCU_NCFK register.
2. Clear the status (flag) bit NCFSx .

The key must be written for each FCCU_NCF_Sx clear operation.

The FCCU_NCFK register is not readable; a 0000_0000h value is always returned in case of read operation.

Address: 0h base + 90h offset = 90h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_NCFK field descriptions

Field	Description
0–31 NCFK	Noncritical fault key = AB34_98FEh

62.10.8 Noncritical Fault Enable (FCCU_NCF_En)

The FCCU_NCF_En registers enable the fault sources to allow a transition from the NORMAL into the FAULT or ALARM state. In case of fault masking, the respective status bit into the FCCU_NCF_Sn register is set (for debugging purposes), only the reaction is masked.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

NOTE

Any enabled fault should be programmed to result in a defined action. For example, set up an ALARM IRQ action by programming the IRQ Alarm Enable Register (FCCU_IRQ_ALARM_ENn).

Noncritical Fault Enable (FCCU_NCF_En) register (value of n)	Offset	NCFEx fields (value of x)

FCCU_NCF_En field descriptions

Field	Description
0–31 NCFEx	Noncritical fault enable For the mapping of the NCFEx fields among registers, see the earlier table in this register description. 0 No actions following the respective noncritical fault assertion 1 FCCU moves to ALARM or FAULT state

62.10.9 Noncritical Fault Timeout Enable (FCCU_NCF_TOEn)

The FCCU_NCF_TOEx registers enable a transition from the NORMAL state into the ALARM state if the respective noncritical fault is enabled (NCFEx and NCFTOEx are set). In case the respective timeout is disabled (NCFTOEx is cleared) and the noncritical fault is enabled (NCFEx is set) the FCCU moves into the FAULT state if the related noncritical fault is asserted. The timer (preset with the timeout value defined by FCCU_TO register) is started when the FCCU moves into the ALARM state. If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

Noncritical Fault Timeout Enable (FCCU_NCF_TOEn) register (value of n)	Offset	NCFTOEx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit
0	A4h	31	0
1	A8h	63	32

Address: 0h base + A4h offset + (4d × i), where i=0d to 1d

FCCU_NCF_TOEn field descriptions

Field	Description
0–31 NCFTOEx	Fault timeout enable For the mapping of the NCFTOEx fields among registers, see the earlier table in this register description. 0 FCCU moves into the FAULT state if the respective fault is enabled 1 FCCU moves into the ALARM state if the respective fault is enabled

62.10.10 Noncritical Fault Timeout (FCCU_NCF_TO)

Defines the preset value of the timer for the recovery of enabled noncritical faults. Once FCCU enters Alarm state, following the assertion of a noncritical fault that is enabled (NCFEa and NCFTOEa are set), the timer starts the countdown.

If the fault is not recovered within the timeout period, the FCCU moves from the Alarm state to the Fault state. The alarm timeout value should be programmed to be less than FOSU_COUNT, or resets may be generated by FOSU timeouts.

NOTE

This register is writable only when FCCU is in Configuration state.

Address: 0h base + B4h offset = B4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_NCF_TO field descriptions

Field	Description
0–31 TO	Noncritical Fault Timeout Timeout = (TO) × T _{RC16MHz}

62.10.11 Configuration-State Timer Interval (FCCU_CFG_TO)

Writable only when FCCU is in Normal, Alarm, or Fault state (not in Configuration state). Not accessible while a Configuration-state timeout (OP14 operation) is in progress. Controls the maximum amount of time that FCCU can be in Configuration state.

NOTE

When a Configuration-state timeout occurs, FCCU changes the value of this register to its reset value.

Register descriptions

Address: 0h base + B8h offset = B8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_CFG_TO field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 TO	Configuration-State Timer Interval Controls the maximum amount of time (T_max) that FCCU can be in Configuration state according to this equation: $T_{\text{max}} = T_{16\text{MHz}} \times 2^{(\text{TO} + 10)}$ If you put FCCU in Configuration state and this timer interval expires (called a Configuration-state timeout), then FCCU: - Automatically leaves Configuration state and enters Normal state. - Changes the value of the Configuration (FCCU_CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration (FCCU_CFG) register's Configuration-state-timeout value, see FCCU_CFG register bit value sources (N and C) by event. For a list of configuration registers, see Configuration registers. NOTE: Make sure the Configuration-state timer interval is less than the FOSU module's timer interval; otherwise, a fault that occurs while FCCU is in Configuration state can cause FOSU to generate a chip reset. The FOSU timer interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information. 000: 64 μs ... 111: 8192 μs

62.10.12 IO Control (FCCU_EINOUT)

The FCCU_EINOUT register allows the following operations typically in NORMAL state:

- to control the EOUT[1] output level when the FCCU is configured in "Test1" or "Test0" fault output mode (FCCU_CFG.FOM)
- to control the EOUT[0] output level when the FCCU is configured in "Test1" or "Test2" fault output mode (FCCU_CFG.FOM)
- to observe the EOUT[1:0] signals in input mode

[Table 62-36](#) shows Bi-stable encoding.

Table 62-36. Bi-stable encoding

Mode = FCCU_CFG.FOM	EOUT[0]	EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

NOTE

Due to the resynchronization stage of the EOUT interface, there is a latency of a few CLKSAFE cycles following a write/read operation of the FCCU_EINOUT register.

Address: 0h base + BCh offset = BCh

* Notes:

- x = Undefined at reset.

FCCU_EINOUT field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FCCU_EINOUT field descriptions (continued)

Field	Description
26 EIN1	Error Input 1 Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the state of the EIN1 signal. 0 Low 1 High
27 EIN0	Error Input 0 Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the state of the EIN0 signal. 0 Low 1 High
28–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 EOUT1	Error out 1 (significant only if the FCCU_CFG.FOM = Test1 or Test0 => EOUT[1] configured in output mode). The EOUT1 set/clear the respective EOUT[1] output signal if FCCU_CFG.FOM = 110 or 101, otherwise it is a "don't-care" value. NOTE: When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value. 0 force EOUT[1] = 0 1 force EOUT[1] = 1
31 EOUT0	Error out 0 (significant only if the FCCU_CFG.FOM = Test1 or Test2 => EOUT[0] configured in output mode). The EOUT0 set/clear the respective EOUT[0] output signal if FCCU_CFG.FOM = 110 or 111, otherwise it is a "don't care" value. NOTE: When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value. 0 force EOUT[0] = 0 1 force EOUT[0] = 1

62.10.13 Status (FCCU_STAT)

The FCCU_STAT register includes the FCCU status for debugging/test purposes. The FCCU finite state machine operates by the RC oscillator clock asynchronous with the system clock. The FCCU status read operation requires a safe mechanism operated by a HW/SW synchronization sequence. The SW application executes a FCCU status read operation by the following sequence:

1. Set the OP3 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU status (FCCU_STAT register).

Address: 0h base + C0h offset = C0h

	001 Configuration
	010 Alarm
	011 Fault
	100 Reserved
	101 Reserved
	110 Reserved
	111 Reserved

62.10.14 NA Freeze Status (FCCU_N2AF_STATUS)

The N2AF_STATUS register contains a unique code to identify the "noncritical fault" source (fccu_ncf[x]) that caused the state transition from the NORMAL state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the N2AF_STATUS read operation by the following sequence:

1. Set the OP4 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2AF_STATUS register.

The SW application executes the N2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

Address: 0h base + C4h offset = C4h

62.10.15 AF Freeze Status (FCCU_A2FF_STATUS)

The A2FF_STATUS register contains a unique code to identify the timeout trigger (noncritical fault) that caused the state transition from the ALARM state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the A2FF_STATUS read operation by the following sequence:

1. Set the OP5 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the A2FF_STATUS register.

The SW application executes the FCCU_AFFS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

62.10.17 FA Freeze Status (FCCU_F2A_STATUS)

The F2AF_STATUS register contains a unique code to identify the source of the noncritical fault (fccu_ncf[x]) that caused the state transition from the FAULT state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the F2AF_STATUS read operation by the following sequence:

1. Set the OP7 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the F2AF_STATUS register.

The SW application executes the F2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.

62.10.18 Noncritical Fault Fake (FCCU_NCFF)

The FCCU_NCFF register contains a unique code to set a noncritical fault in mutually exclusive mode by the external FAULT interface (signal setting). It allows the SW emulation of the noncritical faults, by the injection of the fault directly in the FAULT root, in order to verify the entire path and reaction. The reaction following a fake noncritical fault cannot be masked. The FCCU_NCFF is a write-only register with a set of codes corresponding to each noncritical fault injection.

Address: 0h base + DCh offset = DCh

62.10.19 IRQ Status (FCCU_IRQ_STAT)

The FCCU_IRQ_STAT register provides the FCCU interrupt status related to the following events:

- Configuration timeout error
- Alarm interrupt
- NMI interrupt

The configuration timeout interrupt is asserted if the CFG_TO_STAT bit of the FCCU_IRQ_STAT register is set and the CFG_TO_IEN bit of the FCCU_IRQ_EN register is also set. It is cleared when a 1 is written to the CFG_TO_STAT bit.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the FCCU_IRQ_STAT trace the status of the related interrupt lines.

Address: 0h base + E0h offset = E0h

62.10.21 XTMR (FCCU_XTMR)

The FCCU_XTMR register contains the read values of the Alarm or Watchdog Timer. These timers are clocked by CLKS SAFE.

The SW application executes the timer read operation by the following sequence:

1. Set any of the following operations into the FCCU_CTRL.OPR field:
 - OP17
 - OP19
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_XTMR register.

Table 62-46 shows Timer state/value.

Table 62-46. Timer state/value

FCCU_DELTA_T field descriptions

Field	Description
0–1 Reserved	This field is reserved.
2–15 Reserved	This field is reserved.
16–17 Reserved	This field is reserved.
18–31 DELTA_T	Bistable Minimum Fault-Output (EOUT) Faulty Interval Applies only to Bistable fault-output mode (FOM). Controls the minimum amount of time (T_{min}) that the fault-output (EOUT) timer runs according to this equation: $T_{min} = 250 \mu s + DELTA\_T$ The following values and meanings are for DELTA_T: 00_0000_0000_0000: 0 μs 00_0000_0000_0001: 1 μs ... 11_1111_1111_1110: 16,382 μs 11_1111_1111_1111: 16,383 μs NOTE: The durations shown for the DELTA_T values are for CLKSAFE clock signals running at exactly 16 MHz. However, the CLKSAFE signals are sourced from an internal chip clock signal (for example, IRC)—or an integer division of it (see the chip-specific FCCU information)—that has a trimmed frequency variation. Therefore, the DELTA_T durations may vary. See your chip's data sheet for the trimmed frequency variation (for example, δF_{var}).

62.10.25 IRQ Alarm Enable (FCCU_IRQ_ALARM_ENn)

These registers enable the corresponding IRQ alarm.

IRQ Alarm Enable (FCCU_IRQ_ALARM_ENn) register (value of n)	Offset	IRQENx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit
0	0FCh	31	0
1	100h	63	32

NOTE

FCCU_EOUT_SIG_ENn field descriptions

Field	Description
0–31 EOUTENx	Bistable Fault-Output (EOUT) Mode Signaling Enable x Writable only when FCCU is in Configuration state. Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). When FCCU is configured for Bistable fault-output mode (FOM), controls whether fault-output (EOUT) signaling is enabled for the associated noncritical fault channel (x). (For other fault-output modes, fault-output signaling is always enabled, regardless of the value of this field.)

FCCU_EOUT_SIG_ENn field descriptions (continued)

Field	Description
	When FCCU is configured for a fault-output mode other than Bistable, controls whether FCCU asserts the FIF signal when a fault occurs on the associated noncritical fault channel (x). (When FCCU is configured for Bistable fault-output mode, FCCU always asserts the FIF signal when a fault occurs on the channel, regardless of the value of this field.) NOTE: When FCCU is configured for a fault-output mode other than Bistable, you must set this field to enabled to ensure that FCCU asserts the FIF signal when a fault occurs on the associated noncritical fault channel (x) so the FOSU module doesn't mistakenly generate a chip reset. For the mapping of the EOUTENx fields among registers, see the earlier table in this register description. 0 Disabled 1 Enabled

62.10.28 Configuration registers

62.10.28.1 Definition

Configuration registers are registers that:

- Let you configure FCCU's Alarm-state timer interval, fault channels, and fault-output (EOUT) signals.
- You can write to only when the configuration is not locked (see [Lock and unlock the configuration](#)) and FCCU is in Configuration state (see [Put FCCU in Configuration or Normal state](#)).
- Save the values you write to them while FCCU is in Configuration state only after you manually put FCCU in Normal state. If FCCU automatically leaves Configuration state and enters Normal state because the configuration-timer interval (TO) expires (called a Configuration-state timeout), FCCU changes the value of the FCCU_CFG register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration-state timeout value, see [FCCU_CFG register bit value sources \(N and C\) by event](#).

62.10.28.2 The configuration registers

The following registers are the configuration registers, listed in offset order from lowest to highest:

- [Configuration \(FCCU_CFG\)](#)
- [Noncritical Fault Configuration \(FCCU_NCF_CFGn\)](#)
- [Noncritical Fault State Configuration \(FCCU_NCFS_CFGn\)](#)
- [Noncritical Fault Enable \(FCCU_NCF_En\)](#)

- Noncritical Fault Timeout Enable (FCCU_NCF_TOEn)
- Noncritical Fault Timeout (FCCU_NCF_TO)
- Delta T (FCCU_DELTA_T)
- IRQ Alarm Enable (FCCU_IRQ_ALARM_ENn)
- NMI Enable (FCCU_NMI_ENn)
- Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_ENn)

62.10.29 FCCU_CFG register bit value sources (N and C) by event

Certain events affect the bit values of the [Configuration \(FCCU_CFG\)](#) register; when one of these events occurs, the bit value is either unaffected, or FCCU changes it to one of the following:

- N: a chip-specific (or, for some chips, user-specified) value provided by the bit's associated NVMCFG signal
- C: a chip-specific value provided by the bit's associated constant inside the module

For each bit in the [Configuration \(FCCU_CFG\)](#) register, this table shows the associated NVMCFG signal, if any, and indicates the source of the bit value for the events that affect it. For specific values of *N* and *C* for each bit, see the chip-specific FCCU information.

Bit	NVMCFG signal	FCCU reset	Configuration-state timeout	OP31 operation
0	21	N	C	N
1	20	N	C	N
2	19	N	C	N
3	18	N	C	N
4	17	N	C	N
5	16	N	C	N
6	15	N	C	N
7	—	C	C	(Unaffected)
8	—	C	C	(Unaffected)
9	—	C	C	(Unaffected)

28	3	N	C	N
29	2	N	C	N
30	1	N	C	N
31	0	N	C	N

62.11 FCCU Output Supervision Unit

The FOSU provides a supervision of the primary fault notification path by analyzing FCCU behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after a fault is signaled.

The intention of the FOSU is to provide a secondary fault reaction path in most cases when the FCCU fails but not to needlessly propagate a fault which is already handled by the FCCU in a full chip reset. Only a failed primary fault reaction (that is, FCCU's failure) is a reason for the secondary reaction to take over (and generate a reset request).

There is a 'do nothing' input coming from the FCCU that indicates that the FCCU is programmed for no reaction for ALL FAULTS. It is a "static" input in the sense that it does not change after FCCU configuration. The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted, (i.e., a disabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during CONFIG state.

The FOSU contains a timer with a duration of FOSU_COUNT, driven by CLKSAFE. The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FOSU does not check whether the reaction is the configured one for the faults which occurred):

- Functional reset
- IRQ: NMI or Alarm
- Error out triggered (by FCCU or by SW)

When the timer is stopped, the fault capture logic is cleared in order to ensure that the timer is not restarted due to faults still 'stuck' in the capture logic. The timer will then be restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static "fccu program to do nothing" signal is deasserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.

The FOSU's failure indication output is connected to a reset input of the system reset state machine and is treated like a power-on reset event. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

NOTE

FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times-out without reaction.

Figure 62-56. FOSU connections to the FCCU and system reset state machine

It is important to remember that there will be no FCCU reaction to a fault while the FCCU is in the CONFIG state. For this reason, the FCCU should not be kept in CONFIG for longer than the FOSU_COUNT duration. Otherwise, there is a risk that an incoming error report causing the FOSU to mistakenly see the FCCU as having failed, and then resets the MCU.

NOTE

FCCU and FOSU timeout counter settings: The FCCU counter value should always be programmed less than the FOSU counter value, FOSU_COUNT, or resets may be generated by an FOSU time-out. This ensures that the FOSU reacts only when the FCCU fails to react to any particular fault.

62.12 Use cases and limitations

62.12.1 Configuration guidelines

Follow these guidelines to configure FCCU:

- If you want FCCU to react to a fault on a noncritical fault channel:
 - Enable the channel ([NCFEx](#)).
 - Enable at least one type of Fault-state reaction for the channel: chip reset ([NCFSCx](#)), fault-output (EOUT) signaling ([EOUTENx](#)), or nonmaskable interrupt ([NMIENx](#)).
 - If you enable chip reset as the type of Fault-state reaction for the channel ([NCFSCx](#)), enable either Alarm state ([NCFTOEx](#)) or at least one other type of Fault-state reaction for the channel: fault-output (EOUT) signaling ([EOUTENx](#)) or nonmaskable interrupt ([NMIENx](#)).
 - If you enable Alarm state for the channel ([NCFTOEx](#)), enable the Alarm-state reaction ([IRQENx](#)).
 - If you enable Alarm state for the channel ([NCFTOEx](#)), make sure the Alarm-state timer interval ([TO](#)) is less than the FOSU module's timer interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timer interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information.

NOTE

If you enable a noncritical fault channel but disable all reactions for that channel, FCCU changes state if necessary but doesn't perform any reaction because reactions are disabled. If you enable reactions for a noncritical fault channel but disable that channel, and FCCU is in Normal state when a fault occurs on the channel, FCCU doesn't enter Alarm or Fault state and therefore doesn't perform any reaction.

62.12.2 Recommendations to configure FCCU

1. After a reset cycle in which the FOSU, FCCU, and system are initialized (such as caused by power-up, RESET pin, FOSU reset, or STCU reset), the following steps could be followed to configure FCCU:
 - a. Check and clear any pending fault status
 - b. Verify FCCU is in NORMAL state, else repeat step(a) above
 - c. Configure FCCU
2. After a reset cycle in which the system is re-initialized but the FOSU and FCCU are not re-initialized, the following steps could be followed to reconfigure FCCU:
 - a. If active, wait for the Error out T_min to expire
 - b. Check and clear fault status
 - c. Error pin moves to "non faulty" state, once fault status is cleared and T_min expires

- d. Verify FCCU is in NORMAL state, else repeat step(a) above
- e. Read and verify value in FCCU_NCF_Ex
- f. Reconfigure FCCU, if necessary

Chapter 63

Self-Test Control Unit (STCU2)

63.1 Chip-specific STCU information

The STCU controls the execution of built-in self-tests (BISTs) of the chip.

The STCU manages two primary types of BISTs:

- MBIST: memory (SRAM/ROM) BIST
- LBIST: logic BIST for digital logic

The STCU has two sets of conditions under which it applies a self-test sequence:

- Off-line condition: After the user stores self-test parameters in flash memory and a reset cycle is initiated by a power-up event, RESET pin assertion, or FOSU reset, the STCU loads the stored parameters, executes a self-test, and then resets the chip.
- On-line condition: After the user initiates one or more self-tests during normal chip operation, the STCU executes the self-tests and then resets the chip.

The STCU controls the clocking and the reset of the chip during a self-test.

NOTE

If both MBIST and LBIST are scheduled to be executed, then MBIST should be executed first. LBIST can be executed only after MBIST is completed.

63.1.1 Supported BIST sequences

NXP has validated and therefore supports only particular STCU2 built-in self-test (BIST) sequences for this chip. For descriptions of the supported BIST sequences for this chip, see the Application Note titled *MPC5777C STCU Quick Start Guide* (document AN5288).

63.1.2 Configure or bypass STCU2 off-line self-tests

During reset, the STCU2 has a watchdog timer that can time out and delay exit from reset by at least ~8 ms. To prevent this delay, program DCF records either to configure and run or to bypass STCU2 off-line self-tests at startup.

After programming one set of DCF records either to run or bypass off-line self-tests, do not program subsequent DCF records to change the initial selection of run or bypass.

For information about configuring and running self-tests, see [Supported BIST sequences](#).

To bypass STCU2 off-line self-test operation:

1. Program a DCF record for the client STCU_SKC (see [Table 5-6](#)) to write the Key1 and Key2 codes for off-line self-test. See [STCU2 SK Code Register \(STCU2_SKC\)](#) for details about the register.
2. Program a DCF record for the client STCU_RUN (see [Table 5-6](#)) to write 1 to STCU2_RUN[BYP]. See [STCU2 Run Register \(STCU2_RUN\)](#) for details about STCU2_RUN[BYP].

63.1.3 STCU interfaces to other modules

The STCU interfaces with other modules on the chip, including:

- SSCM: For off-line self-tests, the STCU uses the SSCM DCF bus to load self-test parameters from DCF records in flash memory. After the reset that precedes the off-line self-test, this SSCM interface is able to write the configuration parameters and start the off-line self-test execution only one time.
- IPS bus (Peripheral Bridge):
 - For on-line self-tests, the CPU accesses STCU memory-mapped registers to initiate execution of the self-tests.
 - For both off-line and on-line self-tests, the CPU accesses STCU memory-mapped registers to check self-test results.
- FCCU: For off-line self-tests, the STCU can be configured through DCF records to classify a hardware fault as a critical fault (CF) or non-critical fault (NCF).

- If a subsequent off-line self-test detects a hardware fault that is classified as a NCF, the FCCU's default response is no reaction.
- If a subsequent off-line self-test detects a hardware fault that is classified as a CF, the FCCU responds to the CF by initiating a new reset cycle.

NOTE

On this chip, the critical fault (CF) output of the STCU is connected to a non-critical fault (NCF) input of the FCCU. This input is programmed to issue a reset by default. The FCCU itself is not configured to receive "native" CF inputs.

63.1.4 On-line LBIST and MBIST clock configuration

Before running an on-line LBIST or MBIST, configure clocking as follows to ensure proper execution:

1. PLL0 is the global clock source: Set PLL0 dividers to generate 200 MHz at PLL0's output.
2. Configure PLL0's clock source to be the crystal oscillator (XOSC): Set SIU_SYSDIV[PLL0SEL] to 0.
3. Select the non-FM PLL, PLL0, to drive the system clock: set SIU_SYSDIV[SYSCCLKSEL] to 11b.
4. Disable the Progressive Clock Switch feature: Set SIU_SYSDIV[PCSEN] to 0.
5. Set the System Clock Divider to divide by 1: Set SIU_SYSDIV[SYSCCLKDIV] to 1xx.
6. Set the Peripheral Clock Select: Set SIU_SYSDIV[PERCLKSEL] to 0.
7. Ensure the fm_per_clk divider is 2: Ensure SIU_SYSDIV[FMPPERDIV] is 00b.
8. Set the LFAST clock source to be the peripheral clock coming from PLL: Set SIU_LFCLKCFG[LFCLKSEL] to 10b.
9. Set SIU_SYSDIV[MCANSEL] to 1.
10. Set FlexCAN's CAN_CTRL1[CLKSRC] to 1.
11. Set SWT_A's SWT_CR[CSL] to 0 and SWT_B's SWT_CR[CSL] to 0.

In addition, before executing an on-line MBIST, set the following clock divider values:

1. Set the eTPU clock divider to 2: Set SIU_SYSDIV[ETPUDIV] to 0.
2. Set the TCK divider to 3: Set STCU2_CFG[CLK_CFG] to 010b.

In addition, before executing an on-line LBIST:

- Configure the shift speed clock for the applicable LBIST with a divider equal to or greater than 2: Set the applicable STCU2_LB_CTRL n [SHS] field to a value of 001b or greater.

During an on-line LBIST, clock dividers are bypassed by default.

63.1.5 STCU2_PLL_CFG configuration of PLLDIG_PLL0DV

When used, the STCU2's [PLL interface](#) enables the STCU2 module to control PLL0 during off-line self-test operations. In this case, the values programmed into the fields of the [STCU2 PLL Configuration Register \(STCU2_PLL_CFG\)](#) configure the corresponding fields of the [PLLDIG PLL0 Divider Register \(PLLDIG_PLL0DV\)](#).

The following table shows the correlation between STCU2_PLL_CFG fields and PLLDIG_PLL0DV fields.

Table 63-1. STCU2_PLL_CFG and PLLDIG_PLL0DV field alignment

STCU2_PLL_CFG field	PLLDIG_PLL0DV field
PLLLDF	MFD
PLLIDF	PREDIV
PLLODF	RFDPHI

63.1.6 Wait time for writing to the on-line registers

On this chip, no additional wait time applies to writing the on-line registers.

63.1.7 On-line MBIST

After the STCU2 triggers the execution of an on-line MBIST, the user cannot perform any access until the MBIST ends.

At the end of the execution of an on-line MBIST, the STCU2 does not generate any reset automatically. The reason is that the software application must manage the consequences of write operations that the MBIST's execution performs.

After the execution of an on-line MBIST ends, the user must ensure that memory controllers are in the correct state.

- Reset the chip to clear the memory output.
- If any memory content is destroyed by an MBIST, reload the content after the MBIST.

It is recommended to enable MBIST interrupts only when executing MBISTs exclusively, not MBISTs combined with LBISTs. If an MBIST is combined with an LBIST in the same test run, the LBIST triggers a reset after the test execution, and the MBIST interrupt will be pending coming out of reset.

This chip implements 65 MBIST partitions.

LBIST1	Core0
LBIST2	Checker core, RCCU
LBIST3	Peripheral Bridge B (AIPS_0) and associated peripherals: • SDADC_1 and SDADC_3 • M_CAN Subsystem • CRC • DECFILTER_A to DECFILTER_L • LFAST • DSPI_A, DSPI_B, and DSPI_C • eMIOS_0 • EQADC_A • eSCI_A and eSCI_B • eTPU_C • FCCU including FOSU • FlexCAN_0 and FlexCAN_1 • IGF_0 • PSI5_0 • REACM2 • SRX_0 • SIPI

Table continues on the next page...

Table 63-3. LBIST partition mapping (continued)

LBIST partition	Modules
LBIST4	Peripheral Bridge A (AIPS_1) and associated peripherals: • SDADC_2 and SDADC_4 • CMU_0 to CMU_8 • DSPI_D and DSPI_E • EBI • eMIOS_1 • EQADC_B • eSCI_D, eSCI_E, and eSCI_F • eTPU_A/B • FCCU including FOSU • FlexCAN_2 and FlexCAN_3 • IGF_1 • PIT_RTI • PSI5_1 • SRX_1
LBIST5	Core platform modules: • XBAR • EIM • ERM • PCU • MPU_0 • MPU_1 • CSE • FEC • PFLASH • INTC • PRAMC_0 • PRAMC_1 • eDMA_A • eDMA_B • STM • SWT_A • SWT_B • C55FMC flash memory array

63.1.8.1 Off-line LBIST

The chip supports off-line LBIST operation for all six LBIST partitions.

Summary of an off-line LBIST sequence:

1. The user stores off-line self-test parameters in a DCF record in flash memory. The self-test can include multiple LBIST partitions.
 - For off-line self-tests, LBIST execution on individual LBIST partitions occurs serially. The chip does not support LBIST execution on individual LBIST partitions in parallel.

- An off-line LBIST can run with either the 16 MHz IRC or with PLL0.
 - For an off-line self-test, the STCU can enable and program PLL0 using STCU DCFs.
2. The user resets the chip by cycling power or asserting the RESET pin.
 3. The STCU loads the stored off-line LBIST parameters from the DCF record via the SSCM interface.
 4. The off-line LBIST executes and ends.
 5. Hardware issues a functional reset. The STCU is not affected by this reset.
 6. The user verifies the FCCU channels corresponding to STCU faults. If any fault is flagged, the detailed cause can be checked by reading STCU status registers.

63.1.8.2 On-line LBIST

The chip supports on-line LBIST operation on all six LBIST partitions.

NOTE

When LBIST execution begins, the embedded flash memory must be in an idle state; program or erase operations must not be active. See the [Functional Description](#) of the embedded flash memory for details about its states.

Summary of an on-line LBIST sequence:

1. The user initiates an on-line LBIST by programming STCU memory-mapped registers.
 - An on-line LBIST is able to test only one partition at a time.
 - An on-line LBIST can run with the functional operating frequencies. The maximum-frequency clock for the LBIST partition is derived from PLL0.
 - The user can initiate a sequence of more than one on-line LBIST. Multiple on-line LBISTs can execute serially, with each self-test run on an individual partition.
 - Program the LBRMSW register to generate a global functional reset after an on-line LBIST. Avoid using a dedicated reset due to random data injected by the LBIST Controller.
2. Hardware forces all LBIST partitions into a quiescent state.

3. The on-line LBIST executes and ends.
4. After the completion of the LBIST on-line self-test sequence, hardware issues a functional reset. The STCU is not affected by this reset.
5. The user verifies the FCCU channels corresponding to STCU faults. If any fault is flagged, the detailed cause can be checked by reading STCU status registers.

For on-line LBISTs, this chip does not support the following features:

- Interrupt generation after each LBIST on an individual partition
- Software abort during an on-line LBIST

NOTE

An abort does occur under these conditions:

- A reset cycle is triggered in the middle of a self-test execution.
- The reset source is not POR, RESET pin, FOSU, or the STCU itself.

A reset caused by POR, RESET pin, or FOSU does not cause an abort because it resets the STCU and causes it to run the self-test again. A reset caused by the STCU itself implies successful completion of the self-test procedure.

63.1.8.3 Diagnostic self-test: On-line LBIST from JTAG/Nexus interface

A "diagnostic self-test" is an on-line LBIST that is invoked via the chip's JTAG/Nexus debug/development interface. Via the chip's JTAG pins, a JTAG tool can access the Nexus debug interface in the CPU and use it to configure the STCU without interfering with normal chip operation.

However, after the LBIST of a partition starts, the STCU takes control of the chip, putting all partitions that are not being tested in a quiescent state. The chip resets at the end of the LBIST.

63.1.8.4 Multiple serial LBISTs

The chip allows serial execution of off-line and on-line LBISTs. For example, this sequence is valid:

1. The user programs a DCF record in the flash memory to perform an off-line LBIST.
2. A power-on reset (POR) occurs.
3. The STCU executes the off-line self-test.
4. A functional reset occurs.
5. The CPU boots. The user programs STCU registers using the CPU to execute an on-line LBIST. An on-line LBIST is initiated.
6. A functional reset occurs.
7. The CPU boots again. No off-line or on-line self-test is initiated.

63.1.8.5 LBIST execution and dual cores

On this dual-core chip, either core can program (schedule) execution of an LBIST. After the LBIST of a partition begins, both cores and all other logic not included in that partition are maintained in a reset state. Neither core can operate during the LBIST execution of any partition, regardless of which core initially configured the LBIST.

63.1.9 STCU register default values

The following table documents STCU register default values that are specific to this chip. For the default values of all other STCU registers, see [Register description](#).

NOTE

Some of these registers are DCF clients whose values are overwritten by the values in STCU2-specific DCF records in UTEST flash memory. If the user programs a value for one of these DCF records, the corresponding register reflects the user-programmed value.

Table 63-4. STCU register default values

Register	Default value
STCU2_CFG	0000_0000h
STCU2_PLL_CFG	0000_0000h

Table continues on the next page...

Table 63-4. STCU register default values (continued)

Register	Default value
STCU2_WDG	0000_FFFFh
STCU2_ERR_FM	0000_0000h
STCU2_LBRMSW	0000_003Fh
STCU2_LBUFM	0000_0000h
STCU2_MBUFML, STCU2_MBUFMM, STCU2_MBUFMH	0000_0000h
STCU2_LB_CTRL n	0000_0000h
STCU2_LB_PCS n	0000_0000h
STCU2_LB_MISREL n , STCU2_LB_MISREH n	FFFF_FFFFh
STCU2_LB_MISRR n , STCU2_LB_MISRRH n	0000_0000h
STCU2_LB_MISRELSW n , STCU2_LB_MISREHSW n	FFFF_FFFFh
STCU2_LB_MISRRLSW n , STCU2_LB_MISRRHSW n	0000_0000h
STCU2_MB_CTRL n	0000_0000h

63.1.10 AUTOLOCK_VALUE for register write access and DCF_COMPLETION value for DCF write completion

[Register write-access watchdog timer](#) refers to two clock-cycle values related to the STCU2's write-access watchdog. The following table provides these values on this chip.

Clock-cycle value	Number of STCU2 clock cycles
AUTOLOCK_VALUE	1024
DCF_COMPLETION	16

63.2 Introduction

Self Test Control Unit (STCU2) is a comprehensive programmable hardware module that controls the self test sequence applied both during the Off-Line and/or On-Line conditions. It is able to manage by hardware the device's Logic Built-In Self Test (LBIST) and the SRAM/ROM Built-In Self Test (MBIST) blocks. The STCU2 includes the SSCM DCF bus to load the Self-test parameters (L/MBIST scheduling activity, LBIST setup, Unrecoverable/Recoverable faults management, and MISR expected values, PLL management, and so on) from flash memory during the Off-Line Self-Test phase. This interface is able only to write the configuration parameters and start the Self-

Test execution once after the STCU2 global reset has been applied. The register access by software is granted by an IPS interface with the purpose to check the results of the Off-Line Self-Test but also to load/check the execution of the On-Line Self-Test.

The STCU2 includes:

- A programmable Watchdog timer (WDG) to check the Self-Test operations (both LBIST and MBIST) have been completed within the assigned time slot or the STCU2 RUN or BYPASS bits have been programmed before Watchdog time-out
- The PLL direct control during the Off-Line Self-Test sequence
- Interrupt lines enabled only during the On-Line Self-Test to simplify the software handling of Self-Test execution end
- Two sets of Result registers to collect the L/MBIST result during Off/On-Line Self-Test separately

To increase the security capability of this module, a different Security Key sequence is also required during Off/On-Line Self-Test in order to unlock the write access to the STCU2 registers. The STCU2 also implements two power-saving mechanisms to switch off:

- The global STCU2 clock after Self-Test sequence is completed
- The register ITF clock when the WDG time-out is detected after a Double Security Key sequence is applied during the application run (available only when IPS write access is enabled otherwise the clock is off).

63.3 Main features

- Double registers interface (SSCM DCF with priority over IPS)
- SSCM DCF write one time register interface
- IPS read and write (depends on SSCM enable parameters and STCU2_CFG.WRP bit) register interface
- Programmable scheduler for LBIST/MBIST execution
- LBIST concurrent/sequential execution
- MBIST concurrent/sequential execution
- Programmable LBIST delayed concurrent start

- Programmable Internal clock prescaler to reduce Internal and MBIST/LBIST TCK clocks
- Programmable PLL direct control during Off-Line Self-test sequence
- PLL Lock signal monitoring during Off/On-Line Self Test
- MBIST dedicated On-Line interrupt source generation
- Programmable WDG Timer for Self-Check M/LBIST Time Execution
- Hard Coded WDG time-out to flag off-line initialization faults
- Hard Coded WDG time-out to Auto-lock STCU2 write access after Double-Key sequence
- LBIST and SRAM/ROM MBIST Off-Line status flags
- STCU2 internal errors Off-Line status flag
- LBIST and SRAM/ROM MBIST On-Line status flags
- STCU2 internal errors On-Line Status flag
- LBIST and SRAM/ROM MBIST Off/On-Line programmable failure severity - unrecoverable fault/recoverable fault (UF/RF)
- STCU2 internal errors Off-On/Line programmable failure severity - unrecoverable fault/recoverable fault (UF/RF)
- STCU2 errors (UF/RF) lines for FCCU signaling
- Redundant UF/RF generation logic to improve reliability
- FCCU UF/RF faults injection mechanism
- LBIST MISRE registers access to perform redundant check by software
- Self-Test Bypass capability
- Global write register's protection mechanism based on Double Security Key
- STCU2 Global Auto Power-saving when Self-Test is completed, bypass mode is selected or WDT time-out is detected
- STCU2 ITF/WDG clock wake-up mechanism when software application writes Double Security Key sequence (available when STCU2_CFG.WRP bit is active)
- STCU2 ITF/WDG Auto Power-saving when Hard Coded WDG time-out is detected after software application writes Double Security Key sequence (available when STCU2_CFG.WRP bit is active)

63.4 Block diagram

The top level diagram of the STCU2 module is given in [Figure 63-1](#).

Figure 63-1. STCU2 block diagram

The STCU2 module includes the following sub-modules:

- **Reg interface:** This module includes the registers, the security key logic, the IPS and SSCM DCF bus interface
- **Fault interface:** This module collects the fault conditions related to L/MBIST execution and STCU2 internal failures and, depending on the UF/RF configuration of each one of them, sets the global STCU2 UF or RF flag. It also manages the UF/RF fault lines and the Set/Clear injection mechanism provided by the FCCU. To improve the intrinsic reliability of this critical logic, the generation logic is duplicated.
- **Clock Interface:** This module manages the internal and the L/MBIST TCK clock prescaler, the internal Clock Gating Power Saving and the wake-up clock feature.
- **WDG FSM:** This module includes two different Watchdogs. The first one is Hard Coded and is used to Auto Lock the STCU2 access forcing a reset condition on the Double Security Key registers while the second one has a double functionality. After

a reset event initializes the STCU2, it is used as Hard Coded Watchdog time-out while during L/MBIST run it is used as programmable Watchdog timer to check the L/MBIST have been completed in the assigned L/MBIST time slot.

- **STCU2 Master FSM:** This module includes the main FSM of the STCU2 used to coordinate and schedule all the operations performed during the Self-Test Sequence.
- **STCU2 Load Shifter FSM:** This module includes the common shifter register and the related state machine used to program the L/MBIST registers and read back the data to be checked at the end of each Test operation.
- **LBIST interface:** This module includes the interface between the device's LBIST engines and the STCU2 controllers.
- **MBIST interface:** This module includes the interface between the MBIST controller and STCU2 controllers.

63.5 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus read operations (contiguous byte enables) are supported:

- Word (32 bits) data read operations to any registers
- Low and high half-words (16 bits, data[31:16] or data[15:0]) data read operations to any registers
- Byte(8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data read operations to any registers
- Any other operation (free byte enables or other operations) has to be avoided.

The same operations are also supported in write mode only in the following scenario:

- The Self-Test sequence parameters are loaded before Off-Line Self-test is executed
- The IPS access on a specific register is allowed by software only when the bit STCU2_CFG.WRP is cleared
- In all the other conditions the write operations are not supported and all the STCU2 registers can be only read. Only exceptions are the following read/write bits: STCU2_CFG.WRP, STCU2_ERR_STAT.UFSF and STCU2_ERR_STAT.RFSF. See related register description for additional details

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register
- Any write operation on Double Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Double Security keys have not been applied
- Any write operation performed on registers when the STCU2_CFG.WRP bit is set and the access is performed through software (IPS interface)
- Any write operation performed through software (IPS interface) on Read/On-Line_Write/Off-Line registers
- Any write operation performed off-line on registers in which writing operation is allowed only in the On-Line Self-Test phase when STCU2_CFG[WRP] = 1
- Any write operation performed on Read Only registers

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor or test.

In case there are write operations on bits marked as reserved, the transfer error is not generated.

NOTE

See the chip-specific STCU2 information for the wait time necessary to write to the online registers.

63.6 BISTs and BIST partitions

63.6.1 Definition: BIST

A *built-in self-test (BIST)* is a test that the chip can execute to verify the functional integrity of a part of itself. The chip uses STCU2 and other on-chip hardware to execute a BIST.

63.6.2 Definition: BIST partition

A *built-in self-test (BIST) partition* is a part of a chip for which a BIST has been defined. The hardware that is included in a given BIST partition is chip-specific. For a list of the hardware included in each of the BIST partitions on this chip, see the chip-specific STCU2 information.

63.6.3 Example: BIST partitions on a chip

This is an example of a chip with six built-in self-test (BIST) partitions:

63.6.4 Types of BIST partitions

The STCU2 module on this chip supports the following type or types of built-in self-test (BIST) partitions:

BIST partition type	Description
Memory BIST (MBIST) partition	An SRAM or ROM block
Logic BIST (LBIST) partition	One or more digital modules

63.7 BIST sequences

63.7.1 Definition: BIST sequence

A *built-in self-test (BIST) sequence* is a programmable series of one or more phases, each of which executes one or more individual BISTs.

63.7.2 STCU2 executes MBISTs before LBISTs

If a built-in self-test (BIST) sequence includes both MBISTs and LBISTs, STCU2 executes the MBISTs first.

63.7.3 Example: Single-phase BIST sequence

This is an example of a single-phase BIST sequence in which STCU2 executes only one BIST:

Phase	BIST executed
0	MBIST 16

63.7.4 Example: Multiphase BIST sequence

This is an example of a multiphase BIST sequence in which STCU2 executes more than one BIST in parallel in some phases:

Phase	BISTs executed
0	MBISTs 7, 38
1	MBIST 23
2	MBISTs 6, 16, 29, 23
3	LBIST 12
4	LBISTs 13, 8, 11
5	LBISTs 19, 6

63.7.5 Types of BIST sequences

The STCU2 module on this chip supports these types of built-in self-test (BIST) sequences:

Functional description

BIST sequence type	Description
Online BIST sequence	A BIST sequence that STCU2 executes during runtime at the request of software. Application software configures and initiates execution of the BIST sequence by loading values into STCU2 registers. Use this type of BIST sequence when you want to test the chip hardware but need to minimize the system startup time. Also use it for failure diagnostics and quality control within a manufacturing environment. You can choose the most appropriate point during runtime at which to execute this type of BIST sequence.
Offline BIST sequence	A BIST sequence that STCU2 automatically executes during reset, either when power is first applied to the chip or when the chip resets STCU2. The chip's SSCM module configures and initiates execution of the BIST sequence by loading values into STCU2 registers from Device Configuration Format (DCF) records that are stored in the chip's UTEST flash memory. Use this type of BIST sequence when you want to test the chip hardware before runtime. The location of the DCF record area is chip-specific. The size of the DCF record area is sequence-specific. For the location of the DCF record area, see the chip-specific STCU2 information.

63.7.6 Supported BIST sequences

NXP has validated and therefore supports only specific built-in self-test (BIST) sequences for this chip. For a list of the supported BIST sequences, see the chip-specific STCU2 information.

63.7.7 Definition: Default offline BIST sequence

The *default offline built-in self-test (BIST) sequence* is the offline BIST sequence whose configuration NXP has programmed into the chip's Device Configuration Format (DCF) records that are stored in the chip's UTEST flash memory.

If you choose to use the default offline BIST sequence, or if it's the only one supported by NXP, there is no need to create additional DCF records for the offline BIST sequence.

63.8 Functional description

63.8.1 FSM description

The module has three state machines that work together: Master State Machine, Loader/Shifter State Machine, and the Watchdog State Machine. Basically the Master State Machine is the core unit of the STCU2 module. It coordinates all the Self Test operations and the other State Machines. The Loader/Shifter State Machine is used to program the MBIST and the LBIST parameters and to retrieve the related results depending on the parameters stored into the STCU2 registers and under the control of the Master State Machine. The Watchdog State Machine evaluates all the schedule time for MBIST and LBIST and the time-out in case of wrong STCU2 programming.

63.8.2 Reset management

Assertion of the STCU2 reset input signal initializes the STCU2 module status, forcing the Off-Line Self-Test condition and cleaning up all the registers and state machine of the module.

The reset signals generated by the STCU2 module at the end of the Self-Test execution phase depends on the Self-Test conditions and on the content of the LBRMSW register.

63.8.2.1 Off-Line reset generation

At the end of the Off-Line Self-Test execution the STCU2 raises the global functional reset.

63.8.2.2 On-Line reset generation

See the chip-specific STCU2 information for details about On-Line reset generation.

63.8.3 Built-in self-test scheduling

The STCU2 module has been designed to be very flexible allowing to program the parallel/serial execution of the MBIST or LBIST depending on the power/timing/coverage constraints. The limitation in the programming flexibility is described in [Design implementation information](#).

The mechanism used to provide this flexibility is a linked list where the starting pointer is the bitfield STCU2_CFG.PTR. The first LBIST is mapped on 00h, the second on 01h, and so on. The first MBIST is mapped to the address 10h, the second to 11h and so on.

The additional pointers are in the bitfield STCU2_LB_CTRL[X].PTR for LBIST[X] (where X is the selected LBIST) and STCU2_MB_CTRL[Y].PTR for MBIST (where Y is the selected MBIST) and have to be filled depending on the selected sequence of run. The additional bitfield STCU2_LB_CTRL.CSM and STCU2_MB_CTRL.CSM provide the flexibility to run concurrently or sequentially the chosen set of the LBIST or MBIST or to close the linked list setting the NIL pointer. For more details, see [STCU2 LBIST Control \(STCU2_LB_CTRL_n\)](#) and [STCU2 MBIST Control Register \(STCU2_MB_CTRL_n\)](#).

NOTE

Program operation should ensure that no flash write/erase operations are ongoing when online LBIST is triggered. Otherwise, a flash segment may be corrupted.

63.8.4 PLL interface

The STCU2 module is able to directly control the PLL during the Off-Line Self-Test operations depending on the status of the STCU2_RUN[MBPLEN] and STCU2_RUN[LBPLEN].

When STCU2_RUN[RUN] is set to start the Off-Line Self-test operations, the STCU2 takes control of the PLL and changes the PLL clock configurations parameters according to the values programmed into the STCU2_PLL_CFG register.

When the STCU2_RUN[MBPLEN] is active and the MBIST is currently selected, the STCU2 waits for the PLL lock signal. As soon as the lock happens, the STCU2 forces the clock to switch to the PLL output clock. This allows the MBIST to proceed at the PLL output frequency. At the end of the MBIST run the clock source is reverted to the original one.

Same behavior will be applied when STCU2_RUN[LBPLEN] is active and LBIST is currently selected.

63.8.5 Interrupt interface

Interrupt source:

- Triggered by MBIST (enabled by programming STCU2_RUNSW[MBIE] = 1)

As described in the [STCU2 Run Software Register \(STCU2_RUNSW\)](#) description, the interrupts are generated at the end of any concurrent run. This means that in case of multiple sequential run in the same session, the number of interrupts generated is equivalent to the number of the sequential session providing in such a way a fine granularity with respect to the completed run.

The MBIFLG bit in the [STCU2 Interrupt Flag Register \(STCU2_INT_FLG\)](#) register flag interrupt conditions and allow the clearing of interrupt requests. Interrupt bits are cleared by writing the related flag bit to 1 to enable the next interrupt request.

63.8.6 FCCU interface

The FCCU interface is the hardware flag mechanism towards the system, to indicate the occurrence of an Unrecoverable fault and/or a Recoverable fault failure during the Self Test sequence.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. In this case, the FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set/clear mechanism works.

63.8.7 Watchdogs

The STCU2 implements three different watchdogs to ensure that operations are finished in time.

63.8.7.1 Initialization watchdog timer

The STCU2 has two initialization operating modes: program the self-test sequence and run it (Safety mode) or bypass completely the self-test sequence setting the bit STCU2_CFG.BYP. In case there are faults during the initialization phase preventing the selection of one of these two operating modes, a hard-coded watchdog time-out flags the wrong behavior.

63.8.7.2 Built-in self-test watchdog timer

The LBIST and MBIST execution time has to be configured as described in [STCU2 Watchdog Granularity \(STCU2_WDG\)](#), to account for the overall execution time of the Self-Test sequence. In case the selected LBISTs or MBISTs are not yet completed during the Off-line Self-Test assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into STCU2_ERR_STAT.WDTO and STCU2_MBEL/M/H or STCU2_LBE registers while in case of On-Line Self-Test into STCU2_ERR_STAT.WDTOSW and STCU2_MBELSW/MSW/HSW or STCU2_LBESW.

In case of multiple sequential run in the same On-Line/Off-Line session and the time-out happens in the middle of a sequential run, the next sequential run will be skipped and the execution ends with the current updated status of the registers reported above.

In all the cases, the STCU2 reset generation is managed in one of the modes described in [Reset management](#).

63.8.7.3 Register write-access watchdog timer

As explained in the STCU2_SKC register description:

- A key mechanism protects STCU2 registers during the self-test configuration phase (both online/offline) by preventing any unwanted access.
- A hardware watchdog timer locks register-write access after a number of STCU2 clock cycles. To refresh the hardware watchdog timer before it times out, write only security key 2 to STCU2_SKC.

AUTOLOCK_VALUE is the number of STCU2 clock cycles after which the hardware watchdog timer locks register-write access. See the chip-specific STCU2 information for the value of AUTOLOCK_VALUE.

NOTE

For write completion, each DCF record requires a number of STCU2 clock cycles equal to DCF_COMPLETION. The maximum number of DCF records that can be executed before the watchdog timer must be refreshed is AUTOLOCK_VALUE divided by DCF_COMPLETION. See the chip-specific STCU2 information for the value of DCF_COMPLETION.

The hardware watchdog timer is particularly useful in case STCU2_CFG[WRP] is 0 during the software self-test configuration. In this case, the software application might enable write access to the STCU2 registers.

63.8.8 SSCM interface

The SSCM interface is used to program the STCU2's configuration parameters without the CPU intervention after a reset trigger event initializes the STCU2. This bus interface has the priority over the IPS.

63.9 Register description

During Offline SELFTEST, once the STCU2 registers are configured they cannot be overridden.

During Online SELFTEST, once the STCU2 registers are configured they cannot be overridden via IPS till the selftest is complete.

The STCU2 registers are listed in this section.

STCU2 memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	STCU2 Run Register (STCU2_RUN)	32	R/W	0000_0000h	63.9.1/3166
4	STCU2 Run Software Register (STCU2_RUNSW)	32	R/W	0000_0000h	63.9.2/3167
8	STCU2 SK Code Register (STCU2_SKC)	32	W	0000_0000h	63.9.3/3169
C	STCU2 Configuration Register (STCU2_CFG)	32	R/W	See section	63.9.4/3170
10	STCU2 PLL Configuration Register (STCU2_PLL_CFG)	32	R/W	See section	63.9.5/3173
14	STCU2 Watchdog Granularity (STCU2_WDG)	32	R/W	See section	63.9.6/3174
18	STCU2 Interrupt Flag Register (STCU2_INT_FLG)	32	w1c	0000_0000h	63.9.7/3176

63.9.1 STCU2 Run Register (STCU2_RUN)

The STCU2_RUN register defines the RUN bit to start the off-line self testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0								0							
W						BYP	MBPLEN	LBPLEN								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

STCU2_RUN field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 BYP	Bypass mode 0 Off-Line Self-Test is active. In case the RUN bit into the STCU2_RUN register is not set before the Hard-Coded WDG Time-out, the WDTO error is generated into the STCU2_ERR_STAT register. 1 Off-Line Self-Test is completely bypassed and the access to STCU2 is locked until the STCU2_SKC register is written according to the request access mode.
22 MBPLEN	Off-Line MBIST with PLL Enabled 0 Off-Line MBIST is executed without using the on-chip PLL. 1 Off-Line MBIST is executed enabling the on-chip PLL control interface selecting the parameters defined into STCU2_PLL_CFG register.
23 LBPLEN	Off-Line LBIST with PLL Enabled 0 Off-Line LBIST is executed without using the on-chip PLL. 1 Off-Line LBIST is executed enabling the on-chip PLL control interface selecting the parameters defined into STCU2_PLL_CFG register.
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RUN	RUN: RUN The RUN bit is automatically cleared by the STCU2 when the off-line self testing procedure has been completed. 0 Idle 1 Off-Line Self testing procedure is running

63.9.2 STCU2 Run Software Register (STCU2_RUNSW)

The STCU2_RUNSW register defines the RUN bit to start the on-line self testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when both of the following conditions are true:

- STCU2_CFG[WRP] = 0
- On-line Self-Test phase is active. The On-Line condition starts when the Off-Line is over. In this condition, system is alive and the SW can program the STCU2

STCU2_RUNSW field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 MBIE	MBIST Interrupt Enable 0 Interrupt is not generated at the end of the software MBIST execution phase of the selected Memories. 1 At the end of the software MBIST execution phase of the concurrent selected memories the STCU2 forces an interrupt request to notify that MBISTs of concurrent selected memories are over. In case there is a sequence of concurrent runs in the same Self-Test run, the interrupt request is generated at the end of each concurrent runs provided that the software will clear the STCU2_INT_FLG[MBIFG] bit in between.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 MBSWPLEN	On-Line MBIST with PLL Enabled 0 On-Line MBIST is executed without using the on-chip PLL. 1 On-Line MBIST is executed using the PLL configuration provided by software. STCU2 does not take the PLL control but monitors the PLL lock signal to check if PLL is working correctly.
23 LBSWPLEN	On-Line LBIST with PLL Enabled 0 On-Line LBIST is executed without using the on-chip PLL. 1 On-Line LBIST is executed using the PLL configuration provided by software. STCU2 does not take the PLL control but monitors the PLL lock signal to check if PLL is working correctly.
24–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RUNSW	RUNSW The RUNSW bit is automatically cleared by the STCU2 when the on-line self testing procedure has been completed. 0 Idle 1 On-line self testing procedure is running

63.9.3 STCU2 SK Code Register (STCU2_SKC)

The STCU2_SKC register implements the security key code mechanism needed to access in write mode to the other STCU2 registers. In order to unlock the STCU2 access after:

- The STCU2 asynchronous reset
- The end of the STCU2 run

the software (IPS bus) or the SSCM interfaces have to apply the following sequence:

- write the key1 into the STCU2_SKC register
- write the key2 into the STCU2_SKC register

Depending on the off/on-line test step, the two keys will be different. Byte write operation is not allowed since the full key has to be recognized as one unit.

It should be noted that after the Self-Test sequence has been completed or the Bypass feature has been enabled (setting the bit BYP into the STCU2_CFG), the SSCM interface is no longer available.

In case of invalid access or sequence (Key1/2 have to be applied consecutively), a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked and to unlock the access the sequence has to be applied again.

In case the STCU2 register access lasts more cycles than the one defined into the Hard-coded WDG time-out, the STCU2 write access is locked and the WDG and Register ITF clocks are switched off. Also in this case, in order to enable again the write access to the STCU2 and the WDG and Register ITF clocks, it is required to apply again the sequence.

In case it is required to extend the STCU2 register access cycles before the Hard-coded WDG time-out expires, only the Key2 has to be applied. The effect of this write operation is to re-initialize the WDG time-out counter. In such a condition, Key1 has not to be applied otherwise a transfer error on the IPS bus is asserted depending on the selected source. The STCU2 write access is locked and to unlock the access the sequence has to be applied again.

The STCU2_SKC register is not readable. The value 00000000h is always returned in case of read operation.

63.9.4 STCU2 Configuration Register (STCU2_CFG)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_CFG register includes the global configuration of the STCU2 and can be updated both in the Off/On-Line Test steps.

The access to this register is described in the following figure. It further depends on the state of the WRP bit as follows:

- When WRP = 0: The register can be written during the on-line Self-Test case without restrictions
- When WRP = 1:
 - The only bit that can be written without any restriction is WRP.
 - In case there are software operations that write all the register's bits, a transfer error is raised only if the value of the selected byte written differs from the current status of the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

MBIST can be run in three different test types according to how the STCU2_CFG register bits 27 and 28 are set.

The following table describes the test algorithm and coverage of the different test types.

Table 63-10. MBIST algorithm and coverage according to test type

MBIST Type	STCU2_CFG[PM OSEN]	STCU2_CFG[MB U]	MBIST Algorithm	Internal Nodes/ Circuits Additionally Covered by Test	Use Case	Test Cycle
Full Test	1	0	Test memory using all built in algorithms. Open PMOS algorithm included	Address Decoder and Bitcell as well as resistive defects in the address decoder	Used by MCU production test. Recommended to use in the field for MBIST online self-test.	About 3 to 4x more than Auto Test
Reduced Test	0	0	Test memory using all built in algorithms except the open PMOS algorithm.	Address Decoder and Bitcell	Recommended to use in the field for MBIST online self-test if the Full Test takes too long.	About 10% less than Full Test
Auto Test	x	1	A smaller set of algorithms which target latent defect mechanisms.	Latent defects such as NBTI of the PMOS transistors in the bitcells	Recommended to use for MBIST offline self-test as an optimum balance of test time vs. fault coverage.	About 3 to 4x faster than Full Test

STCU2_CFG field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 PTR	LBIST or MBIST pointer PTR defines the logical pointer to the first LBIST or MBIST to be scheduled when the self testing procedure is enabled. PTR is the entry pointer to a linked list of BIST descriptors. If PTR = 0 then the LBIST0 is initially scheduled.

Table continues on the next page...

STCU2_CFG field descriptions (continued)

Field	Description
	You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0. 0h to (LBIST -1): pointer to LBIST 10h to (10h + MBIST -1): pointer to MBIST 7Fh: pointer to NIL. No BIST execution.
8–15 LB_DELAY	Delay LBIST run LB_DELAY defines the delay between the LBIST starts when more than a single LBIST is selected to be executed concurrently with the purpose of smoothing the power consumption transient. The allowed delay time are the following: 00h: No delay 01h: 1 x16 STCU2 Core clock cycles 02h: 2 x 16 STCU2 Core clock cycles 03h: 3 x 16 STCU2 Core clock cycles ... FDh: 253 x 16 STCU2 Core clock cycles FEh: 254 x 16 STCU2 Core clock cycles FFh: 255 x 16 STCU2 Core clock cycles Note that in case the Frequency of the STCU2 core clock is 16 MHz, the delay parameters is expressed in μs. NOTE: This field should be written with 0xFF for self test run. You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 WRP	Write Protection 0: Specific STCU2 registers can be written through IPS bus interface after Off-Line Self-Test sequence has been completed 1: Specific STCU2 registers cannot be written though IPS also after Off-Line Self-Test sequence has been completed preventing in such a way any user application write operation
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 PMOSEN	MBIST PMOS Test Enable When MBU is 1 then "Auto test" MBIST test type will be selected regardless of the setting of this field. 0 When MBU is 0 then selects the "Reduced test" MBIST test type. 1 When MBU is 0 then selects the "Full test" MBIST test type.
28 MBU	MBIST MBU Test Enabled 0 Either "Full test" or "Reduced test" MBIST test type will be selected according to the PMOSEN value. 1 Selects "Auto test" MBIST test type regardless of the PMOSEN value.

Table continues on the next page...

STCU2_CFG field descriptions (continued)

Field	Description
29–31 CLK_CFG	Logic, Memory BIST and STCU2 core CLK Clock configuration CLK_CFG defines the ratio between the sys_clk and the TCK used to program both the LBIST and the MBIST and the STCU2 core clock. The punch-out mechanism is used to generate the derived clocks. The allowed configurations are the following: 000: sys_clk 001: sys_clk/2 010: sys_clk/3 ... 101: sys_clk/6 110: sys_clk/7 111: sys_clk/8 You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0.

63.9.5 STCU2 PLL Configuration Register (STCU2_PLL_CFG)**NOTE**

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_PLL_CFG register defines the parameters used to program the PLL only when the Off-line L/MBIST are performed and STCU2_RUN[MBPLEN] = 1 or STCU2_RUN[LBPLEN] = 1.

In the On-line condition, these bits are not effective. It is also possible to set the PLL during active On-line mode to prevent any potential functionality issue.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- The reset value is chip-specific; see the chapter that describes how modules are configured and connected. x = Undefined at reset.

STCU2_PLL_CFG field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 PLLODF	PLL Output Division Factor The value of this field drives the Output Division factor of the PLL embedded into the device. Refer to the PLL specifications to define the exact mapping between the PLLODF value and the related PLL's Output Division factor.
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 PLLIDF	PLL Input Division Factor The value of this field drives the Input Division factor of the PLL embedded into the device. Refer to the PLL specifications to define the exact mapping between the PLLIDF value and the related PLL's Input Division factor.
16–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 PLLLDF	PLL Loop Division Factor The value of this field drives the Loop Division factor of the PLL embedded into the device. Refer to the PLL specifications to define the exact mapping between the PLLLDF value and the related PLL's Loop Division factor.

63.9.6 STCU2 Watchdog Granularity (STCU2_WDG)**NOTE**

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_WDG register defines the time limit for LBIST and MBIST execution, providing a protection mechanism in case of deadlock or endless conditions during the self test procedure.

When the offline self test sequence is not run and the STCU2_CFG[BYP] field is not set, bits 15..0 define the time-out before the STCU2_ERR[WDTO] field is set and the STCU2 core clock is switched off.

In case offline/online self test sequence is run, the STCU2_WDG value defines the time-out of the execution run.

The register fields are always readable. You can write to these fields when either of the following conditions is true:

- Offline self test phase is active
- Online self test phase is active and CFG[WRP] = 0

Address: 0h base + 14h offset = 14h

- * Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

STCU2_WDG field descriptions

Field	Description
0–31 WDGEOC	Watchdog End of Count Timer This value defines the time limit for offline and online self test execution to ensure correct operation within the allowed time. NOTE: If this register is programmed while STCU2_RUN[RUN]=1, the new STCU2_WDG value, programmed after STCU2_RUN, does not take effect. The allowed values are: 0000 0000h: 1 × 16 STCU2 Core clock cycles 0000 0001h: 2 × 16 STCU2 Core clock cycles 0000 0002h: 3 × 16 STCU2 Core clock cycles ... FFFF FFFDh: 4294967294 × 16 STCU2 Core clock cycles FFFF FFFEh: 4294967295 × 16 STCU2 Core clock cycles FFFF FFFFh: 4294967296 × 16 STCU2 Core clock cycles

63.9.7 STCU2 Interrupt Flag Register (STCU2_INT_FLG)

The STCU2_INT_FLG register includes an MBIST interrupt pending bit. The bit is effective only during the On-Line Self-Test phase and is managed only when the related control bit in the STCU2_RUNSW register (MBIE) is enabled.

Address: 0h base + 18h offset = 18h

STCU2_INT_FLG field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 MBIFLG	MBIST Interrupt Flag 0 No interrupt is pending 1 An interrupt, highlighting that the On-Line execution of the concurrent scheduled MBIST is completed, is pending. Write 1 to clear the bit.
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

63.9.8 STCU2 Error Register (STCU2_ERR_STAT)

The STCU2_ERR_STAT register includes the status flags related to the STCU2 internal fault conditions occurred during the configuration or the On/Off-Line self testing execution.

The UFSF and RFSF can be set/cleared using the FCCU dedicated channels.

The access to this register is described in the following figure and as follows:

- If you select the byte write capability to write only the UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set/clean capability.

Address: 0h base + 24h offset = 24h

8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 LOCKESW	On-Line LOCK Error You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 In case PLL is enabled, it is correctly locked during the Self-Test sequence 1 When the PLL is enabled, this flag highlight that there has been an unexpected PLL unlock event during the On-Line Self-Test sequence execution. The On-Line Self-test run is stopped and the status of the current running LBISTs or MBISTs is saved into the related registers. The LOCK signal is monitored during the LBIST run when STCU2_RUNSW.LBSWPLEN is set and/or during the MBIST run when STCU2_RUNSW[MBSWPLEN] = 1.
12 WDTOSW	On-Line Watchdog time-out You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 LBIST and MBIST time slot have been completed within the assigned watchdog time. 1 LBIST and MBIST time slot haven't been completed within the assigned watchdog time or there are internal mismatches among End of Execution signals. The conditions that flag the failures are the following: • MBIST BEND status flags that at least one of the selected MBIST run is not finished • lbist_done of the selected LBIST flags the LBIST run is/are not finished
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 ENGESW	On-Line Engine Error

Table continues on the next page...

STCU2_ERR_STAT field descriptions (continued)

Field	Description
	You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: • STCU2 state machines (Watchdog, Master and Loader/Shifter) selects an unused code • Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned • Serial bend status of the selected MBIST and the global BEND flag are not aligned
15 INVPSW	On-Line Invalid Pointer You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: • Initial LBIST or MBIST pointer is out of range • LBIST is selected when MBIST is concurrently running or vice versa • Error in the LBIST/MBIST linking (execution generates an infinite loop)
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 UFSF	Unrecoverable Faults Status Flag This flag reports the global status of the UF. This field can be set or cleared using the FCCU dedicated channel, and can also be set or cleared by software. 0 No errors that trigger the Unrecoverable Faults condition 1 There are errors that trigger the Unrecoverable Faults condition
23 RFSF	Recoverable Faults Status Flag This flag reports the global status of the RF. This field can be set or cleared using the FCCU dedicated channel, and can also be set or cleared by software. 0 No errors that trigger the Recoverable Faults condition 1 There are errors that trigger the Recoverable Faults condition
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LOCKE	Off-Line LOCK Error 0 The PLL is correctly locked during the Self-Test sequence 1 When the PLL is enabled, this flag highlights that there has been an unexpected PLL unlock event during the Off-Line Self-Test sequence execution. The Off-Line Self-test run is stopped and the status of the current running LBISTs or MBISTs is saved into the related registers. The LOCK signal is monitored during the LBIST run when STCU2_RUN[LBPLEN] = 1 and/or during the MBIST run when STCU2_RUN[MBPLEN] = 1.
28 WDTO	Off-Line Watchdog time-out 0 LBIST and MBIST time slot have been completed within the assigned watchdog time. 1 LBIST and MBIST time slot haven't been completed within the assigned watchdog time or there are internal mismatches among End of Execution signals. The conditions that flag the failures are the following: • The STCU2_RUN[RUN] bit or the STCU2_RUN[BYP] bit is not set before the Watchdog reaches the End of Count

Table continues on the next page...

STCU2_ERR_STAT field descriptions (continued)

Field	Description
	• MBIST BEND status flags that at least one of the selected MBIST run is not finished • lbist_done of the selected LBIST flags the LBIST run is/are not finished
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 ENGE	Off-Line Engine Error 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: • STCU2 state machines (Watchdog, Master and Loader/Shifter) selects an unused code • Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned • Serial bend status of the selected MBIST and the global BEND flag are not aligned
31 INVP	Off-Line Invalid pointer 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: • Initial LBIST or MBIST pointer is out of range • LBIST is selected when MBIST is concurrently running or vice versa • Error in the LBIST/MBIST linking (execution generates an infinite loop)

63.9.9 STCU2 Error FM Register (STCU2_ERR_FM)**NOTE**

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_ERR_FM register defines the fault mapping of the STCU2 faults described into the register STCU2_ERR_STAT in terms of Unrecoverable or Recoverable Fault. All sources of internal faults can be routed to UF and RF.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 28h offset = 28h

STCU2_LBE field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 LBE5	Off-Line End status of the selected LBIST 0 LBIST execution not yet completed 1 LBIST execution finished
27 LBE4	Off-Line End status of the selected LBIST 0 LBIST execution not yet completed 1 LBIST execution finished
28 LBE3	Off-Line End status of the selected LBIST 0 LBIST execution not yet completed 1 LBIST execution finished
29 LBE2	Off-Line End status of the selected LBIST 0 LBIST execution not yet completed 1 LBIST execution finished
30 LBE1	Off-Line End status of the selected LBIST 0 LBIST execution not yet completed 1 LBIST execution finished
31 LBE0	Off-Line End status of the selected LBIST 0 LBIST execution not yet completed 1 LBIST execution finished

63.9.12 STCU2 On-Line LBIST Status Register (STCU2_LBSSW)

The STCU2_LBSSW register includes the results corresponding to the execution of the selected On-Line LBIST.

The size of the register depends on the number of LBIST .

The content of this register is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1.

Register description

31 LBESW0	LBESWx: On-Line LBIST End status 0 LBIST execution not yet completed 1 LBIST execution finished

63.9.14 STCU2 On-Line LBIST Reset Management (STCU2_LBRMSW)**NOTE**

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LBRMSW register defines the On-Line reset mapping for each LBIST. Global or specific functional reset can be programmed depending on the On-Line Self-Test requirements and top level integration architecture.

The size of the register depends on the number of LBIST .

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 3Ch offset = 3Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*	x*

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
30 LBRMSW1	On-Line LBIST Reset Management NOTE: In case one of the selected LBIST has this bit set to '1', then only the Global functional reset will be pulsed. 0 Dedicated functional reset is pulsed at the end of LBIST run 1 Global functional reset is pulsed at the end of LBIST run
31 LBRMSW0	On-Line LBIST Reset Management NOTE: In case one of the selected LBIST has this bit set to '1', then only the Global functional reset will be pulsed. 0 Dedicated functional reset is pulsed at the end of LBIST run 1 Global functional reset is pulsed at the end of LBIST run

63.9.15 STCU2 LBIST Unrecoverable FM Register (STCU2_LBUFM)**NOTE**

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LBUFM register defines the fault mapping of each LBIST in terms of Unrecoverable or Recoverable Fault.

The size of the register depends on the number of LBIST .

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 40h offset = 40h

63.9.24 STCU2 On-Line MBIST Status High Register (STCU2_MBSHSW)

The STCU2_MBSHSW register includes the results corresponding to the execution of the selected On-Line MBIST in the range NMCUT = 64..95.

The size of the register depends on the number of BISTed RAMs/ROMs.

The content of this register is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1.

Address: 0h base + 64h offset = 64h

63.9.27 STCU2 On-Line MBIST End Flag High Register (STCU2_MBEHSW)

The STCU2_MBEHSW register includes the End Flag related to the execution of the selected On-Line MBIST in the range NMCUT = 64-95.

The size of the register depends on the number of BISTed RAMs/ROMs.

The content of this register is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1.

Address: 0h base + 70h offset = 70h

STCU2_MBEHSW field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 MBESW64	MBESWx: On-Line End status (64 to 95) of the selected MBIST 0 MBIST execution still ongoing 1 MBIST execution finished

63.9.28 STCU2 MBIST Unrecoverable FM Low Register (STCU2_MBUFML)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_MBUFML register defines the fault mapping, in terms of Unrecoverable or Recoverable fault, of the MBIST in the range NMCUT = 0-31.

The size of the register depends on the number of BISTed RAMs/ROMs.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 74h offset = 74h

63.9.29 STCU2 MBIST Unrecoverable FM Medium Register (STCU2_MBUFMM)**NOTE**

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_MBUFMM register defines the fault mapping, in terms of Unrecoverable or Recoverable fault, of the MBIST in the range NMCUT = 32-63.

The size of the register depends on the number of BISTed RAMs/ROMs.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

STCU2_LB_CTRLn field descriptions

Field	Description
0 CSM	Concurrent/sequential mode

Table continues on the next page...

STCU2_LB_CTRLn field descriptions (continued)

Field	Description
	The next LBIST is scheduled concurrently to the current one if the CSM bit is set to 1; otherwise, it is scheduled sequentially to the completion of the current LBIST execution. 0 Sequential mode 1 Concurrent mode
1–7 PTR	Next LBIST pointer PTR defines the logical pointer to the next LBIST. In case of NIL pointer the CSM bit has to be set Sequential (0) to define this is the end of the list. The self testing procedure is stopped when the current LBIST has been completed. LBIST POINTERS 0000b - pointer to LBIST partition 0 0001b - pointer to LBIST partition 1 0010b - pointer to LBIST partition 2 0011b - pointer to LBIST partition 3 0100b - pointer to LBIST partition 4 0101b - pointer to LBIST partition 5 ... 0x7F - pointer to NIL, end of LBIST execution Values not defined in this list will result in an error being set in the STCU2_ERR register.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 Reserved	This field is reserved. NOTE: This reserved field is writeable but do not write any value to it other than its reset value
12 Reserved	This field is reserved. NOTE: This reserved field is writeable but do not write any value to it other than its reset value
13–15 SHS	Shift speed SHS defines the shift speed 000 Shift at full rate of STCU2 core clock 001 Shift at 1/2 rate of STCU2 core clock 010 Shift at 1/3 rate of STCU2 core clock 011 Shift at 1/4 rate of STCU2 core clock 100 Shift at 1/5 rate of STCU2 core clock 101 Shift at 1/6 rate of STCU2 core clock 110 Shift at 1/7 rate of STCU2 core clock 111 Shift at 1/8 rate of STCU2 core clock
16–19 SCEN_OFF	Scan enable OFF SCEN_OFF defines the number of clock cycles OFF following the falling transition on the SCEN NOTE: Scen_off must be programmed to a value >=1 0000 0 delay cycles 0001 1 delay cycle

Table continues on the next page...

STCU2_LB_CTRLn field descriptions (continued)

Field	Description
	0010 2 delay cycles 0011 3 delay cycles 0100 4 delay cycles 0101 5 delay cycles 0110 6 delay cycles 0111 7 delay cycles 1000 8 delay cycles 1001 9 delay cycles 1010 10 delay cycles 1011 11 delay cycles 1100 12 delay cycles 1101 13 delay cycles 1110 14 delay cycles 1111 15 delay cycles
20–23 SCEN_ON	Scan enable ON SCEN_ON defines the number of clock cycles OFF following the rising transition on the SCEN NOTE: Scen_on delay register value must be programmed to a value ≥ 1 0000 0 delay cycles 0001 1 delay cycle 0010 2 delay cycles 0011 3 delay cycles 0100 4 delay cycles 0101 5 delay cycles 0110 6 delay cycles 0111 7 delay cycles 1000 8 delay cycles 1001 9 delay cycles 1010 10 delay cycles 1011 11 delay cycles 1100 12 delay cycles 1101 13 delay cycles 1110 14 delay cycles 1111 15 delay cycles
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 PFT	Past Flush Test The LBIST controller, by default, applies 32 Flush Test patterns. This bit allows to skip/apply the Flush test pattern sequence. 0 Apply Flush Test Patterns 1 Skip Flush Test Patterns
29–31 CWS	Capture window size CWS defines the capture window size. 000 illegal

Table continues on the next page...

STCU2_LB_CTRLn field descriptions (continued)

Field	Description
001	controller waits 1 shift cycle for capture to finish
010	controller waits 2 shift cycles for capture to finish
011	controller waits 3 shift cycles for capture to finish
100	controller waits 4 shift cycles for capture to finish
101	controller waits 5 shift cycles for capture to finish
110	controller waits 6 shift cycles for capture to finish
111	controller waits 7 shift cycles for capture to finish

63.9.32 STCU2 LBIST PC Stop Register (STCU2_LB_PCSn)**NOTE**

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LB_PCS register defines the pattern counter stop of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 104h offset + (64d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- The reset value is chip-specific; see the chapter that describes how modules are configured and connected. x = Undefined at reset.

STCU2_LB_PCSn field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–31 PCS	Pattern counter stop PCS defines the pattern counter stop value.

63.9.33 STCU2 Off-Line LBIST MISR Expected Low Register (STCU2_LB_MISREL_n)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LB_MISREL register defines the LSB part (31-0) of the Expected MISR of the Off-Line LBIST controller.

The size of the register depends on the number of MISR bits of the related LBIST.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Address: 0h base + 110h offset + (64d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

STCU2_LB_MISRRHSW_n field descriptions

Field	Description
0–31 MISRRSWx	On-Line MISR Read High Bits This field is equivalent to the Low Bits (63-32) of the MISR obtained at the end of the Off-Line LBIST execution.

63.9.41 STCU2 MBIST Control Register (STCU2_MB_CTRL_n)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_MB_CTRL register defines the control setting of MBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

The offset of this register is a function of NMCUT .

Address: 0h base + 600h offset + (4d × i), where i=0d to 64d

STCU2_MB_CTRLn field descriptions

Field	Description
0 CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode
1–7 PTR	Next LBIST or MBIST pointer PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST or MBIST is scheduled concurrently to the current one if the CSM bit is set to 1; otherwise it is scheduled sequentially to the completion of the current MBIST execution. In case of NIL pointer the CSM bit must be set Sequential (0) to define this is the end of the list. The self-testing procedure is stopped when the current MBIST has been completed. 0h to (LBIST -1): pointer to LBIST 10h to (10h + MBIST -1b): pointer to MBIST 7Fh: pointer to NIL. No BIST execution. others: invalid pointer => an error is set into the STCU2_ERR register.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

63.10 Use cases and limitations

The STCU2 module is designed to give high flexibility during the on/off-line test. In the following are reported the programming operations that have to be performed to correctly use the functionality of this module considering the three typical usage cases:

- the Off-line Self Test Sequence after a reset trigger event
- the bypass mode of the Self Test Sequence after a reset trigger event
- the On-line Self-test Sequence

63.10.1 Offline self-test sequence

This is the typical mode of using the STCU2 module after reset trigger event is applied to STCU2. The SSCM DCF bus is used to retrieve the STCU2 schedule and L/MBIST execution parameters stored into the NVM memory. The target is to cover the amount of physical defects in the digital logic and in the System RAMs/ROMs according to the System specifications. The sequence is the following:

- Unlock the Off-Line STCU2 access writing the Key1/Key2 sequence into the STCU2_SKC register
- Program the LBIST fault reaction conditions (UF/RF) setting the STCU2_LBUFM register
- Program the MBIST fault reaction conditions (UF/RF) setting, depending on the number of memories, the STCU2_MBUFML/M/H registers
- Program the STCU2 internal fault reaction conditions (UF/RF) setting the STCU2_ERR_FM register
- Program the STCU2_LB_CTRL, STCU2_LB_PCS, STCU2_MISREL/H registers of each LBIST to be executed.
- Program the STCU2_MB_CTRL registers of each NMCUT to be executed
- Program the STCU2_WDG register to define the time budget assigned for the L/MBIST execution
- Program the STCU2_CFG register to define: the core and LBIST/MBIST TCK clock prescaling factor setting the CLK_CFG bits, the LB_DELAY field to delay the LBIST start when many LBIST are run concurrently to mitigate the potential transient power issue during the start-up phase, the PMOSEN or MBU in order to define the algorithm to be used during MBIST run, and finally set the pointer to the first LBIST/NMCUT to be executed
- In case the PLL usage has been enabled, program the STCU2_PLL_CFG value in order to set the required system frequency
- Program the RUN bit into the STCU2_RUN register to enable the Off-Line Self-Test execution and the L/MBPLEN bits to enable the PLL during L/MBIST execution according to STCU2_PLL_CFG register content
- Start the Off-Line Self-Test and, depending on PLL management and L/MBIST execution order, when PLL LOCK is high.
- Wait the WDGEOC run time execution specified into the STCU2_WDG register.
- The STCU2 switches off the core clock at the end of the Self-Test run and releases the PLL control in case this feature has been enabled.
- The STCU2 resets the STCU2_RUN[RUN] bit and the device exits from boot sequence. In case there are failures, the STCU2 flags these failures toward the FCCU.
- The software application reads the STCU2_LBS flag register to check the failed LBIST when UF or RF conditions is/are detected.
- The software application reads the STCU2_LBE flag register to check the LBIST still on-going when UF or RF is/are detected.

- The software application reads the STCU2_MBSL/M/H flag registers, depending on the number of memories, to check the failed RAMs/ROMs Memory BIST when UF or RF is/are detected.
- The software application reads the STCU2_MBEL/M/H flag registers, depending on the number of memories, to check if the RAMs/ROMs Memory BIST is still on-going when UF or RF is/are detected.
- The software application reads the bits INV, ENGE, WDTO, LOCKE of the STCU2_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF is/are detected.
- The software application reads for each device's LBIST, the STCU2_LBMISREL/H and STCU2_LBIST_MISRRL/H registers to check the coherence with the STCU2_LBS bits.

NOTE

The software application reads operations on the STCU2 and LBIST MISR registers after off-line self test execution has been successfully performed are just an additional reliability layer added to improve the already implemented Auto Self-Test feature included into STCU2.

63.10.2 Online self test sequence

The online self test sequence is the most commonly used STCU2 application mode. The IPS interface is used to program the STCU2 registers and to schedule LBIST and MBIST execution. Since online LBIST and MBIST operations clean-up the content of Digital Logic (LBIST) or RAM (MBIST) tested, activation of this mode must be approached with caution. The suggested sequence is the following:

1. Write the Key1/Key2 sequence to the SKC register to unlock online STCU2 access.
2. Ensure CFG[WRP]=0 to enable IPS bus access to the online self test registers.
3. If required, program the following registers to select the LBIST, MBIST and STCU2 internal fault reaction: LBUFM, MBUFML/M/H and ERR_FM.

NOTE

The LBIST, MBIST and STCU2 internal fault reaction should have been already programmed during the offline self test sequence and so there should be no need to program again. However, in case they have not been

programmed or there is the need of changing them for any reason, they can be overwritten.

4. Select the reset management options for online LBIST execution by programming the LBRMSW register.
5. The LB_CTRL and LB_PCS registers should have been already programmed during offline self test sequence and so they should not need to be programmed again. However, if they have not been programmed or there is the need of changing them for any reason, they can be overwritten. The registers LB_MISRELSW/HSW have to be programmed according to the expected signature.
6. Overwrite/Program the MB_CTRL registers of each NMCUT to be executed.
7. Overwrite/Program the WDG register to define the time budget assigned for the L/MBIST execution
8. Overwrite/Program the CFG register to define: the core and L/MBIST TCK clock prescaling factor setting the CLK_CFG bits, the LB_DELAY field to delay the LBIST start when many LBIST are run concurrently to mitigate the potential transient power issue during the start-up phase, the PMOSEN or MBU in order to define the algorithm to be used during MBIST run, and finally set the pointer to the first LBIST/NMCUT to be executed.
9. Program the RUNSW[RUNSW] field to enable online self test execution; the L/MBSWPLEN bits to enable the PLL lock signal monitor during L/MBIST execution and the MBIE to enable the related Interrupt requests.
10. Start the online self test and depending on PLL management and L/MBIST execution order, also when PLL LOCK is high.
11. Wait the WDGEOC run time execution specified into the WDG register
12. In case the MBIE have been enabled, an interrupt is generated at the end of all the MBIST execution. The software application has to manage these interrupt signals and clean-up the related flag (MBIFLG) into the INT_FLG register.
13. The STCU2 switch-off the core clock at the end of the self test run
14. The functional reset activated is managed by the LBRMSW register (See step 4).
15. In case, at least one of the selected LBIST enables the Global functional reset, the STCU2 requests a functional reset which restarts the system while, when all the selected LBIST enables its own dedicated functional reset, only these local reset lines are applied and only the related LBIST partitions are cleaned-up.
16. The STCU2 resets the RUNSW[RUNSW] field. In both the reset cases and in case of fault/s, the STCU2 flags the failure toward the FCCU.
17. The software application reads the LBSSW flag register to check the failed LBIST when UF or RF conditions is/are detected.
18. The software application reads the LBESW flag register to check if the LBIST is still on-going when UF or RF is/are detected.

19. The software application reads the MBSLSW/MSW/HSW flag registers, depending on the number of memories, to check the failed RAMs/ROMs Memory BIST when UF or RF is/are detected.
20. The software application reads the MBELSW/MSW/HSW flag registers, depending on the number of memories, to check if the RAMs/ROMs Memory BIST is still on-going when UF or RF is/are detected.
21. The software application reads the bit INVPSW, ENGESW, WDTOSW, LOCKESW of the ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF is/are detected.
22. The software application reads for each device's LBIST, the LBMISRELSW/HSW and LBIST_MISRRLSW/HSW registers to check the coherence with the LBS bits

NOTE

1. A reset is necessary after running any kind of online self test.
2. The software application read operations on the STCU2 and LBIST MISR registers after successful online self test execution are an additional reliability layer to improve the auto-self-test feature included in the STCU2.
3. Flash memory must be in the idle state when BIST execution is started. Program and erase functionality must not be enabled when entering BIST execution.

63.10.3 Bypass USER Mode

In this case, the USER application parameters stored in FLASH and read by SSCM are written in order to skip the Self-Test procedure after a reset trigger event is applied. It might be useful in case the device is not configured for applications requiring improved reliability. The sequence is the following:

1. Unlock the STCU2 access writing the Off-Line Key1/Key2 sequence into the STCU2_SKC register
2. Set the BYP bit in the STCU2_RUN register

After BYP bit is set, the core clock is switched off, the Self-Test sequence is not applied and the system can wake up and start the user application.

63.10.4 Design implementation information

The following list reports the limitations related to the current implementation:

- Every NMCUT BIST can be run once during the online or offline self-test procedure.
- It is not possible to run LBIST and MBIST concurrently.
- Because software has full control of the system while applications are running during the online self-test, STCU2 is not allowed to take control of the PLL but can just monitor the lock signal to flag wrong unlock events.

Chapter 64

Cyclic Redundancy Check (CRC) Unit

64.1 Chip-specific CRC information

This chip has one instance of the CRC module. It supports three contexts: $N = 3$.

64.2 Introduction

The Cyclic Redundancy Check (CRC) computing unit is dedicated to the computation of CRC, off-loading the CPU. Each context has a separate CRC computation engine in order to allow the concurrent computation of the CRC of multiple data streams. The CRC computation is performed at speed without wait-state insertion. Bit-swap and bit-inversion operations can be applied on the final CRC signature. Each context can be configured with one of three hard-wired polynomials, normally used for most of the standard communication protocols. The data stream supports multiple data width (byte/halfword/word) formats.

64.3 Main features

- Three contexts for the concurrent CRC computation are supported
- Separate CRC engine for each context
- Zero-wait states during the CRC computation (pipeline scheme)
- Three hard-wired polynomials (CRC-8, CRC-32 ITU-T V.42, and CRC-16-CCITT)
- Support for byte, halfword, or word width of the input data stream

64.3.1 Standard features

- Peripheral bus interface
- CRC-8 VDA CAN
- CRC-16-CCITT
- CRC-32 ITU-T V.42 (see note below)

NOTE

Although the CRC-32 ITU-T V.42 polynomial is used for CRC generation, the generation algorithm differs (MISR) from the one used by the IEEE 802.3 standard.

64.4 Block diagram

The top level diagram of the CRC module is given in the following figure. Refer to [Main features](#) for number of contexts in this module.

Figure 64-1. CRC top level diagram

64.5 External signal description

The CRC module does not generate any external signals.

64.5.1 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration and data streaming (CRC computation) purposes via CPU or DMA. The following bus operations (contiguous byte enables) are supported:

- Word (32 bits) data write/read operations to any registers

- Low and high halfword (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- Byte (8 bits, data[31:24], data[23:16], data[15:8], or data[7:0]) data write/read operations to any registers
- Any other operation (free byte enables or other operations) must be avoided.

The CRC module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

The registers of the CRC module are read/write accessible in each access mode:

- user
- supervisor

The following summarizes bus operation performance:

- Zero wait states (single bus cycle) for each write/read operation to the CRC_CFG and CRC_INP registers
- Zero wait states (single bus cycle) for each write operation to the CRC_CSTAT register
- Double wait states (3 bus cycles) for each read operation to the CRC_CSTAT or CRC_OUTP registers immediately following (next clock cycle) a write operation to the CRC_CSTAT, CRC_INP, or CRC_CFG registers belonging to the same context; in all the other cases, no wait states are inserted

64.6 CRC memory map and registers

CRC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
0	Configuration Register (CRC_CFG1)	32	R/W	See section	64.6.1/3254

8	Current Status Register (CRC_CSTAT1)	32	R/W	FFFF_FFFFh	64.6.3/3256
C	Output Register (CRC_OUTP1)	32	R	FFFF_FFFFh	64.6.4/3257

Table continues on the next page...

CRC memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
10	Configuration Register (CRC_CFG2)	32	R/W	See section	64.6.1/3254
14	Input Register (CRC_INP2)	32	R/W	0000_0000h	64.6.2/3255
18	Current Status Register (CRC_CSTAT2)	32	R/W	FFFF_FFFFh	64.6.3/3256
1C	Output Register (CRC_OUTP2)	32	R	FFFF_FFFFh	64.6.4/3257
20	Configuration Register (CRC_CFG3)	32	R/W	See section	64.6.1/3254
24	Input Register (CRC_INP3)	32	R/W	0000_0000h	64.6.2/3255
28	Current Status Register (CRC_CSTAT3)	32	R/W	FFFF_FFFFh	64.6.3/3256
2C	Output Register (CRC_OUTP3)	32	R	FFFF_FFFFh	64.6.4/3257

64.6.1 Configuration Register (CRC_CFGn)

Access: User read/write.

Address: 0h base + 0h offset + (16d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0								0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31		
R	0										SWAP_BYTEWISE		SWAP_BITWISE		POLYG		SWAP	INV
W																		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	*	*	0	0		

* Notes:

- POLYG field: Reset value is a function of n in CRC_CFGn. When n%2 = 0, reset value = 01b. When n%2 = 1, reset value = 00b. So CRC_CFG1 POLYG reset value = 00b (Since 1%2=1).

CRC_CFGn field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

CRC_CFGn field descriptions (continued)

Field	Description
8–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 SWAP_ BYTEWISE	Swap CRC_INP byte-wise NOTE: INV and SWAP bits are set to 1 for CRC-32 polynomial calculations. 0 Do not swap 1 Perform byte-wise swap on CRC_INP input data internally for CRC-32 polynomial calculations.
27 SWAP_BITWISE	Swap CRC_INP bit-wise 0 Do not swap 1 Perform bit-wise swap on CRC_INP input data internally for CRC-8 and CRC-16 polynomial calculations.
28–29 POLYG	Polynomial selection This bit can be written only during the configuration phase. 00 CRC-CCITT polynomial 01 CRC-32 polynomial 10 CRC-8 polynomial 11 Reserved
30 SWAP	Swap selection This bit can be written only during the configuration phase. The swap operation is a bit-by-bit swapping of the content. 0 No swap selection applied on the CRC_OUTP content 1 Swap selection (MSB to LSB, LSB to MSB) applied on the CRC_OUTP content; in case of CRC-CCITT polynomial, the swap operation is applied on the 16 least-significant bits
31 INV	Inversion selection This bit can be written only during the configuration phase. The inversion operation is a complement (or negation) of the content. 0 No inversion selection applied on the CRC_OUTP content 1 Inversion selection (bit x bit) applied on the CRC_OUTP content

64.6.2 Input Register (CRC_INPn)

Access: User read/write.

NOTE

High level code must be written in a way to realize byte-, halfword- and word-wide writes on assembler code level. Any endianness problem faced can be corrected by appropriate configuration of CRC_CFG[SWAP_BYTEWISE] and CRC_CFG[SWAP_BITWISE].

CRC_CSTAT*n* field descriptions

Field	Description
0–31 CSTAT	CRC signature status This register includes the current status of the CRC signature. No bit swap and inversion are applied to this register. In the case of the CRC-CCITT polynomial, only the 16 least-significant bits are significant. The 16 most-significant bits are set to 0 during the computation. In the case of the CRC-8 polynomial, only the 8 least-significant bits are significant. The 24 most-significant bits are set to 0 during the computation. The CSTAT register can be written at byte, halfword, or word. This register can be written only during the configuration phase.

64.6.4 Output Register (CRC_OUTP_n)

Access: User read-only.

Address: 0h base + Ch offset + (16d × i), where i=0d to 2d

CRC_OUTP_n field descriptions

Field	Description
0–31 OUTP	Final CRC signature This register includes the final signature corresponding to the CRC_CSTAT register value eventually swapped and inverted. In the case of the CRC-CCITT polynomial, only the 16 least-significant bits are significant. The 16 MSB bits are set to 0 during the computation. In the case of the CRC-8 polynomial, only the 8 least-significant bits are significant. The 24 most-significant bits are set to 0 during the computation.

64.7 Functional description

The CRC module supports the CRC computation for each context. Each context has its own complete set of registers, including the CRC engine. The data flow of each context can be interleaved. The data stream can be structured as a sequence of bytes, halfwords, or words. The input data sequence is provided, eventually mixing the data formats (byte, halfword, and word), writing to the input data register (CRC_INP).

The data stream is generally executed by *n* concurrent DMA data transfers (mem2mem) where *n* is less or equal to the number of contexts.

The standard generator polynomials are given in [Figure 64-18](#), [Figure 64-19](#), and [Figure 64-20](#) for the CRC computation of each context. Two separate registers are available: CRC_INP for writing data and CRC_CSTAT for retrieving the (accumulated up to now) CRC.

$$x^8 + x^4 + x^3 + x^2 + 1$$

Figure 64-18. CRC8 VDA CAN

$$x^{16} + x^{12} + x^5 + 1$$

Figure 64-19. CRC-CCITT (x.25 protocol)

$$x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1$$

Figure 64-20. CRC-32 (ITU-T V.42 protocol)

Figure 64-21. CRC-CCITT engine concept scheme

The initial seed value of the CRC can be programmed by initializing the CRC_CSTAT register. A diagram illustrating serial data loading of the CRC engine is shown in [Figure 64-21](#) for the CRC-CCITT. Note that, conceptually, the least-significant, or "right-most," bit shown in [Input Register \(CRC_INP_n\)](#), is fed first into the engine. The actual implementation executes the CRC computation in a single clock cycle (parallel data loading). A pipeline scheme has been adopted to decouple the IPS bus interface from the CRC engine in order to allow the computation of the CRC at speed (zero wait states).

If the CRC signature is used for encapsulation in the data frame of a communication protocol (for example, SPI, etc.), a bit swap (high bit for low bit or low bit for high bit) and/or bit inversion of the final CRC signature can be applied to CRC_OUTP before transmitting the CRC.

Use of the CRC module is summarized in the flow chart given in [Figure 64-22](#).

Figure 64-22. CRC computation flow

64.8 Use cases

64.8.1 Programming example

The number of contexts depends on the application. The overall number of contexts for the CRC peripheral depends on the number of peripherals that concurrently require intervention by the CRC module. Two main use cases are considered:

- Calculation of the CRC of the configuration registers during the process safety time
- Calculation of the CRC on the incoming/outcoming frames for the communication protocols (not protected with CRC by definition of the protocol itself) used as a safety-relevant peripheral

The signature of the configuration registers is computed correctly only if these registers do not contain any status bit.

Assuming that the DMA engine has n channels (greater than or equal to the number of contexts) configurable for the following types of data transfer—mem2mem, periph2mem, mem2periph—the following sequence, as shown in the following figure, is applied to manage the transmission data flow:

1. DMA/CRC module configuration (context x , channel x) by CPU
2. Payload transfer from the MEM to the CRC module (CRC_INP register) after MSB-to-LSB change (input mirroring) to calculate the CRC signature (phase1) by DMA (mem2mem data transfer, channel x)
3. CRC signature copy from the CRC module (CRC_OUTP register) to the MEM (phase 2) by CPU
4. Data block (payload + CRC) transfer from the MEM to the PERIPH module (for example, SPI Tx FIFO) (phase 3) by DMA (mem2periph data transfer, channel x)

Figure 64-23. DMA-CRC transmission sequence

64.8.2 Register programming

- INV and/or SWAP (affecting the output only) can be applied to CRC-8, CRC-16, and CRC-32. Both can be applied together.

Use cases

- SWAP_BITWISE (affecting the input only) can be applied for all polynomials if required by an application.
- SWAP_BYTEWISE (affecting the input only) can be applied for CRC-16 and CRC-32 polynomials only.
- SWAP_BITWISE has priority over SWAP_BYTEWISE when both are applied together.
- When generating CRC-32 for the ITU-T V.42 standard the user needs to set SWAP_BYTEWISE together with INV and SWAP.
- When generating CRC-16 the user needs to set SWAP_BITWISE bit.

Chapter 65

Security Overview

65.1 Introduction

This chip has a comprehensive set of customer-configurable security features designed to protect code and data from unauthorized access.

65.2 Security features summary

The chip's security features include:

- Device censorship based on life cycle model
- Memory security:
 - Password protection for flash memory with PASS module
 - One-time-programmable (OTP) flash memory areas
 - Tamper detection including flash memory erase counter
 - MBIST functionality that can be enabled for execution during an STCU2 off-line condition to initialize RAMs (see the STCU2 chapter for details about MBIST execution in an STCU2 off-line condition)
 - BAM with software routines to initialize RAMs when not booting from internal flash memory
 - Security functions described in the *Secure Hardware Extension (SHE) Functional Specification Version 1.1*
- Monitoring of operating conditions
- Security watchdog
- Secure debug

65.3 Flash memory read, write, and erase protection

[Flash memory read protection scenarios](#) explains the supported options for read protection.

The C55FMC and PASS modules provide write and erase protection:

- The C55FMC_LOCK n registers provide one level of write and erase protection.
- The PASS_LOCK n _PG m registers provide a higher level of password-protected write and erase protection that supersedes C55FMC's protection by overwriting the values of the C55FMC_LOCK n registers.
- After bootup, during which the values of PASS_LOCK n _PG m registers are loaded from DCF records: Users can override these values temporarily, until the next reset, by programming them to different values, thereby also temporarily programming different values for the C55FMC_LOCK n registers.

For details about these registers, see the [Embedded Flash Memory \(C55FMC\)](#) and [Password and Device Security Module \(PASS\)](#) chapters.

Chapter 66

Cryptographic Services Engine (CSE)

66.1 Chip-specific CSE information

This chip has one instance of the CSE module. The module:

- executes the chip's secure boot process. See [Parallel secure boot](#) in the System Boot details.
- has exclusive access to the flash memory blocks mapped to the C55FMC_LOCK1 register, PASS_LOCK1_PGn registers, and TDRn_LOCK1 DCF client. See [C55FMC_LOCK1 register bit mapping](#). The system MPU is automatically configured to prevent other bus masters from interfering with CSE's access to the flash memory.

66.1.1 CSE configuration and SECURE_BOOT execution

The [UTEST Secure Boot Configurations DCF client](#) automatically configures aspects of CSE operation at startup.

See this DCF client's description for details about its factory-programmed value, which ensures that reset logic issues the SECURE_BOOT command to CSE during reset.

66.1.2 Sys Clk Freq for CSE

In the description of CSE_CR[DIV], the mentioned 'Sys Clk Freq' corresponds to the plat_clk frequency on this chip. See the Clocking chapter for more information about plat_clk.

66.1.3 CSE clock: minimum frequency

To ensure compliance with SHE specification performance requirements, the CSE clock source (FM_PER_CLK) must have a minimum frequency of 105 MHz.

66.1.4 CSE debug not supported

This chip has no debug capability for the CSE module. Descriptions of CSE debug features in this chapter do not apply.

66.1.5 CSE command-processing completion before Stop mode entry

To ensure proper CSE operation: Before setting SIU_HLT1[CSE] to 1, ensure CSE_SR[BSY] is 0.

66.2 Introduction

66.2.1 Overview

The Cryptographic Services Engine (CSE) is a peripheral module that implements the security functions described in the *Secure Hardware Extension (SHE) Functional Specification Version 1.1*.

The CSE design includes a host interface with a set of memory mapped registers that are used by the CPU to issue commands and a system bus interface that allows the CSE to directly access system memory. Two dedicated blocks of system flash memory are used by the CSE for secure key storage.

66.2.2 Features

The CSE has the following features:

- Secure storage for cryptographic keys
- AES-128 encryption and decryption
- AES-128 CMAC authentication

- True random number generation
- Secure boot mode
- System bus master interface

66.2.3 Modes of operation

The CSE supports operation in Normal and Debug modes of operation. The use of the cryptographic keys stored by the CSE is controlled based on the activation of the CPU debug port and the successful completion of the secure boot process.

The CSE has a low-power mode that disables the clock to all logic except the host interface. Register accesses are supported in this mode, but commands are not processed.

66.2.4 Block diagram

The CSE design includes a command processor, host interface, system bus interface, local memory, AES logic, and True Random Number Generator (TRNG) as shown below.

Figure 66-1. CSE block diagram

66.3 External signal description

The CSE has no external interface signals.

66.4 Memory Map and Register Definition

The CSE programming model has ten 32-bit registers. The programming model can only be accessed using 32-bit (word) accesses. References using a different size are invalid. The CSE memory map is shown in the table below.

CSE memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	CSE Control Register (CSE_CR)	32	R/W	See section	66.4.1/3268
4	CSE Status Register (CSE_SR)	32	R	0000_0000h	66.4.2/3270
8	CSE Interrupt Register (CSE_IR)	32	w1c	See section	66.4.3/3271
C	CSE Error Code Register (CSE_ECR)	32	R	0000_0000h	66.4.4/3272
20	CSE Command Register (CSE_CMD)	32	R/W	0000_0000h	66.4.5/3273
24	CSE Parameter Register (CSE_P1)	32	R/W	0000_0000h	66.4.6/3274
28	CSE Parameter Register (CSE_P2)	32	R/W	0000_0000h	66.4.6/3274
2C	CSE Parameter Register (CSE_P3)	32	R/W	0000_0000h	66.4.6/3274
30	CSE Parameter Register (CSE_P4)	32	R/W	0000_0000h	66.4.6/3274
34	CSE Parameter Register (CSE_P5)	32	R/W	0000_0000h	66.4.6/3274

66.4.1 CSE Control Register (CSE_CR)

The CSE_CR contains fields for configuring and controlling operation of the CSE.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	DIV								0	KBS		SFE	MDIS	SUS	DRE	CIE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	*

* Notes:

- CIE field: The reset value of this bit is 0 on POR, but when the reset lifts and CSE execution starts, the value of this bit becomes 1. So, after the first read access to this bit, the read value is 1.

CSE_CR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 DIV	TRNG Clock Divider Select. Sets the clock divide ratio for the TRNG clock. The TRNG clock is the system clock divided by a programmable ratio: $\text{TRNG Clk Freq} = \text{Sys Clk Freq} / (2 * (\text{DIV} + 1))$ The divide ratio must be set such that the TRNG clock frequency is between 500 kHz and 2MHz. 0x00 divide by 2 0x01 divide by 4 0x02 divide by 6 ... 0xFE divide by 510 0xFF divide by 512
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 KBS	Key Bank Select. Selects which set of application keys are visible for commands. See Table 66-13 . 0 Select KEY_1-KEY_10 1 Select KEY_11-KEY_20
27 SFE	Security Flag Extension. When the SFE bit is set, the CSE recognizes the VERIFY_ONLY security flag during LOAD_KEY processing; otherwise, it is ignored. The SFE bit has no effect on the enforcement of the VERIFY_ONLY security flag once a key is loaded. 0 Security Flag Extension disabled. 1 Security Flag Extension enabled.
28 MDIS	Module Disable. When the MDIS bit is set, the CSE is put into a low-power mode that disables the clock to all of the CSE logic except for the host interface. The MDIS bit should not be set during command processing (CSE_SR[BSY] = 1). The current command should be canceled and processing stopped (CSE_SR[BSY] = 0) before setting the MDIS bit. 0 Normal mode 1 Low-power mode
29 SUS	Suspend Command Processing. When the SUS bit is set, the CSE suspends processing of the current command until the SUS bit is cleared. The current execution status of the command processor is reflected by the CSE_SR[EX] flag. 0 Enable processing of commands. 1 Suspend command processing.
30 DRE	DMA Request Enable. When the DRE bit is set, the DMA request is asserted when command processing is completed. NOTE: DMA is not implemented on this chip. 0 DMA request not enabled. 1 DMA request enabled.
31 CIE	Command Complete Interrupt Enable. When the CIE bit is set, an interrupt request is generated and the CSE_IR[CIF] flag is set when command processing is completed. 0 Command Complete Interrupt disabled. 1 Command Complete Interrupt enabled.

66.4.2 CSE Status Register (CSE_SR)

The CSE_SR contains flags indicating the status of the CSE. Reading CSE_SR[24:31] is the same as the SHE GET_STATUS command.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0								EX	IDB	EDB	RIN	BOK	BFN	BIN	SB	BSY
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

CSE_SR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 EX	Execute. NOTE: Ignore the status of CSE_SR[EX] when CSE_SR[BSY] flag is '0'. 0 Command processor is idle or suspended. 1 Command processor is executing a command.
24 IDB	Internal Debug. The IDB bit is set by the SECURE_BOOT, INIT_CSE, and DEBUG_AUTH commands when no user keys (i.e. all keys except SECRET_KEY and UID) are stored. It is cleared on reset and by the LOAD_KEY command. 0 Internal Debug functions disabled. 1 Internal Debug functions enabled.
25 EDB	External Debug. The EDB bit is set when the CPU debug port is activated and is cleared on reset. 0 External debugger not attached. 1 External debugger attached.
26 RIN	Random Number Generator Initialized. The RIN bit is set by the INIT_RNG command and is cleared on reset and by the DEBUG_AUTH command. 0 Random number generator not initialized. 1 Random number generator initialized.
27 BOK	Secure Boot OK. The BOK bit is set by the successful completion of the SECURE_BOOT command. It is cleared by reset and by the BOOT_FAILURE command.

Table continues on the next page...

CSE_SR field descriptions (continued)

Field	Description
	0 Secure boot not completed or secure boot failure. 1 Secure boot successful.
28 BFN	Secure Boot Finished. The BFN bit is set by the SECURE_BOOT command when the BIN bit is set, when an error is encountered, or when the BOOT_MAC value does not match. It is also set by the BOOT_OK or BOOT_FAILURE commands. It is cleared on reset. The BFN bit is not set in the event the CSE flash blocks are accessible, but contain an invalid firmware image as detected by a checksum mismatch (CSR_ECR=0x13). 0 Secure boot not finished. 1 Secure boot finished.
29 BIN	Secure Boot Initialization. The BIN bit is set by the SECURE_BOOT command if the BOOT_MAC memory slot is empty and is cleared on reset. 0 Secure boot personalization not completed. 1 Secure boot personalization completed.
30 SB	Secure Boot. The SB bit is set by the SECURE_BOOT command if the BOOT_MAC_KEY slot is not empty, and is cleared on reset. 0 Secure boot not activated. 1 Secure boot activated.
31 BSY	Busy. The BSY bit is set when a command is issued and cleared when command processing is completed. 0 Command processing completed. 1 Command processing not completed.

66.4.3 CSE Interrupt Register (CSE_IR)

The CSE_IR contains the command completion interrupt flag bit.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0															CIF
W																w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	*

* Notes:

- CIF field: The reset value of this bit is 0 on POR, but when the device boots in a mode that supports SECURE_BOOT, the value of this bit becomes 1 upon the command's completion.

CSE_IR field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 CIF	Command Complete Interrupt Flag. The CIF flag reflects the state of the command complete interrupt request. The CIF flag and interrupt request are cleared by writing a 1 to this bit. Writing a 0 has no effect. 0 No interrupt request. 1 Interrupt request due to completion of a command.

66.4.4 CSE Error Code Register (CSE_ECR)

The CSE_ECR contains the error code from the last completed command.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																										EC					
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

CSE_ECR field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 EC	Error Code from the last command completed. 0x00 No error 0x02 Command sequence error 0x03 Key not available 0x04 Invalid key 0x05 Empty key 0x06 No secure boot 0x07 Key write protected 0x08 Key update error 0x09 Random number seed not initialized 0x0A Internal debug not allowed 0x0B Command issued while busy 0x0C System memory error 0x10 Internal memory error 0x11 Invalid command

Table continues on the next page...

CSE_ECR field descriptions (continued)

Field	Description
	0x12 TRNG error
	0x13 CSE flash block error
	0x14 Internal command processor error
	0x15 Length error

66.4.5 CSE Command Register (CSE_CMD)

Commands are issued by first loading the appropriate parameter registers (CSE_Px) and then writing a command code to the command register (CSE_CMD). Reads of the CSE_CMD register have no effect on the operation of the CSE. See [Command processing](#) for a description of command processing and [CSE commands](#) for a description of each command.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CSE_CMD field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 CMD	Command. See CSE commands for details of each command. 0x01 = ENC_ECB 0x02 = ENC_CBC 0x03 = DEC_ECB 0x04 = DEC_CBC 0x05 = GENERATE_MAC 0x06 = VERIFY_MAC 0x07 = LOAD_KEY 0x08 = LOAD_PLAIN_KEY 0x09 = EXPORT_RAM_KEY 0x0A = INIT_RNG 0x0B = EXTEND_SEED 0x0C = RND

Table continues on the next page...

CSE_CMD field descriptions (continued)

Field	Description
	0x0D = SECURE_BOOT
	0x0E = BOOT_FAILURE
	0x0F = BOOT_OK
	0x10 = GET_ID
	0x11 = CANCEL
	0x12 = DEBUG_CHAL
	0x13 = DEBUG_AUTH
	0x14 = TRNG_RND
	0x15 = INIT_CSE
	0x16 = MP_COMPRESS

66.4.6 CSE Parameter Register (CSE_Pn)

The five parameter registers (CSE_Px) are used to hold command parameter values. See [Command processing](#) for a description of how to issue commands and [CSE commands](#) for a description of each command. The parameter registers are read only when the CSE_SR[BSY] bit is set.

Address: 0h base + 24h offset + (4d × i), where i=0d to 4d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CSE_Pn field descriptions

Field	Description
0–31 PARM	Command parameter (data value or address of data value).

66.5 CSE functional description

The CSE implements a comprehensive set of cryptographic functions as described in the *SHE Functional Specification*, including secure key storage, AES encryption, secure boot, AES CMAC authentication, and random number generation.

66.5.1 Host interface

The host interface includes all of the CSE memory mapped registers (see the memory map and register section).

The Control Register (CSE_CR) is used to set configuration options and control operation of the CSE. If the CSE_CR[CIE] bit is set, an interrupt request is generated after the CSE finishes processing each command. The interrupt is cleared by writing a 1 to the CSE_IR[CIF] bit. When the CSE_CR[SUS] bit is set, the CSE suspends processing of the current command and does not respond to new commands including the CANCEL command.

Command processing is resumed by clearing the CSE_CR[SUS] bit. The CSE cannot respond immediately to changes in the CSE_CR[SUS] bit, so the CSE_SR[EX] flag indicates the current status of the CSE command processor. The CSE_SR[EX] flag is set when the CSE command processor is running and is cleared when the CSE is idle or has suspended processing. The CSE_CR[MDIS] bit puts the CSE into a low-power mode. In low-power mode, registers can be accessed but commands are not processed. Before setting the CSE_CR[MDIS] bit or entering any device low-power modes, application software should cancel any pending command and wait for the CSE_SR[BSY] bit to be cleared. The CSE_CR[SFE] bit enables loading of the VERIFY_ONLY flag during the LOAD_KEY command. The CSE_CR[KBS] bit selects which key bank (KEY_1–KEY_10 or KEY_11–KEY_20) is active.

The Status Register (CSE_SR) contains a set of nine status flags. Reading CSE_SR[24:31] is equivalent to the SHE GET_STATUS command. The CSE_SR[BSY] bit indicates when the CSE is processing a command. The flag is cleared when processing is completed. Polling the CSE_SR[BSY] bit is an alternative to interrupt-driven operation. The CSE_SR[SB], CSE_SR[BIN], CSE_SR[BFN] and CSE_SR[BOK] bits reflect the secure boot status (see [Secure boot](#)). The CSE_SR[RIN] bit is set when the PRNG is initialized with a seed value generated by the TRNG. The CSE_SR[EDB] is set if an external debugger is connected. The CSE_SR[IDB] flag is set when internal debugging has been enabled with the DEBUG_CHAL and DEBUG_AUTH commands. The CSE_SR is a read-only register and can be read at any time.

The Error Code Register (CSE_ECR) contains the error code from the last completed command. The CSE_ECR is set to 0 if no error occurred while processing the command. The CSE_ECR is a read-only register.

66.5.2 Command processing

CSE functions are accessed through a set of commands that are listed in [CSE commands](#). Commands are issued by first loading the appropriate parameter registers (CSE_Px) and then writing a command code to the command register (CSE_CMD). CSE_CMD register reads have no effect on the operation of the CSE.

Command inputs and outputs that are 32 bits or less in size are stored directly into a parameter register. Inputs and outputs that are larger than 32 bits are kept in system memory and the address of the data (pointer) is loaded into the parameter register. All data must be aligned on a 32-bit (word) boundary. The two least significant bits of an address are ignored. All data is stored in big-endian format with the most significant byte of the data block stored in the lowest address.

The first command issued to the CSE after reset must be either SECURE_BOOT or INIT_CSE. In some device boot modes, system boot logic or BAM code will issue the SECURE_BOOT command, which initializes the CSE and starts the SHE secure boot protocol (see [Secure boot](#)). For details about how and when the SECURE_BOOT command is issued on this chip, see the chip-specific CSE information. For the other boot modes, application software must issue the INIT_CSE command before issuing other CSE commands. The INIT_CSE command can only be issued one time after reset and only in boot modes that do not issue the SECURE_BOOT command. Application software cannot issue the SECURE_BOOT command.

The CSE can only process one command at a time. Commands take a number of clock cycles to complete, so one of the following must be used to determine when the output data is valid and the next command can be issued:

- The CSE_SR[BSY] flag
- The interrupt request

Parameter registers cannot be modified while the CSE is processing a command. Command processing can be suspended and resumed using the CSE_CR[SUS] bit (see [Host interface](#)). If the CSE_CMD register is written while a command is being processed, processing is aborted and an error is generated with CSE_ECR[EC] = 0x0B. The CANCEL command can be used to abort processing of a command without generating an error. The CSE_ECR is updated and the CSE_SR[BSY] bit is cleared upon completion of command processing (see [Error handling](#)).

66.5.3 Secure storage

The CSE provides secure, nonvolatile storage for cryptographic keys as described in the *SHE Functional Specification*. The keys are stored in 25 memory slots, with one ROM slot, 23 nonvolatile slots, and one RAM slot as shown in [Table 66-13](#). The first four slots have a dedicated use; the other slots are available for application specific keys. The CSE extends the SHE specification by providing 10 extra application key slots (KEY_11–KEY_20) which are enabled by setting the CSE_CR[KBS] bit. The BOOT_MAC slot is loaded with a MAC value used by the secure boot process. All other slots are used for encryption or message authentication keys. The SECRET_KEY slot is programmed with a random value during device fabrication. All CSE encryption and message authentication commands specify a key by its Key ID.

Table 66-13. Memory slots

Slot name	KBS	Key ID	Type
SECRET_KEY	x	0x0	ROM
MASTER_ECU_KEY	x	0x1	nonvolatile
BOOT_MAC_KEY	x	0x2	nonvolatile
BOOT_MAC	x	0x3	nonvolatile
KEY_1–KEY_10	0	0x4–0xD	nonvolatile
KEY_11–KEY_20	1	0x4–0xD	nonvolatile
RAM_KEY	x	0xE	RAM

In addition to the 25 memory slots, the CSE holds a 120-bit read-only unique identification number (UID) that is programmed during device fabrication. The UID is used in the memory update procedure and is available for application-specific uses.

Each memory slot holds a 128-bit value, 6 security flags, and a 28-bit counter. See the *SHE Functional Specification* for the required structure needed for the LOAD_KEY command. The security flags are defined in [Table 66-14](#). The 28-bit counter must be advanced each time a new key is loaded. The counter value is zero for an empty memory slot.

Table 66-14. Memory slot security flags

Flag name	Description
VERIFY_ONLY	If set, the memory slot key cannot be used by the GENERATE_MAC command, only by the VERIFY_MAC command. This bit has no effect if KEY_USAGE = 0.
WRITE_PROT	If set, the memory slot cannot be updated.
BOOT_PROT	If set, the memory slot is disabled if CSE_SR[BOK] = 0 or CSE_SR[BFN] = 0.
DEBUG_PROT	If set, the memory slot is disabled if CSE_SR[EDB] = 1.
KEY_USAGE	If set, the memory slot holds a MAC key; otherwise, it holds an encryption key.
WILDCARD	If set, the memory slot cannot be updated with the wildcard UID.

The memory slot security flags for a specified key are checked against the associated bits in the CSE_SR during command processing as described in the SHE specification. If the memory slot is disabled due to security flag settings, a key not available error (EC = 0x03) is returned by the command. The VERIFY_ONLY security flag is a CSE-specific feature that is not defined in the SHE specification. If the CSE_CR[SFE] bit is set when the LOAD_KEY command is executed, the security flag field (FID) in the M2 message is extended by one bit with the VERIFY_ONLY flag and the adjacent zero fill field is reduced to 94 bits. The CSE_CR[SFE] bit has no effect on the enforcement of the VERIFY_ONLY flag for commands issued after the LOAD_KEY.

A key is loaded into a memory slot using the LOAD_KEY command which implements the SHE memory update protocol. An empty key slot can only be used as the authorization key to update itself (KeyID = AuthID). In this case, the authorization key has a value of 0. The BOOT_PROT and DEBUG_PROT security flags are not enforced for the LOAD_KEY command except when the RAM_KEY slot is loaded. In that case, the BOOT_PROT and DEBUG_PROT flags of the AuthID slot are applied. Additionally, when loading the RAM_KEY slot, the counter and security flag fields in the M2 message must be zero.

The LOAD_PLAIN_KEY command can be used to load a key into the RAM_KEY slot. The EXPORT_RAM_KEY command can then be used to export the key in an encrypted form compatible with the LOAD_KEY command for storage outside the CSE. The BOOT_PROT and DEBUG_PROT security flags of the MASTER_ECU_KEY are enforced for the EXPORT_RAM_KEY command.

Two dedicated blocks in the system flash memory are used to implement the secure storage feature. These blocks are not program visible and only the CSE can read, erase, and program these blocks. The CSE reads and writes to the system flash memory via the system bus master interface during the SECURE_BOOT, INIT_CSE, DEBUG_AUTH, and LOAD_KEY commands. During execution of these commands, the system MPU (if present) must be configured to allow the CSE access to the system flash memory and other bus masters must be programmed properly to avoid interfering with the CSE.

66.5.4 Encryption and decryption

The CSE supports AES-128 encryption and decryption in ECB and CBC modes of operation. The key is selected from one of the memory slots, which must be enabled for the operation. A plaintext key can be loaded into the RAM_KEY slot using the LOAD_PLAIN_KEY command for keys that are not stored in a nonvolatile memory slot.

66.5.5 Message authentication

The CSE uses the AES-128 CMAC algorithm for message authentication. The key for the CMAC operation is selected from one of the memory slots which must be enabled for the operation. A plaintext key can be loaded into the RAM_KEY slot using the LOAD_PLAIN_KEY command for keys that are not stored in a nonvolatile memory slot. The VERIFY_MAC command supports comparison of a calculated MAC with an input MAC value.

66.5.6 Secure boot

The CSE implements the SHE secure boot protocol. In some device boot modes, the BAM or system boot logic issues the SECURE_BOOT command to the CSE, which starts the secure boot process. For details about how and when the SECURE_BOOT command is issued on this chip, see the chip-specific CSE information.

The first step in the process is for the CSE to download the command processor firmware and memory slot data from the CSE flash memory blocks into local memory. If the BOOT_MAC_KEY slot is empty, the CSE_SR[SB] flag is cleared and the process is finished. Otherwise, the CSE_SR[SB] flag is set and CSE calculates the MAC over the specified bootloader code. If the BOOT_MAC slot is empty, the calculated MAC is loaded into the BOOT_MAC slot, the CSE_SR[BIN] and CSE_SR[BFN] flags are set, and the process is finished. Otherwise, the calculated MAC value is compared to the value in the BOOT_MAC slot. If the values match, the CSE_SR[BOK] bit is set; otherwise, the CSE_SR[BFN] bit is set. If the CSE_SR[BOK] flag is set, the user boot code can issue the BOOK_OK command which sets the CSE_SR[BFN] bit. The memory slots that have the BOOT_PROT flag set are enabled when both the CSE_SR[BFN] and CSE_SR[BOK] flags are set.

The SECURE_BOOT command can run either before the user boot code is executed or in parallel with the user boot code. If the parallel mode is used, the user boot code must suspend command processing (set CSE_CR[SUS] to 1) while performing any operations—such as configuring the flash controller—that may interfere with the CSE accessing flash memory. A device-specific bit selects whether to run the SECURE_BOOT command before or in parallel with the user boot code. For details about this bit, see the chip-specific CSE information.

The CSE implements an internal timer that is started when the SECURE_BOOT command is issued. The initial value of the timer is set to 0x00F4_2400 (16,000,000 CSE system clocks). If the timer expires before the SECURE_BOOT command completes, any application code intended to be blocked by the SECURE_BOOT process will instead see the non-completed SECURE_BOOT status of CSE_SR[BSY]=1 and

CSE_SR[BOK]=0. In the event of a SECURE_BOOT timeout, the CSE will continue executing the SECURE_BOOT command until completion, until suspended, or until receiving the CANCEL command from the application code. There is no error code associated with a SECURE_BOOT timeout.

66.5.7 Random number generation

The CSE has both a Pseudo Random Number Generator (PRNG) and a True Random Number Generator (TRNG).

The PRNG has a 128-bit state variable and uses AES in output feedback mode to generate pseudo random values. A key derived from the SECRET_KEY is used for the PRNG. The RND command updates the state of the PRNG and returns the 128-bit random value. The EXTEND_SEED command can be used to add entropy to the PRNG state. The PRNG state is initialized after each reset with the INIT_RNG command, which uses the TRNG to generate a 128-bit seed value for the PRNG. The CSE_SR[RIN] flag is set when the PRNG is initialized.

The INIT_RNG and TRNG_RND commands use the TRNG to generate truly random values. The TRNG hardware runs off of a slower clock derived from the system clock. The CSE_CR[DIV] field needs to be configured for these commands such that the TRNG clock is between 500 kHz and 2 MHz. Random values generated by the TRNG are checked with a statistical test to verify proper operation of the TRNG. If the test fails, a TRNG error (EC = 0x12) is returned. Due to the statistical nature of this test, there is a very small probability ($< 10^{-9}$) that a properly operating TRNG will return an error. If an TRNG error is returned, the command can be issued again.

66.5.8 Error handling

When the CSE command processor encounters an error condition, it stops processing and returns an error code as described in [Table 66-15](#). The CSE_SR[BSY] and CSE_SR[EX] bits are cleared with interrupt requests generated the same as if the command had completed successfully. In most cases, error conditions are detected before data processing begins and no output values are written. Intermediate or invalid output data is never written to the parameter registers or system memory. However, it is possible for outputs to system memory to be partially written when an error occurs. The CSE does not zero out this partially written data.

Table 66-15. Error code summary

Error code	Error description	Error conditions
0x00	No error	1. Command successfully executed with no errors encountered.
0x02	Command sequence error	1. Command issued (except for CANCEL) before the SECURE_BOOT or INIT_CSE command. 2. The DEBUG_AUTH command issued before the DEBUG_CHAL command. 3. SECURE_BOOT or INIT_CSE command issued after an initial SECURE_BOOT or INIT_CSE is issued.
0x03	Key not available	1. A required key is not available due to a BOOT_PROT or DEBUG_PROT security flag restriction (see Secure storage).
0x04	Invalid key	1. The specified key slot is not valid for the command. (See the SHE specification.) 2. The specified key slot is not available due to a KEY_USAGE security flag restriction (see Secure storage).
0x05	Empty key	1. The specified key slot is empty.
0x06	No secure boot	1. SECURE_BOOT issued when secure boot is disabled or the BOOT_MAC_KEY slot is empty. 2. BOOT_FAIL or BOOT_OK issued with incorrect settings for either the CSE_SR[SB], CSE_SR[BFN] or CSE_SR[BOK] flags.
0x07	Key write protected	1. Attempt to load a key slot with the WRITE_PROT security flag set. 2. Attempt to enter internal debug mode (DEBUG_CHAL, DEBUG_AUTH) with a WRITE_PROT security flag set in one or more key slots.
0x08	Key update error	The LOAD_KEY command failed due to one of the following conditions: 1. The M3 MAC value is invalid. 2. The wildcard UID is specified with the WILDCARD flag set. 3. The specified UID does not match the device UID. 4. The update counter or security flag values are not zero when loading the RAM_KEY slot. 5. The specified update counter value is not greater than the current counter value for the slot. (Counter value is zero for an empty slot.)
0x09	Random number seed not initialized	1. RND, EXTEND_SEED, or DEBUG_CHAL command issued before the INIT_RNG command.
0x0A	Internal debug not allowed	1. DEBUG_AUTH command issued with invalid MAC value.
0x0B	Command issued while busy	1. Command issued when the CSE_SR[BSY] bit is set.
0x0C	System memory error	1. A system memory error was encountered while executing the command. (The CSE flash memory block error code is generated for bus errors encountered when accessing the CSE flash memory blocks.)
0x10	Internal memory error	1. An internal memory error was encountered while executing the command.

Table continues on the next page...

Table 66-15. Error code summary (continued)

Error code	Error description	Error conditions
0x11	Invalid command	1. Value written to CSE_CMD register is out of range.
0x12	TRNG error	1. One or more statistical tests run on the TRNG output failed (see Generate Random Number).
0x13	CSE flash memory block error	1. Error reading, programming, or erasing one of the CSE flash memory blocks. 2. UID or SECRET_KEY required but not available.
0x14	Internal command processor error	1. An internal error condition was encountered while executing the command.
0x15	Length error	1. MAC length for VERIFY_MAC command is greater than 128. 2. Message length for GENERATE_MAC, VERIFY_MAC, or MP_COMPRESS command is greater than 0x7FFFFFFF (4 GB).

66.6 CSE commands

This section describes the set of CSE commands. Commands are issued by first loading the appropriate parameter registers (CSE_Px) and then writing a command code to the command register (CSE_CMD) as described in [Command processing](#). The first command issued to the CSE after reset must be INIT_CSE for device boot modes that do not support secure boot. Command inputs and outputs that are 32 bits or less in size are stored directly in a parameter register. Inputs and outputs that are larger than 32 bits are kept in system memory and the address of the data (pointer) is loaded into the parameter register. The data direction indication in the tables below refers to the command parameter value which may be stored in memory.

66.6.1 Encrypt ECB

The ENC_ECB command performs AES-128 encryption in ECB mode on n 128-bit blocks of data with the parameters specified in the table below.

Table 66-16. ENC_ECB command

Register	Value	Data direction
CSE_CMD	0x01	—
CSE_P1	Key ID	Input
CSE_P2	Number of blocks (n)	Input

Table continues on the next page...

Table 66-16. ENC_ECB command (continued)

Register	Value	Data direction
CSE_P3	First plaintext block address	Input
CSE_P4	First ciphertext block address	Output

66.6.2 Encrypt CBC

The ENC_CBC command performs AES-128 encryption on n 128-bit blocks of data in CBC mode with the parameters specified in the table below. The number of blocks parameter is a 32-bit value.

Table 66-17. ENC_CBC command

Register	Value	Data direction
CSE_CMD	0x02	—
CSE_P1	Key ID	Input
CSE_P2	IV address	Input
CSE_P3	Number of blocks (n)	Input
CSE_P4	First plaintext block address	Input
CSE_P5	First ciphertext block address	Output

66.6.3 Decrypt ECB

The DEC_ECB command performs AES-128 ECB decryption on n 128-bit blocks of data with the parameters specified in the table below.

Table 66-18. DEC_ECB command

Register	Value	Data direction
CSE_CMD	0x03	—
CSE_P1	Key ID	Input
CSE_P2	Number of blocks (n)	Input
CSE_P3	First ciphertext block address	Input
CSE_P4	First plaintext block address	Output

66.6.4 Decrypt CBC

The DEC_CBC command performs AES-128 decryption in CBC mode on n 128-bit blocks of data with the parameters specified in the table below. The number of blocks parameter is a 32-bit value.

Table 66-19. DEC_CBC command

Register	Value	Data direction
CSE_CMD	0x04	—
CSE_P1	Key ID	Input
CSE_P2	IV address	Input
CSE_P3	Number of blocks (n)	Input
CSE_P4	First ciphertext block address	Input
CSE_P5	First plaintext block address	Output

66.6.5 Generate MAC

The GENERATE_MAC command calculates the MAC of a given message with the parameters specified in the table below. The AES CMAC algorithm is used to calculate a 128-bit MAC output. The message length input is a 64-bit value that specifies the length of the message in bits. A length error (EC = 0x15) is returned if the message length is greater than 0x7fffffff (4 GB).

Table 66-20. GENERATE_MAC command

Register	Value	Data direction
CSE_CMD	0x05	—
CSE_P1	Key ID	Input
CSE_P2	Message length (bits) address	Input
CSE_P3	Message start address	Input
CSE_P4	MAC address	Output

66.6.6 Verify MAC

The VERIFY_MAC command verifies the MAC of a given message with the parameters specified in [Table 66-21](#). The AES CMAC algorithm is used to calculate a 128-bit MAC that is truncated according to the MAC length parameter, which specifies the number of most significant bits in the MAC to compare. A MAC length value of 0 indicates that all 128 bits are compared; a value greater than 128 returns a length error (EC = 0x15). The

message length input is a 64-bit value that specifies the length of the message in bits. A length error (EC = 0x15) is returned if the message length is greater than 0x7fffffff (4 GB). If the input MAC matches the MAC calculated over the message, the CSE_P5 register is set to 0; otherwise, it is set to 1.

Table 66-21. VERIFY_MAC command

Register	Value	Data direction
CSE_CMD	0x06	—
CSE_P1	Key ID	Input
CSE_P2	Message length (bits) address	Input
CSE_P3	Message start address	Input
CSE_P4	MAC address	Input
CSE_P5	MAC length (bits)/ Verification status	Input / Output

66.6.7 Load Key

The LOAD_KEY command updates a memory slot using parameters specified in [Table 66-22](#) according to the SHE memory slot update protocol (see [Secure storage](#)). The 128-bit M1 message contains the UID, Key ID, and Authentication Key ID. The 256-bit M2 message contains the new security flags, the counter, and the key value all encrypted using a derived key generated from the Authentication Key. The 128-bit M3 message is a MAC generated over messages M1 and M2. The 256-bit M4 message is the concatenation of the UID, Key ID, Authorization Key ID, and the encrypted counter value. The 128-bit M5 message is the MAC calculated over message M4.

The derived keys used to generate messages M2, M3, M4, and M5 deviate from the SHE memory slot update protocol when updating the second bank of user keys (KEY_11–KEY_20). During the generation of M2 and M4, K1 and K3 shall be derived using a constant equal to KEY_UPDATE_ENC_C + 0x00800000_00000000_00000000_00000000. Similarly, during generation of M3 and M5, K2 and K4 shall be derived using a constant equal to KEY_UPDATE_MAC_C + 0x00800000_00000000_00000000_00000000. This is intended to prevent aliasing between the two banks of user keys.

Table 66-22. LOAD_KEY command

Register	Value	Data direction
CSE_CMD	0x07	—
CSE_P1	M1 address	Input

Table continues on the next page...

Table 66-22. LOAD_KEY command (continued)

Register	Value	Data direction
CSE_P2	M2 address	Input
CSE_P3	M3 address	Input
CSE_P4	M4 address	Output
CSE_P5	M5 address	Output

66.6.8 Load Plain Key

The LOAD_PLAIN_KEY command updates the RAM key memory slot with a 128-bit plaintext key with the parameter shown in the table below.

Table 66-23. LOAD_PLAIN_KEY command

Register	Value	Data direction
CSE_CMD	0x08	—
CSE_P1	Key address	Input

66.6.9 Export RAM Key

The EXPORT_RAM_KEY command exports the RAM key data with the parameters in the table below. Only keys loaded with the LOAD_PLAIN_KEY command may be exported. The output messages are compatible with the messages used for LOAD_KEY (see [Load Key](#) for details).

Table 66-24. EXPORT_RAM_KEY command

Register	Value	Data direction
CSE_CMD	0x09	—
CSE_P1	M1 address	Output
CSE_P2	M2 address	Output
CSE_P3	M3 address	Output
CSE_P4	M4 address	Output
CSE_P5	M5 address	Output

66.6.10 Initialize RNG

The INIT_RNG command initializes the internal PRNG state with a seed value generated by the TRNG and sets the CSE_SR[RIN] flag. It takes 2048 TRNG clock cycles to generate a seed value. The CSE_CR[DIV] field must be properly configured before this command is executed (see register descriptions for further information). There is a very small probability that this command may return a TRNG error (EC = 0x12) even when the TRNG is operating properly (see [Random number generation](#)). The INIT_RNG command must be called after each reset before the RND command is issued. The command has no parameters as shown the table below.

Table 66-25. INIT_RNG command

Register	Value	Data direction
CSE_CMD	0x0A	—

66.6.11 Extend PRNG Seed

The EXTEND_SEED command extends the state of the PRNG using a 128-bit entropy input value. The current PRNG state and the input data are compressed into a new PRNG state value. This command is issued with the parameter shown in the table below.

Table 66-26. EXTEND_SEED command

Register	Value	Data direction
CSE_CMD	0x0B	—
CSE_P1	Entropy value address	Input

66.6.12 Generate Random Number

The RND command generates a 128-bit random value and updates the state of the internal PRNG. The PRNG state must be initialized after reset using the INIT_RNG command before this command can be issued. This command is issued with the parameter shown in the table below

Table 66-27. RND command

Register	Value	Data direction
CSE_CMD	0x0C	—
CSE_P1	Random value address	Output

66.6.13 Secure Boot

The SECURE_BOOT command loads the command processor firmware and memory slot data from the CSE flash memory blocks, and then it executes the SHE secure boot protocol using the parameters shown in [Table 66-28](#) (see [Secure boot](#) for details). The bootloader size is a 32-bit value. The CSE firmware version is loaded into CSE_P3 register.

The SECURE_BOOT command is issued during the boot processes by the system boot logic. For details about how and when the SECURE_BOOT command is issued on this chip, see the chip-specific CSE information.

Table 66-28. SECURE_BOOT command

Register	Value	Data direction
CSE_CMD	0x0D	—
CSE_P1	Bootloader size (bytes)	Input
CSE_P2	Bootloader start address	Input
CSE_P3	Firmware version	Output

66.6.14 Boot Failure

The BOOT_FAILURE command sets the CSE_SR[BFN] flag and clears the CSE_SR[BOK] flag to disable use of memory slots that have the BOOT_PROT flag set. This command is issued with no parameters as shown in the table below.

Table 66-29. BOOT_FAILURE command

Register	Value	Data direction
CSE_CMD	0x0E	—

66.6.15 Boot OK

The BOOT_OK command sets the CSE_SR[BFN] flag and leaves the CSE_SR[BOK] flag set to confirm successful completion of the secure boot processes. This enables the use of memory slots that have the BOOT_PROT flag set if they are not disabled for some other reason. This command is issued with no parameters as shown in the table below.

Table 66-30. BOOT_OK command

Register	Value	Data direction
CSE_CMD	0x0F	—

66.6.16 Get ID

The GET_ID command returns the UID, CSE_SR[24:31], and a 128-bit MAC calculated over the concatenation of a 128-bit input challenge value, UID, and CSE_SR[24:31]. The MASTER_ECU_KEY is used for the MAC calculation. A value of 0 is returned for the MAC if the MASTER_ECU_KEY slot is empty. The UID output is a 128-bit value with the 8 least significant bits set to 0. This command is issued with the parameters shown in the table below.

Table 66-31. GET_ID command

Register	Value	Data direction
CSE_CMD	0x10	—
CSE_P1	Challenge address	Input
CSE_P2	UID output address	Output
CSE_P3	CSE_SR[24:31] value	Output
CSE_P4	MAC address	Output

66.6.17 Cancel

The CANCEL command aborts processing of the current command and clears the CSE_SR[BSY] flag. This command is issued with no parameters as shown in the table below.

Table 66-32. CANCEL command

Register	Value	Data direction
CSE_CMD	0x11	—

66.6.18 Debug Challenge

The `DEBUG_CHAL` command generates a 128-bit random challenge output value that is used in conjunction with the `DEBUG_AUTH` command. The PRNG state must be initialized after reset using the `INIT_RNG` command before this command can be issued. This command is issued with the parameter shown in the table below.

Table 66-33. `DEBUG_CHAL` command

Register	Value	Data direction
CSE_CMD	0x12	—
CSE_P1	Challenge address	Output

66.6.19 Debug Authorization

The `DEBUG_AUTH` command erases all user keys and sets the `CSE_SR[IDB]` flag which enables internal debugging if the 128-bit authorization input value is valid and no memory slots are write protected. The authorization input is generated using the `DEBUG_CHAL` command output and the UID as described in the *SHE Functional Specification*. If the `DEBUG_CHAL` command is not issued before the `DEBUG_AUTH` command, a command sequence error (`EC = 0x02`) is returned. However, other commands may be issued between the `DEBUG_CHAL` and `DEBUG_AUTH` commands. This command is issued with the parameter shown in the table below.

Table 66-34. `DEBUG_AUTH` command

Register	Value	Data direction
CSE_CMD	0x13	—
CSE_P1	Authorization address	Input

66.6.20 Generate TRNG Random Number

The `TRNG_RND` command generates a 128-bit random output value using the TRNG. It takes 2048 TRNG clock cycles to generate a random value. The `CSE_CR[DIV]` field must be properly configured before this command is executed (see the register descriptions section for further information). This command takes much longer to execute than the `RND` command that should normally be used to generate random values. There is a very small probability that this command may return a TRNG error (`EC = 0x12`) even when the TRNG is operating properly (see [Random number generation](#)). This command is issued with the parameter shown in the table below.

Table 66-35. TRNG_RND Command

Register	Value	Data direction
CSE_CMD	0x14	—
CSE_P1	Random value address	Output

66.6.21 Initialize CSE

The INIT_CSE command loads the command processor firmware and memory slot data from the CSE flash memory blocks into local memory. It does not execute the secure boot protocol. The CSE firmware version is loaded into the CSE_P1 register as shown in the table below. This command must be issued before any other command when secure boot is not enabled.

Table 66-36. INIT_CSE Command

Register	Value	Data direction
CSE_CMD	0x15	—
CSE_P1	Firmware version	Output

66.6.22 Miyaguchi-Preneel (MP) Compression

The MP_COMPRESS command is a one-way compression function used to derive a 128-bit output from a given message with the parameters specified in [Table 66-37](#). The AES ECB algorithm is used to derive the 128-bit output as described in the SHE specification. The message length input is a 64-bit value which specifies the length of the message in bits. A length error (EC=0x15) is returned if the message length is greater than 0x7fffffff (4GB).

Table 66-37. MP_COMPRESS Command

Register	Value	Data direction
CSE_CMD	0x016	
CSE_P1	Message length (bits) address	Input
CSE_P2	Message start address	Input

Chapter 67

Password and Device Security Module (PASS)

67.1 Chip-specific PASS information

This chip has one instance of the PASS module. PASS implements password-based read and write protection for flash memory blocks.

This chip implements four protection regions.

67.1.1 Accesses to unimplemented PASS registers

On this chip, accesses to unimplemented PASS registers generate bus aborts.

67.1.2 PASS_LOCKm_PGn register bit mapping

Each password group defined in the DCF records is associated with a set of four PASS_LOCKm_PGn registers. Each implemented bit in these registers maps to a specific memory block.

NOTE

These registers are initialized via DCF records, so the reset values depend on user settings.

67.1.2.1 PASS_LOCK0_PGn register bit mapping

The flash memory blocks mapped to the Password Group *n* - Lock 0 Status Register (PASS_LOCK0_PGn) bits, and the corresponding PASS protection regions, are as follows.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

67.1.2.2 PASS_LOCK1_PG n register bit mapping

The flash memory blocks mapped to the [Password Group \$n\$ - Lock 1 Status Register \(PASS_LOCK1_PG \$n\$ \)](#) bits, and the corresponding PASS protection region, are as follows.

NOTE

This register cannot be used to manage the blocks mapped to the register's implemented bits because the CSE module has exclusive access to these blocks. The bits' value is 1 to reflect

the corresponding blocks' locked state, and the bits cannot be written to change that state.

			0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Protection Region	PASS Read Lock Protection Region 1																															

67.1.2.4 PASS_LOCK3_PGn register bit mapping

The flash memory blocks mapped to the [Password Group *n* - Lock 3 Status Register \(PASS_LOCK3_PGn\)](#) bits, and the corresponding PASS protection region, are as follows.

Reserved bits read as 0.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table continues on the next page...

[illegible]

67.1.3 PASS chip select (client select)

On this chip, the chip select (client select) for the PASS module is CS[3].

For details about CS[3], see the DCF Records chapter.

67.1.4 Flash memory read protection scenarios

The following table summarizes the scenarios of read lock (RL) region protection on this chip. For more information, see [Flash Memory Read Protection](#).

Table 67-1. Flash memory read protection truth table

Inputs				Outputs	
Life Cycle	Censorship DCF client	Debug Interface	LOCK3[RLx]	Read Protected RL[0] (UTest)	Read Protected RL[3:1] (other regions) ^{1, 2}
Customer Delivery	Don't care	Don't care	Don't care	Readable	Readable

Table continues on the next page...

Table 67-1. Flash memory read protection truth table (continued)

Inputs				Outputs	
Life Cycle	Censorship DCF client	Debug Interface	LOCK3[RLx]	Read Protected RL[0] (UTest)	Read Protected RL[3:1] (other regions) ^{1, 2}
OEM Production or In Field	0x55AA ³	Don't care	Don't care	Readable	Readable
	Any other value	Blocked	Don't care	Readable	Readable
		Enabled	Locked	Read Blocked ⁴	Read Blocked ⁴
			Unlocked	Readable	Readable
Failure Analysis	0x55AA	Don't care	Don't care	Readable	Readable
	Any other value	Don't care	Locked	Readable	Read Blocked
			Unlocked	Readable	Readable

1. When Life Cycle is other than In Field: If the BAM cannot find a valid RCHW because the corresponding regions are Read Blocked, the boot mode is switched to serial.
2. After the Life Cycle state OEM Production, the UTest space reserved for passwords is protected by the flash memory interface instead of PASS. PASS has no effect on the space.
3. This condition is also valid if the JTAG password is used to break the censorship scheme.
4. When Life Cycle is In Field, the BAM will not switch to serial boot mode. Instead, it will keep searching for a valid RCHW until SWT requests a reset.

67.1.5 Debug Interface Access

Whether the Debug Interface Access is enabled or blocked depends on multiple input conditions. The following table shows the the Debug Interface Access scenarios on this chip.

Table 67-2. Debug Interface Access truth table

Life Cycle	Production Disable	Censorship DCF client	Debug Enable LOCK3[DBL] bit	JTAG Password	Debug Interface Access status
Customer Delivery	Don't care	Don't care	Don't care	Don't care	Enabled
OEM Production	Don't care	0x55AA	Don't care	Don't care	Enabled
		Any other value	Unlocked (DBL = 0)	Don't care	Enabled
			Locked (DBL = 1)	Matched	Enabled
				Not Matched	Blocked
In Field	Off	0x55AA	Don't care	Don't care	Enabled
		Any other value	Unlocked (DBL = 0)	Don't care	Enabled
			Locked (DBL = 1)	Matched	Enabled
				Not Matched	Blocked
	On	Don't care	Don't care	Don't care	Blocked
Failure Analysis ¹	Don't care	0x55AA	Don't care	Don't care	Enabled
		Any other value	Unlocked (DBL = 0)	Don't care	Enabled
			Locked (DBL = 1)	Matched	Enabled
				Not Matched	Blocked

1. When advancing the Life Cycle to FA, program the Censorship DCF client with 0x55AA to enable the Debug Interface Access for Freescale.

When the Life Cycle is Customer Delivery, the Debug Interface Access is fully enabled regardless of any boundary conditions.

When the Life Cycle is OEM Production, In Field, or Failure Analysis, the Debug Interface Access depends on the Censorship DCF client settings, the 256-bit JTAG Password entered via JTAG mechanism, and the LOCK3[DBL] bit.

For the Life Cycle of In Field, the Debug Interface is further conditioned by the Production Disable feature. If the Production Disable feature is enabled when the Life Cycle is In Field, the Debug Interface Access may be permanently blocked because Production Disable overrides all other debug controls. The preceding table emphasizes this scenario by shading the set of conditions and the result in grey.

67.1.6 Duration of Debug Interface Access via JTAG password

[JTAG Password Challenge](#) explains the method for enabling Debug Interface Access by writing the [JTAG_PASSWORD register](#) via an external tool. Debug Interface Access granted by a password match remains enabled until the next "destructive" reset. On this chip, a "destructive" reset is any of the following:

- POR
- A reset caused by:
 - LVD or HVD event
 - Temperature threshold detection event
 - RESET pin
 - STCU2 self test
 - FOSU timeout

67.1.7 Production Disable enablement

The enablement of the Production Disable feature is done via a DCF client that is not accessible by software and that is automatically loaded during the reset phase of the device. For more information, see [Production disable](#).

CAUTION

Be careful when configuring the Production Disable feature because enabling Production Disable might permanently block the Debug Interface Access.

67.1.8 PASS_LCSTAT[LIFE] value source

On this chip, the SSCM is the "external" module from which PASS_LCSTAT[LIFE] derives its reset value. The value of PASS_LCSTAT[LIFE] directly reflects the value of SSCM_LCSTAT[LC].

67.2 Introduction**67.2.1 Overview**

The Password and device security (PASS) module shown in the following figure, receives password challenges and determines their validity. It also maintains the device security and access states.

Figure 67-1. PASS module block diagram

67.2.2 Features

The PASS includes these distinctive features:

- Life Cycle status
- Password comparison
- JTAG password comparison
- Production Disable control
- Flash read, write, and erase control

67.2.3 Modes of operation

The PASS operates identically in all system modes.

67.3 Memory map and register definition

This section provides a detailed description of all memory-mapped registers and DCF clients in the PASS.

Where a DCF client is listed, the reset value of that register may automatically be pre-loaded during reset based on the data stored in DCF Records in flash UTEST region.

The following table shows the memory map for the PASS. Note that all addresses are offsets; the absolute address for registers may be calculated by adding the specified offset to the base address of the PASS. The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section of the Reference Manual.

NOTE

Non-implemented registers generate bus aborts if enabled.

The following registers are available in the PASS. The shaded bits are reserved for future use. For future compatibility, only write '0' to these bits; they always read '0'.

PASS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Life Cycle Status Register (PASS_LCSTAT)	32	R	See section	67.3.1/3303

67.3.1 Life Cycle Status Register (PASS_LCSTAT)

The Life Cycle Status Register reflects the production status and DCF Censorship client status of the device. It is possible to mature the device (move the device life cycle forward), but never to revert the life cycle to an earlier state.

The reset value of the LCSTAT register LIFE field derives from an external life cycle management module (like SSCM). It is a 3-bit life cycle. This register simply displays the life cycle input from external blocks.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CNS	JUN	1	0												
W																
Reset	*	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0												LIFE			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	*	*	*

* Notes:

- LIFE field: Reset value is the Life Cycle of the device, and is unaffected by reset.
- CNS field: Reset value depends on the Censorship DCF client

PASS_LCSTAT field descriptions

Field	Description
0 CNS	This field indicates whether the DCF Censorship client has been written with a DCF record to 0x55AA or if the DCF Censorship client contains any other value than 0x55AA.

Table continues on the next page...

PASS_LCSTAT field descriptions (continued)

Field	Description
	The bit can be set (or cleared) via DCF Record in UTest Flash. NOTE: If no DCF record has been written to affect the value of the CNS bit, its reset value will be 1. 1 DCF Censorship Client value is anything other than 0x55AA. 0 DCF Censorship client value is 0x55AA.
1 JUN	This field indicates whether the device has been temporarily uncensored. Successful transmission of the JTAG password sets this bit to '1', otherwise it will be 0. (In life cycle FA, the JUN bit will always be 0.) Unsuccessful transmission clears this bit.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
3–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 LIFE	The life cycle setting is manipulated externally (SSCM). Pass displays a 3-bit input life cycle 000 Failure Analysis 001 Reserved 010 OEM Production 011 Customer Delivery 100 Reserved 101 Reserved 110 MCU Production 111 In Field

67.3.2 Challenge Selector Register (PASS_CHSEL)

This register determines which password group is challenged via the Challenge Input Register.

When the Master Only (MO) bit of the PASS_LOCK3_PGn register is set, only the master that unlocked access to the passgroup settings will be able to access these registers. The CMST field of the Challenge Status Register will reflect the locking master. When the Master Only (MO) bit of the PASS_LOCK3_PGn register is not set, the passgroup settings can be accessed by any master.

When a master writes this register, its ID sets the CMST field of the Challenge Status register.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PASS_CSTAT field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 CMST	ID of the master which has last written the CHSEL register

67.3.4 Challenge Input Register (PASS_CINn)

This register is used to provide the Challenge word *n* for a password group as selected by the Challenge Selector Register.

After programming the Challenge Selector Register, the password challenge needs to be written with eight 32-bit writes from CIN0 to CIN7 in that order. The most significant 32 bits of the password challenge must be written to CIN0. Once CIN7 is written, the password is compared. The write access only completes after the comparison has been

executed. In case of a successful password comparison, the PASS module stores the ID of the master which has written CIN0 to CIN7 in the PASS_LOCK3_PGn register of the selected password group, as well as clears the PGL bit of that register.

All accesses to these registers need to be made by the bus master that wrote the CHSEL register previously. If another master writes any of the CIN registers before the original master has written CIN7, the comparison fails.

Address: 0h base + 20h offset + (4d × i), where i=0d to 7d

PASS_CINn field descriptions

Field	Description
0–31 PW32	32 bits of the 256-bit password challenge. Only 32-bit writes may be used.

67.3.5 Password Group n - Lock 0 Status Register (PASS_LOCK0_PGn)

Each Password Group has one Lock 0 Status register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked the register becomes writable. For additional details of the LOCK bits, refer to the Flash memory description.

The LOCK bits do not come into effect before the life cycle has matured to *OEM Production* or older.

LOCK0_PGn register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset. The default value before any DCF record is written is '1', indicating that a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes to this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is OEM Production or older, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 100h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

* Notes:

- MIDLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to '1'.
- LOWLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to '1'.
- TSLOCK field: If no DCF records have been written to change the TS bit state, the bit will reset to '1'.

PASS_LOCK0_PGn field descriptions

Field	Description
0 TSLOCK	UTest NVM Lock. This bit is used to lock the UTest NVM block from programs (erase protection not needed since UTest NVM is OTP and not erasable).
1 Reserved	This field is reserved.
2–15 LOWLOCK	Low Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.
16–31 MIDLOCK	Mid Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

67.3.6 Password Group *n* - Lock 1 Status Register (PASS_LOCK1_PG*n*)

Each Password Group has one Lock 1 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable . For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the life cycle matures to OEM Production or older.

LOCK1_PG*n* register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset . The default value before any DCF record is written is '1', which indicates a block is locked. If no DCF records have been written to change the lock state, the bits will reset to '1'.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group to prevent permanent and irreversible locking of Flash blocks.

CAUTION

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is older than OEM Production, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 104h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- HIGHLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to '1'.

PASS_LOCK1_PG n field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 HIGHLOCK	High Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

67.3.7 Password Group n - Lock 2 Status Register (PASS_LOCK2_PG n)

Each Password Group has one Lock 2 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the life cycle is matured to OEM Production or older.

NOTE

Lock registers can only be accessed with 32-bit operations.

LOCK2_PG n register functions are as shown in this section.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset. The default value before any DCF record is written is '1', which indicates a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is older than OEM Production, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 108h offset + (16d × i), where i=0d to 3d

- * Notes:
- L_256LCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit resets to '1'.

PASS_LOCK2_PGn field descriptions

Field	Description
0–31 L_256LCK	Lower 256KByte Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

67.3.8 Password Group n - Lock 3 Status Register (PASS_LOCK3_PGn)

Each Password Group has one Lock 3 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable.

The LOCK bits do not come into effect before the life cycle matures to OEM Production or older.

LOCK3_PGn register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset. The default value before any DCF record is written is '1', which indicates a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is older than OEM Production, the Flash blocks are always unlocked, regardless of the values in the password groups.

Once a censored device enters the Failure Analysis life cycle, read protection is active regardless whether the system is in debug mode or not. It is still possible to unlock Flash regions with the correct passwords, however. Flash Utest region controlled by LOCK3[0] is read unlocked in Failure Analysis life cycle.

NOTE

Do not toggle DBL and RLx bits with the same write command. Use one instruction to program the DBL bit and a separate instruction to toggle the RLx bits.

Address: 0h base + 10Ch offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*

* Notes:

- U_256LCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to '1'.
- RL0 field: If no DCF records have been written to change the RL0 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL1 field: If no DCF records have been written to change the RL1 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.

Memory map and register definition

- RL2 field: If no DCF records have been written to change the RL2 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL3 field: If no DCF records have been written to change the RL3 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- Reserved field: The reset value is chip-specific. See the chip-specific PASS information
- MO field: If no DCF records have been written to change the MO bit lock state, the bit will reset to '1'.
- DBL field: If no DCF records have been written to change the DBL bit lock state, the bit will reset to '1'.
- PGL field: Reset value depends on life cycle. If life cycle is Customer Delivery or earlier, the value will be 0, otherwise 1.

PASS_LOCK3_PGn field descriptions

Field	Description
0 PGL	Password Group Lock. This bit may be set in software to lock the password group, when the device is older than Customer Delivery. Before that the value of the bit is always 0. This bit is only updatable from SW path. It cannot be updated from DCF load from Flash. This bit would be automatically locked once Flash Scanning is finished after functional reset. This bit can be cleared by writing a valid password to the Password Challenge Input Registers. 0 Password group registers are unlocked. All four registers in the Password group may be read and written without restriction. 1 Password group registers are locked. Writes to the password group registers have no effect. Read accesses work normally. (If life cycle is Customer Delivery or earlier, this bit has no effect and the registers are always unlocked.)
1 DBL	Debug Interface Lock. The default value of this bit would be '1' if not updated from flash. At power on, this bit would be updated from DCF records in flash. This bit cannot be updated from FLASH after first functional reset. After first functional reset, it can only be updated by writing to it once the passgroup has been unlocked via the PASS Password challenge mechanism. 0 Debug interface is unlocked. Accessed to all JTAG clients is allowed 1 Debug interface is locked. Only access to JTAG password challenge register is possible. Access to all other JTAG clients is blocked
2 MO	Master Only. 0 All masters can modify the passgroup settings if PGL is cleared 1 Only the Master which unlocked the passgroup can change the passgroup settings
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 MSTR	Master Access. Only the Master with this matching master ID can change the passgroup settings. This field is loaded with the ID of the master which unlocked the passgroup once the correct password is provided.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PASS_LOCK3_PGn field descriptions (continued)

Field	Description
12 RL3	Region 3 is protected. The default value of this bit would be '1' if not updated from flash. At power on, this bit would be updated from records loaded in flash. This bit cannot be updated from FLASH after first functional reset. After first functional reset, It can only be updated by Test Access Port or Through PASS Password challenge mechanism. 0 Region 3 is not protected. 1 Region 3 is protected.
13 RL2	Region 2 is protected. The default value of this bit would be '1' if not updated from flash. At power on, this bit would be updated from records loaded in flash. This bit cannot be updated from FLASH after first functional reset. After first functional reset, It can only be updated by Test Access Port or Through PASS Password challenge mechanism. 0 Region 2 is not protected. 1 Region 2 is protected.
14 RL1	Region 1 is protected. The default value of this bit would be '1' if not updated from flash. At power on, this bit would be updated from records loaded in flash. This bit cannot be updated from FLASH after first functional reset. After first functional reset, It can only be updated by Test Access Port or Through PASS Password challenge mechanism. 0 Region 1 is not protected. 1 Region 1 is protected.
15 RL0	Region 0 is protected. The default value of this bit would be '1' if not updated from flash. At power on, this bit would be updated from records loaded in flash. This bit cannot be updated from FLASH after first functional reset. After first functional reset, It can only be updated by Test Access Port or Through PASS Password challenge mechanism. 0 Region 0 is not protected. 1 Region 0 is protected.
16–31 U_256LCK	Upper 256 KB Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

67.4 DCF clients

The following table shows the DCF clients for the PASS.

Where a DCF client is listed, the reset value of that register may automatically be pre-loaded during reset based on the data stored in DCF Records in Flash UTEST region.

The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section of the Reference Manual or in DCF sheet attached to this document.

Table 67-36. PASS DCF clients

Offset	Register	Access	Reset Value	DCF Client Address (ADDR[14:0])	Section
Censorship					
None	Censorship	None	0x0000_0000	0x00B0	Censorship
Production Disable					
None	Production Disable	None	0x0000_0000	0x00C0	Production Disable

67.4.1 Censorship

Censorship is a DCF client that is *not* accessible by software. It is automatically pre-loaded during reset with data stored in DCF Record format in the Flash UTEST region.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

² This value is loaded by DCF Record during reset

Field	Description
16:31	Censorship If this value is 0x55AA the MCU is NOT censored If this value is anything other than 0x55AA, the MCU is censored

67.4.2 Production Disable

Production Disable is a DCF client that is not accessible by software. It is automatically pre-loaded during reset with data stored in DCF Record format in the Flash UTEST region. The Production disable DCF client defines the Debug Disable aspects of the Production Disable feature.

The DCF client implements 1 bit with a default value of '0'. The DCF client can only be written once and writes from subsequent DCF records are ignored.

For more information on Production disable, see [Production disable](#)

DCF Client Address: 0x00C0 Production Disable

Figure 67-34. Production Disable DCF client

Table 67-37. Production Disable DCF Client field descriptions

Field	Description
0-30	This bit is reserved and always has the value 0.
31	Debug disable.
DD	'0' = Debug Interface is Enabled and Disabled using Censorship, JTAG password and PASS_LOCK3[DBL] bit (see chip-specific PASS information). '1' = Debug Interface is disabled

67.4.2.1 Debug Disable (DD)

Debug Disable is an optional feature that, once the life cycle is In Field or beyond, overrides all other debug controls and disables the debug interface. The Debug Disable feature has a higher priority than Censorship, JTAG password and the PASS LOCK3[DBL] bit.

67.5 Functional description

The primary purpose of the PASS is to provide fine-grained access control to the Flash and debugger interface. It utilizes the DCF mechanism, as described in the SSCM section.

67.5.1 Censorship

Censorship is the overall control that enables and disables two independent security features: Debug Interface access and flash memory read protection.

The Debug Interface access is controlled by the CNS and LIFE bits of the LCSTAT register ([Life Cycle Status Register \(PASS_LCSTAT\)](#)) according to the Debug Interface Access truth table. The flash memory read protection is also controlled by the CNS and LIFE bits of the LCSTAT register according to the Flash memory read protection truth table.

The CNS bit is set or cleared by executing a DCF record that writes to the Censorship DCF client (See [Censorship](#)). The LIFE bits of the LCSTAT register are controlled by the SSCM using user programmed values from specific locations in the UTEST flash.

67.5.2 Debug Interface Access

The debug interface is fully enabled in Customer Delivery life cycle. But from OEM Production life cycle, it can be blocked using censorship and unlocked by either entering a 256 bits password via JTAG or by software clearing the DBL bit the PASS_LOCK3 registers (See [Password Group \$n\$ - Lock 3 Status Register \(PASS_LOCK3_PG \$n\$ \)](#)). Both these debug enabling options are further conditioned by life cycle and Production Disable.

The debug interface enable truth table for this chip is shown in the device specific PASS section of this chapter.

67.5.2.1 JTAG Password Challenge

To enable the Debug Interface Access, the JTAG password challenge register in the JTAGC, needs to be written by an external tool. If that password matches the JTAG password stored in UTEST flash, Debug Interface Access is enabled until the next destructive reset.

67.5.3 Flash Memory Read Protection

Flash Memory Read Protection is a security feature that can selectively make regions of the flash memory unreadable. Any attempt to read a region of flash that is read protected results in the read access terminating with a transfer error. This is consistent for all bus masters including debug bus masters.

The assertion of flash memory region read protection is controlled by Life Cycle, Censorship and whether the Debug Interface access is enabled or blocked. The Flash memory read protection truth table describes the combination of conditions that drive Flash Memory Read Protection.

The intention of the feature is to protect the contents of the flash from being read. The flash memory is readable in normal operation, allowing the application to run, but becomes read protected when a Debug tool is attached and enabled (JTAG password or LOCK3[DBL] bit).

The flash memory is also read protected when the life cycle status is Failure Analysis. This life cycle is used for a module field failure, where the device is returned for failure analysis. This protection prevents the contents of the flash memory from being read.

The flash memory is divided into a number of Regions (3 to 5 depending on the device). The assignment of the regions is defined in the device reference manual.

The memory read protection truth table for this chip is shown in the device specific PASS information.

67.5.4 Production Disable

67.5.4.1 Overview and rationale

Production Disable is an optional feature that, once enabled, allows the MCU to function completely normally without any constraints, except the Debug interface is disabled.

67.5.4.2 Enabling

The feature is enabled via the Production Disable DCF client in the PASS module. Bit 0 enables the Debug Interface Disable. See [Production Disable](#) for details.

This information can be written by adding a DCF Record to the DCF record list in Flash UTEST. The DCF Client is configured to accept only one write. Subsequent DCF records that write to this DCF client are ignored.

If no DCF Record writes to this client, the default state of this feature is disabled. If, for a particular application, there is no intention of ever using this feature, it would be good practice to add a DCF Record that writes this client to 0x0000_0000. This is not essential, but ensures the feature can not be enabled accidentally.

67.6 Initialization/application information

67.6.1 Reset

The reset state of each individual bit is shown within the Register Description section. However, many bits receive their values based on DCF records stored in the UTEST Flash memory block.

67.6.2 Setting lock bits in a password group

There is no restriction on setting and clearing lock registers in the UTEST Flash, apart from the available space for DCF records. It is possible to set and clear them multiple times.

Table 67-38. CS/ADDR Values for Lock Registers

Register	DCF Command Word
PW Group 0

1. Value depends on the DCF Client Select assigned to the PASS module in the device. See chip specific PASS information for the Client Select assignment

In order to set the MIDLOCK field in the Lock0 register of password group 1 to the value 0x00FF and other fields to 0, the DCF record has to be added as shown in [Table 67-39](#).

Table 67-39. Setting some bits in the MIDLOCK field

ADDR offset	DATA	Description
0x00	0x05AA_55AF	Start Record
0x04	0x0000_0000	
0x08	0x0000_00FF	PW Group 1, Lock0 Set MIDLOCK to 0xFF
0x0C	0xxxxx_0110	
0x10	0xFFFF_FFFF	Non-Programmed Addresses
0x14	0xFFFF_FFFF	
...	...	

Chapter 68

Tamper Detection Module (TDM)

68.1 Chip-specific TDM information

This chip has one instance of the TDM. The TDM and its associated DCF clients enable the user to:

- Select a flash memory block for tamper detection protection by assigning the block to a Tamper Detection Region (TDR)
- Override a block's tamper detection protection under certain circumstances
- Disable the override of a block's tamper detection protection
- Configure a flash memory block as One Time Programmable (OTP), meaning the block can be written only once

CAUTION

Specifying flash memory blocks to be monitored by the TDM and configuring flash memory blocks as OTP is done by defining DCF records. Use caution when assigning flash memory blocks to TDRs or configuring blocks as OTP. Some DCF records can be written only one time. Many DCF records can be written more than once, but the setting defined in each write is irreversible. For details about TDM-related DCF records and DCF clients, see [DCF clients](#). For additional information, see the chip-level [Device Configuration Format \(DCF\) Records](#) details.

68.1.1 Disabling the override of tamper detection

The [Tamper Region Override \(TO\) DCF client](#) allows the user to override tamper detection protection. The override cancels tamper detection protection for all blocks in a TDR and is irreversible.

The [Software Tamper Region Override Disable \(STO_DIS\) DCF client](#) allows the user to disable the override option permanently.

To optimize security on this chip, disable the Tamper Region Override option permanently by using the Software Tamper Region Override Disable DCF client.

68.1.2 TDR_n_LOCK_m DCF client bit mapping

The TDR_n_LOCK_m DCF clients provide a means to select flash memory blocks for inclusion in a TDR. Specific memory blocks map to particular bits in TDR_n_LOCK_m clients.

68.1.2.1 TDR_n_LOCK0 DCF client bit mapping

The flash memory blocks mapped to the [Tamper Region Assignment DCF client \(TDR_n_LOCK0\)](#) bits are as follows.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Register Field	Reserved															256KBOTPEN[15:0]																
Flash Memory Block Name																																

68.2 Overview

The Tamper Detection Module provides a type of flash memory erase protection mechanism that requires software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. The mechanism does not *prohibit* an erase operation on any block within a TDR—it requires a record to be written before the operation can execute. Collectively, the records are referred to as a “diary”. At minimum, the diary serves as an erase counter. Because the diary record content is customer-defined, the diary can also serve as a history.

Up to 6 TDRs can be defined via DCF records.

The following figure shows the block diagram of the TDM and its interface to other system components.

Figure 68-1. Tamper Detection Module block diagram

Security information is passed to the TDM by the SSCM module via the DCF bus. Among the data are:

- OTP (One Time Programmable) settings for each of the flash blocks
- Base address for the diary in the flash
- Block assignments for the TDRs
- Tamper region override information
- Software tamper region disable

The TDM module controls the flash blocks for erase operations and sets them as OTP.

The two flash buses are used to control the flash blocks for erase operation and set them as OTP. OTP means that flash erase of the entire block is disabled and the only words that are already erased can be programmed. Over-programming is not possible.

NOTE

The pass module provides the control for erase operation for each flash block as well as for each region of flash memory, and the PASS settings have priority over the settings of TDM.

The flash block indicates to the TDM the address of the programmed word. This address is internally decoded and provides a means to verify whether the block is part of any TDRs. The memory map registers interface provides a means to the user to read information of the TDM registers.

68.3 Features

The Tamper Detection Module supports these distinctive features:

- Erase counter (diary) for each TDR to record up to 256 write attempts on the flash blocks
 - The diary is divided into 6 parts (TDRs), each consisting of 256 64-bit records.
 - The diary block should be assigned as OTP region in flash.
 - The diary area can store any type of relevant information.
- Tamper Detection Region Block Assignment
 - Any flash block can be assigned to any TDR and be controlled.
- 32-bit Erase Lock DCF clients for each flash memory TDR defined.
- 32-bit OTP Enable DCF clients to disable the erase operation for an entire flash block
- Override TDR via DCF records¹
 - Allows block assigned to a TDR to be unlocked for erase even if the TDR is locked for this operation.
- Memory mapped registers interface for reading via software of specific registers.

68.4 External signal description

There are no external signals driving or being driven by the TDM.

1. The Tamper Region Override DCF record is a "write one only" DCF record. If an override is applied to a TDR it is permanent and cannot be reversed.

68.5 DCF clients

TDM-related DCF records perform the following functions:

- Establish a permanent diary base address
- Define Tamper Detect Regions (TDRs) to monitor on-chip flash memory program/erase activity
- Permanently disable one or more Tamper Regions
- Permanently disable ability for software to permanently override one or more TDRs
- Configure flash memory as One Time Programmable (OTP) on a per-block basis

The following table gives an overview on the TDM DCF clients implemented.

Table 68-1. DCF clients

DCF Client Name	Description	Strategy
Diary Base Address	Stores the base address of the tamper detection diary	write once, write 1 to 0 only
Tamper Region Override	Stores information of which TDR is to be overridden	write 0 to 1 only
Software Tamper Region Override Disable	Stores information to disable the software mechanism to override the TDR	write once, write 0 to 1 only
OTPEN[nb] (OTP Enable)	Stores information of which flash blocks is to be assigned as OTP (One Time Programmable) - nb means one register for each Lock register of the flash memory	write 0 to 1 only
TDR[n]_LOCK[m] Region Assignment	Stores information of which flash block is assigned to a TDR. • n specifies a TDR • m specifies the flash blocks as per the LOCK registers of the flash memory.	write 0 to 1 only

68.5.1 Diary Base Address (DBA) DCF client

This DCF client holds base address information of the diary. The following diagram depicts this client.

CAUTION

This write-once DCF client can be written only one time. After one DCF record has written to this client, all subsequent writes are ignored.

**Table 68-2. Diary Base Address (DBA) DCF client field description**

Field	Description
0–31 DBA	Diary Base Address. This field holds the base address of the diary. This information is then used to verify if the diary being programmed matches any TDR region. NOTE: Diary Base Address must be on a 16 KB boundary.

68.5.2 Tamper Region Override (TO) DCF client

This DCF client holds override information for each TDR. The following figure shows the diagram for this register.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the override of a TDR permanent.

Table 68-3. Tamper Region Override (TO) DCF client field descriptions

Field	Description				
0–25 Reserved	This field is reserved and should be written with all zeroes when programming the TOE fields.				
26–31 TOE5 to TOE0	TDR Override Enable. Each TOE _n field, where <i>n</i> represents the TDRs, holds information of the Override Enable status for each TDR. <table border="1" data-bbox="440 389 1469 528"> <tr> <td>0</td><td>Normal operation. Blocks assigned to this TDR can NOT be erased until the diary is written.</td></tr> <tr> <td>1</td><td>Diary override. The blocks assigned to this TDR can be erased WITHOUT writing to the diary.</td></tr> </table>	0	Normal operation. Blocks assigned to this TDR can NOT be erased until the diary is written.	1	Diary override. The blocks assigned to this TDR can be erased WITHOUT writing to the diary.
0	Normal operation. Blocks assigned to this TDR can NOT be erased until the diary is written.				
1	Diary override. The blocks assigned to this TDR can be erased WITHOUT writing to the diary.				

68.5.3 Software Tamper Region Override Disable (STO_DIS) DCF client

This DCF client holds information to disable the software mechanism to override the tamper detect regions.

CAUTION

This write-once DCF client can be written only one time. After one DCF record has written to this client, all subsequent writes are ignored.

DCF Client Address: 0x0002

Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 68-4. Software Tamper Region Override Disable (STO_DIS) DCF client field descriptions

Field	Description
0–25 Reserved	This field is reserved and should be written with all zeroes when programming the STO_DIS fields.

Table continues on the next page...

Table 68-4. Software Tamper Region Override Disable (STO_DIS) DCF client field descriptions (continued)

Field	Description
26–31 STO_DIS5 to STO_DIS0	Software TDR Override Disable TDR _n . Each STO_DIS _n field, where <i>n</i> represents the TDR number, holds information to disable the software mechanism to override TDR _n .
0	Software tamper detect override mechanism supported
1	Software tamper detect override mechanism disabled. Any attempt to override TDR _n by loading a service key value in STO_KEY _n register is ignored.

68.5.4 One Time Programmable Enable (OTPEN0) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK0 register of the flash memory. The following diagram depicts this client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

DCF Client Address: 0x0008

Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 68-5. One Time Programmable Enable (OTPEN0) DCF client

Field	Description
0–3 Reserved	This field is reserved and should be written with all zeroes when writing to this client.
4–15 LOWOTPEN	Low Block OTP Enable. This field affects flash memory blocks in Low address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module.
0	Corresponding flash blocks are not assigned as OTP
1	Corresponding flash blocks are assigned as OTP
16–31 MIDOTPEN	Mid Block OTP Enable. This field affects flash memory blocks in Mid address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module.
0	Corresponding flash blocks are not assigned as OTP
1	Corresponding flash blocks are assigned as OTP

68.5.5 One Time Programmable Enable (OTPEN1) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK1 register of the flash memory. The following diagram depicts the client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

Table 68-6. One Time Programmable Enable (OTPEN1) DCF client field descriptions

Field	Description
0–15 Reserved	This field is reserved and should be written with zeroes when writing to this client.
16–31 HIGHOTPEN	High Block OTP Enable. This field affects flash memory blocks in High address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP

68.5.6 One Time Programmable Enable (OTPEN2) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK2 register of the flash memory. The following diagram depicts the client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

Table 68-7. One Time Programmable Enable (OTPEN2) DCF client field descriptions

Field	Description
0–31 256KBOTPEN	256 KB Block OTP Enable. This field affects flash memory blocks in 256KB address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module.
0	Corresponding flash blocks are not assigned as OTP
1	Corresponding flash blocks are assigned as OTP

68.5.7 One Time Programmable Enable (OTPEN3) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK3 register of the flash memory. The following diagram depicts the client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

Table 68-8. One Time Programmable Enable (OTPEN3) DCF client field descriptions

Field	Description
0–15 Reserved	This field is reserved and should be written with zeroes when writing to this client.
16–31 256KBOTPEN	256 KB Block OTP Enable. This field affects flash memory blocks in the upper range of 256KB address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module.
0	Corresponding flash blocks are not assigned as OTP
1	Corresponding flash blocks are assigned as OTP

68.5.8 Tamper Region Assignment DCF client (TDRn_LOCK0)

This DCF client holds the assignment information of flash memory blocks to a specific TDR. Each flash memory block can be assigned to any TDR (n varies from 0 to 5). This DCF client holds the assignment information for only those blocks specified in the LOCK0 register in the flash memory. For that reason, the layout of this DCF client mirrors the LOCK0 register in the flash memory. The following diagram depicts the TDRn_LOCK0 DCF client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the assignment of a flash memory block to a TDR irreversible unless the entire TDR is overridden.

DCF Client Address: $0x0014 + ((n \times 4) + 0)$

Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

0	Corresponding flash blocks are not assigned to the TDRn
1	Corresponding flash blocks are assigned to the TDRn

68.5.10 Tamper Region Assignment DCF client (TDRn_LOCK2)

This DCF client holds the assignment information of flash memory blocks to a specific TDR. Each flash memory block can be assigned to any TDR (*n* varies from 0 to 5). This DCF client holds the assignment information for only those blocks specified in the LOCK2 register in the flash memory. For that reason, the layout of this DCF client mirrors the LOCK2 register in the flash memory. The following diagram depicts the TDRn_LOCK2 DCF client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the assignment of a flash memory block to a TDR irreversible unless the entire TDR is overridden.

DCF Client Address: $0x0014 + ((n \times 4) + 2)$

Access: DCF write

68.5.11 Tamper Region Assignment DCF client (TDRn_LOCK3)

This DCF client holds the assignment information of flash memory blocks to a specific TDR. Each flash memory block can be assigned to any TDR (n varies from 0 to 5). This DCF client holds the assignment information for only those blocks specified in the LOCK3 register in the flash memory. For that reason, the layout of this DCF client mirrors the LOCK3 register in the flash memory. The following diagram depicts the TDRn_LOCK3 DCF client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the assignment of a flash memory block to a TDR irreversible unless the entire TDR is overridden.

68.6.1 TDR Status Register (TDM_TDRSR)

This register contains the current status, i.e., locked or unlocked, of each tamper region, i.e., TDR.

- If a tamper region is locked, the blocks assigned to that tamper region cannot be erased.
- If a region is unlocked, the blocks within the tamper region can be erased.

The register contains a status bit for each TDR. Status is determined as follows:

1. The default status for each TDR is '1', which indicates that the erase operation is disabled for all flash blocks associated with the TDR.
2. The status bit for a TDR is set to '0' (indicating that the erase operation for all flash blocks associated with the TDR is enabled) if either a successful programming operation to the TDR diary region has been performed or the TDR Override bit for that TDR is set.

NOTE

- TDRSR is a read-only register and writes have no effect on it. Write operations result in a transfer error.
- If the reset value for this register is determined by a DCF record, it will be noted in the chip-specific information at the beginning of this chapter. Otherwise, the reset value is as shown.

Address: 0h base + 0h offset = 0h

TDM_STO_KEYn field descriptions

Field	Description
0–31 STO_KEY	Software Tamper Override Key Diary n. This field holds the service key value for overriding Tamper Detect Region n. By loading STO_KEYn with the correct signature of 0x55AA5A5A, Tamper Detect Region n is overridden, and the flash blocks assigned to Tamper Detect Region n are open for erase. This field has no effect when STO_DISn field of STO_DIS DCF client is set. Caution: The STO_KEYn registers can only be written once.

TDM_STO_KEY n field descriptions (continued)

Field	Description

68.7 Functional description

The primary purpose of the TDM is to provide a Tamper Detection mechanism by enabling an Erase Counter (or diary) for regions within the flash. These regions are called Tamper Detection Regions. The following sections cover the entire functionality of this module.

68.7.1 Flash erase counter and tamper detection

A flash region block or part of it is assigned for implementing the diary. The base address for the diary is defined by a DCF Record.

The diary is divided into 6 parts where each part consists of 256×64 -bit records, to record up to 256 write attempts on the flash blocks assigned to each Tamper Detection Region. For correct operation, the diary should reside in a flash block that is assigned as OTP.

Each flash block can be assigned to any of the TDRs. Related to each TDR is a group of 4×32 -bit internal hardware registers that are initialized by DCF records that define the tamper region. These registers mirror exactly the LOCK registers bits from the flash module.

Each TDR n _LOCK m register is loaded at boot time by the SSCM, which defines if the associated flash block is Locked for Erase in a particular TDR:

- '1' means the flash block is locked for erase
- '0' means the flash block is not locked for erase

Before performing an erase in one of the blocks locked for erase and associated to a TDR, a program operation has to be performed on the diary part for that TDR. As the diary should be OTP, successive writes are allowed on unprogrammed double words only. This ensures that diary records can only increase and that data recorded in the diary is not modifiable by software.

At the end of a successful double-word program operation, the flash module indicates to the TDM the address of the programmed double word. The TDM determines whether the programmed data was written to the correct TDR diary location and then unlocks the

blocks for erase operation for the corresponding TDR. The TDM ensures that this erase operation on unlocked blocks is allowed until the completion of the erase sequence or until next destructive reset.

When attempting to update the TDM diary and erase flash blocks, set MCR[PECIE] in the Embedded Flash Memory registers to enable interrupt notification for program and erase operations. Then clear MCR[PECIE] to service the interrupt after each program or erase operation. This sequence must be executed before attempting to update the TDM diary, and then again before attempting to erase the unlocked flash blocks.

NOTE

All blocks associated to a TDR where an erase operation is allowed can be erased all together.

The data programmed in the diary location is flexible, and may include count information or other important customer information.

NOTE

There is no restriction on the type or format of data that can be programmed in the diary, so software must verify whether the diary is full. If a TDR's diary area is full, the tamper detect mechanism can be disabled for that TDR by creating a Tamper Region Override (TO) DCF record with the TDR's corresponding TDR Override Enable (TOE) bit set to '1'. This allows erase operations to be performed to the TDR without any diary entry.

The setting from “override tamper region lock” DCF record ([Diary](#)) has priority over the settings in the TDR_n_LOCK0 – 3 registers. In other words, if a TDR is unlocked for erase by the override tamper region lock, the TDR_n_LOCK_m bits have no effect on the TDR that has been overridden, but the tamper detection remains active for all TDRs not having the override bit set.

Moreover, if a block is locked by the PASS_LOCK_x_PG_n registers or by TDR_n_LOCK_m, the block is locked for erase.

NOTE

The settings in the Tamper Region Override Register have priority over the TDR_n_LOCK_m registers. The PASS module also has priority over the settings done in the TDM. For instance, if blocks in a TDR are unlocked for erase operation via the TDM, but the same blocks are programmed to be locked for erase operation in PASS, the blocks end up being locked for erase operation.

Attempts to erase the flash without first writing the diary will be ignored by the flash. The contents in the flash block will remain unchanged and MCR[PEG] will be asserted, indicating the operation was successful and the contents of the block are properly protected from the erase operation.

68.7.2 Assigning blocks to Tamper Detect Regions (TDR)

Each TDR is defined by a group of 4 x 32-bit DCF records and clients, with each containing bits that map to specific blocks in a flash region. These mappings mirror exactly the LOCK registers bits from the flash module. Hence, the block assignment registers are named as $TDR_n\_LOCK_m$ where n is the number of a tamper region, that is, 0- 5 and m varies from 0-3 as flash contains four Lock registers.

In these DCF records:

- '1' means that the corresponding flash block is assigned to this TDR
- '0' means that the corresponding flash block is not assigned to this TDR (Default)

DCF clients are not visible to software. They can not be read nor written. They can only be initialized by DCF record within the UTest flash block during reset. The value of these registers can be evaluated by reading all the UTest DCF records and searching for records that correspond to these clients.

NOTE

No flash block should be assigned to more than one TDR. Each block should correspond to a single TDR. For example, if a single block is assigned to TDR0 and TDR1, then even if the Diary is programmed for both TDR0 and TDR1, this flash block will never be unlocked for erase operation.

68.7.3 Diary

The diary is a region of the flash memory where records of block erases for each TDR are stored. The format and size of the records are not fixed. The only requirements are that each diary has a maximum size of 2 KB, and the minimum size of any programming operation is 8 bytes to honor OTP restrictions. Therefore, each diary can hold a maximum of 256 64-bit entries.

A flash region block or part of it must be assigned for implementing the diary. The base address for the diary is determined by a value written in a DCF record. The diary can be placed within any flash block in flash array, and history records in it can be read by any core.

NOTE

To maintain the security of the TDR, the block where the diary is placed must be assigned as OTP within the OTP registers.

The base address of the diary is implemented using a DCF Client. The DCF client is only writable once and the default bit state is 1.

The DCF clients can not be read nor written by software. They can only be initialized by DCF record from within UTEST block during reset. The value of these registers can be evaluated by reading all the UTEST DCF records and searching for records that write these DCF clients.

68.7.4 Specifying the diary base address

The diary is a region of flash memory where records of block erases for each TDR are stored. The format and size of these records is defined by the customer. The only hardware constraints are that each diary has a maximum size of 2 KB and the minimum size of any programming operation is 8 bytes. Therefore, each diary region limits the erases of the assigned blocks to 256 erases.

The diary can be placed within any flash block in the flash array. To maintain the security of the TDR, the block where the diary is placed, must be assigned as OTP within the OTP registers, while in customer delivery or OEM production life cycle states.

The base address of the diary is implemented with a 20-bit DCF client that can be initialized by the SSCM during reset. The DCF client is writable once and the default bit state is '1'.

The base address register is not visible to software. It cannot be read nor written. It can only be initialized by DCF record within UTest flash during reset. The value of this register can be evaluated by reading all the UTest flash DCF Records and searching for record that writes this register.

Each TDR is assigned a 2 KB section of the diary. With 6 TDRs, 12 KB of diary space is required.

The diary base address must be at a 16 KB boundary. Therefore the least significant 14 bits of the base address must all be '0'.

The Base address of the diary is represented by:

Diary_Base_Address = 0bxxxx_xxxx_xxxx_xxxx_xx00_0000_0000_0000

The base address of each TDR is shown below:

- TDR0 = Diary_Base_Address + 0b00_0000_0000_0000

- $\text{TDR1} = \text{Diary\_Base\_Address} + 0b00\_1000\_0000\_0000$
- $\text{TDR2} = \text{Diary\_Base\_Address} + 0b01\_0000\_0000\_0000$
- $\text{TDR3} = \text{Diary\_Base\_Address} + 0b01\_1000\_0000\_0000$
- $\text{TDR4} = \text{Diary\_Base\_Address} + 0b10\_0000\_0000\_0000$
- $\text{TDR5} = \text{Diary\_Base\_Address} + 0b10\_1000\_0000\_0000$
- End of the diary = $\text{Diary\_Base\_Address} + 0b11\_0000\_0000\_0000$

68.7.5 TDR lock status

The status of whether a TDR is locked for erase is maintained by the TDM. This is accomplished by implementing a register with as many bits as the number of TDRs. The default state of these bits is 1, which is defined as "TDR Erase Blocked". See [TDR Status Register \(TDM_TDRSR\)](#) for further details about this register.

When the flash memory module has completed a programming operation, the address of the location programmed is output from the flash module. The TDM in turn compares that address to determine if it falls within the range of any TDR diary regions. If it is within any TDR, the corresponding status bit is set to 0 meaning "TDR Erase Enabled".

These status bits are all reset to 1 when the flash module signals an erase complete by asserting the PEC (Program Erase Complete) signal.

The state of the 6 status bits can be read through the TDRSR. See [TDR Status Register \(TDM_TDRSR\)](#). The address of the last successful programming operation provided from the flash memory to the TDM can be read through the LFPAR. See [Last Flash Programmed Address Register \(TDM_LFPAR\)](#).

68.7.6 TDR override

Before a block protected by a tamper detect region can be erased, a record must be written to the associated diary. Software must search through the diary to find the end of the records, where the next available diary location that can be written. After a maximum of 256 records are programmed to the diary, a TDR diary is full. Full means that at least 1 bit has been programmed to '0' in each 64 bit double word within the 2 KB diary.

If software determines that a particular TDR diary is full it may override the diary to allow erasing to continue or it may choose to stop further erases and to flag an error.

Diary Override bits are implemented with a DCF client consisting of 6 bits, one for each TDR. See the device configuration information at the beginning of this chapter for TDM DCF client details.

The Diary Override bits are by default set to '0'; which means the diary must be written before an erase can occur. The DCF client can be written many times but the bits can only be written to '1'. Writes to '0' are ignored. In this way, by default, all Tamper Detect Regions are active. The Tamper detect region diaries can be individually overridden by writing a DCF record that sets that corresponding bit to '1'. In this mode, the TDR status bit is permanently set to 0 to allow flash erase.

The application can also override the diary by loading a service key to the `STO_KEYn` program-visible register, where *n* denotes the tamper detect region. By loading the value `0x55AA5A5A` into `STO_KEYn` register, the corresponding tamper detect region is overridden. This software override mechanism is disabled if the `STO_DISn` field of the `STO_DIS` DCF Client is set.

68.7.7 One time programmable (OTP)

68.7.7.1 Overview

Any flash block within the flash array can be assigned, at any time, to be OTP. Once a flash block is assigned OTP, it cannot be changed back.

OTP means that flash erase of the entire block is disabled and only 64-bit double words that are already erased (that is, flash content is `0xFFFF_FFFF_FFFF_FFFF`) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block will become OTP after the next functional reset.

Appendix A

Release Notes

A.1 General changes throughout and Preface

- In eDMA chapter, removed "Lockstep" section

A.2 Introduction changes

- No substantial content changes

A.3 Signal Description changes

- No substantial content changes

A.4 Memory Map, Interrupts, and DMA Requests changes

- In [Table 4-3](#) of [Memory map](#)
 - In footnote associated with row for Unique Chip Identifier (UID), changed Freescale to NXP
 - In row for Life cycle slot 0 and associated footnote, changed "Freescale Production" to "MCU Production"
- In [Table 4-4](#) of [Interrupt vector assignments](#)
 - Changed every *ETPU* reference to *eTPU*
 - In rows for vectors 68-99, changed eTPU_CISR_A to eTPU_GCR_CISR_ENG1
 - In rows for vectors 243-274, changed eTPU_CISR_B to eTPU_GCR_CISR_ENG2
 - In rows for vectors 370-393 and 493-500, changed eTPU_CISR_C to eTPU_GCR_CISR_ENG1

A.5 Device Configuration Format (DCF) Records changes

- Added new note in multiple sections: "Be careful when programming the UTEST Miscellaneous, XOSC ANA, and VREG Enable DCF clients. DCF records are processed sequentially in the order they are read from flash memory. DCF records that control actions such as enabling/disabling voltage regulators or detectors should not be programmed more than once with different values."
 - In [Table 5-6](#) of [DCF clients](#) added as new footnote referenced in "DCF client special strategy" column for UTEST Miscellaneous, UTEST XOSC ANA, and VREG Enable clients
 - Added as Note in descriptions of:
 - [UTEST Miscellaneous DCF client](#)
 - [UTEST Analog External Oscillator \(XOSC ANA\) DCF client](#)
 - [UTEST PMC Voltage Regulator Enable \(VREG ENB\) DCF client](#)
- In [DCF clients](#) section, in first body row of [Table 5-6](#) about STCU2 clients, removed reference to "32-bit PRPG"

 - Updated NOTE "An example of determining the HFREF_{Actual}..."
- In [CMU Interrupt Status Register \(CMU_ISR\)](#)
 - Updated NOTE "All flags in the CMU_ISR are set asynchronously. This..."
- In [CMU Interrupt Status Register \(CMU_ISR\)](#)
 - Updated NOTE "Before entering low-power stop modes,..."
- [CMU Control Status Register \(CMU_CSR\)](#)
 - Added note to CSR[SFM] field description, "MSR[MD] must be written before enabling..."

A.23 Embedded Memories changes

- No substantial content changes

A.24 RAM Controller (PRAMC) changes

A.24.1 Chip-specific PRAMC information changes

- No substantial content changes

A.24.2 PRAMC module changes

- No substantial content changes

A.25 Flash Memory Controller (PFLASH) changes

A.25.1 Chip-specific PFLASH information changes

- No substantial content changes

A.25.2 Flash memory controller module changes

- [Flash memory controller memory map](#) :
 - Typo fixed: "If application software functionality includes invalidating a port read buffer, t recommended method..." changed to, "If application software functionality includes invalidating a port read buffer, the recommended method..."
- [ECC on data flash accesses](#) :
 - Content significantly rearranged.

A.26 Embedded Flash Memory (C55FMC) changes

A.26.1 Chip-specific C55FMC information changes

- No substantial content changes

A.26.2 c55fmc module changes

- No substantial content changes

A.27 External Bus Interface (EBI) changes

A.27.1 Chip-specific EBI information changes

- No substantial content changes

A.27.2 EBI module changes

- No substantial content changes

A.28 Analog Modules Overview changes

- No substantial content changes

A.29 Sigma Delta Analog-to-Digital Converter (SDADC) Digital Interface changes

A.29.1 Chip-specific SDADC information changes

- No substantial content changes

A.29.2 SDADC module changes

- No substantial content changes

A.30 Enhanced Queued Analog-to-Digital Converter (EQADC) changes

A.30.1 Chip-specific EQADC information changes

- No substantial content changes

A.30.2 EQADC module changes

- In [Conversion command format for the standard configuration](#) removed stray line between bits 22 and 23 in [Figure 30-117](#)

A.31 Decimation Filter (DECFILTER) changes

A.31.1 Chip-specific DECFILTER information changes

- No substantial content changes

A.31.2 DECFILTER module changes

- No substantial content changes

A.32 Temperature Sensor changes

A.32.1 Chip-specific Temperature Sensor information changes

- No substantial content changes

A.32.2 Temperature Sensor changes

- No substantial content changes

A.33 System Timer Module (STM) changes

A.33.1 Chip-specific STM information changes

- No substantial content changes

A.33.2 STM module changes

- No substantial content changes

A.34 Software Watchdog Timer (SWT) changes

A.34.1 Chip-specific SWT information changes

- In [SWT time-out events and invalid accesses: configuring reset and interrupt requests](#)
 - Added information about invalid accesses and SWT_CR[RIA], including [Table 34-3](#)
 - Reorganized section to accommodate new information

A.34.2 SWT module changes

- In "Memory Map and Registers"
 - In introductory text, incorporated minor edits and reorganized some paragraph text as list
 - Incorporated minor edits in each register description
- In [SWT Control Register \(SWT_CR\)](#) description of [ITR](#) field
 - In Note, changed "reset requests" to "reset requests and interrupt requests"
- In [SWT Control Register \(SWT_CR\)](#) description of [RIA](#) field
 - Added a Note: "For a description of how this chip implements SWT reset requests resulting from SWT invalid accesses, see the chip-specific SWT information."
 - Edited description of field value 1
- In [Window mode](#) edited and reorganized entire section

A.35 Periodic Interrupt Timer (PIT-RTI) changes

A.35.1 Chip-specific PIT information changes

- No substantial content changes

A.35.2 PIT module changes

- No substantial content changes

A.36 Enhanced Modular IO Subsystem (eMIOS) changes

A.36.1 Chip-specific eMIOS information changes

- No substantial content changes

A.36.2 eMIOS module changes

- No substantial content changes

A.37 Enhanced Time Processing Unit (eTPU) changes

A.37.1 Chip-specific eTPU information changes

- No substantial content changes

A.37.2 eTPU module changes

- Editorial changes (including the addition of cross-references for improved usability).
- Throughout the chapter, revised register names so that they are always consistent with the official register names as specified in these tables:
 - "eTPU_SCR memory map" in [System Configuration memory map and registers](#)
 - "eTPU_TBR memory map" in [Timebase memory map and registers](#)
 - "eTPU_ER memory map" in [Engine memory map and registers](#)
 - "eTPU_LMR memory map" in [Latency Monitor memory map and registers](#)
 - "eTPU_MESR memory map" in [Memory Error Support memory map and registers](#)
 - "eTPU_GCR memory map" in [Global Channel memory map and registers](#)
 - "eTPU_CCCR memory map" in [Channel Configuration Control memory map and registers](#)
 - "eTPU_SSIR memory map" in [Shared Subsystem Integration memory map and registers](#)
- So, for example, the chapter now consistently uses:
 - eTPU_MESR_CERDR instead of ETPUCERD
 - eTPU_GCR_CDTRER_ENG1 and eTPU_GCR_CDTRER_ENG2 instead of ETPUCDTRER
 - eTPU_TBR_STAC_ENG1 and eTPU_TBR_STAC_ENG2 instead of ETPUREDCE
- In [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#), revised the CIE field description.
- In [eTPU Channel n Configuration Register for Engine 1 \(eTPU_CCCR_CnCR_ENG1\)](#), in the DTRE field description, changed "This bit is mirrored from [eTPU Channel Data Transfer Request Enable Register for Engine 2 \(eTPU_GCR_CDTRER_ENG2\)](#)" to "This bit is mirrored from [eTPU Channel Data Transfer Request Enable Register for Engine 1 \(eTPU_GCR_CDTRER_ENG1\)](#)."
- In [eTPU Channel n Configuration Register for Engine 2 \(eTPU_CCCR_CnCR_ENG2\)](#), in the T4DIS field description, added "For more details, see [Channel timing modes](#)."
- In [Table 37-344](#), deleted the footnote "See the eTPU integration guide..."
- In [Latency Monitor](#), in the last bulleted list, changed "after each latency measurement, the value measured is compared with the MAXLAT value in the register ETPULMnMR; and if MAXLAT is not zero and the new measured value is greater." to "After each latency measurement, the value measured is compared with the LATENCY value in [eTPU Latency Monitor Measure Register for Engine 1 \(eTPU_LMR_LMnMR_ENG1\)](#) and [eTPU Latency Monitor Measure Register for Engine 2 \(eTPU_LMR_LMnMR_ENG2\)](#). If the new measured value is greater, it replaces the old value in [eTPU Latency Monitor Measure Register for Engine 1 \(eTPU_LMR_LMnMR_ENG1\)](#) and [eTPU Latency Monitor Measure Register for Engine 2 \(eTPU_LMR_LMnMR_ENG2\)](#)."
- In [Using Worst-Case Latency estimates to evaluate performance](#), changed "Refer to Freescale Programming Note" to "See NXP Programming Note".
- In [Execution and channel timing](#), deleted "For timings of eTPU block internal interface signals, consult the eTPU Integration Guide. For timings internal to the eTPU, refer to the eTPU Creation Guide."

- Editorial changes in [PRSS - Pin Request Service Sample](#).
- In [Unsigned Fractional Multiplication \(fmultu\)](#), added the footnote "24-bit fractional signed/unsigned multiplication is equivalent to mults/multu." to the second sentence.
- In [TDLA/B - Transition Detect Latches](#), added the footnote "In TPU3, when TCR1 was counting at maximum rate of eTPU clock divided by 2, the next value was captured." to the fourth paragraph.

A.38 Reaction Module (REACM2) changes

A.38.1 Chip-specific REACM2 information changes

- No substantial content changes

A.38.2 REACM2 module changes

- No substantial content changes

A.39 Input Glitch Filter (IGF) changes

A.39.1 Chip-specific IGF information changes

- No substantial content changes

A.39.2 IGF module changes

- No substantial content changes

A.40 FlexCAN (CAN) changes

A.40.1 Chip-specific FlexCAN information changes

- No substantial content changes

A.40.2 FlexCAN module changes

- No substantial content changes

A.41 Modular CAN (M_CAN) changes

A.41.1 Chip-specific M_CAN information changes

- No substantial content changes

A.41.1.1 M_CAN Subsystem changes

- No substantial content changes

A.41.2 M_CAN module changes

- In second Note of [Protocol Status Register \(M_CAN_PSR\)](#) description, revised text and reorganized into list
 - from: "The Bus_Off recovery sequence (see CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting CCCR[INIT]. If the device goes Bus_Off, it will set CCCR[INIT] of its own accord, stopping all bus activities. Once CCCR[INIT] has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR[INIT], each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to PSR.LEC, enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR.REC is used to count these sequences."
 - to: "The Bus_Off recovery sequence (see CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting CCCR[INIT].
 1. If the device goes Bus_Off, it sets CCCR[INIT] and PSR[BO], stopping all bus activities.
 2. After the user clears CCCR[INIT], the user must then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before normal CAN operation can resume.
 - During the waiting period, each time the device monitors a sequence of 11 recessive bits, a Bit0Error code (101b) is written to PSR[LEC].
 - These code writes enable the user to check readily whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence.
 - ECR[REC] is used to count these sequences.
 3. After the observation of the 129 occurrences of Bus Idle, the device clears PSR[BO]."

A.42 Deserial Serial Peripheral Interface (DSPI) changes

A.42.1 Chip-specific DSPI information changes

- No substantial content changes

A.42.2 DSPI module changes

- In section, [Memory Map/Register Definition](#) : Added note
- In [Serial Peripheral Interface \(SPI\) configuration](#) removed redundant list item for "Transmit First In First Out (TX FIFO) buffering mechanism"
- In [Transmit FIFO Fill Interrupt or DMA Request](#) added text to Note: "Configure the DMA to fill only one FIFO location per transfer."
- In [Receive FIFO Drain Interrupt or DMA Request](#) added text: "Configure the DMA to drain only one FIFO location per transfer."

- In [PUSH TX FIFO Register In Master Mode \(DSPI_PUSHR\)](#) description, changed second sentence from "Only 16-bits can be written into TXDATA field" to "User must write 16-bits data into TXDATA field."
- Updated bit field descriptions for [SR\[TFFF, RFDF\]](#)
- In [Status Register \(DSPI_SR\)](#), changed access of [Reserved](#) field from read-only to "write 1 to clear"
- In [Status Register \(DSPI_SR\)](#), edited field description of:
 - [RFDF](#)
 - [TFFF](#)
- In [Memory Map/Register Definition](#) Note, edited text and reorganized items as a list

A.43 Zipwire changes

A.43.1 Chip-specific Zipwire information changes

- No substantial content changes

A.43.2 Zipwire module changes

- No substantial content changes

A.44 Serial Interprocessor Interface (SIPI) changes

A.44.1 Chip-specific SIPI information changes

- No substantial content changes

A.44.2 SIPI module changes

- In section [DMA programming sequence](#)
 - List item 5 changed from "If SIPI has received..., move to Step 8." to "When SIPI receives read...moves to step 8."
 - List item 6 changed from "As soon as ipd_request is asserted, AHB transfer...SIPI registers and RAM." to "When SIPI initiates DMA request,...SIPI and RAM."

A.45 LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications changes

A.45.1 Chip-specific LFAST information changes

- No substantial content changes

A.45.2 LFAST module changes

- Added bit description text "*This field can only be written when MCR[DRFEN] = 1.*" in [CLKTST](#), [LPON](#), [PNGREQ](#) and [USNDRQ](#) bits.
- In [LFAST PLL Control Register \(LFAST_PLLCR\)](#) register: updated "LPCFG" bit as Reserved now.

A.46 Fast Ethernet Controller (FEC) changes

A.46.1 Chip-specific FEC information changes

- No substantial content changes

A.46.2 FEC module changes

- No substantial content changes

A.47 Peripheral Sensor Interface (PSI5) changes

A.47.1 Chip-specific PSI5 information changes

- In [PSI5 GTM interface](#) clarified that this chapter refers to eTPU_C as the general timer module (GTM)

A.47.2 PSI5 module changes

- In "Memory map and register description," updated bitfield descriptions for PSI5_CH0_DCR[DMA_PM_DS_WM] and [DMA_EN_SF].

A.48 SENT Receiver (SRX) changes

A.48.1 Chip-specific SRX information changes

- No substantial content changes

A.48.2 SRX/SENT module changes

- No substantial content changes

A.49 Enhanced Serial Communication Interface (eSCI) changes

A.49.1 Chip-specific eSCI information changes

- No substantial content changes

A.49.2 eSCI module changes

- In the [Control Register 1 \(eSCI_CR1\)Table 49-7](#), corrected table header typo "RSCR" to "RSRC".

A.50 Resets changes

- No substantial content changes

A.51 System Boot changes

- In [Features](#) changed Freescale to NXP in second list item
- In [Reset Configuration Half Word \(RCHW\)](#) description of VLE, changed Freescale to NXP

A.52 System Status and Configuration Module (SSCM) changes

A.52.1 Chip-specific SSCM information changes

- In [Life Cycle \(LC\) slots](#) changed "Freescale Production" to "MCU Production" in final column of first body row in [Table 52-1](#)

A.52.2 SSCM module changes

- "Freescale production" is changed to "MCU Production" in following topics:
 - In bitfield value description of 110 in [LC](#).
 - [Life Cycle](#).
 - [Table 52-14](#)
- In [Figure 52-6](#) updated "Freescale production" to "MCU Production".
- In [SSCM \(SSCM\)](#) added a note "Reserved IPS register access is prohibited"

A.53 Power Management changes

- No substantial content changes

A.54 PMC changes

- No substantial content changes

A.55 JTAG Controller (JTAGC) changes

A.55.1 Chip-specific JTAGC information changes

- No substantial content changes

A.55.2 JTAGC module changes

- In [Table 55-2](#) of [External signal description](#) :
 - Moved content from Pull column to Reset State column and removed Pull column
 - Updated "Up" to "Weak pullup"
 - Updated "Down" to "Weak pulldown"

A.56 CJTAG changes

- No substantial content changes

A.57 JDC changes

- No substantial content changes

A.58 Nexus Development Interface (NDI) changes

- No substantial content changes

A.59 Nexus Port Controller (NPC) changes

A.59.1 Chip-specific NPC information changes

- No substantial content changes

A.59.2 NPC module changes

- Minor editorial change in [IEEE 1149.1-2001 \(JTAG\) TAP](#).

A.60 Nexus eTPU Development Interface (NDEDI) changes

A.60.1 Chip-specific NDEDI information changes

- No substantial content changes

A.60.2 NDEDI module changes

- No substantial content changes

A.61 DTS changes

- No substantial content changes

A.62 Fault Collection and Control Unit (FCCU) changes

A.62.1 Chip-specific FCCU information changes

- No substantial content changes

A.62.2 FCCU module changes

- In [More about the EOUT interface](#), changed *<i>NA</i> (not applicable) appears in the following table* to *NA (not applicable) appears in the following table*.
- In the [Bistable Fault-Output \(EOUT\) Mode Signaling Enable \(FCCU_EOUT_SIG_ENn\)](#) register description, rewrote the register's function description and the [EOUTENx](#) field's function description.
- In [Signals](#), revised the function description for the FIF signal.

- Throughout the chapter, changed *non-critical* to *noncritical*.
- In each of the following register descriptions, changed the format of the table in the register function summary and reworded the sentence in the field function summary that refers to the table:
 - [Noncritical Fault Configuration \(FCCU_NCF_CFGn\)](#)
 - [Noncritical Fault Status \(FCCU_NCF_Sn\)](#)
 - [Noncritical Fault Enable \(FCCU_NCF_En\)](#)
 - [Noncritical Fault Timeout Enable \(FCCU_NCF_TOEn\)](#)
 - [IRQ Alarm Enable \(FCCU_IRQ_ALARM_ENn\)](#)
 - [Bistable Fault-Output \(EOUT\) Mode Signaling Enable \(FCCU_EOUT_SIG_ENn\)](#) (no sentence rewording)
- In [Introduction](#), changed *One of the error out pins is high* to *One of the fault-output (EOUT) signals is high*.
- In the [Signals](#) table, deleted the rows for:
 - WKPU interface (divider row)
 - NMIWKPU
 - WAKEWKPU

A.63 Self-Test Control Unit (STCU2) changes

A.63.1 Chip-specific STCU2 information changes

- In [STCU register default values](#) table, removed rows about STCU2_LB_PRPGLn and STCU2_LB_PRPGHn registers

A.63.2 STCU2 module changes

- Added the following sections to clarify terminology:
 - [BISTs and BIST partitions](#)
 - [BIST sequences](#)
- [STCU2 Watchdog Granularity \(STCU2_WDG\)](#) :
 - Throughout: Edited for clarity
 - Note added to WDG[WDGEOC] field description: "If this register is programmed while STCU2_RUN[RUN]=1, the new STCU2_WDG value, programmed after STCU2_RUN, does not take effect."
- [STCU2 LBIST Control \(STCU2_LB_CTRLn\)](#) :
 - Changed 4-bit, RO field (bits 8 - 11) to 3-bit field
 - Changed access level of reserved RO bit 11 to RW
 - Replaced PRPGEN field with R/W reserved field
- [STCU2 LBIST PRPG Low Register \(STCU2_LB_PRPGLn\)](#) :
 - Register removed
- [STCU2 LBIST PRPG High Register \(STCU2_LB_PRPGHn\)](#) :
 - Register removed
- [Offline self-test sequence](#) :
 - Removed: "Optionally, also the STCU2_LB_PRPGL/H can be programmed in order to load a specific seed."
- In the [STCU2 Off-Line MBIST Status Medium Register \(STCU2_MBSM\)](#) register description, in the note in each of the field descriptions, changed STCU2_MBEL to STCU2_MBEH.
- In the [STCU2 Off-Line MBIST Status High Register \(STCU2_MBSH\)](#) register description, in the note in each of the field descriptions, changed STCU2_MBEL to STCU2_MBEH.

- [Online self test sequence](#) :
 - Numerous editorial changes
 - Steps changed to a numbered sequence instead of a bulleted list
 - STCU2 Register names referenced in this section are no longer prefixed with "STCU2_".
- In the [STCU2 Configuration Register \(STCU2_CFG\)](#) register description, changed *FSL production* to *MCU production*.

A.64 Cyclic Redundancy Check (CRC) Unit changes

A.64.1 Chip-specific CRC information changes

- No substantial content changes

A.64.2 CRC module changes

- In [Configuration Register \(CRC_CFGn\)](#), updated reset value footnote for POLYG field.

A.65 Security Overview changes

- Added section: [Flash memory read, write, and erase protection](#)

A.66 Cryptographic Services Engine (CSE) changes

A.66.1 Chip-specific CSE information changes

- Added section: [CSE clock: minimum frequency](#)
- Changed content of [CSE command-processing completion before Stop mode entry](#)
 - from: "To ensure proper CSE operation: Before the chip enters Stop mode, CSE_SR[BSY] must be 0."
 - to: "To ensure proper CSE operation: Before setting SIU_HLT1[CSE] to 1, ensure CSE_SR[BSY] is 0."

A.66.2 CSE module changes

- No substantial content changes

A.67 Password and Device Security Module (PASS) changes

A.67.1 Chip-specific PASS information changes

- No substantial content changes

A.67.2 PASS module changes

- In register bit field: [LIFE](#) :
 - Changed 'Freescale Production' to 'MCU Production'
- Editorial change: Added cross ref in [Censorship](#)

A.68 Tamper Detection Module (TDM) changes

A.68.1 Chip-specific TDM information changes

- No substantial content changes

A.68.2 TDM module changes

- In section [Flash erase counter and tamper detection](#)
 - Removed text "Alternatively,...the diary length for that TDR." from second note in this section.
